9 A joint conjunctive use and groundwater banking project was evaluated by the  
10 East San Joaquin Parties Water Authority and East Bay Municipal Utility District,  
11 named the Mokelumne Aquifer Recharge and Storage Project (NSJCGBA 2004).  
12 The goal of this project was to store surface water underground in wet years, and  
13 in dry years, East Bay Municipal Utility District would extract and export the  
14 recovered water supply (NSJCGBA 2004, 2009). Several studies have concluded  
15 that the test area is suitable for recharge and recovery of groundwater; however,  
16 more testing needs to be done to further evaluate the feasibility of this project.

17 The Central Valley Regional Water Quality Control Board recently adopted  
18 general waste discharge requirements to protect groundwater, as well as surface  
19 water, within the San Joaquin County and Delta areas. The new requirements do  
20 not address protection of groundwater related to use of recycled water on crops  
21 because those operations would require separate discharge permits from the  
22 Central Valley Regional Water Quality Board and are not anticipated to be widely  
23 used in this area due to availability of recycled water near farms. However, the  
24 supporting information recognizes the potential for groundwater impairment due  
25 to the water quality of applied water to crops if the applied water quality contains  
26 high concentrations of constituents of concern (CVRWQCB 2014b).

#### 27 *Modesto Subbasin*

28 Groundwater is used for agricultural and domestic water supplies in the Modesto  
29 subbasin (Reclamation and DWR 2011). Groundwater is used by many  
30 agricultural water users and the community of Modesto (DWR 2004r; Stanislaus  
31 County 2010).

#### 32 *Turlock Subbasin*

33 Groundwater is used for agricultural and domestic water supplies in the Turlock  
34 subbasin (Reclamation and DWR 2011). Groundwater is used by many  
35 agricultural water users and the community of Turlock in Stanislaus County and  
36 the communities of Delhi and Hilmar in Merced County (DWR 2006k; Stanislaus  
37 County 2010; Merced County 2012).

#### 38 *Merced Subbasin*

39 Groundwater is used for agricultural and domestic water supplies in the Merced  
40 subbasin (Reclamation and DWR 2011). Groundwater is used by many  
41 agricultural water users and the communities of Atwater, El Nido, Le Grand,  
42 Livingston, Merced, Planada, and Winton (DWR 2004s; Merced County 2012).

1                    *Chowchilla Subbasin*

2 Groundwater is used for agricultural and domestic water supplies in the  
 3 Chowchilla subbasin (Reclamation and DWR 2011). Groundwater is used by  
 4 many agricultural water users and the community of Chowchilla (DWR 2006k;  
 5 Madera County 2002).

6                    *Madera Subbasin*

7 Groundwater is used for agricultural and domestic water supplies in the Madera  
 8 subbasin (Reclamation and DWR 2011). Groundwater is used by many  
 9 agricultural water users and the community of Madera (DWR 2006k; Madera  
 10 County 2002, 2008).

11 **7.3.3.4.2 Tulare Lake Area of the San Joaquin Valley Groundwater Basin**

12 The Tulare Lake Area overlies seven groundwater subbasins of the San Joaquin  
 13 Valley Groundwater Basin, as defined by DWR (DWR 2003a): the Westside,  
 14 Kings, Tulare Lake, Kaweah, Tule, Pleasant Valley, and Kern subbasins, as  
 15 shown in Figure 7.7. The Kern and Pleasant Valley subbasins have distinct  
 16 hydrogeology and groundwater management from the other subbasins, and  
 17 therefore are described separately.

18 *Northern Tulare Lake Area: Westside, Kings, Tulare Lake, Kaweah, Tule,*  
 19 *Pleasant Valley, and Kern Subbasins*

20                    *Hydrogeology and Groundwater Conditions*

21                    *Hydrogeology*

22 The aquifer system in the Tulare Lake Area consists of younger and older  
 23 alluvium, flood-basin deposits, lacustrine and marsh deposits and unconsolidated  
 24 continental deposits. These deposits are configured within most parts of the basin  
 25 to form an unconfined to semi-confined upper aquifer and a confined lower  
 26 aquifer. These aquifers are separated by the Corcoran Clay (E-Clay) member of  
 27 the Tulare Formation, which occurs at depths between 200 and 850 feet within the  
 28 central and western portions of the basin, specifically in the Westside and Tulare  
 29 Lake subbasins and in the western Kings, Kaweah, and Tule subbasins.  
 30 Fine-grained lacustrine deposits up to 3,600 feet thick also are present in the  
 31 Tulare Lake region (DWR 2003a, 2004v, 2004w, 2006l, 2006m, 2006n, 2006o,  
 32 2006p).

33 Prior to extensive use of groundwater in the basin, groundwater generally flowed  
 34 toward Tulare Lake. Due to depressed groundwater levels and interception of  
 35 surface water, the Tulare Lake Area is dry except during extreme flood events;  
 36 and recharge of the Tulare Lake Area is limited.

37 Groundwater withdrawals in the Tulare Lake Area account for approximately  
 38 38 percent of the total groundwater withdrawals in the state of California  
 39 (DWR 2013i). The CVP and SWP surface water supplies are used by many  
 40 agricultural water users and several communities in the Tulare Lake Area to  
 41 reduce reliance on groundwater and allow for groundwater recharge. In drier  
 42 years when the CVP and SWP water supplies are limited, extensive groundwater  
 43 pumping occurs to meet the water demands. In drier years, water users in the

1 Westside, Kings, Tulare Lake, and Kaweah subbasins may use groundwater for  
2 up to 75 percent of their water supply (DWR 2013i).

3 Areal recharge from precipitation provides most of the groundwater recharge, and  
4 seepage from stream channels provides the remaining groundwater recharge.  
5 Most of the recharge occurs as mountain-front recharge in the coarse-grained  
6 upper alluvial fans where streams enter the basin (USGS 2009). Prior to  
7 development of the Tulare Lake Area, surface water and groundwater exchange  
8 occurred throughout the basin in response to hydrologic conditions. When rapid  
9 agricultural growth and groundwater development occurred, the primary  
10 interaction of surface water with groundwater occurred as stream flow loss to  
11 underlying aquifers. In areas of severe overdraft in the Tulare Lake Area of the  
12 San Joaquin Valley Groundwater Basin, complete disconnection between  
13 groundwater and overlying surface water systems has occurred. In some areas  
14 with disconnected hydrology where streambeds are used as conveyance elements  
15 for irrigation purposes and to recharge groundwater, the streams become losing  
16 streams. Recent information indicates that between the spring 2010 and spring  
17 2014, groundwater levels declined at some wells in this area by up to 10 feet  
18 (DWR 2014c, 2014d). The groundwater levels in some areas declined up to  
19 10 feet between fall 2013 and fall 2014, and in some areas more than 10 feet.

#### 20 *Groundwater Quality*

21 In the northern Tulare Lake Area (including the Westside, Tulare Lake, Kings,  
22 Kaweah, and Tule subbasins), groundwater in the upper unconfined/semi-  
23 confined aquifer is characterized by high calcium and magnesium sulfate as well  
24 as high TDS (DWR 2006l, 2006m, 2006n, 2013c). The lower confined aquifer is  
25 approximately 300 feet below the ground surface and above the Corcoran Clay,  
26 and is characterized by high sodium sulfates and less dissolved solids than the  
27 upper aquifer.

28 Groundwater quality in the northern Tulare Lake Area is poor in portions of the  
29 upper aquifer, due to agricultural drainage issues and naturally occurring high  
30 salinity soils. Groundwater in the Westside subbasin is of poor quality due to  
31 historical agricultural drainage. The high clay content of the soils that comprise  
32 the upper aquifer restricts the movement of groundwater in the aquifer, further  
33 contributing to water quality impacts from root zone drainage. Studies have  
34 shown that the quality of the upper 20 to 200 feet of the saturated groundwater  
35 zone have been affected by crop irrigation and drainage issues (Reclamation  
36 2006). The eastward movement of saline groundwater from the Westside  
37 subbasin also adversely affects the groundwater quality in adjacent subbasins,  
38 such as in the vicinity of the City of Mendota and Fresno Slough  
39 (Reclamation 2006).

40 The Westside and Kings subbasins also have localized areas with high boron  
41 concentrations (CVRWQCB 2011). The Kings and Tulare Lake subbasins have  
42 localized areas with high arsenic and hydrogen sulfide. In the Kaweah subbasin  
43 and the northern portion of the Tule subbasin, groundwater is of the calcium  
44 bicarbonate type with high TDS and localized areas with high nitrate  
45 concentrations (DWR 2004v, 2004w, 2013c). In the Kaweah subbasin,

1 groundwater is characterized by moderate to high TDS concentrations  
2 (DWR 2004v, 2013c). In the Tule subbasin, low to moderate TDS concentrations  
3 occur in the most of the subbasin with high concentrations in areas with poor  
4 drainage (DWR 2004w, 2013c). On the western side of the subbasin there is  
5 shallow saline water. The eastern side of the subbasin has areas of high nitrates  
6 (DWR 2013c, 2004b). The Westside and Kings subbasins also have localized  
7 areas with high boron concentrations (CVRWQCB 2011). The Kings and Tulare  
8 Lake subbasins have localized areas with high arsenic and hydrogen sulfide. In  
9 the Kaweah subbasin and the northern portion of the Tule subbasin, groundwater  
10 is of the calcium bicarbonate type with high TDS and localized areas with high  
11 nitrate concentrations (DWR 2004v, 2004w, 2013c). Portions of the Kings  
12 subbasin are characterized by high nitrate concentrations due to historical  
13 agricultural practices (CVRWQCB 2011; DWR 2006n, 2013c). High DBCP and  
14 other pesticides concentrations occur in localized areas within the Westside,  
15 Kings, Tulare Lake, Kaweah, and Tule subbasins (CVRWQCB 2011).

16 A recent study evaluated high nitrate concentrations in groundwater and related  
17 public health issues in four community water systems with recorded violations  
18 related to nitrates in drinking water (Pacific Institute 2011). The communities  
19 served by the water systems were evaluated to assess the quality of groundwater  
20 provided by their water distribution systems and potential costs to the  
21 communities. Overall, this significant degradation of groundwater quality  
22 throughout the area has implications on public health and economic sustainability  
23 of the region. The findings of the report indicated that improved notification  
24 procedures, new funding mechanisms, and improved regulations and incentives  
25 are needed to provide safe drinking water, as described in Chapter 18, Public  
26 Health. The four water systems included Beverly Grand Mutual Water Company  
27 (Tule subbasin), Lemon Cove Water Company (east of Tule subbasin), El Monte  
28 Village Mobile Home Park (Kings subbasin), and Soult's Mutual Water Company  
29 (Kings subbasin) in Tulare County.

30 High groundwater salinity occurs in many locations in the Tulare Lake Area.  
31 Salts are imported into the Tulare Lake Area through irrigation with Delta water  
32 and salts added through application of fertilizers, and other salt containing  
33 materials. Except in very wet years, the Tulare Lake Area has no natural  
34 drainage, so imported salts accumulate in the groundwater unless captured and  
35 sequestered. This salt accumulation causes groundwater quality degradation for  
36 potable and agricultural uses.

37 To the high nitrate and salinity problems, the Central Valley Salinity  
38 Alternatives for Long-Term Sustainability (CV-Salts) was formed as a strategic  
39 initiative to address accumulation of salts and nitrates throughout the region in a  
40 comprehensive, consistent and sustainable manner (CVRWQCB 2015; SWRCB  
41 2015). The Central Valley Regional Water Quality Control Board and the State  
42 Water Resources Control Board in cooperation with stakeholders and the Central  
43 Valley Salinity Coalition collaborate to review and update the Water Quality  
44 Control Plans for the Sacramento Valley and San Joaquin Valley groundwater  
45 basins and the Delta Plan for salinity management, as described in Chapter 6,

1 Surface Water Quality. The goals of this program are to address groundwater  
2 nitrate legacy conditions and current loadings, direct impacts of high nitrates on  
3 drinking water supplies from diverse sources, and economic costs for water  
4 treatment or alternate supplies. A final Salinity and Nitrate Management Plan is  
5 scheduled to be completed in May 2016.

6 *Overall Groundwater Conditions*

7 The Westside, Kings, Tulare Lake, Kaweah, Tule, and Kern subbasins were  
8 designated by the CASGEM program as high priority. The Pleasant Valley  
9 subbasin was designated as low priority.

10 *Groundwater Use and Management*

11 The northern Tulare Lake Area uses groundwater for its many water needs.  
12 Groundwater is used conjunctively with surface water, where possible, when  
13 surface water supplies are not sufficient to meet the region's demand for  
14 agricultural, industrial, and municipal uses (DWR 2003a). For example, the cities  
15 of Fresno and Visalia are almost entirely dependent on groundwater for their  
16 water supplies. Most groundwater subbasins in the Tulare Lake Area are in a  
17 state of overdraft as a consequence of groundwater pumping that exceeds the  
18 basin's safe yield (the amount of natural and induced recharge available to  
19 replenish the basin). As a result, the aquifers in these groundwater basins contain  
20 a significant amount of potential storage space that can be filled with additional  
21 recharged water. However, cities in the northern Tulare Lake Area are  
22 considering other water sources and/or groundwater banking programs.

23 *Westside Subbasin*

24 The Westside subbasin is located within western Fresno County and northwestern  
25 Kings County. The majority of lands within the Westside subbasin are within the  
26 Westlands Water District which uses CVP surface water, water transferred from  
27 other agencies, and groundwater. Groundwater levels in the Westside subbasin  
28 have fluctuated over the past 46 years in response to the availability of surface  
29 water deliveries from the CVP (WWD 2013). The lowest recorded average  
30 groundwater level below the Corcoran Clay between 1950 and 1968 (prior to  
31 delivery of CVP water to the subbasin) was 156 feet below mean sea level, which  
32 occurred in 1967. Groundwater elevations increased after 1968 to 89 feet above  
33 mean sea level in 1987.

34 Groundwater levels are closely related to the availability of surface water. In the  
35 1977 drought when CVP water supplies were substantially reduced, groundwater  
36 withdrawals decreased the groundwater elevation by 97 feet in 1 year  
37 (WWD 2013). In 1991 and 1992 (during the 1987 to 1992 drought), the  
38 groundwater elevation declined to 62 feet below mean sea level. In 1996, the  
39 Westlands Water District adopted a groundwater management plan to preserve  
40 and enhance reliable groundwater resources; provide long-term availability of  
41 high quality groundwater; maintain local control of groundwater in the district;  
42 and minimize the cost and impact of groundwater use (WWD 2013a). The  
43 groundwater levels recovered following the drought that ended in 1992.  
44 However, in 2010, the CVP allocation was 45 percent of the contract amount, and

1 the average groundwater elevation was 9 feet above mean sea level (WWD 2011).  
2 In 2012, the CVP allocation was 40 percent of the contract amount, and the  
3 average groundwater elevation decreased to 1 foot above mean sea level (WWD  
4 2013). Recent information indicates that between the spring 2013 and spring  
5 2014, groundwater levels have declined at some wells in the Westside subbasin  
6 by up to 40 feet within the 1-year period (DWR 2014c, 2014d).

7 Subsidence has occurred in the Westside subbasin as a result of the high rate of  
8 historic groundwater pumping resulting in reduced groundwater levels and the  
9 compaction of fine grained soils. In some areas, the land surface elevation has  
10 decreased substantially. It is estimated that extensive groundwater pumping prior  
11 to delivery of CVP water resulted in compaction of water bearing sediments and  
12 land subsidence of 1 to 24 feet between 1926 and 1972 (WWD 2013). The  
13 Westland Water District has referenced that the Department of Water Resources  
14 estimated the amount of subsidence since 1983 to be almost 2 feet in some areas  
15 of the District with most of that subsidence occurring since 1989 (WWD 2013).  
16 The USGS monitoring between 2003 and 2010 indicated no subsidence in the  
17 Westside subbasin area during the same time period while at least 1.8 feet of  
18 subsidence occurred in the Delta-Mendota subbasin area near the southern part of  
19 the Delta-Mendota Canal (USGS 2013a).

20 *Kings Subbasin*

21 The Kings subbasin includes most of central and eastern Fresno County, and  
22 northern Kings and Tulare County (DWR 2006n, 2013c). Two major  
23 groundwater depressions occur near the Fresno-Clovis urban area and  
24 approximately 20 miles southwest of Fresno in the Raisin City Water District  
25 (DWR 2013c). On average, the majority of this subbasin has experienced  
26 generalized declines in groundwater levels of approximately 20 feet between 2003  
27 and 2011 (KRCD 2012a). The Kings subbasin is in overdraft condition and  
28 overdraft continues to be a major long-term problem due to increasing water  
29 demand and reduced surface water supply reliability. Recent information  
30 indicates that between the spring 2010 and spring 2014, groundwater levels  
31 declined at some wells in the Kings subbasin by up to 20 feet (DWR 2014c,  
32 2014d).

33 Groundwater is used for a portion of agricultural water demands and for most of  
34 the domestic and industrial water demands in Fresno County, including for water  
35 users in the communities of Fresno, Clovis, Sanger, Fowler, Selma, Kingsburg,  
36 Reedley, Dinuba, Orange Cove, Raisin City, and Riverdale (CVRWQCB 2011;  
37 Fresno County 2000; KRCD 2012a).

38 The City of Fresno, which previously used groundwater for the municipal water  
39 supplies, has developed a surface water supply program. The groundwater is  
40 recharged through direct recharge and from applied agricultural water, and  
41 groundwater inflows from the adjacent foothills (City of Fresno 2015).

42 Several water agencies are coordinating efforts in the Kings subbasin to mitigate  
43 the extensive historical declines in groundwater levels resulting from pumping  
44 withdrawals. Current Kings subbasin groundwater recharge efforts include a total

1 of 4,000 acres of dedicated recharge ponds (CGRA 2012). One of the biggest  
2 groundwater recharge efforts in the Kings subbasin area is the McMullin On-farm  
3 Flood Capture and Recharge Project near Raisin City (KRCD 2013).

4 *Tulare Lake Subbasin*

5 The Tulare Lake subbasin includes most of Kings County (DWR 2006m, 2013c).  
6 In the Tulare Lake subbasin, water levels have declined nearly 17 feet on average  
7 from 1970 through 2000. Fluctuations in water levels have been most  
8 exaggerated in the Tulare Lakebed area of the subbasin, which has experienced  
9 both the steepest declines and the steepest rises over time. Groundwater overdraft  
10 conditions also prevail in this subbasin, similar to the Kings subbasin. Recent  
11 information indicates that between the spring 2010 and spring 2014, groundwater  
12 levels declined at some wells in the Tulare Lake subbasin by up to 20 feet  
13 (DWR 2014c, 2014d).

14 Groundwater is used for a portion of agricultural water demands and for most of  
15 the domestic and industrial water demands in Kings County, including the  
16 communities of Corcoran, Hanford, Lemoore, and Kettleman Hills  
17 (CVRWQCB 2011; KRCD 2012a).

18 *Kaweah Subbasin*

19 The Kaweah subbasin includes a portion of eastern Kings County and  
20 northwestern Tulare County. Water levels in this subbasin declined about 12 feet  
21 on average from 1970 through 2000 (DWR 2004v, 2013c). The basin is subject  
22 to large fluctuations in water levels since the 1970s to as low as 35 feet lower than  
23 the 1970 water level in 1995 to 25 feet higher in 1988. These fluctuations  
24 correspond to successive dry years (declines) and wet years (rebounds),  
25 respectively. Recent information indicates that between the spring 2010 and  
26 spring 2014, groundwater levels declined at some wells in the Kaweah subbasin  
27 by up to 20 feet (DWR 2014c, 2014d). The Kaweah Delta Water Conservation  
28 District operates recharge facilities to supplement groundwater recharge that  
29 occurs along the natural stream channels (KDWCD 2006). Water is released  
30 from the Terminus Reservoir on the Kaweah River to flow into over 40 recharge  
31 basins throughout the basin. Use of CVP water from the Friant-Kern Canal by  
32 Tulare Irrigation District and Ivanhoe Irrigation District reduces the need for  
33 groundwater withdrawals when the CVP water is available.

34 Groundwater is used for a portion of agricultural water demands and for most of  
35 the domestic and industrial water demands in the subbasin, including for water  
36 users in the communities of Visalia, Tulare, and Lindsay (CVRWQCB 2011;  
37 Tulare County 2010).

38 *Tule Subbasin*

39 The Tule subbasin includes southwestern Tulare County. Water levels in this  
40 subbasin increased by about 4 feet on average from 1970 through 2000  
41 (DWR 2004w, 2013c). Water levels have fluctuated during dry and wet years  
42 between 16 feet below the 1970 water level in 1995 to 20 feet above the 1970  
43 water level in 1988. Recent information indicates that between the spring 2010  
44 and spring 2014, groundwater levels declined at some wells in the Tule subbasin

1 by up to 20 feet (DWR 2014c, 2014d). The Deer Creek and Tule River Authority  
2 implemented a groundwater management plan in 2006 in the Tule Subbasin  
3 (DCTRA 2012). The plan participants include Lower Tule River Irrigation  
4 District, Pixley Irrigation District, Porterville Irrigation District, Terra Bella  
5 Irrigation District, Saucelito Irrigation District, Tea Pot Dome Irrigation District,  
6 Vandalia Irrigation District, Tipton Community Services District, Poplar  
7 Community Services District (primarily the City of Porterville), and Woodville  
8 Public Utility District. Many of these agencies have CVP water service contracts  
9 and some of these agencies have surface water rights. Groundwater recharge  
10 occurs in more than 25 groundwater recharge basins and along the Tule River and  
11 Deer Creek channels.

12 *Southern Tulare Lake Area: Kern County Subbasin*

13 The Kern County subbasin is located between the Tule and Tulare Lake  
14 groundwater subbasins on the north, the Sierra Nevada and Tehachapi Mountains  
15 granitic rock on the east, and the marine sediments of the Coast Ranges on the  
16 west. The major water suppliers within the Kern County subbasin include Kern  
17 County Water Agency and the City of Bakersfield.

18 *Hydrogeology and Groundwater Conditions*

19 The unconfined aquifer in the Kern County Groundwater subbasin is composed  
20 primarily of sediments that were deposited during the tertiary and quaternary age.  
21 The Tulare Formation, located in the western portion of the subbasin, includes the  
22 Corcoran Clay unit which occurs at depths of 300 to 650 feet and overlies the  
23 confined aquifer (DWR 2006o, 2013c).

24 Net groundwater level changes in the Kern County subbasin varied in different  
25 portions of the subbasin between 1970 and 2000 (DWR 2006o, 2013c). Since the  
26 late 1970s, the groundwater levels have ranged from an increase of over 30 feet in  
27 the southeastern portion of the subbasin to a decrease of up to 25 feet near  
28 Bakersfield and 50 feet near McFarland/Shafter. Recent information indicates  
29 that between the spring 2013 and spring 2014, groundwater levels declined at  
30 some wells in the Kern County subbasin by up to 40 feet (DWR 2014c, 2014d).  
31 The groundwater levels in some areas declined up to 10 feet between fall 2013  
32 and fall 2014, and in some areas more than 10 feet.

33 Complete hydraulic disconnection between the groundwater and overlying surface  
34 water systems has occurred in the Kern County area. Kern River, a losing stream,  
35 is used as a conveyance element for irrigation purposes and to recharge  
36 groundwater.

37 Groundwater quality in the region is generally characterized by calcium  
38 bicarbonate in the shallow aquifers, and the groundwater quality is generally  
39 suitable for most uses. Lower aquifers have higher sodium concentrations  
40 (DWR 2006o, 2013c). Salinity is a significant groundwater quality issue in the  
41 region. Salt from imported CVP and SWP water accumulates annually in  
42 groundwater because the Tulare Lake is a closed system without any natural  
43 outlets (KCWA 2011).

1 Shallow groundwater with high salinity occurs in the western and southern  
2 portions of the Kern County subbasin and is related to drainage problems for  
3 irrigated agriculture (DWR 2006o, 2013c). An agricultural drainage study  
4 showed that shallow groundwater occurs between 0 and 30 feet below the ground  
5 surface in the southern portion of the Kern County subbasin (DWR 2013j). The  
6 shallow groundwater is characterized by high TDS, sodium chloride, selenium,  
7 and sulfates (DWR 2013j). Areas with high nitrate and pesticide concentrations  
8 occur in localized areas due to historic agricultural practices including irrigation  
9 and dairy wastes (CVRWQCB 2011; DWR 2006o). Elevated arsenic  
10 concentrations tend to occur in isolated areas associated with lakebed deposits.  
11 Selenium and chromium also naturally occur in portions of the subbasin  
12 (KCWA 2011).

13 *Groundwater Use and Management*

14 The Kern County subbasin is located in western Kern County. The majority of  
15 the lands within the Kern County subbasin are within Kern County Water Agency  
16 or the City of Bakersfield. Water supplies in the subbasin include local surface  
17 water, CVP and SWP water supplies, and groundwater. The subbasin includes a  
18 portion of the land evaluated in the Tulare Lake Basin Portion of the Kern Region  
19 IRWMP. It is estimated that over the long-term, approximately 39 percent of  
20 water supplies in this area are met by groundwater (KCWA 2011). Groundwater  
21 can provide up to 60 percent of the total water supply in drier years.

22 Much of the groundwater is withdrawn by individuals or farmers who do not  
23 maintain groundwater extraction records. Historically, groundwater extractions  
24 were estimated based upon electricity use, changes in groundwater storage, or  
25 changes in crop patterns and/or water requirements (DWR 2004o, 2013c;  
26 KCWA 2011).

27 Most of the groundwater is used by agriculture and the communities of  
28 Bakersfield, Rosedale, Shafter, Delano, Taft, and Wasco (KCWA 2011). The  
29 City of Bakersfield and surrounding unincorporated areas use surface water and  
30 groundwater. The groundwater supplies in 2010 include water provided by  
31 California Water Service Company; East Niles Community Services District;  
32 Kern County Water Agency Improvement District No. 4 and North of the River  
33 Municipal Water District; and Vaughn Water Company (California Water Service  
34 Company 2011a; ENCSD 2011; KCWA 2011; KCWA and NORMWD 2011;  
35 Vaughn Water Company, Inc. 2011). The water entities along with adjacent  
36 water agencies manage the groundwater basin levels through ongoing recharge  
37 projects and conjunctive use projects.

38 *Conjunctive Use and Groundwater Banking*

39 Conjunctive use is an important component of water management in the Kern  
40 County subbasin. Many groundwater banking facilities supplement water  
41 supplies delivered to customers in dry years, when insufficient surface water  
42 supplies are available to meet demands.

43 More than 30,000 acres of groundwater recharge ponds are estimated to exist in  
44 the Kern County subbasin area (KCWA 2011). Infrastructure used for

1 groundwater banking includes recharge basins, recharge canals, recovery wells,  
2 and conveyance pipelines. In addition, connections to regional conveyance  
3 infrastructure conveys water from the local water supplies, including the Kern  
4 River; Friant-Kern Canal; the Cross Valley Canal; and California Aqueduct to the  
5 recharge areas. Groundwater banking programs have developed various interties  
6 to the regional conveyance systems, such as the Semitropic Water Storage District  
7 Intake Canal and the Kern Water Bank Canal (KCWA 2011).

8 The major groundwater banking programs in Kern County include the Kern  
9 Water Bank operated by the Kern Water Bank Authority; the Semitropic  
10 Groundwater Bank, operated by the Semitropic Water Storage District; a  
11 groundwater bank operated by the North Kern Water Storage District; a  
12 groundwater bank operated by the City of Bakersfield; and a groundwater bank  
13 operated by Rosedale-Rio Bravo Water Storage District.

14 The Kern Water Bank Authority is located west of Bakersfield and covers nearly  
15 30 square miles of the Kern County subbasin. The Kern Water Bank includes  
16 recharge ponds where water from local surface streams and the SWP infiltrates  
17 into the aquifer (KCWA n.d.; KWBA 2011). Eighty-four recovery wells are used  
18 to pump groundwater out of the aquifer in dry years when additional water is  
19 needed for irrigation since the program began operations in 1995 (KCWA 2011).

20 The Semitropic Water Storage District is located west of Wasco and covers more  
21 than 220,000 acres (SWSD 2011a). The Semitropic Water Storage District Stored  
22 Water Recovery Unit (a subunit of the overall Semitropic Water Storage District  
23 Water Bank) partnered with the Antelope Valley Water Bank, located close to  
24 Rosamond in the Kern County portion of the Antelope Valley, to form the  
25 Semitropic-Rosamond Water Bank Authority (SWSD 2011b). The major banking  
26 partners of Semitropic Water Storage District include (SWSD 2014):

- 27 • Metropolitan Water District of Southern California
- 28 • Santa Clara Valley Water District
- 29 • Alameda County Water District
- 30 • Zone 7 Water Agency
- 31 • Poso Creek Water Company
- 32 • Newhall Land & Farming Company
- 33 • San Diego County Water Authority
- 34 • Homer, LLC
- 35 • City of Tracy
- 36 • Harris Farms

37 Other banking programs include (KCWA and NORMWD 2011; KCWA  
38 2011, n.d.):

- 39 • Arvin-Edison Water Storage District Banking

- 1 • Buena Vista Water Storage District Banking
- 2 • Cawelo Water District Banking
- 3 • City of Bakersfield 2800 Acres Recharge Facility
- 4 • Kern County Water Agency Improvement District No. 4 Pioneer Project and
- 5 Allen Road Complex Well Field
- 6 • Kern Delta Water District Banking
- 7 • Kern Tulare and Rag Gulch Water Districts Banking
- 8 • Rosedale-Rio Bravo Water Storage District Banking (developed with Kern
- 9 County Water Agency Improvement District No. 4)

10 *Western Tulare Lake Area: Pleasant Valley Subbasin*

11 The Pleasant Valley subbasin is located within the western portions of Fresno and  
12 Kings Counties.

13 *Hydrogeology and Groundwater Conditions*

14 Tertiary continental and marine sediments of the Coast Ranges and Kettleman  
15 Hills form the western boundary of the Pleasant Valley subbasin (DWR 2006p,  
16 2013c). Alluvium of the San Joaquin Valley extends into the subbasin from the  
17 north, east, and south. Ephemeral streams from the Coast Ranges and Kettleman  
18 Hills flow into the subbasin. Groundwater recharge occurs primarily along these  
19 and other streams within the subbasin.

20 In the Pleasant Valley subbasin, groundwater levels are generally continuing a  
21 historical trend of decline. DWR measurements indicated a decline of 5 to 25 feet  
22 during the 1990s (DWR 2006p, 2013c).

23 Water quality in the Pleasant Valley subbasin is characterized by high TDS  
24 (CVRWQCB 2011; DWR 2006p, 2013c). Localized areas of high concentrations  
25 of boron, calcium, chlorides, magnesium, pesticides, sodium, bicarbonates, and  
26 sulfates occur in the groundwater.

27 The Pleasant Valley subbasin was designated by the CASGEM program as low  
28 priority.

29 *Groundwater Use and Management*

30 Groundwater is used to meet agricultural and municipal water demands in the  
31 Pleasant Valley subbasin (DWR 2006p, 2013c). Due to limited recharge  
32 capabilities in the subbasin, surface water is used either completely or  
33 conjunctively in western Fresno and Kings Counties. The communities of Avenal  
34 and Coalinga use CVP surface water due to groundwater quality, as described in  
35 Chapter 5, Surface Water Resources and Water Supplies (Reclamation 2012).

36 **7.3.4 San Francisco Bay Area Region**

37 The San Francisco Bay Area Region includes portions of Contra Costa, Alameda,  
38 Santa Clara, and San Benito counties that are within the CVP and SWP service

1 areas. The SWP water users in Napa County do not use groundwater. Therefore,  
 2 groundwater resources for Napa County are not described in this EIS.

3 There are several groundwater basins in the San Francisco Bay Area Region;  
 4 however, only some of the basins are within the CVP and SWP service areas  
 5 evaluated in this EIS. The portions of the San Francisco Bay Area Region within  
 6 the CVP and/or SWP service areas include the Pittsburg Plain, Clayton Valley,  
 7 Ygnacio Valley, Arroyo Del Hambre Valley, San Ramon Valley, Livermore  
 8 Valley, Castro Valley, and Santa Clara Valley groundwater basins within the San  
 9 Francisco Bay Hydrologic Region; and Gilroy-Hollister Valley Groundwater  
 10 Basin within the Central Coast Hydrologic Region.

11 Groundwater represents approximately 15 percent of the agricultural, municipal,  
 12 and industrial water supplies in the San Francisco Bay Area (DWR 2013i).  
 13 Conjunctive use programs have been implemented by several agencies to  
 14 optimize the use of groundwater and surface water sources.

15 Groundwater quality in the San Francisco Bay Area is generally suitable for most  
 16 agricultural and municipal uses, but concerns exist about groundwater  
 17 contamination from industrial and agricultural chemical spills, leaky underground  
 18 and above ground storage tanks, landfill leachate, and poorer-quality surface  
 19 water bodies. There were over 800 groundwater cleanup projects in the area with  
 20 the majority resulting from leaky fuel tanks (DWR 2013i). Portions of the San  
 21 Francisco Bay Area Region along the shorelines include aquifers that are  
 22 susceptible to seawater intrusion.

23 In the southern San Francisco Bay Area Region, groundwater and surface water  
 24 are connected through in-stream and off-stream artificial recharge projects, in  
 25 which surface water is delivered to water bodies that permit the infiltration of  
 26 water to recharge underlying aquifers. Surface waters recharge aquifers in other  
 27 regions of the San Francisco Bay Area Region along streambeds, especially in  
 28 areas with depressed groundwater levels that have resulted from extensive  
 29 groundwater pumping.

30 This section describes groundwater in subbasins within CVP and/or SWP water  
 31 service areas, including Pittsburg Plain, Clayton Valley, Arroyo Del Hambre  
 32 Valley, Ygnacio Valley, and San Ramon Valley subbasins in Contra Costa  
 33 County; East Bay Plain and Livermore Valley subbasins in Contra Costa and  
 34 Alameda counties; Castro Valley subbasin in Alameda County; Santa Clara and  
 35 Llagas Area subbasins in Santa Clara County; and Bolsa, Hollister, and San Juan  
 36 Bautista Area subbasins in San Benito County, as shown in Figure 7.8.

37 **7.3.4.1 San Francisco Bay Hydrologic Region**

38 **7.3.4.1.1 Hydrogeology and Groundwater Conditions**

39 Each of these groundwater basins in the San Francisco Bay Hydrologic Region  
 40 contains unique hydrogeologic characteristics. However, generally the water  
 41 bearing materials consist of alluvial, unconsolidated sand, sand and gravel, and  
 42 clay (DWR 2004x, 2004y, 2004z, 2004aa, 2004ab, 2004ac, 2004ad, 2004ae,

1 2006q, 2006r, 2013d). Aquifers in these basins are hydrologically connected to  
2 surface water bodies, such as the San Joaquin River, Suisun Bay, local streams,  
3 and San Francisco Bay.

4 The movement of groundwater is locally influenced by features such as faults and  
5 structural depressions and operating production wells; however, groundwater  
6 generally flows toward the nearby bays. Groundwater levels in the area exhibit  
7 seasonal variation and have been historically depressed from significant  
8 groundwater use. However, as groundwater use decreased over the last few  
9 decades following implementation of surface water projects, groundwater levels  
10 have risen significantly. Over the entire period of record, groundwater levels  
11 have shown only a slight decline and are stable in more recent years.

12 *Pittsburg Plain, Clayton Valley, Ygnacio Valley, and Arroyo Del Hambre Valley*  
13 *Groundwater Basins*

14 The Pittsburg Plain, Clayton Valley, Ygnacio Valley, and Arroyo Del Hambre  
15 Valley groundwater basins represent the majority of groundwater storage in  
16 northern Contra Costa County. Except for portions of the Pittsburg Plain, most of  
17 these groundwater basins are not located within the Delta.

18 These basins extend inland from Suisun Bay towards Mt. Diablo. The Pittsburg  
19 Plain Groundwater Basin is composed of Pleistocene deposits of consolidated and  
20 unconsolidated clay sediments; overlain by alluvial soft water-saturated muds,  
21 peat, and loose sands (DWR 2004x, 2013d). The Clayton Valley and Ygnacio  
22 Valley groundwater basins are composed of unconsolidated alluvium and semi-  
23 consolidated alluvium interbedded with clay, sand, and gravel lenses. Along  
24 Suisun Bay, the water bearing formations are composed of alluvial soft water-  
25 saturated muds, peat, and loose sands (DWR 2004y, 2004z, 2004aa, 2013d).

26 Groundwater levels are relatively stable because the groundwater is recharged  
27 from streams (DWR 2004x, 2004y, 2004z, 2004aa, 2013d). The streams include  
28 Kirker and Willow creeks in the Pittsburg Plain Groundwater Basin; Marsh Creek  
29 in the Clayton Valley Groundwater Basin; Walnut and Grayson creeks in the  
30 Ygnacio Valley Groundwater Basin; and Alhambra Creek in the Arroyo Del  
31 Hambre Valley Groundwater Basin. There are no recent data for these basins  
32 related to groundwater levels or storage capacities.

33 The groundwater in this area is characterized by moderate to high TDS  
34 (DWR 2004x, 2004y, 2004z, 2004aa, 2013d). High nitrate concentrations occur  
35 in some rural areas of these basins (Contra Costa County 2005).

36 The Pittsburg Plain, Clayton Valley, Ygnacio Valley, and Arroyo Del Hambre  
37 Valley groundwater basins were designated by the CASGEM program as very  
38 low priority.

39 *San Ramon Valley Groundwater Basin*

40 The San Ramon Valley Groundwater Basin is located in southern Contra Costa  
41 County and extends from the Alamo area southward under the Town of Danville  
42 and City of San Ramon to the county boundary.

1 The basin is a closed basin characterized by alluvial fan deposits of sand, gravel,  
2 silt, and clay sediments (DWR 2004ab, 2013d). Multiple faults within the basin  
3 affect groundwater movement.

4 There are no recent data for this basin related to groundwater levels, storage  
5 capacities, or quality (DWR 2004ab, 2013d).

6 The San Ramon Valley Groundwater Basin was designated by the CASGEM  
7 program as very low priority.

8 *Livermore Valley Groundwater Basin*

9 The Livermore Valley Groundwater Basin extends under northeastern Alameda  
10 County and southern Contra Costa County. The Livermore Valley Groundwater  
11 Basin contains groundwater-bearing materials originating from continental  
12 deposits from alluvial fans, outwash plains, and lakes (DWR 2006q, 2013d).

13 The Main Basin is the aquifer that includes the highest yielding aquifers and  
14 highest quality groundwater (Zone 7 2012). The Main Basin generally is divided  
15 into the Upper Aquifer Zone and Lower Aquifer Zone which are separated by a  
16 relatively continuous silty clay lens. Water from the Upper Aquifer Zone moves  
17 into the Lower Aquifer Zone when groundwater levels in the upper zone are high.

18 Well yields are mostly adequate and in some areas can produce large quantities of  
19 groundwater for all types of wells (DWR 2006q, 2013d). The movement of  
20 groundwater is locally impeded by structural features such as faults that act as  
21 barriers to groundwater flow, resulting in varying water levels in the basin.  
22 Groundwater follows a westerly flow pattern, similar to the surface water streams,  
23 along the structural central axis of the valley toward municipal pumping centers  
24 (Zone 7 2005).

25 Groundwater levels in the main portion of the Livermore Valley Groundwater  
26 Basin started declining in the early 1900s when groundwater pumping removed  
27 large quantities of groundwater (Zone 7 2005, 2010, 2013). This trend continued  
28 until the late 1960s when Zone 7 Water Agency began importing SWP water.  
29 Subsequently, Zone 7 Water Agency developed surface water projects to capture  
30 local runoff. Local runoff and SWP water is stored in Lake Del Valle and used to  
31 recharge groundwater within the Livermore Valley. The importation of additional  
32 surface water alleviated the pressure on the aquifer, and groundwater levels  
33 started to rise in the 1970s. However, historical lows were reached during periods  
34 of drought. During the recent dry period, groundwater levels declined 7 to 17 feet  
35 throughout the aquifers used by Zone 7 Water Agency between 2011 and 2012.

36 The Livermore Valley Groundwater Basin is characterized by localized areas of  
37 high boron, nitrate, and TDS (DWR 2006q, 2013; Zone 7 2012). High boron  
38 levels can be attributed to marine sediments adjacent to the basin.

39 Nitrate concentrations generally are within potable water criteria; however, high  
40 nitrate concentrations occur in some locations of the upper aquifer (Zone 7 2012).  
41 The source of nitrates appears to be related to agricultural activities, wastewater  
42 disposal, and natural sources from decaying vegetation.

1 Salinity of the aquifer depends upon the quality of the water used for recharge  
2 operations. Salinity has increased over the past 30 years (Zone 7 2012) especially  
3 in the western portion of the Main Basin. Aquifers in the central and eastern  
4 portions of the Livermore Valley Groundwater Basin are generally recharged  
5 through streambeds and are characterized by lower salinity due to the high  
6 recharge rate.

7 The Livermore Valley Groundwater Basin was designated by the CASGEM  
8 program as medium priority.

9 *Castro Valley Groundwater Basin*

10 The Castro Valley Groundwater Basin is located in the Castro Valley area of  
11 Alameda County between San Lorenzo Creek on the east and the Hayward Fault  
12 on the west (Castro Valley 2012).

13 The basin is composed of alluvial deposits of sand, gravel, silt, and clay sediments  
14 (DWR 2004ac, 2013d). Previous studies indicated that the maximum yield was  
15 about 140,000 gallons per day (Castro Valley 2012).

16 The groundwater is characterized by bicarbonates with calcium and sodium.  
17 Localized contamination has occurred in this shallow aquifer related to  
18 agricultural activities and underground storage tanks (Castro Valley 2012).

19 The Castro Valley Groundwater Basin was designated by the CASGEM program  
20 as very low priority.

21 *Santa Clara Valley Groundwater Basin*

22 The Santa Clara Valley Groundwater Basin includes three subbasins in areas that  
23 are within the CVP and/or SWP service areas. The three subbasins include the  
24 East Bay Plain subbasin in Contra Costa and Alameda counties, Niles Cone  
25 subbasin in Alameda County, and Santa Clara subbasin in Santa Clara County.

26 *East Bay Plain Subbasin*

27 The East Bay Plain subbasin is an alluvial plain that extends from San Pablo Bay  
28 southward to the Niles Cone subbasin, and extends under San Francisco Bay  
29 (DWR 2004ad, 2013d; EBMUD 2013). The alluvium consists of unconsolidated  
30 sediments of mud, silts, sands, and clays. Multiple faults within the subbasin  
31 affect groundwater movement. Groundwater levels declined to approximately  
32 250 feet below the ground surface until the mid-1960s when groundwater levels  
33 began to increase. By 2000, groundwater levels were close to the ground surface.  
34 The groundwater quality is characterized as calcium and sodium bicarbonate with  
35 moderate to high TDS. Higher TDS concentrations occur near San Francisco Bay  
36 where localized sea water intrusion has occurred. High nitrate concentrations  
37 occur in localized areas due to historic agricultural activities.

38 The East Bay Plain subbasin was designated by the CASGEM program as  
39 medium priority.

40 *Niles Cone Subbasin*

41 The Niles Cone subbasin is mainly comprised of the alluvial fan along Alameda  
42 Creek. The Hayward Fault crosses the Niles Cone subbasin and further separates

1 the subbasin into the Below Hayward Fault (west of the Hayward Fault) and  
 2 Above Hayward Fault (east of the Hayward Fault) subbasins (ACWD 2012;  
 3 DWR 2006r, 2013d).

4 The Niles Cone subbasin was in overdraft condition through the early 1960s.  
 5 After 1962, groundwater levels increased as SWP water was delivered to the area  
 6 and used to recharge the groundwater subbasin (DWR 2006r, 2013d).

7 The main groundwater quality impairment in the Niles Cone subbasin is saltwater  
 8 intrusion caused by groundwater pumping (ACWD 2012; DWR 2006r, 2013d).  
 9 In the 1950s the migration of saline water extended into the Above Hayward Fault  
 10 subbasin, and migrated into deeper aquifers. Alameda County Water District has  
 11 developed aquifer reclamation programs to help control the movement of saline  
 12 water and restore the quality of groundwater in the affected aquifers, as described  
 13 below.

14 Niles Cone subbasin was designated by the CASGEM program as medium  
 15 priority.

16 *Santa Clara Subbasin*

17 The Santa Clara subbasin is located within Santa Clara County along a structural  
 18 trough that parallels the Coast Ranges and extends from the Diablo Range and  
 19 Santa Cruz Mountains. The water bearing formations of the Santa Clara subbasin  
 20 include unconsolidated to semi-consolidated gravel, sand, silt and clay  
 21 (DWR 2004ac, 2013d). The upper alluvial fan in the northern portion of the  
 22 subbasin is characterized by coarse-grained sediments (SCVWD 2010). Towards  
 23 the central portion of the subbasin, thick silty clay lenses are inter-bedded with  
 24 thin sand and gravel lenses. The northern and central portions of the subbasin are  
 25 locally referred to as the Santa Clara Plain (SCVWD 2011). The southern portion  
 26 of the subbasin consists of extensive alluvial deposits of unconsolidated and semi-  
 27 consolidated sediments and is referred to as the Coyote Valley (SCVWD 2010).  
 28 The central portions and areas along the edges of the Santa Clara Plain subbasin  
 29 consist of unconfined aquifers that provide recharge to the basin (SCVWD 2010,  
 30 2011). The Shallow Aquifer consists of water-bearing sediments that are less  
 31 than 150 feet deep. The Principal Aquifer provides most of the groundwater  
 32 supply for the Santa Clara Valley and is separated from the Shallow Aquifer by a  
 33 confining lens in some areas of the Santa Clara Plain. The groundwater recharge  
 34 primarily occurs due to percolation of water on the soil from precipitation or  
 35 artificial recharge operations (as described below), seepage from stream beds, and  
 36 subsurface inflow from surrounding hills.

37 In the Coyote subbasin, the groundwater aquifer is primarily unconfined with  
 38 areas of perched groundwater above discontinuous clay deposits (SCVWD 2010,  
 39 2011). Groundwater recharge occurs along the streambeds. When the  
 40 groundwater levels are high in the Coyote subbasin, groundwater seeps into the  
 41 streams.

42 The movement of groundwater in the Santa Clara subbasin is locally influenced  
 43 by groundwater recharge activities, proximity to streams, and operating

1 production wells (SCVWD 2010). Regionally, groundwater in the Santa Clara  
2 Subbasin generally flows northwest toward the San Francisco Bay.

3 The Santa Clara subbasin has historically experienced decreasing groundwater  
4 level trends. Between 1900 and 1960, water level declines of more than 200 feet  
5 from groundwater pumping have induced unrecoverable land subsidence of nearly  
6 13 feet (SCVWD 2011). Importation of surface water using CVP, SWP, and San  
7 Francisco Public Utilities District water supplies; and the development of an  
8 artificial recharge program have resulted in rising groundwater levels since the  
9 late 1960s. The groundwater levels in some portions of this subbasin declined up  
10 to 10 feet between fall 2013 and fall 2014, and in some areas more than 10 feet.

11 The groundwater quality in the Santa Clara subbasin is good to excellent and  
12 suitable for most beneficial uses. The groundwater meets all drinking water  
13 standards and can be used without additional treatment (SCVWD 2001, 2010).  
14 Some areas affected by historical saltwater intrusion exist in the northern portion  
15 of the Santa Clara subbasin in the Shallow Aquifer. Recent groundwater  
16 monitoring has indicated that seawater intrusion appears to be stabilizing  
17 (SCVWD 2012a). High nitrate concentrations occur in the Coyote Valley.

18 Santa Clara subbasin was designated by the CASGEM program as medium  
19 priority.

#### 20 **7.3.4.1.2 Groundwater Use and Management**

21 Use of groundwater in the San Francisco Bay Hydrologic Region varies  
22 extensively. In the basins within Contra Costa County (Pittsburg Plain, Clayton  
23 Valley, Ygnacio Valley, Arroyo Del Hambre Valley, and San Ramon Valley),  
24 local wells are used for small agricultural activities and landscape irrigation by  
25 individual land owners. In the Livermore Valley Groundwater Basin,  
26 groundwater is used for a major portion of the water supply.

#### 27 *Pittsburg Plain, Clayton Valley, Ygnacio Valley, and Arroyo Del Hambre Valley* 28 *Groundwater Basins*

29 Groundwater use is limited within northern Contra Costa County within the  
30 Pittsburg Plain, Clayton Valley, Ygnacio Valley, and Arroyo Del Hambre Valley  
31 groundwater basins. This area is located within the Contra Costa Water District  
32 or East Bay Municipal Utilities District service areas. These districts provide  
33 surface water to most water users in this area.

34 Within the Contra Costa Water District service area, groundwater use is limited  
35 (CCWD 2011). The use of existing Contra Costa Water District wells at the  
36 Mallard Well Fields is limited because of the threat of contamination from  
37 adjacent industrial areas.

38 The City of Pittsburg operates two municipal wells from the Pittsburg Plain  
39 Groundwater Basin (Pittsburg 2011).

40 The City of Martinez operates up to two wells in the Arroyo Del Hambre Valley  
41 Groundwater Basin to provide irrigation water to a municipal park  
42 (Martinez 2011).

1 *San Ramon Valley Groundwater Basin*

2 Groundwater use is limited within the San Ramon Valley Groundwater Basin  
3 located in southern Contra Costa County. Local wells are used for small  
4 agricultural activities and landscape irrigation by individual land owners. This  
5 area is located within the East Bay Municipal Utilities District service area. The  
6 district provides surface water to most water users in this area.

7 *Livermore Valley Groundwater Basin*

8 In the Livermore Valley Groundwater Basin, Zone 7 Water Agency administers  
9 oversight of the groundwater basins used for water supply and provides water to  
10 California Water Service Company, Dublin San Ramon Services District, City of  
11 Livermore, and City of Pleasanton. Zone 7 Water Agency only withdraws  
12 groundwater that has been recharged using surface water supplies (Zone 7 2010).  
13 The California Water Service Company, Dublin San Ramon Services District, and  
14 City of Pleasanton also withdraw groundwater (California Water Service  
15 Company 2011h; DSRSD 2011; City of Livermore 2011; City of  
16 Pleasanton 2011).

17 Zone 7 Water Agency manages the groundwater levels and quality in the  
18 Livermore Valley Groundwater Basin to maintain groundwater levels that would  
19 avoid subsidence and provide emergency reserves for the worst credible drought  
20 (DWR 2006q, 2013d).

21 Zone 7 Water Agency artificially recharges the Livermore Valley Groundwater  
22 Basin with local surface water supplies and SWP water by releasing the surface  
23 waters into the Arroyo Mocho and Arroyo Valle (Zone 7 2005, 2010). The  
24 infiltrated water is then pumped from the groundwater basin for various uses,  
25 mostly during the summer and during drought periods when local surface water  
26 supplies are diminished and the available SWP water supplies are less than the  
27 entitlement value Zone 7 Water Agency, City of Livermore, City of Pleasanton,  
28 Dublin San Ramon Services District, and California Water Service Company are  
29 permitted to withdraw groundwater from this subbasin.

30 In 2009, the Zone 7 Water Agency began operation of the Mocho Groundwater  
31 Demineralization Plant (Zone 7 2010). This plant is a wellhead treatment plant  
32 that produces potable water using reverse osmosis to remove TDS and hardness  
33 from the Main Basin.

34 *Castro Valley Groundwater Basin*

35 Groundwater use is limited within the Castro Valley Groundwater Basin. Local  
36 wells are used for small agricultural activities and landscape irrigation by  
37 individual land owners (Castro Valley 2012). This area is located within the East  
38 Bay Municipal Utilities District service area. The district provides surface water  
39 to most water users in this area.

40 *Santa Clara Valley Groundwater Basin*

41 The Santa Clara Valley Groundwater Basin includes the East Bay Plain, Niles  
42 Cone, and Santa Clara subbasins.

1        *East Bay Plain Subbasin*

2 Groundwater use is limited within the East Bay Plains subbasin. Local wells are  
3 used for small agricultural activities and landscape irrigation by individual land  
4 owners (DWR 2004ad, 2013d; EBMUD 2013). Well fields that served the  
5 communities were initially constructed in the late 1800s and early 1900s, and  
6 were closed by 1930. This area is located within the East Bay Municipal Utilities  
7 District service area. The district provides surface water to most water users in  
8 this area. East Bay Municipal Utilities District initiated the Bayside Groundwater  
9 Project in 2009 to store surface water in wet years for use during droughts.

10        *Niles Cone Subbasin*

11 Alameda County Water District is the primary water agency that relies upon the  
12 Niles Cone subbasin. This Alameda County Water District uses fresh  
13 groundwater from the Niles Cone subbasin and desalinated brackish groundwater  
14 in addition to local and imported surface water supplies. The Niles Cone subbasin  
15 is primarily recharged in the Alameda Creek watershed by percolation of local  
16 runoff and SWP water (ACWD 2011, 2012). In wetter years, when local water  
17 supplies are abundant, Alameda County Water District diverts some of the SWP  
18 allocation to the Semitropic Water Storage District in Kern County through a  
19 water banking agreement (as described above for the Kern County subbasin).  
20 This agreement allows Alameda County Water District to subsequently recover  
21 this water during drier years through an exchange agreement with Semitropic  
22 Water Storage District (ACWD 2012).

23 Alameda County Water District provides retail water supplies to the cities of  
24 Fremont, Newark, and Union City. The district has implemented treatment of  
25 brackish groundwater to allow previously unused groundwater to be used as a  
26 potable water source (ACWD 2011, 2012). In 2003, the Alameda County Water  
27 District Newark Desalination Facility began to remove salts and other constituents  
28 from the Niles Cone subbasin groundwater that is subject to seawater intrusion  
29 using a reverse-osmosis process. The aquifer reclamation program also includes  
30 withdrawing water to prevent a plume of brackish water in the Centerville-  
31 Fremont Aquifer from further migrating toward the Alameda County Water  
32 District Mowry Wellfield. Future groundwater desalination facilities are being  
33 evaluated by the district.

34        *Santa Clara Subbasin*

35 Local water agencies and individual landowners use groundwater in the Santa  
36 Clara subbasin. The Santa Clara subbasin is primarily recharged from percolation  
37 of local runoff and water supplied by the CVP and/or SWP that is discharged to  
38 streambeds and recharge facilities (SCVWD 2011).

39 Treated water is provided by the Santa Clara Valley Water District to retail water  
40 agencies in order to promote conjunctive use of groundwater. The water entities  
41 in the Santa Clara subbasin that use treated surface water include the cities of  
42 Milpitas, Mountain View, Palo Alto, San Jose, Santa Clara, and Sunnyvale;  
43 California Water Service (Los Altos), Purissima Water District, and San Jose

1 Water Company. Several of these entities also use surface water from San  
2 Francisco Public Utilities Commission as part of their overall water supply.  
3 In the Santa Clara subbasin, groundwater is withdrawn by local water suppliers  
4 and private well owners to meet municipal, domestic, agricultural, and industrial  
5 water needs (SCVWD 2011). Groundwater provides approximately 40 to  
6 50 percent of total water supply in Santa Clara County in average water year  
7 conditions (SCVWD 2010). Within the Santa Clara subbasin, the users of the  
8 most groundwater include San Jose Water Company, City of Santa Clara, Great  
9 Oaks Water Company, California Water Service, and individual land owners  
10 primarily in the southern portion of the subbasin (SCVWD 2012a).

11 The Santa Clara Valley Water District is responsible for groundwater  
12 management in the Santa Clara subbasin, and operates a robust and flexible  
13 conjunctive use program that uses a variety of surface water sources: local  
14 supplies, imported SWP and CVP supplies, and imported transfer options.  
15 Surface water is also supplied to some water users by the San Francisco Public  
16 Utilities Commission (SCVWD 2001, 2010). The district operates an extensive  
17 system of in-stream and off-stream artificial recharge facilities to replenish the  
18 groundwater basin and provide more flexibility to manage water supplies.  
19 Eighteen major recharge systems allow local reservoir water and imported water  
20 to be released in over 30 local creeks and 71 percolation ponds that provide 393  
21 acres for artificial recharge to the groundwater basin. Recharge in this subbasin  
22 occurs along streambeds and off-stream managed basins. Most of the recharge  
23 facilities are located in the Santa Clara subbasin. Two major recharge facilities,  
24 the Lower Llagas and Upper Llagas recharge systems, are located in the Llagas  
25 subbasin of the Gilroy-Hollister Groundwater Basin, as described below  
26 (SCVWD 2011, 2012a). The amount of water artificially recharged throughout  
27 the entire district depends upon the availability of local, CVP, and/or SWP surface  
28 water supplies.

29 **7.3.4.2 Central Coast Hydrologic Region: Gilroy-Hollister Valley**  
30 **Groundwater Basin**

31 Portions of the Gilroy-Hollister Valley Groundwater Basin within the CVP and/or  
32 SWP water service areas include the Llagas Area, Hollister Area, and San Juan  
33 Bautista Area subbasins.

34 **7.3.4.2.1 Hydrogeology and Groundwater Conditions**

35 Each of these groundwater basins in the Gilroy-Hollister Valley Groundwater  
36 Basin contains unique hydrogeologic characteristics. However, generally the  
37 water bearing materials consist of alluvial, unconsolidated sand, sand and gravel,  
38 and clay. Within four subbasins in the study area of this EIS, groundwater flows  
39 towards the Pajaro River which flows to Monterey Bay (DWR 2004af, 2004ag,  
40 2004ah, 2004ai, 2013d).

41 *Llagas Area Subbasin*

42 The water bearing formations of the Llagas subbasin include continental deposits  
43 of unconsolidated to semi-consolidated gravel, sand, silt and clay (DWR 2004af,

1 2013d; SCVWD 2010, 2011). Alluvium along the edges and the center portions  
2 of the subbasin are underlain by dense clayey soils. Younger alluvium does not  
3 have a well-defined clay subsoil.

4 As described above for the Santa Clara subbasin in the Santa Clara Valley  
5 Groundwater Basin, Santa Clara Valley Water District manages groundwater in  
6 the Llagas Area subbasin. Groundwater withdrawals in the Llagas subbasin have  
7 been relatively stable in recent years; and groundwater elevation has been stable  
8 since the late 1990s (SCVWD 2012a).

9 The groundwater quality in the Llagas subbasin is of good to excellent mineral  
10 composition and suitable for most beneficial uses (SCVWD 2010, 2012a). High  
11 nitrate concentrations occur in localized areas throughout the subbasin due to  
12 historical agricultural practices and wastewater effluent disposal. Santa Clara  
13 Valley Water District implemented a Nitrate Management Program in 1997 and  
14 nitrate concentrations are beginning to decline.

15 *Bolsa Area, Hollister Area, and San Juan Bautista Subbasins*

16 The Bolsa Area, Hollister Area, and San Juan Bautista Area subbasins extend  
17 over northern San Benito County. The subbasins are comprised of a sedimentary  
18 sequence that contains the principal aquifers underlying the Hollister and San  
19 Juan Valleys. The water bearing formation includes clay, silt, sand, and gravel  
20 (DWR 2004ag, 2004ah, 2004ai, 2013e).

21 The main water bearing formation in this area is composed of alluvium in the  
22 Bolsa Area and Hollister Area subbasins (San Benito County Water District  
23 2012). The water bearing formations in the northern San Juan Bautista Area  
24 consist of alluvium (San Benito County Water District 2012). Groundwater  
25 movement within the aquifers is affected by the numerous faults, including the  
26 San Andreas and Calaveras Faults. Groundwater aquifers in this area include  
27 both unconfined and confined aquifer conditions with surficial clay deposits in the  
28 northern portions of these subbasins.

29 Groundwater in these subbasins is characterized by artesian conditions when  
30 groundwater levels are high, such as in the early 1900s (San Benito County Water  
31 District 2012). After the mid-1940s, groundwater levels declined with increased  
32 withdrawals. One of the lowest levels occurred in the late 1970s when the  
33 groundwater elevation was approximately 150 feet lower than the high water level  
34 conditions. In 2012, groundwater elevations ranged from 80 feet above mean sea  
35 level in the Bolsa Area subbasin to 700 feet above mean sea level in the San Juan  
36 Bautista Area subbasin.

37 The Bolsa Area, Hollister Area, and San Juan Bautista Area subbasins have  
38 localized areas with high concentrations of boron, chloride, hardness, metals,  
39 nitrate, sulfate, potassium, and TDS (San Benito County Water District 2012).  
40 The most substantial constituents include high TDS concentrations in the  
41 southeastern Bolsa Area subbasin, Hollister Area subbasin, and northern San Juan  
42 Bautista Area subbasin. High nitrate concentrations occur in the northern San  
43 Juan Bautista Area subbasin.

1 *Overall Groundwater Conditions*

2 The Llagas Area subbasin was designated by the CASGEM program as high  
3 priority. The Hollister Area and San Juan Bautista Area subbasins were  
4 designated as medium priority.

5 **7.3.4.2.2 Groundwater Use and Management**

6 *Llagas Area Subbasin*

7 As described in Chapter 5, Surface Water Resources and Water Supplies,  
8 groundwater is the primary water supply for local water agencies and individual  
9 landowners in the Llagas Area subbasin. The subbasin is primarily recharged  
10 from percolation of local runoff and water supplied by the CVP that is discharged  
11 to recharge facilities managed by Santa Clara Valley Water District, as described  
12 above for the Santa Clara subbasin in the Santa Clara Valley Groundwater Basin  
13 (SCVWD 2011). The two major recharge facilities in the Llagas Area subbasin  
14 include the Lower Llagas and Upper Llagas recharge systems (SCVWD 2010).

15 The primary municipal water suppliers are the cities of Gilroy and Morgan Hill.  
16 Groundwater is used by these local water suppliers and private well owners to  
17 meet municipal, domestic, agricultural, and industrial water needs  
18 (SCVWD 2011).

19 *Bolsa Area, Hollister Area, and San Juan Bautista Subbasins*

20 Local water agencies and individual landowners use groundwater in the Bolsa  
21 Area, Hollister Area, and San Juan Bautista subbasins. The subbasins are  
22 primarily recharged from percolation of local runoff in streambeds, including  
23 water from Hernandez and Paicines Reservoirs that is released to Tres Pinos  
24 Creek (San Benito County Water District 2012).

25 San Benito County Water District provides CVP water to the cities of Hollister  
26 and San Juan Bautista, Sunnyslope County Water District, residential areas  
27 surrounding Hollister and Tres Pinos, and agricultural areas in northern San  
28 Benito County to reduce groundwater use by these areas (San Benito County  
29 Water District 2012). Most other water users in the subbasins rely upon  
30 groundwater and/or local surface water stored in Hernandez and Paicines  
31 Reservoirs.

32 In 2011, groundwater supplies provided 49 percent of the water used for  
33 agriculture, municipal, domestic, and industrial supply in the areas of the subbasin  
34 supplied by CVP water (San Benito County Water District 2012).

35 **7.3.5 Central Coast Region**

36 The Central Coast Region includes portions of San Luis Obispo and Santa  
37 Barbara counties served by the SWP. The Central Coast Region encompasses the  
38 southern planning area of the Central Coast Hydrologic Region (DWR 2009a).

39 The SWP water is provided to the Central Coast Region by the Central Coast  
40 Water Authority (CCWA 2013a). The facilities divert water from the SWP  
41 California Aqueduct at Devil's Den and convey the water to the 43 million gallon  
42 per day water treatment plant at Polonto Pass. The treated water is conveyed to

1 municipal water users in San Luis Obispo and Santa Barbara counties to reduce  
2 groundwater overdraft in these areas.

3 Portions of the Central Coast Region that use SWP water are included in the  
4 Central Coast Hydrologic Region which includes 50 delineated groundwater  
5 basins, as defined by DWR (DWR 2003a). The basins vary from large extensive  
6 alluvial aquifers to small inland valleys and coastal terraces. Groundwater in the  
7 large alluvial aquifers exists in thick unconfined and confined basins.

8 Groundwater is generally used for urban and agricultural use in the Central Coast  
9 Region.

### 10 **7.3.5.1 Hydrogeology and Groundwater Conditions**

11 The areas within the SWP service area in the Central Coast Region include the  
12 Morro Valley and Chorro Valley groundwater basins in San Luis Obispo County;  
13 Santa Maria River Valley Groundwater Basin in San Luis Obispo and Santa  
14 Barbara counties; and San Antonio Creek Valley, Santa Ynez River Valley,  
15 Goleta, Foothill, Santa Barbara, Montecito, and Carpinteria groundwater basins in  
16 Santa Barbara County, as shown in Figure 7.9.

#### 17 **7.3.5.1.1 Morro Valley and Chorro Valley Groundwater Basins**

18 In the portions of San Luis Obispo County within the SWP service area near  
19 Morro Bay, groundwater is provided by Morro Valley and Chorro Valley  
20 groundwater basins. The water bearing formations are alluvium that consists of  
21 clays, silts, sands, and gravel that extend into the Pacific Ocean (DWR 2004aj,  
22 2004ak, 2013e). The alluvium is recharged by seepage from streambeds and  
23 precipitation and irrigation water applied to the soils.

24 The groundwater has moderate TDS (DWR 2004aj, 2004ak, 2013e). Localized  
25 areas have high nitrate concentrations (Morro Bay 2011). Localized areas with  
26 organic contamination are also present; however, actions have been implemented  
27 to reduce the concentrations. Seawater intrusion occurs in localized areas near the  
28 Pacific Ocean.

29 The Morro Valley and Chorro Valley groundwater basins were designated by the  
30 CASGEM program as high priority.

#### 31 **7.3.5.1.2 Santa Maria River Valley Groundwater Basin**

32 The Santa Maria River Valley Groundwater Basin is located in San Luis Obispo  
33 and Santa Barbara counties. The water bearing formation is primarily unconfined  
34 alluvium with localized confined areas near the coast (DWR 2004 al, 2013e;  
35 SMVMA 2012). Recharge occurs along the streambeds. Groundwater levels in  
36 the Basin have fluctuated over the past 100 years with declining groundwater  
37 levels until the mid-1970s, recovery through the mid-1980s, and declining levels  
38 through the mid-1990s. Following importation of SWP water, groundwater levels  
39 increased to historic high levels. However, in the last decade, groundwater levels  
40 have gradually declined which could be partially due to reductions in Twitchell  
41 Reservoir releases for groundwater recharge since 2000. Groundwater levels  
42 have been maintained at levels above 15 feet above mean sea level in shallow and

1 deep aquifers near the coast to avoid seawater intrusion. Groundwater recharge  
2 occurs along streambeds. Water released from Twitchell and Lopez reservoirs  
3 increase groundwater recharge rates (SMVMA 2012).

4 Groundwater quality issues in the Santa Maria Valley Groundwater Basin include  
5 hardness, nitrates, salinity, sulfate and volatile organic compounds (DWR 2004a,  
6 2013e; San Luis Obispo County 2011; SMVMA 2012). TDS concentrations are  
7 moderate to high. There are localized areas in the basin with high sulfate  
8 concentrations. Volatile organic compound contamination was a major issue for  
9 two wells used by the City of San Luis Obispo in the late 1980s. High nitrate  
10 concentrations occur in the shallow aquifer due to historic agricultural practices.  
11 Higher salinity levels occur in the shallow aquifer near the coast than within the  
12 inland areas or in the deep aquifer.

13 The Santa Maria River Valley Groundwater Basin was designated by the  
14 CASGEM program as high priority.

15 **7.3.5.1.3 San Antonio Creek Valley Groundwater Basins**

16 San Antonio Creek Valley Groundwater Basin is located along the Pacific Ocean  
17 within San Luis Obispo and Santa Barbara counties. The water bearing  
18 formations are characterized by unconsolidated alluvial and terrace deposits of  
19 sand, clay, silt, and gravel (DWR 2004dq, 2013e). Groundwater flows towards  
20 the Pacific Ocean. A groundwater barrier to the east of the Pacific Ocean creates  
21 the Barka Slough. Groundwater has declined in some areas of the basin over the  
22 past 60 years. Groundwater quality issues include areas with high salinity near  
23 the Pacific Ocean.

24 The San Antonio Creek Valley Groundwater Basin was designated by the  
25 CASGEM program as medium priority.

26 **7.3.5.1.4 Santa Ynez River Valley Groundwater Basins**

27 Several groundwater basins in Santa Barbara County are in a state of overdraft,  
28 including the Santa Ynez River Valley Groundwater Basin. The Santa Ynez  
29 Groundwater Basin is located along the Pacific Ocean in southwestern Santa  
30 Barbara County. The water bearing formations are characterized by  
31 unconsolidated alluvial and terrace deposits of gravel, sand, silt, and clay  
32 (DWR 2004an, 2013e). Groundwater flows towards the Santa Ynez River, and  
33 then towards the Pacific Ocean. Groundwater recharge occurs along the stream  
34 beds.

35 Groundwater quality is generally good for municipal and agricultural uses. There  
36 are localized areas with high TDS near the Pacific Ocean due to seawater  
37 intrusion (DWR 2004an, 2013e).

38 The Santa Ynez River Valley Groundwater Basin was designated by the  
39 CASGEM program as medium priority.

1 **7.3.5.1.5 Goleta, Foothill, Santa Barbara, Montecito, and Carpinteria**  
2 **Groundwater Basins**

3 The Goleta, Foothill, Santa Barbara, Montecito, and Carpinteria groundwater  
4 basins are located in southwestern Santa Barbara County along the Pacific Ocean  
5 and near the boundary with Ventura County. The water bearing formations in the  
6 Goleta, Foothill, Santa Barbara, and Montecito groundwater basins are  
7 unconsolidated alluvium of clay, silt, sand, and/or gravel that overlays the  
8 generally confined Santa Barbara Formation of marine sand, silt, and clay  
9 (DWR 2004an, 2004ao, 2004ap, 2004aq, 2013e).

10 In the Carpinteria Groundwater Basin, the alluvium extends under the agricultural  
11 plain (DWR 2004ar, 2013e). A confined aquifer occurs under a thick clay bed in  
12 the lower part of the alluvium. This basin includes the Santa Barbara Formation;  
13 as well as the Carpinteria Formation, of unconsolidated to poorly consolidated  
14 sand with gravel and cobble; and the Casitas Formation, of poorly to moderately  
15 consolidated clay, silt, sand, and gravel.

16 Several faults restrict groundwater flow throughout these basins. Recharge occurs  
17 along streambeds and from subsurface inflow into the basin from upland areas.  
18 Water released from Lake Cachuma increases groundwater recharge rates.

19 The groundwater levels in portions of these groundwater basins declined up to  
20 10 feet between fall 2013 and fall 2014, and in some areas more than 10 feet  
21 (DWR 2014d).

22 Groundwater quality is generally good for municipal and agricultural uses. There  
23 are localized areas with high TDS near the Pacific Ocean due to seawater  
24 intrusion (DWR 2004an, 2004ao, 2004ap, 2004aq, 2004ar, 2013e; GWD and  
25 LCMWC 2010). High concentrations of nitrate, iron, and manganese occur in  
26 localized areas in the Goleta Groundwater Basin. Localized areas of high nitrate  
27 and sulfate concentrations occur within the Foothill Groundwater Basin. High  
28 concentrations of calcium, magnesium, bicarbonate, and sulfate occur in localized  
29 areas of the Santa Barbara Groundwater Basin. High concentrations of iron and  
30 manganese occur in localized areas of the Montecito Groundwater Basin.

31 Localized areas with high nitrates occur within the Carpinteria Groundwater  
32 Basin. Other basins are in equilibrium due to management of the basin through  
33 conjunctive use by local water districts (Santa Barbara County 2007). The Goleta  
34 Groundwater Basin generally is near or above historical groundwater conditions  
35 (Goleta Groundwater Basin and La Cumbre Mutual Water Company 2010), with  
36 the northern and western portions of the basin having groundwater levels near the  
37 ground surface. High groundwater levels may result in degradation to building  
38 foundations and agricultural crops (water levels within the crop root zone).

39 The Goleta Groundwater Basin was designated by the CASGEM program as  
40 medium priority. Goleta, Foothill, Santa Barbara, Montecito, and Carpinteria  
41 groundwater basins were designated as very low priority.

1 **7.3.5.2 Groundwater Use and Management**

2 Groundwater is an important source of water supply for the population of the  
3 Central Coast; it is the region’s primary water source.

4 **7.3.5.2.1 Morro Valley and Chorro Valley Groundwater Basins**

5 As described in Chapter 5, Surface Water Resources and Water Supplies, the City  
6 of Morro Bay uses groundwater from Morro Valley and Chorro Valley  
7 groundwater basins. These basins have been designated by the State Water  
8 Resources Control Board as riparian underflow basins. The City of Morro Bay  
9 and other users of these basins have received water rights permits which limits the  
10 rate and volume of groundwater withdrawals (Morro Bay 2011).

11 **7.3.5.2.2 Santa Maria River Valley Groundwater Basin**

12 The Santa Maria River Valley Groundwater Basin is the primary water supply for  
13 irrigation in southwestern San Luis Obispo County and northwestern Santa  
14 Barbara County. Groundwater also is a major portion of the water supplies for  
15 the communities of Pismo Beach, Grover Beach, Arroyo Grande, Oceano,  
16 Nipomo, and several smaller communities in San Luis Obispo County; and  
17 Guadalupe, Santa Maria, and Orcutt in Santa Barbara County (City of Grover  
18 Beach 2011). In many cases, groundwater is the total water supply for these  
19 communities including Nipomo Community Services District (NCSD 2011).

20 The groundwater basin was adjudicated as defined by a settlement agreement, or  
21 stipulation, in 2005 that was filed in 2008. The stipulation defined the safe yield  
22 of the basin and measures to protect groundwater supplies (Pismo Beach 2011,  
23 Arroyo Grande 2012, NCSD 2011, Santa Maria 2011). The stipulation provided  
24 for the Northern Cities Management Area, Nipomo Mesa Management Area, and  
25 Santa Maria Valley Management Area. The groundwater adjudication considers  
26 groundwater recharge from precipitation and applied irrigation water; and water  
27 released from Reclamation’s Twitchell Reservoir and San Luis Obispo Flood  
28 Control and Water Conservation District’s Lopez Reservoir that recharge the  
29 basin from the downstream stream beds.

30 The cities of Pismo Beach, Grover Beach, Arroyo Grande; Oceano Community  
31 Services District; San Luis Obispo County; and San Luis Obispo Flood Control  
32 and Water Conservation District have formed the Northern Cities Management  
33 Area to manage and protect groundwater supplies in accordance with the  
34 adjudication stipulation (Pismo Beach 2011, Arroyo Grande 2012, NCSD 2011).  
35 Historical monitoring reporting indicates that the groundwater levels have varied  
36 from 20 feet above to 20 feet below mean sea level. When groundwater levels are  
37 below mean sea level, there is a potential for sea water intrusion. In 2008,  
38 groundwater levels in this area were approximately 10 feet below mean sea level.  
39 In 2010, groundwater levels had recovered and ranged from 0 to 20 feet above  
40 mean sea level. Overdraft conditions occurred more frequently prior to the  
41 groundwater adjudication and completion of the Central Coast Water Authority  
42 project that provides SWP water supplies to the area. There is a deep aquifer

1 under the City of Arroyo Grande (Pismo Formation) that provides groundwater  
2 not addressed in the adjudicated Santa Maria Groundwater Basin.

3 Agricultural water users and the communities of Guadalupe, Orcutt, and Santa  
4 Maria use groundwater in the Santa Maria Valley Management Area of the Santa  
5 Maria Groundwater Basin (SMVMA 2012). Historically, groundwater was used  
6 to provide almost 50 percent of the water supply to the City of Santa Maria.  
7 Recently, groundwater supplies have become 10 to 20 percent of the total water  
8 supply to the city (Santa Maria 2011). Groundwater provides most of the water  
9 supplies in Orcutt (Golden State Water Company 2011a).

#### 10 **7.3.5.2.3 San Antonio Creek Valley Groundwater Basin**

11 Groundwater is used for agricultural and domestic water supplies in the San  
12 Antonio Creek Valley Groundwater Basin, including the Los Alamos area  
13 (DWR 2004dq, 2013e).

#### 14 **7.3.5.2.4 Santa Ynez River Valley Groundwater Basin**

15 Groundwater is used for agricultural and domestic water supplies in the Santa  
16 Ynez River Valley Groundwater Basin. As described in Chapter 5, Surface Water  
17 Resources and Water Supplies, groundwater is used by all agricultural water users  
18 and the communities of Buellton, Lompoc, Solvang, Mission Hills, Vandenberg  
19 Village, and Santa Ynez (DWR 2004am, 2013e; Santa Barbara County 2007).

#### 20 **7.3.5.2.5 Goleta, Foothill, Santa Barbara, Montecito, and Carpinteria** 21 **Groundwater Basins**

22 Groundwater is used agricultural and domestic water supplies in the Goleta,  
23 Foothill, Santa Barbara, Montecito, and Carpinteria groundwater basins within  
24 Santa Barbara County. Goleta Water District and La Cumbre Mutual Water  
25 Company are the major communities that use groundwater in the Goleta  
26 Groundwater Basin (DWR 2004an; GWD 2011; GWD and LCMWC 2010). This  
27 basin is operated under an adjudication settlement in 1989 and a voter-passed  
28 groundwater management plan. Historically, Goleta Water District provided up  
29 to 14 percent of the water supply by groundwater. As described in Chapter 5,  
30 Surface Water Resources and Water Supplies, Goleta Water District has increased  
31 use of surface water from Lake Cachuma and the SWP; and decreased long-term  
32 average use of groundwater to about 5 percent of the total water supply.

33 Portions of the La Cumbre Mutual Water Company and City of Santa Barbara use  
34 groundwater from the Foothill Groundwater Basin. The City of Santa Barbara  
35 also relies upon groundwater from the Santa Barbara Groundwater Basin. The  
36 City of Santa Barbara manages groundwater in accordance with the Pueblo Water  
37 Rights (Santa Barbara 2011).

38 Montecito Water District uses groundwater from the Montecito Groundwater  
39 Basin. Carpinteria Valley Water District uses groundwater from the Carpinteria  
40 Groundwater Basin (Carpinteria Valley WD 2011). Total groundwater pumping  
41 averages approximately 3,700 acre-feet per year.

1 **7.3.6 Southern California Region**

2 The Southern California Region includes portions of Ventura, Los Angeles,  
 3 Orange, San Diego, Riverside, and San Bernardino counties served by the SWP.  
 4 The Southern California Region groundwater basins are as varied as the geology  
 5 that occurs in different geographic portions of the region. Therefore, the  
 6 following discussions are organized in the following subregions.

- 7 • Ventura County and northwestern Los Angeles County
- 8 • Central and southern Los Angeles County and Orange County
- 9 • Western San Diego County
- 10 • Western and central Riverside County and southern San Bernardino County
- 11 • Antelope Valley and Mojave Valley

12 **7.3.6.1 Western Ventura County and Northwestern Los Angeles County**

13 The areas within the SWP service area in Ventura County and northwestern  
 14 Los Angeles County in the Southern California Region include the Acton Valley  
 15 Groundwater Basin in Los Angeles County; Santa Clara River Valley, Thousand  
 16 Oaks Area, and Russell Valley groundwater basins in Ventura and Los Angeles  
 17 counties; and Simi Valley, Las Posas Valley, Pleasant Valley, Arroyo Santa Rosa  
 18 Valley, Tierra Rejada, and Conejo Valley groundwater basins in Ventura County,  
 19 as shown in Figure 7.10.

20 **7.3.6.1.1 Hydrogeology and Groundwater Conditions**

21 *Acton Valley Groundwater Basin*

22 The Acton Valley Groundwater Basin is located upgradient of the Santa Clara  
 23 River Valley Groundwater Basin and drains towards the Santa Clara River.  
 24 Water bearing formations include unconsolidated alluvium of sand, gravel, silt,  
 25 and clay with cobbles and boulders; and poorly consolidated terraced deposits  
 26 (DWR 2004as; 2013f). Recharge occurs along the streambed, water applied to  
 27 the soils, and subsurface inflow. Groundwater is characterized by calcium,  
 28 magnesium, and sulfate bicarbonate with localized areas of high concentrations of  
 29 TDS, sulfate, nitrate, and chlorides.

30 Acton Valley Groundwater Basin was designated by the CASGEM program as  
 31 very low priority.

32 *Santa Clara River Valley Groundwater Basin*

33 The Santa Clara River Valley Groundwater Basin is the source of local  
 34 groundwater along the Santa Clara River watershed from the Santa Clarita Valley  
 35 in northwestern Los Angeles County to the Pacific Ocean near the City of Oxnard  
 36 in Ventura County. The Santa Clara River Valley Groundwater Basin includes  
 37 the Piru, Fillmore, Santa Paula, Mound, and Oxnard subbasins in Ventura county;  
 38 and Santa Clara River Valley East Subbasin in Los Angeles County.

39 Groundwater movement is effected by the occurrence of several fault zones  
 40 (DWR 2004at, 2004au, 2006s, 2006t, 2006u, 2013f). Groundwater recharge

1 occurs along the Santa Clara River and its tributaries, and by percolation of  
2 precipitation and applied irrigation water.

3 The Santa Clara River Valley East Subbasin is characterized by unconsolidated  
4 alluvium of sand, gravel, silt, and clay; poorly consolidated terrace deposits of  
5 gravel, sand, and silt; and the Saugus Formation of poorly consolidated sandstone,  
6 siltstone, and conglomerate (DWR 2006s, 2013f).

7 The Piru, Fillmore, Santa Paula, Mound, and Oxnard subbasins are characterized  
8 by alluvium of silts and clays interbedded with sand and gravel lenses; and the  
9 San Pedro Formation of fine sands and gravels over the alluvium (DWR 2004at,  
10 2004au, 2006t, 2006u, 2006v, 2013f).

11 Groundwater quality in the Santa Clara River Valley Groundwater Basin is  
12 suitable for a variety of beneficial uses. However, some areas have been impaired  
13 by elevated TDS, nitrate, and boron concentrations (DWR 2004at, 2004au, 2006t,  
14 2006u, 2006v, 2013f; CLWA et al. 2012). Groundwater quality is characterized  
15 by fluctuating salinity that increases during dry periods. Localized areas of high  
16 nitrates and organic compounds occur due to historic agricultural activities and  
17 wastewater disposal.

18 The Piru, Oxnard, and Santa Clara River Valley East subbasins were designated  
19 by the CASGEM program as high priority. The Fillmore, Santa Paula, and  
20 Mound subbasins were designated as medium priority.

21 *Simi Valley Groundwater Basin*

22 The Simi Valley Groundwater Basin is located in Ventura County (DWR 2004av,  
23 2013f). Water bearing formations in this basin are characterized by generally  
24 unconfined alluvium of gravel, clays, and sands; with local clay lenses that  
25 provide confined aquifers. The Simi Fault confines the basin on the northern  
26 boundary. Groundwater recharge occurs along stream beds. Groundwater quality  
27 is characterized as calcium sulfate with localized areas of high TDS and organic  
28 contaminants.

29 Simi Valley Groundwater Basin was designated by the CASGEM program as low  
30 priority.

31 *Las Posas Valley and Pleasant Valley Groundwater Basins*

32 The Las Posas Valley and Pleasant Valley groundwater basins are located in  
33 western Ventura County. Groundwater is found within these basins in thick  
34 alluvium that is dominated by sand and gravel in the eastern part of the Las Posas  
35 Valley Groundwater Basin; and by silts and clays with lenses of sands and gravels  
36 in the western part of the Las Posas Valley Groundwater Basin and the Pleasant  
37 Valley Groundwater Basin (DWR 2006w, 2006x, 2013f). Underlying the  
38 alluvium are the San Pedro and Santa Barbara formations of gravels, sands, silts  
39 and clays with a discontinuous aquitard located within the Santa Barbara  
40 Formation. The movement of groundwater is locally influenced by features such  
41 as faults, structural depressions and constrictions and operating production wells;  
42 however, groundwater generally flows west-southwest toward the Oxnard  
43 Subbasin. Hydrographs from the Las Posas Valley and Pleasant Valley

1 Groundwater Basins have exhibited a variety of groundwater-level histories over  
2 the past couple decades. Most hydrographs in the eastern part of the Las Posas  
3 Valley Groundwater Basin indicate relatively unchanged groundwater levels or a  
4 slight rise since 1994. Most hydrographs in the western Las Posas Valley and  
5 Pleasant Valley groundwater basins indicate that groundwater levels have risen to  
6 and been maintained at moderate levels since 1992.

7 Groundwater quality in the Las Posas Valley and Pleasant Valley groundwater  
8 basins is suitable for a variety of beneficial uses. Moderate to high TDS  
9 concentrations occur in the Las Posas Valley Groundwater Basin and the Pleasant  
10 Valley Groundwater Basin (DWR 2006w, 2006x, 2013f).

11 The Las Posas Valley and Pleasant Valley groundwater basins were designated by  
12 the CASGEM program as high priority.

13 *Arroyo Santa Rosa Valley Groundwater Basin*

14 The Arroyo Santa Rosa Valley Groundwater Basin is located within Ventura  
15 County. The water bearing formations include alluvium of gravel, sand, and clay;  
16 and the alluvial San Pedro Formation of sand and gravel (DWR 2006y, 2013f).  
17 Groundwater recharge occurs along the Santa Clara River and the tributaries, and  
18 by percolation of precipitation and applied irrigation water. Fault zones affect  
19 groundwater movement within the basin. Groundwater quality is adequate for  
20 community and agricultural water uses. Localized areas of high sulfate and  
21 nitrate concentrations occur within the basin.

22 Arroyo Santa Rosa Valley Groundwater Basin was designated by the CASGEM  
23 program as medium priority.

24 *Tierra Rejada Valley, Conejo Valley, and Thousand Oaks Area Groundwater*  
25 *Basins*

26 The Tierra Rejada Valley, Conejo Valley, and Thousand Oaks groundwater basins  
27 in southern Ventura County are characterized by shallow alluvium that overlays  
28 marine sandstone and shale of the Modelo and Topanga formations (DWR  
29 2004aw, 2004ax, 2004ay, 2013f). In some portions of the basin, the Topanga  
30 Formation of volcanic tuff, debris flow, and basaltic flow occurs. Groundwater  
31 recharge occurs along the streambeds and by percolation of precipitation and  
32 applied irrigation water. Fault zones affect groundwater movement within the  
33 basins. Groundwater quality is adequate for community and agricultural water  
34 uses. Localized areas of high alkalinity and nitrate concentrations occur within  
35 the basins. High iron and TDS occur in the Thousand Oaks Area Groundwater  
36 Basin (Thousand Oaks 2011).

37 Conejo Valley Groundwater Basin was designated by the CASGEM program as  
38 low priority. The Tierra Rejada Valley and Thousand Oaks Area groundwater  
39 basin were designated as very low priority.

40 *Russell Valley Groundwater Basin*

41 The Russell Valley Groundwater Basin is located along the boundaries of Ventura  
42 and Los Angeles counties (DWR 2004az, 2013f). This small groundwater basin  
43 is characterized by unconsolidated, poorly bedded, sand, gravel, silt, and clay with

1 cobbles and boulders. The groundwater is recharged by precipitation within the  
2 basin. Groundwater quality is characterized by sodium bicarbonate and calcium  
3 bicarbonate with high sulfates and TDS in some localized areas.  
4 Russell Valley Groundwater Basin was designated by the CASGEM program as  
5 very low priority.

#### 6 **7.3.6.1.2 Groundwater Use and Management**

7 Groundwater is an important water supply throughout the Southern California  
8 Region. Many of the basins have been adjudicated and groundwater management  
9 agencies have been established to manage, preserve, and regulate groundwater  
10 withdrawals and recharge actions. In Ventura County, the Fox Canyon  
11 Groundwater Management Agency was established in 1982 to implement a  
12 groundwater plan that identifies withdrawal allocations and groundwater elevation  
13 and quality criteria (MWDSC 2007).

#### 14 *Acton Valley Groundwater Basin*

15 As described in Chapter 5, Surface Water Resources and Water Supplies, the  
16 Acton community primarily uses groundwater supplemented by SWP water  
17 treated at the Antelope Valley East Kern Acton Water Treatment Plant (Los  
18 Angeles County 2014b).

#### 19 *Santa Clara River Valley Groundwater Basin*

20 Communities and agricultural water users in the Santa Clara River Valley  
21 Groundwater Basin use a combination of surface water and groundwater to meet  
22 water demands. Agricultural use of groundwater is greater than community use  
23 of groundwater in this basin (UCWD 2012).

24 Four retail water purveyors provide water service to most residents of the Santa  
25 Clara River Valley East Subbasin. These water purveyors include the Castaic  
26 Lake Water Agency; Santa Clarita Water Division, Los Angeles County  
27 Waterworks District Number 36; Newhall County Water District; and Valencia  
28 Water Company. Groundwater is used by the communities of Santa Clarita,  
29 Saugus, Canyon Country, Newhall, Val Verde, Hasley Canyon, Valencia, Castaic,  
30 Stevenson Ranch (CLWA et al. 2012).

31 Water purveyors in the Piru, Fillmore, Santa Paula, Mound, and Oxnard subbasins  
32 include United Water Conservation District and Ventura County. United Water  
33 Conservation District operates surface water facilities to encourage groundwater  
34 protection through conjunctive use (UWCD 2012). Groundwater issues within  
35 the United Water Conservation District service area (which includes all of the  
36 basin) include overdraft conditions, sea water intrusion, and high nitrate  
37 concentrations.

#### 38 *Simi Valley Groundwater Basin*

39 The Simi Valley area primarily relies upon surface water supplies, including SWP  
40 water supplies. Groundwater is used to supplement these supplies and by users  
41 that cannot be easily served with surface water. Groundwater is provided by  
42 Golden State Water Company service area and Ventura County Waterworks

1 District No. 8. The Golden State Water Company provides less 10 percent of the  
2 total water supply to the area (Golden State Water Company 2011b). Ventura  
3 County Waterworks District No. 8 provides groundwater to a golf course, nursery,  
4 and industrial user in the Simi Valley area (VCWD8 2011).

5 *Las Posas Valley and Pleasant Valley Groundwater Basins*

6 Communities and agricultural water users in the Las Posas Valley and Pleasant  
7 Valley groundwater basins use a combination of surface water and groundwater to  
8 meet water demands. Agricultural use of groundwater is greater than community  
9 use of groundwater in this basin (UCWD 2012). United Water Conservation  
10 District and Ventura County manage water service to many residents of the Las  
11 Posas Valley and Pleasant Valley groundwater basins.

12 As described above, United Water Conservation District operates surface water  
13 facilities to encourage groundwater protection through conjunctive use  
14 (UWCD 2012). Groundwater is used within the United Water Conservation  
15 District service area, which includes western Las Posas Valley and Pleasant  
16 Valley groundwater basins. The Oxnard Subbasin of the Santa Clara River  
17 Valley Groundwater Basin and Las Posas Valley and Pleasant Valley  
18 groundwater basins are within the groundwater management plan established by  
19 the Fox Canyon Groundwater Management Agency (Fox Canyon GMA 2013).  
20 The groundwater management agency manages and monitors groundwater in  
21 areas with groundwater overdraft and seawater intrusion which includes the  
22 communities of Port Hueneme, Oxnard, Camarillo, and Moorpark. The long-term  
23 average groundwater use within Fox Canyon Groundwater Management Agency  
24 includes a portion of the withdrawals reported by United Water Conservation  
25 District.

26 The Calleguas Municipal Water District, in partnership with Metropolitan Water  
27 District of Southern California (Metropolitan), operates the Las Posas Basin  
28 Aquifer Recharge and Recovery project. Calleguas Municipal Water District  
29 stores SWP surplus water in the Las Posas Valley Groundwater Basin, near the  
30 City of Moorpark. The current Aquifer Recharge and Recovery system includes  
31 18 wells (Calleguas MWD 2011).

32 *Arroyo Santa Rosa Valley Groundwater Basin*

33 Communities and agricultural water users in the Arroyo Santa Rosa Valley  
34 Groundwater Basin use a combination of surface water and groundwater to meet  
35 water demands. Camarosa Water District and Fox Canyon Groundwater  
36 Management Agency manage groundwater supplies within the basin (Camarosa  
37 WD 2013).

38 *Tierra Rejada Valley, Conejo Valley, and Thousand Oaks Area Groundwater*  
39 *Basins*

40 Groundwater in the Tierra Rejada Valley, Conejo Valley, and Thousand Oaks  
41 Area groundwater basins is primarily used by agricultural and individual  
42 residential water users. Portions of the Tierra Rejada Valley Groundwater Basin  
43 is within the Camarosa Water District; however, this area is primarily open space  
44 and agricultural land uses with individual wells (Camarosa WD 2013). The City

1 of Thousand Oaks does operate two wells; however, the city primarily relies upon  
2 SWP water supplies because of the high iron concentrations and salinity in the  
3 groundwater (Thousand Oaks 2011).

#### 4 *Russell Valley Groundwater Basin*

5 Most groundwater users in the Russell Valley Groundwater Basin are agricultural  
6 and individual residential water users. Portions of the basin are located within the  
7 Calleguas Municipal Water District. However, the district does not use water  
8 from this basin (Calleguas MWD 2011). The Las Virgenes Municipal Water  
9 District withdraws groundwater from the Russell Basin to augment recycled water  
10 supplies (GLCIRWMR 2014).

### 11 **7.3.6.2 Western Los Angeles County and Orange County**

12 The areas within the SWP service area in Central and Southern Los Angeles  
13 County and Orange County in the Southern California Region include the San  
14 Fernando Valley, Raymond, San Gabriel Valley, Coastal Plain of Los Angeles,  
15 and Malibu Valley groundwater basins in Los Angeles County; Coastal Plain of  
16 Orange County and San Juan Valley groundwater basins in Orange County, as  
17 shown in Figure 7.10.

#### 18 **7.3.6.2.1 Hydrogeology and Groundwater Conditions**

##### 19 *San Fernando Valley Groundwater Basin*

20 The San Fernando Valley Groundwater Basin extends under the Los Angeles  
21 River watershed. Groundwater flows toward the middle of the basin, beneath the  
22 Los Angeles River Narrows, to the Central Subbasin of the Coastal Plain of  
23 Los Angeles Basin. The water bearing formation is mainly unconfined gravel and  
24 sand with clay lenses that provide some confinement in the western part of the  
25 basin (DWR 2004ba).

26 Groundwater movement is affected by the occurrence of several fault zones  
27 (DWR 2004ba). Groundwater is recharged naturally from precipitation and  
28 stream flow and from imported water and reclaimed wastewater that percolates  
29 into the groundwater from stormwater spreading grounds.

30 In the San Fernando Valley Groundwater Basin, the groundwater is characterized  
31 by calcium, magnesium, radioactive material, and sulfate bicarbonate with  
32 localized areas of high TDS, volatile organic compounds, petroleum compounds,  
33 chloroform, pesticides, nitrate, and sulfate (DWR 2004ba, ULARAW 2013).

34 There are several ongoing groundwater remediation programs within the  
35 groundwater basin to reduce volatile organic compounds and one program to  
36 reduce hexavalent chromium.

37 San Fernando Valley Groundwater Basin was designated by the CASGEM  
38 program as medium priority.

##### 39 *Raymond Groundwater Basin*

40 The Raymond Groundwater Basin is located to the north of the San Gabriel  
41 Valley Groundwater Basin. Groundwater flow is affected by the occurrence of  
42 several fault zones; and causes the groundwater to flow into the San Gabriel

1 Valley Groundwater Basin. The water bearing formations are mainly  
2 unconsolidated gravel, sand, and silt with local areas of confinement  
3 (DWR 2004bb). Groundwater is recharged naturally from precipitation and  
4 stream flow and from water that percolates into the groundwater from spreading  
5 grounds and local dams.

6 In the Raymond Groundwater Basin, the groundwater is characterized by calcium,  
7 magnesium, and sulfate bicarbonate with localized areas of high volatile organic  
8 compounds, nitrate, radioactive material, and perchlorate (DWR 2004bb). There  
9 is an ongoing groundwater remediation program within the groundwater basin to  
10 reduce volatile organic compounds and perchlorate.

11 Raymond Groundwater Basin was designated by the CASGEM program as  
12 medium priority.

13 *San Gabriel Valley Groundwater Basin*

14 Groundwater in the San Gabriel Valley Groundwater Basin flows from the  
15 San Gabriel Mountains towards the west under the San Gabriel Valley to the  
16 Whittier Narrows where it discharges into the Coastal Plain of the Los Angeles  
17 Groundwater Basin (DWR 2004bc). Groundwater in the San Gabriel Valley  
18 Groundwater Basin also is interconnected to groundwater in the Chino subbasin  
19 of the Upper Santa Ana Valley Groundwater Basin in Riverside County. The  
20 northeastern portion of the San Gabriel Valley Groundwater Basin adjacent to the  
21 Chino subbasin includes six subbasins and is known as “Six Basins.” The water-  
22 bearing formations include unconsolidated to semi-consolidated alluvium deposits  
23 of gravel, sands, and silts.

24 Groundwater recharge occurs from direct percolation of precipitation and stream  
25 flow, including treated wastewater effluent conveyed in the San Gabriel River  
26 (DWR 2004bc). In the San Gabriel Valley Groundwater Basin, the groundwater  
27 is characterized by calcium bicarbonate with localized areas of high TDS, carbon  
28 tetrachloride nitrate, and volatile organic compounds (DWR 2004bc).

29 San Gabriel Valley Groundwater Basin was designated by the CASGEM program  
30 as high priority.

31 *Coastal Plain of Los Angeles Groundwater Basin*

32 The Coastal Plain of Los Angeles Groundwater Basin includes the Hollywood,  
33 Santa Monica, Central, and West Coast subbasins.

34 *Hollywood Subbasin*

35 The Hollywood subbasin is located to the north of the Central subbasin and  
36 upgradient of the Santa Monica subbasin. Groundwater flows towards the Pacific  
37 Ocean (DWR 2004bd). The water bearing formations are mainly alluvial gravel.  
38 Groundwater is recharged naturally from precipitation and stream flow.

39 The Hollywood subbasin was designated by the CASGEM program as very low  
40 priority.

1           *Santa Monica Subbasin*

2   The Santa Monica subbasin is located to the north of the West Coast subbasin and  
3   to the west of the Hollywood subbasin. Groundwater flows towards the west and  
4   the Hollywood subbasin (DWR 2004be). The water bearing formations are  
5   mainly alluvial gravel and sand with semi-perched areas over silt and clay  
6   deposits. Unconfined shallow aquifers occur in the northern and eastern portions  
7   of the subbasin. Confined deeper aquifers occur in the remaining portion of the  
8   subbasin. Groundwater is recharged naturally from precipitation and stream flow.  
9   The Santa Monica subbasin was designated by the CASGEM program as high  
10  priority.

11           *Central Subbasin*

12   The Central subbasin is located to the east of the West Coast subbasin. The  
13   Central subbasin is characterized by shallow sediments and extends from the Los  
14   Angeles River Narrows with groundwater flows from the San Gabriel Valley  
15   (DWR 2004bf).

16   The non-pressurized, or forebay, portions of the subbasin are located in the  
17   northern portion of the subbasin in unconfined aquifers underlying the Los  
18   Angeles and San Gabriel rivers (DWR 2004bf). These areas provide the major  
19   recharge areas for the subbasin. The “pressure” areas are confined aquifers  
20   composed of permeable sands and gravel separated by less permeable sandy clay  
21   and clay, and constitute the main water-bearing formations. Several faults and  
22   uplifts create some restrictions to groundwater flow in the subbasin while others  
23   run parallel to the groundwater flow and do not restrict flow.

24   In the Central subbasin, the groundwater is characterized by localized areas of  
25   high inorganics and volatile organic compounds (DWR 2004bf).

26   The Central subbasin was designated by the CASGEM program as high priority.

27           *West Coast Subbasin*

28   The West Coast subbasin is located on the southern coast of Los Angeles County  
29   to the west of the Central subbasin. The water bearing formations are composed  
30   of unconfined and semi-confined aquifers composed of sands, silts, clays, and  
31   gravels (DWR 2004bg). Several fault zones paralleling the coast act as partial  
32   barriers to groundwater flow in certain areas. The general regional groundwater  
33   flow pattern is southward and westward toward the Pacific Ocean. Recharge  
34   occurs through groundwater flow from the Central subbasin, and from infiltration  
35   along the Los Angeles and San Gabriel rivers. Seawater intrusion occurs along  
36   the Pacific Ocean coast.

37   In the West Coast subbasin, the most critical issue is high TDS along the Pacific  
38   Ocean coast due to seawater intrusion. As described below, several agencies have  
39   implemented sea water barrier projects to protect the groundwater quality.

40   The West Coast subbasin was designated by the CASGEM program as high  
41   priority.

1 *Malibu Valley Groundwater Basin*

2 The Malibu Valley Groundwater Basin is an isolated alluvial basin in northern  
3 Los Angeles County along the Pacific Ocean Coast under the Malibu Creek  
4 watershed (DWR 2004bh). Groundwater flows towards the Pacific Ocean. The  
5 water bearing formations are mainly gravel, sand, clays, and silt (DWR 2004bb).  
6 Groundwater is recharged naturally from precipitation and stream flow.

7 In the Malibu Valley Groundwater Basin, the groundwater is characterized by  
8 localized areas of high TDS due to sea water intrusion along the Pacific Ocean  
9 coast (DWR 2004bh).

10 The Malibu Valley Groundwater Basin was designated by the CASGEM program  
11 as very low priority.

12 *Coastal Plain of Orange County Groundwater Basin*

13 The Coastal Plain of Orange County Groundwater Basin is located under a coastal  
14 alluvial plain in northern Orange County (DWR 2004 bi). Groundwater is  
15 recharged naturally from precipitation and injection wells to reduce seawater  
16 intrusion. The water bearing formations are mainly interbedded marine and  
17 continental sand, silt, and clay deposits (DWR 2004bi). The Newport-Inglewood  
18 fault zone parallels the coast and generally forms a barrier to groundwater flow.  
19 Groundwater recharge occurs along the Santa Ana River. Water levels are  
20 characterized by seasonal fluctuations (DWR 2013f; Orange County 2009).  
21 Groundwater flowed towards the Pacific Ocean prior to recent development.  
22 However, due to extensive groundwater withdrawals, there are groundwater  
23 depressions that result in potential sea water intrusion. Groundwater levels have  
24 increased since the 1990s following implementation of several recharge programs.

25 In the Coastal Plain of Orange County Groundwater Basin, the groundwater is  
26 characterized as sodium-calcium bicarbonate with localized areas of high TDS  
27 due to sea water intrusion along the Pacific Ocean coast, as well as nitrate, and  
28 volatile organic compounds (DWR 2004bi).

29 The Coastal Plain of Orange County Groundwater Basin was designated by the  
30 CASGEM program as medium priority.

31 *San Juan Valley Groundwater Basin*

32 The San Juan Valley Groundwater Basin is located in southern Orange County  
33 (DWR 2004bj). Groundwater flows towards the Pacific Ocean. The water  
34 bearing formations are mainly sand, clays, and silt. Groundwater is recharged  
35 naturally from precipitation and stream flows from San Juan and Oso creeks and  
36 Arroyo Trabuca.

37 In the San Juan Valley Groundwater Basin, the groundwater is characterized as  
38 calcium bicarbonate, bicarbonate-sulfate, calcium-sodium sulfate, and sulfate-  
39 chloride with localized areas of high TDS due to sea water intrusion along the  
40 Pacific Ocean coast and high fluoride near hot springs near Thermal Canyon  
41 (DWR 2004bj).

1 The San Juan Valley Groundwater Basin was designated by the CASGEM  
2 program as low priority.

### 3 **7.3.6.2.2 Groundwater Use and Management**

4 Groundwater is an important water supply throughout the Southern California  
5 Region. Many of the groundwater basins in Los Angeles and Orange counties  
6 have been adjudicated, as summarized in Table 7.1, and groundwater  
7 management agencies have been established to manage, preserve, and regulate  
8 groundwater withdrawals and recharge actions.

#### 9 *San Fernando Valley Groundwater Basin*

10 The communities and agricultural users in the San Fernando Valley Groundwater  
11 Basin use a combination of surface water and groundwater to meet water demands  
12 (GLCIRWMR 2014; ULARAW 2013). The Metropolitan Water District of  
13 Southern California provides wholesale surface water supplies to several  
14 communities. The cities of Los Angeles, Glendale, Burbank, San Fernando,  
15 Crescenta Valley, Bell Canyon, and Hidden Hills provide retail water supplies,  
16 including groundwater, to the communities. The groundwater basin has been  
17 adjudicated and is managed by the Upper Los Angeles River Area Watermaster.

18 Groundwater is recharged in the San Fernando Valley Groundwater Basin through  
19 seepage of precipitation within the groundwater basin, including the recharge of  
20 stormwater at spreading grounds between 1968 and 2012; and storage of imported  
21 water (ULARAW 2013). The spreading basins for stormwater flows are operated  
22 by Los Angeles County and the cities of Los Angeles and Burbank. A portion of  
23 the extracted groundwater is exported to areas that overly other groundwater  
24 basins.

25 The operations of the San Fernando Valley Groundwater Basin are defined by the  
26 Upper Los Angeles River Area January 26, 1979 Final Judgment; the Sylmar  
27 Basin Stipulations of August 26, 1983; and subsequent agreements. These  
28 agreements, as managed by the Upper Los Angeles River Area Watermaster,  
29 provide for the right to extract a percent of surface water, including applied  
30 recycled water, that enters within specified subbasins of the San Fernando Valley  
31 Groundwater Basin with specific calculations to identify maximum withdrawals  
32 for the cities of Burbank, Glendale, Los Angeles, and San Fernando and  
33 Crescenta Valley Water District; the right to store and withdraw water within  
34 specified subbasins by the cities of Burbank, Glendale, Los Angeles, and San  
35 Fernando; and the acknowledgment that the City of Los Angeles has an exclusive  
36 Pueblo Water Right for the native safe yield of the San Fernando subbasin within  
37 the larger San Fernando Valley Groundwater Basin.

#### 38 *Raymond Groundwater Basin*

39 The communities in the Raymond Groundwater Basin use a combination of  
40 surface water and groundwater to meet water demands (GLCIRWMR 2014). The  
41 Metropolitan Water District of Southern California and Foothills Municipal Water  
42 District provide wholesale surface water supplies to several communities. The  
43 cities of Alhambra, Arcadia, Pasadena, San Marino, and Sierra Madre; Upper San

1 Gabriel Municipal Water District; and Valley Water Company and several other  
 2 private water companies, provide retail water supplies, including groundwater, to  
 3 the communities to Altadena, Las Crescenta-Montrose, La Cañada Flintridge,  
 4 Rubio Canyon, and South Pasadena. The City of Alhambra and San Gabriel  
 5 Valley Municipal Water District; can withdraw groundwater from the Raymond  
 6 Basin, but currently are not operating wells within this groundwater basin (City of  
 7 Alhambra 2011).

8 The groundwater basin was the first adjudicated groundwater basin in California  
 9 and is managed by the Raymond Basin Management Board as the Watermaster  
 10 (RBMB 2014). The Raymond Basin Management Board limits the amount of  
 11 groundwater withdrawals in different areas of the basin, and allows for short-term  
 12 and long-term storage of water in the groundwater basin.

13 Groundwater is recharged in the Raymond Groundwater Basin through seepage of  
 14 precipitation within the groundwater basin, injection wells, and spreading basins  
 15 operated by Los Angeles County and the cities of Pasadena and Sierra Madre  
 16 (MWDC 2007). Water from Metropolitan Water District of Southern California,  
 17 which is generally a combination of SWP water and Colorado River water, cannot  
 18 be used for direct recharge if the TDS is greater than 450 milligrams/liter  
 19 (RBMB 2014). A portion of the extracted groundwater is exported to areas that  
 20 overly other groundwater basins.

21 *San Gabriel Valley Groundwater Basin*

22 The communities in the San Gabriel Valley Groundwater Basin use a combination  
 23 of surface water and groundwater to meet water demands (GLCIRWMR 2014;  
 24 MWDC 2007). The Metropolitan Water District of Southern California, San  
 25 Gabriel Valley Municipal Water District, Upper San Gabriel Municipal Water  
 26 District; Three Valleys Municipal Water District, and Covina Irrigating Company  
 27 provide wholesale surface water and/or groundwater supplies to several  
 28 communities. The cities of Alhambra, Arcadia, Azusa, Covina, El Monte,  
 29 Glendora, La Verne, Monrovia, Pomona, San Marino, and Upland; San Gabriel  
 30 County Water District and Valley County Water District; Golden State Water  
 31 Company, San Antonio Water Company, San Gabriel Valley Water Company,  
 32 Suburban Water Systems, Valencia Heights Water Company, and several other  
 33 private water companies, provide retail water supplies, including groundwater, to  
 34 users within their communities and to the communities of Baldwin Park,  
 35 Bradbury, Claremont, Duarte, Hacienda Heights, Irwindale, La Puente,  
 36 Montebello, Monterey Park, Pico Rivera, Rosemead, San Dimas, San Gabriel,  
 37 Santa Fe Springs, Sierra Madre, South El Monte, South San Gabriel, Temple City,  
 38 Valinda, and Whittier (City of Alhambra 2011; City of Arcadia 2011; City of La  
 39 Verne 2011; City of Pomona 2011; City of Upland 2011; Golden State Water  
 40 Company 2011c; SGCWD 2011; SGVWC 2011; Suburban Water Systems 2011;  
 41 SAWCO 2011; TVMWD 2011; USGVMWD 2011).

42 The San Gabriel Valley Groundwater Basin includes several adjudicated basins.  
 43 A portion of the groundwater basin is managed by the San Gabriel River  
 44 Watermaster and the Main San Gabriel Basin Watermaster (MWDC 2007;  
 45 SGVWC 2011). The Watermasters coordinate groundwater elevation and water

1 quality monitoring, coordinate imported water supplies, coordinate recharge  
2 operations with imported water and recycled water, manage the amount of  
3 groundwater withdrawals in different areas of the basin by balancing the amount  
4 of groundwater recharge, and allow for short-term and long-term storage of water  
5 in the groundwater basin. Groundwater is recharged through seepage of  
6 precipitation within the groundwater basin, injection wells, and spreading basins  
7 operated by Los Angeles County and a private water company (MWDSC 2007).  
8 Water recharged into the spreading basins from Metropolitan Water District of  
9 Southern California and San Gabriel Valley Municipal Water District.

10 The Six Basins portion of the groundwater basin also is adjudicated and managed  
11 by the Six Basins Watermaster Board (MWDSC 2007). The Watermaster  
12 manages withdrawals and requires replenishment obligation of equal amounts for  
13 withdrawals over the operating safe yield of the basin. The Pomona Valley  
14 Protective Agency conveys flows from San Antonio Creek and SWP water to the  
15 San Antonio Spreading Grounds; and from local waters to the Thompson Creek  
16 Spreading Grounds. The City of Pomona conveys flows from local surface  
17 waters to the Pomona Spreading Grounds. Los Angeles County Department of  
18 Public Works conveys flows from local surface water and SWP water to the Live  
19 Oak Spreading Grounds.

20 The cities of Alhambra, Arcadia, La Verne, Monterey Park, San Gabriel Valley  
21 Water Company, and other water entities operate groundwater treatment facilities  
22 to remove dichloroethane, chloroform, other volatile organic compounds, and/or  
23 nitrates (City of Alhambra 2011; City of Arcadia 2011; City of Monterey  
24 Park 2012; MWDSC 2007; SGVWC 2011).

25 *Coastal Plain of Los Angeles Groundwater Basin*

26 The Coastal Plain of Los Angeles Groundwater Basin includes four subbasins:  
27 Hollywood, Santa Monica, Central and West Coast.

28 *Hollywood Subbasin*

29 The primary user of groundwater in the Hollywood subbasin is the City of  
30 Beverly Hills (MWDSC 2007). The basin is not adjudicated. The city manages  
31 the groundwater subbasin through limits on withdrawals and discharges to the  
32 groundwater. Groundwater is recharged through seepage of precipitation within  
33 the groundwater subbasin (City of Beverly Hills 2011). All groundwater  
34 withdrawn by the city is treated to reduce salinity.

35 *Santa Monica Subbasin*

36 The primary user of groundwater in the Santa Monica subbasin is the City of  
37 Santa Monica (MWDSC 2007). The basin is not adjudicated. Groundwater is  
38 recharged through seepage of precipitation within the groundwater subbasin  
39 (City of Santa Monica 2011; MWDSC 2007). Groundwater treatment is provided  
40 to a portion of the subbasin withdrawals to reduce volatile organic compounds,  
41 and methyl tertiary butyl ether.

1            *Central Subbasin*

2    The communities in the Central subbasin use a combination of surface water and  
 3    groundwater to meet water demands (GLCIRWMR 2014; MWDSC 2007). The  
 4    Metropolitan Water District of Southern California and Central Basin Municipal  
 5    Water District provide wholesale surface water supplies to several communities.  
 6    The cities of Bell, Bell Gardens, Cerritos, Compton, Cudahy, Downey,  
 7    Huntington Park, Lakewood, Long Beach, Los Angeles, Lynwood, Monterey  
 8    Park, Norwalk, Paramount, Pico Rivera, Santa Fe Springs, Signal Hill, South  
 9    Gate, Vernon, and Whittier; Los Angeles County Water District, La Habra  
 10   Heights County Water District, Orchard Dale Water District, and Paramount  
 11   Water District; Golden State Water Company, Suburban Water Systems,  
 12   Bellflower-Somerset Mutual Water Company, Montebello Land & Water  
 13   Company; Park Water Company, Dominguez Water Corp, California Water  
 14   Service Company, San Gabriel Valley Water Company, Walnut Park Mutual  
 15   Water Company, and several other private water companies, provide retail water  
 16   supplies, including groundwater, to users within their communities and to the  
 17   communities of Artesia, Commerce, Dominguez, East La Mirada, East Los  
 18   Angeles, East Rancho, Florence-Graham, Hawaiian Gardens, La Mirada, Los  
 19   Nieto, Maywood, Montebello, South Whittier, Walnut Park, Westmount, West  
 20   Whittier, and Willow Brook (CBMWD 2011; BSMWC 2011; City of Compton  
 21   2011; City of Downey 2012; City of Huntington Park 2011; City of Lakewood  
 22   2011; City of Long Beach 2011; City of Los Angeles 2011; City of Monterey  
 23   Park 2012; City of Norwalk 2011; City of Paramount 2011; City of Pico Rivera  
 24   2011; City of Santa Fe Springs 2011; City of South Gate; City of Vernon 2011;  
 25   City of Whittier 2011; LHHWCWD 2012; Golden State Water Company 2011d,  
 26   2011e, 2011f, 2011g; Suburban Water Systems 2011).

27   The Central subbasin was adjudicated, and is managed by DWR. The  
 28   adjudication specifies a total amount of allowed annual withdrawals (or  
 29   Allowable Pumping Allocation) in the Central subbasin (MWDSC 2007; WRD  
 30   2013a). Approximately 25 percent of the water users of groundwater from the  
 31   Central subbasin are not located on the land that overlies the subbasin (CBMWD  
 32   2011). Groundwater from the San Gabriel Valley Groundwater Basin also is used  
 33   by water users that overlie the Central subbasin.

34   The Water Replenishment District of Southern California has the statutory  
 35   authority to replenish the groundwater in the Central and West Coast subbasins of  
 36   the Coastal Plain of Los Angeles Groundwater Basin. The Water Replenishment  
 37   District of Southern California purchases water for water replenishment facilities  
 38   operated by Los Angeles County Department of Public Works at the Montebello  
 39   Forebay near the Rio Hondo and San Gabriel Rivers near the boundaries of the  
 40   Central and West Coast subbasins (CBMWD 2011; Los Angeles County 2015;  
 41   WRD 2013a). The Montebello Forebay includes the Rio Hondo Coastal Basin  
 42   Spreading Grounds along the Rio Hondo Channel; the San Gabriel River Coastal  
 43   Basin Spreading Grounds; and the unlined reach of the lower San Gabriel River  
 44   from Whittier Narrows Dam to Florence Avenue (LACDPW 2014, WRD 2013a).

1 The replenishment water is purchased water from two different sources: recycled  
2 water from various regional treatment facilities, and imported water (WRD  
3 2013a). The recycled water is used for groundwater recharge at the spreading  
4 grounds and at the seawater barrier wells. Water Replenishment District of  
5 Southern California must blend recycled water with other water sources to meet  
6 the groundwater recharge water quality and volumetric requirements established  
7 by the State Water Resources Control Board. This blended water is either  
8 imported water from the SWP and/or the Colorado River, or untreated surface  
9 water flows from the San Gabriel River, Rio Hondo River, and waterways in the  
10 San Gabriel Valley (CBMWD 2011). Up to 35 percent of the replenishment  
11 water can be provided from recycled water supplies. Several recent projects have  
12 been implemented to store stormwater flows for increased replenishment water  
13 volumes.

14 In the Central subbasin, the Water Replenishment District of Southern California  
15 also purchases imported and recycled water for injection by the Los Angeles  
16 County Department of Public Works into the portion of the Alamitos Barrier  
17 Project located in Los Angeles County to reduce seawater intrusion  
18 (MWDC 2007; WRD 2007). Initially, imported SWP water was used to prevent  
19 seawater intrusion. However, over the past 20 years, recycled water has been  
20 used for a substantial amount of the groundwater injection program. The Water  
21 Replenishment District of Southern California is planning to fully use recycled  
22 water at the Alamitos Gap Barrier Project by 2014 (WRD 2013b).

23 The cities of Long Beach, Monterey Park, South Gate, and Whittier operate  
24 groundwater treatment facilities in the Central subbasin (City of Long Beach  
25 2012; City of Monterey Park 2012; City of South Gate; City of Whittier 2011).

26 *West Coast Subbasin*

27 The communities in the Central subbasin use a combination of surface water and  
28 groundwater to meet water demands (GLCIRWMR 2014; MWDC 2007). The  
29 Metropolitan Water District of Southern California and West Basin Municipal  
30 Water District provide wholesale surface water supplies to several communities.  
31 The cities of Inglewood, Lomita, Manhattan Beach, and Torrance; Golden State  
32 Water Company, California Water Service Company, and several other private  
33 water companies, provide retail water supplies, including groundwater, to users  
34 within their communities and to the communities of Athens, Carson, Compton,  
35 Del Aire, Gardena, Hawthorne, Hermosa Beach, Inglewood, Lawndale, Lennox,  
36 Redondo Beach, Torrance (WBMWD 2011a; City of Inglewood 2011; City of  
37 Lomita 2011; City of Manhattan Beach 2011; City of Torrance 2011; Golden  
38 State Water 2011h; California Water Service Company 2011b, 2011c, 2011d,  
39 2011e). The communities of El Segundo, Long Beach, and Los Angeles overlie  
40 the West Coast subbasin; however, no groundwater from this subbasin is used in  
41 these communities due to water quality issues and facilities locations.  
42 Groundwater use is primarily for emergency uses, including firefighting, in the  
43 communities of Hawthorne, Lomita, and Torrance due to high concentrations of  
44 minerals (e.g., iron and manganese), sulfides, and/or volatile organic compounds.

1 The West Coast subbasin was adjudicated, and is managed by DWR. The  
 2 adjudication specifies a total amount of allowed annual withdrawals (or  
 3 Allowable Pumping Allocation) in the West Coast subbasin (MWDC 2007;  
 4 WBMWD 2011a; WRD 2013a). Groundwater from the Central subbasin is used  
 5 by some water users that overlie the West Coast subbasin.

6 The Water Replenishment District of Southern California has the statutory  
 7 authority to replenish the groundwater in the Central and West Coast subbasins of  
 8 the Coastal Plain of Los Angeles Groundwater Basin. In the West Coast  
 9 subbasin, the Water Replenishment District of Southern California purchases  
 10 imported and recycled water for injection by the Los Angeles County Department  
 11 of Public Works into the West Coast Barrier Project and the Dominguez Barrier  
 12 Project (MWDC 2007; WRD 2007; WRD 2013). Water is purchased by the  
 13 Water Replenishment District of Southern California for injection at the barrier  
 14 projects (WRD 2013). Initially, imported SWP water was used to prevent  
 15 seawater intrusion. However, over the past 20 years, recycled water has been  
 16 used for a substantial amount of the groundwater injection program. The Water  
 17 Replenishment District of Southern California is planning to fully use recycled  
 18 water at the West Coast Barrier Project and the Dominguez Barrier Project by  
 19 2014 and 2017, respectively (WRD 2013b).

20 California Water Service Company operates groundwater treatment facilities  
 21 within the community of Hawthorne (California Water Service Company 2011b).  
 22 The Water Replenishment District of Southern California operates the Robert W.  
 23 Goldsworthy Desalter near Torrance to reduce salinity for up to 18,000 acre-  
 24 feet/year of groundwater that is located inland of the West Coast Basin Barrier  
 25 (WRD 2013a).

26 The West Basin Municipal Water District treats brackish groundwater at the  
 27 C. Marvin Brewer Desalter Facility for two wells near Torrance that are affected  
 28 by a saltwater plume in the West Coast subbasin (WBMWD 2011a).

29 *Malibu Valley Groundwater Basin*

30 No groundwater is used by the communities in this groundwater basin, including  
 31 the Malibu area (Los Angeles County 2011; MWDC 2007).

32 *Coastal Plain of Orange County Groundwater Basin*

33 The communities in the Coastal Plain of Orange County Groundwater Basin use a  
 34 combination of surface water and groundwater to meet water demands  
 35 (MWDC 2007). The Municipal Water District of Orange County, Orange  
 36 County Water District, and East Orange County Water District provide wholesale  
 37 surface water supplies to several communities. The cities of Anaheim, Buena  
 38 Park, Fountain Valley, Fullerton, Garden Grove, Huntington Beach, La Habra,  
 39 La Palma, Newport Beach, Orange, Santa Ana, Seal Beach, Tustin, and  
 40 Westminster; East Orange County Water District, Irvine Ranch Water District,  
 41 Mesa Consolidated Water District, Rowland Water District, Serrano Water  
 42 District, Walnut Valley Water District, and Yorba Linda Water District; Golden  
 43 State Water Company, California Water Service Company, California Domestic  
 44 Water Company, and several other private water companies, provide retail water

1 supplies, including groundwater, to users within their communities and to the  
2 communities of Brea, Costa Mesa, Cypress, Diamond Bar, Garden Grove,  
3 Hacienda Heights, Industry, Irvine, La Palma, La Puente, Los Alamitos, Midway  
4 City, Newport Beach, Orange, Panorama Heights, Placentia, Pomona, Rowland  
5 Heights, Rossmoor, Seal Beach, Stanton, Villa Park, Walnut, West Covina, West  
6 Orange, and Yorba Linda (City of Anaheim 2011; City of Brea 2011; City of  
7 Buena Park 2011; City of Fountain Valley 2011; City of Fullerton 2011; City of  
8 Garden Grove 2011; City of Huntington Beach 2011; City of La Habra 2011; City  
9 of La Palma 2011; City of Newport Beach 2011; City of Orange 2011; City of  
10 Santa Ana 2011; City of Seal Beach 2011; City of Tustin 2011; City of  
11 Westminster 2011; IRWD 2011; MCWD 2011; RWD 2011; SWD 2011; WVWD  
12 2011; YLWD 2011; Golden State Water Company 2011i, 2011j). Groundwater  
13 use is primarily for non-potable water uses in West Covina and for supplemental  
14 supplies for users of recycled water in Rowland Heights.

15 The Coastal Plain of Orange County Groundwater Basin is managed by Orange  
16 County Water District in accordance with special State legislation to increase  
17 supply and provide uniform costs for groundwater (MWDSC 2007). The basin is  
18 managed to maintain a water balance over several years using two step pricing  
19 levels to incentivize users to obtain alternative water supplies after withdrawing a  
20 basin production target. The groundwater basin is managed to provide  
21 approximately a three-year drought supply.

22 Orange County Water District manages an extensive groundwater recharge  
23 program in the Coastal Plain of Orange County Basin (Orange County Water  
24 District 2014). The Orange County Water District manages spreading basins  
25 along the Santa Ana River and Santiago Creek for groundwater recharge  
26 (MWDSC 2007). Water is supplied to these basins with flows diverted from the  
27 Santa Ana River into the recharge basins at inflatable rubber dams, SWP water,  
28 and recycled water from the Orange County Water District/Orange County  
29 Sanitation District Groundwater Replenishment System Advanced Water  
30 Purification Facility (OCWD n.d.).

31 The Orange County Water District also injects water into the Talbert Barrier and  
32 the portion of the Alamitos Barrier Project within Orange County. Water supplies  
33 for the seawater barriers include water from the Groundwater Replenishment  
34 System and SWP water (GWRS n.d.; MWDSC 2007).

35 The Irvine Desalter Project was initiated in 2007 by Orange County Water  
36 District, Irvine Ranch Water District, Metropolitan Water District of Orange  
37 County, Metropolitan Water District of Southern California, and the U.S. Navy to  
38 reduce TDS and salts (IRWD 2011; MWDSC 2007). Several other treatment  
39 facilities remove volatile organic compounds. The city of Tustin operates the  
40 Tustin Seventeenth Street Desalter to reduce TDS within the Tustin community  
41 (MWDSC 2007). The City of Garden Grove and Mesa County Water District  
42 operate treatment facilities to reduce nitrates and compounds that change the color  
43 of the water, respectively (City of Garden Grove 2011; MCWD 2011).

1 *San Juan Valley Groundwater Basin*

2 The communities in the San Juan Groundwater Basin use a combination of  
3 surface water and groundwater to meet water demands (MWDSC 2007). The  
4 Municipal Water District of Orange County provides wholesale surface water  
5 supplies to several communities. The City of San Juan Capistrano; Moulton  
6 Niguel Water District, Santa Margarita Water District, and South Coast Water  
7 District provide retail water supplies to users within their communities and to the  
8 communities of Coto de Caza, Dana Point, Laguna Forest, Laguna Woods, Las  
9 Flores, Ladera Ranch, Mission Viejo, Rancho Santa Margarita, South Laguna,  
10 Talega, (City of San Juan Capistrano 2011; MNWD 2011; SCWD 2011;  
11 SMWD 2011). Most of the groundwater use occurs within or near the City of San  
12 Juan Capistrano. Groundwater use is small or does not occur within the Santa  
13 Margarita Water District, South Coast Water District, and Moulton Niguel Water  
14 District service areas.

15 The San Juan Basin Authority manages water resources development in the  
16 San Juan Valley Groundwater Basin and in the surrounding San Juan watershed to  
17 protect water quality and water resources (MWDSC 2007; SJBA 2013). In  
18 addition to community uses, groundwater also is used for agricultural and  
19 industrial purposes and golf course irrigation. Overall, groundwater provides less  
20 than 10 percent of the total water supply within the groundwater basin.

21 The City of San Juan Capistrano Groundwater Recovery Plant reduces iron,  
22 manganese, and TDS concentrations. This city is modifying the treatment plant to  
23 reduce recently observed high concentrations of methyl tertiary butyl ether  
24 (MTBE) (City of San Juan Capistrano 2011; MWDSC 2007). The South Coast  
25 Water District operates the Capistrano Beach Groundwater Recovery Facility in  
26 Dana Point to reduce iron and manganese concentrations (SCWD 2011;  
27 MWDSC 2007).

28 **7.3.6.3 Western San Diego County**

29 The areas within the SWP service area in western San Diego County in the  
30 Southern California Region include the San Mateo Valley Groundwater Basin in  
31 Orange and San Diego counties; and the San Onofre Valley, Santa Margarita  
32 Valley, San Luis Rey Valley, Escondido Valley, San Marcos Area, Batiquitos  
33 Lagoon Valley, San Elijo Valley, San Dieguito Creek, Poway Valley, San Diego  
34 River Valley, El Cajon Valley, Mission Valley, Sweetwater Valley, Otay Valley,  
35 Tijuana Basin groundwater basins in San Diego County, as shown in Figure 7.11.

36 **7.3.6.3.1 Hydrogeology and Groundwater Conditions**

37 In San Diego County, several smaller groundwater basins exist, in the western  
38 portion of the county. The most productive groundwater basins are characterized  
39 by narrow river valleys filled with shallow sand and gravel deposits.  
40 Groundwater occurs farther inland in fractured bedrock and semi consolidated  
41 sedimentary deposits with limited yield and storage (SDCWA et al. 2013).

1 *San Mateo Valley, San Onofre Valley, and Santa Margarita Valley*  
2 *Groundwater Basins*

3 The San Mateo Valley Groundwater Basin is located in southern Orange County  
4 and northern San Diego County (DWR 2004bk). The San Onofre Valley and  
5 Santa Margarita Valley groundwater basins are located in northwestern San Diego  
6 County (DWR 2004bl, 2004bm). Groundwater flows towards the Pacific Ocean.  
7 The water bearing formations are mainly gravel, sand, clays, and silt.  
8 Groundwater is recharged naturally from precipitation and stream flows. In the  
9 San Mateo Valley and San Onofre Valley groundwater basins, treated wastewater  
10 effluent discharged from the Marine Corps Base Camp Pendleton wastewater  
11 treatment plants into local streams also recharges the groundwater. In the San  
12 Mateo Valley and Santa Margarita Valley groundwater basins, the groundwater is  
13 characterized as calcium-sulfate-chloride. In the San Onofre Valley Groundwater  
14 Basin, the groundwater is characterized as calcium-sodium bicarbonate-sulfate.  
15 Localized areas with high boron, chloride, magnesium, nitrate, sulfate, and TDS  
16 occur in the Santa Margarita Valley Groundwater Basin.

17 Santa Margarita Valley Groundwater Basin was designated by the CASGEM  
18 program as medium priority. San Mateo Valley and San Onofre Valley  
19 groundwater basins were designated as very low priority.

20 *San Luis Rey Valley Groundwater Basin*

21 The San Luis Rey Valley Groundwater Basin is located in northwestern  
22 San Diego County (DWR 2004bn). Groundwater flows towards the Pacific  
23 Ocean. The water bearing formations are mainly gravel and sand. Under some  
24 portions of the alluvial aquifer, partially consolidated marine terrace deposits of  
25 partly consolidated sandstone, mudstone, siltstone, and shale occur. Groundwater  
26 is recharged naturally from precipitation and stream flows, and from runoff that  
27 flows into the streams from lands irrigated with SWP water. The groundwater is  
28 characterized as calcium-sodium bicarbonate-sulfate with localized areas of high  
29 magnesium, nitrate, and TDS (MWDC 2007).

30 San Luis Rey Valley Groundwater Basin was designated by the CASGEM  
31 program as medium priority.

32 *San Marcos Valley, Escondido Valley, San Pasqual Valley, Pamo Valley, Santa*  
33 *Maria Valley, and Poway Valley Groundwater Basins*

34 The San Marcos Valley, Escondido Valley, San Pasqual Valley, Pamo Valley,  
35 Santa Maria Valley, and Poway Valley groundwater basins are located in the  
36 foothills within central, western San Diego County. The water bearing formations  
37 are mainly alluvium of sand, gravel, clay, and silt; consolidated sandstone; or  
38 weathered crystalline basement rock (DWR 2004bo, 2004bp, 2004bq, 2004br,  
39 2004bs, 2004bt). The basins area bounded by semi-permeable marine and non-  
40 marine deposits and impermeable granitic and metamorphic rocks. Groundwater  
41 is recharged naturally from precipitation and stream flows, and from runoff that  
42 flows into the streams from irrigated lands. The groundwater is characterized  
43 with moderate to high concentrations of salinity. There are localized areas with

1 high sulfate and nitrate concentrations in the Santa Maria Valley Groundwater  
2 Basin.

3 San Pasqual Valley Groundwater Basin was designated by the CASGEM program  
4 as medium priority. San Marcos Valley, Escondido Valley, Pamo Valley, Santa  
5 Maria, and Poway Valley groundwater basins were designated as very low  
6 priority.

7 *Batiquitos Lagoon Valley, San Elijo Valley, and San Dieguito Valley*  
8 *Groundwater Basins*

9 The Batiquitos Lagoon Valley, San Elijo Valley, and San Dieguito Valley  
10 groundwater basins are located along the central San Diego County coast of the  
11 Pacific Ocean. The water bearing formations are mainly alluvium of sand, gravel,  
12 clay, and silt with areas of consolidated sandstone (DWR 2004bu, 2004bv,  
13 2004bw). Some areas of the Batiquitos Lagoon Valley Groundwater Basin are  
14 bounded by impermeable crystalline rock. Groundwater is recharged naturally  
15 from precipitation and stream flows, and from runoff that flows into the streams  
16 from irrigated lands. The groundwater is characterized with moderate to high  
17 concentrations of salinity.

18 Batiquitos Valley, San Elijo Valley, and San Dieguito Valley groundwater basins  
19 were designated by the CASGEM program as very low priority.

20 *San Diego River Valley, El Cajon, Mission Valley, Sweetwater Valley, Otay*  
21 *Valley, and Tijuana Groundwater Basins*

22 The San Diego River Valley, El Cajon, Mission Valley, Sweetwater Valley, Otay  
23 Valley, and Tijuana groundwater basins are located in the southwestern portion of  
24 San Diego County. The water bearing formations are mainly alluvium of sand,  
25 gravel, cobble, clay, and silt; or siltstone and sandstone (DWR 2004bx, 2004by,  
26 2004bz, 2004ca, 2004cb, 2004cc). Groundwater is recharged naturally from  
27 precipitation and stream flows, and from runoff that flows into the streams from  
28 irrigated lands. The groundwater is characterized with moderate to high levels of  
29 salinity. A recent study by USGS evaluated the sources and movement of saline  
30 groundwater in these groundwater basins (USGS 2013b). The chloride  
31 concentrations ranged from 57 to 39,400 mg/L. The sources of salinity were  
32 natural geologic sources and sea water intrusion. There are localized areas with  
33 high sulfate and magnesium concentrations.

34 San Diego River Valley Groundwater Basin was designated by the CASGEM  
35 program as medium priority. El Cajon, Mission Valley, Sweetwater Valley, Otay  
36 Valley, and Tijuana groundwater basins were designated as very low priority.

37 **7.3.6.3.2 Groundwater Use and Management**

38 Groundwater production and use in the San Diego region is currently limited due  
39 to a lack of aquifer storage capacity, available recharge, and degraded water  
40 quality due to high salinity. Groundwater currently represents about 3 percent of  
41 the water supply portfolio within the areas of San Diego County that could be  
42 served by SWP water (SDCWA et al. 2013).

1 *San Mateo Valley, San Onofre Valley, and Santa Margarita Valley Groundwater*  
2 *Basins*

3 The primary user of groundwater in the San Mateo Valley, San Onofre Valley,  
4 and Santa Margarita Valley groundwater basins is the Marine Corps Base Camp  
5 Pendleton (FPUD 2011; MWDSC 2007; SCWD 2011; SDCWA et al. 2013). The  
6 Marine Corps Base Camp Pendleton withdraws approximately 8,500 acre-  
7 feet/year from the three groundwater basins and operates spreading basins to  
8 recharge the groundwater in the Santa Margarita Valley Groundwater Basin.  
9 Portions of the South Coast Water District overlie the northern portions of the San  
10 Mateo Valley Groundwater Basin; however, the district does not withdraw water  
11 from that basin. Fallbrook Public Utility District overlies northern portions of the  
12 Santa Margarita Valley Groundwater Basin; however, the district currently uses a  
13 small amount of groundwater to meet their water demand (FPUD 2011).

14 The Santa Margarita Valley Groundwater Basin is within an adjudicated  
15 watershed (SMRW 2011). The Santa Margarita River Watermaster manages both  
16 surface water and groundwater that contributes direct or indirect flows into the  
17 Santa Margarita River in accordance with the Modified Final Judgment and  
18 Decrees of 1966 by the U.S. District Court in the *United States v. Fallbrook*  
19 *Public Utility et al.* The watershed includes the Santa Margarita Valley  
20 Groundwater Basin near the Pacific Ocean and the Temecula Valley groundwater  
21 basins in the upper Santa Margarita River Watershed within Riverside County, as  
22 discussed in the following subsection. Within San Diego County, the only  
23 groundwater user in the Santa Margarita Valley Groundwater Basin is the Marine  
24 Corps Base Camp Pendleton.

25 *San Luis Rey Valley Groundwater Basin*

26 The communities in the San Luis Rey Valley Groundwater Basin use a  
27 combination of surface water and groundwater to meet water demands (City of  
28 Oceanside 2011; MWDSC 2007; RMWD 2011; VCMWD 2011; YMWD 2014a,  
29 2014b). The San Diego County Water Authority provides wholesale surface  
30 water supplies to several communities. The City of Oceanside; Rainbow  
31 Municipal Water District, Valley Center Municipal Water District, and Yuima  
32 Municipal Water District; and Rancho Pauma Mutual Water Company and  
33 several other private water companies provide retail water supplies to users within  
34 their communities. Groundwater use is small or does not occur within the  
35 Rainbow Municipal Water District or Valley Center Municipal Water District.  
36 Groundwater also is used on agricultural lands, especially for orchards in the  
37 Pauma area (San Diego County 2010). The Tribal lands also depend upon  
38 groundwater including lands within the La Jolla Reservation, Los Coyotes  
39 Reservation, Pala Reservation, Pauma & Yuima Reservation, Rincon Reservation,  
40 and Santa Ysabel Reservation (SDCWA et al. 2013).

41 There are three municipal water districts that overlie the San Luis Rey Valley  
42 Groundwater Basin that manage water rights protection efforts. Groundwater is  
43 the only water supply within the Pauma Municipal Water District and the primary  
44 water supplies within the Mootamai Municipal Water District and the San Luis  
45 Rey Municipal Water District (SDLAFCO 2011; SDCWA et al. 2013). The

1 districts protect groundwater, surface water rights, and water storage; and to  
2 coordinate planning studies and legal activities within the San Luis Rey River  
3 watershed. Vista Irrigation District withdraws and stores groundwater in Lake  
4 Henshaw and withdraws groundwater in a subbasin located upgradient the  
5 San Luis Rey Valley Groundwater Basin.

6 *San Marcos, Escondido Valley, San Pasqual Valley, Pamo Valley, Santa Maria*  
7 *Valley, and Poway Valley Groundwater Basins*

8 The communities in the San Marcos, Escondido Valley, San Pasqual Valley,  
9 Pamo Valley, Santa Maria Valley, and Poway Valley groundwater basins use a  
10 combination of surface water and groundwater to meet water demands (City of  
11 Escondido 2011; City of Poway 2011; Ramona MWD 2011; RDDMWD 2011;  
12 VWD 2011). The San Diego County Water Authority provides wholesale surface  
13 water supplies to several communities. The cities of Escondido and Poway;  
14 Ramona Municipal Water District, Rincon del Diablo Municipal Water District,  
15 Vallecitos Water District, and Vista Irrigation District; and private water  
16 companies provide retail water supplies to users within their communities.  
17 Groundwater use is small or does not occur within the cities of Escondido and  
18 Poway, Ramona Municipal Water District, Rincon del Diablo Municipal Water  
19 District, and Vallecitos Water District. Ramona Municipal Water District used to  
20 use groundwater until high nitrate concentrations required the district to abandon  
21 the wells.

22 *Batiquitos Lagoon Valley, San Elijo Valley, and San Dieguito Valley*  
23 *Groundwater Basins*

24 The communities in the Batiquitos Lagoon Valley, San Elijo Valley, and San  
25 Dieguito Valley groundwater basins primarily use surface water to meet water  
26 demands (CMWD 2011; OMWD 2011; SDLAFCO 2011; SDWD 2011; SFID  
27 2011). The San Diego County Water Authority provides wholesale surface water  
28 supplies to several communities. Groundwater use is limited to private wells  
29 within the Carlsbad Municipal Water District, including the City of Carlsbad;  
30 Olivenhain Municipal Water District, including the cities of Encinitas, Carlsbad,  
31 San Diego, Solano Beach, and San Marcos, and the communities of Olivenhain,  
32 Leucadia, Elfin Forest, Rancho Santa Fe, Fairbanks Ranch, Santa Fe Valley, and  
33 4S Ranch; San Dieguito Water District, including the communities of Encinitas,  
34 Cardiff-by-the-Sea, New Encinitas, and Old Encinitas; and Santa Fe Irrigation  
35 District, including the City of Solana Beach and the communities of Rancho Santa  
36 Fe and Fairbanks Ranch. Groundwater was used within the Carlsbad Municipal  
37 Water District area until high salinity caused the area to abandon the wells.  
38 Questhaven Municipal Water District manages groundwater for a recreation  
39 community located to the west of Escondido.

40 *San Diego River Valley, El Cajon, Mission Valley, Sweetwater Valley, Otay*  
41 *Valley, and Tijuana Groundwater Basins*

42 The communities in the San Diego River Valley, El Cajon, Mission Valley,  
43 Sweetwater Valley, Otay Valley, and Tijuana groundwater basins use a  
44 combination of surface water and groundwater to meet water demands (California  
45 American Water Company 2012; City of San Diego 2011; HWD 2011; OWD

1 2011; PDMWD 2011; SDCWA et al. 2013; Sweetwater Authority 2011). The  
2 San Diego County Water Authority provides wholesale surface water supplies to  
3 several communities. The City of San Diego, Helix Water District, and  
4 Sweetwater Authority provide retail surface water and/or groundwater supplies to  
5 users within cities of La Mesa, Lemon Grove, National City, and San Diego;  
6 portions of Chula Vista and El Cajon; and all or portions of the communities of  
7 Bonita, Lakeside, and Spring Valley. The County of San Diego–Campo Water  
8 and Sewer Maintenance District, Cuyamaca Water District, Decanso Community  
9 Services District, Julian Community Services District, Majestic Pines Community  
10 Services District, Wynola Water District, Lake Morena Oak Shores Mutual  
11 Water Company, Pine Hills Mutual Water Company, and Pine Valley Mutual  
12 Water Company rely upon groundwater to meet their water demands.  
13 Groundwater is not used for water supplies within Padre Dam Municipal Water  
14 District which serves the City of Santee and portions of the City of El Cajon; Otay  
15 Water District which serves portions of the cities of Chula Vista, El Cajon, and La  
16 Mesa, and several unincorporated communities; and California American Water  
17 which serves the City of Imperial Beach and portions of the cities of Chula Vista,  
18 Coronado, and San Diego. Sweetwater Authority operates the Desalination  
19 Facility to treat brackish groundwater (San Diego County LAFCO 2011).

20 **7.3.6.4 Western Riverside County and Southwestern San Bernardino**  
21 **County**

22 The areas within the SWP service area in western and central Riverside County  
23 and southern San Bernardino County in the Southern California Region include  
24 the Upper Santa Ana Valley Groundwater Basin in Riverside and San Bernardino  
25 counties; the Elsinore, San Jacinto Groundwater Basin in Riverside County; and  
26 the Temecula Valley Groundwater Basin in Riverside and San Diego counties, as  
27 shown in Figure 7.12.

28 **7.3.6.4.1 Hydrogeology and Groundwater Conditions**

29 *Upper Santa Ana Valley Groundwater Basin*

30 The Upper Santa Ana Valley Groundwater Basin consists of the Cucamonga,  
31 Chino, Riverside-Arlington, Temescal, Rialto-Colton, Cajon, Bunker Hill,  
32 Yucaipa, and San Timoteo groundwater subbasins.

33 *Cucamonga Subbasin*

34 The Cucamonga subbasin is located within San Bernardino County in the upper  
35 Santa Ana River watershed (DWR 2004 cd; MWDSC 2007). Groundwater is  
36 contained within the basin by the Red Hill fault. The water bearing formations  
37 are mainly alluvium of gravel, sand, and silt with beds of compacted clay.  
38 Groundwater is recharged naturally from precipitation and stream flows, water  
39 discharged to spreading basins, and runoff that flows into the streams from  
40 irrigated lands, including lands irrigated with SWP water. The groundwater is  
41 characterized as calcium-sodium bicarbonate with moderate to high TDS and  
42 nitrates, and localized areas with high volatile organic compounds, perchlorate,  
43 and dibromochloropropane (DBCP) (MWDSC 2007).

1 The Cucamonga subbasin was designated by the CASGEM program as medium  
2 priority.

3 *Chino Subbasin*

4 The Chino subbasin is located in San Bernardino County. The Chino subbasin is  
5 composed of alluvial material. The Rialto-Colton, San Jose, and the Cucamonga  
6 faults act as groundwater flow barriers (DWR 2006z). Along the southern  
7 boundary of the subbasin, groundwater can rise to the elevation of the Santa Ana  
8 River and be discharged into the stream. Groundwater is recharged naturally  
9 from precipitation and stream flows along the Santa Ana River and its tributaries,  
10 water discharged to spreading basins, and runoff that flows into the streams from  
11 irrigated lands, including lands irrigated with SWP water.

12 The Chino subbasin is characterized with high TDS and nitrate concentrations and  
13 localized areas of high volatile organic compounds, and perchlorate  
14 (MWDC 2007).

15 The Chino subbasin was designated by the CASGEM program as high priority.

16 *Riverside-Arlington Subbasin*

17 The Riverside-Arlington subbasin is located within the Santa Ana River Valley in  
18 southwestern San Bernardino County and northwestern Riverside County  
19 (DWR 2004ce). Water bearing formations include alluvial deposits of sand,  
20 gravel, silt, and clay. The Rialto-Colton Fault separates this subbasin from the  
21 Rialto-Colton subbasin. The Riverside and Arlington portions of the subbasin are  
22 also separated. Groundwater flows to the northwest and to the Arlington Gap in  
23 the southwest area of the subbasin; and continues into the Temescal subbasin.  
24 Groundwater is recharged naturally from precipitation and stream flows in the  
25 Santa Ana River, and flow from adjacent subbasins. The groundwater is  
26 characterized as calcium-sodium bicarbonate with moderate to high TDS and  
27 nitrates, and localized areas with high volatile organic compounds, perchlorate,  
28 and DBCP (MWDC 2007).

29 The Riverside-Arlington subbasin was designated by the CASGEM program as  
30 high priority.

31 *Temescal Subbasin*

32 The Temescal subbasin is located within the Santa Ana River Valley in Riverside  
33 County. Water bearing formations consist of alluvium bounded by the Elsinore  
34 fault zone on the west and the Chino fault zone on the northwest (DWR 2006aa).  
35 Groundwater is recharged naturally from precipitation and stream flows in the  
36 tributaries of the Santa Ana River. The groundwater is characterized as calcium-  
37 sodium bicarbonate with moderate to high TDS and nitrates, and localized areas  
38 with high volatile organic compounds, perchlorate, iron, and manganese  
39 (MWDC 2007).

40 The Temescal subbasin was designated by the CASGEM program as medium  
41 priority.

1           *Cajon Subbasin*

2   The Cajon subbasin is located within the upper Santa Ana River Valley in San  
3   Bernardino County. Water bearing formations consist of alluvium bounded by  
4   the San Andreas Fault zone on the south and impermeable rock formations on the  
5   east and west (DWR 2004cf). Groundwater is recharged naturally from  
6   precipitation, stream flows in the tributaries of the Santa Ana River, and runoff  
7   that flows into the streams from irrigated lands, including lands irrigated with  
8   SWP water. The groundwater quality is good for the beneficial uses.

9   The Cajon subbasin was designated by the CASGEM program as very low  
10   priority.

11           *Rialto-Colton Subbasin*

12   The Rialto-Colton subbasin is located within the upper Santa Ana River Valley in  
13   southwestern San Bernardino County and northwestern Riverside County. Water  
14   bearing formations consist of alluvium bounded by the Rialto-Colton and San  
15   Jacinto fault zones (DWR 2004cg). Groundwater is recharged naturally from  
16   precipitation and stream flows. The groundwater quality is good for the  
17   beneficial uses with localized areas of high volatile organic compounds.

18   The Rialto-Colton subbasin was designated by the CASGEM program as medium  
19   priority.

20           *Bunker Hill Subbasin*

21   The Bunker Hill subbasin is located in San Bernardino County. The water  
22   bearing formations include alluvium of sand, gravel, and boulders with deposits  
23   of silt and clay bounded by the Rialto-Colton and San Jacinto fault zones  
24   (DWR 2004ch). Groundwater is recharged naturally from precipitation, stream  
25   flows in the Santa Ana River and its tributaries, water discharged to spreading  
26   basins, and runoff that flows into the streams from irrigated lands, including lands  
27   irrigated with SWP water. The groundwater quality is good for the beneficial  
28   uses. The groundwater is characterized as calcium- bicarbonate with localized  
29   areas of high volatile organic compounds and perchlorate within several  
30   contamination plumes (*Lockheed Martin Corporation v. United States, Civil*  
31   *Action No. 2008-1160*).

32   The Bunker Hill subbasin was designated by the CASGEM program as high  
33   priority.

34           *Yucaipa Subbasin*

35   The Yucaipa subbasin is located within the upper Santa Ana River Valley in San  
36   Bernardino County. Water bearing formations include alluvial deposits of sand,  
37   gravel, boulders, silt, and clay (DWR 2004ci). Several fault zones restrict  
38   groundwater movement. The San Timoteo formation along the western boundary  
39   of the basin causes the water to rise to the elevation of the San Timoteo Wash, a  
40   tributary of the Santa Ana River. Groundwater is recharged naturally from  
41   precipitation and stream flows, and water discharged to recharge basins. The  
42   groundwater is characterized as calcium-sodium bicarbonate with moderate TDS

1 and high nitrate concentrations, and localized areas with high volatile organic  
2 compounds.

3 The Yucaipa subbasin was designated by the CASGEM program as medium  
4 priority.

5 *San Timoteo Subbasin*

6 The San Timoteo subbasin is located within the upper Santa Ana River Valley in  
7 Riverside County. Water bearing formations include alluvial deposits of gravel,  
8 silt, and clay (DWR 2004cj). Several fault zones restrict groundwater movement.  
9 Groundwater is recharged naturally from precipitation and stream flows, and  
10 water discharged to recharge basins. The groundwater is characterized as  
11 calcium-sodium bicarbonate and good quality for the beneficial uses.

12 The San Timoteo subbasin was designated by the CASGEM program as medium  
13 priority.

14 *San Jacinto Groundwater Basin*

15 The San Jacinto Groundwater Basin is located in upper Santa Ana River Valley in  
16 Riverside County, and underlies the San Jacinto, Perris, Moreno and Menifee  
17 valleys and Lake Perris. The water bearing formations are alluvium over  
18 crystalline basement rock (DWR 2006ab). Several fault zones restrict  
19 groundwater movement. Groundwater is recharged naturally from precipitation  
20 and stream flows along the San Jacinto River and its tributaries, percolation from  
21 Lake Perris, and water discharged to recharge basins. The groundwater is  
22 characterized as calcium-sodium bicarbonate with high TDS and nitrate  
23 concentrations and localized areas with high iron, manganese, sulfides, volatile  
24 organic compounds, and perchlorate (DWR 2006ac; MWDSC 2007).

25 The San Jacinto Groundwater Basin was designated by the CASGEM program as  
26 high priority.

27 *Elsinore Groundwater Basin*

28 The Elsinore Groundwater Basin is located in upper Santa Ana River Valley in  
29 Riverside County. The water bearing formations are alluvial fan, floodplain, and  
30 lacustrine deposits underlain by alluvium of gravel, sand, silt, and clay  
31 (DWR 2006ac). Several fault zones restrict groundwater movement.  
32 Groundwater is recharged naturally from precipitation and stream flows along the  
33 San Jacinto River, and water discharged to recharge basins. The groundwater is  
34 characterized as calcium-sodium bicarbonate with moderate salinity and localized  
35 areas with high fluoride, arsenic, nitrate, iron, manganese, volatile organic  
36 compounds, and perchlorate (DWR 2006ac; MWDSC 2007).

37 The Elsinore Groundwater Basin was designated by the CASGEM program as  
38 high priority.

39 *Temecula Valley Groundwater Basin*

40 The Temecula Valley Groundwater Basin is located in the upper Santa Margarita  
41 River watershed within Riverside and San Diego counties. The water bearing  
42 formations are alluvium of sand, tuff, and silt underlain by fractured bedrock

1 (DWR 2004ck). Several fault zones restrict groundwater movement.  
2 Groundwater is recharged naturally from precipitation and stream flows. The  
3 groundwater is characterized as calcium-sodium bicarbonate with high TDS,  
4 fluoride, nitrate, volatile organic compounds, and perchlorate (DWR 2006ac;  
5 MWDC 2007).

6 The Temecula Valley Groundwater Basin was designated by the CASGEM  
7 program as high priority.

#### 8 **7.3.6.4.2 Groundwater Use and Management**

##### 9 *Upper Santa Ana Valley Groundwater Basin*

10 The Upper Santa Ana Valley Groundwater Basin consists of the Cucamonga,  
11 Chino, Riverside-Arlington, Temescal, Rialto-Colton, Cajon, Bunker Hill,  
12 Yucaipa, and San Timoteo groundwater subbasins.

##### 13 *Cucamonga and Chino Subbasins*

14 The communities in the Cucamonga and Chino subbasins use a combination of  
15 surface water and groundwater to meet water demands (City of Chino 2011; City  
16 of Ontario 2011; City of Pomona 2011; City of Upland 2011; Cucamonga Valley  
17 WD 2011; FWC 2011; JCSD 2011; MWDC 2007; MVWD 2011; SAWC 2011;  
18 WMWD 2011). The cities of Chino, Ontario, Pomona, and Upland; Cucamonga  
19 Valley Water District, Jurupa Community Services District, Monte Vista Water  
20 District, and Western Municipal Water District; San Antonio Water Company,  
21 Fontana Water Company, Santa Ana River Water Company, and Marygold  
22 Mutual Water Company, and Golden State Water Company provide wholesale  
23 and/or retail water supplies, including groundwater, to users within their  
24 communities and to portions of the City of Rialto, Montclair, Rancho Cucamonga,  
25 and San Antonio Heights.

26 The Cucamonga subbasin was adjudicated in 1958 to allocate groundwater rights  
27 in the basin and surface water rights to Cucamonga Creek (City of Chino 2011;  
28 Cucamonga Valley WD 2011; MWDC 2007). The water supplies are allocated  
29 to the Cucamonga Valley Water District, San Antonio Water Company, and the  
30 West End Consolidated Water Company. The City of Upland has agreements  
31 with San Antonio Water Company and the West End Consolidated Water  
32 Company to divert from the subbasin.

33 The Chino subbasin was adjudicated in 1978 through the Chino Basin Judgment  
34 which established the Chino Basin Watermaster to manage the subbasin and  
35 enforce the provisions of the judgment (City of Chino 2011; Cucamonga Valley  
36 WD 2011; MWDC 2007). The judgment and subsequent agreements allocated  
37 the available safe yield to three categories, or pools: Overlying Agricultural Pool,  
38 including dairies, farms, and the State of California; Overlying Non-Agricultural  
39 Pool for industrial users; and the Appropriative Pool Committee, including local  
40 cities, public water agencies, and private water companies. The judgment and  
41 subsequent agreements included provisions for reallocation of water rights,  
42 groundwater replenishment if the subbasin is operated in a controlled overdraft  
43 condition, and development of a groundwater management plan. Through “Peace

1 Agreements” adopted in 2000 and amended in 2004, included provisions to allow:  
 2 members of the Overlying Non-Agricultural Pool to transfer their water within  
 3 their pool or to the Watermaster, appropriators to provide water service to  
 4 overlying lands, and the Watermaster to allocate unallocated safe yield. The  
 5 Peace Agreement also addressed use of local storage facilities, management of the  
 6 subbasin under the Dry Year Yield program when imported water, including SWP  
 7 water, is not fully available. Groundwater replenishment is allowed through  
 8 spreading basins, percolation, groundwater injection, and in-lieu use of other  
 9 water supplies, including SWP water. The Chino Basin Watermaster also was  
 10 required to develop an Optimum Basin Management Plan, adopted in 1998, to  
 11 address approaches that would enhance basin water supplies, protect and enhance  
 12 water quality, enhance management of the basin, and equitably finance  
 13 implementation of programs identified in the plan. The Peace II Agreement was  
 14 adopted in 2007 addressed procedures related to basin reoperation under  
 15 controlled overdraft conditions using the Chino Desalters to meet the  
 16 replenishment obligation and to maintain hydraulic control in the subbasin, and  
 17 transfers. The Groundwater Recharge Master Plan update was prepared by the  
 18 Watermaster in 2010.

19 The Santa Ana Regional Water Quality Control Board adopted a Water Quality  
 20 Control Plan in 2004 for the entire Santa Ana River Basin which included a  
 21 Maximum Benefit Basin Plan, recommended by the Chino Basin Watermaster  
 22 and the Inland Empire Utilities Agency. The plan established water quality  
 23 objectives in groundwater quality objectives for TDS and Total Inorganic  
 24 Nitrogen and wasteload allocations to allow use of recycled water for  
 25 groundwater recharge. The Maximum Benefit Basin Plan includes commitments  
 26 for surface water and groundwater monitoring programs; implementation of up to  
 27 40 million gallons/day of treated groundwater at desalters; implementation of  
 28 recharge facilities, conjunctive use programs, and recycled water quality  
 29 management programs; and groundwater management to provide hydraulic  
 30 controls to protect the Santa Ana River water quality.

31 Operations of the Chino Basin portion of the upper Santa Ana River are also  
 32 affected by surface water right judgments administered by the Santa Ana River  
 33 Watermaster.

34 A large portion of the natural runoff in the upper Santa Ana River watershed is  
 35 captured and used to recharge the groundwater aquifers. Flood control channels  
 36 and percolation basins are operated by San Bernardino County Flood Control  
 37 District to allow for flood control and groundwater recharge (MWDSC 2007).  
 38 Groundwater recharge also occurs in spreading basins operated by the City of  
 39 Upland, San Antonio Water Company, and San Antonio Water Company. The  
 40 Chino Basin Water Conservation District operates percolation ponds and  
 41 spreading basins to facilitate groundwater recharge (IEUA 2011).

42 The Inland Empire Utilities Agency manages production and treatment of  
 43 recycled water supplies that are used in groundwater recharge operations and as  
 44 part of conjunctive use programs in the cities of Chino, Chino Hills, Ontario, and  
 45 Upland; and in the service areas of the Cucamonga Valley Water District, Monte

1 Vista Water District, Fontana Water Company, and San Antonio Water Company  
2 (IEUA 2011). The district is a member of the Chino Basin Watermaster Board of  
3 Directors. The Inland Empire Utilities Agency operates several recharge facilities  
4 in the Chino subbasin. Recharge water comes from three sources: recycled water,  
5 stormwater, and imported SWP water. The Inland Empire Utilities Agency  
6 operates the Chino Desalter Authority's Chino I and Chino II Desalters that treat  
7 water from 22 wells. The Chino Desalter Authority is a joint powers authority  
8 that includes the cities of Chino, Chino Hills, Norco, and Ontario; and the Jurupa  
9 Community Services District, Santa Ana River Water Company, Western  
10 Municipal Water District, and Inland Empire Utilities Agency. The treated water  
11 from the desalters is used for potable water supplies, groundwater recharge with  
12 water with reduced salts and nitrates, and improved water quality of the Santa  
13 Ana River.

14 *Riverside-Arlington and Temescal Subbasins*

15 The communities in the Riverside-Arlington and Temescal subbasins use a  
16 combination of surface water and groundwater to meet water demands (City of  
17 Corona 2011; City of Norco 2014; City of Rialto 2011; City of Riverside 2011;  
18 JCSD 2011; MWDSC 2007; RCWD 2011; SBVMWD 2011; WMWD 2011).  
19 The San Bernardino Valley Municipal Water District and Western Municipal  
20 Water District provide wholesale and retail water supplies, including  
21 groundwater, in the areas that overlay the Riverside-Arlington and Temescal  
22 subbasins. The cities of Colton, Corona, Norco, Rialto, and Riverside; Elsinore  
23 Valley Municipal Water District; Jurupa Community Services District, Lee Lake  
24 Water District; Rubidoux Community Services District, San Bernardino Valley  
25 Municipal Water District, Western Municipal Water District, and West Valley  
26 Water District; and Box Springs Mutual Water Company, Riverside Highland  
27 Mutual Water Company, and Terrace Water Company provide retail water  
28 supplies, including groundwater, to users within their communities. The Jurupa  
29 Community Services District uses wells within the Riverside-Arlington subbasin  
30 for non-potable uses (JCSD 2011).

31 The Riverside portion of the Riverside-Arlington subbasin was adjudicated in  
32 1969 through the stipulated judgment for the *Western Municipal Water District of*  
33 *Riverside County et al. versus East San Bernardino County Water District, et al.*  
34 The judgment provided average annual extraction volumes and replenishment  
35 schedules for the separate sections of the subbasin as defined by the San  
36 Bernardino County and Riverside County boundary (Riverside North and  
37 Riverside South portions of the subbasin) (City of Riverside 2011; MWDSC  
38 2007). Within the Riverside North portion, the judgment affects only withdrawals  
39 that are to be used in Riverside County because withdrawals for use of water in  
40 San Bernardino County are not limited. The Western-San Bernardino  
41 Watermaster manages the monitoring and reporting of groundwater conditions of  
42 the Riverside portion of the subbasin.

43 The northern portion of the Riverside portion of the subbasin also was part of the  
44 1969 judgment in the *Orange County Water District v. City of Chino et al.* This  
45 judgment primarily includes the Bunker Hill subbasin and small portions of the

1 northern Riverside, Rialto-Colton, and Yucaipa subbasins; and requires minimum  
 2 downstream flows into the lower Santa Ana River (SBVMWD 2011). To meet  
 3 the flow obligations, the San Bernardino Valley Municipal Water District is  
 4 responsible to manage groundwater and surface waters within the San Bernardino  
 5 Basin Area, as defined in the judgment. The district manages the groundwater by  
 6 allocation of groundwater withdrawal amounts and requiring replenishment when  
 7 additional groundwater is withdrawn.

8 The Arlington portion of the Riverside-Arlington subbasin and the Temescal  
 9 subbasins are not adjudicated (City of Corona 2011; MWDCS 2007). In 2008, an  
 10 agreement was adopted between Elsinore Valley Municipal Water District and the  
 11 City of Corona for use of water from the southern portion of the Temescal  
 12 subbasin.

13 The City of Riverside operates two water treatment plants as part of the North  
 14 Riverside Water Project to remove volatile organic compounds. The City of  
 15 Corona operates the Temescal Basin Desalter Treatment Plant/Facility and the  
 16 Western Municipal Water District operates the Arlington Desalter (City of Corona  
 17 2011; WMWD 2011) to reduce TDS. The City of Norco operates a groundwater  
 18 treatment plant to reduce iron, manganese, and hydrogen sulfide (City of  
 19 Norco 2014).

20 *Cajon, Rialto-Colton, Bunker Hill, Yucaipa, and San Timoteo Subbasins*

21 The communities in the Cajon, Rialto-Colton, Bunker Hill, Yucaipa, and San  
 22 Timoteo subbasins use a combination of surface water and groundwater to meet  
 23 water demands (City of Rialto 2011; City of Riverside 2011; MWDCS 2007;  
 24 SBVMWD 2011; YVWD 2011; WMWD 2011; West Valley WD 2014a). The  
 25 San Bernardino Valley Municipal Water District and Western Municipal Water  
 26 District provide wholesale and retail water supplies, including groundwater, in the  
 27 areas that overlay the Cajon, Rialto-Colton, Bunker Hill, Yucaipa, and San  
 28 Timoteo subbasins. The cities of Colton, Loma Linda, Redlands, Rialto,  
 29 Riverside, and San Bernardino; Beaumont-Cherry Valley Water District, East  
 30 Valley Water District, South Mesa Water District, West Valley Water District,  
 31 Western Municipal Water District, West Valley Water District, and Yucaipa  
 32 Valley Water District; and several private water companies provide retail water  
 33 supplies, including groundwater, to users within their communities and to portions  
 34 of the cities of Beaumont, Calimesa, and Yucaipa; the communities of Cherry  
 35 Valley, Mission Grove, Orange Crest, and Woodcrest; and numerous private  
 36 water companies.

37 Groundwater adjudication in these subbasins have occurred over the past 90  
 38 years. A portion of the Bunker Hill subbasin underlays the Lytle Creek watershed  
 39 (City of Rialto 2011). The remaining portion of the Lytle Creek watershed  
 40 overlays the Lytle Creek groundwater basin that is not included in the DWR  
 41 Bulletin 118. The entire Lytle Creek groundwater basin, including the portion in  
 42 the Bunker Hill subbasin, is a major groundwater recharge source to the Bunker  
 43 Hill and Rialto-Colton subbasins; and was adjudicated in 1924. The stipulation of  
 44 the judgment allocated groundwater withdrawal right to the City of Rialto,

1 Citizens Land and Water Company, Lytle Creek Water and Improvement  
2 Company, Rancheria Water Company, and Mutual Water Company.

3 The Rialto-Colton subbasin was adjudicated in 1961 under the *Lytle Creek Water*  
4 *& Improvement Company vs. Fontana Ranchos Water Company et al* (City of  
5 Rialto 2011). The adjudication allocated groundwater withdrawals between the  
6 cities of Rialto and Colton, West Valley Water District, and Fontana Union Water  
7 Company based upon spring groundwater levels at three index wells between  
8 March and May of each water year. The groundwater subbasin is managed by the  
9 Rialto Basin Management Association. The stipulation of the judgment allocated  
10 groundwater withdrawal right to the City of Rialto, Citizens Land and Water  
11 Company, Lytle Creek Water and Improvement Company, and private well users.  
12 Use of this aquifer has been limited due to contamination with volatile organic  
13 compounds which are currently being treated. The City of Rialto also has  
14 agreements with San Bernardino Municipal Water District to store SWP water in  
15 the Rialto subbasin. The city can withdraw the stored water without affecting the  
16 water allowed to be withdrawn under the 1961 decree.

17 As described above under the Riverside-Arlington and Temescal Subbasins  
18 section, in 1969 the stipulated judgment for the *Western Municipal Water District*  
19 *of Riverside County et al. versus East San Bernardino County Water District,*  
20 *et al.* to preserve the safe yield of the San Bernardino Basin Area through  
21 entitlements to groundwater withdrawals to protect the safe yield and  
22 establishment of replenishment schedules when the safe yield is exceeded (City of  
23 Rialto 2011; SBVMWD 2011). The San Bernardino Basin Area includes the  
24 Bunker Hill subbasin and portions of the Rialto-Colton and Yucaipa subbasins;  
25 and portions of the Mill Creek, Lytle Creek, and upper Santa Ana River  
26 watersheds. The Western-San Bernardino Watermaster, which includes Western  
27 Municipal Water District and San Bernardino Municipal Water District, manages  
28 the monitoring and reporting of groundwater conditions. The primary users of the  
29 groundwater under this decree include the cities of Colton, Loma Linda,  
30 Redlands, and Rialto; East Valley Water District, San Bernardino Municipal  
31 Water District, West Valley Water District, and Yucaipa Valley Water District;  
32 Riverside-Highland Water Company and 13 private water companies.

33 In 2002, the City of Beaumont, Beaumont-Cherry Valley Water District, South  
34 Mesa Water Company, and Yucaipa Valley Water District formed the San  
35 Timoteo Watershed Management Authority to enhance water supplies and water  
36 quality, manage groundwater in the Beaumont Basin (part of the San Timoteo  
37 subbasin), protect riparian habitat in San Timoteo Creek, and allocate benefits and  
38 costs of these programs (Beaumont Basin Watermaster 2013; SBVMWD 2011).  
39 One of the issues that the authority initiated was negotiations related to  
40 groundwater withdrawals by the City of Banning. A Stipulated Agreement was  
41 adopted in 2004 in accordance with the judgment for the *San Timoteo Watershed*  
42 *Management Authority, vs. City of Banning et al.* The judgment established a  
43 Watermaster committee of the cities of Banning and Beaumont, Beaumont-Cherry  
44 Valley Water District, South Mesa Water Company, and Yucaipa Valley Water

1 District. The judgment allocated groundwater supplies in a manner that allows  
2 for storage of groundwater recharge from spreading basins or in-lieu programs.

3 The Seven Oaks Accord, a settlement agreement, was signed by the City of  
4 Redlands; East Valley Water District, San Bernardino Valley Municipal Water  
5 District, and Western Municipal Water District; and Bear Valley Mutual Water  
6 Company, Lugonia Water Company, North Fork Water Company, and Redlands  
7 Water Company to recognize prior rights of water users of a portion of the natural  
8 flow of the Santa Ana River (SBVMWD 2011). The Seven Oaks Accord requires  
9 that San Bernardino Valley Municipal Water District, and Western Municipal  
10 Water District develop a groundwater spreading program to recharge the  
11 groundwater in cooperation with other parties to the accord to maintain relatively  
12 constant groundwater levels.

13 In 2005, the San Bernardino Valley Municipal Water District entered into an  
14 agreement with the San Bernardino Valley Water Conservation District to work  
15 cooperatively to develop and implement a groundwater management plan which  
16 includes groundwater banking programs (SBVMWD 2011).

17 The City of Rialto, San Bernardino Valley Municipal Water District, West Valley  
18 Water District, and Riverside Highland Water District have jointly constructed the  
19 Baseline Feeder to convey groundwater from the Bunker Hill subbasin to the  
20 Rialto area and West Valley Water District to be used in an in-lieu program that  
21 would reduce reliance on SWP water supplies (City of Rialto 2011; West Valley  
22 WD 2014c, 2014d).

23 West Valley Water District implemented a bioremediation wellhead treatment  
24 system (West Valley Water District 2014b).

25 *San Jacinto Groundwater Basin*

26 The communities in the San Jacinto Groundwater Basin use a combination of  
27 surface water and groundwater to meet water demands (City of Hemet 2011; City  
28 of San Jacinto 2011; EMWD 2011; LHMWD 2011; MWDSC 2007; RCWD  
29 2011). The Eastern Municipal Water District provides wholesale and retail water  
30 supplies, including groundwater, in the areas that overlay the San Jacinto  
31 Groundwater Basin. The cities of Hemet and San Jacinto; and Eastern Municipal  
32 Water District and Rancho California provide retail water supplies, including  
33 groundwater, to users within their communities and to portions of the cities of  
34 Menifee, Moreno Valley, Murrieta, and Temecula; Lake Hemet Municipal Water  
35 District; Nuevo Water Company and numerous private water companies; and the  
36 communities of Edgemont, Homeland, Juniper Flats, Lakeview, Mead Valley,  
37 North Perris Water System, Romoland, Sunnymead, Valle Vista, and Winchester.  
38 The City of Perris overlays a portion of the San Jacinto Groundwater Basin;  
39 however, the city does not use groundwater. A substantial portion of the  
40 groundwater supplies within the San Jacinto Groundwater Basin are used by  
41 agricultural water users.

42 The 1954 Fruitvale Judgment allows for Eastern Municipal Water District to  
43 withdraw water from the San Jacinto Groundwater Basin if the groundwater  
44 elevation is greater than a specified elevation (EMWD 2009, 2011, 2014). The

1 judgment includes a maximum withdrawal volume for use outside of the  
2 groundwater basin. There are further restrictions within the Canyon Basin  
3 subbasin of the San Jacinto Groundwater Basin. DWR worked with the cities of  
4 Hemet and San Jacinto, Lake Hemet Municipal Water District, Eastern Municipal  
5 Water District, and private groundwater companies to file a stipulated judgment in  
6 2007 to form a Watermaster to develop and implement the Hemet/San Jacinto  
7 Water Management Plan, including the Hemet/San Jacinto Integrated Recharge  
8 and Recovery Program, Recycled Water In-Lieu Project, and Hemet Filtration  
9 Plant. The stipulated judgment also limited groundwater withdrawals to protect  
10 the groundwater basin, provide for recharge programs, expand water production,  
11 and protect water quality. The program uses SWP water and San Jacinto River  
12 runoff to recharge the San Jacinto-Upper Pressure Groundwater Management  
13 Zone. In 2013, the judgment was filed with the court to adopt the Hemet/San  
14 Jacinto Water Management Plan and create the Watermaster Board.

15 The stipulated judgment also addressed methods to fulfil the Soboba Band of  
16 Luiseño Indians water rights in accordance with the findings of the Court for the  
17 *Soboba Band of Luiseño Indians Water Settlement Agreement* in 2006. In 2008,  
18 the Soboba Settlement Act was signed by the President of the United States to  
19 provide an annual water supply and provide funds for economic development.  
20 The legislation also provides funds to construct recharge facilities and provisions  
21 for the Soboba Tribe to participate in restoration efforts.

22 The Eastern Municipal Water District adopted the West San Jacinto Groundwater  
23 Basin Management Plan in 1995. The management plan includes the Nuevo  
24 Water Company, City of Moreno Valley, City of Perris, and McCanna Ranch  
25 Water Company (MWDSC 2007).

26 Eastern Municipal Water District operates two desalination plants to treat  
27 brackish water within the San Jacinto Groundwater Basin as part of the  
28 Groundwater Salinity Management Program (EMWD 2011). Other wells within  
29 the Eastern Municipal Water District also include treatment facilities to reduce  
30 hydrogen sulfide, iron, and/or manganese.

### 31 *Elsinore Groundwater Basin*

32 The communities in the Elsinore Groundwater Basin use a combination of surface  
33 water and groundwater to meet water demands (EVMWD 2011; MWDSC 2007).  
34 The Elsinore Valley Municipal Water District provides wholesale and retail water  
35 supplies, including groundwater, in the areas that overlay the Elsinore  
36 Groundwater Basin. The cities of Lake Elsinore, Canyon Lake, and Wildomar;  
37 Elsinore Valley Municipal Water District and Elsinore Water District; and Farm  
38 Mutual Water Company provide retail water supplies, including groundwater, to  
39 users within their communities and to portions of Cleveland Ranch, Farm,  
40 Horsethief Canyon, Lakeland Village, Meadowbrook, Rancho Capistrano –  
41 El Cariso Village, and Temescal Canyon.

42 The Elsinore Groundwater Basin is not adjudicated. The Elsinore Valley  
43 Municipal Water District was responsible for over 90 percent of the groundwater  
44 withdrawals in mid-2000s (EVMWD 2011). The Elsinore Basin Groundwater

1 Management Plan, adopted by Elsinore Valley Municipal Water District in 2005,  
2 identifies conjunctive use projects, including direct recharge projects. The direct  
3 recharge projects use imported water, including SWP water.

4 *Temecula Valley Groundwater Basin*

5 The communities in the Temecula Valley Groundwater Basin use a combination  
6 of surface water and groundwater to meet water demands (MWDSC 2007;  
7 RCSD 2011; WMWD 2011). The Rancho California Water District and Western  
8 Municipal Water District (including Murrieta County Water District) provide  
9 wholesale and retail water supplies, including groundwater, in the areas that  
10 overlay the Temecula Valley Groundwater Basin, including the cities of Murrieta  
11 and Temecula. The Pechanga Indian Reservation operates groundwater wells  
12 within the Temecula Valley Groundwater Basin (MWDSC 2007).

13 The Temecula Valley Groundwater Basin is located within the Santa Margarita  
14 River watershed. As described above for the San Mateo Valley, San Onofre  
15 Valley, and Santa Margarita Valley Groundwater Basins, the groundwater basins  
16 that contribute direct or indirect flows into the Santa Margarita River have been  
17 adjudicated and are managed by the Santa Margarita River Watermaster in  
18 accordance with the 1940 Stipulated Judgment, the 1966 Modified Final  
19 Judgment and Decree, and subsequent court orders (MWDSC 2007;  
20 RCWD 2011; SMRW 2011; WMWD 2011). The court-appointed steering  
21 committee for the Watermaster includes Eastern Municipal Water District,  
22 Fallbrook Public Utility District, Metropolitan Water District of Southern  
23 California, Pechanga Band of Luiseno Mission Indians of the Pechanga  
24 Reservation, Rancho California Water District, Western Municipal Water District,  
25 and Marine Corps Base Camp Pendleton. In accordance with the judgment, the  
26 Rancho California Water District prepares the annual Groundwater Audit and  
27 Recommended Groundwater Production Report that allocates groundwater  
28 withdrawals based upon rainfall, recharge area, and pumping capacity. The  
29 subsequent orders adopted following 1966 included the Cooperative Water  
30 Resource Management Agreement between Rancho California Water District and  
31 the Marine Corps Base Camp Pendleton to manage groundwater levels and  
32 surface water flows; water rights to Vail Lake on Temecula Creek; and an  
33 agreement between the Rancho California Water District and the Pechanga Band  
34 of Luiseno Mission Indians of the Pechanga Reservation.

35 Rancho California Water District provides imported water, including SWP water,  
36 and natural runoff released from Vail Lake to the Valle de Los Caballos Recharge  
37 Basins (RCWD 2011). The district also has implemented the Vail Lake  
38 Stabilization and Conjunctive Use Project to store imported water in Vail Lake for  
39 subsequent groundwater recharge (RCWD et al. 2014).

40 **7.3.6.5 Central Riverside County**

41 The areas within the SWP service area which receive Colorado River water in-  
42 lieu of SWP water deliveries are located within the Coachella Valley  
43 Groundwater Basin. The Coachella Valley Groundwater Basin includes the

1 Desert Hot Springs, Indio, Mission Creek, and San Gorgonio Pass subbasins, as  
2 shown in Figure 7.12.

### 3 **7.3.6.5.1 Hydrogeology and Groundwater Conditions**

4 The Coachella Valley Groundwater Basin underlies the entire floor of the  
5 Coachella Valley. Primary water-bearing materials in the Coachella Valley  
6 Groundwater Basin are unconsolidated alluvial deposits along the valley floor  
7 which consist of older alluvium and a thick sequence of poorly bedded coarse  
8 sand and gravel; terrace deposits under the surrounding foothills in the Mission  
9 Creek subbasin; and partly consolidated fine to coarse sandstone in the  
10 surrounding mountains in the San Gorgonio Pass subbasin (DWR 2004cm,  
11 2004cn, 2004co, 2004cp). The movement of groundwater is locally influenced by  
12 features such as faults, structural depressions, and constrictions; however,  
13 groundwater generally flows to the southeast towards the Salton Sea.  
14 Groundwater recharge occurs along stream beds and from groundwater inflows  
15 from adjacent subbasins. Within the Indio subbasin, groundwater also is  
16 recharged from spreading basins and injection wells.

17 The groundwater quality is characterized as calcium-sodium bicarbonate.  
18 Groundwater quality is adequate for community and agricultural water uses  
19 within the San Gorgonio Pass, Mission Creek, and Indio subbasins. There are  
20 localized areas with high fluoride near the Banning and San Andreas fault zones.  
21 Groundwater quality in the Desert Hot Springs subbasin is poor due to the  
22 geothermal activity which results in high sodium sulfate, TDS, and chlorides.  
23 The hot springs water is only used by a resort for bathing.

24 Desert Hot Springs Groundwater Basin was designated by the CASGEM program  
25 as low priority. Indio, Mission Creek, and San Gorgonio Pass groundwater basins  
26 were designated as medium priority.

### 27 **7.3.6.5.2 Groundwater Use and Management**

#### 28 *Coachella Valley Groundwater Basin*

29 The Coachella Valley Groundwater Basin includes the San Gorgonio Pass,  
30 Mission Creek, Desert Hot Springs, and Indio subbasins.

#### 31 *San Gorgonio Pass Subbasin*

32 The communities in the San Gorgonio Pass subbasin use a combination of surface  
33 water and groundwater to meet water demands (BCVWD 2013; City of Banning  
34 2011; SGPWA 2010). The City of Banning, Beaumont-Cherry Valley Water  
35 District, Cabazon Water District, and High Valley Water District provide retail  
36 water supplies, including groundwater, in the areas that overlay the San Gorgonio  
37 Pass subbasin, including the City of Banning and the eastern portion of the City of  
38 Beaumont; Banning Heights Mutual Water Company; and the community of  
39 Cabazon. The Morongo Band of Mission Indians operates groundwater wells  
40 within the San Gorgonio Pass subbasin.

41 The western portion of the San Gorgonio Pass subbasin is located within the  
42 Beaumont Basin (USGS 1974). As described above, the City of Beaumont,

1 Beaumont-Cherry Valley Water District, South Mesa Water Company, and  
 2 Yucaipa Valley Water District formed the San Timoteo Watershed Management  
 3 Authority to enhance water supplies and water quality, manage groundwater,  
 4 protect riparian habitat in San Timoteo Creek, and allocate benefits and costs of  
 5 these programs (Beaumont Basin Watermaster 2013). One of the issues that the  
 6 authority initiated was negotiations related to groundwater withdrawals by the  
 7 City of Banning. A Stipulated Agreement was adopted in 2004 in accordance  
 8 with the judgment for the *San Timoteo Watershed Management Authority, vs. City*  
 9 *of Banning et al.* The judgment established a Watermaster committee of the cities  
 10 of Banning and Beaumont, Beaumont-Cherry Valley Water District, South Mesa  
 11 Water Company, and Yucaipa Valley Water District. The judgment allocated  
 12 groundwater supplies in a manner that allows for storage of groundwater recharge  
 13 from spreading basins or in-lieu programs.

14 *Mission Creek, Desert Hot Springs, and Indio Subbasins*

15 The communities in the Mission Creek, Desert Hot Springs, and Indio subbasins  
 16 use a combination of surface water and groundwater to meet water demands (City  
 17 of Coachella 2011; CVWD 2011, 2012; DWA 2011; IWA 2010; MSWD 2011).  
 18 The City of Coachella, Coachella Valley Water District, Desert Water Agency,  
 19 Indio Water Authority, and Mission Springs Water District provide retail water  
 20 supplies, including groundwater, in the areas that overlay the Mission Creek,  
 21 Desert Hot Springs, and Indio subbasins, including the cities of Cathedral City,  
 22 Coachella, Desert Hot Springs, Indian Wells, Indio, La Quinta, Palm Desert, Palm  
 23 Springs, and Rancho Mirage; and the communities of Barton Canyon, Bermuda  
 24 Dunes, Bombay Beach, Desert Crest, Desert Edge, Indio Hills, Mecca, Mecca  
 25 Hills, Palm Springs Crest, Salton City, Thermal, and West Palm Springs Village.  
 26 The Cabazon Band of Mission Indians and the Torres-Martinez Desert Cahuilla  
 27 Indians operate groundwater wells within the subbasins.

28 The Coachella Valley Water District, Desert Water Agency, and Mission Springs  
 29 Water District all participate in groundwater management programs within the  
 30 subbasins (CVWD 2011, 2012; DWA 2011; MSWD 2011). These programs  
 31 include purchasing imported Colorado River water for groundwater recharge and  
 32 in-lieu programs, conjunctive use programs, and conservation programs.  
 33 Coachella Valley Water District and Desert Water Agency are SWP water  
 34 contractors. However, because no conveyance facilities exist to deliver the SWP  
 35 water, these districts have agreements with the Metropolitan Water District of  
 36 Southern California to exchange SWP water for Colorado River water  
 37 (CVWD 2012). Since 1973, these agencies have recharged more than 2.6 million  
 38 acre-feet of water in the groundwater basin with delivery of Colorado River water  
 39 to the Whitewater River Recharge Facility. The Metropolitan Water District of  
 40 Southern California also has an agreement with Coachella Valley Water District  
 41 and Desert Water Agency to store water in the Coachella Valley Groundwater  
 42 Basin. The Coachella Valley Water District also operates the Thomas E. Levy  
 43 Groundwater Replenishment Facility and the Martinez Canyon Pilot Recharge  
 44 Facility. Coachella Valley Water District and Desert Water Agency also provide  
 45 recycled water for in-lieu programs. The Coachella Valley Water District has

1 agreed to operate groundwater recharge facilities to store Colorado River water  
2 for Imperial Irrigation District (CVWD 2011).

3 These groundwater recharge programs and broader groundwater management  
4 programs for the Indio subbasin have been developed in accordance with the  
5 Whitewater Basin Water Management Plan developed by Coachella Valley Water  
6 District and Desert Water Agency, and the Coachella Valley Water Management  
7 Plan developed by Coachella Valley Water District (CVWD 2011, 2012;  
8 DWA 2011).

9 The Coachella Valley Water District, Desert Water Agency, and Mission Springs  
10 Water District jointly manage the Mission Creek subbasin in accordance with the  
11 2004 Mission Creek Settlement Agreement (DWA 2011; MSWD 2011). The  
12 Coachella Valley Water District and Desert Water Agency also manage portions  
13 of the subbasin in accordance with the 2003 Mission Creek Groundwater  
14 Replenishment Agreement. These agreements provide for the allocation of  
15 available Colorado River water under the SWP water exchange agreement with  
16 the Metropolitan Water District of Southern California between the Mission  
17 Creek and Indio (also known as the Whitewater) subbasins.

#### 18 **7.3.6.6 Antelope Valley and Mojave Valley**

19 The areas within the SWP service area in the Antelope Valley and Mojave Valley  
20 include Salt Wells Valley, Cuddeback Valley, Pilot Knob Valley, Grass Valley,  
21 Superior Valley, El Mirage Valley, Upper Mojave River Valley, Middle Mojave  
22 River Valley, Lower Mojave River Valley, Caves Canyon Valley, Langford  
23 Valley, Cronise Valley, Coyote Lake Valley, Kane Wash Area, Iron Ridge Area,  
24 Bessemer Valley, Lucerne Valley, Johnson Valley, Means Valley, Deadman  
25 Valley, Twentynine Palms Valley, Joshua Tree, Ames Valley, Copper Mountain  
26 Valley, Warren Valley, and Morongo Valley groundwater basins in San  
27 Bernardino County; Harper Valley and Fremont Valley groundwater basins in  
28 San Bernardino Kern counties; Lost Horse Valley in Riverside and San  
29 Bernardino counties; Antelope Valley Groundwater Basin in San Bernardino,  
30 Kern, and Los Angeles counties; and Indian Wells and Searles Valley  
31 groundwater basin in San Bernardino, Inyo, and Kern counties, as shown in  
32 Figure 7.13.

#### 33 **7.3.6.6.1 Hydrogeology and Groundwater Conditions**

##### 34 *Indian Wells Valley Groundwater Basin*

35 Indian Wells Valley Groundwater Basin is located in Inyo, Kern, and San  
36 Bernardino Counties. Water bearing formations consist of unconsolidated  
37 lakebed, stream, and alluvial fan deposits with upper and lower aquifers  
38 (DWR 2004cn). The lower aquifer is more productive and has a saturated  
39 thickness of approximately 1000 feet. The upper aquifer provides low yield and  
40 has low quality. The lower aquifer is considered unconfined in most of the valley.  
41 There is indication that some faults within the valley could obstruct groundwater  
42 flow. Groundwater is recharged from runoff on the southwest to northeast sides  
43 of the valley. Groundwater levels have been declining since 1945. Groundwater

1 quality varies throughout the groundwater basin from appropriate for beneficial  
2 uses to areas with poor water quality due to wastewater disposal practices. Areas  
3 near geothermal activity are characterized by high chloride, boron, and arsenic  
4 concentrations.

5 Indian Wells Valley Groundwater Basin was designated by the CASGEM  
6 program as medium priority.

7 *Salt Wells Valley Groundwater Basin*

8 Salt Wells Valley Groundwater Basin is located in San Bernardino County.  
9 Water bearing formations consist of unconsolidated to poorly consolidated  
10 alluvium (DWR 2004co). Groundwater is recharged from the Indian Wells  
11 Groundwater Basin and percolation of rainfall on the valley floor. The regional  
12 groundwater flow direction is towards the east into the Searles Valley  
13 Groundwater Basin. The groundwater has extremely high salinity, TDS, and  
14 boron.

15 Salt Wells Valley Groundwater Basin was designated by the CASGEM program  
16 as very low priority.

17 *Searles Valley Groundwater Basin*

18 Searles Valley Groundwater Basin is located in San Bernardino, Inyo, and Kern  
19 Counties. Water bearing formations consist of alluvium with unconsolidated to  
20 semi-consolidated deposits (DWR 2004cp). The Garlock fault may be a barrier to  
21 groundwater flow in the southern part of the basin. Groundwater is recharged  
22 from percolation of mountain runoff through the alluvial fan deposits and  
23 subsurface inflow from Salt Wells Valley and Pilot Knob Valley groundwater  
24 basins. Groundwater flows towards Searles Lake except in the northern portion  
25 of the basin where pumping by industrial water users has altered the groundwater  
26 flow. Groundwater levels near Searles Lake are close to the lake bed elevations.  
27 Groundwater quality is generally appropriate for beneficial uses with localized  
28 areas with high levels of fluoride and nitrate. In the vicinity of Searles Lake, the  
29 groundwater quality is poor with high levels of fluoride, boron, sodium, chloride,  
30 sulfate, and TDS.

31 Searles Valley Groundwater Basin was designated by the CASGEM program as  
32 very low priority.

33 *Cuddeback Valley, Pilot Knob Valley, Grass Valley, and Superior Valley,*  
34 *Groundwater Basins*

35 Cuddeback Valley, Pilot Knob Valley, Grass Valley, and Superior Valley  
36 Groundwater basins are located in northern San Bernardino County. Water  
37 bearing formations consist of unconsolidated to poorly consolidated alluvium  
38 (DWR 2004cq, 2004cr, 2004cs, 2004ct). Several fault zones restrict groundwater  
39 movement. Groundwater is recharged in the Cuddeback Valley, Pilot Knob  
40 Valley, Grass Valley, and Superior Valley groundwater basins primarily through  
41 groundwater inflow into the basins and percolation of precipitation at the valley  
42 margins. Groundwater within Cuddeback Valley, Grass Valley, and Superior  
43 Valley groundwater basins flows towards the Harper Valley Groundwater Basin.

1 Groundwater in the Cuddeback Valley Groundwater Basin also flows towards  
2 Cuddeback Lake. Groundwater in Pilot Knob Valley Groundwater Basin flows  
3 towards the Searles Valley and Brown Mountain Valley groundwater basins.  
4 Groundwater quality is characterized as sodium chloride-bicarbonate with high  
5 salinity and TDS in the Cuddeback Valley Groundwater Basin and high  
6 concentrations of sodium and fluoride in the Superior Valley Groundwater Basin.  
7 Cuddeback Valley, Pilot Knob Valley, Grass Valley, and Superior Valley  
8 groundwater basins were designated by the CASGEM program as very low  
9 priority.

10 *Harper Valley Groundwater Basin*

11 Harper Valley Groundwater Basin is located in western San Bernardino County  
12 and eastern Kern County. Water bearing formations consist of lacustrine deposits  
13 and unconsolidated to semi-consolidated alluvial deposits (DWR 2004cu). The  
14 alluvial deposits at the center of the basin are generally more interbedded with  
15 lacustrine silty clay. Faults in the Harper Valley Groundwater Basin cause at least  
16 partial barriers to groundwater flow. Groundwater is recharged from percolation  
17 of rainfall and runoff through alluvial fan material at the valley edges and  
18 underflow from Cuddeback Valley, Grass Valley, Superior Valley, and Middle  
19 Mojave River Valley groundwater basins. Regional groundwater flows toward  
20 the south and Harper Lake. Groundwater quality is characterized as sodium  
21 chloride-bicarbonate with high concentrations of boron, fluoride, and sodium.

22 Harper Valley Groundwater Basin was designated by the CASGEM program as  
23 low priority.

24 *Fremont Valley Groundwater Basin*

25 The Fremont Valley Groundwater Basin is located in eastern Kern County and in  
26 northwestern San Bernardino County. Water bearing formations consist of  
27 alluvial and lacustrine deposits (DWR 2004cv). The alluvial deposits are  
28 generally unconfined and the lacustrine deposits may exhibit locally confined  
29 conditions. Fault zones, including the Garlock and El Paso fault zones, are  
30 barriers to groundwater flow. Groundwater is recharged along streambeds in the  
31 Sierra Nevada Mountains. Groundwater flow is generally toward the center of the  
32 valley and Koehn Lake. Groundwater is characterized as sodium bicarbonate  
33 with high concentrations of calcium, chloride, fluoride, and sodium.

34 Fremont Valley Groundwater Basin was designated by the CASGEM program as  
35 low priority.

36 *Antelope Valley Groundwater Basin*

37 The Antelope Valley Groundwater Basin is located in Kern, Los Angeles, and San  
38 Bernardino counties. Water bearing formations consist of unconsolidated alluvial  
39 and lacustrine deposits consisting of compact gravels, sand, silt, and clay (DWR  
40 2004cw). Several fault zones restrict groundwater movement. Groundwater is  
41 recharged along streams from the surrounding mountains, including Big Rock  
42 Creek and Little Rock Creek. The regional groundwater flow direction  
43 historically was towards the dry lakebeds of Rosamond, Rogers, and Buckhorn

1 Lakes. However, extensive groundwater pumping has caused subsidence and  
2 reduced the groundwater storage and flow direction. The groundwater is  
3 characterized as sodium bicarbonate with localized areas of high nitrate and  
4 boron.

5 Antelope Valley Groundwater Basin was designated by the CASGEM program as  
6 high priority.

7 *El Mirage Valley Groundwater Basin*

8 The El Mirage Valley Groundwater Basin is located in San Bernardino County.

9 Water bearing formations consist of unconsolidated to semi-consolidated

10 alluvium (DWR 2003c). Several fault zones restrict groundwater movement.

11 Groundwater is recharged in alluvial deposits at the mouth of Sheep Creek. The

12 regional groundwater flow direction is generally north toward El Mirage Lake.

13 The groundwater is characterized as sodium bicarbonate with localized areas of

14 high levels of fluoride, sulfate, sodium, and TDS.

15 El Mirage Valley Groundwater Basin was designated by the CASGEM program  
16 as medium priority.

17 *Upper Mojave River Valley, Middle Mojave River Valley, Lower Mojave River  
18 Valley, and Caves Canyon Valley Groundwater Basins*

19 The Upper Mojave River Valley, Middle Mojave River Valley, Lower Mojave

20 River Valley, and Caves Canyon Valley groundwater basins are located along the

21 Mojave River in southwestern and central San Bernardino County. The water

22 bearing formations consist of alluvial fan deposits overlain by river channel,

23 floodplain, or lake deposits (DWR 2004cx, 2004cy, 2003d, 2003e). The general

24 groundwater flow direction follows the Mojave River north through the Upper

25 Mojave River Valley Groundwater Basin, and east through the Middle Mojave

26 River Valley, Lower Mojave River Valley, and Caves Canyon Valley

27 groundwater basins. Several fault zones restrict groundwater movement.

28 Groundwater is recharged from precipitation on the valley floor, underflow from

29 the Mojave River, streamflow, and flow between the basins. Treated wastewater

30 and irrigation return flows also provide a source of groundwater recharge in these

31 basins. Groundwater quality in the Upper Mojave River Valley, Middle Mojave

32 River Valley, Lower Mojave River Valley, and Caves Canyon Valley

33 groundwater basins varies throughout the basins due to geological formations and

34 includes areas dominated by calcium bicarbonate, calcium-sodium bicarbonate,

35 calcium-sodium sulfate, sodium-calcium sulfate, and sodium sulfate-chloride.

36 There are localized areas of high nitrate, iron, and manganese in the Upper

37 Mojave River Valley Groundwater Basin; and areas with high nitrates, fluoride,

38 and boron in the Middle Mojave River Valley and Lower Mojave River Valley

39 groundwater basins. Localized areas with high volatile organic compounds occur

40 in the Upper Mojave River Valley and Lower Mojave River Valley groundwater

41 basins.

42 Upper Mojave River Valley Groundwater Basin was designated by the CASGEM

43 program as high priority. Lower Mojave River Valley Groundwater Basin was

44 designated as medium priority. Middle Mojave River Valley Groundwater Basin

1 was designated as low priority. Caves Canyon Valley Groundwater Basin was  
2 designated as very low priority.

3 *Langford Valley Groundwater–Langford Well Lake Subbasin, and Cronise Valley*  
4 *and Coyote Lake Valley Groundwater Basins*

5 The Langford Well Lake subbasin and the Cronise Valley and Coyote Lake  
6 Valley groundwater basins are located in central San Bernardino County. Water  
7 bearing formations consist of unconsolidated to semi-consolidated alluvium  
8 (DWR 2004cz, 2004da, 2004db). Groundwater is recharged from precipitation,  
9 stream flows into alluvial deposits along the mountains at the basin boundaries,  
10 and subsurface inflow from other groundwater basins including the Superior  
11 Valley Groundwater Basin. Groundwater quality is poor due to high  
12 concentrations of fluoride, boron, and TDS, and localized areas with high iron in  
13 the Langford Well Lake subbasin.

14 Langford Well Lake subbasin and the Cronise Valley and Coyote Lake Valley  
15 groundwater basins were designated by the CASGEM program as very low  
16 priority.

17 *Kane Wash Area Groundwater Basin*

18 The Kane Wash Area Groundwater Basin is located in San Bernardino County.  
19 Water bearing formations consist of unconsolidated to semi-consolidated  
20 alluvium with undissected coarse gravel to sand in the younger deposits and  
21 dissected gravel sand and silt in the older deposits (DWR 2004dc). Groundwater  
22 is recharged from precipitation and stream flows. The groundwater is  
23 characterized as sodium sulfate-bicarbonate with moderate TDS concentrations.

24 Kane Wash Area Groundwater Basin was designated by the CASGEM program  
25 as very low priority.

26 *Iron Ridge Area Groundwater Basin*

27 The Iron Ridge Area Groundwater Basin is located in southern San Bernardino  
28 County. Water bearing formations consist of unconsolidated to semi-consolidated  
29 alluvium (DWR 2004dd). Several fault zones restrict groundwater movement.  
30 Groundwater is recharged from precipitation and stream flows from the nearby  
31 mountains.

32 Iron Ridge Area Groundwater Basin was designated by the CASGEM program as  
33 very low priority.

34 *Bessemer Valley Groundwater Basin*

35 The Bessemer Valley Groundwater Basin is located in eastern San Bernardino  
36 County. Water bearing formations consist of unconsolidated to semi-consolidated  
37 alluvial deposits, fanglomerate, and playa lake deposits (DWR 2004de). More  
38 recent deposits consist of unconsolidated, undissected coarse gravel to sand.  
39 Older deposits consist of gravel, sand, and silt from dissected alluvial fans.  
40 Several fault zones restrict groundwater movement. Groundwater is recharged  
41 from precipitation and stream flows at the valley margins.

1 Bessemer Valley Groundwater Basin was designated by the CASGEM program  
2 as very low priority.

3 *Lucerne Valley Groundwater Basin*

4 The Lucerne Valley Groundwater basin is located in San Bernardino County.  
5 Water bearing formations consist of unconsolidated or semi-consolidated alluvial  
6 deposits and dune sand deposits composed of gravel, sand, silt, clay, and  
7 occasional boulders (DWR 2004df). Several fault zones restrict groundwater  
8 movement. Groundwater is recharged from precipitation and stream flows.  
9 Groundwater levels have declined throughout the basin and caused subsidence.  
10 The groundwater is characterized as calcium-magnesium bicarbonate or  
11 magnesium-sodium sulfate with TDS and nitrates.

12 Lucerne Valley Groundwater Basin was designated by the CASGEM program  
13 low priority.

14 *Johnson Valley Groundwater Basin*

15 The Johnson Valley Groundwater Basin is located in San Bernardino County and  
16 includes the Soggy Lake and Upper Johnson Valley subbasins. Water bearing  
17 formations in both subbasins consist of alluvial deposits with mainly sand and  
18 gravel in the Soggy Lake subbasin and silt, clay, sand, and gravel in the Upper  
19 Johnson Valley subbasin (DWR 2004dg, 2004dh). Springs occur throughout the  
20 Soggy Lake subbasin. Groundwater flows from Soggy Lake subbasin into the  
21 Upper Johnson Valley subbasin. Several fault zones restrict groundwater  
22 movement. The groundwater is characterized with moderate to high TDS and  
23 localized areas with high fluoride.

24 Johnson Valley Groundwater Basin was designated by the CASGEM program as  
25 very low priority.

26 *Means Valley Groundwater Basin*

27 The Means Valley Groundwater Basin is located in south central part of San  
28 Bernardino County. Water bearing formations consist of alluvial and lacustrine  
29 deposits with unconsolidated fine to coarse grained sand, pebbles, and boulders;  
30 and varying silt and clay deposits throughout the basin (DWR 2004di). Several  
31 fault zones restrict groundwater movement. Groundwater is recharged from  
32 precipitation and subsurface inflow from the Johnson Valley Groundwater Basin.  
33 The groundwater is characterized as sodium-chloride bicarbonate with high TDS,  
34 fluoride, and nitrates.

35 Means Valley Groundwater Basin was designated by the CASGEM program as  
36 very low priority.

37 *Deadman Valley Groundwater Basin*

38 The Deadman Valley Groundwater Basin is located in San Bernardino County.  
39 The Deadman Valley Groundwater Basin includes the Deadman Lake and  
40 Surprise Spring subbasins. Water bearing formations consist of unconsolidated to  
41 partly consolidated continental deposits including interbedded gravels,  
42 conglomerates, clays, and silts in alluvial fan units (DWR 2004dj, 2004dk).  
43 Several fault zones restrict groundwater movement. Groundwater is recharged

1 from precipitation and stream flows. Groundwater flows from the Surprise Spring  
2 subbasin into the Deadman Lake subbasin, and from Deadman Lake subbasin to  
3 the dry Mesquite Lake. Groundwater also flows from the Ames Valley  
4 Groundwater Basin into the Surprise Spring subbasin. The groundwater is  
5 characterized as sodium bicarbonate with moderate to high TDS and localized  
6 areas of high fluoride.

7 Deadman Valley Groundwater Basin was designated by the CASGEM program as  
8 very low priority.

9 *Twentynine Palms Valley, Joshua Tree, Ames Valley, Copper Mountain Valley,*  
10 *and Warren Valley Groundwater Basins*

11 The Twentynine Palms Valley, Ames Valley, and Copper Mountain Valley  
12 groundwater basins are located in southern San Bernardino County. The Joshua  
13 Tree and Warren Valley groundwater basins are located in southern San  
14 Bernardino County and northern Riverside County. Water bearing formations  
15 consist of unconfined, unconsolidated to partly consolidated continental deposits  
16 with interbedded gravels, conglomerates, lake playa, silts, clays, and sandy-clay  
17 deposits (DWR 2004di, 2004dj, 2004dk, 2004dl, 2004dm). Several fault zones  
18 restrict groundwater movement. Groundwater is recharged from precipitation,  
19 stream flows, and wastewater effluent disposal. Groundwater flows from the  
20 Joshua Tree Groundwater Basin into the Copper Mountain Valley Groundwater  
21 Basin. Groundwater recharge in the Warren Valley Groundwater Basin also  
22 occurs at spreading grounds. The groundwater is characterized as calcium-  
23 sodium bicarbonate or sodium sulfate with moderate to high TDS in all of the  
24 basins except the Copper Mountain Valley Groundwater Basin; and localized  
25 areas with high fluoride, nitrate, sulfate, and chloride.

26 Warren Valley Groundwater Basin was designated by the CASGEM program as  
27 medium priority. Twentynine Palms Valley was designated as low priority.  
28 Joshua Tree, Ames, and Copper Mountain Valley groundwater basins were  
29 designated as very low priority.

30 *Morongo Valley Groundwater Basin*

31 The Morongo Valley Groundwater basin is located in southern San Bernardino  
32 County. Water bearing formations consist of alluvial deposits composed of sand,  
33 gravel, silt, and clay (DWR 2003f). Several fault zones restrict groundwater  
34 movement. Groundwater is recharged from precipitation and stream flows in the  
35 Big Morongo and Little Morongo creeks. The groundwater is characterized as  
36 calcium-sodium bicarbonate with moderate TDS.

37 Morongo Valley Groundwater Basin was designated by the CASGEM program as  
38 very low priority.

39 *Lost Horse Valley Groundwater Basin*

40 The Lost Horse Valley Groundwater Basin is located on the border between  
41 southeastern San Bernardino County and northeastern Riverside County. Water  
42 bearing formations consist of unconsolidated to semi-consolidated alluvial

1 deposits (DWR 2004dn). Groundwater is recharged from precipitation and  
 2 stream flows.  
 3 Lost Horse Valley Groundwater Basin was designated by the CASGEM program  
 4 as very low priority.

5 **7.3.6.6.2 Groundwater Use and Management**

6 Within the Antelope Valley and Mojave Valley, groundwater management is  
 7 facilitated by the Antelope Valley-East Kern Water Agency and Mojave Water  
 8 Agency. These agencies purchase SWP water and other water supplies to be used  
 9 for groundwater recharge or in-lieu uses to protect groundwater within the  
 10 Antelope and Mojave valleys.

11 *Antelope Valley*

12 The Antelope Valley-East Kern Water Agency (AVEK) provides SWP water to  
 13 areas that overlay portions of the Antelope Valley, Fremont Valley, and Indian  
 14 Wells Valley groundwater basins. To maintain groundwater aquifers in the area,  
 15 the AVEK provides treated SWP water to users through the Domestic-  
 16 Agricultural Water Network and untreated SWP water to some agricultural users  
 17 (AVEK 2011a). The AVEK participates in groundwater banking programs.  
 18 Communities within the AVEK service area also use groundwater, including the  
 19 cities of California City, Lancaster, and Palmdale; Edwards Air Force Base;  
 20 County of Los Angeles Waterworks District No. 40; Boron Community Services  
 21 District, Desert Lake Community Services District, Indian Wells Water District  
 22 (including the City of Ridgecrest), Mojave Public Utilities District, Palmdale  
 23 Water District, Palm Ranch Irrigation District, Quartz Hill Water District, and  
 24 Rosamond Community Services District; and California Water Service Company  
 25 (Antelope Valley, Lake Hughes, areas outside of the City of Lancaster, and Leona  
 26 Valley), Edgemont Crest Municipal Water Company, El Dorado Mutual Water  
 27 Company, Lake Elizabeth Mutual Water Company, Shadow Acres Mutual Water  
 28 Company, Sunnyside Farm Mutual Water Company, Westside Park Mutual Water  
 29 Company, and White Fence Farms Mutual Water Company provide retail  
 30 groundwater supplies (AVEK 2011a; AVRWC 2011; California Water Service  
 31 Company 2011f; City of California City 2013; IWVWD 2011; Los Angeles  
 32 County et al. 2011; PWD 2011; Rosamond CSD 2011).

33 In 2004, the County of Los Angeles Waterworks District No. 40 and Palmdale  
 34 Water District filed for the adjudication of the Antelope Valley Groundwater  
 35 Basin (DWR 2014a; Los Angeles County et al. 2011; PWD 2011). The request of  
 36 the filing is to allocate groundwater rights within the basin to these districts, other  
 37 municipal and industrial water users, and Overlying Landowners and provide for  
 38 a program to replace groundwater withdrawals in excess of a specified yield in  
 39 order to stabilize or reverse groundwater declines.

40 *Mojave Valley*

41 Within the Mojave Water Agency service area, most of the water supply is from  
 42 groundwater (AVRWC 2011; City of Adelanto 2011; Golden State Water  
 43 Company 2011k; HDWD 2011; Hesperia Water District 2011; JBWD 2011;

1 MWA 2011; PPHCSD 2011; San Bernardino County 2012; TPWD 2014;  
2 Victorville Water District 2011). The Mojave Water Agency uses natural surface  
3 water flows, recycled water imported from outside of the agency's service area,  
4 SWP water, and return flows from water users of groundwater within the service  
5 area to recharge groundwater. These water supplies are provided as wholesale  
6 water supplies to retail groundwater users to maintain groundwater levels in the  
7 area. The Mojave Water Agency overlays all or portions of all of the  
8 groundwater basins described in this subsection. The City of Adelanto; Hesperia  
9 Water District, Hi-Desert Water District, Joshua Water District, Twentynine  
10 Palms Water District, Victorville Water District, Apple Foothill County Water  
11 District, Apple Heights County Water District, Juniper Riviera County Water  
12 District, Thunderbird County Water District, Daggett Community Services  
13 District, Helendale Community Services District, Phelan Piñon Hills Community  
14 Services District, Yermo Community Services District, Bighorn-Desert View  
15 Water Agency, and San Bernardino County Service Areas numbers 64 and 70;  
16 and Golden State Water Company, Apple Valley Ranchos Water Company,  
17 Jubilee Water Company, and Rancharitos Mutual Water Company provide retail  
18 groundwater supplies. These entities provide water to the cities of Adelanto,  
19 Barstow, Hesperia, Twentynine Palms, Victorville; towns of Apple Valley and  
20 Yucca; Joshua Tree National Park; Twentynine Palms Marine Corps Base; and  
21 the communities of Apple Heights, Apple Valley, Daggett, Flamingo Heights,  
22 Helendale, Johnson Valley, Landers, Lucerne Valley, Newberry Springs, Oak  
23 Hills, Spring Valley Lake, Yermo, and users between these communities. The  
24 Morongo Band of Mission Indians also rely upon groundwater from this area.

25 The Mojave Water Agency has implemented 13 groundwater recharge facilities  
26 (MWA 2011). The SWP water is delivered to the recharge facilities throughout  
27 the Mojave Water Agency service area.

28 The area known as the Mojave Basin Area has been adjudicated. This area  
29 includes all or portions of Cuddeback Valley, Superior Valley, Harper Valley,  
30 Antelope Valley, El Mirage Valley, Upper Mojave River Valley, Middle Mojave  
31 River Valley, Lower Mojave River Valley, Caves Canyon Valley, Langford  
32 Valley, Cronise Valley, Coyote Lake Valley, Kane Wash Area, Iron Ridge Area,  
33 Lucerne Valley, and Johnson Valley groundwater basins (Golden State Water  
34 Company 2011k; MWA 2011). The Mojave Basin Judgment allocated  
35 groundwater withdrawals in the area and required groundwater users that  
36 withdraw more than the allocated amount to purchase replenishment SWP water  
37 from the Watermaster or from another entity within the judgment. The judgment  
38 considers local surface water sources, including groundwater recharge near  
39 Hesperia with treated wastewater effluent from Lake Arrowhead Community  
40 Services District (LACSD 2011). The judgment also provides for carry over  
41 storage between water years. The Mojave Water Agency has been appointed as  
42 the Watermaster.

43 The Warren Valley Groundwater Basin was adjudicated in 1977 (MWA 2011).  
44 The Hi-Desert Water District was appointed as the Watermaster to manage

1 groundwater withdrawals and groundwater quality; to provide SWP water,  
2 captured stormwater, and recycled water; and to encourage conservation.  
3 In 1991, the Bighorn-Desert Water Agency and the Hi-Desert Water District  
4 agreed to the court approved Ames Valley Basin Water Management Agreement.  
5 In accordance with this agreement, the Hi-Desert Water District implemented the  
6 Mainstream Wells and expansion to conveyance and monitoring approaches.

## 7 **7.4 Impact Analysis**

8 This section describes the potential mechanisms and analytical methods for  
9 change in groundwater resources, results of the impact analysis, potential  
10 mitigation measures, and cumulative effects.

### 11 **7.4.1 Potential Mechanisms for Change and Analytical Methods**

12 As described in Chapter 4, Approach to Environmental Analysis, the impact  
13 analysis considers changes in groundwater conditions related to changes in CVP  
14 and SWP operations under the alternatives as compared to the No Action  
15 Alternative and Second Basis of Comparison.

#### 16 **7.4.1.1 Changes in Groundwater Use and Groundwater Levels**

17 Changes in availability of CVP and SWP water supplies could result in changes in  
18 groundwater use. For example, if CVP and SWP water supplies are decreased,  
19 water users may increase the amount of groundwater withdrawals in response.

20 Historically, groundwater resources were the only source of water supply in the  
21 Central Valley. The heavy use of groundwater has caused groundwater quality  
22 issues, drainage issues, groundwater overdraft, and land subsidence (as discussed  
23 in Section 7.3). Throughout many areas of the San Joaquin Valley, shallow  
24 groundwater is characterized by high salinity. Use of this groundwater for  
25 irrigation deposited salts along with agricultural chemicals (nutrients and  
26 fertilizers) in the upper soil layer. These constituents leached into the underlying  
27 shallow groundwater aquifers and caused them to be unsuitable for irrigation.  
28 Surface water was provided through the CVP and SWP to provide irrigation water  
29 of higher quality than was available in local groundwater. The expanded use of  
30 surface water for irrigation has resulted in a reduction in the degree of  
31 groundwater overdraft of local groundwater basins.

32 Generally, when available, agricultural water users in the San Joaquin Valley  
33 prefer to use surface water for irrigation because the water quality is better than  
34 for groundwater. When adequate surface water is not available, they will use  
35 groundwater (USGS 2009).

36 As previously described in Section 7.2.3, Sustainable Groundwater Management  
37 Act, most groundwater users in California must develop Groundwater  
38 Sustainability Plans (GSPs) by 2020 or 2022, and meet the sustainable goal within  
39 20 years after adoption of the plan. The timeframe of this EIS analysis is 2030.  
40 Therefore, the EIS analysis assumes that groundwater users have developed the

1 GSPs before that timeframe (by 2020 or 2022), and have begun to plan, design,  
2 and possibly construct alternative water supply facilities or implement water  
3 conservation measures to achieve full compliance by 2040 or 2042. However,  
4 this EIS analysis assumes that the new facilities or conservation measures are not  
5 fully implemented by 2030. Therefore, reductions in groundwater use in  
6 accordance with the SGMA are not anticipated until after 2030 and are discussed  
7 under Section 7.4.39, Cumulative Effects Analysis.

8 Changes in groundwater use by users of or providers to CVP and SWP water  
9 supplies could result in changes in groundwater storage and groundwater levels.  
10 For example, if CVP and SWP water supplies are decreased and water users  
11 increase the amount of groundwater withdrawals, groundwater levels could  
12 decline. Changes in groundwater levels resulting in levels declining could result  
13 in a decrease in well yields. Changes in groundwater levels also could result in  
14 different groundwater pumping costs, as analyzed in Chapter 12, Agricultural  
15 Resources, and Chapter 14, Socioeconomics, for agricultural and municipal water  
16 users of CVP and SWP water supplies, respectively.

#### 17 **7.4.1.1.1 Use of Central Valley Hydrologic Model**

18 There are many groundwater models that have been developed for portions of the  
19 Central Valley. However, most of these models were not developed in a manner  
20 that would allow for analysis of groundwater changes throughout the Central  
21 Valley which includes the majority of CVP and SWP agricultural water users. As  
22 described in Appendix 7A, Groundwater Model Documentation, changes in  
23 groundwater use, and levels in the Central Valley have been evaluated using the  
24 Central Valley Hydrologic Model (CVHM) because this model is readily  
25 available and covers the entire Central Valley. CVHM is a regional-scale  
26 calibrated historical finite-difference, block-centered saturated groundwater flow  
27 model application developed by the USGS and uses the MODFLOW-2000  
28 computer code (USGS 2000b). The CVHM model spans a 42-year simulation  
29 period between water years 1962 and 2003.

30 CVHM is used to estimate the changes in groundwater levels and groundwater  
31 withdrawals under the alternatives as compared to the No Action Alternative and  
32 Second Basis of Comparison. CVHM model output is also used as input files of  
33 the State Wide Agricultural Production (SWAP) model to simulate agricultural  
34 production changes based on groundwater pumping costs, as described in  
35 Chapter 12, Agricultural Resources.

36 The CVHM domain is subdivided into 21 WBSs, as summarized in Figure 7.14  
37 (USGS 2009). Applied water requirements for each WBS are computed based on  
38 crop type and available water from precipitation, shallow groundwater uptake,  
39 and surface water, as limited by surface water rights and CVP and SWP water  
40 supply deliveries.

41 CVHM simulates primarily subsurface and limited surface hydrologic processes  
42 over the entire Central Valley at a uniform grid-cell spacing of 1 mile. Boundary  
43 conditions were modified to reflect anticipated changes in surface water  
44 availability, including the effects of climate change.

1 Surface water inflows from the CalSim II model were used to define boundary  
2 conditions for CVHM for each alternative and the Second Basis of Comparison.  
3 The CalSim II model simulates the operation of the major SWP and CVP  
4 facilities in the Central Valley by calculating river flows; and CVP and SWP  
5 reservoir storage, exports, and deliveries (see Appendix 5A for more details on  
6 CalSim II). The CalSim II outputs are included in the CVHM input files.

7 The CVHM uses the FMP process (described in Appendix 7A) to estimate  
8 agricultural water supply needs and assumes that when surface water deliveries  
9 are available, they are used first, before groundwater is pumped for additional  
10 water supplies.

11 Changes in agricultural groundwater pumping under the alternatives are compared  
12 to groundwater pumping under the No Action Alternative and Second Basis of  
13 Comparison. The data for these results were processed from the FMP output  
14 files, which include the amount of water used from each available source by the  
15 farm, based on the computed crop water demand for each WBS.

16 For the analyses presented in this chapter, changes in groundwater use, elevation,  
17 and pumping volumes between the alternatives, No Action Alternative, and  
18 Second Basis of Comparison are described for agricultural water users only in the  
19 Central Valley Region.

#### 20 **7.4.1.1.2 Analysis of Changes in Municipal and Industrial** 21 **Groundwater Use**

22 Due to the regional scale of the CVHM model, municipal and industrial  
23 groundwater use is a very small portion of total groundwater use due to the  
24 predominance of agricultural groundwater use. Therefore, in the CVHM model,  
25 municipal and industrial groundwater use in the Central Valley was assumed to  
26 continue at the 2003 calibrated volume throughout the predictive simulations.

27 For municipal and industrial groundwater use in the Central Valley, the CWEST  
28 model is a more appropriate model than CVHM. The CWEST model evaluates  
29 total water use by municipal and industrial water users in the Central Valley, San  
30 Francisco Bay Area, Central Coast, and Southern California regions based upon  
31 economic decisions.

32 It is recognized that municipal and industrial pumping in urban areas in the  
33 Central Valley could cause localized impacts to groundwater levels from  
34 increased drawdown. The increased withdrawals could also impact groundwater  
35 quality due to the migration of existing plumes, as described in the Affected  
36 Environment section.

#### 37 **7.4.1.1.3 Analysis of Changes in Agricultural Groundwater Use Outside of** 38 **the Central Valley Region**

39 Agricultural groundwater use by CVP and SWP water users located outside of the  
40 Central Valley primarily occurs in Santa Clara and San Benito counties in the San  
41 Francisco Bay Area Region; San Luis Obispo and Santa Barbara counties in the  
42 Central Coast Region; and Ventura, Orange, San Bernardino, and Riverside

1 counties in the Southern California Region. Basin adjudication programs in many  
2 portions of these counties will minimize changes in groundwater use and levels as  
3 a result of changes in CVP and SWP water supplies. There are no regional  
4 groundwater flow models available that uniformly help analyze groundwater use  
5 and elevation in these areas linked to CVP and SWP water supply deliveries, in a  
6 similar manner as CVHM simulates in the Central Valley, however in some areas  
7 local models have been developed to support groundwater management activities.  
8 Therefore, changes in groundwater use and related changes in groundwater levels  
9 are assumed to be correlated to availability of CVP and SWP water supplies. It is  
10 generally assumed that an increase in CVP and SWP water supplies would result  
11 in a decrease in groundwater use in these areas. Similarly, a decrease in CVP and  
12 SWP water supplies could result in a short-term increase in groundwater use and  
13 associated groundwater level decrease. In adjudicated basins, groundwater use  
14 restrictions limit the amount of groundwater that can be pumped, even when  
15 surface water availability is reduced. In those basins, long-term groundwater use  
16 is assumed to not increase, and agricultural production could decrease if CVP and  
17 SWP water supplies decrease.

#### 18 **7.4.1.2 Changes in Land Subsidence**

19 Extensive groundwater withdrawals from confined and unconfined aquifers  
20 increases the potential for land subsidence. In aquifers with clay and silt lenses,  
21 decreased groundwater levels can result in compaction of fine-grained deposits  
22 which could lead to irreversible land subsidence. Subsidence could result in  
23 structural damage to roads, railroad tracks, pipelines and associated structures,  
24 drainage, buildings, and wells. Subsidence can also result in the permanent loss  
25 of groundwater storage potential within an aquifer system.

26 Subsidence is related to changes in groundwater levels; and a review of simulated  
27 changes in groundwater elevation output from the CVHM model as compared  
28 between alternatives is used to provide an indication of the potential occurrence of  
29 subsidence.

30 CVHM includes a module known as the SUB package that computes the  
31 cumulative compaction of each model layer during the model simulation. The  
32 cumulative layer compactions at the end of the simulation are summed into a total  
33 subsidence. However, this version of the SUB package does not consider the  
34 potential reduction in the rate of subsidence that would occur as the magnitude of  
35 compaction approaches the physical thickness of the affected fine-grained  
36 interbeds. Thus, subsidence forecasts from the predictive versions of CVHM  
37 were not used as they may not accurately depict long-term changes in subsidence  
38 using the current version of the SUB package. Therefore, a qualitative approach  
39 was used for the estimation of the potential for increased land subsidence in areas  
40 of the Central Valley that have historically experienced inelastic subsidence due  
41 to the compaction of fine-grained interbeds.

42 Potential changes in subsidence due to changes in municipal and industrial  
43 groundwater use were qualitatively analyzed for regions with historic or existing

1 subsidence issues, such as in Santa Clara County in the San Francisco Bay Area  
2 Region.

3 **7.4.1.3 Changes in Groundwater Quality**

4 Changes in groundwater quality could occur in several ways under  
5 implementation of the alternatives as compared to the No Action Alternative and  
6 Second Basis of Comparison. Reductions in groundwater levels could change  
7 groundwater flow directions, potentially causing poorer quality groundwater to  
8 migrate into areas with higher quality groundwater, or cause intrusion of poor  
9 water quality (e.g. from aquitards) as water levels decline.

10 Groundwater quality also could change due to changes in availability of CVP  
11 and/or SWP water supplies used by agricultural water users. For example, if  
12 reductions in CVP and/or SWP water supplies result in increased use of  
13 groundwater with higher salinity than CVP and/or SWP supplies, shallow  
14 groundwater could become more saline and soil salinity could increase, as  
15 described in Chapter 11, Geology and Soils. In addition, the reduced availability  
16 of higher quality surface water for use in recharge facilities may decrease the  
17 overall groundwater quality in those localized areas.

18 Changes in groundwater quality due to changes in CVP and SWP water supply  
19 availability could occur under the following mechanisms:

- 20 • Migration of reduced quality groundwater towards areas of groundwater  
21 withdrawals, including seawater intrusion and migration of contaminant  
22 plumes
- 23 • Depletion of the freshwater aquifer that overlays poorer quality groundwater,  
24 and the upwelling of the poorer quality groundwater into the upper aquifers
- 25 • Percolation of applied water with poorer water quality than underlying  
26 groundwater

27 Within the Central Valley, changes in groundwater use and groundwater flow  
28 direction are analyzed using the CVHM. The model does not directly simulate  
29 changes in groundwater quality. However, in regions with existing poorer quality  
30 groundwater, changes in groundwater levels or flow directions can be used to  
31 evaluate potential impacts to groundwater quality. For example, declines in  
32 groundwater levels that result in seawater intrusion, or the migration of good  
33 quality groundwater into areas with poor quality can result in groundwater quality  
34 degradation. Further, reduction in groundwater quality could also occur due to  
35 migration or upwelling of poorer quality groundwater into areas with good quality  
36 groundwater.

37 Long-term use of poorer quality groundwater due to changes in CVP and SWP  
38 water supplies could also result in a reduction in shallow aquifer groundwater  
39 quality. Application of poorer quality groundwater also could increase soil  
40 salinity, as described in Chapter 11, Geology and Soils Resources.

41 **7.4.1.4 Effects Related to Water Transfers**

42 Historically water transfer programs have been developed on an annual basis.

1 The demand for water transfers is dependent upon the availability of water  
2 supplies to meet water demands. Water transfer transactions have increased over  
3 time as CVP and SWP water supply availability has decreased, especially during  
4 drier water years.

5 Parties seeking water transfers generally acquire water from sellers who have  
6 available surface water who can make the water available through releasing  
7 previously stored water, pump groundwater instead of using surface water  
8 (groundwater substitution); idle crops; or substitute crops that uses less water in  
9 order to reduce normal consumptive use of surface water.

10 Water transfers using CVP and SWP Delta pumping plants and south of Delta  
11 canals generally occur when there is unused capacity in these facilities. These  
12 conditions generally occur during drier water year types when the flows from  
13 upstream reservoirs plus unregulated flows are adequate to meet the Sacramento  
14 Valley water demands and the CVP and SWP export allocations. In non-wet  
15 years, the CVP and SWP water allocations would be less than full contract  
16 amounts; therefore, capacity may be available in the CVP and SWP conveyance  
17 facilities to move water from other sources.

18 Projecting future groundwater conditions related to water transfer activities is  
19 difficult because specific water transfer actions required to make the water  
20 available, convey the water, and/or use the water would change each year due to  
21 changing hydrological conditions, CVP and SWP water availability, specific local  
22 agency operations, and local cropping patterns. Reclamation recently prepared a  
23 long-term regional water transfer environmental document which evaluated  
24 potential changes in groundwater conditions related to water transfer actions  
25 (Reclamation 2014c). Results from this analysis were used to inform the impact  
26 assessment of potential effects of water transfers under the alternatives as  
27 compared to the No Action Alternative and the Second Basis of Comparison.

#### 28 **7.4.2 Conditions in Year 2030 without implementation of** 29 **Alternatives 1 through 5**

30 The impact analysis in this EIS is based upon the comparison of the alternatives to  
31 the No Action Alternative and the Second Basis of Comparison in the Year 2030.  
32 Changes that would occur over the next 15 years without implementation of the  
33 alternatives are not analyzed in this EIS. However, the changes that are assumed  
34 to occur by 2030 under the No Action Alternative and the Second Basis of  
35 Comparison are summarized in this section. Many of the changed conditions  
36 would occur in the same manner under both the No Action Alternative and the  
37 Second Basis of Comparison.

38 This section of Chapter 7 provides qualitative projections of the No Action  
39 Alternative as compared to existing conditions described under the Affected  
40 Environment; and qualitative projections of the Second Basis of Comparison as  
41 compared to “recent historical conditions.” Recent historical conditions are not  
42 the same as existing conditions which include implementation of the  
43 2008 U.S. Fish and Wildlife Service (USFWS) biological opinion (BO) and 2009  
44 National Marine Fisheries Service (NMFS) BO; and consider changes that would

1 have occurred without implementation of the 2008 USFWS BO and the 2009  
2 NMFS BO.

3 **7.4.2.1 Common Changes in Conditions under the No Action**  
4 **Alternative and Second Basis of Comparison**

5 Conditions in 2030 would be different than existing conditions due to:

- 6 • Climate change and sea-level rise
- 7 • General plan development throughout California, including increased water  
8 demands in portions of Sacramento Valley
- 9 • Implementation of reasonable and foreseeable water resources management  
10 projects to provide water supplies

11 These changes would result in a decline of the long-term average CVP and SWP  
12 water supply deliveries by 2030 as compared to recent historical long-term  
13 average deliveries, as described in Chapter 5, Surface Water Resources and Water  
14 Supplies.

15 **7.4.2.1.1 Changes in Conditions due to Climate Change and Sea-Level Rise**

16 It is anticipated that climate change would result in more short-duration high-  
17 rainfall events and less snowpack in the winter and early spring months. The  
18 reservoirs would be full more frequently by the end of April or May by 2030 than  
19 in recent historical conditions. However, as the water is released in the spring,  
20 there would be less snowpack to refill the reservoirs. This condition would  
21 reduce reservoir storage and available water supplies to downstream uses in the  
22 summer. The reduced end of September storage also would reduce the ability to  
23 release stored water to downstream regional reservoirs. These conditions would  
24 occur for all reservoirs in the California foothills and mountains, including  
25 non-CVP and SWP reservoirs.

26 Climate change also would reduce groundwater supplies due to reduced  
27 groundwater recharge potential and increased groundwater overdraft potential as  
28 surface water supplies decline. However, in some locations, sustainable  
29 groundwater supplies could remain similar to recent historical conditions or rise  
30 due to implementation of groundwater management plans to reduce groundwater  
31 overdraft, including the completion of ongoing groundwater recharge and  
32 recovery programs.

33 **7.4.2.1.2 General Plan Development in California**

34 Counties and cities throughout California have adopted general plans which  
35 identify land use classifications including those for municipal and industrial uses  
36 and those for agricultural uses. Preparation of general plans includes an  
37 environmental evaluation under the California Environmental Quality Act to  
38 identify adverse impacts to the physical environment and to provide mitigation  
39 measures to reduce those impacts to a level of less than significance. Most of the  
40 counties where CVP and SWP water supplies are delivered have adopted general  
41 plans following the environmental review of the plans and appropriate

1 alternatives. Population projections from those general plan evaluations are  
2 provided to the State Department of Finance and are used to project future water  
3 needs and the potential for conversion of existing undeveloped lands and  
4 agricultural lands. Many of the existing general plans for counties with municipal  
5 areas recently have been modified to include land use and population projections  
6 through 2030. The No Action Alternative and the Second Basis of Comparison  
7 assume that land uses will develop through 2030 in accordance with existing  
8 general plans.

9 The assumptions related to 2030 municipal water demands are based upon a  
10 review of the 2010 Urban Water Management Plans (UWMPs) prepared by CVP  
11 and SWP water users. The No Action Alternative and the Second Basis of  
12 Comparison assumptions related to future water supplies presented in the  
13 UWMPs were evaluated to determine if the projects were reasonable and certain  
14 to occur by 2030. Projects that had undergone environmental review, were under  
15 design, or under construction were included in the future water supply  
16 assumptions for 2030 in the No Action Alternative and the Second Basis of  
17 Comparison. Projects described in the UWMPs that currently were under  
18 evaluation were included in the Cumulative Effects analysis for future water  
19 supplies.

20 Under the No Action Alternative and Second Basis of Comparison, it is assumed  
21 that water demands would be met on a long-term basis and in dry and critical dry  
22 years using a combination of conservation, CVP and SWP water supplies, other  
23 imported water supplies, groundwater, recycled water, infrastructure  
24 improvements, desalination water treatment, and water transfers and exchanges.  
25 It is anticipated that individual communities or users could be in a situation that  
26 would not allow for affordable water supply options, and that water demands  
27 could not be fully met. However, on a regional scale, it is anticipated that water  
28 demands would be met.

#### 29 **7.4.2.1.3 Reasonable and Foreseeable Water Resources Management** 30 **Projects**

31 The No Action Alternative and the Second Basis of Comparison assumes  
32 completion of water resources management and environmental restoration  
33 projects that would have occurred without implementation of the 2008 USFWS  
34 BO and 2009 NMFS BO by 2030, as described in Chapter 3, Description of  
35 Alternatives. Many of these future actions could affect groundwater conditions  
36 and use of groundwater.

37 The No Action Alternative and the Second Basis of Comparison assume that  
38 groundwater would continue to be used even if groundwater overdraft conditions  
39 continue or become worse. It is recognized that SGMA was enacted in September  
40 2014. The SGMA requires the formation of GSPs in groundwater basins or  
41 subbasins that DWR designates as medium or high priority based upon  
42 groundwater conditions identified using the CASGEM results by 2022.  
43 Sustainable groundwater operations must be achieved within 20 years following  
44 completion of the GSPs. In some areas with adjudicated groundwater basins,

1 sustainable groundwater management could be achieved and/or maintained by  
 2 2030. However, to achieve sustainable conditions in many areas, measures could  
 3 require several years to design and construct water supply facilities to replace  
 4 groundwater, such as seawater desalination. Therefore, it does not appear to be  
 5 reasonable and foreseeable that sustainable groundwater management would be  
 6 achieved by 2030; and it is assumed that groundwater pumping will continue to  
 7 be used to meet water demands not fulfilled with surface water supplies or other  
 8 alternative water supplies in 2030.

9 **7.4.2.1.4 Potential Future Groundwater Conditions in 2030 due to**  
 10 **Common Changes**

11 *Groundwater Conditions*

12 In the Central Valley Region, the combination of increased groundwater  
 13 withdrawals due to reductions in CVP and SWP water deliveries as compared to  
 14 recent historical long-term deliveries and reduced groundwater recharge due to  
 15 climate change could result in continued reductions in groundwater levels in the  
 16 same manner as recent declines of up to 10 feet in the Sacramento Valley and  
 17 more than 20 feet in the San Joaquin Valley, as described in Section 7.3.4, Central  
 18 Valley Region. It is also assumed that full implementation of SGMA GSPs would  
 19 not occur by 2030; and therefore, groundwater pumping will continue to be used  
 20 to meet water demands not fulfilled with surface water supplies or other  
 21 alternative water supplies in 2030, as described above.

22 Under the No Action Alternative and Second Basis of Comparison, groundwater  
 23 banks and other management programs would continue to be implemented, and  
 24 possibly expanded, including ongoing groundwater recharge efforts in the Eastern  
 25 San Joaquin, Kings, Kaweah, and Kern subbasins in the San Joaquin Valley  
 26 Groundwater Basin. These programs could result in groundwater levels that are  
 27 similar or higher as compared to recent groundwater conditions. If local agencies  
 28 fully implement GSPs in accordance with the state SGMA prior to the regulatory  
 29 deadline, groundwater levels could remain similar to recent conditions or rise.

30 Localized groundwater levels in portions of the Central Valley Region could  
 31 increase due to seepage in lands adjacent to the ecosystem restoration areas in the  
 32 Yolo Bypass, Cache Slough, and Suisun Marsh areas depending upon local  
 33 geological and soil conditions.

34 In the Southern California Region, several SWP water users have purchased  
 35 transferred water, expanded groundwater storage within their service areas,  
 36 implemented wastewater recycling and stormwater recycling programs to provide  
 37 water supplies for groundwater recharge, and participated in groundwater banks  
 38 outside of their service areas as part of ongoing sustainable groundwater  
 39 management programs. Under the No Action Alternative and the Second Basis of  
 40 Comparison, groundwater banks and other management programs would continue  
 41 to be implemented, and possibly expanded. Several of the programs include  
 42 expansion of groundwater storage by Kern County and Antelope Valley-East  
 43 Kern Water Agency; groundwater recharge programs using recycled stormwater  
 44 by the Los Angeles Department of Water and Power; groundwater recharge

1 programs using recycled wastewater by the Water Replenishment District; and  
2 groundwater treatment by City of Oxnard and Western Municipal Water District  
3 (AVEK 2011b; City of Los Angeles 2011; City of Oxnard 2013; Reclamation  
4 2010b; WMWD 2012; WRD 2015). Expansion of these programs could result in  
5 maintenance of groundwater levels in accordance with objectives in the current  
6 groundwater management plans even with reduced SWP water supplies under the  
7 No Action Alternative and Second Basis of Comparison.

#### 8 *Potential Land Subsidence*

9 Land subsidence due to groundwater withdrawals historically occurred in the  
10 Yolo subbasin of the Sacramento Valley Groundwater Basin and Delta-Mendota  
11 and Westside subbasins of the San Joaquin Valley Groundwater Basin in the  
12 Central Valley Region; Santa Clara Valley Groundwater Basin in the San  
13 Francisco Bay Area Region; and the Antelope Valley and Lucerne Valley  
14 groundwater basins in the Southern California Region. Under the No Action  
15 Alternative, it is anticipated that increased groundwater withdrawals due to  
16 reductions in CVP and SWP water supplies and reduced groundwater recharge  
17 due to climate change could result in increased irreversible land subsidence in  
18 these areas.

#### 19 *Groundwater Quality*

##### 20 *Central Valley Region*

21 As described in Section 7.3, Affected Environment, in the Central Valley, there  
22 are localized areas of high salinity related to natural geologic formations and/or  
23 historic land uses; high naturally occurring arsenic, calcium, iron, and/or  
24 manganese; and high levels of boron, and/or phosphates related to historic land  
25 use practices. High concentrations of nitrates due to current anthropogenic  
26 sources and legacy sources occur in many locations in the San Joaquin Valley  
27 Groundwater Basin, especially in the Eastern San Joaquin, Modesto, Merced,  
28 Kings, Kaweah, Tule, and Tulare Lake subbasins. Under the No Action  
29 Alternative, it is anticipated that these conditions would continue to occur; and  
30 that groundwater quality could be further degraded due to reduction of  
31 groundwater elevation that can cause adjacent poorer quality water to flow  
32 towards the groundwater withdrawals.

33 Groundwater quality in the Grasslands Drainage Area and near Mud Slough and  
34 the San Joaquin River is anticipated to improve as compared with historic  
35 conditions due to the implementation of the Grasslands Bypass project. This  
36 program would reduce seepage from unlined canals and capture, treat, and/or  
37 reuse drainage flows (Reclamation 2009).

38 In the Tulare Lake Area of the San Joaquin Valley Groundwater Basin (in the  
39 Westside, Tulare Lake, Kings, Kaweah, and Tule subbasins within Fresno, Kern,  
40 Kings, and Tulare counties) high salinity groundwater occurs in the shallow  
41 aquifers due to agricultural drainage issues and naturally occurring high saline  
42 soils. Salts are imported into the Tulare Lake Area through the use of CVP and  
43 SWP irrigation water supplies and introduced into groundwater from dissolution

1 of salts in the local soil from agricultural land use. Groundwater salinity increases  
 2 because the Tulare Lake Area is a closed basin.

3 The CV-SALTS program is preparing a Salinity and Nitrate Management Plan for  
 4 publication in 2016 (CVRWQCB 2015). The plan will include sustainable salt  
 5 management alternatives, including treatment and salt recovery technologies, such  
 6 as, reverse osmosis; and related brine disposal/storage options that could range  
 7 from deep well injection to dedicated disposal locations to conveyance of brine to  
 8 locations outside of the San Joaquin Valley. This plan also will address current  
 9 and legacy sources of nitrates; assimilative capacity of the groundwater subbasins  
 10 and aquifers; drinking water protection measures, including waste discharge  
 11 requirements from irrigated lands and dairies; and measurable and enforceable  
 12 milestones that do not disproportionately impact disadvantaged communities; and  
 13 measures that minimize costs and maximize benefits to the community and water  
 14 users. The 2015 CV-SALTS work plan projects completion of Central Valley  
 15 Basin Plan amendments and Water Quality Control Plans for the Sacramento  
 16 Valley and San Joaquin Valley updates to incorporate recommendations of  
 17 CV-SALTS by 2018, including source control strategies and real time  
 18 management strategies (CVRWQCB 2015; SWRCB 2015). The *2015 CV-SALTS*  
 19 *Annual Report* indicated that structural best management practices would not be  
 20 fully selected until 2018 and may not be implemented until after 2030  
 21 (SWRCB 2015). Under the No Action Alternative and Second Basis of  
 22 Comparison it is assumed that non-structural measures would be implemented by  
 23 2030 to reduce salinity and nitrate loadings; however, structural improvements  
 24 that would reduce total groundwater salinity and nitrate concentrations generally  
 25 would not be implemented. Therefore, water quality under the No Action  
 26 Alternative and the Second Basis of Comparison is anticipated to be poorer in  
 27 some portions of the Central Valley than under recent groundwater quality  
 28 conditions.

29 Poor groundwater quality occurs near urban areas in the Central Valley due to  
 30 contamination from municipal and industrial land use practices. In many of these  
 31 areas, groundwater quality improvement programs have been implemented, as  
 32 described above. However, in many areas, groundwater quality is managed by  
 33 reducing groundwater drawdown near contaminant plumes to avoid transporting  
 34 the contaminants into other portions of the aquifer. Under the No Action  
 35 Alternative and the Second Basis of Comparison, it is assumed that these  
 36 programs would continue. However, as CVP and SWP water supplies become  
 37 less available in 2030 as compared to recent conditions, increased reliance on  
 38 groundwater could cause groundwater contamination of portions of the aquifers  
 39 near existing wells.

40 *San Francisco Bay Area Region*

41 In the San Francisco Bay Area Region, there are localized areas of moderate to  
 42 high salinity due to natural geologic formations and/or seawater intrusion near  
 43 San Francisco Bay. High levels of boron due to natural geologic formations and  
 44 nitrates related to historic land use practices occur in the Livermore Valley and  
 45 the Gilroy-Hollister- Valley groundwater basins. Under the No Action

1 Alternative and the Second Basis of Comparison, it is anticipated that these  
2 conditions would continue to occur; and that groundwater quality could be further  
3 degraded due to reduction of groundwater elevation that can cause adjacent  
4 poorer quality water to flow towards the groundwater withdrawals, especially in  
5 locations with seawater intrusion near the coast.

6 *Central Coast Region*

7 In the Central Coast Region, there are localized areas of moderate to high salinity  
8 due to seawater intrusion near the coast. High levels of iron and manganese due  
9 to natural geologic formations and nitrates related to historic land use practices  
10 occur in local areas of the Central Coast Region. Under the No Action  
11 Alternative and Second Basis of Comparison, it is anticipated that these  
12 conditions would continue to occur. Seawater intrusion could increase and further  
13 degrade groundwater quality in groundwater adjacent to the coast if groundwater  
14 levels decline in the future.

15 *Southern California Region*

16 In the Southern California Region, there are localized areas of moderate to high  
17 salinity due to natural geologic formations, percolation of high salinity applied  
18 water supplies, and/or seawater intrusion near the coast. High levels of calcium,  
19 sulfate, magnesium, iron, manganese, and fluoride due to natural geologic  
20 formations, and nitrates and organic compounds related to historic land use  
21 practices. Under the No Action Alternative and the Second Basis of Comparison,  
22 it is anticipated that these conditions would continue to occur; and that  
23 groundwater quality could be further degraded due to reduction of groundwater  
24 elevation that can cause adjacent poorer quality water or seawater to flow towards  
25 the groundwater withdrawals.

26 **7.4.2.2 Changes in Conditions under the No Action Alternative**

27 Due to the climate change and sea-level rise and increased water demands in the  
28 Sacramento Valley, CVP and SWP water deliveries would be less in 2030 than  
29 under recent historical conditions. It is anticipated that these reductions in CVP  
30 and SWP water availability would result in a greater reliance on groundwater,  
31 especially during dry and critical dry year.

32 **7.4.2.3 Changes in Conditions under the Second Basis of Comparison**

33 Due to the climate change and sea-level rise and increased water demands in the  
34 Sacramento Valley, CVP and SWP water deliveries would be less in 2030 than  
35 under recent historical conditions. It is anticipated that these reductions in CVP  
36 and SWP water availability would result in a greater reliance on groundwater,  
37 especially during dry and critical dry year. However, as described in Chapter 5,  
38 Surface Water Resources and Water Supplies, the availability of CVP and SWP  
39 water supplies would be greater under the Second Basis of Comparison as  
40 compared to the No Action Alternative because CVP and SWP water operations  
41 would not include requirements of the 2008 USFWS BO and 2009 NMFS BO.  
42 However, reliance on groundwater in 2030 under the Second Basis of Comparison  
43 is anticipated to increase as compared to recent historical conditions due to the

1 climate change and sea-level rise and increased water demands in the  
2 Sacramento Valley.

3 **7.4.3 Evaluation of Alternatives**

4 As described in Chapter 4, Approach to Environmental Analysis, Alternatives 1  
5 through 5 have been compared to the No Action Alternative; and the No Action  
6 Alternative and Alternatives 1 through 5 have been compared to the Second Basis  
7 of Comparison.

8 During review of the numerical modeling analyses used in this EIS, an error was  
9 determined in the CalSim II model assumptions related to the Stanislaus River  
10 operations for the Second Basis of Comparison, Alternative 1, and Alternative 4  
11 model runs. Appendix 5C includes a comparison of the CalSim II model run  
12 results presented in this chapter and CalSim II model run results with the error  
13 corrected. Appendix 5C also includes a discussion of changes in the comparison  
14 of groundwater conditions for the following alternative analyses.

- 15 • No Action Alternative compared to the Second Basis of Comparison
- 16 • Alternative 1 compared to the No Action Alternative
- 17 • Alternative 3 compared to the Second Basis of Comparison
- 18 • Alternative 5 compared to the Second Basis of Comparison.

19 **7.4.3.1 No Action Alternative**

20 The No Action Alternative is compared to the Second Basis of Comparison.

21 **7.4.3.1.1 Trinity River Region**

22 Groundwater conditions in the Trinity River Region are not directly related to  
23 CVP and SWP water supplies or operations. Therefore, groundwater use, related  
24 groundwater levels, potential for land subsidence, and groundwater quality under  
25 the No Action Alternative would be the same as under the Second Basis of  
26 Comparison.

27 **7.4.3.1.2 Central Valley Region**

28 *Groundwater Use and Elevation*

29 In areas of the Central Valley Region that do not use CVP and SWP water  
30 supplies, areas that use CVP water under Sacramento River Exchange Settlement  
31 Contracts, and areas that use San Joaquin River Exchange Contracts water, under  
32 the No Action Alternative water supplies would be the same as under the Second  
33 Basis of Comparison. Therefore, in these areas of the Central Valley Region,  
34 groundwater use and groundwater levels under the No Action Alternative would  
35 be the same as under the Second Basis of Comparison.

36 In areas of the Central Valley Region that use CVP water service contract and  
37 SWP entitlement contract water supplies, the CVP and SWP water supplies would  
38 be less under the No Action Alternative as compared to the Second Basis of  
39 Comparison. The differences would result in increased groundwater use and

1 decreased groundwater levels in the San Joaquin Valley Groundwater Basin under  
2 the No Action Alternative as compared to the Second Basis of Comparison.  
3 Results of CVHM simulations indicate that groundwater levels would be similar  
4 in the Redding and Sacramento Valley Groundwater Basins and the northern  
5 portion of the San Joaquin Valley Groundwater Basin, as shown in Figures 7.15  
6 through 7.19. The CVHM simulation primarily focuses on changes in agricultural  
7 groundwater use in response to changes in the availability of CVP and SWP  
8 water. However, it is recognized that in the vicinity of some communities, such  
9 as in the area in the American River watershed served with CVP water supplies,  
10 groundwater use also would increase with the reduction in surface water  
11 availability. However, these changes are not considered to be substantial under  
12 the No Action Alternative as compared to the Second Basis of Comparison  
13 because the long-term reductions in CVP municipal water supplies are anticipated  
14 to be up to 7,000 acre-feet per year (or 6 percent) over the long-term condition, up  
15 to 8,000 acre-feet per year (or 8 percent) in dry years, and similar (or 5 percent or  
16 less) in critical dry years. The water demands are consistent between the No  
17 Action Alternative and Second Basis of Comparison; therefore, it is anticipated  
18 that reduced surface water supplies would result in increased groundwater use.

19 Groundwater levels decline under the No Action Alternative in the central and  
20 southern San Joaquin Valley Groundwater Basin as compared to the Second Basis  
21 of Comparison with greater reductions occurring in wet years than in critical dry  
22 years. Figures 7.20 and 7.21 present the simulated changes in groundwater levels  
23 over the 42-year CVHM study period. Simulated average July agricultural  
24 groundwater pumping under the No Action Alternative as compared to the  
25 Second Basis of Comparison is presented in Figures 7.22 and 7.23.

26 Overall, under the No Action Alternative as compared to the Second Basis of  
27 Comparison, July average groundwater levels decrease approximately 2 to 10 feet  
28 in most of the central and southern San Joaquin Valley Groundwater Basin in all  
29 water year types. July average groundwater levels decline 10 to 50 feet in the  
30 Delta-Mendota, Tulare Lake, and Kern County subbasins; and 50 to 200 feet in  
31 the Westside subbasin in all water year types. In critical dry years, groundwater  
32 levels decline by up to 100 feet on average in the Westside subbasin.  
33 Groundwater level changes in the Sacramento Valley are forecast to be less than  
34 2 feet. The groundwater level change hydrographs show that in the central and  
35 southern San Joaquin Valley, groundwater levels can fluctuate up to 200 feet in  
36 some areas due to climatic variations under the No Action Alternative compared  
37 to the Second Basis of Comparison.

38 The change in groundwater pumping in the Sacramento Valley would result in  
39 similar conditions (less than 5 percent change). Therefore, groundwater pumping  
40 in the Sacramento Valley is similar under the No Action Alternative compared to  
41 the Second Basis of Comparison.

42 Groundwater pumping in the San Joaquin and Tulare Basins would increase by  
43 approximately 8 percent under the No Action Alternative as compared to the  
44 Second Basis of Comparison. Figure 7.23 shows that the biggest change in  
45 groundwater pumping under the No Action Alternative as compared to the

1 Second Basis of Comparison occurs in the Westside subbasin, with an average  
2 July increase close to 40 thousand acre-feet (TAF).

3 *Land Subsidence*

4 Land subsidence due to groundwater withdrawals historically occurred in the  
5 Yolo subbasin of the Sacramento Valley Groundwater Basin. CVP and SWP  
6 water supplies are not used extensively in this area. The conditions under the No  
7 Action Alternative would be similar as conditions under the Second Basis of  
8 Comparison.

9 Under the No Action Alternative, potential for land subsidence due to  
10 groundwater withdrawals in the Delta-Mendota and Westside subbasins of the  
11 San Joaquin Valley Groundwater Basin would increase as compared to the  
12 Second Basis of Comparison due to the increased groundwater withdrawals.

13 Groundwater level-induced land subsidence has the highest potential to occur in  
14 the San Joaquin Groundwater Basin, based on historical data, if groundwater  
15 pumping substantially increases. Under the No Action Alternative, CVP and  
16 SWP water supplies are expected to decrease in the San Joaquin Valley as  
17 compared to the Second Basis of Comparison. Decreased surface water deliveries  
18 could result in an increase in groundwater pumping. The increased groundwater  
19 pumping would result in lower groundwater levels, and therefore, the potential for  
20 groundwater level-induced land subsidence is increased under the No Action  
21 Alternative as compared to the Second Basis of Comparison.

22 *Groundwater Quality*

23 Under the No Action Alternative, groundwater conditions, including groundwater  
24 quality, in areas that do not use CVP and SWP water supplies would be the same  
25 as under the Second Basis of Comparison.

26 In areas that use CVP and SWP water supplies, groundwater quality under the No  
27 Action Alternative could be reduced as compared to the Second Basis of  
28 Comparison in the central and southern San Joaquin Valley Groundwater Basin  
29 due to increased groundwater withdrawals and resulting potential changes in  
30 groundwater flow patterns. For example, potential impacts to groundwater  
31 quality may arise from deeper pumping close to the base of freshwater, where  
32 higher TDS water exists. Large areas in the San Joaquin Valley also experience  
33 impairments due to nitrate and other fertilizers used in agriculture, which could  
34 migrate to areas with better quality water due to increased pumping and potential  
35 changes in groundwater flow directions.

36 As described above, it is assumed that measures implemented in accordance with  
37 the CV-SALTS program or future sustainable groundwater management plans  
38 implemented in accordance with SGMA would not be fully implemented by 2030.  
39 Therefore, groundwater quality could decline under the No Action Alternative as  
40 compared to the Second Basis of Comparison.

41 *Effects Related to Cross Delta Water Transfers*

42 Potential effects to groundwater resources could be similar to those identified in a  
43 recent environmental analysis conducted by Reclamation for long-term water

1 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c).  
2 Potential effects to groundwater were identified as reduced groundwater levels  
3 and potentially subsidence in areas that sold water using groundwater substitution  
4 practices. Because all water transfers would be required to avoid adverse impacts  
5 to other water users and biological resources (see Section 3.A.6.3, Transfers),  
6 including impacts to other groundwater users, the analysis indicated that water  
7 transfers would not result in substantial changes in groundwater because  
8 mitigation and monitoring plans would be required. The mitigation measures  
9 would require reductions in providing water from groundwater substitutions if the  
10 monitoring results indicated substantial declines in groundwater levels. For the  
11 purposes of this EIS, it is anticipated that similar conditions would occur during  
12 implementation of cross Delta water transfers under the No Action  
13 Alternative and the Second Basis of Comparison.

14 Groundwater use in areas that purchase the transferred water could be reduced if  
15 additional surface water is provided. However, if the transferred water is used to  
16 meet water demands that would not have been met (e.g., crops that had been  
17 idled), groundwater conditions would be similar with or without water transfers.

18 Under the No Action Alternative, the timing of cross Delta water transfers would  
19 be limited to July through September and include annual volumetric limits, in  
20 accordance with the 2008 USFWS BO and 2009 NMFS BO. Under the Second  
21 Basis of Comparison, water could be transferred throughout the year without an  
22 annual volumetric limit. Overall, the potential for cross Delta water transfers  
23 would be less under the No Action Alternative than under the Second Basis of  
24 Comparison.

#### 25 **7.4.3.1.3 San Francisco Bay Area, Central Coast, and Southern** 26 **California Regions**

##### 27 *Groundwater Use and Elevation*

28 Under the No Action Alternative, it is anticipated that CVP and SWP water  
29 supplies in the San Francisco Bay Area, Central Coast, and Southern California  
30 regions would be reduced as compared to CVP and SWP water supplies under the  
31 Second Basis of Comparison, as discussed in Chapter 5, Surface Water Resources  
32 and Water Supplies. The reduction in surface water supplies could result in  
33 increased groundwater withdrawals, decreased groundwater recharge, and  
34 decreased groundwater levels in areas with CVP and SWP water users. It may be  
35 legally impossible to extract additional groundwater in adjudicated basins without  
36 gaining the permission of watermasters and accounting for groundwater pumping  
37 entitlements and various parties under their adjudicated rights.

##### 38 *Land Subsidence*

39 Increased use of groundwater and reductions in groundwater levels would result  
40 in an increased potential for additional land subsidence under the No Action  
41 Alternative as compared to the Second Basis of Comparison in the Santa Clara  
42 Valley Groundwater Basin in the San Francisco Bay Area Region, and the  
43 Antelope Valley and Lucerne Valley groundwater basins in the Southern  
44 California Region.

1 *Groundwater Quality*

2 As described in Section 7.3, Affected Environment, there are localized areas of  
3 moderate to high salinity due to natural geologic formations and/or seawater  
4 intrusion in the San Francisco Bay Area, Central Coast, and Southern California  
5 regions. Under the No Action Alternative as compared to the Second Basis of  
6 Comparison, it is anticipated that the increased groundwater withdrawals would  
7 cause poorer quality groundwater to flow towards the groundwater withdrawals,  
8 especially near the coast. This would result in poorer quality groundwater in  
9 some areas under the No Action Alternative as compared to the Second Basis of  
10 Comparison.

11 **7.4.3.2 Alternative 1**

12 Alternative 1 is identical to the Second Basis of Comparison. As described in  
13 Chapter 4, Approach to Environmental Analysis, Alternative 1 is compared to the  
14 No Action Alternative and the Second Basis of Comparison. However, because  
15 groundwater conditions under Alternative 1 are identical to groundwater  
16 conditions under the Second Basis of Comparison; Alternative 1 is only compared  
17 to the No Action Alternative.

18 **7.4.3.2.1 Alternative 1 Compared to the No Action Alternative**

19 *Trinity River Region*

20 Groundwater conditions in the Trinity River Region are not directly related to  
21 CVP and SWP water supplies or operations. Therefore, groundwater use, related  
22 groundwater levels, potential for land use subsidence, and groundwater quality  
23 degradation under Alternative 1 would be the same as under the No Action  
24 Alternative.

25 *Central Valley Region*

26 *Groundwater Use and Elevation*

27 In areas of the Central Valley Region that do not use CVP and SWP water  
28 supplies, areas that use CVP water under Sacramento River Exchange Settlement  
29 Contracts, and areas that use San Joaquin River Exchange Contracts under  
30 Alternative 1 water supplies would be the same as under the No Action  
31 Alternative. Therefore, in these areas of the Central Valley Region, groundwater  
32 use and groundwater levels under Alternative 1 would be the same as under the  
33 No Action Alternative.

34 In areas of the Central Valley Region that use CVP water service contract and  
35 SWP entitlement contract water supplies, the CVP and SWP water supplies would  
36 be greater under Alternative 1 as compared to the No Action Alternative. The  
37 differences would result in decreased groundwater use and increased groundwater  
38 levels in the San Joaquin Valley Groundwater Basin under Alternative 1 as  
39 compared to the No Action Alternative. Results of CVHM simulation indicate  
40 that groundwater levels would be similar in the Redding and Sacramento Valley  
41 groundwater basins and the northern portion of the San Joaquin Valley  
42 Groundwater Basin, as shown in Figures 7.24 through 7.28. The CVHM  
43 simulation primarily focuses on changes in agricultural groundwater use in

1 response to changes in the availability of CVP and SWP water. However, it is  
2 recognized that in the vicinity of some communities, such as in the area in the  
3 American River watershed served with CVP water supplies, groundwater use also  
4 would increase with the reduction in surface water availability. However, these  
5 changes are not considered to be substantial under Alternative 1 as compared to  
6 the No Action Alternative because the long-term increases in CVP municipal  
7 water supplies are anticipated to be up to 7,000 acre-feet per year (or up to 6  
8 percent) over the long-term condition, up to 8,000 acre-feet per year (or up to 8  
9 percent) in dry years, and up to 5,000 acre-feet per year (or up to 7 percent) in  
10 critical dry years. The water demands are consistent between Alternative 1 and  
11 the No Action Alternative; therefore, it is anticipated that increased surface water  
12 supplies would result in reduced groundwater use.

13 Groundwater levels increase under Alternative 1 in the central and southern San  
14 Joaquin Valley Groundwater Basin as compared to the No Action  
15 Alternative with greater increases occurring in wet years than in critical dry years  
16 (up to 100 feet). Figures 7.29 and 7.30 present the simulated changes in  
17 groundwater levels over the 42-year CVHM study period. Simulated average July  
18 agricultural groundwater pumping under Alternative 1 as compared to the No  
19 Action Alternative is presented in Figures 7.31 and 7.32.

20 Overall, under Alternative 1 as compared to the No Action Alternative, July  
21 average groundwater levels increase approximately 2 to 10 feet in most of the  
22 central and southern San Joaquin Valley Groundwater Basin in all water year  
23 types. July average groundwater levels rise 10 to 50 feet in the Delta-Mendota,  
24 Tulare Lake, and Kern County subbasins; and 50 to 200 feet in the Westside  
25 subbasin in most water year types. In critical dry years, groundwater levels  
26 increase by up to 100 feet on average in the Westside subbasin. The groundwater  
27 level change hydrographs show that in the central and southern San Joaquin  
28 Valley subbasins, groundwater levels can fluctuate up to 200 feet in some areas  
29 due to climatic variations under Alternative 1 compared to the No Action  
30 Alternative.

31 The change in groundwater pumping in the Sacramento Valley is less than  
32 5 percent. Therefore, groundwater pumping in the Sacramento Valley is similar  
33 under Alternative 1 as compared to the No Action Alternative.

34 Groundwater pumping in the San Joaquin and Tulare Basins would decrease by  
35 approximately 8 percent under Alternative 1 as compared to the No Action  
36 Alternative. Figure 7.32 shows that the biggest change in groundwater pumping  
37 under the Alternative 1 compared to the No Action Alternative occurs in the  
38 Westside subbasin with an average July decrease close to 40 TAF.

### 39 *Land Subsidence*

40 Land subsidence due to groundwater withdrawals historically occurred in the  
41 Yolo subbasin of the Sacramento Valley Groundwater Basin. CVP and SWP  
42 water supplies are not used extensively in this area. The conditions under  
43 Alternative 1 would be similar as conditions under the No Action Alternative.

1 Under Alternative 1, potential for land subsidence due to groundwater  
2 withdrawals in the Delta-Mendota and Westside subbasins of the San Joaquin  
3 Valley Groundwater Basin would decrease under Alternative 1 as compared to the  
4 No Action Alternative due to the decreased groundwater withdrawals.

5 Groundwater level-induced land subsidence has the highest potential to occur in  
6 the San Joaquin Valley Groundwater Basin, based on historical data, if  
7 groundwater pumping substantially increases. Under Alternative 1 CVP and  
8 SWP water supplies are expected to increase in the San Joaquin Valley as  
9 compared to the No Action Alternative. Increased surface water deliveries could  
10 result in a decrease in groundwater pumping. The decreased groundwater  
11 pumping would result in higher groundwater levels, and therefore, the potential  
12 for groundwater level-induced land subsidence is reduced under Alternative 1 as  
13 compared to the No Action Alternative.

14 *Groundwater Quality*

15 Under Alternative 1, groundwater conditions, including groundwater quality, in  
16 areas that do not use CVP and SWP water supplies would be the same as under  
17 the No Action Alternative.

18 In areas that use CVP and SWP water supplies, groundwater quality under  
19 Alternative 1 could be improved as compared to the No Action Alternative in the  
20 central and southern San Joaquin Valley Groundwater Basin due to decreased  
21 groundwater withdrawals. As described above, it is assumed that measures  
22 implemented in accordance with the CV-SALTS program or future sustainable  
23 groundwater management plans implemented in accordance with SGMA would  
24 not be fully implemented by 2030. However, due to the increased availability of  
25 CVP and SWP water supplies and related reduction in groundwater use, the  
26 groundwater quality would be improved under Alternative 1 as compared to the  
27 No Action Alternative.

28 *Effects Related to Water Transfers*

29 Potential effects to groundwater resources could be similar to those identified in a  
30 recent environmental analysis conducted by Reclamation for long-term water  
31 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
32 described above under the No Action Alternative compared to the Second Basis  
33 of Comparison. For the purposes of this EIS, it is anticipated that similar  
34 conditions would occur during implementation of cross Delta water transfers  
35 under Alternative 1 and the No Action Alternative, and that groundwater impacts  
36 would not be substantial in the seller's service area due implementation  
37 requirements of the transfer programs.

38 Groundwater use in areas that purchase the transferred water could be reduced if  
39 additional surface water is provided. However, if the transferred water is used to  
40 meet water demands that would not have been met (e.g., crops that had been  
41 idled), groundwater conditions would be similar with or without water transfers.

42 Under Alternative 1, water could be transferred throughout the year without an  
43 annual volumetric limit. Under the No Action Alternative, the timing of cross

1 Delta water transfers would be limited to July through September and include  
2 annual volumetric limits, in accordance with the 2008 USFWS BO and 2009  
3 NMFS BO. Overall, the potential for cross Delta water transfers would be greater  
4 under Alternative 1 as compared to the No Action Alternative.

5 *San Francisco Bay Area, Central Coast, and Southern California Regions*  
6 *Groundwater Use and Elevation*

7 Under Alternative 1, it is anticipated that CVP and SWP water supplies in the San  
8 Francisco Bay Area, Central Coast, and Southern California regions would be  
9 increased as compared to CVP and SWP water supplies under the No Action  
10 Alternative, as discussed in Chapter 5, Surface Water Resources and Water  
11 Supplies. The increase in surface water supplies could result in decreased  
12 groundwater withdrawals by CVP and SWP water users, resulting in increased  
13 groundwater recharge, and increased groundwater levels in areas with CVP and  
14 SWP water users.

15 *Land Subsidence*

16 Decreased use of groundwater and higher groundwater levels would result in a  
17 decreased potential for additional land subsidence under Alternative 1 as  
18 compared to the No Action Alternative in the Santa Clara Valley Groundwater  
19 Basin in the San Francisco Bay Area Region, and the Antelope Valley and  
20 Lucerne Valley groundwater basins in the Southern California Region.

21 *Groundwater Quality*

22 As described in Section 7.3, Affected Environment, there are localized areas of  
23 moderate to high salinity due to natural geologic formations and/or seawater  
24 intrusion in the San Francisco Bay Area, Central Coast, and Southern California  
25 regions. Under Alternative 1 as compared to the No Action Alternative, it is  
26 anticipated that the decreased groundwater withdrawals would cause improved  
27 groundwater quality, especially near the coast.

28 **7.4.3.2.2 Alternative 1 Compared to the Second Basis of Comparison**

29 Alternative 1 is identical to the Second Basis of Comparison.

30 **7.4.3.3 Alternative 2**

31 The CVP and SWP operations under Alternative 2 are identical to the CVP and  
32 SWP operations under the No Action Alternative; therefore, the groundwater  
33 conditions under Alternative 2 is only compared to the Second Basis of  
34 Comparison.

35 **7.4.3.3.1 Alternative 2 Compared to the Second Basis of Comparison**

36 Changes to groundwater resources under Alternatives 2 as compared to the  
37 Second Basis of Comparison would be the same as the impacts described in  
38 Section 7.4.3.1, No Action Alternative.

39 **7.4.3.4 Alternative 3**

40 As described in Chapter 3, Description of Alternatives, CVP and SWP operations  
41 under Alternative 3 are similar to the Second Basis of Comparison and

1 Alternative 1 with modified Old and Middle River flow criteria. Alternative 3 is  
2 compared to the No Action Alternative and the Second Basis of Comparison.

3 **7.4.3.4.1 Alternative 3 Compared to the No Action Alternative**

4 *Trinity River Region*

5 Groundwater conditions in the Trinity River Region are not directly related to  
6 CVP and SWP water supplies or operations. Therefore, groundwater use, related  
7 groundwater levels, potential for land use subsidence, and groundwater quality  
8 under Alternative 3 would be the same as under the No Action Alternative.

9 *Central Valley Region*

10 *Groundwater Use and Elevation*

11 In areas of the Central Valley Region that do not use CVP and SWP water  
12 supplies, areas that use CVP water under Sacramento River Exchange Settlement  
13 Contracts, and areas that use San Joaquin River Exchange Contracts under  
14 Alternative 3 water supplies would be the same as under the No Action  
15 Alternative. Therefore, in these areas of the Central Valley Region, groundwater  
16 use and groundwater levels under Alternative 3 would be the same as under the  
17 No Action Alternative. The CVHM simulation primarily focuses on changes in  
18 agricultural groundwater use in response to changes in the availability of CVP and  
19 SWP water. However, it is recognized that in the vicinity of some communities,  
20 such as in the area in the American River watershed served with CVP water  
21 supplies, groundwater use also would increase with the reduction in surface water  
22 availability. However, these changes are not considered to be substantial under  
23 Alternative 3 as compared to the No Action Alternative because the long-term  
24 increases in CVP municipal water supplies are anticipated to be up to 7,000 acre-  
25 feet (up to 7 percent) in dry years, and similar (or 5 percent or less) in long-term  
26 conditions and critical dry years. The water demands are consistent between  
27 Alternative 3 and the No Action Alternative; therefore, it is anticipated that  
28 increased surface water supplies would result in reduced groundwater use.

29 In areas of the Central Valley Region that use CVP water service contract and  
30 SWP entitlement contract water supplies, the CVP and SWP water supplies would  
31 be greater under Alternative 3 as compared to the No Action Alternative. The  
32 differences would result in decreased groundwater use and increased groundwater  
33 levels in the San Joaquin Valley Groundwater Basin under Alternative 3 as  
34 compared to the No Action Alternative. Results of CVHM simulation indicate  
35 that groundwater levels would be similar in the Redding and Sacramento Valley  
36 groundwater basins and the northern portion of the San Joaquin Valley  
37 Groundwater Basin (changes would be plus/minus 2 feet), as shown in  
38 Figures 7.33 through 7.37.

39 Groundwater levels increase under Alternative 3 in the central and southern San  
40 Joaquin Valley Groundwater Basin as compared to the No Action  
41 Alternative with greater increases occurring in wet years than in critical dry years.  
42 Figures 7.38 and 7.39 present the simulated changes in groundwater levels over  
43 the 42-year CVHM model study period. Simulated average July agricultural

1 groundwater pumping under Alternative 3 as compared to the No Action  
2 Alternative is presented in Figures 7.31 and 7.32.

3 Overall, under Alternative 3 as compared to the No Action Alternative, July  
4 average groundwater levels increase approximately 2 to 10 feet in most of the  
5 central and southern San Joaquin Valley Groundwater Basin in all water year  
6 types. July average groundwater levels increase 10 to 50 feet in the  
7 Delta-Mendota, Tulare Lake, and Kern County subbasins; and 50 to 200 feet in  
8 the Westside subbasin in most water year types. In critical dry years,  
9 groundwater levels increase by up to 50 feet on average in the Westside subbasin.  
10 The groundwater level change hydrographs show that in the central and southern  
11 San Joaquin Valley, groundwater levels can fluctuate up to 200 feet in some areas  
12 due to climatic variations under Alternative 3 compared to the No Action  
13 Alternative.

14 The change in groundwater pumping in the Sacramento Valley is less than  
15 5 percent. Therefore, groundwater pumping in the Sacramento Valley is similar  
16 under Alternative 3 compared to the No Action Alternative.

17 Groundwater pumping in the San Joaquin and Tulare Basins decreases by  
18 approximately 6 percent under Alternative 3 as compared to the No Action  
19 Alternative. Figure 7.32 shows that the largest change in groundwater pumping  
20 under Alternative 3 as compared to the No Action Alternative occurs in the  
21 Westside subbasin with an average July decrease of approximately 35 TAF.

#### 22 *Land Subsidence*

23 Land subsidence due to groundwater withdrawals historically occurred in the  
24 Yolo subbasin of the Sacramento Valley Groundwater Basin. CVP and SWP  
25 water supplies are not used extensively in this area. The conditions under  
26 Alternative 3 would be similar as conditions under the No Action Alternative.

27 Under Alternative 3, potential for land subsidence due to groundwater  
28 withdrawals in the Delta-Mendota and Westside subbasins of the San Joaquin  
29 Valley Groundwater Basin would decrease under Alternative 3 as compared to the  
30 No Action Alternative due to the decreased groundwater withdrawals.

31 Groundwater level-induced land subsidence has the highest potential to occur in  
32 the San Joaquin Valley Groundwater Basin, based on historical data, if  
33 groundwater pumping substantially increases. Under Alternative 3 CVP and  
34 SWP water supplies are expected to increase in the San Joaquin Valley as  
35 compared to the No Action Alternative. Increased surface water deliveries could  
36 result in a decrease in groundwater pumping. The decreased groundwater  
37 pumping would result in higher groundwater levels, and therefore, the potential  
38 for groundwater level-induced land subsidence is reduced under Alternative 3 as  
39 compared to the No Action Alternative.

#### 40 *Groundwater Quality*

41 Under Alternative 3, groundwater conditions, including groundwater quality, in  
42 areas that do not use CVP and SWP water supplies would be the same as under  
43 the No Action Alternative.

1 In areas that use CVP and SWP water supplies, groundwater quality under  
 2 Alternative 3 could be improved as compared to the No Action Alternative in the  
 3 central and southern San Joaquin Valley Groundwater Basin due to decreased  
 4 groundwater withdrawals. As described above, it is assumed that measures  
 5 implemented in accordance with the CV-SALTS program or future sustainable  
 6 groundwater management plans implemented in accordance with SGMA would  
 7 not be fully implemented by 2030. However, due to the increased availability of  
 8 CVP and SWP water supplies and related reduction in groundwater use, the  
 9 groundwater quality would be improved under Alternative 3 as compared to the  
 10 No Action Alternative.

11 *Effects Related to Water Transfers*

12 Potential effects to groundwater resources could be similar to those identified in a  
 13 recent environmental analysis conducted by Reclamation for long-term water  
 14 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
 15 described above under the No Action Alternative compared to the Second Basis  
 16 of Comparison. For the purposes of this EIS, it is anticipated that similar  
 17 conditions would occur during implementation of cross Delta water transfers  
 18 under Alternative 3 and the No Action Alternative, and that groundwater impacts  
 19 would not be substantial in the seller’s service area due implementation  
 20 requirements of the transfer programs.

21 Groundwater use in areas that purchase the transferred water could be reduced if  
 22 additional surface water is provided. However, if the transferred water is used to  
 23 meet water demands that would not have been met (e.g., crops that had been  
 24 idled), groundwater conditions would be similar with or without water transfers.

25 Under Alternative 3, water could be transferred throughout the year without an  
 26 annual volumetric limit. Under the No Action Alternative, the timing of cross  
 27 Delta water transfers would be limited to July through September and include  
 28 annual volumetric limits, in accordance with the 2008 USFWS BO and 2009  
 29 NMFS BO. Overall, the potential for cross Delta water transfers would be greater  
 30 under Alternative 3 as compared to the No Action Alternative.

31 *San Francisco Bay Area, Central Coast, and Southern California Regions*  
 32 *Groundwater Use and Elevation*

33 Under Alternative 3, it is anticipated that CVP and SWP water supplies in the San  
 34 Francisco Bay Area, Central Coast, and Southern California regions would be  
 35 increased as compared to CVP and SWP water supplies under the No Action  
 36 Alternative, as discussed in Chapter 5, Surface Water Resources and Water  
 37 Supplies. The increase in surface water supplies could result in decreased  
 38 groundwater withdrawals by CVP and SWP water users, resulting in increased  
 39 groundwater recharge, and increased groundwater levels. It may be legally  
 40 impossible to extract additional groundwater in adjudicated basins without  
 41 gaining the permission of watermasters and accounting for groundwater pumping  
 42 entitlements and various parties under their adjudicated rights.

1        *Land Subsidence*

2        Decreased use of groundwater and higher groundwater levels would result in a  
3        decreased potential for additional land subsidence under Alternative 3 as  
4        compared to the No Action Alternative in the Santa Clara Valley Groundwater  
5        Basin in the San Francisco Bay Area Region, and the Antelope Valley and  
6        Lucerne Valley groundwater basins in the Southern California Region.

7        *Groundwater Quality*

8        As described in Section 7.3, Affected Environment, there are localized areas of  
9        moderate to high salinity due to natural geologic formations and/or seawater  
10       intrusion in the San Francisco Bay Area, Central Coast, and Southern California  
11       regions. Under Alternative 3 as compared to the No Action Alternative, it is  
12       anticipated that the decreased groundwater withdrawals would cause improved  
13       groundwater quality, especially near the coast.

14       **7.4.3.4.2 Alternative 3 Compared to the Second Basis of Comparison**

15       *Trinity River Region*

16       Groundwater conditions in the Trinity River Region are not directly related to  
17       CVP and SWP water supplies or operations. Therefore, groundwater use, related  
18       groundwater levels, potential for land use subsidence, and groundwater quality  
19       under Alternative 3 would be the same as under the Second Basis of Comparison.

20       *Central Valley Region*

21       *Groundwater Use and Elevation*

22       In areas of the Central Valley Region that do not use CVP and SWP water  
23       supplies, areas that use CVP water under Sacramento River Exchange Settlement  
24       Contracts, and areas that use San Joaquin River Exchange Contracts under  
25       Alternative 3 water supplies would be the same as under the Second Basis of  
26       Comparison. Therefore, in these areas of the Central Valley Region, groundwater  
27       use and groundwater levels under Alternative 3 would be the same as under the  
28       Second Basis of Comparison. The CVHM simulation primarily focuses on  
29       changes in agricultural groundwater use in response to changes in the availability  
30       of CVP and SWP water. However, it is recognized that in the vicinity of some  
31       communities, such as in the area in the American River watershed served with  
32       CVP water supplies, groundwater use also would increase with the reduction in  
33       surface water availability. However, these changes are considered to be similar  
34       under Alternative 3 as compared to the Second Basis of Comparison because the  
35       CVP municipal water supplies are similar (or 5 percent or less) in long-term  
36       conditions, dry years, and critical dry years. The water demands are consistent  
37       between Alternative 3 and the Second Basis of Comparison; therefore, it is  
38       anticipated that similar surface water supplies would result in similar groundwater  
39       use.

40       In areas of the Central Valley Region that use CVP water service contract and  
41       SWP entitlement contract water supplies, the CVP and SWP water supplies would  
42       be less under Alternative 3 as compared to the Second Basis of Comparison. The  
43       differences would result in increased groundwater use and decreased groundwater

1 levels in the San Joaquin Valley Groundwater Basin under Alternative 3 as  
 2 compared to the Second Basis of Comparison. Results of CVHM simulation  
 3 indicate that groundwater levels would be similar in the Redding and Sacramento  
 4 Valley groundwater basins and the northern portion of the San Joaquin Valley  
 5 Groundwater Basin, as shown in Figures 7.40 through 7.44.

6 Groundwater levels generally decrease under Alternative 3 in the central and  
 7 southern San Joaquin Valley Groundwater Basin as compared to the Second Basis  
 8 of Comparison. Figures 7.45 and 7.46 present the simulated change in  
 9 groundwater levels over the 42-year CVHM study period. Simulated average July  
 10 agricultural groundwater pumping under Alternative 3 as compared to the Second  
 11 Basis of Comparison is presented in Figures 7.22 and 7.23.

12 Overall, under Alternative 3 as compared to the Second Basis of Comparison,  
 13 July average groundwater levels decrease approximately 2 to 10 feet areas of the  
 14 western and southern San Joaquin Valley Groundwater Basin in all water year  
 15 types. July average groundwater levels decline up to 25 feet in the Delta-  
 16 Mendota, Tulare Lake, and Kern County subbasins; and decline up to 25 feet in  
 17 Westside subbasin, in most water year types. However, groundwater levels in the  
 18 Westside subbasin increase by up to 10 feet on average in wet years, due to  
 19 increased CVP water deliveries to this region in wet years. Groundwater level  
 20 changes in the Sacramento Valley are forecast to be less than 2 feet. The  
 21 groundwater level change hydrographs show that in the central and southern San  
 22 Joaquin Valley, groundwater levels can fluctuate up to 200 feet in some areas due  
 23 to climatic variations under Alternative 3 compared to the Second Basis of  
 24 Comparison.

25 The change in groundwater pumping in the Sacramento Valley is less than  
 26 5 percent. Therefore, groundwater pumping in the Sacramento Valley is similar  
 27 under Alternative 3 compared to the Second Basis of Comparison.

28 Groundwater pumping in the San Joaquin and Tulare Basins changes by less than  
 29 5 percent under Alternative 3 as compared to the Second Basis of Comparison,  
 30 and is therefore considered similar. Figure 7.23 shows that the biggest change in  
 31 groundwater pumping under Alternative 3 compared to the Second Basis of  
 32 Comparison occurs in WBS 18, with an average July increase close to 10 TAF.

33 *Land Subsidence*

34 Groundwater pumping would be similar in the Sacramento and San Joaquin  
 35 valleys, therefore, the potential for groundwater level-induced land subsidence  
 36 would be similar under Alternative 3 as compared to the Second Basis of  
 37 Comparison.

38 *Groundwater Quality*

39 Groundwater pumping would be similar in the Sacramento and San Joaquin  
 40 valleys, therefore, groundwater quality would be similar under Alternative 3 as  
 41 compared to the Second Basis of Comparison.

1           *Effects Related to Water Transfers*

2 Potential effects to groundwater resources could be similar to those identified in a  
3 recent environmental analysis conducted by Reclamation for long-term water  
4 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
5 described above under the No Action Alternative compared to the Second Basis  
6 of Comparison. For the purposes of this EIS, it is anticipated that similar  
7 conditions would occur during implementation of cross Delta water transfers  
8 under Alternative 3 and the Second Basis of Comparison, and that groundwater  
9 impacts would not be substantial in the seller's service area due implementation  
10 requirements of the transfer programs.

11 Groundwater use in areas that purchase the transferred water could be reduced if  
12 additional surface water is provided. However, if the transferred water is used to  
13 meet water demands that would not have been met (e.g., crops that had been  
14 idled), groundwater conditions would be similar with or without water transfers.

15 Under Alternative 3 and the Second Basis of Comparison, water could be  
16 transferred throughout the year without an annual volumetric limit. Therefore, the  
17 potential for cross Delta water transfers would be similar under Alternative 3 and  
18 the Second Basis of Comparison.

19           *San Francisco Bay Area, Central Coast, and Southern California Regions*  
20           *Groundwater Use and Elevation*

21 Under Alternative 3, it is anticipated that CVP and SWP water supplies in the San  
22 Francisco Bay Area, Central Coast, and Southern California regions would be  
23 decreased as compared to CVP and SWP water supplies under the Second Basis  
24 of Comparison, as discussed in Chapter 5, Surface Water Resources and Water  
25 Supplies. The decrease in surface water supplies could result in increased  
26 groundwater withdrawals by CVP and SWP water users, resulting in decreased  
27 groundwater recharge, and decreased groundwater levels in areas with CVP and  
28 SWP water users.

29           *Land Subsidence*

30 Increased use of groundwater and lower groundwater levels would result in an  
31 increased potential for additional land subsidence under Alternative 3 as  
32 compared to the Second Basis of Comparison in the Santa Clara Valley  
33 Groundwater Basin in the San Francisco Bay Area Region, and the Antelope  
34 Valley and Lucerne Valley groundwater basins in the Southern California Region.

35           *Groundwater Quality*

36 As described in Section 7.3, Affected Environment, there are localized areas of  
37 moderate to high salinity due to natural geologic formations and/or seawater  
38 intrusion in the San Francisco Bay Area, Central Coast, and Southern California  
39 regions. Under Alternative 3 as compared to the Second Basis of Comparison, it  
40 is anticipated that the increased groundwater withdrawals would cause poorer  
41 groundwater quality, especially near the coast.

1 **7.4.3.5 Alternative 4**

2 Groundwater conditions under Alternative 4 would be identical to groundwater  
3 conditions under the Second Basis of Comparison; therefore, Alternative 4 is only  
4 compared to the No Action Alternative.

5 **7.4.3.5.1 Alternative 4 Compared to the No Action Alternative**

6 Changes in groundwater conditions under Alternative 4 as compared to the No  
7 Action Alternative would be the same as the impacts described in  
8 Section 7.4.3.2.1, Alternative 1 Compared to the No Action Alternative.

9 **7.4.3.6 Alternative 5**

10 CVP and SWP operations under Alternative 5 are similar to the No Action  
11 Alternative with modified Old and Middle River flow criteria and New Melones  
12 Reservoir operations. As described in Chapter 4, Approach to Environmental  
13 Analysis, Alternative 5 is compared to the No Action Alternative and the Second  
14 Basis of Comparison.

15 **7.4.3.6.1 Alternative 5 Compared to the No Action Alternative**

16 *Trinity River Region*

17 Groundwater conditions in the Trinity River Region are not directly related to  
18 CVP and SWP water supplies or operations. Therefore, groundwater use, related  
19 groundwater levels, potential for land use subsidence, and groundwater quality  
20 under Alternative 5 would be the same as under the No Action Alternative.

21 *Central Valley Region*

22 *Groundwater Use and Elevation*

23 In areas of the Central Valley Region that do not use CVP and SWP water  
24 supplies, areas that use CVP water under Sacramento River Exchange Settlement  
25 Contracts, and areas that use San Joaquin River Exchange Contracts under  
26 Alternative 5 water supplies would be the same as under the No Action  
27 Alternative. Therefore, in these areas of the Central Valley Region, groundwater  
28 use and groundwater levels under Alternative 5 would be the same as under the  
29 No Action Alternative. The CVHM simulation primarily focuses on changes in  
30 agricultural groundwater use in response to changes in the availability of CVP and  
31 SWP water. However, it is recognized that in the vicinity of some communities,  
32 such as in the area in the American River watershed served with CVP water  
33 supplies, groundwater use also would increase with the reduction in surface water  
34 availability. However, these changes are not considered to be substantial under  
35 Alternative 5 as compared to the No Action Alternative because the CVP  
36 municipal water supplies are anticipated to be similar in long-term conditions, dry  
37 years, and critical dry years. The water demands are consistent between  
38 Alternative 5 and the No Action Alternative; therefore, it is anticipated that  
39 similar surface water supplies would result in similar groundwater use.

40 In areas of the Central Valley Region that use CVP water service contract and  
41 SWP entitlement contract water supplies, the CVP and SWP water supplies would  
42 be slightly lower under Alternative 5 as compared to the No Action Alternative.

1 The differences would result in increased groundwater use and decreased  
2 groundwater levels in the San Joaquin Valley Groundwater Basin under  
3 Alternative 5 as compared to the No Action Alternative. Results of CVHM  
4 simulations indicate that groundwater levels would be similar in the Redding and  
5 Sacramento Valley groundwater basins and the northern portion of the San  
6 Joaquin Valley Groundwater Basin, as shown in Figures 7.47 through 7.51.

7 Groundwater levels decrease under Alternative 5 in the central and southern San  
8 Joaquin Valley Groundwater Basin as compared to the No Action  
9 Alternative with the greatest decreases occurring in above normal years.  
10 Figures 7.52 and 7.53 present the simulated change in groundwater levels over the  
11 42-year CVHM study period. Simulated average July agricultural groundwater  
12 pumping under Alternative 5 as compared to the No Action Alternative is  
13 presented in Figures 7.31 and 7.32.

14 Overall, under Alternative 5 as compared to the No Action Alternative, July  
15 average groundwater levels decrease approximately 2 to 10 feet on average in  
16 some of the Westside subbasin and the northern portion of the Kern County  
17 subbasin in most water year types, and decrease approximately by up to 25 feet in  
18 dry and above normal water years in the Westside subbasin. The groundwater  
19 level change hydrographs show that in the central and southern San Joaquin  
20 Valley, groundwater levels usually fluctuate by no more than 50 feet in some  
21 areas due to seasonal and climatic variations under Alternative 5 compared to the  
22 No Action Alternative.

23 The change in groundwater pumping in the Sacramento Valley is less than  
24 5 percent. Therefore, groundwater pumping in the Sacramento Valley is similar  
25 under Alternative 5 compared to the No Action Alternative.

26 Groundwater pumping in the San Joaquin and Tulare Basins changes by less than  
27 5 percent under Alternative 5 as compared to the No Action Alternative, and is  
28 therefore considered similar. Figure 7.32 shows that the biggest change in  
29 groundwater pumping under Alternative 5 compared to the No Action  
30 Alternative occurs in the Western San Joaquin Valley.

31 *Land Subsidence*

32 Groundwater pumping would be similar in the Sacramento and San Joaquin  
33 valleys, therefore, the potential for groundwater level-induced land subsidence  
34 would be similar under Alternative 5 as compared to the No Action Alternative.

35 *Groundwater Quality*

36 Groundwater pumping would be similar in the Sacramento and San Joaquin  
37 valleys, therefore, groundwater quality would be similar under Alternative 5 as  
38 compared to the No Action Alternative.

39 *Effects Related to Water Transfers*

40 Potential effects to groundwater resources could be similar to those identified in a  
41 recent environmental analysis conducted by Reclamation for long-term water  
42 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
43 described above under the No Action Alternative compared to the Second Basis

1 of Comparison. For the purposes of this EIS, it is anticipated that similar  
2 conditions would occur during implementation of cross Delta water transfers  
3 under Alternative 5 and the No Action Alternative, and that groundwater impacts  
4 would not be substantial in the seller's service area due implementation  
5 requirements of the transfer programs.

6 Groundwater use in areas that purchase the transferred water could be reduced if  
7 additional surface water is provided. However, if the transferred water is used to  
8 meet water demands that would not have been met (e.g., crops that had been  
9 idled), groundwater conditions would be similar with or without water transfers.

10 Under Alternative 5 and the No Action Alternative, the timing of cross Delta  
11 water transfers would be limited to July through September and include annual  
12 volumetric limits, in accordance with the 2008 USFWS BO and 2009 NMFS BO.  
13 Overall, the potential for cross Delta water transfers would be similar under  
14 Alternative 5 as compared to the No Action Alternative.

15 *San Francisco Bay Area, Central Coast, and Southern California Regions*  
16 *Groundwater Use and Elevation*

17 Under Alternative 5, it is anticipated that CVP and SWP water supplies in the San  
18 Francisco Bay Area, Central Coast, and Southern California regions would be  
19 similar to CVP and SWP water supplies under the No Action Alternative, as  
20 discussed in Chapter 5, Surface Water Resources and Water Supplies. Therefore,  
21 groundwater pumping would be similar.

22 *Land Subsidence*

23 Because the groundwater pumping would be similar under Alternative 5 as  
24 compared to the No Action Alternative; therefore, the potential for additional land  
25 subsidence would be similar.

26 *Groundwater Quality*

27 Because the groundwater pumping would be similar under Alternative 5 as  
28 compared to the No Action Alternative; therefore, groundwater quality would be  
29 similar.

30 **7.4.3.6.2 Alternative 5 Compared to the Second Basis of Comparison**

31 *Trinity River Region*

32 Groundwater conditions in the Trinity River Region are not directly related to  
33 CVP and SWP water supplies or operations. Therefore, groundwater use, related  
34 groundwater levels, potential for land use subsidence, and groundwater quality  
35 under Alternative 5 would be the same as under the Second Basis of Comparison.

36 *Central Valley Region*

37 *Groundwater Use and Elevation*

38 In areas of the Central Valley Region that do not use CVP and SWP water  
39 supplies, areas that use CVP water under Sacramento River Exchange Settlement  
40 Contracts, and areas that use San Joaquin River Exchange Contracts under  
41 Alternative 5 water supplies would be the same as under the Second Basis of

1 Comparison. Therefore, in these areas of the Central Valley Region, groundwater  
2 use and groundwater levels under Alternative 5 would be the same as under the  
3 Second Basis of Comparison. The CVHM simulation primarily focuses on  
4 changes in agricultural groundwater use in response to changes in the availability  
5 of CVP and SWP water. However, it is recognized that in the vicinity of some  
6 communities, such as in the area in the American River watershed served with  
7 CVP water supplies, groundwater use also would increase with the reduction in  
8 surface water availability. However, these changes are not considered to be  
9 substantial under Alternative 5 as compared to the Second Basis of Comparison  
10 because the long-term reductions in CVP municipal water supplies are anticipated  
11 to be up to 7,000 acre-feet per year (up to 6 percent) over the long-term condition,  
12 up to 9,000 acre-feet per year (up to 9 percent) in dry years, and up to 6,000 acre-  
13 feet per year (up to 8 percent) in critical dry years. The water demands are  
14 consistent between Alternative 5 and the Second Basis of Comparison; therefore,  
15 it is anticipated that reduced surface water supplies would result in increased  
16 groundwater use.

17 In areas of the Central Valley Region that use CVP water service contract and  
18 SWP entitlement contract water supplies, the CVP and SWP water supplies would  
19 be lower under Alternative 5 as compared to the Second Basis of Comparison.  
20 The differences would result in increased groundwater use and decreased  
21 groundwater levels in the San Joaquin Valley Groundwater Basin under  
22 Alternative 5 as compared to the Second Basis of Comparison. Results of CVHM  
23 simulations indicate that groundwater levels would be similar in the Redding and  
24 Sacramento Valley groundwater basins and the northern portion of the San  
25 Joaquin Valley Groundwater Basin, as shown in Figures 7.54 through 7.58.

26 Groundwater levels generally decrease under Alternative 5 in the central and  
27 southern San Joaquin Valley Groundwater Basin as compared to the Second Basis  
28 of Comparison. Figures 7.59 and 7.60 present the simulated change in  
29 groundwater levels over the 42-year CVHM study period. Simulated average July  
30 agricultural groundwater pumping under Alternative 5 as compared to the Second  
31 Basis of Comparison is presented in Figures 7.22 and 7.23.

32 Overall, under Alternative 5 as compared to the Second Basis of Comparison,  
33 July average groundwater levels decrease approximately 2 to 10 feet in most of  
34 the central and southern San Joaquin Valley Groundwater Basin in all water year  
35 types. July average groundwater levels decline 10 to 50 feet in the Delta-  
36 Mendota, Tulare Lake, and Kern County subbasins; and can decline up to 200 feet  
37 in the Westside subbasin, in below normal, above normal and dry water year  
38 types. Groundwater level changes in the Sacramento Valley are forecast to be  
39 less than 2 feet. The groundwater level change hydrographs show that in the  
40 central and southern San Joaquin Valley, groundwater levels can fluctuate up to  
41 200 feet in some areas due to seasonal and climatic variations under Alternative 5  
42 compared to the Second Basis of Comparison.

43 The change in groundwater pumping in the Sacramento Valley is less than  
44 5 percent. Therefore, groundwater pumping in the Sacramento Valley is similar  
45 under Alternative 5 compared to the Second Basis of Comparison.

1 Groundwater pumping in the San Joaquin and Tulare Basins increases by  
2 approximately 8 percent under the Alternative 5 as compared to the Second Basis  
3 of Comparison. Figure 7.23 shows that the biggest change in groundwater  
4 pumping under Alternative 5 compared to the Second Basis of Comparison occurs  
5 in WBS 14, with an average July increase of almost 40 TAF.

6 *Land Subsidence*

7 Land subsidence due to groundwater withdrawals historically occurred in the  
8 Yolo subbasin of the Sacramento Valley Groundwater Basin. CVP and SWP  
9 water supplies are not used extensively in this area. The conditions under  
10 Alternative 5 would be similar as conditions under the Second Basis of  
11 Comparison.

12 Under Alternative 5, potential for land subsidence due to groundwater  
13 withdrawals in the Delta-Mendota and Westside subbasins of the San Joaquin  
14 Valley Groundwater Basin would increase under Alternative 5 as compared to the  
15 Second Basis of Comparison due to the increased groundwater withdrawals.

16 Groundwater level-induced land subsidence has the highest potential to occur in  
17 the San Joaquin Groundwater Basin, based on historical data, if groundwater  
18 pumping substantially increases. Under Alternative 5, CVP and SWP water  
19 supplies are expected to decrease in the San Joaquin Valley as compared to the  
20 Second Basis of Comparison. Decreased surface water deliveries could result in  
21 an increase in groundwater pumping. The increased groundwater pumping would  
22 result in lower groundwater levels, and therefore, the potential for groundwater  
23 level-induced land subsidence is increased under Alternative 5 as compared to the  
24 Second Basis of Comparison.

25 *Groundwater Quality*

26 Under Alternative 5, groundwater conditions, including groundwater quality, in  
27 areas that do not use CVP and SWP water supplies would be the same as under  
28 the Second Basis of Comparison.

29 In areas that use CVP and SWP water supplies, groundwater quality under  
30 Alternative 5 could be reduced as compared to the Second Basis of Comparison in  
31 the central and southern San Joaquin Valley Groundwater Basin due to increased  
32 groundwater withdrawals and resulting potential changes in groundwater flow  
33 patterns. As described above, it is assumed that measures implemented in  
34 accordance with the CV-SALTS program or future sustainable groundwater  
35 management plans implemented in accordance with SGMA would not be fully  
36 implemented by 2030. Therefore, groundwater quality may be affected under  
37 Alternative 5 as compared to the Second Basis of Comparison.

38 *Effects Related to Water Transfers*

39 Potential effects to groundwater resources could be similar to those identified in a  
40 recent environmental analysis conducted by Reclamation for long-term water  
41 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
42 described above under the No Action Alternative compared to the Second Basis  
43 of Comparison. For the purposes of this EIS, it is anticipated that similar

1 conditions would occur during implementation of cross Delta water transfers  
2 under Alternative 5 and the Second Basis of Comparison, and that groundwater  
3 impacts would not be substantial in the seller's service area due implementation  
4 requirements of the transfer programs.

5 Groundwater use in areas that purchase the transferred water could be reduced if  
6 additional surface water is provided. However, if the transferred water is used to  
7 meet water demands that would not have been met (e.g., crops that had been  
8 idled), groundwater conditions would be similar with or without water transfers.

9 Under Alternative 5 and the Second Basis of Comparison, water could be  
10 transferred throughout the year without an annual volumetric limit. Therefore, the  
11 potential for cross Delta water transfers would be similar under Alternative 5 and  
12 the Second Basis of Comparison.

13 *San Francisco Bay Area, Central Coast, and Southern California Regions*  
14 *Groundwater Use and Elevation*

15 Under Alternative 5, it is anticipated that CVP and SWP water supplies in the San  
16 Francisco Bay Area, Central Coast, and Southern California regions would be  
17 decreased as compared to CVP and SWP water supplies under the Second Basis  
18 of Comparison, as discussed in Chapter 5, Surface Water Resources and Water  
19 Supplies. The decrease in surface water supplies could result in increased  
20 groundwater withdrawals by CVP and SWP water users, resulting in decreased  
21 groundwater recharge, and decreased groundwater levels in areas with CVP and  
22 SWP water users. It may be legally impossible to extract additional groundwater  
23 in adjudicated basins without gaining the permission of watermasters and  
24 accounting for groundwater pumping entitlements and various parties under their  
25 adjudicated rights.

26 *Land Subsidence*

27 Increased use of groundwater and lower groundwater levels would result in a  
28 decreased potential for additional land subsidence would increase under  
29 Alternative 5 as compared to the Second Basis of Comparison in the Santa Clara  
30 Valley Groundwater Basin in the San Francisco Bay Area Region, and the  
31 Antelope Valley and Lucerne Valley groundwater basins in the Southern  
32 California Region.

33 *Groundwater Quality*

34 As described in Section 7.3, Affected Environment, there are localized areas of  
35 moderate to high salinity due to natural geologic formations and/or seawater  
36 intrusion in the San Francisco Bay Area, Central Coast, and Southern California  
37 regions. Under Alternative 5 as compared to the Second Basis of Comparison, it  
38 is anticipated that the increased groundwater withdrawals would cause poorer  
39 groundwater quality, especially near the coast.

40 **7.4.3.7 Summary of Impact Analysis**

41 The results of the impact analysis of implementation of Alternatives 1 through 5  
42 as compared to the No Action Alternative and the Second Basis of Comparison  
43 are presented in Tables 7.3 and 7.4.

1 **Table 7.3 Comparison of Alternatives 1 through 5 to No Action Alternative**

<b>Alternative</b>	<b>Potential Change</b>	<b>Consideration for Mitigation Measures</b>
Alternative 1	<p><b>Trinity River Region</b> Groundwater conditions would be similar.</p> <p><b>Central Valley Region</b> Groundwater pumping and levels in the Sacramento Valley would be similar. Groundwater pumping in the San Joaquin Valley would decrease by approximately 8 percent. July groundwater levels in all water year types would be higher by approximately 2 to 10 feet in most of the central and southern San Joaquin Valley; 10 to 50 feet in the Delta-Mendota, Tulare Lake, and Kern County subbasins; and 50 to 200 feet in the Westside subbasin. The higher groundwater levels would reduce the potential for land subsidence. Groundwater quality in the San Joaquin Valley Groundwater Basin could decline.</p> <p><b>San Francisco Bay Area, Central Coast, and Southern California Regions</b> Increases in CVP and SWP water supplies, could decrease groundwater pumping and decrease the potential for land subsidence.</p>	None needed
Alternative 2	No effects on groundwater resources or water supplies.	None needed
Alternative 3	<p><b>Trinity River Region</b> Groundwater conditions would be similar.</p> <p><b>Central Valley Region</b> Groundwater pumping and levels in the Sacramento Valley would be similar. Groundwater pumping in the San Joaquin Valley would decrease by approximately 6 percent. July groundwater levels in all water year types would be higher by approximately 2 to 10 feet in most of the central and southern San Joaquin Valley; 10 to 50 feet in the Delta-Mendota, Tulare Lake, and Kern County subbasins; and 50 to 200 feet in the Westside subbasin. The higher groundwater levels would reduce the potential for land subsidence. Groundwater quality in the San Joaquin Valley Groundwater Basin could decline.</p> <p><b>San Francisco Bay Area, Central Coast, and Southern California Regions</b> Increases in CVP and SWP water supplies, could decrease groundwater pumping and decrease the potential for land subsidence.</p>	None needed

Alternative	Potential Change	Consideration for Mitigation Measures
Alternative 4	Same effects as described for Alternative 1 compared to the No Action Alternative.	None needed
Alternative 5	<p><b>Trinity River Region</b> Groundwater conditions would be similar.</p> <p><b>Central Valley Regions</b> Groundwater pumping and levels in the Sacramento Valley would be similar. Groundwater pumping, levels, and quality in the San Joaquin Valley would be similar. July groundwater levels in all water year types would decline approximately 2 to 10 feet in most of the central and southern San Joaquin Valley; and up to 25 feet in the Westside subbasin.</p> <p><b>San Francisco Bay Area, Central Coast, and Southern California Regions</b> Because the CVP and SWP water deliveries would be similar; groundwater pumping would be similar the potential for land subsidence would be similar.</p>	None needed

- 1 Note:
- 2 \*Due to the limitations and uncertainty in the CalSim II monthly model and other
- 3 analytical tools, incremental differences of 5 percent or less between alternatives and the
- 4 Second Basis of Comparison are considered to be “similar.”

1 **Table 7.4 Comparison of No Action Alternative and Alternatives 1 through 5 to**  
 2 **Second Basis of Comparison**

Alternative	Potential Change	Consideration for Mitigation Measures
No Action Alternative	<p><b>Trinity River Region</b>                      Groundwater conditions would be similar.</p> <p><b>Central Valley Regions</b>                      Groundwater pumping and levels in the Sacramento Valley would be similar.                      Groundwater pumping in the San Joaquin Valley would increase by approximately 8 percent. July groundwater levels in all water year types would decline approximately 2 to 10 feet in most of the central and southern San Joaquin Valley; 10 to 50 feet in the Delta-Mendota, Tulare Lake, and Kern County subbasins; and 100 to 200 feet in the Westside subbasin. The reduction in groundwater levels could cause additional land subsidence.                      Groundwater quality in the San Joaquin Valley Groundwater Basin could decline.</p> <p><b>San Francisco Bay Area, Central Coast, and Southern California Regions</b>                      Reductions in CVP and SWP water supplies, could increase groundwater pumping and increase the potential for land subsidence.</p>	Not considered for this comparison.
Alternative 1	No effects on groundwater resources or water supplies.	None needed.
Alternative 2	Same effects as described for No Action Alternative as compared to the Second Basis of Comparison.	Not considered for this comparison.
Alternative 3	<p><b>Trinity River Region</b>                      Groundwater conditions would be similar.</p> <p><b>Central Valley Regions</b>                      Groundwater pumping and levels in the Sacramento Valley would be similar.                      Groundwater pumping, levels, and quality in the San Joaquin Valley would be similar. July groundwater levels in all water year types would decline approximately 2 to 10 feet in the areas of the western and southern San Joaquin Valley; up to 25 feet in the Delta-Mendota, Tulare Lake, Kern County and in Westside subbasins.</p> <p><b>San Francisco Bay Area, Central Coast, and Southern California Regions</b>                      Reductions in CVP and SWP water supplies, could increase groundwater pumping and increase the potential for land subsidence.</p>	Not considered for this comparison.

Alternative	Potential Change	Consideration for Mitigation Measures
Alternative 4	No effects on groundwater resources or water supplies.	None needed
Alternative 5	<p><b>Trinity River Region</b> Groundwater conditions would be similar.</p> <p><b>Central Valley Regions</b> Groundwater pumping and levels in the Sacramento Valley would be similar.</p> <p>Groundwater pumping in the San Joaquin Valley would increase by approximately 8 percent. July groundwater levels in all water year types would decline approximately 2 to 10 feet in most of the central and southern San Joaquin Valley; 10 to 50 feet in the Delta-Mendota, Tulare Lake and Kern County subbasins; and up to 200 feet in the Westside subbasin. The reduction in groundwater levels could cause additional land subsidence.</p> <p>Groundwater quality in the San Joaquin Valley Groundwater Basin could decline.</p> <p><b>San Francisco Bay Area, Central Coast, and Southern California Regions</b> Reductions in CVP and SWP water supplies, could increase groundwater pumping and increase the potential for land subsidence.</p>	Not considered for this comparison.

1 Note:  
 2 \*Due to the limitations and uncertainty in the CalSim II monthly model and other  
 3 analytical tools, incremental differences of 5 percent or less between alternatives and the  
 4 Second Basis of Comparison are considered to be “similar.”

5 **7.4.3.8 Potential Mitigation Measures**

6 Mitigation measures are presented in this section to avoid, minimize, rectify,  
 7 reduce, eliminate, or compensate for adverse environmental effects of  
 8 Alternatives 1 through 5 as compared to the No Action Alternative. Mitigation  
 9 measures were not included to address adverse impacts under the alternatives as  
 10 compared to the Second Basis of Comparison because this analysis was included  
 11 in this EIS for information purposes only.

12 As described above and summarized in Table 7.3, implementation of  
 13 Alternatives 1 through 5 as compared to the No Action Alternative would result in  
 14 either similar or less groundwater pumping and potential for land subsidence; and  
 15 similar groundwater quality conditions. Therefore, there would be no adverse  
 16 impacts to groundwater; and no mitigation measures are needed.

1 **7.4.3.9 Cumulative Effects Analysis**

2 As described in Chapter 3, the cumulative effects analysis considers projects,  
 3 programs, and policies that are not speculative; and are based upon known or  
 4 reasonably foreseeable long-range plans, regulations, operating agreements, or  
 5 other information that establishes them as reasonably foreseeable.

6 The cumulative effects analysis for Alternatives 1 through 5 for Groundwater  
 7 Resources are summarized in Table 7.5.

8 **Table 7.5 Summary of Cumulative Effects on Groundwater Resources of**  
 9 **Alternatives 1 through 5 as Compared to the No Action Alternative**

Scenarios	Actions	Cumulative Effects of Actions
Past & Present, and Future Actions included in the No Action Alternative in All Alternatives in Year 2030	Consistent with Affected Environment conditions plus: Actions in the 2008 USFWS BO and 2009 NMFS BO that would have occurred without implementation of the BOs, as described in Section 3.3.1.2 (of Chapter 3, Descriptions of Alternatives), including climate change and sea level rise Actions not included in the 2008 USFWS BO and 2009 NMFS BO that would have occurred without implementation of the BOs, as described in Section 3.3.1.3 (of Chapter 3, Descriptions of Alternatives): - Implementation of Federal and state policies and programs, including Clean Water Act (e.g., Total Maximum Daily Loads); Safe Drinking Water Act; Clean Air Act; and flood management programs - General plans for 2030. - Trinity River Restoration Program. - Central Valley Project Improvement Act programs - Iron Mountain Mine Superfund Site - Nimbus Fish Hatchery Fish Passage Project - Folsom Dam Water Control Manual Update	These effects would be the same in all alternatives. Climate change and sea level rise, development under the general plans, FERC relicensing projects, and some future projects to improve water quality and/or habitat are anticipated to reduce availability of CVP and SWP water supplies; and therefore, increase groundwater use, reduce groundwater elevations, and increase potential subsidence. Future water supply projects are anticipated to both increase surface water supply reliability due to increased surface water supplies and to accommodate planned growth in the general plans. Most of these programs were initiated prior to implementation of the 2008 USFWS BO and 2009 NMFS BO which reduced CVP and SWP water supply reliability. Developments under the general plans and future water supply, water quality improvement, and restoration projects are anticipated to potentially affect future groundwater resources.

<b>Scenarios</b>	<b>Actions</b>	<b>Cumulative Effects of Actions</b>
	<ul style="list-style-type: none"> <li>- FERC Relicensing for the Middle Fork of the American River Project</li> <li>- Lower Mokelumne River Spawning Habitat Improvement Project</li> <li>- Dutch Slough Tidal Marsh Restoration</li> </ul>	<p>However, development of these future programs would include preparation of environmental documentation that would identify methods to minimize adverse impacts to groundwater resources.</p>
	<ul style="list-style-type: none"> <li>- Suisun Marsh Habitat Management, Preservation, and Restoration Plan Implementation</li> <li>- Tidal Wetland Restoration: Yolo Ranch, Northern Liberty Island Fish Restoration Project, Prospect Island Restoration Project, and Calhoun Cut/Lindsey Slough Tidal Habitat Restoration Project</li> <li>- San Joaquin River Restoration Program</li> <li>- Stockton Deep Water Ship Channel Dissolved Oxygen Project</li> <li>- Grasslands Bypass Project</li> <li>- Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS)</li> <li>- Future water supply projects, including water recycling, desalination, groundwater banks and wellfields, and conveyance facilities (projects with completed environmental documents)</li> </ul>	<p>Some of the future actions would reduce the effects of agricultural drainage and/or reduce salinity in the San Joaquin River and the Delta. These programs would result in a beneficial impact to groundwater quality.</p>

Scenarios	Actions	Cumulative Effects of Actions
<p>Future Actions considered as Cumulative Effects Actions in All Alternatives in Year 2030</p>	<p>Actions as described in Section 3.5 (of Chapter 3, Descriptions of Alternatives):</p> <ul style="list-style-type: none"> <li>- Bay-Delta Water Quality Control Plan Update</li> <li>- FERC Relicensing Projects</li> <li>- Bay Delta Conservation Plan (including California WaterFix alternative)</li> <li>- Shasta Lake Water Resources, North-of-the-Delta Offstream Storage, Los Vaqueros Reservoir Expansion Phase 2, and Upper San Joaquin River Basin Storage Investigations</li> <li>- El Dorado Water and Power Authority Supplemental Water Rights Project</li> <li>- Sacramento River Water Reliability Project</li> </ul>	<p>These effects would be the same in all alternatives.</p> <p>Most of the future reasonably foreseeable actions are anticipated to reduce water supply impacts due to climate change, sea level rise, increased water allocated to improve habitat conditions, and future growth.</p> <p>Some of the future reasonably foreseeable actions related to improved water quality and habitat conditions (e.g., Water Quality Control Plan Update and FERC Relicensing Projects), could in further reductions in CVP and SWP water deliveries.</p>
	<ul style="list-style-type: none"> <li>- Semitropic Water Storage District Delta Wetlands</li> <li>- North Bay Aqueduct Alternative Intake</li> <li>- Irrigated Lands Regulatory Program</li> <li>- San Luis Reservoir Low Point Improvement Project</li> <li>- Westlands Water District v. United States Settlement</li> <li>- Future water supply projects, including water recycling, desalination, groundwater banks and wellfields, and conveyance facilities (projects that did not have completed environmental documents during preparation of the EIS)</li> </ul>	<p>Developments under the future projects are anticipated to potentially affect groundwater resources. However, development of these future programs would include preparation of environmental documentation that would identify methods to minimize adverse impacts to groundwater resources.</p> <p>Some of the future reasonably foreseeable actions would reduce the effects of agricultural drainage and/or reduce salinity in the San Joaquin River and the Delta. These programs would result in a beneficial impact to groundwater quality.</p>

<b>Scenarios</b>	<b>Actions</b>	<b>Cumulative Effects of Actions</b>
<p>No Action Alternative with Associated Cumulative Effects Actions in Year 2030</p>	<p>Full implementation of the 2008 USFWS BO and 2009 NMFS</p>	<p>Climate change and sea level rise, development under the general plans, FERC relicensing projects, and some future projects to improve water quality and/or habitat are anticipated to reduce availability of CVP and SWP water supplies, and increase groundwater use as compared to past conditions. Future water supply projects are anticipated to both increase water supply reliability due to increased surface water supplies and to accommodate planned growth in the general plans. Some of the future actions would reduce the effects of agricultural drainage and/or reduce salinity in the San Joaquin River and the Delta, and improve groundwater quality.</p>
		<p>Groundwater substitution water transfers could result in reduced groundwater levels and potential subsidence in areas that sell water using groundwater substitution practices. Because all water transfers would be required to avoid adverse impacts to other water users and biological resources, including impacts to other groundwater users, it is anticipated that water transfers would not result in substantial changes in groundwater conditions</p>
<p>Alternative 1 with Associated Cumulative Effects Actions in Year 2030</p>	<p>No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant)</p>	<p>Implementation of Alternative 1 with future reasonably foreseeable would result in increased surface water availability and reduced groundwater use as compared to the No Action Alternative with the added actions.</p>

Scenarios	Actions	Cumulative Effects of Actions
Alternative 2 with Associated Cumulative Effects in Year 2030	Full implementation of the 2008 USFWS BO and 2009 NMFS BO CVP and SWP operational actions No implementation of structural improvements or other actions that require further study to develop a more detailed action description.	Implementation of Alternative 2 with future reasonably foreseeable would result in similar surface water availability and similar groundwater use as compared to the No Action Alternative with the added actions.
Alternative 3 with Associated Cumulative Effects in Year 2030	No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant) Slight increase in positive Old and Middle River flows in the winter and spring months	Implementation of Alternative 3 with future reasonably foreseeable would result in increased surface water availability and reduced groundwater use as compared to the No Action Alternative with the added actions.
Alternative 4 with Associated Cumulative Effects in Year 2030	No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant)	Implementation of Alternative 4 with future reasonably foreseeable would result in increased surface water availability and reduced groundwater use as compared to the No Action Alternative with the added actions.
Alternative 5 with Associated Cumulative Effects in Year 20530	Full implementation of the 2008 USFWS BO and 2009 NMFS BO Positive Old and Middle River flows and increased Delta outflow in spring months	Implementation of Alternative 5 with future reasonably foreseeable would result in similar surface water availability and similar groundwater use as compared to the No Action Alternative with the added actions.

1 There would be no adverse impacts associated with implementation of the  
2 alternatives as compared to the No Action Alternative. Therefore, Alternatives 1  
3 through 5 would not contribute cumulative impacts to groundwater as compared  
4 to the No Action Alternative. However, implementation of No Action  
5 Alternative and Alternative 5 (in the Central Valley, San Francisco Bay Area,  
6 Central Coast, and Southern California regions) and Alternative 3 (in the San  
7 Francisco Bay Area, Central Coast, and Southern California regions) as compared  
8 to the Second Basis of Comparison would result in increased groundwater  
9 pumping and associated potential for land subsidence and poorer groundwater  
10 quality; and could contribute to cumulative impacts related to groundwater  
11 conditions as compared to the Second Basis of Comparison conditions.

## Chapter 8

# 1 Energy

## 2 8.1 Introduction

3 This chapter describes the hydroelectric generation facilities and power demands  
4 for the Central Valley Project (CVP) and State Water Project (SWP) related to  
5 changes that could occur as a result of implementing the alternatives evaluated in  
6 this Environmental Impact Statement (EIS). Implementation of the alternatives  
7 could affect CVP and SWP power generation and energy demands through  
8 potential changes in operation of the CVP and SWP facilities.

9 Changes in CVP and SWP operations are described in more detail in Chapter 5,  
10 Surface Water Resources and Water Supplies.

## 11 8.2 Regulatory Environment and Compliance 12 Requirements

13 Potential actions that could be implemented under the alternatives evaluated in  
14 this EIS could affect CVP and/or SWP hydroelectric generation and electricity  
15 use. The changes in power production and energy use would need to be  
16 compliant with appropriate Federal and state agency policies and regulations, as  
17 summarized in Chapter 4, Approach to Environmental Analysis.

## 18 8.3 Affected Environment

19 This section describes CVP and SWP hydroelectric generation and electricity use  
20 of the generated electricity within the study area.

21 The study area includes CVP and SWP hydroelectric generation facilities at the  
22 CVP and SWP reservoirs; transmission of the generated electricity; and the CVP  
23 and SWP facilities and other users throughout California that rely upon electricity  
24 generated by the CVP and SWP hydroelectric facilities. These CVP and SWP  
25 energy generation facilities are located in the Trinity River and Central Valley  
26 regions. CVP and SWP energy use primarily occurs in the Central Valley,  
27 San Francisco Bay Area, Central Coast, and Southern California regions, as  
28 defined below.

### 29 8.3.1 Central Valley Project and State Water Project Electric 30 Generation Facilities

31 Hydroelectric facilities are located at most of the CVP and SWP dams, as shown  
32 on Figure 8.1. As water is released from the CVP and SWP reservoirs, the  
33 generation facilities produce power that is used by the CVP and SWP pumping  
34 plants, respectively. The SWP also generates hydroelectricity along the

1 California Aqueduct at energy recovery plants (California Department of Water  
2 Resources [DWR] 2013a, 2013b). Between 1983 and 2013, the DWR owned a  
3 portion of the Nevada Power Company’s coal-fired Reid Gardner Unit 4  
4 Powerplant. However, this agreement was not renewed upon expiration in 2013.

5 Power generated by the CVP is transmitted by Western Area Power  
6 Administration (Western) to CVP facilities. Power that is excess to CVP needs is  
7 marketed by Western to electric utilities, government and public installations, and  
8 commercial “preference” customers who have 20-year contracts (Bureau of  
9 Reclamation [Reclamation] 2012a). Power generated by the SWP is transmitted  
10 by Pacific Gas & Electric Company, Southern California Edison, and California  
11 Independent System Operator through other facilities (DWR 2013a, 2013b). The  
12 SWP also markets energy in excess of the SWP demands to a utility and members  
13 of the Western Systems Power Pool.

14 Hydropower is an important renewable energy and supplies between 14 and  
15 28 percent of electricity used in California depending upon the water year type  
16 (The California Energy Commission [CEC] 2014a; Hydropower Working Group  
17 [HWG] 2014). In 1992, at the end of the 1987-to-1992 drought, hydropower  
18 provided less than 11 percent of the electricity used in California. However,  
19 during a wetter year (1995), hydropower provided approximately 28 percent of  
20 electricity used in California. Between 1982 and 2012, approximately  
21 33,927 gigawatt-hours were generated in California by hydropower, including  
22 approximately 4,810 and 2,613 gigawatt-hours generated by the CVP and SWP,  
23 respectively.

#### 24 **8.3.1.1 CVP Hydroelectric Generation Facilities**

25 The CVP power facilities include 11 hydroelectric powerplants and have a total  
26 maximum generating capacity of 2,076 megawatts, as presented in Table 8.1.  
27 Hydrology can vary significantly from year to year, which then affects the  
28 hydropower production. Typically, in an average water year, approximately  
29 4,500 gigawatt-hours of energy is produced (Reclamation 2012a). Major factors  
30 that influence powerplant operations include required downstream water releases,  
31 electric system needs, and project use demand. The power generated from CVP  
32 powerplants is dedicated to first meeting the requirements of the CVP facilities.  
33 The remaining energy is marketed by Western to preferred customers in northern  
34 California.

1 **Table 8.1 Central Valley Project Hydroelectric Powerplants**

Facility	Installed Capacity (Megawatts)
Trinity Powerplant	140
Lewiston Powerplant	0.35
Judge Francis Powerplant	154
Shasta Powerplant	710
Spring Creek Powerplant	180
Keswick Powerplant	117
Folsom Powerplant	207
Nimbus Powerplant	17
New Melones Powerplant	383
O'Neill Pump-Generating Plant	14.4
San Luis Powerplant (CVP portion of the William R. Gianelli/San Luis Pump-Generating Plant)	202

2 Sources: Reclamation 2013a, 2013b, 2013c, 2013d, 2013e, 2013f, 2013g, 2013h, 2013i,  
3 2013j, 2013k, 2013l

#### 4 **8.3.1.1.1 Trinity Division Powerplants**

5 The Trinity Powerplant is located along the Trinity River (Reclamation 2013b).  
6 Primary releases of Trinity Dam are made through the powerplant. Trinity  
7 County has first preference to the power from this plant.

8 The Lewiston Powerplant is located at the Lewiston Dam along the Trinity River  
9 (Reclamation 2013c). It is operated in conjunction with the spillway gates to  
10 maintain the minimum flow in the Trinity River downstream. The turbines are  
11 usually set at maximum output with the spillway gates adjusted to regulate river  
12 flow. The turbine capacity is less than the Trinity River minimum flow criteria,  
13 as described in Chapter 5, Surface Water Resources and Water Supplies. The  
14 Lewiston Powerplant provides power to the adjacent fish hatchery.

15 The Judge Francis Carr Powerplant is a peaking powerplant located on the Clear  
16 Creek Tunnel (Reclamation 2013d). It generates power from water exported from  
17 the Trinity River Basin. Similar to Trinity Powerplant, Trinity County has first  
18 preference to the power benefit from this facility.

#### 19 **8.3.1.1.2 Sacramento River Powerplants**

20 The Shasta Powerplant is a peaking powerplant located downstream of Shasta  
21 Dam along the Sacramento River (Reclamation 2013a, 2013e). Until early 1990s,  
22 concerns with downstream temperatures resulted in the bypasses of outflows  
23 around the powerplant and lost hydropower generation. Installation of the Shasta  
24 Temperature Control Device enabled operators to decide the depth of the  
25 reservoir from which the water feeding into the penstocks originates. The system  
26 has shown significant success in controlling the water temperature of powerplant

1 releases through Shasta Dam. The Shasta Powerplant also provides water supply  
2 for the Livingston Stone National Fish Hatchery.

3 The Spring Creek Powerplant is a peaking plant located along Spring Creek, at  
4 the foot of Spring Creek Debris Dam (Reclamation 2013f). Water discharged via  
5 the Judge Francis Carr Powerplant flows into the Whiskeytown Reservoir and  
6 then provides the source of water for the Spring Creek Powerplant generation.  
7 Trinity County has first preference to the power benefits from Spring Creek  
8 Powerplant. Water from Spring Creek Powerplant is discharged into Keswick  
9 Reservoir. Releases from Spring Creek Powerplant also are operated to maintain  
10 water quality in the Spring Creek arm of Keswick Reservoir.

11 The Keswick Powerplant is located at Keswick Dam along the Sacramento River  
12 downstream of Shasta Dam and regulates the flows into the Sacramento River  
13 from both Shasta Lake and Spring Creek releases and can be considered as a run-  
14 of-the-river powerplant (Reclamation 2013g).

#### 15 **8.3.1.1.3 American River Powerplants**

16 The Folsom Powerplant is a peaking powerplant located at Folsom Dam along the  
17 American River (Reclamation 2013h). The Folsom Powerplant is operated in an  
18 integrated manner with flood control operations at Folsom Lake. One of the  
19 integrated operations is related to coordinating early flood control releases with  
20 power generation. It also provides power for the pumping plant that supplies the  
21 local domestic water supply. Folsom Powerplant supports voltage support for the  
22 Sacramento Region during summer heavy load times.

23 The Nimbus Powerplant is located at Nimbus Dam along the American River,  
24 downstream of Folsom Dam (Reclamation 2013i). The Nimbus Powerplant  
25 regulates releases from Folsom Dam into the American River and can be  
26 considered as a run-of-the river powerplant.

#### 27 **8.3.1.1.4 Stanislaus River Powerplants**

28 The New Melones Powerplant is a peaking powerplant located along the  
29 Stanislaus River (Reclamation 2013j). Primary reservoir releases are made  
30 through the powerplant. This plant provides significant voltage support to the  
31 Pacific Gas and Electric Company system during summer heavy load periods.

#### 32 **8.3.1.1.5 San Luis Reservoir Powerplants**

33 The O'Neill Pump-Generating Plant is located on a channel that conveys water  
34 between the Delta-Mendota Canal and the O'Neill Forebay (Reclamation 2013k).  
35 This pump-generating plant only generates power when water is released from the  
36 O'Neill Reservoir to the Delta-Mendota Canal. When water is conveyed from the  
37 Delta-Mendota Canal to O'Neill Forebay, the units serve as pumps, not  
38 hydroelectric generators. The generated power is used to support CVP pumping  
39 and irrigation actions of the CVP.

40 The William R. Gianelli (San Luis) Pump-Generating Plant is located along the  
41 along the western boundary of the O'Neill Forebay at the San Luis Dam

1 (Reclamation 2013l). This pump-generating plant is owned by the Federal  
 2 government but is operated as a joint Federal-State facility that is shared by the  
 3 CVP and SWP. Energy is generated when water is needed to be conveyed from  
 4 San Luis Reservoir back into O’Neill Forebay for continued conveyance to the  
 5 Delta-Mendota Canal. The plant is operated in pumping mode when water is  
 6 moved from O’Neill Forebay to San Luis Reservoir for storage until heavier water  
 7 demands develop. The generated power is used to offset CVP and SWP pumping  
 8 loads. The powerplant can generate up to 424 megawatts, with the CVP share of  
 9 the total capacity being 202 megawatts. This facility is operated and maintained  
 10 by the State of California under an operation and maintenance agreement with  
 11 Reclamation.

12 **8.3.1.2 SWP Electric Generation Facilities**

13 The SWP power facilities are operated primarily to provide power for the SWP  
 14 facilities (DWR 2013b). The SWP power facilities and capacities are summarized  
 15 in Table 8.2. The SWP has power contracts with electric utilities and the  
 16 California Independent System Operator that act as exchange agreements with  
 17 utility companies for transmission and power sales/purchases. In all years, the  
 18 SWP must purchase additional power to meet pumping requirements.

19 **Table 8.2 State Water Project Hydroelectric Powerplants**

Facility	Installed Capacity (Megawatts)
Oroville Facilities	–
Hyatt Pumping-Generating Plant	645
Thermalito Diversion Dam Powerplant	3
Thermalito Pumping-Generating Plant	114
William R. Gianelli (San Luis) Pumping-Generating Plant (SWP share)	222
Alamo Powerplant	17
Mojave Siphon Powerplant	30
Devil Canyon Powerplant	276
Warne Powerplant	74

20 Source: DWR 2012

21 **8.3.1.2.1 Feather River Powerplants**

22 The Hyatt Pumping-Generating Plant is located on the channel between Lake  
 23 Oroville and the Thermalito Diversion Pool (DWR 2007). Water in the  
 24 Thermalito Diversion Pool can be pumped back to Lake Oroville to be released  
 25 through the Hyatt Pumping-Generating Plant and generate more electricity;  
 26 released through the Thermalito Diversion Dam Powerplant for delivery to the  
 27 low flow channel upstream of Thermalito Forebay; or conveyed to Thermalito  
 28 Forebay for subsequent release through the Thermalito Pumping-Generating  
 29 Plant. The combined Hyatt Pumping-Generating Plant and Thermalito Pumping-  
 30 Generating Plant generate approximately 2,200 gigawatt-hours of energy in a

1 median water year, while the 3 megawatts generated by Thermalito Diversion  
2 Dam Powerplant adds another 24 gigawatt-hours per year (DWR 2013).

### 3 **8.3.1.2.2 San Luis Reservoir Powerplant**

4 As described above, the William R. Gianelli (San Luis) Pump-Generating Plant is  
5 owned by the Federal government and is operated as a joint Federal-state facility  
6 that is shared by the CVP and SWP. The SWP water flows from the California  
7 Aqueduct into O'Neill Forebay downstream of the CVP's O'Neill Pump-  
8 Generating Plant. The pump-generating plant is located along the western  
9 boundary of the O'Neill Forebay at the San Luis Dam (DWR 2013a, 2013b,  
10 Reclamation 2013l). Electricity is generated when water is transferred from  
11 San Luis Reservoir back to O'Neill Forebay for continued conveyance in the  
12 California Aqueduct. The plant acts as a pumping plant when water is transferred  
13 from O'Neill Forebay to San Luis Reservoir. The generated power is used to  
14 offset CVP and SWP pumping loads. The powerplant can generate up to  
15 424 megawatts, with the SWP share of the total capacity being 222 megawatts.  
16 This facility is operated and maintained by the State of California under an  
17 operation and maintenance agreement with Reclamation.

### 18 **8.3.1.2.3 East Branch and West Branch Powerplants**

19 Downstream of the Antelope Valley, the California Aqueduct divides into the  
20 East Branch and West Branch. The Alamo Powerplant, Mojave Powerplant, and  
21 Devil Canyon Powerplant are located along the East Branch which conveys water  
22 into San Bernardino County (DWR 2013a, 2013b). The Warne Powerplant is  
23 located along the West Branch which conveys water into Los Angeles County.  
24 The generation rates vary at these powerplants depending upon the amount of  
25 water conveyed.

### 26 **8.3.1.2.4 Other Energy Resources for the State Water Project**

27 Other energy supplies have been obtained by DWR from other utilities and energy  
28 marketers under agreements that allow DWR to buy, sell, or exchange energy on  
29 a short-term hourly basis or a long-term multi-year basis (DWR 2013a, 2013b).

30 For example, DWR jointly developed the 1,254-megawatt Castaic Powerplant on  
31 the West Branch with the Los Angeles Department of Water and Power (DWR  
32 2012, 2013). The power is available to DWR at the Sylmar Substation.

33 DWR has a long-term purchase agreement with the Kings River Conservation  
34 District for the approximately 400 million kilowatt-hours of energy from the  
35 165-megawatt hydroelectric Pine Flat Powerplant (DWR 2012, 2013). DWR also  
36 purchases energy from five hydroelectric plants with 30 megawatts of installed  
37 capacity that are owned and operated by Metropolitan Water District of Southern  
38 California (DWR 2012, 2013).

39 DWR also purchases energy under short-term purchase agreements from utilities  
40 and energy marketers of the Western Systems Power Pool (DWR 2012, 2013). In  
41 addition, the 1988 Coordination Agreement between DWR and Metropolitan

1 Water District of Southern Californian enables DWR to purchase and exchange  
2 energy (DWR 2012, 2013).

### 3 **8.3.2 Other Hydroelectric Generation Facilities**

4 Hydroelectric facilities in addition to CVP and SWP hydroelectric facilities in the  
5 study area are owned by investor-owned utility companies, such as Pacific Gas &  
6 Electric Company and Southern California Edison; municipal agencies, such as  
7 Sacramento Municipal Utility District; and by local and regional water agencies.  
8 Some of the larger facilities outside the CVP and SWP systems and within or  
9 adjacent to the study area include (DWR 2013d; 2013e; YCWA 2012):

- 10 • Pacific Gas and Electric Company
  - 11 – Helms Pumped Storage (1,200 megawatts) in Fresno County.
  - 12 – Pit System (320 megawatts) and McCloud-Pit System (370 megawatts,  
13 total) in Shasta County.
  - 14 – Upper North Fork Feather River System (360 megawatts) in Plumas  
15 County.
- 16 • Sacramento Municipal Utility District Upper American River Project System  
17 (688 megawatts) in El Dorado County.
- 18 • City and County of San Francisco Hetch Hetchy Power System  
19 (390 megawatts) in Tuolumne County.
- 20 • Southern California Edison
  - 21 – Big Creek System and Eastwood Pump Storage (approximately  
22 1,000 megawatts) in Fresno and Madera counties.
  - 23 – Mammoth Pool Project (187 megawatts) in Fresno and Madera counties.
- 24 • Turlock Irrigation District and Modesto Irrigation District New Don Pedro  
25 Project (203 megawatts) in Tuolumne County.
- 26 • Yuba County Water Agency Yuba River Development Project  
27 (390 megawatts) in Yuba County.

### 28 **8.3.3 CVP and SWP System Energy Demands**

29 Power generation at CVP and SWP hydropower facilities fluctuates in response to  
30 reservoir releases and conveyance flows. Reservoir releases are significantly  
31 affected by hydrologic conditions, minimum stream flow requirements, flow  
32 fluctuation restrictions, water quality requirements, and non-CVP and non-SWP  
33 water rights which must be met prior to releases for CVP water service  
34 contractors and SWP entitlement holders.

#### 35 **8.3.3.1 CVP Power Generation and Energy Use**

36 The CVP power generation facilities were developed to meet CVP energy use  
37 loads.

1 The majority of the energy used by the CVP is needed for pumping plants located  
 2 in the Delta, at San Luis Reservoir, and along the Delta-Mendota Canal and San  
 3 Luis Canal portion of the California Aqueduct. Table 8.3 presents historical  
 4 average annual CVP hydropower generation and use. Monthly power generation  
 5 pattern follows seasonal reservoir releases, with peaks during the irrigation  
 6 season, as shown on Figure 8.2. The hydropower generation between January and  
 7 June decreases after 2007 because the potential to convey CVP water across the  
 8 Delta during this period was reduced after 2007 to reduce reverse flows in Old  
 9 and Middle River, in accordance with legal decisions and subsequently through  
 10 implementation of the biological opinions.

11 **Table 8.3 Hydropower Generation and Energy Use by the CVP**

Calendar Year	Water Year Type <sup>a</sup>	Net CVP Hydropower Generation (Gigawatt-hours)	Energy Used CVP Facilities (Gigawatt-hours)
2000	AN	5,667	–
2001	D	4,107	957
2002	D	4,322	1,090
2003	AN	5,483	1,170
2004	BN	5,186	1,172
2005	AN	4,599	1,150
2006	W	7,284	1,037
2007	D	4,276	1,064
2008	C	3,659	923
2009	D	3,560	803
2010	BN	3,624	1,001
2011	W	5,469	1,276
2012	BN	4,849	990

12 Sources: Reclamation 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008a-l, 2009a-l,  
 13 2010a-l, 2011a-l, 2012b-m.

14 Note:

15 a. Water Year Type based on Sacramento Valley 40-30-30 Index, as described in  
 16 Chapter 5, Surface Water Resources and Water Supplies.

17 Recently, the California Public Utilities Commission (CPUC) evaluated the  
 18 “energy intensity” of several types of water supplies (CPUC 2010). The energy  
 19 intensity is defined as the average amount of energy required to convey and/or  
 20 treat water on a unit basis, such as per 1 acre-foot. Substantial quantities of  
 21 energy are required by the CVP pumping plants to convey large amounts of water  
 22 over long distances with significant changes in elevation. The study indicated  
 23 that the energy intensity of CVP water delivered to users downstream of San Luis  
 24 Reservoir ranged from 0.292 megawatt-hours/acre-foot for users along the Delta-  
 25 Mendota Canal; to 0.428 megawatt-hours/acre-foot for users along the San Luis

1 Canal/California Aqueduct; to 0.870 megawatt-hours/acre-foot in San Benito and  
2 Santa Clara counties.

### 3 **8.3.3.2 SWP Power Generation and Energy Use**

4 The SWP power generation facilities also were developed to meet SWP energy  
5 use loads. The majority of the energy used by the SWP is needed for pumping  
6 plants located in the Delta, at the San Luis Reservoir, and along the California  
7 Aqueduct. Table 8.4 presents historical average annual SWP hydropower  
8 generation and use. Monthly power generation pattern follows seasonal reservoir  
9 releases, with peaks during the irrigation season, as shown on Figure 8.3.  
10 Table 8.4 presents SWP power use and generation values for the period 2001  
11 through 2012 that indicate the SWP generates approximately 63 percent of the  
12 energy needed for deliveries (DWR 2002, 2004a, 2004b, 2005, 2006, 2007, 2008,  
13 2012a, 2012b, 2013). The energy generation and purchases and energy use  
14 decreases after 2007 because the potential to convey SWP water across the Delta  
15 was reduced in accordance with legal decisions and subsequently through  
16 implementation of the biological opinions.

17 **Table 8.4 Hydropower Generation and Energy Use by the State Water Project**

Calendar Year	Water Year Type <sup>a</sup>	SWP Hydropower Generation (Gigawatt-hour)	Energy Acquired through Long-term Agreements and Purchases (Gigawatt-hour)	Energy Used by SWP Facilities (Gigawatt-hour)
2000	AN	6,372	5,741	9,190
2001	D	4,295	4,660	6,656
2002	D	4,953	4,610	8,394
2003	AN	5,511	4,668	9,175
2004	BN	6,056	4,429	9,868
2005	AN	5,151	5,367	8,308
2006	W	7,056	5,811	9,158
2007	D	5,577	6,642	9,773
2008	C	3,541	4,603	5,745
2009	D	4,295	4,660	6,656
2010	BN	4,953	4,610	8,394
2011	W	5,511	4,668	9,175
2012	BN	6,056	4,429	9,868

18 Sources: DWR 2002, 2004a, 2004b, 2005, 2006, 2007, 2008, 2012a, 2012b, 2013

19 Note:

20 a. Water Year Type based on Sacramento Valley 40-30-30 Index, as described in  
21 Chapter 5, Surface Water Resources and Water Supplies.

1 The energy intensity values calculated by the California Public Utilities  
2 Commission for the SWP ranged from 1.128 megawatt-hours/acre-foot for water  
3 users along the South Bay Aqueduct; to 1.157 megawatt-hours/acre-foot for water  
4 users in Kern County; to 4,644 megawatt-hours/acre-foot for water users at the  
5 terminal end of the East Branch Extension of the California Aqueduct (CPUC  
6 2010).

### 7 **8.3.4 Energy Demands for Groundwater Pumping**

8 Groundwater provided approximately 37 percent of the state’s agricultural,  
9 municipal, and industrial water supply of the average water needs between 1998  
10 and 2010, or approximately 16 million acre-feet/year of groundwater (DWR  
11 2013). The use of groundwater varies regionally throughout the State. For  
12 example in some areas, groundwater provides less than 10 percent to more than  
13 90 percent, as described in Chapter 7, Groundwater Resources and Groundwater  
14 Quality.

15 The amount of energy used statewide to pump groundwater is not well quantified  
16 (CPUC 2010). The California Public Utilities Commission estimated  
17 groundwater energy use by hydrologic region and by type of use to evaluate the  
18 water and energy relationships. Groundwater pumping estimates were calculated  
19 in each DWR Planning Areas for agricultural and municipal water demands.  
20 Groundwater energy use was estimated based upon assumptions of well depths  
21 and pump efficiencies. Some wells use natural gas for individual engines instead  
22 of electricity; however, the amount of natural gas pumping versus electric  
23 pumping is generally unknown. In 2010, average groundwater use in the state  
24 was approximately 14.7 million acre-feet, or 36 percent of total agricultural,  
25 municipal, and industrial water supplies (DWR 2013). The California Public  
26 Utilities Commission estimated that in 2010, statewide groundwater pumping  
27 accounted for more electricity use between May and August than the total  
28 electricity use by the CVP and SWP during that time period (CPUC 2010). Over  
29 the entire year, it was estimated that groundwater pumping used approximately  
30 10 percent more electricity than the SWP and approximately 5 percent less than  
31 the CVP and SWP combined.

## 32 **8.4 Impact Analysis**

33 This section describes the potential mechanisms for change in energy generation  
34 and analytical methods; results of the impact analyses; potential mitigation  
35 measures; and cumulative effects.

### 36 **8.4.1 Potential Mechanisms for Change and Analytical Tools**

37 The environmental consequences assessment considers changes in energy  
38 resources conditions related to changes in CVP and SWP operations under the  
39 alternatives as compared to the No Action Alternative and Second Basis of  
40 Comparison.

1     **8.4.1.1     Changes in Energy Resources Related to CVP and SWP Water**  
 2                   **Users**

3     Energy generation is limited on a monthly bases by the average power capacity of  
 4     each generation facility based upon reservoir elevations and water release  
 5     patterns. The majority of the CVP and SWP energy use is for the conveyance  
 6     facilities located in the Delta and south of the Delta. Energy use would change  
 7     with changes in CVP and SWP deliveries.

8     Reservoir elevations and flow patterns through pumping facilities output from the  
 9     CalSim II model (see Chapter 5, Surface Water Resources and Water Supplies)  
 10    are used with LTGen and SWP Power tools, as described in Appendix 8A, Power  
 11    Model Documentation. These tools estimate average annual peaking power  
 12    capacity, energy use, and energy generation at CVP and SWP facilities,  
 13    respectively. The tools estimate average annual energy generation and use and  
 14    net generation. When net generation values are negative, the CVP or SWP would  
 15    purchase power from other generation facilities. When net generation values are  
 16    positive, power would be available for use by non-CVP and SWP electricity  
 17    users.

18    When CVP and SWP water deliveries change, water users would be anticipated  
 19    to change their use of groundwater, recycled water, and/or desalinated water, as  
 20    described in Chapter 5, Surface Water Resources and Water Supplies, Chapter 12,  
 21    Agricultural Resources, and Chapter 19, Socioeconomics. Specific responses by  
 22    water users to changes in CVP and SWP water deliveries are not known; and  
 23    therefore, energy use for the alternate water supplies cannot be quantified in this  
 24    analysis. It is not known whether the net change in energy use for the CVP and  
 25    SWP would or would not be similar to the net change in energy use for alternate  
 26    water supplies (e.g., groundwater pumping, water treatment, water conveyance).

27    **8.4.1.2     Effect Related to Cross Delta Water Transfers**

28    Historically water transfer programs have been developed on an annual basis.  
 29    The demand for water transfers is dependent upon the availability of water  
 30    supplies to meet water demands. Water transfer transactions have increased over  
 31    time as CVP and SWP water supply availability has decreased, especially during  
 32    drier water years. Water transfers using CVP and SWP Delta pumping plants and  
 33    south of Delta canals generally occur when there is unused capacity in these  
 34    facilities, especially in drier years.

35    Parties seeking water transfers generally acquire water from sellers who have  
 36    available surface water who can make the water available through releasing  
 37    previously stored water, pump groundwater instead of using surface water  
 38    (groundwater substitution); idle crops; or substitute crops that uses less water in  
 39    order to reduce normal consumptive use of surface water.

40    Changes in net energy generation could occur statewide during cross Delta water  
 41    transfers due to following reasons:

- 42    • Changed reservoir release patterns at CVP and SWP reservoirs
- 43    • Changed conveyance patterns at the CVP and SWP pumping plants

- 1 • Increased groundwater pumping in the seller’s service area if groundwater  
2 substitution is used to make the transferred water available
- 3 • Reductions in groundwater pumping in the purchaser’s service area if less  
4 groundwater would be used due to the water transfer

5 Reclamation recently prepared a long-term regional water transfer environmental  
6 document which evaluated potential changes in surface water conditions related to  
7 water transfer actions (Reclamation 2014c). Results from this analysis were used  
8 to inform the impact assessment of potential effects of water transfers under the  
9 alternatives as compared to the No Action Alternative and the Second Basis of  
10 Comparison.

#### 11 **8.4.2 Conditions in Year 2030 without Implementation of** 12 **Alternatives 1 through 5**

13 The impact analysis in this EIS is based upon the comparison of the alternatives to  
14 the No Action Alternative and the Second Basis of Comparison in the Year 2030.  
15 Changes that would occur over the next 15 years without implementation of the  
16 alternatives are not analyzed in this EIS. However, the changes that are assumed  
17 to occur by 2030 under the No Action Alternative and the Second Basis of  
18 Comparison are summarized in this section.

19 Many of the changed conditions would occur in the same manner under both the  
20 No Action Alternative and the Second Basis of Comparison. Other future  
21 conditions would be different under the No Action Alternative as compared to the  
22 Second Basis of Comparison due to the implementation of the 2008 U.S. Fish and  
23 Wildlife Service (USFWS) Biological Opinion (BO) and 2009 National Marine  
24 Fisheries Service (NMFS) BO under the No Action Alternative.

25 This section of Chapter 8 provides qualitative projections of the No Action  
26 Alternative as compared to existing conditions described under the Affected  
27 Environment; and qualitative projections of the Second Basis of Comparison as  
28 compared to “recent historical conditions.” Recent historical conditions are not  
29 the same as existing conditions which include implementation of the 2008  
30 USFWS BO and 2009 NMFS BO; and consider changes that would have occurred  
31 without implementation of the 2008 USFWS BO and the 2009 NMFS BO.

##### 32 **8.4.2.1 Common Changes in Conditions under the No Action Alternative** 33 **and Second Basis of Comparison**

34 Conditions in 2030 would be different than existing conditions due to:

- 35 • Climate change and sea-level rise
- 36 • General plan development throughout California, including increased water  
37 demands in portions of Sacramento Valley
- 38 • Implementation of reasonable and foreseeable water resources management  
39 projects to provide water supplies

40 These changes would result in a decline of the long-term average CVP and SWP  
41 water supply deliveries by 2030 as compared to recent historical long-term

1 average deliveries, as described in Chapter 5, Surface Water Resources and Water  
2 Supplies.

#### 3 **8.4.2.1.1 Changes in Conditions due to Climate Change and Sea Level Rise**

4 It is anticipated that climate change would result in more short-duration high-  
5 rainfall events and less snowpack in the winter and early spring months. The  
6 reservoirs would be full more frequently by the end of April or May by 2030 than  
7 in recent historical conditions. However, as the water is released in the spring,  
8 there would be less snowpack to refill the reservoirs. This condition would  
9 reduce reservoir storage and potential hydropower generation in the summer.  
10 These conditions would occur for all reservoirs in the California foothills and  
11 mountains, including non-CVP and SWP reservoirs.

#### 12 **8.4.2.1.2 General Plan Development in California**

13 Counties and cities throughout California have adopted general plans which  
14 identify land use classifications including those for municipal and industrial uses  
15 and those for agricultural uses. Population projections from those general plan  
16 evaluations are provided to the State Department of Finance and are used to  
17 project future water needs and the potential for conversion of existing  
18 undeveloped lands and agricultural lands. Many of the existing general plans for  
19 counties with municipal areas recently have been modified to include land use and  
20 population projections through 2030. The No Action Alternative and the Second  
21 Basis of Comparison assume that land uses will develop through 2030 in  
22 accordance with existing general plans.

23 Statewide the increased population would result in increased energy demands.  
24 Under the No Action Alternative and Second Basis of Comparison, it is assumed  
25 that energy demands would be met on a long-term basis and in dry and critical dry  
26 years using a combination of conservation, increased efficiency in energy  
27 generation and transmission, and renewable energy sources.

#### 28 **8.4.2.1.3 Reasonable and Foreseeable Water Resources Management** 29 **Projects**

30 The No Action Alternative and the Second Basis of Comparison assumes  
31 completion of water resources management and environmental restoration  
32 projects that would have occurred without implementation of the 2008 USFWS  
33 BO and 2009 NMFS BO by 2030, as described in Chapter 3, Description of  
34 Alternatives. Many of these future actions involve additional water treatment and  
35 conveyance facilities that would change statewide energy demands.

#### 36 **8.4.2.2 Changes in Conditions under the No Action Alternative**

37 Due to the climate change and sea level rise and increased water demands in the  
38 Sacramento Valley, CVP and SWP energy generation would be less in the  
39 summer months when energy demand is high for water conveyance and air  
40 conditioning equipment throughout the state. It is also anticipated that water  
41 deliveries would be less in 2030 than under recent historical conditions; and,

1 therefore, energy use for CVP and SWP water conveyance facilities would be  
2 less.

3 **8.4.2.3 Changes in Conditions under the Second Basis of Comparison**

4 Due to the climate change and sea level rise and increased water demands in the  
5 Sacramento Valley, CVP and SWP energy generation would be less in the  
6 summer months when energy demand is high for water conveyance and air  
7 conditioning equipment throughout the State. It is also anticipated that water  
8 deliveries would be less in 2030 than under recent historical conditions; and,  
9 therefore, energy use for CVP and SWP water conveyance facilities would be  
10 less.

11 As described in Chapter 5, Surface Water Resources and Water Supplies, the  
12 availability of CVP and SWP water supplies would be greater under the Second  
13 Basis of Comparison as compared to the No Action Alternative because CVP and  
14 SWP water operations would not include requirements of the 2008 USFWS BO  
15 and 2009 NMFS BO. Therefore, CVP and SWP energy use would be greater, and  
16 possibly groundwater pumping use would be less, under the Second Basis of  
17 Comparison as compared to the No Action Alternative.

18 **8.4.3 Evaluation of Alternatives**

19 As described in Chapter 4, Approach to Environmental Analysis, Alternatives 1  
20 through 5 have been compared to the No Action Alternative; and the No Action  
21 Alternative and Alternatives 1 through 5 have been compared to the Second Basis  
22 of Comparison.

23 During review of the numerical modeling analyses used in this EIS, an error was  
24 determined in the CalSim II model assumptions related to the Stanislaus River  
25 operations for the Second Basis of Comparison, Alternative 1, and Alternative 4  
26 model runs. Appendix 5C includes a comparison of the CalSim II model run  
27 results presented in this chapter and CalSim II model run results with the error  
28 corrected. Appendix 5C also includes a discussion of changes in the comparison  
29 of groundwater conditions for the following alternative analyses.

- 30 • No Action Alternative compared to the Second Basis of Comparison
- 31 • Alternative 1 compared to the No Action Alternative
- 32 • Alternative 3 compared to the Second Basis of Comparison
- 33 • Alternative 5 compared to the Second Basis of Comparison

34 **8.4.3.1 No Action Alternative**

35 The No Action Alternative is compared to the Second Basis of Comparison.

36 **8.4.3.1.1 Potential Changes in Energy Resources Related to CVP and SWP**  
37 **Water Users**

38 Changes in CVP and SWP operations under the No Action Alternative as  
39 compared to the Second Basis of Comparison would result in a reduction of CVP  
40 and SWP water deliveries to areas located south of the Delta; and therefore,

1 annual energy use would result in changes in CVP and SWP energy resources, as  
 2 summarized in Table 8.5. The CVP net generation over the long-term conditions  
 3 (averaged over the 81-year model simulation period, as described in Chapter 5)  
 4 and in dry and critical dry years would be similar (within 5 percent) under the  
 5 No Action Alternative and the Second Basis of Comparison. The SWP net  
 6 generation would be reduced by 29 percent over the long-term condition and by  
 7 37 percent in dry and critical dry years. Changes in monthly energy use are  
 8 presented in Appendix 8A, Power Model Documentation.

9 **Table 8.5 Energy Generation, Energy Use, and Net Generation under the No Action**  
 10 **Alternative as Compared to the Second Basis of Comparison**

<b>Project</b>	<b>Water Year</b>	<b>Energy (Gigawatt-hours)</b>	<b>No Action Alternative (NAA)</b>	<b>Second Basis of Comparison (SBC)</b>	<b>Changes between NAA and SBC</b>
CVP Facilities	Long-term Average	Energy Generation	4,558	4,604	-46
		Energy Use	1,113	1,289	-177
		Net Generation	3,445	3,315	131
	Dry and Critical Water Years	Energy Generation	2,696	2,773	-77
		Energy Use	699	773	-75
		Net Generation	1,997	2,000	-2
SWP Facilities	Long-term Average	Energy Generation	4,202	4,721	-520
		Energy Use	7,798	9,802	-2,004
		Net Generation	-3,597	-5,081	1,484
	Dry and Critical Water Years	Energy Generation	1,914	2,494	-579
		Energy Use	3,929	5,686	-1,757
		Net Generation	-2,015	-3,192	1,177

11 Under the No Action Alternative as compared to the Second Basis of  
 12 Comparison, CVP and SWP water deliveries would be less and it is anticipated

1 that CVP and SWP water users would use more alternate water supplies. These  
2 alternate water supplies would require energy. Specific changes in energy use  
3 would depend upon specific responses by water users, and are not known at this  
4 time. Therefore, it is uncertain whether the increased regional and local water  
5 supply energy requirements would be similar to the reduced energy use by the  
6 CVP and SWP operations in 2030 under the No Action Alternative as compared  
7 to the Second Basis of Comparison. For the purposes of this analysis, a worse-  
8 case scenario is assumed, and that total energy use by CVP and SWP water users  
9 could be higher under the No Action Alternative than under the Second Basis of  
10 Comparison.

#### 11 **8.4.3.1.2 Effects Related to Cross Delta Water Transfers**

12 Potential effects to energy resources could be similar to those identified in a  
13 recent environmental analysis conducted by Reclamation for long-term water  
14 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c).  
15 Potential effects to energy resources were identified as changes in power  
16 generation patterns at the reservoirs due to changes in reservoir release patterns  
17 and surface water elevation patterns. These potential changes were not  
18 considered to be substantial because the total amount of electricity generated  
19 would be similar and the power loss would be minimal due to changes in release  
20 patterns. For the purposes of this EIS, it is anticipated that similar conditions  
21 would occur during implementation of cross Delta water transfers under the  
22 No Action Alternative and the Second Basis of Comparison.

23 Groundwater pumping in areas that purchase the transferred water could be  
24 reduced if additional surface water is provided. However, if the transferred water  
25 is used to meet water demands that would not have been met (e.g., crops that had  
26 been idled), groundwater pumping would be similar with or without water  
27 transfers.

28 Under the No Action Alternative, the timing of cross Delta water transfers would  
29 be limited to July through September and include annual volumetric limits, in  
30 accordance with the 2008 USFWS BO and 2009 NMFS BO. Under the Second  
31 Basis of Comparison, water could be transferred throughout the year without an  
32 annual volumetric limit. Overall, the potential for cross Delta water transfers  
33 would be less under the No Action Alternative than under the Second Basis of  
34 Comparison; however, energy resources conditions would be similar.

#### 35 **8.4.3.2 Alternative 1**

36 Alternative 1 is identical to the Second Basis of Comparison. Alternative 1 is  
37 compared to the No Action Alternative and the Second Basis of Comparison.  
38 However, because energy resource conditions under Alternative 1 are identical to  
39 energy resource conditions under the Second Basis of Comparison; Alternative 1  
40 is only compared to the No Action Alternative.

1 **8.4.3.2.1 Alternative 1 Compared to the No Action Alternative**

2 *Potential Changes in Energy Resources Related to CVP and SWP Water Users*

3 Changes in CVP and SWP operations under Alternative 1 as compared to the No  
 4 Action Alternative would result in an increase of CVP and SWP water deliveries  
 5 to areas located south of the Delta; and therefore, annual energy use would result  
 6 in changes in CVP and SWP energy resources, as summarized in Table 8.6. The  
 7 CVP net generation over the long-term conditions and in dry and critical dry years  
 8 would be similar under Alternative 1 as compared to the No Action Alternative.  
 9 The SWP net generation would be increased by 41 percent over the long-term  
 10 condition and by 58 percent in dry and critical dry years. Changes in monthly  
 11 energy use are presented in Appendix 8A, Power Model Documentation.

12 **Table 8.6 Energy Generation, Energy Use, and Net Generation under Alternative 1**  
 13 **as Compared to the No Action Alternative**

Project	Water Year	Energy (Gigawatt-hours)	Alternative 1	No Action Alternative (NAA)	Changes between Alternative 1 and NAA
CVP Facilities	Long-term Average	Energy Generation	4,604	4,558	46
		Energy Use	1,289	1,113	177
		Net Generation	3,315	3,445	-131
	Dry and Critical Water Years	Energy Generation	2,773	2,696	77
		Energy Use	773	699	75
		Net Generation	2,000	1,997	2
SWP Facilities	Long-term Average	Energy Generation	4,721	4,202	520
		Energy Use	9,802	7,798	2,004
		Net Generation	-5,081	-3,597	-1,484
	Dry and Critical Water Years	Energy Generation	2,494	1,914	579
		Energy Use	5,686	3,929	1,757
		Net Generation	-3,192	-2,015	-1,177

1 Under Alternative 1 as compared to the No Action Alternative, CVP and SWP  
2 water deliveries would be increased and it is anticipated that CVP and SWP water  
3 users would use less alternate water supplies. Specific changes in energy use  
4 would depend upon specific responses by water users, and are not known at this  
5 time. Therefore, it is uncertain whether the decreased regional and local water  
6 supply energy requirements would be similar to the increased energy use by the  
7 CVP and SWP operations in 2030 under Alternative 1 as compared to the No  
8 Action Alternative. For the purposes of this analysis, a worse-case scenario is  
9 assumed, and that total energy use by CVP and SWP water users could be lower  
10 under Alternative 1 as compared to the No Action Alternative.

#### 11 *Effects Related to Cross Delta Water Transfers*

12 Potential effects to energy resources could be similar to those identified in a  
13 recent environmental analysis conducted by Reclamation for long-term water  
14 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
15 described above under the No Action Alternative compared to the Second Basis  
16 of Comparison. For the purposes of this EIS, it is anticipated that similar energy  
17 conditions would occur during implementation of cross Delta water transfers  
18 under Alternative 1 and the No Action Alternative.

19 Under Alternative 1, water could be transferred throughout the year without an  
20 annual volumetric limit. Under the No Action Alternative, the timing of cross  
21 Delta water transfers would be limited to July through September and include  
22 annual volumetric limits, in accordance with the 2008 USFWS BO and 2009  
23 NMFS BO. Overall, the potential for cross Delta water transfers would be  
24 increased under Alternative 1 as compared to the No Action Alternative; however,  
25 energy resources conditions would be similar.

#### 26 **8.4.3.2 Alternative 1 Compared to the Second Basis of Comparison**

27 Alternative 1 is identical to the Second Basis of Comparison.

#### 28 **8.4.3.3 Alternative 2**

29 The CVP and SWP operations under Alternative 2 are identical to the CVP and  
30 SWP operations under the No Action Alternative; therefore, the energy resources  
31 conditions under Alternative 2 is only compared to the Second Basis of  
32 Comparison.

#### 33 **8.4.3.3.1 Alternative 2 Compared to the Second Basis of Comparison**

34 Changes to energy resources under Alternatives 2 as compared to the Second  
35 Basis of Comparison would be the same as the impacts described in  
36 Section 8.4.3.1, No Action Alternative.

#### 37 **8.4.3.4 Alternative 3**

38 CVP and SWP operations under Alternative 3 are similar to the Second Basis of  
39 Comparison with modified Old and Middle River flow criteria and New Melones  
40 Reservoir operations. Alternative 3 would include changed water demands for  
41 American River water supplies as compared to the No Action Alternative or

1 Second Basis of Comparison. Alternative 3 would provide water supplies of up to  
 2 17 TAF/year under a Warren Act Contract for El Dorado Irrigation District and  
 3 15 TAF/year under a Warren Act Contract for El Dorado County Water Agency.  
 4 These demands are not included in the analysis presented in this section of the  
 5 EIS. A sensitivity analysis comparing the results of the analysis with and without  
 6 these demands is presented in Appendix 5B of this EIS.

#### 7 **8.4.3.4.1 Alternative 3 Compared to the No Action Alternative**

##### 8 *Potential Changes in Energy Resources to CVP and SWP Water Users*

9 Changes in CVP and SWP operations under Alternative 3 as compared to the No  
 10 Action Alternative would result in changes in CVP and SWP energy resources, as  
 11 summarized in Table 8.7. The CVP net generation over the long-term conditions  
 12 and in dry and critical dry years would be similar under Alternative 3 as compared  
 13 to the No Action Alternative. The SWP net generation would be increased by  
 14 27 percent over the long-term condition and by 16 percent in dry and critical dry  
 15 years. Changes in monthly energy use are presented in Appendix 8A, Power  
 16 Model Documentation.

17 **Table 8.7 Energy Generation, Energy Use, and Net Generation under Alternative 3**  
 18 **as Compared to the No Action Alternative**

Project	Water Year	Energy (Gigawatt-hours)	Alternative 3	No Action Alternative (NAA)	Changes between Alternative 3 and NAA
CVP Facilities	Long-term Average	Energy Generation	4,582	4,558	24
		Energy Use	1,238	1,113	125
		Net Generation	3,344	3,445	-102
	Dry and Critical Water Years	Energy Generation	2,798	2,696	102
		Energy Use	715	699	16
		Net Generation	2,084	1,997	86
SWP Facilities	Long-term Average	Energy Generation	4,537	4,202	335
		Energy Use	9,115	7,798	1,317
		Net Generation	-4,578	-3,597	-981

Project	Water Year	Energy (Gigawatt-hours)	Alternative 3	No Action Alternative (NAA)	Changes between Alternative 3 and NAA
	Dry and Critical Water Years	Energy Generation	2,128	1,914	214
		Energy Use	4,455	3,929	526
		Net Generation	-2,327	-2,015	-312

1 Under Alternative 3 as compared to the No Action Alternative, CVP and SWP  
 2 water deliveries would be increased and it is anticipated that CVP and SWP water  
 3 users would use less alternate water supplies. Specific changes in energy use  
 4 would depend upon specific responses by water users, and are not known at this  
 5 time. Therefore, it is uncertain whether the decreased regional and local water  
 6 supply energy requirements would be similar to the increased energy use by the  
 7 CVP and SWP operations in 2030 under Alternative 3 as compared to the No  
 8 Action Alternative. For the purposes of this analysis, a worse-case scenario is  
 9 assumed, and that total energy use by CVP and SWP water users could be lower  
 10 under Alternative 3 as compared to the No Action Alternative.

11 *Effects Related to Cross Delta Water Transfers*

12 Potential effects to energy resources could be similar to those identified in a  
 13 recent environmental analysis conducted by Reclamation for long-term water  
 14 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
 15 described above under the No Action Alternative compared to the Second Basis  
 16 of Comparison. For the purposes of this EIS, it is anticipated that similar energy  
 17 conditions would occur during implementation of cross Delta water transfers  
 18 under Alternative 3 and the No Action Alternative.

19 Under Alternative 3, water could be transferred throughout the year without an  
 20 annual volumetric limit. Under the No Action Alternative, the timing of cross  
 21 Delta water transfers would be limited to July through September and include  
 22 annual volumetric limits, in accordance with the 2008 USFWS BO and 2009  
 23 NMFS BO. Overall, the potential for cross Delta water transfers would be  
 24 increased under Alternative 3 as compared to the No Action Alternative; however,  
 25 energy resources conditions would be similar.

26 **8.4.3.4.2 Alternative 3 Compared to the Second Basis of Comparison**

27 *Potential Changes in Energy Resources to CVP and SWP Water Users*

28 Changes in CVP and SWP operations under Alternative 3 as compared to the  
 29 Second Basis of Comparison would result in changes in CVP and SWP energy  
 30 resources, as summarized in Table 8.8. The CVP net generation over the long-

1 term conditions and in dry and critical dry years would be similar under  
 2 Alternative 3 as compared to the Second Basis of Comparison. The SWP net  
 3 generation would be reduced by 10 percent over the long-term condition and by  
 4 58 percent in dry and critical dry years. Changes in monthly energy use are  
 5 presented in Appendix 8A, Power Model Documentation.

6 **Table 8.8 Energy Generation, Energy Use, and Net Generation under Alternative 3**  
 7 **as Compared to the Second Basis of Comparison**

Project	Water Year	Energy (Gigawatt-hours)	Alternative 3	Second Basis of Comparison (SBC)	Changes between Alternative 3 and SBC
CVP Facilities	Long-term Average	Energy Generation	4,582	4,604	-22
		Energy Use	1,238	1,289	-51
		Net Generation	3,344	3,315	29
	Dry and Critical Water Years	Energy Generation	2,798	2,773	25
		Energy Use	715	773	-59
		Net Generation	2,084	2,000	84
SWP Facilities	Long-term Average	Energy Generation	4,537	4,721	-184
		Energy Use	9,115	9,802	-687
		Net Generation	-4,578	-5,081	503
	Dry and Critical Water Years	Energy Generation	2,128	2,494	-366
		Energy Use	4,455	5,686	-1,230
		Net Generation	-2,327	-3,192	865

8 Under Alternative 3 as compared to the Second Basis of Comparison, CVP and  
 9 SWP water deliveries would be decreased and it is anticipated that CVP and SWP  
 10 water users would use more alternate water supplies. Specific changes in energy  
 11 use would depend upon specific responses by water users, and are not known at  
 12 this time. Therefore, it is uncertain whether the increased regional and local water  
 13 supply energy requirements would be similar to the decreased energy use by the  
 14 CVP and SWP operations in 2030 under Alternative 3 as compared to the Second  
 15 Basis of Comparison. For the purposes of this analysis, a worse-case scenario is

1 assumed, and that total energy use by CVP and SWP water users could be higher  
2 under Alternative 3 as compared to the Second Basis of Comparison.

3 *Effects Related to Cross Delta Water Transfers*

4 Potential effects to energy resources could be similar to those identified in a  
5 recent environmental analysis conducted by Reclamation for long-term water  
6 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
7 described above under the No Action Alternative compared to the Second Basis  
8 of Comparison. For the purposes of this EIS, it is anticipated that similar energy  
9 conditions would occur during implementation of cross Delta water transfers  
10 under Alternative 3 as compared to the Second Basis of Comparison.

11 Under Alternative 3 and the Second Basis of Comparison, water could be  
12 transferred throughout the year without an annual volumetric limit. Overall, the  
13 potential for cross Delta water transfers would be similar under Alternative 3 as  
14 compared to the Second Basis of Comparison; and energy resources conditions  
15 would be similar.

16 **8.4.3.5 Alternative 4**

17 Energy resources under Alternative 4 would be identical to the conditions under  
18 the Second Basis of Comparison. Alternative 4 is only compared to the No  
19 Action Alternative.

20 **8.4.3.5.1 Alternative 4 Compared to the No Action Alternative**

21 Changes in energy resources under Alternative 4 as compared to the No Action  
22 Alternative would be the same as the impacts described in Section 8.4.3.2.1,  
23 Alternative 1 Compared to the No Action Alternative.

24 **8.4.3.6 Alternative 5**

25 The CVP and SWP operations under Alternative 5 are similar to the No Action  
26 Alternative with modified Old and Middle River flow criteria and New Melones  
27 Reservoir operations. Alternative 5 would include changed water demands for  
28 American River water supplies as compared to the No Action Alternative or  
29 Second Basis of Comparison. Alternative 5 would provide water supplies of up to  
30 17 TAF/year under a Warren Act Contract for El Dorado Irrigation District and  
31 15 TAF/year under a Warren Act Contract for El Dorado County Water Agency.  
32 These demands are not included in the analysis presented in this section of the  
33 EIS. A sensitivity analysis comparing the results of the analysis with and without  
34 these demands is presented in Appendix 5B of this EIS.

35 **8.4.3.6.1 Alternative 5 Compared to the No Action Alternative**

36 *Potential Changes in Energy Resources to CVP and SWP Water Users*

37 Changes in CVP and SWP operations under Alternative 5 as compared to the No  
38 Action Alternative would result in changes in CVP and SWP energy resources, as  
39 summarized in Table 8.9. The CVP and SWP net generation over the long-term  
40 conditions and in dry and critical dry years would be similar under Alternative 5

1 as compared to the No Action Alternative. Changes in monthly energy use are  
 2 presented in Appendix 8A, Power Model Documentation.

3 **Table 8.9 Energy Generation, Energy Use, and Net Generation under Alternative 5**  
 4 **as Compared to the No Action Alternative**

Project	Water Year	Energy (Gigawatt-hours)	Alternative 3	Second Basis of Comparison (SBC)	Changes between Alternative 3 and SBC
CVP Facilities	Long-term Average	Energy Generation	4,552	4,558	-6
		Energy Use	1,110	1,113	-3
		Net Generation	3,442	3,445	-4
	Dry and Critical Water Years	Energy Generation	2,684	2,696	-12
		Energy Use	699	699	0
		Net Generation	1,986	1,997	-11
SWP Facilities	Long-term Average	Energy Generation	4,191	4,202	-11
		Energy Use	7,732	7,798	-66
		Net Generation	-3,541	-3,597	56
	Dry and Critical Water Years	Energy Generation	1,904	1,914	-10
		Energy Use	3,841	3,929	-88
		Net Generation	-1,937	-2,015	78

5 Under Alternative 5 as compared to the No Action Alternative, CVP and SWP  
 6 water deliveries would be similar, and it is anticipated that CVP and SWP water  
 7 users would use similar alternate water supplies. Therefore, for the purposes of  
 8 this analysis, it is assumed that total energy use by CVP and SWP water users  
 9 could be similar under Alternative 5 as compared to the No Action Alternative.

10 *Effects Related to Cross Delta Water Transfers*

11 Potential effects to energy resources could be similar to those identified in a  
 12 recent environmental analysis conducted by Reclamation for long-term water  
 13 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
 14 described above under the No Action Alternative compared to the Second Basis

1 of Comparison. For the purposes of this EIS, it is anticipated that similar energy  
 2 conditions would occur during implementation of cross Delta water transfers  
 3 under Alternative 5 and the No Action Alternative.

4 Under Alternative 5 and the No Action Alternative, the timing of cross Delta  
 5 water transfers would be limited to July through September and include annual  
 6 volumetric limits, in accordance with the 2008 USFWS BO and 2009 NMFS BO.  
 7 Overall, the potential for cross Delta water transfers would be similar under  
 8 Alternative 5 as compared to the No Action Alternative; and energy resources  
 9 conditions would be similar.

10 **8.4.3.6.2 Alternative 5 Compared to the Second Basis of Comparison**

11 *Potential Changes in Energy Resources to CVP and SWP Water Users*

12 Changes in CVP and SWP operations under Alternative 5 as compared to the  
 13 Second Basis of Comparison would result in changes in CVP and SWP energy  
 14 resources, as summarized in Table 8.10. The CVP net generation over the long-  
 15 term conditions and in dry and critical dry years would be similar under  
 16 Alternative 3 as compared to the Second Basis of Comparison. The SWP net  
 17 generation would be reduced by 30 percent over the long-term condition and by  
 18 39 percent in dry and critical dry years. Changes in monthly energy use are  
 19 presented in Appendix 8A, Power Model Documentation.

20 **Table 8.10 Energy Generation, Energy Use, and Net Generation under Alternative 5**  
 21 **as Compared to the Second Basis of Comparison**

Project	Water Year	Energy (Gigawatt-hours)	Alternative 5	Second Basis of Comparison (SBC)	Changes between Alternative 5 and SBC
CVP Facilities	Long-term Average	Energy Generation	4,552	4,604	-52
		Energy Use	1,110	1,289	-179
		Net Generation	3,442	3,315	127
	Dry and Critical Water Years	Energy Generation	2,684	2,773	-89
		Energy Use	699	773	-75
		Net Generation	1,986	2,000	-14
SWP Facilities	Long-term Average	Energy Generation	4,191	4,721	-530
		Energy Use	7,732	9,802	-2,070
		Net Generation	-3,541	-5,081	1,540

Project	Water Year	Energy (Gigawatt-hours)	Alternative 5	Second Basis of Comparison (SBC)	Changes between Alternative 5 and SBC
	Dry and Critical Water Years	Energy Generation	1,904	2,494	-590
		Energy Use	3,841	5,686	-1,845

1 Under Alternative 5 as compared to the Second Basis of Comparison, CVP and  
2 SWP water deliveries would be decreased and it is anticipated that CVP and SWP  
3 water users would use more alternate water supplies. Specific changes in energy  
4 use would depend upon specific responses by water users, and are not known at  
5 this time. Therefore, it is uncertain whether the increased regional and local water  
6 supply energy requirements would be similar to the decreased energy use by the  
7 CVP and SWP operations in 2030 under Alternative 5 as compared to the Second  
8 Basis of Comparison. For the purposes of this analysis, a worse-case scenario is  
9 assumed, and that total energy use by CVP and SWP water users could be higher  
10 under Alternative 5 as compared to the Second Basis of Comparison.

#### 11 *Effects Related to Cross Delta Water Transfers*

12 Potential effects to energy resources could be similar to those identified in a  
13 recent environmental analysis conducted by Reclamation for long-term water  
14 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014c), as  
15 described above under the No Action Alternative compared to the Second Basis  
16 of Comparison. For the purposes of this EIS, it is anticipated that similar energy  
17 conditions would occur during implementation of cross Delta water transfers  
18 under Alternative 5 as compared to the Second Basis of Comparison.

19 Under Alternative 5, the timing of cross Delta water transfers would be limited to  
20 July through September and include annual volumetric limits, in accordance with  
21 the 2008 USFWS BO and 2009 NMFS BO. Under Second Basis of Comparison,  
22 water could be transferred throughout the year without an annual volumetric limit.  
23 Overall, the potential for cross Delta water transfers would be reduced under  
24 Alternative 5 as compared to the Second Basis of Comparison; however, energy  
25 resources conditions would be similar.

#### 26 **8.4.3.7 Summary of Impact Analysis**

27 The results of the environmental consequences of implementation of Alternatives  
28 1 through 5 as compared to the No Action Alternative and the Second Basis of  
29 Comparison are presented in Tables 8.11 and 8.12.

1 **Table 8.11 Comparison of Alternatives 1 through 5 to No Action Alternative**

Alternative	Potential Change	Consideration for Mitigation Measures
Alternative 1	<p>CVP annual net generation would be similar.</p> <p>SWP annual net generation would be increased by 41 percent over the long-term condition; and by 58 percent in dry and critical dry years.</p> <p>Total energy use by CVP and SWP water users, including energy for alternate water supplies, is assumed to decrease.</p>	None needed.
Alternative 2	No effects on energy resources.	None needed.
Alternative 3	<p>CVP annual net generation would be similar.</p> <p>SWP annual net generation would be increased by 27 percent over the long-term condition and by 16 percent in dry and critical dry years.</p> <p>Total energy use by CVP and SWP water users, including energy for alternate water supplies, is assumed to decrease.</p>	None needed.
Alternative 4	Same effects as described for Alternative 1 compared to the No Action Alternative.	None needed.
Alternative 5	<p>CVP and SWP annual net generation would be similar.</p> <p>Total energy use by CVP and SWP water users, including energy for alternate water supplies, is assumed to be similar.</p>	None needed.

Note: Due to the limitations and uncertainty in the CalSim II monthly model and other analytical tools, incremental differences of 5 percent or less between alternatives and the No Action Alternative are considered to be “similar.”

1 **Table 8.12 Comparison of No Action Alternative and Alternatives 1 through 5 to**  
 2 **Second Basis of Comparison**

Alternative	Potential Change	Consideration for Mitigation Measures
No Action Alternative	CVP annual net generation would be similar. SWP annual net generation would be reduced by 29 percent over the long-term condition and by 37 percent in dry and critical dry years. Total energy use by CVP and SWP water users, including energy for alternate water supplies, is assumed to increase.	Not considered for this comparison.
Alternative 1	No effects on energy resources.	Not considered for this comparison.
Alternative 2	Same effects as described for No Action Alternative as compared to the Second Basis of Comparison.	Not considered for this comparison.
Alternative 3	CVP annual net generation would be similar. SWP annual net generation would be reduced by 10 percent over the long-term condition and by 58 percent in dry and critical dry years. Total energy use by CVP and SWP water users, including energy for alternate water supplies, is assumed to increase.	Not considered for this comparison.
Alternative 4	No effects on energy resources.	Not considered for this comparison.
Alternative 5	CVP annual net generation would be similar. SWP annual net generation would be reduced by 30 percent over the long-term condition and by 39 percent in dry and critical dry years. Total energy use by CVP and SWP water users, including energy for alternate water supplies, is assumed to increase.	Not considered for this comparison.

Note: Due to the limitations and uncertainty in the CalSim II monthly model and other analytical tools, incremental differences of 5 percent or less between alternatives and the No Action Alternative are considered to be "similar."

3 **8.4.3.8 Potential Mitigation Measures**

4 Mitigation measures are presented in this section to avoid, minimize, rectify,  
 5 reduce, eliminate, or compensate for adverse environmental effects of  
 6 Alternatives 1 through 5 as compared to the No Action Alternative. Mitigation  
 7 measures were not included to address adverse impacts under the alternatives as

1 compared to the Second Basis of Comparison because this analysis was included  
 2 in this EIS for information purposes only.

3 Changes under Alternatives 1 through 5 as compared to the No Action Alternative  
 4 would result in similar or increased net energy generation, and reduced potential  
 5 energy use by CVP and SWP water users for alternate water supplies. Therefore,  
 6 there would be no adverse impacts to energy resources as compared to the No  
 7 Action Alternative; and no mitigation measures are needed.

8 **8.4.3.9 Cumulative Effects Analysis**

9 As described in Chapter 3, the cumulative effects analysis considers projects,  
 10 programs, and policies that are not speculative; and are based upon known or  
 11 reasonably foreseeable long-range plans, regulations, operating agreements, or  
 12 other information that establishes them as reasonably foreseeable.

13 The cumulative effects analysis Alternatives 1 through 5 for Energy Resources  
 14 are summarized in Table 8.13.

15 **Table 8.13 Summary of Cumulative Effects on Energy Resources of Alternatives 1**  
 16 **through 5 as Compared to the No Action Alternative**

Scenarios	Actions	Cumulative Effects of Actions
Past & Present, and Future Actions included in the No Action Alternative and in All Alternatives in Year 2030	Consistent with Affected Environment conditions plus: Actions in the 2008 USFWS BO and 2009 NMFS BO that Would Have Occurred without Implementation of the Biological Opinions, as described in Section 3.3.1.2 (of Chapter 3, Descriptions of Alternatives), including climate change and sea level rise Actions not included in the 2008 USFWS BO and 2009 NMFS BO that Would Have Occurred without Implementation of the Biological Opinions, as described in Section 3.3.1.3 (of Chapter 3, Descriptions of Alternatives):  - Implementation of Federal and state policies and programs, including Clean Water Act (e.g., Total Maximum Daily Loads); Safe Drinking Water Act; Clean Air Act; and flood management programs - General plans for 2030. - Trinity River Restoration Program. - Central Valley Project Improvement Act programs	These effects would be the same in all alternatives. Climate change and sea level rise, development under the general plans, FERC relicensing projects, and some future projects to improve water quality and/or habitat are anticipated to reduce carryover storage in reservoirs and changes in stream flow patterns in a manner that could reduce hydroelectric generation in the summer and fall months. Reduced CVP and SWP water deliveries south of the Delta would also reduce CVP and SWP electricity use. Future water supply projects are anticipated to both improve water supply reliability due to reduced surface water supplies and to accommodate planned growth in the general plans. It is anticipated that some of these projects could increase energy use, such as implementation of desalination projects.

Scenarios	Actions	Cumulative Effects of Actions
	<ul style="list-style-type: none"> <li>- Folsom Dam Water Control Manual Update</li> <li>- FERC Relicensing for the Middle Fork of the American River Project</li> <li>- San Joaquin River Restoration Program</li> <li>- Future water supply projects, including water recycling, desalination, groundwater banks and wellfields, and conveyance facilities (projects with completed environmental documents)</li> </ul>	<p>However, other projects, such as water recycling, would not substantially increase energy use because most of the energy use was previously required for wastewater treatment. It is anticipated that energy required for water treatment of alternative water supplies would be similar as treatment for CVP and SWP water supplies. Increased use of groundwater pumps would increase energy use; however, this energy use would be similar or less than the energy used for CVP and SWP water conveyance.</p> <p>Most of these programs were initiated prior to implementation of the 2008 USFWS BO and 2009 NMFS BO which reduced CVP and SWP water supply reliability.</p>
<p>Future Actions considered as Cumulative Effects Actions in All Alternatives in Year 2030</p>	<p>Actions as described in Section 3.5 (of Chapter 3, Descriptions of Alternatives):</p> <ul style="list-style-type: none"> <li>- Bay-Delta Water Quality Control Plan Update</li> <li>- FERC Relicensing Projects</li> <li>- Bay Delta Conservation Plan (including the California WaterFix alternative)</li> <li>- Shasta Lake Water Resources, North-of-the-Delta Offstream Storage, Los Vaqueros Reservoir Expansion Phase 2, and Upper San Joaquin River Basin Storage Investigations</li> <li>- El Dorado Water and Power Authority Supplemental Water Rights Project</li> <li>- Sacramento River Water Reliability Project</li> <li>- Semitropic Water Storage District Delta Wetlands</li> <li>- North Bay Aqueduct Alternative Intake</li> <li>- Irrigated Lands Regulatory Program</li> </ul>	<p>These effects would be the same in all alternatives.</p> <p>Most of the future reasonably foreseeable actions are anticipated to improve water supplies in California to reduce impacts due to climate change, sea level rise, increased water allocated to improve habitat conditions, and future growth. If CVP and SWP water supply reliability increases, energy use for conveyance of CVP and SWP water supplies also would increase.</p> <p>Some of the future reasonably foreseeable actions are anticipated to potentially reduce CVP and SWP water supply reliability (e.g., Water Quality Control Plan Update and FERC Relicensing Projects).</p> <p>Future water supply projects are anticipated to both improve water supply reliability due to reduced</p>

<b>Scenarios</b>	<b>Actions</b>	<b>Cumulative Effects of Actions</b>
	<ul style="list-style-type: none"> <li>- San Luis Reservoir Low Point Improvement Project</li> <li>- Westlands Water District v. United States Settlement</li> <li>- Future water supply projects, including water recycling, desalination, groundwater banks and wellfields, and conveyance facilities (projects that did not have completed environmental documents during preparation of the EIS)</li> </ul>	<p>surface water supplies and to accommodate planned growth in the general plans. It is anticipated that some of these projects could increase energy use, such as implementation of desalination projects. However, other projects, such as water recycling, would not substantially increase energy use because most of the energy use was previously required for wastewater treatment. It is anticipated that energy required for water treatment of alternative water supplies would be similar as treatment for CVP and SWP water supplies. Increased use of groundwater pumps would increase energy use; however, this energy use would be similar or less than the energy used for CVP and SWP water conveyance.</p>
<p>No Action Alternative with Associated Cumulative Effects Actions in Year 2030</p>	<p>Full implementation of the 2008 USFWS BO and 2009 NMFS BO CVP and SWP</p>	<p>Implementation of No Action Alternative future reasonably foreseeable actions would result in changes stream flows and related changes in hydroelectric generation patterns, and reduced CVP and SWP water supplies as compared to conditions prior to the BOs.</p> <p>If CVP and SWP water supply reliability decreases, energy use for conveyance of CVP and SWP water supplies also would decrease and energy use for alternative water supplies could increase.</p>
<p>Alternatives 1 and 4 with Associated Cumulative Effects Actions Year 2030</p>	<p>No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant)</p>	<p>Implementation of Alternatives 1 and 4 future reasonably foreseeable actions would result in changes in stream flows and related hydroelectric generation patterns, and increased CVP and SWP</p>

Scenarios	Actions	Cumulative Effects of Actions
		<p>water supplies as compared to the No Action Alternative with the added actions.</p> <p>Increased CVP and SWP water supply reliability would increase energy use for conveyance of CVP and SWP water supplies; and it is anticipated that energy use for alternative water supplies would decrease as compared to the No Action Alternative with the added actions.</p>
Alternative 2 with Associated Cumulative Effects Actions Year 2030	<p>Full implementation of the 2008 USFWS BO and 2009 NMFS BO CVP and SWP operational actions</p> <p>No implementation of structural improvements or other actions that require further study to develop a more detailed action description.</p>	Implementation of Alternative 2 future reasonably foreseeable actions with future reasonably foreseeable actions for energy resources would be the same as for the No Action Alternative with the added actions.
Alternative 3 with Associated Cumulative Effects Actions Year 2030	<p>No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant)</p> <p>Slight increase in positive Old and Middle River flows in the winter and spring months</p>	<p>Implementation of Alternative 3 future reasonably foreseeable actions would result in changes in stream flows and related hydroelectric generation patterns, and increased CVP and SWP water supplies as compared to the No Action Alternative with the added actions.</p> <p>Increased CVP and SWP water supply reliability would increase energy use for conveyance of CVP and SWP water supplies; and it is anticipated that energy use for alternative water supplies would decrease as compared to the No Action Alternative with the added actions.</p>
Alternative 5 with Associated Cumulative Effects Actions Year 20530	<p>Full implementation of the 2008 USFWS BO and 2009 NMFS BO</p> <p>Positive Old and Middle River flows and increased Delta outflow in spring months</p>	Implementation of Alternative 5 would result in changes in stream flows and related hydroelectric generation patterns, and reduced CVP and SWP water supplies as compared to the No Action

Scenarios	Actions	Cumulative Effects of Actions
		<p>Alternative with the added actions.</p> <p>Reduced CVP and SWP water supply reliability would decrease energy use for conveyance of CVP and SWP water supplies; and it is anticipated that energy use for alternative water supplies would increase as compared to the No Action Alternative with the added actions.</p>

## Chapter 9

# 1 Fish and Aquatic Resources

## 2 9.1 Introduction

3 This chapter describes the fish and aquatic resources that occur in the portions of  
4 the project area that could be affected as a result of implementing the alternatives  
5 evaluated in this Environmental Impact Statement (EIS). Implementation of the  
6 alternatives could affect aquatic resources through changes in ecological attributes  
7 as a result of potential changes in long-term operation of the Central Valley  
8 Project (CVP) and State Water Project (SWP) and ecosystem restoration.

## 9 9.2 Regulatory Environment and Compliance 10 Requirements

11 Potential actions implemented under the alternatives evaluated in this EIS could  
12 affect fish and aquatic resources. Actions located on public agency lands, or  
13 implemented, funded, or approved by Federal and state agencies, would need to  
14 be compliant with appropriate Federal and state agency policies and regulations,  
15 as summarized in Chapter 4, Approach to Environmental Analyses.

## 16 9.3 Affected Environment

17 This section describes fish and aquatic resources that could be affected by the  
18 implementation of the alternatives considered in this EIS. Changes in aquatic  
19 resources due to changes in CVP and SWP operations may occur in the Trinity  
20 River, Central Valley, San Francisco Bay Area, Central Coast, and Southern  
21 California regions.

22 The following description of the affected environment focuses on CVP and SWP  
23 reservoirs, rivers downstream of CVP and SWP reservoirs, the Sacramento-San  
24 Joaquin Rivers Delta Estuary (Delta), and conditions downstream of the Delta that  
25 are affected by operation of the CVP and SWP.

26 This section is organized by geographic area, generally in an upstream to  
27 downstream direction. This format does not necessarily coincide with the use by  
28 fish and aquatic species, which can move among geographic areas either  
29 seasonally or during different phases of their life history.

30 The descriptions of species and biological and hydrodynamic processes in this  
31 chapter frequently use the terms “Delta” and “San Francisco Estuary.” The Delta  
32 refers to the Sacramento-San Joaquin Delta, as legally defined in the Delta  
33 Protection Act. The San Francisco Estuary refers to the portion of the  
34 Sacramento-San Joaquin Rivers watershed downstream of Chipps Island that is

1 influenced by tidal action and where fresh water and salt water mix, which  
 2 includes the following waterbodies: Suisun, San Pablo, and San Francisco bays.

3 **9.3.1 Fish and Aquatic Species Evaluated**

4 Many fish and aquatic species use the project area during all or some portion of  
 5 their lives; however, certain fish and aquatic species were selected to be the focus  
 6 of the analysis of alternatives considered in this EIS based on their sensitivity and  
 7 their potential to be affected by changes in the operation of the CVP and SWP  
 8 implemented under the alternatives considered in this EIS, as summarized in  
 9 Table 9.1. While many of the species identified in Table 9.1 also occur in  
 10 tributaries to the major rivers, the focus of this EIS is on the waterbodies  
 11 influenced by operations of the CVP and SWP. Operation of the CVP and SWP  
 12 would not directly affect ocean conditions; however, operations have the potential  
 13 to affect Southern Resident Killer Whales indirectly by influencing the number of  
 14 Chinook Salmon (produced in the Sacramento-San Joaquin River and associated  
 15 tributaries) that enter the Pacific Ocean and become available as a food supply for  
 16 the whales.

17 These focal species are fish and marine mammal species listed as threatened or  
 18 endangered or at risk of being listed as endangered or threatened, legally  
 19 protected, or are otherwise considered sensitive by the U.S. Fish and Wildlife  
 20 Service (USFWS), National Marine Fisheries Service (NMFS), or California  
 21 Department of Fish and Wildlife (CDFW) (previously known as Department of  
 22 Fish and Game [DFG]) and fish that have tribal, commercial or recreational  
 23 importance. In addition, salmon, steelhead, sturgeon, Striped Bass, and American  
 24 Shad are managed in accordance with Section 3406 of the Central Valley Project  
 25 Improvement Act. Details on the status, life history, habitat requirements, and  
 26 population trends for each of the aquatic focal species are provided in  
 27 Appendix 9B.

28 **Table 9.1 Focal Fish Species by Region of Occurrence**

Species or Population <sup>a</sup>	Federal Status	State Status <sup>b</sup>	Tribal, Commercial, or Recreational Importance	Occurrence within Area of Analysis
<b>Trinity River Region</b>				
Coho Salmon <i>Southern Oregon/Northern California Coast ESU</i>	Threatened	Threatened	Yes	Trinity River, Klamath River
Eulachon <i>Southern DPS</i>	Threatened	None	Yes	Klamath River
Green Sturgeon <i>Southern DPS</i>	Threatened	Species of Special Concern	Yes	Trinity River, Klamath River
Spring-run Chinook Salmon <i>Upper Klamath-Trinity River ESU</i>	None	Species of Special Concern	Yes	Trinity River, Klamath River
Steelhead (winter- and summer-run) <i>Klamath Mountains Province DPS</i>	None	Species of Special Concern <sup>c</sup>	Yes	Trinity River, Klamath River
American Shad	None	None	Yes	Trinity River
Pacific Lamprey	None	None	Yes	Trinity River, Klamath River

Chapter 9: Fish and Aquatic Resources

Species or Population <sup>a</sup>	Federal Status	State Status <sup>b</sup>	Tribal, Commercial, or Recreational Importance	Occurrence within Area of Analysis
White Sturgeon	None	None	Yes	Trinity River, Klamath River
Black Bass (Largemouth, Smallmouth, Spotted)	None	None	Yes	Trinity River
<b>Central Valley Region</b>				
Winter-run Chinook Salmon <i>Sacramento River ESU</i>	Endangered	Endangered	Yes	Sacramento River <sup>d</sup> , Delta, and Suisun Marsh
Spring-run Chinook Salmon <i>Central Valley ESU</i>	Threatened	Threatened	Yes	Clear Creek, Sacramento River, Feather River, American River, Delta, and Suisun Marsh
Steelhead <i>Central Valley DPS</i>	Threatened	None	Yes	Clear Creek, Feather River, Sacramento River; American River, Stanislaus River, San Joaquin River, Delta and Suisun Marsh
Green Sturgeon <i>Southern DPS</i>	Threatened	Species of Special Concern	Yes	Feather River, Sacramento River, Delta and Suisun Marsh
Delta Smelt	Threatened	Endangered	No	Delta and Suisun Marsh
Longfin Smelt <i>Bay Delta DPS</i>	Candidate	Threatened	No	Delta and Suisun Marsh
Fall-/late Fall-run Chinook Salmon <i>Central Valley ESU</i>	None	Species of Special Concern	Yes	Clear Creek, Feather River, Sacramento River, American River, Stanislaus River, San Joaquin River, Delta and Suisun Marsh
Sacramento Splittail	None	Species of Special Concern	No	Feather River, American River, Sacramento River, Delta and Suisun Marsh, San Joaquin River
Hardhead	None	Species of Special Concern	No	Clear Creek, Feather River, Sacramento River, American River, Delta, Stanislaus River, San Joaquin River
Sacramento-San Joaquin Roach	None	Species of Special Concern	No	Clear Creek, Feather River, American River, Sacramento River, Delta, Stanislaus River, San Joaquin River

Chapter 9: Fish and Aquatic Resources

Species or <i>Population</i> <sup>a</sup>	Federal Status	State Status <sup>b</sup>	Tribal, Commercial, or Recreational Importance	Occurrence within Area of Analysis
River Lamprey	None	None	Yes	Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
Pacific Lamprey	None	None	Yes	Clear Creek, Feather River, Sacramento River, American River, Delta, Stanislaus River, San Joaquin River
White Sturgeon	None	None	Yes	Feather River, Sacramento River, American River, San Joaquin River, Delta and Suisun Marsh
American Shad	None	None	Yes	Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
Black Bass (Largemouth, Smallmouth, Spotted)	None	None	Yes	Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
Striped Bass	None	None	Yes	Feather River, American River, Sacramento River, Delta and Suisun Marsh, Stanislaus River, San Joaquin River
<b>San Francisco Bay and Pacific Ocean Waters</b>				
Steelhead Central California Coast DPS	Threatened	None	Yes	San Francisco Bay region
Killer Whale <i>Southern Resident DPS</i>	Endangered	None	Yes	Pacific Coast

1  
2  
3  
4  
5  
6  
7  
8  
9

Notes:

- a. The term *population* refers to the listed Evolutionarily Significant Unit (ESU) or Distinct Population Segment (DPS) for that species.
- b. Includes species listed by the State of California as threatened, endangered, or considered a Species of Special Concern.
- c. The California Species of Special Concern designation refers only to the summer-run of the Klamath Mountains Province DPS steelhead population
- d. Also includes lower reaches of tributaries (e.g., American River) used for nonnatal rearing areas by juvenile salmon.

10 The life history attributes (e.g., timing of juvenile outmigration) for most of the  
11 species listed above, along with the ecological attributes important to the species  
12 and potentially influenced by the alternatives, are discussed in this chapter

1 according to the geographic areas (regions/subregions) where the species occurs;  
 2 Pacific Lamprey, Green Sturgeon, White Sturgeon, American Shad, and Striped  
 3 Bass are discussed in detail only in those regions where they spend the majority of  
 4 their life cycle such that geographic information is available. There are also  
 5 several species (i.e., River Lamprey, Sacramento-San Joaquin Roach, and  
 6 Hardhead) for which little geographic information is available; therefore, they are  
 7 not discussed in detail in this chapter, but are described in the species accounts  
 8 presented in Appendix 9B. Additionally, these species are only generally  
 9 addressed in the analysis of impacts presented in the Environmental  
 10 Consequences section of this chapter.

11 The level of detail presented in the Affected Environment section is tailored to  
 12 correspond the level of resolution of the analysis, which relies on modeling tools  
 13 that broadly characterize the changes in CVP and SWP operations on reservoir  
 14 storage and flows. This level of detail is intended to support an understanding of  
 15 the resources potentially affected and the context within which the project is  
 16 evaluated. The inclusion of unnecessary detail is avoided.

### 17 **9.3.2 Critical Habitat**

18 Critical habitat refers to areas designated by USFWS or NMFS for the  
 19 conservation of their jurisdictional species listed as threatened or endangered  
 20 under the Endangered Species Act (ESA). When a species is proposed for listing  
 21 under the ESA, USFWS or NMFS considers whether there are certain areas  
 22 essential to the conservation of the species. Critical habitat is defined in  
 23 Section 3, Provision 5 of the ESA as follows.

24 *(5)(A) The term “critical habitat” for a threatened or endangered species*  
 25 *means—*

26 *(i) the specific areas within the geographical area occupied by a species*  
 27 *at the time it is listed in accordance with the Act, on which are found those*  
 28 *physical or biological features (I) essential to the conservation of the*  
 29 *species, and (II) which may require special management considerations or*  
 30 *protection; and*

31 *(ii) specific areas outside the geographical area occupied by a species at*  
 32 *the time it is listed in accordance with the provisions of section 4 of this*  
 33 *Act, upon a determination by the Secretary that such areas are essential*  
 34 *for the conservation of the species.*

35 Any Federal action (permit, license, or funding) in critical habitat requires that the  
 36 Federal agency consult with USFWS or NMFS where the action has potential to  
 37 adversely modify the habitat for the listed species.

38 ESA regulations state that the physical and biological features essential to the  
 39 conservation of the species include space for individual and population growth  
 40 and for normal behavior; food, water, air, light, minerals, or other nutritional or  
 41 physiological requirements; cover or shelter; sites for breeding, reproduction, and  
 42 rearing of offspring; and habitats that are protected from disturbance or are  
 43 representative of the historical geographical and ecological distribution of a

1 species. These principal biological and physical features are known as Primary  
2 Constituent Elements (PCEs)<sup>1</sup>. Specific PCEs identified for salmonids, Green  
3 Sturgeon, Delta Smelt, and Eulachon are described below.

#### 4 **9.3.2.1 Anadromous Salmonids**

5 In designating critical habitat for anadromous salmonids (70 Federal Register  
6 [FR] 52536), NMFS identified the following PCEs as essential to the conservation  
7 of the listed populations:

- 8 • Freshwater spawning sites with water quantity and quality conditions and  
9 substrate that support spawning, incubation, and larval development.
- 10 • Freshwater rearing sites with:
  - 11 – Water quantity and floodplain connectivity to form and maintain physical  
12 habitat conditions and support juvenile growth and mobility
  - 13 – Water quality and forage supporting juvenile development
  - 14 – Natural cover such as shade, submerged and overhanging large wood, log  
15 jams and beaver dams, aquatic vegetation, large rocks and boulders, side  
16 channels, and undercut banks
- 17 • Freshwater migration corridors free of obstruction and excessive predation  
18 with water quantity and quality conditions and natural cover such as  
19 submerged and overhanging large wood, aquatic vegetation, large rocks and  
20 boulders, side channels, and undercut banks supporting juvenile and adult  
21 mobility and survival.
- 22 • Estuarine areas free of obstruction and excessive predation with:
  - 23 – Water quality, water quantity, and salinity conditions supporting juvenile  
24 and adult physiological transitions between fresh water and salt water
  - 25 – Natural cover such as submerged and overhanging large wood, aquatic  
26 vegetation, large rocks and boulders, and side channels
  - 27 – Juvenile and adult forage, including aquatic invertebrates and fishes,  
28 supporting growth and maturation

29 Critical habitat in nontidal waters includes the stream channels in the designated  
30 stream reaches, the lateral extent of which generally defined by the ordinary  
31 high-water line.

##### 32 **9.3.2.1.1 Central Valley Spring-run Chinook Salmon ESU**

33 This ESU consists of spring-run Chinook Salmon in the Sacramento River Basin,  
34 including spring-run Chinook Salmon from the Feather River Hatchery.  
35 Designated critical habitat for Central Valley spring-run Chinook Salmon  
36 includes stream reaches of the American, Feather, Yuba, and Bear rivers;

---

<sup>1</sup> The U.S. Fish and Wildlife Service and National Marine Fisheries Service have proposed discontinuing the use of the term "Primary Constituent Elements" to simplify and clarify the critical habitat process and to provide consistency with the language contained in the Endangered Species Act, which uses the term "physical or biological features."

1 tributaries of the Sacramento River, including Big Chico, Butte, Deer, Mill,  
 2 Battle, Antelope, and Clear creeks; and the main stem of the Sacramento River  
 3 from Keswick Dam through the Delta. Designated critical habitat in the Delta  
 4 includes portions of the Delta Cross Channel (DCC); Yolo Bypass; and portions  
 5 of the network of channels in the northern Delta. Critical habitat for spring-run  
 6 Chinook Salmon was not designated for the Stanislaus or San Joaquin River.

7 The spring-run Chinook Salmon critical habitat potentially affected by operation  
 8 of the CVP and SWP includes the network of channels in the northern Delta,  
 9 Sacramento River up to Keswick Dam, Clear Creek up to Whiskeytown Dam, the  
 10 Feather River up to the Fish Barrier Dam, and the American River up to Watt  
 11 Avenue in the Sacramento Valley subregion. The section of the American River  
 12 denoted as critical habitat serves only as juvenile nonnatal rearing habitat;  
 13 spring-run Chinook Salmon do not spawn in the American River. Operation of  
 14 the CVP and SWP would have no effect on designated critical habitat for spring-  
 15 run Chinook Salmon in the Yuba River and Big Chico, Butte, Deer, Mill, Battle,  
 16 and Antelope creeks or other tributaries of the Sacramento River. Operation of  
 17 the CVP and SWP could affect designated critical habitat in the Delta subregion.  
 18 There is no designated critical habitat for spring-run Chinook Salmon in the San  
 19 Joaquin Valley subregion.

#### 20 **9.3.2.1.2 Sacramento River Winter-run Chinook Salmon ESU**

21 The Sacramento River winter-run Chinook Salmon ESU consists of only one  
 22 population confined to the upper Sacramento River. This ESU includes all fish  
 23 spawning naturally in the Sacramento River and its tributaries, as well as fish that  
 24 are propagated at the Livingston Stone National Fish Hatchery (NFH), operated  
 25 by USFWS (NMFS 2005a). Critical habitat was delineated as the Sacramento  
 26 River from Keswick Dam to Chipps Island at the westward margin of the Delta;  
 27 all waters from Chipps Island westward to the Carquinez Bridge, including  
 28 Honker Bay, Grizzly Bay, Suisun Bay, and the Carquinez Strait; all waters of San  
 29 Pablo Bay westward of the Carquinez Bridge; and all waters of San Francisco  
 30 Bay (north of the San Francisco-Oakland Bay Bridge) to the Golden Gate Bridge  
 31 (NMFS 1993).

#### 32 **9.3.2.1.3 Central Valley Steelhead DPS**

33 The California Central Valley Steelhead DPS includes all naturally spawned  
 34 populations of steelhead in the Sacramento and San Joaquin rivers and their  
 35 tributaries, excluding steelhead from San Francisco and San Pablo bays and their  
 36 tributaries. Two artificial propagation programs, the Coleman NFH and Feather  
 37 River Hatchery steelhead hatchery programs, are considered to be part of the  
 38 DPS. Critical habitat for Central Valley Steelhead includes stream reaches of the  
 39 American, Feather, Yuba, and Bear rivers and their tributaries, and tributaries of  
 40 the Sacramento River including Deer, Mill, Battle, Antelope, and Clear creeks in  
 41 the Sacramento River Basin; the Mokelumne, Calaveras, Stanislaus, Tuolumne,  
 42 and Merced rivers in the San Joaquin River Basin; and portions of the Sacramento  
 43 and San Joaquin rivers. Designated critical habitat in the Delta includes portions  
 44 of the DCC, Yolo Bypass, Ulatis Creek, and portions of the network of channels

1 in the Sacramento River portion of the Delta; and portions of the San Joaquin,  
2 Cosumnes, and Mokelumne rivers and portions of the network of channels in the  
3 San Joaquin portion of the Delta.

4 The Central Valley Steelhead critical habitat potentially affected by operation of  
5 the CVP and SWP includes the Sacramento River up to Keswick Dam, Clear  
6 Creek up to Whiskeytown Dam, the Feather River up to the Fish Barrier Dam,  
7 and the American River up to Nimbus Dam in the Sacramento Valley subregion.  
8 Operation of the CVP and SWP would have no effect on designated critical  
9 habitat for steelhead in the Yuba River and Big Chico, Butte, Deer, Mill, Battle,  
10 and Antelope creeks or other tributaries of the Sacramento River.

#### 11 **9.3.2.1.4 Central California Coast Steelhead DPS**

12 The Central California Coast Steelhead DPS includes all naturally spawned  
13 populations of steelhead in streams from the Russian River to Aptos Creek, Santa  
14 Cruz County (inclusive). It also includes the drainages of San Francisco and San  
15 Pablo bays. Critical habitat for Central California Coast Steelhead includes  
16 stream reaches in the Russian River, Bodega, Marin Coastal, San Mateo, Bay  
17 Bridge, Santa Clara, San Pablo, and Big Basin Hydrologic Units. Operation of  
18 the CVP and SWP would not affect designated critical habitat for this DPS of  
19 Central California Coast Steelhead, and NMFS (2009a) concluded that operation  
20 would not likely adversely affect individual fish; therefore, this species is not  
21 addressed in this EIS.

#### 22 **9.3.2.1.5 Southern Oregon/Northern California Coastal Coho Salmon ESU**

23 The Southern Oregon/Northern California Coast Coho Salmon ESU consists of  
24 populations from Cape Blanco, Oregon, to Punta Gorda, California, including  
25 Coho Salmon in the Trinity River. In the Trinity River Region, all Trinity River  
26 reaches downstream of Lewiston Dam, the south fork of the Trinity River, and the  
27 entire lower Klamath River are designated as critical habitat with the exception of  
28 tribal lands (NMFS 1999).

#### 29 **9.3.2.2 North American Green Sturgeon Southern DPS**

30 The North American Green Sturgeon Southern DPS consists of coastal and  
31 Central Valley populations south of the Eel River, with the only known spawning  
32 population in the Sacramento River. In designating critical habitat for the North  
33 American Green Sturgeon Southern DPS, NMFS (74 FR 52345) identified PCEs  
34 as essential to the conservation of this species in freshwater riverine systems,  
35 estuarine areas, and nearshore marine waters. The PCEs for each area largely  
36 overlap and include the following items:

- 37 • **Food Resources.** Abundant prey items for larval, juvenile, subadult, and  
38 adult life stages.
- 39 • **Substrate Type or Size (i.e., structural features of substrates).** Substrates  
40 suitable for egg deposition and development (e.g., bedrock sills and shelves,  
41 cobble and gravel, or hard clean sand, with interstices or irregular surfaces to  
42 “collect” eggs and provide protection from predators, and free of excessive silt

- 1 and debris that could smother eggs during incubation), larval development  
 2 (e.g., substrates with interstices or voids providing refuge from predators and  
 3 from high-flow conditions), and subadults and adults (e.g., substrates for  
 4 holding and spawning).
- 5 • **Water Flow.** A flow regime (i.e., the magnitude, frequency, duration,  
 6 seasonality, and rate-of-change of fresh water discharge over time) necessary  
 7 for normal behavior, growth, and survival of all life stages.
  - 8 • **Water Quality.** Water quality, including temperature, salinity, oxygen  
 9 content, and other chemical characteristics, necessary for normal behavior,  
 10 growth, and viability of all life stages.
  - 11 • **Migratory Corridor.** A migratory pathway necessary for the safe and timely  
 12 passage of Southern DPS fish within riverine habitats and between riverine  
 13 and estuarine habitats (e.g., an unobstructed river or dammed river that still  
 14 allows for safe and timely passage).
  - 15 • **Water Depth.** Deep (greater than 5 meters [m]) holding pools for both  
 16 upstream and downstream holding of adult or subadult fish, with adequate  
 17 water quality and flow to maintain the physiological needs of the holding  
 18 adult or subadult fish.
  - 19 • **Sediment Quality.** Sediment quality (i.e., chemical characteristics) necessary  
 20 for normal behavior, growth, and viability of all life stages.

21 Critical habitat in freshwater riverine habitats includes the stream channels in the  
 22 designated stream reaches with the lateral extent defined by the ordinary high-  
 23 water line. The ordinary high-water line on nontidal rivers is defined as “the line  
 24 on the shore established by the fluctuations of water and indicated by physical  
 25 characteristics such as a clear, natural line impressed on the bank; shelving;  
 26 changes in the character of soil; destruction of terrestrial vegetation; the presence  
 27 of litter and debris, or other appropriate means that consider the characteristics of  
 28 the surrounding areas” [33 Code of Federal Regulations 329.11(a)(1)].

29 Within the study area, critical habitat includes the Sacramento River from the  
 30 I-Street Bridge upstream to Keswick Dam, including areas in the Yolo Bypass  
 31 and the Sutter Bypass and the lower American River from the confluence with the  
 32 Sacramento River upstream to the State Route 160 bridge over the American  
 33 River; the lower Feather River from the confluence with the Sacramento River  
 34 upstream to the Fish Barrier Dam; and the lower Yuba River from the confluence  
 35 with the Feather River upstream to Daguerre Dam. Critical habitat also includes  
 36 all waterways of the Delta up to the elevation of mean higher high water except  
 37 for certain excluded areas and all tidally influenced areas of San Francisco Bay,  
 38 San Pablo Bay, and Suisun Bay up to the elevation of mean higher high water  
 39 (NMFS 2009b).

1     **9.3.2.3     Delta Smelt**

2     In designating critical habitat for Delta Smelt (59 FR 65256), USFWS identified  
3     the following PCEs essential to the conservation of the species: (1) suitable  
4     substrate for spawning; (2) water of suitable quality and depth to support survival  
5     and reproduction (e.g., temperature, turbidity, lack of contaminants); (3) sufficient  
6     Delta flow to facilitate spawning migrations and transport of larval Delta Smelt to  
7     appropriate rearing habitats; and (4) salinity, which influences the extent and  
8     location of the low salinity zone where Delta Smelt rear. The location of the low  
9     salinity zone (or X2) is described in terms of the average distance of the two  
10    practical salinity units isohaline from the Golden Gate Bridge. Critical habitat for  
11    Delta Smelt includes all water and submerged lands below ordinary high water  
12    and the entire water column bounded by and contained in Suisun Bay (including  
13    the contiguous Grizzly and Honker bays); the length of Goodyear, Suisun, Cutoff,  
14    First Mallard (Spring Branch), and Montezuma sloughs; and the existing  
15    contiguous waters contained in the legal Delta (as defined in Section 12220 of the  
16    California Water Code) (USFWS 1994a).

17    **9.3.2.4     Eulachon Southern DPS**

18    In designating critical habitat for Eulachon, NMFS (76 FR 65323) identified the  
19    following physical or biological features essential to the conservation of the  
20    Eulachon Southern DPS fall reflecting key life history phases of Eulachon:  
21    (1) freshwater spawning and incubation sites with water flow, quality and  
22    temperature conditions and substrate supporting spawning and incubation, and  
23    with migratory access for adults and juveniles; (2) freshwater and estuarine  
24    migration corridors associated with spawning and incubation sites that are free of  
25    obstruction and with water flow, quality and temperature conditions supporting  
26    larval and adult mobility, and with abundant prey items supporting larval feeding  
27    after the yolk sac is depleted; and (3) nearshore and offshore marine foraging  
28    habitat with water quality and available prey, supporting juveniles and adult  
29    survival.

30    Within the study area, critical habitat for Eulachon includes the Klamath River  
31    from the mouth upstream to the confluence with Omogar Creek. The critical  
32    habitat designation specifically excludes all lands of the Yurok Tribe and  
33    Reshigini Rancheria, based upon a determination that the benefits of exclusion  
34    outweigh the benefits of designation (NMFS 2011b). Exclusion of these areas  
35    will not result in the extinction of the Southern DPS because the  
36    overall percentage of critical habitat on Indian lands is so small (approximately  
37    5 percent of the total are designated), and it is likely that Eulachon production on  
38    these lands represents a small percent of the total annual production for the DPS  
39    (NMFS 2011a, 2011b).

40    **9.3.3        Trinity River Region**

41    The Trinity River Region includes Trinity Lake, Lewiston Reservoir and the  
42    Trinity River from Lewiston Reservoir to the confluence with the Klamath River;  
43    and the portion of the lower Klamath River watershed in Humboldt and Del Norte  
44    counties from the confluence with the Trinity River to the Pacific Ocean. The

1 CVP Trinity Lake and Lewiston Reservoir are located upstream of the  
 2 confluences of several Trinity River tributaries (i.e., north fork, south fork, and  
 3 New River) and flows on these tributaries are not affected by CVP facilities. The  
 4 Trinity River flows approximately 112 miles from Lewiston Reservoir to its  
 5 confluence with the Klamath River, traversing through Trinity and Humboldt  
 6 counties and the Hoopa Indian Reservation within Trinity and Humboldt counties.  
 7 The Trinity River is the largest tributary to the Klamath River (DOI and  
 8 DFG 2012).

9 The lower Klamath River flows 43.5 miles from the confluence with the Trinity  
 10 River to the Pacific Ocean (USFWS et al. 1999). Downstream of the Trinity  
 11 River confluence, the Klamath River flows through Humboldt and Del Norte  
 12 counties and through the Hoopa Indian Reservation, Yurok Indian Reservation,  
 13 and Resighini Indian Reservation within Humboldt and Del Norte counties (DOI  
 14 and DFG 2012). There are no dams located in the Klamath River watershed  
 15 downstream of the confluence with the Trinity River. The Klamath River estuary  
 16 extends from approximately 5 miles upstream of the Pacific Ocean. This area is  
 17 generally under tidal effects, and salt water can occur up to 4 miles from the  
 18 coastline during high tides in summer and fall when Klamath River flows are low.

#### 19 **9.3.3.1 Trinity Lake and Lewiston Reservoir**

20 Trinity Lake is created by Trinity Dam and is considered relatively unproductive,  
 21 with low-standing crops of phytoplankton and zooplankton (USFWS et al. 2004).  
 22 The fish in Trinity Lake include cold-water and warm-water species. Trinity  
 23 Lake supports a trophy Smallmouth Bass fishery and provides substantial sport  
 24 fishing for Largemouth Bass, Rainbow and Brown Trout, and Kokanee Salmon  
 25 (landlocked Sockeye Salmon). Other fish species in Trinity Lake include  
 26 Speckled Dace, Klamath Smallscale Sucker, Coast Range Sculpin, and the  
 27 nonnative Green Sunfish and Brown Bullhead.

28 Lewiston Reservoir is a re-regulating reservoir for Trinity Lake. The water  
 29 surface elevation is relatively constant. The reservoir contains Rainbow, Brown,  
 30 and Brook Trout and Kokanee Salmon. Other fish species present include Pacific  
 31 Lamprey, Speckled Dace, Klamath Smallscale Sucker, Coast Range Sculpin, and  
 32 Smallmouth Bass (USFWS et al. 2004).

#### 33 **9.3.3.2 Trinity River from Lewiston Reservoir to Klamath River**

34 The Trinity River flows out of Trinity Lake and Lewiston Reservoir. Native  
 35 anadromous salmonids in the mainstem Trinity River and its tributaries  
 36 downstream of Lewiston Dam are spring- and fall-run Chinook Salmon, Coho  
 37 Salmon, and steelhead (NCRWQCB et al. 2009). Native non-salmonid  
 38 anadromous species that inhabit the Trinity River Basin include Green Sturgeon,  
 39 White Sturgeon, Pacific Lamprey, and Eulachon.

40 The hydrologic and geomorphic changes following construction of the Trinity and  
 41 Lewiston dams changed the character of the river channel substantially and  
 42 altered the quantity and quality of aquatic habitat. Riparian vegetation was  
 43 allowed to encroach on areas that had previously been scoured by flood flows,

1 resulting in the formation of a riparian berm that armored and anchored the river  
2 banks and prevented meandering of the river channel (USFWS et al. 1999). The  
3 berm reduced the potential for encroachment and maturation of woody vegetation  
4 along the stabilized channel.

5 The ongoing Trinity River Restoration Program includes specific minimum  
6 instream flows (as described in Chapter 5, Surface Water Resources and Water  
7 Supplies); mechanical channel rehabilitation; fine and coarse sediment  
8 management; watershed restoration; infrastructure improvement; and adaptive  
9 management components (NCRWQCB et al. 2009, USFWS et al. 1999). The  
10 mechanical channel rehabilitation includes removal of fossilized riparian berms  
11 that had been anchored by extensive woody vegetation root systems and had  
12 confined the river. Following removal of the berms, the areas have been  
13 re-vegetated to support native vegetation, re-establish alternate point bars, and  
14 re-establish complex fish habitat similar to conditions prior to construction of the  
15 dams. Sediment management activities include introduction of coarse sediment at  
16 locations to support spawning and other aquatic life stages; and relocation of sand  
17 outside of the floodway. In areas closer to Lewiston Dam with limited gravel  
18 supply, gravel/cobble point bars are being rebuilt to increase gravel storage and  
19 improve channel dynamics. Riparian vegetation planted on the restored  
20 floodplains and flows will be managed to encourage natural riparian growth on  
21 the floodplain and limit encroachment on the newly formed gravel bars.  
22 Improvement projects have been completed and others are under construction or  
23 in the planning phases. These restoration actions are occurring in the 40-mile  
24 restoration reach between Lewiston Dam and the confluence with north fork of  
25 the Trinity River (TRRP 2014).

#### 26 **9.3.3.2.1 Fish in the Trinity River**

27 The following focal fish species that occur in the Trinity River are considered in  
28 this EIS.

- 29 • Coho Salmon
- 30 • Chinook Salmon (spring- and fall-run)
- 31 • Steelhead (winter-and summer-run)
- 32 • Green Sturgeon
- 33 • White Sturgeon
- 34 • Pacific Lamprey
- 35 • American Shad

#### 36 *Coho Salmon*

37 Coho Salmon in the Trinity River are thought to be exclusively 3-year lifecycle  
38 fish, living a full year in the river as juveniles before migrating to the ocean.  
39 Most returning adult Coho Salmon enter rivers between August and January.  
40 Spawning in the Trinity River and tributaries occurs primarily in November and  
41 December. Most of the spawning by Coho Salmon in the mainstem Trinity River  
42 occurs from Lewiston Dam downstream to the North Fork Trinity confluence  
43 (NMFS 2014a). Coho Salmon eggs incubate from 35 to more than 100 days,

1 depending on water temperature, and emerge from the gravel 2 weeks to 7 weeks  
2 after hatching. Because juvenile Coho Salmon remain in their spawning stream  
3 for a full year after emerging from the gravel, they are exposed to a broad range  
4 of freshwater conditions. Coho Salmon smolts typically migrate to the ocean  
5 between March and June, with most leaving in April and May (the term “smolt”  
6 refers to young salmon prior to entering the ocean that have undergone the  
7 physiological changes necessary for life in salt water).

8 Coho Salmon were not likely the dominant species of salmon in the Trinity River  
9 before dam construction. However, the species was widespread in the Trinity  
10 River Basin, ranging as far upstream as Stuarts Fork above present-day Trinity  
11 Dam. Passage for Coho Salmon and other anadromous salmonids is now blocked  
12 at Lewiston Dam, which prevents access to roughly 109 miles of upstream habitat  
13 for Coho Salmon (DOI 2000). The Trinity River Salmon and Steelhead Hatchery  
14 (Trinity River Hatchery) produces Coho Salmon with an annual production goal  
15 of 500,000 yearlings to mitigate the upstream habitat loss (CHSRG 2012).

16 Several interrelated factors affect Coho Salmon abundance and distribution in the  
17 Trinity River. These factors include degradation of spawning and rearing habitat,  
18 sparse spawning gravel recruitment, lack of deep pools, stressful late summer  
19 water temperatures, water diversions, channelization and confinement, irregular  
20 timing of flows, fragmentation of populations, genetic and ecological interactions  
21 with hatchery salmonids, migration barriers, water quality problems, and  
22 unscreened diversions (NMFS 2014a). Current CVP operations primarily affect  
23 water temperature, water flow, and habitat suitability in the Trinity River  
24 (Reclamation 2008a). Currently accessible habitat downstream of Lewiston Dam  
25 represents about 50 percent of historically available habitat (USFWS 1999).

26 Habitat in the Trinity River has changed since flow regulation that began with the  
27 completion of Trinity and Lewiston dams, with the encroachment of riparian  
28 vegetation restricting channel movement and limiting fry rearing habitat (Trush  
29 et al. 2000). The Trinity River Restoration Program is implemented to provide  
30 higher peak flows to restore attributes of a fully functioning alluvial river, such as  
31 alternating bar features and additional off-channel habitat, and to provide better  
32 rearing habitat for Coho Salmon (Reclamation 2008a, TRRP 2013). Several  
33 restoration actions have been completed to reconnect the river with the floodplain,  
34 including selective removal of terraces and riparian berms and physical alteration  
35 of the adjacent floodplain to increase inundation frequency. Releases from  
36 Trinity Lake occur on a variable flow schedule with higher spring releases to  
37 promote the restored geomorphic processes and habitat.

38 An estimated 21,906 adult Coho Salmon migrated into the Trinity River Basin  
39 upstream of Willow Creek (about 88 miles downstream of Lewiston Dam) in  
40 2013, of which 6,631 entered Trinity River Hatchery (located near Lewiston  
41 Dam) and 15,275 were estimated to have spawned in the river (CDFW 2014).  
42 The run-size estimates have ranged from 852 fish in 1994 to 59,079 fish in 1987.  
43 The 2011 run was ranked 10th of the 37 years on record and is 27.6 percent of the  
44 17,161 average (CDFW 2014). Both intra- and inter-specific redd  
45 superimposition on the spawning grounds can affect salmon reproductive success

1 and the spawning areas downstream of Lewiston Dam are likely near carrying  
2 capacity (NMFS 2014a).

3 *Spring-run Chinook Salmon*

4 Adult spring-run Chinook Salmon migrate upstream in the Trinity River from  
5 April through September, with most fish arriving at the mouth of the North Fork  
6 Trinity by the end of July. These fish remain in deep pools until the onset of the  
7 spawning season, which typically begins the third week of September, peaks in  
8 October, and continues through November. The distribution of spawning extends  
9 upstream to Lewiston Dam, and is concentrated in the reaches immediately  
10 downstream of the dam to the mouth of the North Fork Trinity River. Williams  
11 et al. (2011) concluded that although abundance is low compared with historical  
12 abundance, the current spring-run Chinook Salmon population (which includes  
13 hatchery fish) appears to have been fairly stable for the past 30 years. In 2013, an  
14 estimated 8,961 spring-run Chinook Salmon entered the Trinity River upstream of  
15 Junction City, including the 2,578 fish that entered the Trinity River Hatchery and  
16 6,129 natural area spawners (CDFW 2014). This run-size estimate is  
17 approximately 51 percent of the 34-year average spring-run Chinook Salmon run-  
18 size of 17,402, which has ranged from 2,381 fish in 1991 to 62,692 fish in 1988  
19 (CDFW 2014).

20 Emergence of spring-run Chinook Salmon fry in the Trinity River begins in  
21 December and continues into mid-April. Juvenile spring-run Chinook Salmon  
22 typically outmigrate after a year of growth in the Trinity River. Outmigration  
23 from the lower Trinity River, as indicated by monitoring near Willow Creek,  
24 peaks in May and June.

25 *Fall-run Chinook Salmon*

26 The adult fall-run Chinook Salmon migration in the Trinity River begins in  
27 August and continues into December, with spawning beginning in mid-October.  
28 Spawning activity peaks in November, and continues through December.  
29 Spawning of fall-run Chinook Salmon occurs throughout the mainstem Trinity  
30 River from Lewiston Dam to the Hoopa Valley (Myers et al. 1998). The first  
31 spawning activity usually occurs just downstream from Lewiston Dam and  
32 extends farther downstream as the spawning season progresses.

33 Like spring-run Chinook Salmon, emergence of fall-run Chinook Salmon fry  
34 begins in December and continues into mid-April. Juvenile fall-run Chinook  
35 Salmon typically outmigrate after a few months of growth in the Trinity River.  
36 Outmigration from the upper river, as indicated by monitoring near Junction City,  
37 begins in March and peaks in early May, ending by late May or early June.  
38 Outmigration of fall-run Chinook Salmon fry in the lower Trinity River occurs  
39 over approximately the same time period described above for the spring run.

40 An estimated 36,989 fall-run Chinook Salmon migrated into the Trinity River  
41 upstream of Willow Creek in 2013, of which 3,852 entered Trinity River  
42 Hatchery and 32,257 spawned naturally (CDFW 2014). This estimate is  
43 approximately 84.5 percent of the 43,762 mean run-size for the years since 1977,  
44 which has ranged from 9,207 fish in 1991 to 147,888 fish in 1986 (CDFW 2014).

1 *Steelhead*

2 Steelhead in the Trinity River exhibit two primary life history strategies: a  
3 summer-run that is stream maturing and a winter-run that is ocean maturing. The  
4 winter-run is considered by some to be composed of a fall-run and a winter-run  
5 based upon the timing of the adult migration. Summer-run steelhead have been  
6 observed in the north and south forks of the Trinity River and in the tributaries of  
7 New River and Canyon Creek (BLM 1995).

8 Adult summer-run steelhead enter the Trinity River from April through  
9 September and over-summer in deep pools within the mainstem. Some enter the  
10 smaller tributary streams of the Trinity River during the first November rains  
11 (Hill 2010), with most fish spawning in both the mainstem and tributaries from  
12 February through April (USFWS et al. 2004). Summer-run steelhead spawner  
13 escapements for the Trinity River upstream of Lewiston Dam prior to its  
14 construction were estimated to average 8,000 adults annually. Post-dam survey  
15 (reported in 2004) ranged from 20 to 1,037 adult summer steelhead in the  
16 tributaries and Trinity River (USFWS et al. 2004).

17 Juvenile summer-run steelhead may rear in fresh water for up to three years  
18 before outmigrating. Rearing in the Trinity River is highly variable, but most  
19 summer-run steelhead either outmigrate as young-of-the-year (YOY) or at age 1+  
20 (Scheiff et al. 2001, Pinnix and Quinn 2009, Pinnix et al. 2013). For juveniles  
21 that rear at least a year in fresh water, survival appears to be higher for those that  
22 outmigrate to the ocean at age 2+ (DFG 1998a). Juveniles outmigrating from the  
23 tributaries as 0+ or age 1+ may rear in the mainstem or in nonnatal tributaries  
24 (particularly during periods of poor water quality) for one or more years before  
25 smolting. Juvenile outmigration can occur from spring through fall, with three  
26 peak migration periods including March, May/June, and October/November  
27 (USFWS et al. 2004).

28 Fall-run and winter-run steelhead also are widely distributed throughout the  
29 Trinity River. Adult fall-run steelhead enter the Klamath River system in  
30 September and October (Hill 2010) and likely spawn in tributaries such as the  
31 Trinity River from January through April. Adult winter-run steelhead begin their  
32 upstream migration in the Klamath River from November through March  
33 (USFWS 1997). Winter-run steelhead primarily spawn in Klamath River  
34 tributaries (including the Trinity River) from January through April (USFWS  
35 1997), with peak spawn timing in February and March (NRC 2004).

36 An estimated run-size of 16,594 adult fall-run steelhead migrated into the Trinity  
37 River upstream of Willow Creek in 2013, including the 2,375 fish (80 natural-  
38 origin and 2,295 hatchery-origin) that entered the Trinity River Hatchery and  
39 13,560 natural area spawners (9,039 of natural origin and 4,521 of hatchery  
40 origin) (CDFW 2014). Since 1980, run-size estimates have ranged from 2,972 in  
41 1998 to 53,885 in 2007. The estimated abundance of steelhead in 2013 was  
42 8.4 percent above the average since 1980 (CDFW 2014).

1 *Green Sturgeon*

2 Limited Green Sturgeon data has been collected in the Trinity River, so most  
3 information on life history characteristics for Green Sturgeon in the Trinity River  
4 is based on data from the Klamath River. Green Sturgeon in the Klamath River  
5 sampled during their spawning migration ranged in age from 16 to 40 years (Van  
6 Eenennaam et al. 2006). Green Sturgeon are generally believed to have a life  
7 span of at least 50 years and spawn every four years on average after around  
8 age 16 (Klimley et al. 2007). Green Sturgeon enter the Trinity and Klamath rivers  
9 to spawn from February through July, and most spawning occurs from the middle  
10 of April to the middle of June (NRC 2004). After spawning, around 25 percent of  
11 Green Sturgeon migrate directly back to the ocean (Benson et al. 2007), and the  
12 remainder hold in mainstem pools through November. During the onset of fall  
13 rainstorms and increased river flow, adult sturgeon move downstream and leave  
14 the river system (Benson et al. 2007). Juvenile Green Sturgeon may rear for one  
15 to three years in the Klamath River system before they migrate to the estuary and  
16 Pacific Ocean (NRC 2004, FERC 2007a, CALFED 2007), usually during summer  
17 and fall (Emmett et al. 1991, Hardy and Addley 2001).

18 In the Trinity River Basin, Green Sturgeon are known to spawn in the mainstem  
19 from the confluence with the Klamath to as far upstream as Gray's Falls near  
20 Burnt Ranch. Juveniles are captured in rotary screw traps at Willow Creek on the  
21 Trinity River (Scheiff et al. 2001, Pinnix and Quinn 2009).

22 *White Sturgeon*

23 White Sturgeon are uncommon in the Klamath and Trinity rivers and spawning  
24 may not occur (NRC 2004). Historically there may have been small spawning  
25 runs in these rivers; almost all of the sturgeon occurring above the Klamath  
26 estuary are Green Sturgeon (Moyle 2002).

27 *Pacific Lamprey*

28 Pacific Lamprey are the only anadromous lamprey species in the Trinity River  
29 Basin. This species is important to local tribes and supports a subsistence fishery  
30 on the lower Trinity River. Although no systematic distribution surveys are  
31 available for the Trinity River Basin, they are expected to have a distribution  
32 similar to anadromous salmonids that use the mainstem Trinity River and  
33 accessible reaches of larger tributaries. No current status assessments are  
34 available for Pacific Lamprey in the Trinity River, but information from tribal  
35 fishermen who catch lampreys in the lower Klamath River suggests a decline that  
36 mirrors that observed across the species' range (Petersen Lewis 2009).

37 Adult Pacific Lampreys have been documented entering the Klamath River from  
38 the ocean during all months of the year, with peak upstream migration to holding  
39 areas from December through June (Larson and Belchik 1998, Petersen Lewis  
40 2009). Migration up the Trinity River is expected to begin slightly later. After  
41 entering fresh water as sexually immature adults and undergoing an initial  
42 migration, Pacific Lampreys hold through summer and most of winter before  
43 spawning the following spring when they reach sexual maturity (Robinson and  
44 Bayer 2005, Clemens et al. 2012). After the holding period, individuals undergo

1 a secondary migration in the late winter or early spring from holding areas to  
2 spawning grounds (Robinson and Bayer 2005, Clemens et al. 2012, Lampman  
3 2011). Thus, adult Pacific Lampreys with varying levels of sexual maturity may  
4 be in the Trinity River throughout the year. Ammocoetes (the larval stage of  
5 lamprey) inhabit fine substrates in depositional areas, rearing in the Trinity River  
6 and tributaries year-round for up to 7 years before outmigrating to the ocean  
7 (Moyle 2002, Reclamation and Trinity County 2006).

8 Little information is available on factors that influence populations of Pacific  
9 Lamprey in the Trinity River, but they are affected by many of the same factors as  
10 salmon and steelhead, because of parallels in their life cycles. Lack of access to  
11 historical spawning habitats caused by the mainstem dams and other migration  
12 barriers, modification of spawning and rearing habitat because of downstream  
13 impacts from dams, altered hydrology, and predation by nonnative invasive  
14 species such as Brown Trout have likely contributed to adverse effects on the  
15 Trinity River Pacific Lamprey population.

#### 16 *American Shad*

17 American Shad, an introduced, anadromous fish, has become established in the  
18 Klamath and Trinity rivers. American Shad occur in the lowermost portions of  
19 the Trinity River, but are primarily found in the lower Klamath River. Adult fish  
20 enter estuaries or streams in late spring or early summer and spawn soon  
21 afterward in fresh water. Juvenile shad have been captured regularly in the  
22 rotary-screw traps at the Pear Tree and Willow Creek sites during salmonid  
23 outmigrant monitoring (Scheiff et al. 2001, Pinnix and Quinn 2009, Pinnix et al.  
24 2013). Sport fishing for American Shad occurs seasonally throughout the lower  
25 Trinity River.

#### 26 **9.3.3.2.2 Hatcheries on the Trinity River**

27 The Trinity River Hatchery is located immediately downstream of Lewiston Dam,  
28 and is operated by CDFW and funded by Reclamation to mitigate the loss of  
29 salmonid production upstream of Lewiston Dam resulting from the Trinity Dam  
30 (Reclamation 2008a). The hatchery produces Coho Salmon, fall-run Chinook  
31 Salmon, spring-run Chinook Salmon, and steelhead. The hatchery's Coho  
32 Salmon program currently uses only endemic Coho Salmon broodstock and  
33 releases approximately 500,000 yearlings annually from March 15 to May 15.  
34 The fall-run Chinook Salmon program has a goal of releasing two million sub-  
35 yearlings in June and 900,000 yearlings in October from in-river broodstock, and  
36 the spring-run Chinook Salmon program has a goal of releasing one million  
37 subyearlings in June and 400,000 yearlings in October from in-river broodstock.  
38 The steelhead program currently uses only in-river broodstock with a goal to  
39 release 800,000 steelhead smolts (approximately six inches) from March 15 to  
40 May 1.

1     **9.3.3.3     Lower Klamath River from Trinity River to Pacific Ocean**

2     The Lower Klamath River begins where the Trinity River flows into it near  
3     Weitchpec, which is located about 43 miles upstream from the Pacific Ocean.  
4     The Trinity River is the largest tributary of the Klamath River and makes a  
5     substantial contribution to the flows in the lower Klamath River. This section of  
6     the Klamath River serves primarily as a migration corridor for salmonids, with  
7     most spawning and rearing upstream of the confluence with the Trinity River or  
8     in the larger tributaries (e.g., Blue Creek) to the mainstem Klamath River.

9     **9.3.3.3.1     Fish in the Lower Klamath River**

10    Focal fish species that occur in the lower Klamath River downstream of the  
11    Trinity River confluence are included for analysis in this EIS and include all those  
12    found in the Trinity River, as described above, with the exception of Eulachon.

13    Eulachon is a smelt species in the Klamath River system found upstream of the  
14    estuary. Eulachon are anadromous broadcast spawners that spawn in the lower  
15    reaches of rivers and tributaries and usually die after spawning. Eulachon are  
16    sexually mature at 2 years and spawn at ages 3, 4, and/or 5 (Scott and Crossman  
17    1973). Timing of the spawning migration in the Klamath River is similar to other  
18    known runs of Eulachon, beginning in December and continuing until May, with  
19    a peak in March and April (YTFP 1998, Larson and Belchik 1998).

20    In the Klamath River, adult Eulachon generally migrate as high as Brooks Riffle,  
21    about 40 kilometers (about 24 miles) upstream of the mouth, but have been  
22    observed as high as Pecwan Creek and even Weitchpec during exceptional years  
23    (YTFP 1998); specific spawning areas are unknown. Eggs hatch in 20 to 40 days  
24    depending on water temperature, taking longer at cooler temperatures. After  
25    hatching, the larvae are passively carried from spawning grounds to the ocean via  
26    river currents (Scott and Crossman 1973).

27    This species was historically important to local tribes and supported a subsistence  
28    fishery on the lower Klamath River. According to accounts of Yurok Tribal  
29    elders, there were annual runs so great that one had no problem catching “as many  
30    as you wanted;” however, the last noticeable runs of Eulachon were observed in  
31    1988 and 1989 by Tribal fishers (Larson and Belchik 1998). In 1996, YTFP  
32    sampling efforts to capture Eulachon were unsuccessful, although a Yurok Tribal  
33    member gave the YTFP a Eulachon he had caught while fishing for lamprey at the  
34    mouth of the river (Larson and Belchik 1998). However, it is likely that the  
35    Eulachon has been extirpated or nearly so on the lower Klamath River  
36    (NMFS 2015).

37    **9.3.4     Central Valley Region**

38    Fish and aquatic resources in the Central Valley Region are described in this  
39    section in accordance with the following major waterbodies.

- 40    • Shasta Lake and Keswick Reservoir
- 41    • Whiskeytown Lake
- 42    • Clear Creek

- 1 • Sacramento River from Keswick Reservoir to the Delta (near Freeport)
- 2 • Battle Creek
- 3 • Feather River
- 4 • Yuba and Bear Rivers
- 5 • American River
- 6 • Delta
- 7 • Yolo Bypass
- 8 • Millerton Lake
- 9 • San Joaquin River from the Stanislaus River confluence to the Delta (near
- 10 Vernalis)
- 11 • New Melones Reservoir, Tulloch Reservoir, and the reservoir formed by
- 12 Goodwin Dam
- 13 • Stanislaus River
- 14 • San Luis Reservoir

#### 15 **9.3.4.1 Shasta Lake and Keswick Reservoir**

16 Shasta Lake is formed by Shasta Dam, which is located on the Sacramento River  
 17 just downstream of the confluence of the Sacramento, McCloud, and Pit rivers.  
 18 Shasta Dam has no fish passage facilities; however, the dam has a fish trapping  
 19 facility that operates in conjunction with Livingston Stone National Fish Hatchery  
 20 below Shasta Dam.

##### 21 **9.3.4.1.1 Shasta Lake**

22 Shasta Lake fish species include native and introduced warm-water and cold-  
 23 water species. Major nonfish aquatic animal species assemblages in Shasta Lake  
 24 include benthic macroinvertebrates and zooplankton (Reclamation 2013b).  
 25 Shasta Lake is typically thermally stratified from April through November, during  
 26 which time the upper layer (epilimnion) can reach a peak water temperature of  
 27 80 degrees Fahrenheit (°F) (Reclamation 2003). The upper layer of Shasta Lake  
 28 supports warm-water game fish, and the lower layers (metalimnion and  
 29 hypolimnion) support cold-water fishes. Nonnative, warm-water fish species in  
 30 Shasta Lake include Smallmouth Bass, Largemouth Bass, Spotted Bass, Black  
 31 Crappie, Bluegill, Green Sunfish, Channel Catfish, White Catfish, and Brown  
 32 Bullhead (DWR et al. 2013). Cold-water species include Rainbow Trout, Brown  
 33 Trout, landlocked White Sturgeon, landlocked Coho Salmon (Reclamation et al.  
 34 2003), and landlocked Chinook Salmon (Reclamation 2013). Other fish species  
 35 in Shasta Lake include Golden Shiner, Threadfin Shad, Common Carp, and the  
 36 native Hardhead, Sacramento Sucker, and Sacramento Pikeminnow (DWR et al.  
 37 2013, Reclamation 2013).

1 Water quality in Shasta Lake is generally considered good, largely because of the  
2 continual inflow of cool, high-quality water from the major tributaries to the lake.  
3 The primary water quality concerns in the lake is turbidity, typically associated  
4 with heavy rainfall events that move soils and runoff from abandoned mines in  
5 the area into the lake.

6 Warm-water fish habitat in Shasta Lake is influenced primarily by fluctuations in  
7 the lake level and the availability of shoreline cover (Reclamation 2003). Water  
8 surface elevations in Shasta Lake can fluctuate approximately 55 feet annually as  
9 a result of operation of Shasta and Sacramento River diversions (Reclamation  
10 2003). Reservoir surface elevation fluctuations can disturb shallow, nearshore  
11 habitats, including spawning and rearing habitat for warm-water fish species. The  
12 shoreline of Shasta Lake is generally steep, which limits shallow, warm-water fish  
13 habitat, and is not conducive to the establishment of vegetation or other shoreline  
14 cover (Reclamation 2003).

#### 15 **9.3.4.1.2 Keswick Reservoir**

16 Keswick Reservoir is a re-regulating reservoir for Shasta Lake. The water surface  
17 elevation is relatively constant. Residence time for water in Keswick Reservoir is  
18 about a day, compared with a residence time of about a year for water in Shasta  
19 Lake. Consequently, water temperatures tend to be controlled by releases from  
20 Shasta Dam and average less than 55°F. Despite the cool temperatures, the  
21 reservoir supports warm-water and cold-water fishes, including Largemouth Bass,  
22 crappie and catfish, and Rainbow Trout (Reclamation 2003).

#### 23 **9.3.4.2 Whiskeytown Lake**

24 Water is diverted from the Trinity River at Lewiston Dam and discharged via the  
25 Clear Creek Tunnel into Whiskeytown Lake on Clear Creek. From Whiskeytown  
26 Lake, water is released into the lower portion of Clear Creek via Whiskeytown  
27 Dam and into Keswick Reservoir through the Spring Creek Tunnel. There are  
28 two temperature control curtains in Whiskeytown Lake: Oak Bottom and Spring  
29 Creek (Reclamation 2008a). The Oak Bottom temperature control curtain serves  
30 as a barrier to prevent warm water in the reservoir from mixing with cold water  
31 from Lewiston Lake entering through the Carr Powerhouse. The Oak Bottom  
32 curtain is damaged and cannot be fully deployed; it is scheduled to be repaired in  
33 2015. The Spring Creek temperature control curtain was replaced in 2011 and  
34 aids cold-water movement into the underwater intake for the Spring Creek  
35 Tunnel.

36 The fish assemblage in Whiskeytown Lake includes cold-water and warm-water  
37 species. Common fishes known to occur in Whiskeytown Lake include Rainbow  
38 Trout, Brown Trout, Kokanee Salmon, Largemouth Bass, crappie, sunfish,  
39 catfish, and bullhead (USFWS et al. 2004).

#### 40 **9.3.4.3 Clear Creek**

41 The project area includes the reach of Clear Creek extending from Whiskeytown  
42 Dam to the confluence with the Sacramento River. Since 1995, extensive habitat  
43 and flow restoration in Clear Creek has occurred under the Central Valley Project

1 Improvement Act (CVPIA) and CALFED programs and in accordance with the  
2 NMFS 2009 BO. The Clear Creek Technical Team has been working since 1996  
3 to facilitate implementation of CVPIA anadromous salmonid restoration actions  
4 (Brown et al. 2012). Restoration efforts have resulted in increased stocks of  
5 fall-run Chinook Salmon and re-established populations of spring-run Chinook  
6 Salmon and steelhead.

#### 7 **9.3.4.3.1 Fish in Clear Creek**

8 This analysis is focused on Chinook Salmon, steelhead, and Pacific Lamprey in  
9 Clear Creek.

##### 10 *Spring-run Chinook Salmon*

11 Clear Creek currently supports a modest run of spring-run Chinook Salmon,  
12 which since 1998 has ranged from 0 in 2001 to an estimated high of 659 fish in  
13 2013 (CDFW 2014). Adult spring-run Chinook Salmon migrate into Clear Creek  
14 from April through September. Adult fish tend to move as far upstream as  
15 possible to access cooler temperatures downstream of Whiskeytown Dam and  
16 hold over in summer until spawning in September through October. In the NMFS  
17 2009 BO, NMFS expressed concern that spring-run Chinook Salmon unable to  
18 enter Clear Creek for spawning could hybridize with fall-run Chinook Salmon  
19 spawning in the Sacramento River (NMFS 2009a).

20 NMFS (2009a) reported that insufficient instream flows could fail to attract adult  
21 spring-run holding in the Sacramento River mainstem into Clear Creek. Adult  
22 spring-run Chinook Salmon tend to spread downstream of their holding areas  
23 prior to spawning (from Whiskeytown Dam downstream to the Clear Creek Road  
24 Bridge) from September through October. Egg incubation occurs from  
25 September through December, and juveniles rear from October through April  
26 (NMFS 2009a).

27 Spawning gravel is annually augmented in Clear Creek downstream of  
28 Whiskeytown Dam under the CVPIA Clear Creek Restoration Program and in  
29 accordance with the 2009 NMFS BO (Reclamation 2013a). Additionally, water  
30 temperature criteria to protect spring-run Chinook Salmon during spawning and  
31 incubation are generally met; however, in recent years, water temperatures in  
32 Clear Creek during the spawning and incubation period (i.e., September 15 to  
33 October 31) have exceeded the temperature targets at times (Brown et al. 2012).

34 Based on rotary screw trap captures, juvenile spring-run Chinook Salmon  
35 outmigrate from Clear Creek from May through February. Peak outmigration  
36 occurs over a 9-week period from early December 2008 through early February  
37 2009 (Earley et al. 2010). Trap data indicate that the majority of juveniles  
38 identified as spring-run (based on length-at-date size criteria) leave as age-0 fish,  
39 less than 40 millimeter (mm) in fork length (USFWS 2008b, Earley et al. 2010).

##### 40 *Fall-/Late Fall-run Chinook Salmon*

41 Since 1995, restoration activities implemented in accordance with programs  
42 implemented under the CVPIA, CALFED, and the 2009 NMFS BO have  
43 increased stocks of fall-run Chinook Salmon by more than 400 percent (Brown

1 2011). In 2014, fall-run Chinook Salmon estimated escapement was 15,794  
2 compared to the average baseline (1967-1991) estimated escapement of 1,689.

3 Fall/late fall-run Chinook Salmon primarily use the lower reaches of Clear Creek  
4 for all life history phases. Fall-run Chinook migrate into Clear Creek between the  
5 spring- and late fall-runs and spawn in October through December (USFWS  
6 2015). A picket weir installed about 7.4 miles upstream of the confluence with  
7 the Sacramento River from August 1 to November 1 is used to prevent fall-run  
8 Chinook Salmon from spawning in the upper reaches with spring-run.

9 Late-fall-run Chinook Salmon migrate into Clear Creek from November through  
10 April, with peak migration in December; peak spawning occurs in January.

11 Based on rotary screw trap captures and length-at-date size criteria, fall-run  
12 Chinook Salmon make up the vast majority of all Chinook Salmon outmigrating  
13 from lower Clear Creek. Late fall-run juveniles constitute a small percentage of  
14 juvenile Chinook Salmon leaving Clear Creek. Juvenile fall-/late fall-run  
15 Chinook Salmon primarily outmigrate from Clear Creek as age-0 fish less than  
16 40 mm in fork length (USFWS 2008b, Earley et al. 2010). Peak age-0  
17 outmigration in 2008/2009 was from January and February for fall-run Chinook  
18 Salmon and during April to May for late fall-run Chinook Salmon (Earley et al.  
19 2010).

20 *Steelhead*

21 Operation of Whiskeytown Dam supports cold-water habitat for steelhead in  
22 Clear Creek, the amount of which depends on flow releases which range from  
23 30 to 200 cubic feet per second (cfs) depending on water year type (Reclamation  
24 2008a). Steelhead have recolonized the habitat that became accessible with the  
25 removal of the McCormick-Saeltzer Dam in 2000. Redd surveys conducted since  
26 2003 indicate that a small, but increasing population of steelhead resides in Clear  
27 Creek, with the highest density in the first mile below Whiskeytown Dam  
28 (USFWS 2007).

29 Adult steelhead immigration into Clear Creek usually occurs from August through  
30 March, with a peak occurring from September to November (USFWS 2008b).  
31 Adult steelhead tend to hold in the upper reaches of Clear Creek from September  
32 to December.

33 Spawning typically begins in December and continues through early March. Peak  
34 spawning occurs from late January to early February (USFWS 2007). The  
35 embryo incubation life stage begins with the onset of spawning in late December  
36 and generally extends through April.

37 Spawning distribution has recently expanded from the upper 4 miles of lower  
38 Clear Creek to the entire 17 miles of lower Clear Creek, although it appears to be  
39 concentrated in areas of newly added spawning gravels. Recently, more steelhead  
40 were observed spawning in the lowest reach of the creek where resulting juveniles  
41 can be subject to warmer water temperatures during summer (Brown 2011).

1 Summertime water temperatures are often critical for steelhead rearing and limit  
2 rearing habitat quality in many streams. Instream flow releases are intended to  
3 maintain suitable water temperatures throughout most of Clear Creek during  
4 summer. Snorkel surveys from 1999 to 2002 indicate that rearing steelhead may  
5 be present throughout all of lower Clear Creek (Good et al. 2005). Based on  
6 rotary screw trap captures, fry make up the vast majority of all steelhead/Rainbow  
7 Trout captured in lower Clear Creek. Peak outmigration of juvenile steelhead fry  
8 occurred from mid-March through April of 2009 (Earley et al. 2010).

#### 9 *Pacific Lamprey*

10 Pacific Lamprey is expected to inhabit all reaches in Clear Creek upstream to  
11 Whiskeytown Dam. The loss of access to historical habitat and apparent  
12 population declines throughout California and the Sacramento and San Joaquin  
13 River basins indicate the population is likely reduced compared with historical  
14 levels (Moyle et al. 2009). Little information is available on factors influencing  
15 populations of Pacific Lamprey in Clear Creek, but they are likely affected by  
16 many of the same factors as salmon and steelhead because of parallels in their  
17 life cycles.

18 Ocean stage adult Pacific Lampreys likely migrate into Clear Creek in summer,  
19 where they hold for approximately 1 year before spawning (Hanni et al. 2006).  
20 No information is available on spawning in Clear Creek; however, spawning  
21 period documented by Hannon and Deason (2008) for Pacific Lampreys in the  
22 American River of early January to late May, with peak spawning typically in  
23 early April, may also apply to Clear Creek. Pacific Lamprey ammocoetes rear in  
24 Clear Creek for all or part of their 5- to 7-year freshwater residence. Data from  
25 rotary screw trapping in Clear Creek suggest that some outmigration of Pacific  
26 Lampreys may occur year-round, but peak outmigration occurs from early winter  
27 through spring (Hanni et al. 2006).

#### 28 **9.3.4.3.2 Extent and Status of Aquatic Habitat**

29 Whiskeytown Dam limits the contribution of coarse sediment for transport  
30 downstream in Clear Creek, which NMFS (2009a) reported has resulted in riffle  
31 coarsening, fossilization of alluvial features, loss of fine sediments available for  
32 overbank deposition, and considerable loss of spawning gravels. These  
33 conditions affect spawning and rearing habitat on Clear Creek. Water flows and  
34 temperatures conditions on Clear Creek are presented in Chapter 5, Surface Water  
35 Resources and Water Supplies, and Chapter 6, Surface Water Quality,  
36 respectively.

#### 37 *Spawning Habitat*

38 An unpublished study conducted by USFWS (as cited in Brown 2011) suggested  
39 that gravel transport blocked by the construction of Whiskeytown Dam reduced  
40 spawning habitat in Clear Creek by 92 percent. Plans developed under CVPIA  
41 implementation included a goal to create and maintain 347,288 square feet of  
42 usable spawning habitat between Whiskeytown Dam to the former  
43 McCormick-Saeltzer Dam by 2020. This area is equivalent to the spawning  
44 habitat that existed before construction of Whiskeytown Dam (CVPIA 2014).

1 Brown (2011) noted that much of the degraded habitat has been restored by gravel  
2 augmentation, but continued augmentation will be required. Spawning gravel is  
3 annually augmented in Clear Creek downstream of Whiskeytown Dam, pursuant  
4 to CVPIA implementation and Action of I.1.3 of the 2009 NMFS BO Reasonable  
5 and Prudent Alternative (RPA). The CVPIA annual spawning gravel target is  
6 25,000 tons per year; however, an average of 9,574 tons has been placed annually  
7 since 1996. In 2012, a total of 9,974 tons of gravel was placed at four sites:  
8 Guardian Rock site, Placer Bridge, Clear Creek Road Crossing, and at Tule  
9 Backwater. A gravel injection project did not occur in 2013 (CVPIA 2014).

10 Most supplemental spawning gravel is placed into Clear Creek at long-term  
11 injection sites awaiting high flows to move gravel into the creek. These gravel  
12 addition projects have successfully created habitat suitable for spring-run Chinook  
13 Salmon spawning as evidenced by the number of redds directly observed in  
14 supplemental gravel or in supplemental gravel integrated into native gravel  
15 (USFWS 2007, 2008b). Spawning area mapping performed annually since 2000  
16 indicates the overall amount of area used by spawning fall-run Chinook Salmon  
17 has been increasing, despite the adult population abundance remaining stable.  
18 The amount of area used in 2008 was the highest measured and more than double  
19 the amount used in 2000, suggesting that the gravel augmentation program has  
20 been successful in creating new spawning habitat. Gravel augmentation also has  
21 increased the amount of steelhead spawning habitat available in the lower reaches  
22 of Clear Creek, and NMFS (2009a) has indicated that this directly relates to  
23 higher fish abundance in recent years. In most locations, gravel additions created  
24 spawning habitat that did not exist or had limited prior use.

25 Studies to determine the availability of fish habitat, expressed as Weighted  
26 Useable Area (WUA), have been conducted by USFWS for Clear Creek  
27 (USFWS 2006). For spring-run Chinook Salmon, it was determined that  
28 spawning WUA peaked at the highest modeled flow (900 cfs) in the upstream  
29 alluvial segment from Whiskeytown Dam to the NEED Camp Bridge. In the  
30 canyon segment downstream (NEED Camp Bridge to the Clear Creek Road  
31 Bridge) spawning habitat peaked at 650 cfs. The WUA for steelhead/Rainbow  
32 Trout spawning habitat peaked at 350 cfs and 600 cfs in these segments,  
33 respectively (USFWS 2007). In the lower reach downstream of the Clear Creek  
34 Road Bridge, WUA for both fall-run Chinook Salmon and steelhead/Rainbow  
35 Trout spawning habitat peaked at 300 cfs (USFWS 2011a).

36 At all flows, the amount of spawning habitat present in Clear Creek is less than  
37 the amount needed to achieve the abundance recovery goal of spring-run Chinook  
38 Salmon spawning (based on the original USFWS [2007] estimates). However,  
39 the increased spawning habitat availability due to gravel additions since 2003  
40 suggests that spawning habitat for spring-run Chinook Salmon is now more than  
41 sufficient to support the recovery goal at all flows. At flows greater than 50 cfs,  
42 the amount of spawning habitat present in Clear Creek is greater than the amount  
43 of spawning habitat needed to achieve the abundance recovery goal for steelhead.  
44 In contrast, the amount of spawning habitat present in Clear Creek is less than the

1 amount of spawning habitat needed to support 7,920 adult fall-run Chinook  
2 Salmon in Clear Creek (USFWS 2015).

### 3 *Rearing Habitat*

4 The WUA for spring-run Chinook Salmon fry rearing peaked at 600 cfs in the  
5 upstream alluvial segment from Whiskeytown Dam to the NEED Camp Bridge.  
6 In the canyon segment downstream (NEED Camp Bridge to Clear Creek Road  
7 Bridge), fry rearing habitat peaked at the highest modeled flow (900 cfs). The  
8 WUA for steelhead/Rainbow Trout fry rearing habitat peaked at 700 cfs and  
9 900 cfs (the maximum flow modeled) in these segments, respectively (USFWS  
10 2011b). The WUA for spring-run Chinook Salmon and steelhead/Rainbow Trout  
11 juvenile rearing habitat peaked at the highest modeled flow (900 cfs) in the upper  
12 alluvial segment and 650 cfs in the canyon segment downstream. In the lower  
13 reach downstream of the Clear Creek Road Bridge, WUA for both fall-run  
14 Chinook Salmon and steelhead/Rainbow Trout fry rearing habitat peaked at  
15 50 cfs; fry rearing habitat for spring-run Chinook Salmon peaked at 900 cfs.  
16 Spring-run Chinook Salmon and steelhead/Rainbow Trout juvenile rearing habitat  
17 peaked at 850 cfs, while fall-run Chinook Salmon juvenile rearing habitat peaked  
18 at 350 cfs (USFWS 2013a).

19 As described above for spawning habitat, USFWS (2015) compared the total  
20 amount of rearing habitat available for spring-run Chinook Salmon and  
21 steelhead/Rainbow Trout to the amount of rearing habitat needed to support an  
22 annual escapement of 833 adults for each species. The total amount of rearing  
23 habitat available for fall-run Chinook Salmon was compared to the amount of  
24 habitat needed to support an average escapement of 7,920 fall-run Chinook  
25 Salmon. At all flows, the amount of rearing habitat present in Clear Creek is  
26 greater than the amount needed to achieve the abundance recovery goal for  
27 spring-run Chinook Salmon and steelhead. In contrast, the amount of rearing  
28 habitat present in Clear Creek is less than the amount needed to support  
29 7,920 adult fall-run Chinook Salmon in Clear Creek.

### 30 **9.3.4.3.3 Fish Passage**

31 Whiskeytown Dam blocks access to 25 miles of historical spring-run Chinook  
32 Salmon and steelhead spawning and rearing habitat (Yoshiyama et al. 1996).  
33 Until 2000, the McCormick-Saeltzer Dam was a barrier to upstream migration for  
34 anadromous salmonids. After its removal, anadromous salmonids recolonized an  
35 additional 12 miles of habitat upstream to Whiskeytown Dam. With the removal  
36 of McCormick-Saeltzer Dam, passage of spring-run Chinook Salmon has  
37 increased. Stream surveys and juvenile monitoring results also suggest that dam  
38 removal has allowed reestablishment of spring-run Chinook Salmon and  
39 steelhead. NMFS (2009a) reported that compared to fall-run Chinook Salmon,  
40 spring-run Chinook Salmon historically spawned earlier and at locations farther  
41 upstream in Clear Creek. However, NMFS (2009a) concluded that the  
42 construction of Whiskeytown Dam likely caused a high degree of spatial overlap  
43 between the fall-run and spring-run fish during spawning, resulting in a higher  
44 probability of hybridization. To address this concern, USFWS has been

1 separating adult fall-run fish from the spring-run fish holding in the upper reaches  
2 of Clear Creek with a segregation weir that is operated from August 1 to  
3 November 1. After November 1, fall-run Chinook Salmon have access to the  
4 entire river for spawning.

5 **9.3.4.4 Sacramento River from Keswick Reservoir to the Delta near**  
6 **Freeport**

7 Aquatic resources in the Sacramento River are affected by the habitat along the  
8 river and along the tributaries that connect to the river. Habitat along the river  
9 ranges from artificial structures used for water supply and flood management to  
10 open spaces that provide more natural types of habitat. The flow regime in the  
11 Sacramento River is managed for water supply and flood management, as  
12 described in Chapter 5, Surface Water Resources and Water Supplies. The  
13 following discussion focuses on the fish in the Sacramento River and aquatic  
14 habitat conditions.

15 **9.3.4.4.1 Fish in the Sacramento River**

16 The analysis is focused on the following species:

- 17 • Chinook Salmon (winter-, spring-, and fall/late fall-run)
- 18 • Steelhead
- 19 • Green Sturgeon
- 20 • White Sturgeon
- 21 • Sacramento Splittail
- 22 • Pacific Lamprey
- 23 • Striped Bass
- 24 • American Shad

25 *Winter-run Chinook Salmon*

26 Adult winter-run Chinook Salmon return to fresh water during winter but delay  
27 spawning until spring and summer. Adults enter fresh water in an immature  
28 reproductive state, similar to spring-run Chinook, but winter-run Chinook move  
29 upstream much more quickly and then hold in the cool waters downstream of  
30 Keswick Dam for an extended period before spawning. Juveniles spend about  
31 5 to 9 months in the river and estuary systems before entering the ocean. This  
32 life-history pattern differentiates the winter-run Chinook from other Sacramento  
33 River Chinook runs and from all other populations within the range of Chinook  
34 Salmon (DFG 1985, 1998b).

35 Access to approximately 58 percent of the original winter-run Chinook Salmon  
36 habitat has been blocked by dam construction (Reclamation 2008a). The  
37 remaining accessible habitat occurs in the Sacramento River downstream of  
38 Keswick Dam and in Battle Creek. The number of winter-run Chinook Salmon in  
39 Battle Creek is unknown, but if they do occur, they are scarce (Reclamation and  
40 SWRCB 2003).

1 Escapement data indicate that the winter-run Chinook Salmon population  
2 declined from its levels in the 1970s to relatively low levels through the 1980s  
3 and 1990s, with a small rebound in the early 2000s (Azat 2012).

4 Adult winter-run Chinook Salmon migrate upstream past the location of the Red  
5 Bluff Diversion Dam (RBDD) beginning in mid-December and continuing into  
6 early August. Most of the run passes RBDD between January and May, with the  
7 peak in mid-March (DFG 1985). Winter-run Chinook Salmon spawn only in the  
8 Sacramento River, almost exclusively above RBDD, with the majority spawning  
9 upstream of Balls Ferry, based on aerial redd survey data collected after passage  
10 was provided past the Anderson-Cottonwood Irrigation District (ACID) diversion.  
11 Aerial redd surveys have indicated that the winter-run Chinook Salmon spawning  
12 distribution has shifted upstream since gravel introductions began in the upper  
13 river near Keswick Dam; a high proportion of winter run Chinook spawn on the  
14 recently placed gravel (USFWS and Reclamation 2008). Spawning occurs May  
15 through July, with the peak in early June. Fry emergence occurs from mid-June  
16 through mid-October and fry disperse to areas downstream for rearing. Juvenile  
17 migration past RBDD may begin in late July, generally peaks in September, and  
18 can continue until mid-March in drier years (Vogel and Marine 1991). The  
19 majority (75 percent) of winter-run Chinook Salmon outmigrate past RBDD as  
20 fry (Martin et al. 2001), where they rear before outmigrating to the Delta  
21 primarily in December through April (Appendix 9B). Between 44 and 81 percent  
22 (mean 65 percent) of juvenile winter-run Chinook Salmon used areas downstream  
23 of RBDD for nursery habitat, and the relative usage of rearing habitat upstream  
24 and downstream of RBDD appeared to be influenced by river flow during fry  
25 emergence (Martin et al. 2001). Winter-run Chinook Salmon usually migrate past  
26 Knight's Landing once flows at Wilkins Slough rise to about 14,000 cfs; most  
27 juvenile winter-run Chinook Salmon outmigrate past Chipps Island by the end of  
28 March (del Rosario et al. 2013).

### 29 *Spring-run Chinook Salmon*

30 Historically, spring-run Chinook Salmon in the Sacramento River Basin were  
31 found in the upper and middle reaches (1,000 to 6,000 feet) of the American,  
32 Yuba, Feather, Sacramento, McCloud and Pit rivers, as well as smaller tributaries  
33 of the upper Sacramento River downstream of present-day Shasta Dam  
34 (NMFS 2009a). Estimates indicate that 82 percent of the approximately  
35 2,000 miles of salmon spawning and rearing habitat available in the mid-1800s is  
36 unavailable or inaccessible today (Yoshiyama et al. 1996). Naturally spawning  
37 populations of spring-run Chinook Salmon currently are restricted to accessible  
38 reaches of the upper Sacramento River, Antelope Creek, Battle Creek, Beegum  
39 Creek, Big Chico Creek, Butte Creek, Clear Creek, Deer Creek, Feather River,  
40 Mill Creek, and Yuba River (DFG 1998b). Most of these reaches are outside the  
41 project area; however, all spring-run Chinook Salmon migratory life stages must  
42 pass through the project area.

43 Spring-run Chinook Salmon abundance in the Sacramento River mainstem has  
44 apparently declined sharply through time, with escapement estimates ranging  
45 from approximately 5,000 to 23,000 fish in the 1980s, 100 to 4,100 fish in the

1 1990s, and 0 to 621 fish between 2000 and 2014 (CDFW 2015). However, the  
2 criteria for run classification at RBDD have changed so no conclusions can be  
3 reached about changes in the number of spring-run Chinook Salmon in the  
4 Sacramento River. Chinook Salmon expressing spring-run timing do spawn in  
5 the mainstem Sacramento River between RBDD and Keswick Dam (NMFS  
6 2009a). The Sacramento River now serves primarily as a migratory corridor for  
7 the adult and juvenile life stages of spring-run (and other runs) of Chinook  
8 Salmon.

9 In fresh water, juvenile spring-run Chinook Salmon rear in natal tributaries, the  
10 Sacramento River mainstem, and nonnatal tributaries to the Sacramento River  
11 (DFG 1998b). Outmigration timing is highly variable, as they may migrate  
12 downstream as YOY or as juveniles or yearlings. The outmigration period for  
13 spring-run Chinook Salmon extends from November to early May, with up to  
14 69 percent of the YOY fish outmigrating through the lower Sacramento River and  
15 Delta during this period (DFG 1998b). Peak movement of juvenile spring-run  
16 Chinook Salmon in the Sacramento River at Knights Landing occurs in December  
17 and again in March (Snider and Titus 1998, 2000b, c, d; Vincik et al. 2006;  
18 Roberts 2007). Migratory cues, such as increased flows, increasing turbidity from  
19 runoff, changes in day length, or intraspecific competition from other fish in their  
20 natal streams, may spur outmigration of juveniles from the upper Sacramento  
21 River basin when they have reached the appropriate stage of maturation (NMFS  
22 2009a). Spring-run juveniles that remain in the Sacramento River over summer  
23 are confined to approximately 100 miles of the upper mainstem, where cool water  
24 temperatures are maintained by dam releases.

#### 25 *Fall-/Late Fall-run Chinook Salmon*

26 The fall-run Chinook Salmon is an ocean-maturing type of salmon adapted for  
27 spawning in lowland reaches of big rivers, including the mainstem Sacramento  
28 River; the late fall-run Chinook Salmon is mostly a stream-maturing type  
29 (Moyle 2002). Similar to spring-run, adult late fall-run Chinook Salmon typically  
30 hold in the river for 1 to 3 months before spawning, while fall-run Chinook  
31 Salmon generally spawn shortly after entering fresh water. Fall-run Chinook  
32 Salmon migrate upstream past RBDD on the Sacramento River between July and  
33 December, typically spawning in upstream reaches from October through March.  
34 Late fall-run Chinook Salmon migrate upstream past RBDD from August to  
35 March and spawn from January to April (NMFS 2009a, TCCA 2008). The  
36 majority of young fall-run Chinook Salmon migrate to the ocean during the first  
37 few months following emergence, although some may remain in fresh water and  
38 migrate as yearlings. Late fall-run juveniles typically enter the ocean after 7 to  
39 13 months of rearing in fresh water, at 150- to 170 mm in fork length,  
40 considerably larger and older than fall-run Chinook Salmon (Moyle 2002).

41 The primary spawning area used by fall- and late fall-run Chinook Salmon in the  
42 Sacramento River is the area from Keswick Dam downstream to RBDD.  
43 Spawning densities for each of the runs are generally highest in this reach.

1 Annual fall-run and late fall-run Chinook Salmon escapement to the Sacramento  
2 River and its tributaries has generally been declining in the last decade, following  
3 peaks in the late 1990s to early 2000s (Azat 2012).

#### 4 *Steelhead*

5 Although steelhead can be divided into two life history types, summer-run  
6 steelhead and winter-run steelhead, based on their state of sexual maturity at the  
7 time of river entry, only winter-run steelhead are currently found in Central  
8 Valley rivers and streams. Existing wild steelhead stocks in the Central Valley  
9 are mostly confined to the upper Sacramento River and its tributaries, including  
10 Antelope, Deer, and Mill creeks and the Yuba River. Populations may exist in  
11 other tributaries, and a few naturally spawning steelhead are produced in the  
12 American and Feather rivers (McEwan and Jackson 1996).

13 Adult steelhead migrate upstream past the Fremont Weir between August and  
14 March, primarily from August through October; they migrate upstream past  
15 RBDD during all months of the year, but primarily during September and October  
16 (NMFS 2009a). The primary spawning area used by steelhead in the Sacramento  
17 River is the area from Keswick Dam downstream to RBDD. Unlike salmon,  
18 steelhead may live to spawn more than once and generally rear in freshwater  
19 streams for 2 to 4 years before outmigrating to the ocean. Both spawning areas  
20 and migratory corridors are used by juvenile steelhead for rearing prior to  
21 outmigration. The Sacramento River functions primarily as a migration channel,  
22 although some rearing habitat remains in areas with setback levees (primarily  
23 upstream of Colusa) and flood bypasses (e.g., Yolo Bypass) (NMFS 2009a).

24 Recent steelhead monitoring data are scarce for the upper portion of the  
25 Sacramento River system. In 1989, Hallock (1989) reported that steelhead had  
26 declined drastically in the Sacramento River upstream of the Feather River  
27 confluence. In the 1950s, the average estimated spawning population size  
28 upstream of the Feather River confluence was 20,540 fish (McEwan and Jackson  
29 1996). In 1991–1992, the annual run size for the total Sacramento River system  
30 was likely fewer than 10,000 adult fish (McEwan and Jackson 1996). From 1967  
31 to 1993, the estimated number of steelhead passing the Red Bluff Pumping Plant  
32 ranged from a low of 470 to a high of 19,615 (CHSRG 2012). Steelhead  
33 escapement surveys at the site of RBDD ended in 1993.

#### 34 *Green Sturgeon*

35 The Sacramento River provides habitat for Green Sturgeon spawning, adult  
36 holding, foraging, and juvenile rearing. Suitable spawning temperatures and  
37 spawning substrate exist for Green Sturgeon in the Sacramento River upstream  
38 and downstream of RBDD (Reclamation 2008a). Although the upstream extent  
39 of historical Green Sturgeon spawning in the Sacramento River is unknown, the  
40 observed distribution of sturgeon eggs, larvae, and juveniles indicates that  
41 spawning occurs from Hamilton City to as far upstream as Ink's Creek confluence  
42 and possibly up to the Cow Creek confluence (Brown 2007, Poytress et al. 2013).  
43 Based on the distribution of sturgeon eggs, larvae, and juveniles in the  
44 Sacramento River, DFG (2002) indicated that Green Sturgeon spawn in late

1 spring and early summer. Peak spawning is believed to occur between April  
2 and June.

3 Spawning migrations and spawning by Green Sturgeon in the Sacramento River  
4 mainstem have been well documented over the last 15 years (Beamesderfer et al.  
5 2004). Anglers fishing for White Sturgeon or salmon commonly report catches of  
6 Green Sturgeon from the Sacramento River as far upstream as Hamilton City  
7 (Beamesderfer et al. 2004). Eggs, larvae, and post-larval Green Sturgeon are now  
8 commonly reported in sampling directed at Green Sturgeon and other species  
9 (Beamesderfer et al. 2004, Brown 2007). YOY Green Sturgeon have been  
10 observed annually since the late 1980s in fish sampling efforts at RBDD and the  
11 Glenn-Colusa Irrigation District (GCID) intake (Beamesderfer et al. 2004).  
12 Acoustically tagged Green Sturgeon were detected upstream of RBDD from 2004  
13 to 2006 (Heublein et al. 2009). Adult Green Sturgeon that migrate upstream in  
14 April, May, and June are completely blocked by the ACID diversion dam  
15 (NMFS 2009b), rendering approximately 3 miles of spawning habitat upstream of  
16 the diversion dam inaccessible.

17 Green Sturgeon from the Sacramento River are genetically distinct from their  
18 northern counterparts, indicating a spawning fidelity to their natal rivers (Israel  
19 et al. 2004), even though individuals can range widely (Lindley et al. 2008).  
20 Larval Green Sturgeon have been regularly captured during their dispersal stage  
21 at about 2 weeks of age (24 to 34 mm fork length) in rotary screw traps at RBDD  
22 (DFG 2002a) and at about 3 weeks old when captured at the GCID intake (Van  
23 Eenennaam et al. 2001).

24 Young Green Sturgeon appear to rear for the first 1 to 2 months in the Sacramento  
25 River between Keswick Dam and Hamilton City (DFG 2002a). Rearing habitat  
26 condition and function may be affected by variation in annual and seasonal river  
27 flow and temperature characteristics.

28 Empirical estimates of Green Sturgeon abundance are not available for the  
29 Sacramento River population or any west coast population (Reclamation 2008a),  
30 and the current population status is unknown (Beamesderfer et al. 2007,  
31 Adams et al. 2007). A genetic analysis of Green Sturgeon larvae captured in the  
32 Sacramento River resulted in an estimate of the number of adult spawning pairs  
33 upstream of RBDD ranging from 32 to 124 between 2002 and 2006 (Israel 2006).  
34 NMFS (2009b) noted that, similar to winter-run Chinook Salmon, the restriction  
35 of spawning habitat for Green Sturgeon to only one reach of the Sacramento  
36 River increases the vulnerability of this spawning population to catastrophic  
37 events. This was one of the primary reasons that the Southern DPS of Green  
38 Sturgeon was federally listed as a threatened species in 2006.

### 39 *White Sturgeon*

40 In California, White Sturgeon are most abundant within the Delta region, but the  
41 population spawns mainly in the Sacramento River; a small part of the population  
42 is also thought to spawn in the Feather River (Moyle 2002). In addition to  
43 spawning, White Sturgeon embryo development and larval rearing occur in the  
44 Sacramento River (Moyle 2002, Israel et al. 2008). White Sturgeon are found in

1 the Sacramento River primarily downstream of RBDD (TCCA 2008), with most  
2 spawning between Knights Landing and Colusa (Schaffter 1997).

3 The population status of White Sturgeon in the Sacramento River is unclear.  
4 Overall, limited information on trends in adult and juvenile abundance in the  
5 Delta population suggests that numbers are declining (Reis-Santos et al. 2008).  
6 Spawning stage adults generally move into the lower reaches of the Sacramento  
7 River during winter prior to spawning, then migrate upstream in response to  
8 higher flows to spawn from February to early June (Schaffter 1997, McCabe and  
9 Tracy 1994). Most spawning in the Sacramento River occurs in April and May  
10 (Kohlhorst 1976). YOY White Sturgeon make an active downstream migration  
11 that disperses them widely to rearing habitat throughout the lower Sacramento  
12 River and Delta (McCabe and Tracy 1994, Israel et al. 2008).

### 13 *Sacramento Splittail*

14 Historically, Sacramento Splittail were widespread in the Sacramento River from  
15 Redding to the Delta (Rutter 1908 as cited in Moyle et al. 2004). This distribution  
16 has become somewhat reduced in recent years (Sommer et al. 1997, 2007b).  
17 During drier years there is evidence that spawning occurs farther upstream  
18 (Feyrer et al. 2005). Adult splittail migrate upstream in the lower Sacramento  
19 River to above near the mouth of the Feather River and into the Sutter and Yolo  
20 bypasses (Sommer et al. 1997, Feyrer et al. 2005, Sommer et al. 2007b). Each  
21 year, mainly during the spring spawning season, a small number of individuals  
22 have been documented at the Red Bluff Pumping Plant and the entrance to the  
23 GCID intake (Moyle et al. 2004).

24 Nonreproductive adult splittail are most abundant in moderately shallow, brackish  
25 areas, but can also be found in freshwater areas with tidal or riverine flow  
26 (Moyle et al. 2004). Adults typically migrate upstream from brackish areas in  
27 January and February and spawn in fresh water on inundated floodplains in March  
28 and April (Moyle et al. 2004, Sommer et al. 2007b). In the Sacramento drainage,  
29 the most important spawning areas appear to be the Yolo and Sutter bypasses;  
30 however, some spawning occurs almost every year along the river edges and  
31 backwaters created by small increases in flow. Splittail spawn in the Sacramento  
32 River from Colusa to Knights Landing in most years (Feyrer et al. 2005).

33 Most juvenile splittail move from upstream areas downstream into the Delta from  
34 April through August (Meng and Moyle 1995, Sommer et al. 2007b). The  
35 production of YOY Sacramento Splittail is largely influenced by extent and  
36 period of inundation of floodplain spawning habitats, with abundance spiking  
37 following wet years and declining after dry years (Sommer et al. 1997, Moyle  
38 et al. 2004, Feyrer et al. 2006). Other factors that may affect the Sacramento  
39 Splittail adult population include flood control operations and infrastructure,  
40 entrainment by irrigation diversion, recreational fishing, changed estuarine  
41 hydraulics, pollutants, and nonnative species (Moyle et al. 2004,  
42 Sommer et al. 2007b).

1 *Pacific Lamprey*

2 Pacific Lampreys are anadromous, rearing in fresh water before outmigrating to  
3 the ocean, where they grow to full size prior to returning to their natal streams to  
4 spawn. Data from mid-water trawls in Suisun Bay and the lower Sacramento  
5 River indicate that adults likely migrate into the Sacramento River and tributaries  
6 from late fall (November) through early-summer (June) (Hanni et al. 2006).  
7 Adult Pacific Lampreys, either immature or spawning stage, have been detected at  
8 the GCID diversion from December through July and nearly all year at RBDD  
9 (Hanni et al. 2006). Hannon and Deason (2008) documented Pacific Lampreys  
10 spawning in the American River between early January and late May, with peak  
11 spawning typically in early April. Spawning in the Sacramento River is expected  
12 to occur during a similar timeframe. Pacific Lamprey ammocoetes rear in parts of  
13 the Sacramento River for all or part of their 5- to 7-year freshwater residence.  
14 Data from rotary screw trapping at sites on the mainstem Sacramento River  
15 indicate that outmigration of Pacific Lamprey peaks from early winter through  
16 early summer, but some outmigration is observed year-round at both RBDD and  
17 the GCID diversion dam (Hanni et al. 2006).

18 *Striped Bass*

19 Striped Bass are anadromous; adult Striped Bass are distributed mainly in the  
20 lower bays and ocean during summer, and in the Delta during fall and winter.  
21 Spawning takes place in spring from April to mid-June (Leet et al. 2001) at which  
22 time Striped Bass swim upstream to spawning grounds. Striped Bass are not  
23 believed to spawn or rear in the Sacramento River upstream of RBDD  
24 (TCCA 2008). Most Striped Bass spawning occurs in the lower Sacramento  
25 River between Colusa and the confluence of the Sacramento and Feather rivers  
26 (Moyle 2002). About one-half to two-thirds of the eggs are spawned in the  
27 Sacramento River and the remainder in the Delta (Leet et al. 2001). After  
28 spawning, most adult Striped Bass move downstream into brackish and salt water  
29 for summer and fall.

30 Eggs are free-floating and negatively buoyant, hatching as they drift downstream  
31 with larvae occurring in shallow and open waters of the lower reaches of the  
32 Sacramento and San Joaquin rivers, the Delta, Suisun Bay, Montezuma Slough,  
33 and Carquinez Strait. The Sacramento River functions primarily as a migration  
34 corridor for both adults and drifting eggs/larvae.

35 **9.3.4.4.2 Aquatic Habitat**

36 The mainstem Sacramento River provides habitat for native and introduced  
37 (nonnative) fish and other aquatic species. The diversity of aquatic habitats  
38 ranges from fast-water riffles and glides in the upper reaches to tidally influenced  
39 slow-water pools and glides in the lower reaches (Vogel 2011).

40 A few miles downstream of Keswick Dam, near Redding, the river enters the  
41 valley and the floodplain broadens. Historically, this area likely had wide  
42 expanses of riparian forests, but much of the river's riparian zone is subject to  
43 urban encroachment, particularly in the Anderson/Redding area. In the middle  
44 Sacramento River between Red Bluff and Chico Landing, the mainstem channel

1 is flanked by broad floodplains (TNC 2007a). In the lower reaches downstream  
 2 of Verona, much of the Sacramento River is constrained by levees. Dredging,  
 3 dams, levee construction, urban encroachment, and other human activities in the  
 4 Sacramento River have modified aquatic habitat, altered sediment dynamics,  
 5 simplified stream bank and riparian habitat, reduced floodplain connectivity, and  
 6 modified hydrology (NMFS 2009a). However, some complex floodplain habitats  
 7 remain in the system such as reaches with setback levees and the Yolo and  
 8 Sutter bypasses.

#### 9 *Holding Habitat*

10 An abundance of deep, cold-water pools in the mainstem Sacramento River  
 11 provide habitat for holding adult anadromous salmonids during all months of the  
 12 year (Vogel 2011). Green Sturgeon also use deep pools for holding but can  
 13 tolerate warmer water temperatures than salmon and, therefore, can hold farther  
 14 downstream. Large numbers of adult Green Sturgeon have been observed holding  
 15 during summer in deep pools in the Sacramento River near Hamilton City  
 16 (Vogel 2011).

#### 17 *Spawning Habitat*

18 Spawning habitat on the Sacramento River is affected by lack of sediment and  
 19 flow patterns as determined by the operations of the CVP and local water  
 20 diverters.

#### 21 *Sediment Conditions*

22 Shasta and Keswick dams substantially influence sediment transport in the upper  
 23 Sacramento River because they block sediment that would normally have been  
 24 transported downstream (TNC 2007a, DWR 1985). The result has been a net loss  
 25 of coarse sediment, including gravel particle sizes suitable for salmon spawning,  
 26 in the Sacramento River downstream of Keswick Dam (Reclamation 2013b).  
 27 To address the issue of spawning gravel loss downstream of Keswick Dam,  
 28 Reclamation has placed approximately 5,000 tons of washed spawning gravel into  
 29 the Sacramento River downstream of Keswick about every other year since 1997  
 30 (Reclamation 2010a).

#### 31 *Spawning Habitat Availability*

32 Winter-run Chinook Salmon spawning in the upper reaches of the Sacramento  
 33 River is affected by the operations of the seasonal ACID diversion dam, which  
 34 involves placement of flashboards in the river between April and May. Flows in  
 35 the river vary with the operation of the diversion dam and releases of water from  
 36 Shasta Lake into the river. When the dam is installed in the river, the WUA  
 37 upstream of the Cow Creek confluence is higher than when the dam is removed.  
 38 Farther downstream, there is less variability in WUA.

39 The WUA for winter-run Chinook Salmon spawning peaks at around 10,000 cfs  
 40 in the upstream reach upstream of the ACID intake when the dam flashboards are  
 41 in. With the boards out, the peak is around 5,500 cfs. In the next reach  
 42 downstream (ACID intake to Cow Creek), spawning WUA also peaked at around  
 43 10,000 cfs. In the lower reach (Cow Creek to Battle Creek), WUA spawning

1 habitat peaks at around 5,250 cfs, but there is low variability in spawning WUA  
2 from 3,250 to 8,000 cfs

3 Overall, spawning habitat WUA values differ for fall-run and late fall-run  
4 Chinook Salmon, but the flow versus habitat relationship is about the same for the  
5 two runs. Upstream of the ACID intake, spawning habitat WUA for fall- and late  
6 fall-run Chinook Salmon peaks at the lowest flow analyzed (3,250 cfs) with the  
7 dam flashboards out and at about 6,000 cfs with the flashboards in. Between the  
8 ACID intake and Cow Creek, spawning habitat WUA peaks at around 5,000 cfs  
9 for both runs. Between Cow Creek and Battle Creek, spawning habitat WUA for  
10 both runs peaks at about 3,500 cfs. The highest density of redds for fall- and late  
11 fall-run Chinook Salmon occur in the middle ACID intake to Cow Creek reach.

12 The spawning habitat WUA values for steelhead peaks at the lowest river flow  
13 analyzed (3,250 cfs) in the reach upstream of the ACID intake. This habitat  
14 relationship held regardless of whether the flashboards were in or out. In the  
15 reach between the ACID intake and Cow Creek, spawning habitat WUA peaks at  
16 river flows around 6,000 cfs. In the lower reach, from Cow Creek to Battle  
17 Creek, spawning habitat WUA also peaks at river flows of about 6,500 cfs, but do  
18 not vary substantially in a flow range between about 4,000 and 8,000 cfs.

19 USFWS (2005b) conducted limiting life-stage analyses for winter-, fall-, and  
20 late-fall-run Chinook Salmon in the Sacramento River upstream of the Battle  
21 Creek confluence and found that in most cases, juvenile habitat is limiting. In  
22 some cases (fall- and late fall-run in between the ACID intake and Cow Creek),  
23 spawning habitat may be limiting at higher flows.

24 USFWS (2005a) developed spawning flow-habitat relationships for fall-run  
25 Chinook Salmon spawning habitat in the Sacramento River between Battle Creek  
26 and Deer Creek. Between Battle Creek and RBDD, spawning habitat WUA  
27 values for fall-run Chinook Salmon peaked at approximately 3,750 cfs, but  
28 showed little variation over flows from 3,250 cfs (the lowest flow evaluated) and  
29 6,000 cfs, but declined substantially at higher flows. Between the Red Bluff  
30 Pumping Plant and Deer Creek, spawning habitat WUA values for fall-run  
31 Chinook salmon peaked at 5,500 cfs, with little variation at flows from 4,250 to  
32 8,000 cfs (USFWS 2005a).

### 33 *Rearing Habitat*

34 In the Sacramento River between Red Bluff and Chico Landing, the mainstem  
35 channel is flanked by broad floodplains. Ongoing sediment deposition in these  
36 areas provides evidence of continued inundation of floodplains in this reach  
37 (DWR 1994). Between Chico Landing and Colusa, the Sacramento River is  
38 bounded by levees that provide flood protection for cities and agricultural areas.  
39 However, the levees in this portion of the Sacramento River are, for the most part,  
40 set back from the mainstem channel such that flooding can be significant within  
41 the river corridor (TNC 2007b).

42 Fry rearing habitat WUA for winter-run Chinook Salmon fry rearing habitat peaks  
43 at around 5,500 cfs in the reach upstream of the ACID intake when the dam  
44 flashboards are in. With the boards out, the peak is around 6,500 cfs. In the next

1 reach downstream (ACID intake to Cow Creek), fry rearing habitat WUA for  
2 winter-run Chinook Salmon peaks at around 31,000 cfs (the highest flow  
3 evaluated). In the lower reach (Cow Creek to Battle Creek), fry rearing habitat  
4 WUA for winter-run Chinook Salmon also peaked at around 31,000 cfs, but there  
5 was little variation at flows.

6 The fry rearing habitat WUA values differ for fall-run and late fall-run Chinook  
7 Salmon, but the flow versus habitat relationship was similar for the two runs.  
8 Upstream of the ACID intake, fry rearing habitat WUA for fall- and late fall-run  
9 Chinook Salmon peaks at the lowest flow analyzed (3,250 cfs) with the dam  
10 flashboards in. With the flashboards out, fry rearing habitat WUA peaks at  
11 around 23,000 cfs for both species. Between the ACID intake and Cow Creek,  
12 fry rearing habitat WUA for fall- and late fall-run Chinook Salmon peaked at  
13 around 3,750 cfs for both runs, with little variation from 3,250 cfs to 6,000 cfs  
14 and only slightly lower WUA values at flows greater than 21,000 cfs. Between  
15 Cow Creek and Battle Creek, fry rearing habitat WUA for both runs peaks at  
16 3,250 cfs (the lowest flow evaluated), declining as flows increase.

17 Juvenile rearing habitat WUA for winter-run Chinook Salmon juvenile rearing  
18 habitat peaks at around 8,000 cfs in the upstream reach above the ACID intake  
19 when the dam flashboards are in. With the boards out, the peak is around  
20 9,000 cfs. However, there is little variation in juvenile winter-run Chinook  
21 Salmon rearing habitat WUA from around 5,500 to 11,000 cfs in this reach. In  
22 the next reach downstream between the ACID intake to Cow Creek, juvenile  
23 rearing habitat WUA for winter-run Chinook Salmon peaks at around 31,000 cfs  
24 (the highest flow evaluated). In the lower reach (Cow Creek to Battle Creek),  
25 juvenile rearing habitat WUA for winter-run Chinook Salmon peaks at around  
26 3,500 cfs but shows only moderate (<50 percent) reductions in WUA over the  
27 entire range of flows evaluated.

28 The juvenile rearing habitat WUA values differ for fall-run and late fall-run  
29 Chinook Salmon, but the flow versus habitat relationship is similar for the two  
30 runs. Upstream of the ACID intake, juvenile rearing habitat WUA for fall- and  
31 late fall-run Chinook Salmon peaked in the 5,000- to 6,000-cfs range with the  
32 dam flashboards in or out; there were only moderate (<50 percent) reductions in  
33 juvenile rearing WUA over the entire range of flows evaluated. Between the  
34 ACID intake and Cow Creek, fry rearing WUA peaked at around 3,250 cfs (the  
35 lowest flow evaluated) for both runs, declining to a minimum at around  
36 15,000 cfs and increasing to around 70 percent of the maximum at flows above  
37 21,000 cfs. Between Cow Creek and Battle Creek, fry rearing WUA for both runs  
38 peaked at 3,250 cfs (the lowest flow evaluated), declining as flow increased.

39 Vogel (2011) suggested that the mainstem Sacramento River may not provide  
40 adequate rearing areas for fry-stage anadromous salmonids, as evidenced by rapid  
41 displacement of fry from upstream to downstream areas and into nonnatal  
42 tributaries during increased flow events. Underwater observations of salmon fry  
43 in the mainstem Sacramento River suggest that optimal habitats for rearing may  
44 be limited at higher flows (Vogel 2011). USFWS (2005) conducted limiting  
45 life-stage analyses for winter-, fall-, and late-fall-run Chinook Salmon in the

1 Sacramento River above Battle Creek and found that in most cases, juvenile  
2 habitat is limiting. An important limitation of this analysis is that it did not take  
3 into account fry and juvenile rearing habitat below Battle Creek or in the Delta.  
4 The minimum required Sacramento River flow is 3,250 cfs. Flows during  
5 summer generally exceed this amount in order to meet temperature requirements  
6 for winter-run Chinook Salmon. The water temperature requirements established  
7 for winter-run Chinook Salmon result in water temperatures also suitable for  
8 year-round rearing of steelhead in the upper Sacramento River.

9 **9.3.4.4.3 Fish Passage and Entrainment**

10 Historically, anadromous salmonids had access to a minimum of approximately  
11 493 miles of habitat in the Sacramento River (Yoshiyama et al. 1996). After  
12 completion of Shasta Dam in 1945, access to approximately 207 miles was  
13 blocked. Keswick Dam, just downstream of Shasta Dam, is now the upstream  
14 extent of available habitat for anadromous fish in the Sacramento River.

15 Until recently, three large-scale, upper Sacramento River diversions, including the  
16 ACID and GCID intakes and RBDD, were of particular concern as potential  
17 passage or entrainment problems for Chinook Salmon, steelhead, and other  
18 migratory fish species (NRC 2012, NMFS 2009a, McEwan and Jackson 1996).  
19 Recently, RBDD was eliminated, the GCID fish screens were installed, and fish  
20 passage at the ACID intake was improved (NRC 2012). At the ACID intake, new  
21 fish ladders and fish screens were installed around the diversion and were  
22 operated starting in the summer 2001 diversion period. However, adult Green  
23 Sturgeon that migrate upstream in April, May, and June are completely blocked  
24 by the ACID intake (NMFS 2009a), rendering approximately 3 miles of spawning  
25 habitat upstream of the diversion dam inaccessible. Adult Green Sturgeon that  
26 pass upstream of the intake before April are delayed for 6 months until the  
27 flashboards are pulled before returning downstream to the ocean. Newly emerged  
28 Green Sturgeon larvae that hatch upstream of the ACID intake would need to hold  
29 for 6 months upstream of the dam or pass over it and be subjected to higher  
30 velocities and turbulent flow below the intake (NMFS 2009a).

31 Numerous other diversions are located on the Sacramento River. Herren and  
32 Kawasaki (2001) documented up to 431 diversions from the Sacramento River  
33 between Shasta Dam and the City of Sacramento. Hanson (2001) studied juvenile  
34 Chinook Salmon entrainment at unscreened diversions at the Princeton Pumping  
35 Plant and documented the entrainment of approximately 0.05 percent of juvenile  
36 Chinook Salmon passing the diversion. Similar to the results of Hanson (2001),  
37 Vogel (2013) found that entrainment of juvenile salmon in 12 unscreened  
38 diversions was low relative to other fish species. The study did not discern  
39 measurable effects of factors such as size of the diversion, longitudinal location in  
40 the river, water temperatures, localized habitat conditions, intake position in the  
41 river channel, and depth of the intakes on salmonid entrainment. It appeared that  
42 juvenile salmon were entrained in a much lower proportion than the proportion of  
43 flow diverted (Vogel 2013), similar to results noted by Hanson (2001). Mussen  
44 et al. (2014) examined the risk to Green Sturgeon from unscreened water

1 diversions and found that juvenile Green Sturgeon entrainment susceptibility (in a  
2 laboratory setting) was high relative to that estimated for Chinook Salmon,  
3 suggesting that unscreened diversions could be a contributing mortality source for  
4 threatened Southern DPS Green Sturgeon.

5 Reclamation is currently coordinating with USFWS to support improvements at  
6 other fish screens. In 2013, CVPIA funds were used to construct the Natomas  
7 Mutual Sankey Fish Screen on the Sacramento River that replaced two existing  
8 diversions on the Natomas Cross Canal. This project also resulted in the removal  
9 of an anadromous fish migration barrier (seasonal diversion dam) on the Natomas  
10 Cross Canal. The fish screening program also completed construction of four fish  
11 screens on the Sacramento River and one fish screen in the Delta.

12 Potential barriers to migration for adult Green Sturgeon into the upper reaches of  
13 the Sacramento River include structures such as the ACID intake, Sacramento  
14 River Deep Water Ship Channel locks, Fremont Weir, Sutter Bypass, and DCC  
15 gates on the Sacramento River (70 FR 17386). A set of locks at the end of the  
16 Sacramento River Deep Water Ship Channel at the connection with the  
17 Sacramento River “blocks the migration of all fish from the deep-water ship  
18 channel back to the Sacramento River” (DWR 2005).

#### 19 **9.3.4.4.4 Hatcheries**

20 The Livingston Stone NFH, located at the foot of Shasta Dam, is a conservation  
21 hatchery that has been producing and releasing juvenile winter-run Chinook  
22 Salmon since 1998. There is growing concern about the potential genetic effects  
23 that may result from the use of a conventional hatchery program to supplement  
24 winter-run Chinook Salmon populations. To maintain a low risk of compromised  
25 genetic fitness, Lindley et al. (2007) recommend that no more than 5 percent of  
26 the naturally spawning population should be composed of hatchery fish. Since  
27 2001, more than 5 percent of the winter-run Chinook Salmon run has been  
28 composed of hatchery-origin fish, and in 2005 the contribution of hatchery fish  
29 was more than 18 percent (Lindley et al. 2007).

30 The Livingston Stone NFH minimizes hatchery affects in the population by  
31 preferentially collecting wild adult winter-run Chinook Salmon for brood stock  
32 (USFWS 2011b). Up to 15 percent of the estimated run size for winter-run  
33 Chinook Salmon run may be collected for brood stock use (up to a maximum of  
34 120 natural-origin winter-run Chinook Salmon per brood year). Although  
35 there is no adult production goal, Livingston Stone NFH releases up to  
36 250,000 winter-run Chinook Salmon a year in late January or early February.  
37 Winter-run Chinook Salmon are released at the pre-smolt stage and are intended  
38 to rear in the freshwater environment prior to smoltification. The pre-smolts are  
39 released into the Sacramento River at Caldwell Park in Redding, about 10 miles  
40 downstream of the hatchery. All juvenile winter-run Chinook Salmon produced  
41 at Livingston Stone NFH are adipose fin-clipped and coded wire-tagged  
42 (CHSRG 2012).

1 The Delta Smelt propagation program at the Livingston Stone NFH is operated as  
2 a captive broodstock program. Delta Smelt propagation at Livingston Stone NFH  
3 functions as a backup refugial population. No Delta Smelt from the Livingston  
4 Stone NFH are currently released (USFWS 2011b).

#### 5 **9.3.4.4.5 Predation**

6 On the mainstem Sacramento River, high rates of predation have been known to  
7 occur at the diversion facilities and areas where rock revetment has replaced  
8 natural river bank vegetation (NMFS 2009a). Chinook Salmon fry, juveniles, and  
9 smolts are more susceptible to predation at these locations because Sacramento  
10 Pikeminnow and Striped Bass congregate in areas that provide predator refuge  
11 (Williams 2006, Tucker et al. 2003).

#### 12 **9.3.4.5 Battle Creek**

13 Battle Creek is a tributary that enters the Sacramento River about 20 miles  
14 southeast of Redding. The cold, spring-fed waters of Battle Creek historically  
15 supported large runs of Chinook Salmon and steelhead. Diversion dams  
16 constructed in the early 1900s for hydroelectric power production reduced  
17 instream flow and blocked anadromous salmonids from accessing habitat in large  
18 portions of the north and south forks of Battle Creek.

19 Coleman NFH, located on Battle Creek, was established in 1942 by Reclamation  
20 to partially mitigate habitat and fish losses from historical spawning areas caused  
21 by construction of two CVP features, Shasta and Keswick dams. The hatchery is  
22 funded by Reclamation and operated by USFWS. The steelhead program at the  
23 hatchery was initiated in 1947 to mitigate losses resulting from the CVP  
24 (USFWS 2012). The weir at the hatchery is a barrier to anadromous fish passage,  
25 as are various Pacific Gas & Electric Company (PG&E) dams (e.g., Wildcat)  
26 located on Battle Creek (Yoshiyama et al. 1996). Yoshiyama et al. (1996)  
27 reported that the Coleman South Fork Diversion Dam is the first impassible  
28 barrier on Battle Creek.

29 Beginning in 1995, planning was initiated to restore naturally spawning  
30 anadromous fish populations in Battle Creek, and construction began in 2010 on  
31 the Battle Creek Salmon and Steelhead Restoration Project (Reclamation 2014a).  
32 When complete, the Battle Creek restoration project will restore ecological  
33 processes along 42 miles of Battle Creek and 6 miles of tributaries while  
34 minimizing reductions to hydroelectric power generation, although five dams are  
35 decommissioned (Wildcat, Coleman, South, Lower Ripley, and Soap Creek  
36 feeder diversion dams). New fish screens and fish ladders that meet NMFS and  
37 CDFW criteria will be constructed at three diversion dams (North Battle Creek  
38 Feeder, Eagle Canyon, and Inskip Diversion Dams). Connectors are proposed  
39 that prevent the discharge of North Fork Battle Creek water to South Fork Battle  
40 Creek and the mixing of flow sources. Higher minimum flow requirements will  
41 increase instream flows, subsequently cooling water temperatures, increasing  
42 stream area, and providing reliable passage conditions for adult salmonids in  
43 downstream reaches. The project will result in 42 miles of newly accessible  
44 anadromous fish habitat and improved water quality for the Coleman NFH.

#### 1 **9.3.4.6 Lake Oroville and Thermalito Complex**

2 Lake Oroville on the Feather River is formed by Oroville Dam, approximately  
3 70 miles upstream from its confluence with the Sacramento River. Lake Oroville  
4 is fed by the north, middle, and south forks of the Feather River. A portion of the  
5 water released from Lake Oroville flows into the Thermalito Complex, as  
6 described in Chapter 5, Surface Water Resources and Water Supplies.

##### 7 **9.3.4.6.1 Fish in Lake Oroville**

8 Lake Oroville thermally stratifies in spring, destratifies in fall, and remains  
9 destratified throughout winter. FERC (2007b) reports indicate that surface water  
10 temperatures of the epilimnion begin to warm in the early spring, reach maximum  
11 temperatures (approximately mid-80°F) during late July, and gradually decline to  
12 winter minimums. The transition zone (i.e., metalimnion) between the upper  
13 warmer and lower colder waters typically ranges from about 30 to 50 feet below  
14 the lake surface during midsummer. The deeper water of the hypolimnion can  
15 reach a temperature of about 44°F near the reservoir bottom during periods of  
16 stratification (FERC 2007b). Cold-water fish species include Coho Salmon,  
17 Rainbow Trout, Brown Trout, and Lake Trout. The Lake Oroville cold-water  
18 fishery is not self-sustaining, possibly because of insufficient spawning and  
19 rearing habitat in the reservoir and accessible tributaries; cold-water spawning is  
20 not known to occur in Lake Oroville. The Coho Salmon fishery is sustained by a  
21 “put-and-grow” hatchery stocking program (FERC 2007b). The Lake Oroville  
22 warm-water fishery is a regionally important self-sustaining recreational fishery  
23 and is the site of several annual bass fishing tournaments. Spotted Bass are the  
24 most abundant bass species in Lake Oroville, followed by Largemouth Bass,  
25 Redeye Bass, and Smallmouth Bass, respectively. Other important warm-water  
26 species include catfish, crappie, and sunfish. Common carp are also abundant in  
27 Lake Oroville.

##### 28 **9.3.4.6.2 Fish in Thermalito Forebay and Afterbay**

29 Ambient meteorological conditions and the temperature of the water released  
30 from Lake Oroville generally affect water temperatures in the Thermalito  
31 Diversion Pool and Thermalito Forebay (FERC 2007b). Thermalito Forebay is an  
32 open, cold, shallow reservoir that remains cold throughout the year because it is  
33 supplied with water from Thermalito Diversion Pool, although pump-back  
34 operations from Thermalito Afterbay can increase water temperatures in the  
35 forebay. Thermalito Forebay provides habitat primarily for cold-water fish  
36 species, although the same warm-water fish species found in Lake Oroville are  
37 believed to exist in the forebay in low numbers (FERC 2007b). Additionally,  
38 CDFW manages a “put-and-take” trout fishery in Thermalito Forebay.

39 Thermalito Afterbay provides habitat for cold-water and warm-water fish species  
40 including Largemouth Bass, Smallmouth Bass, Rainbow Trout, Brown Trout,  
41 Bluegill, Redear Sunfish, Black Crappie, Channel Catfish, carp, and large schools  
42 of Wakasagi (FERC 2007b). A popular Largemouth Bass fishery currently exists,  
43 large trout are sometimes caught near the inlet, and an experimental steelhead  
44 fishery occurs in the Afterbay. Only limited salmonid stocking occurs at the

1 afterbay, so these fish most likely passed through the Thermalito Pumping-  
2 Generating Plant from the forebay.

3 **9.3.4.7 Feather River from Lake Oroville and the Thermalito Complex to**  
4 **the Sacramento River**

5 The Feather River is a major tributary to the Sacramento River, providing  
6 approximately 25 percent of the flow in the Sacramento River (FERC 2007b).  
7 The lower Feather River extends downstream from the Fish Barrier Dam to the  
8 confluence with the Sacramento River near Verona. The Fish Barrier Dam is  
9 located downstream of the Thermalito Diversion Dam and immediately upstream  
10 of the Feather River Fish Hatchery (FERC 2007b).

11 **9.3.4.7.1 Fish in the Feather River**

12 The Feather River below Oroville supports a variety of anadromous and resident  
13 fish species. The distribution of anadromous fish in the Feather River is limited  
14 to approximately 67 miles of river downstream from the Fish Barrier Dam. At  
15 least 44 species of fish have been reported to historically or currently occur in the  
16 lower Feather River system, including numerous resident native and introduced  
17 species and several anadromous species (FERC 2007b).

18 The analysis is focused on the following species:

- 19 • Chinook Salmon (winter-, spring-, and fall/late fall-run)
- 20 • Steelhead
- 21 • Green Sturgeon
- 22 • White Sturgeon
- 23 • Sacramento Splittail
- 24 • Pacific Lamprey
- 25 • Striped Bass
- 26 • American Shad

27 *Spring-run Chinook Salmon*

28 Approximately two-thirds of the natural spring-run and fall-run Chinook Salmon  
29 spawning occur in the low-flow channel of the lower Feather River, downstream  
30 of the Fish Barrier Dam, and one-third of the spawning occurs in the high-flow  
31 channel downstream of the Thermalito Afterbay Outlet (FERC 2007b). NMFS  
32 (2009a) indicated that significant redd superimposition occurs in the lower  
33 Feather River because of oversaturation of the natural carrying capacity of the  
34 available spawning habitat (e.g., Sommer et al. 2001b) with an overproduction of  
35 hatchery spring-run Chinook Salmon and a lack of physical separation between  
36 spring-run and fall-run Chinook Salmon adults.

37 Adult spring-run Chinook Salmon typically enter fresh water in spring, hold over  
38 summer, and spawn in fall. Juveniles typically spend a year or more in fresh  
39 water before outmigrating. Adult spring-run Chinook Salmon begin their  
40 upstream migration from the ocean in late January and early February  
41 (DFG 1998b) and migrate from the Sacramento River into spawning tributaries  
42 primarily between mid-April and mid-June (Lindley et al. 2004). Adult Chinook

1 Salmon exhibiting the typical life history of the spring-run have been found  
2 holding at the Thermalito Afterbay Outlet and the Fish Barrier Dam as early as  
3 April (FERC 2007b). Spring-run Chinook Salmon spawning occurs during  
4 September and October, depending on water temperatures (NMFS 2012a).  
5 Spring-run Chinook Salmon fry emerge from the gravel from November to March  
6 (Moyle 2002). Most juvenile spring-run Chinook Salmon outmigrate from the  
7 lower Feather River within a few days of emergence, and 95 percent of the  
8 juvenile Chinook have typically outmigrated from the Oroville facilities project  
9 area by the end of May (FERC 2007b).

10 An independent population of spring-run Chinook Salmon historically occurred in  
11 the lower Feather River downstream of Oroville Dam, and a naturally spawning  
12 population of spring-run Chinook Salmon may persist in this reach (Lindley et al.  
13 2004). The number of naturally spawning spring-run Chinook Salmon in the  
14 Feather River has been estimated only periodically since the 1960s, with estimates  
15 ranging from 2 fish in 1978 to 2,908 in 1964. However, the genetic integrity of  
16 this population is questionable because of the significant temporal and spatial  
17 overlap between spawning populations of spring-run Chinook Salmon and  
18 fall-run Chinook Salmon (Good et al. 2005).

19 Substantial numbers of spring-run Chinook Salmon, as identified by run timing,  
20 return to the Feather River Fish Hatchery. From 1986 to 2011, the median  
21 number of spring-run Chinook Salmon returning to the Feather River Fish  
22 Hatchery was 3,655, compared to a median of 7,869 spring-run Chinook Salmon  
23 returning to the entire Sacramento River Basin (NMFS 2012a). Abundance  
24 estimates of lower Feather River spring-run Chinook Salmon may be distorted by  
25 naturally occurring genetic introgression with fall-run Chinook Salmon, Feather  
26 River Fish Hatchery practices, and Federal and state escapement estimation  
27 methodology. Coded wire tags obtained from Feather River Fish Hatchery  
28 returns indicate substantial introgression has occurred between spring-run  
29 Chinook Salmon and fall-run Chinook Salmon populations within the lower  
30 Feather River (NMFS 2009a).

### 31 *Fall-run Chinook Salmon*

32 Fall-run Chinook Salmon generally begin upstream migration into the lower  
33 Feather River during summer months (FERC 2007b). Although timing of fall-run  
34 Chinook Salmon spawning may be influenced by water temperature conditions  
35 (FERC 2007b), spawning activity in the lower Feather River occurs from late  
36 August through December and generally peaks during mid- to late November  
37 (Myers et al. 1998). Concurrent spawning with spring-run Chinook Salmon,  
38 which generally occurs from September to October, has led to hybridization  
39 between the spring- and fall-run Chinook Salmon in the lower Feather River  
40 (NMFS 2012a).

41 In the lower Feather River, fall-run Chinook Salmon embryo incubation and  
42 alevin (yolk-sac fry) emergence generally occurs from mid-October through  
43 March, depending on water temperature conditions (FERC 2007b). Fall-run  
44 Chinook Salmon fry emergence generally occurs in the lower Feather River  
45 downstream of the Fish Barrier Dam from late December through March, and

1 most juvenile fall-run Chinook Salmon outmigrate from the lower Feather River  
2 within a few days of emergence (FERC 2007b).

3 *Steelhead*

4 Steelhead immigrate into the Feather River from July to March (McEwan 2001).  
5 Currently, most of the natural steelhead spawning in the lower Feather River  
6 occurs in the low-flow channel downstream of the Fish Barrier Dam; however,  
7 limited spawning also occurs downstream of the Thermalito Afterbay Outlet  
8 (FERC 2007b). Results of a 13-week redd survey conducted between January 6  
9 and April 3, 2003, indicated that redd construction generally occurs in the lower  
10 Feather River between late December and March, peaking in late January  
11 (FERC 2007b). The FERC (2007b) study suggests that nearly half (48 percent) of  
12 all redds were constructed in the uppermost mile of the low-flow channel  
13 downstream of the Fish Barrier Dam. Redd density in this 1-mile section of the  
14 low-flow channel was approximately 36 redds per mile, more than 10 times more  
15 than any other section of the lower Feather River (FERC 2007b).

16 A moderate percentage of the steelhead fry appear to outmigrate from the lower  
17 Feather River soon after emerging from the gravel. Juvenile steelhead that do not  
18 outmigrate may rear in the river for up to 1 year. Juvenile steelhead in the Feather  
19 River outmigrate from about February through September, with peak  
20 outmigration occurring from March through mid-April. In-river juvenile rearing  
21 is generally associated with secondary channels in the low-flow channel  
22 (e.g., Hatchery Ditch) (FERC 2007b).

23 *Pacific Lamprey*

24 The Pacific Lamprey inhabits accessible reaches of the lower Feather River  
25 (DWR 2003a). Information on Pacific Lamprey status in the lower Feather River  
26 is limited, but the loss of access to historical habitat and apparent population  
27 declines throughout California and the Sacramento and San Joaquin River basins  
28 indicate populations are greatly decreased compared with historical levels  
29 (Moyle et al. 2009). Little information is available on factors limiting Pacific  
30 Lamprey populations in the lower Feather River, but they are likely affected by  
31 many of the same factors as salmon and steelhead because of parallels in their  
32 life cycles.

33 Ocean-stage adults likely migrate into the lower Feather River in spring and early  
34 summer, where they hold for approximately 1 year before spawning (Hanni et al.  
35 2006). Hannon and Deason (2008) have documented Pacific Lamprey spawning  
36 in the nearby American River from between early January and late May, with  
37 peak spawning typically occurring in early April. Pacific Lamprey ammocoetes  
38 rear in the lower Feather River for all or part of their 5- to 7-year freshwater  
39 residence. Data from rotary screw trapping suggest that outmigration of Pacific  
40 Lamprey generally occurs from early winter through early summer (Hanni et al.  
41 2006), although some outmigration likely occurs year-round as observed in the  
42 mainstem Sacramento River (Hanni et al. 2006) and in other river systems  
43 (Moyle 2002).

1 *Sacramento Splittail*

2 Sacramento Splittail enter the lower Feather River, primarily in wet years, with  
3 most individuals collected in the high-flow channel downstream of Thermalito  
4 Afterbay Outlet (DWR 2004a). On the lower Feather River, February through  
5 May was assumed to encompass the period of splittail spawning, egg incubation,  
6 and initial rearing (Sommer et al. 2008, DWR 2004a). Splittail use shallow  
7 flooded vegetation for spawning and are infrequently observed in the Feather  
8 River from the confluence with the Sacramento River up to Honcut Creek. The  
9 majority of spawning activity in the Feather River is thought to occur downstream  
10 of the Yuba River confluence (FERC 2007b). The primary factor that likely  
11 limits the lower Feather River splittail population is availability of spawning and  
12 rearing habitats as related to inundation of floodplains (Moyle et al. 2004,  
13 DWR 2004a).

14 *Green Sturgeon*

15 Historically, Green Sturgeon likely spawned in the Sacramento, Feather, and San  
16 Joaquin rivers (Adams et al. 2007). A substantial amount of habitat in the Feather  
17 River was lost with the construction of Oroville Dam. Although the presence of  
18 Green Sturgeon in the Sacramento River has been supported by direct angler  
19 observations and rotary screw trapping of eggs, larvae, and YOY Green Sturgeon,  
20 only intermittent observations of Green Sturgeon have been reported in the lower  
21 Feather River (Beamesderfer et al. 2007). The occasional capture of larval Green  
22 Sturgeon in outmigrant traps suggests that Green Sturgeon spawn in the lower  
23 Feather River (Moyle 2002). However, prior to 2011 only two records of adult  
24 Green Sturgeon in the lower Feather River were confirmed (NMFS 2005b). In  
25 2011, videography monitoring conducted by the Anadromous Fish Restoration  
26 Program confirmed Green Sturgeon spawning activity in the lower Feather River  
27 and found evidence of spawning behavior in the Yuba River (AFRP 2011).  
28 Seesholtz et al. (2014) provided the first documentation of Green Sturgeon  
29 spawning in the Feather River.

30 *White Sturgeon*

31 White Sturgeon are known to use the lower Feather River primarily for spawning,  
32 embryo development, and early rearing. Limited quantitative information is  
33 available on the status of White Sturgeon in the lower Feather River, but the  
34 spawning population was most likely much larger prior to construction of  
35 Oroville Dam in 1961 (Israel et al. 2008). Seesholtz (2003) reported no evidence  
36 of sturgeon was found in the lower Feather River after an exhaustive search for  
37 their presence in 2003. However, 16 White Sturgeon were recorded from creel  
38 surveys and sightings during 2006, and more were captured by anglers in 2007  
39 (Israel et al. 2008). Numerous factors likely limit the success of the White  
40 Sturgeon population in the lower Feather River, but loss of historical habitat,  
41 alteration of temperatures and flows caused by Oroville Dam and other  
42 impoundments in the watershed, and recreational fishing and poaching are  
43 expected to be among the most important factors.

1 *Striped Bass*

2 Striped Bass occur in the lower Feather River and have been reported to occur in  
3 the Thermalito Forebay (FERC 2007b). Striped Bass are a popular sport fish in  
4 the lower Feather River during periods when they migrate upstream to spawn.

5 *American Shad*

6 American Shad enter the Feather River annually in spring to spawn and are  
7 popular for sport fishing. American Shad are present in the lower Feather River  
8 from May through mid-December during the adult immigration, spawning, and  
9 outmigration periods of their life cycle (DWR 2003a).

10 **9.3.4.7.2 Aquatic Habitat**

11 Historically, spawning habitat suitable for anadromous salmonid species likely  
12 existed above the current location of Oroville Dam on the Feather River  
13 (Yoshiyama et al. 2001). Extensive mining, irrigation, and development of  
14 hydroelectric dams significantly reduced the amount of suitable habitat for these  
15 species (Yoshiyama et al. 2001). Schick et al. (2005) estimated approximately  
16 71 miles of suitable habitat was historically available for spring-run Chinook  
17 Salmon in the lower Feather River.

18 Most Chinook Salmon and steelhead spawning is concentrated in the uppermost  
19 3 miles of accessible habitat in the lower Feather River downstream of the Feather  
20 River Fish Hatchery (FERC 2007b). As a result, salmonid spawning is  
21 concentrated to unnaturally high levels in the low-flow channel of the lower  
22 Feather River directly downstream of Oroville Dam and the Fish Barrier Dam. A  
23 physical habitat simulation analysis conducted by the California Department of  
24 Water Resources (DWR) in 2002 indicated that Chinook spawning habitat  
25 suitability in the low-flow channel reached a maximum between 800 and 825 cfs,  
26 and in the high-flow channel, it reached a maximum at 1,200 cfs. The steelhead  
27 spawning habitat index in the low-flow channel had no distinct optimum over the  
28 range of flow between 150 and 1,000 cfs. In the high-flow channel, spawning  
29 habitat suitability was maximized at a flow just under 1,000 cfs (DWR 2004b).

30 The FERC (2007b) study reported that an estimated 97 percent of the sediment  
31 from the upstream watershed is trapped in Lake Oroville, such that only very fine  
32 sediment is discharged from Lake Oroville to the lower Feather River. As a  
33 result, gravel and large woody material from upstream reaches are limited along  
34 the lower Feather River. The FERC (2007b) study reported that the median  
35 gravel diameter (D50) of surface samples suggests that gravels in the low-flow  
36 channel generally are too large for successful redd construction by steelhead or  
37 salmon and that armoring is particularly evident in this reach; however, suitability  
38 of gravel sizes for spawning Chinook Salmon generally increased with distance  
39 downstream of Oroville Dam. The study suggested that size distributions of  
40 subsurface gravel samples were similar in the low- and high-flow channels.  
41 Analyses of fine sediment (less than 6 mm in diameter) suggested that fine  
42 sediment within gravels in the lower Feather River were suitable for incubating  
43 Chinook Salmon and steelhead embryos (FERC 2007b).

#### 1 **9.3.4.7.3 Fish Passage**

2 The Oroville facilities, including Oroville Dam, Thermalito Diversion Dam, and  
3 the Fish Barrier Dam, currently block the upstream migration of anadromous fish  
4 to historically available spawning areas in the upstream tributaries of the Feather  
5 River. In a study of Green Sturgeon passage impediments, FERC identified three  
6 potential physical barriers to upstream migration by Green Sturgeon in the lower  
7 Feather River during representative low-flow conditions (approximately 2,074 cfs  
8 during November 2002) and high-flow conditions (approximately 9,998 cfs  
9 during July 2003) (FERC 2007b). The three potential physical barriers are  
10 Shanghai Bench, the Sunset Pumps, and Steep Riffle (located 2 miles upstream of  
11 the Thermalito Afterbay Outlet). However, the study also noted that  
12 determinations of potential passage barriers in the lower Feather River are  
13 speculative.

#### 14 **9.3.4.7.4 Hatcheries**

15 The Feather River Fish Hatchery is part of the SWP Oroville Complex and is a  
16 mitigation hatchery for loss of habitat upstream of DWR's Oroville Dam that is  
17 no longer accessible to anadromous fish species (NMFS 2009a). Three hatchery  
18 programs are conducted here, producing fall-run Chinook Salmon, spring-run  
19 Chinook Salmon, and steelhead. The Feather River Fish Hatchery supports the  
20 only spring-run Chinook Salmon hatchery program currently in the Central Valley  
21 (CHSRG 2012). Spring-run Chinook Salmon produced at the Feather River Fish  
22 Hatchery are included in the listed spring-run Chinook Salmon ESU  
23 (70 FR 37160). FERC is in consultation with NMFS on the effects of  
24 relicensing Oroville Dam (including the effects of Feather River Fish Hatchery).

25 Fall-run Chinook Salmon in the Feather River are trapped and spawned at the  
26 hatchery with a goal of producing 6 million fall-run Chinook Salmon smolts for  
27 release into Carquinez Straits between April and June. Up to 2 million additional  
28 fish may be reared as part of a separate ocean enhancement program. Feather  
29 River fall-run Chinook Salmon are currently marked at a 25 percent rate (constant  
30 fractional marking) with an adipose fin-clip and a coded wire-tag (CHSRG 2012).

31 Adult hatchery-produced spring-run Chinook are intended to spawn naturally or  
32 to be genetically integrated with the natural population through artificial  
33 propagation. There are no specific goals for the number of adult spring-run  
34 Chinook Salmon; however, the juvenile production goal is to release 2 million  
35 smolts during April or May. These fish are all released into the Feather River  
36 south of Yuba City at the Boyd's Pump Boat Launch (44 miles downstream of the  
37 hatchery). Juvenile hatchery-produced spring-run Chinook Salmon are currently  
38 100 percent marked with an adipose fin-clip and a coded wire-tag  
39 (CHSRG 2012).

40 The steelhead program at the Feather River Hatchery traps and artificially spawns  
41 both marked hatchery-origin and unmarked natural-origin steelhead. Only a few  
42 unmarked fish are trapped annually. Currently, only fish returning to the Feather  
43 River Basin are used for broodstock. There are no specific goals for the number  
44 of adult steelhead produced by this program; however, the juvenile production

1 goal is to release 450,000 yearling steelhead annually during late January or  
2 February. All Feather River Hatchery steelhead are marked with an adipose  
3 fin-clip prior to release. These fish are all released into the Feather River south of  
4 Yuba City at the Boyd's Pump Boat Launch or at the confluence of the Feather  
5 and Sacramento rivers (Verona Marina) (CHSRG 2012).

6 Prior to 2004, separation of spring-run and fall-run Chinook Salmon returning to  
7 the Feather River Fish Hatchery was solely based on run timing, which resulted in  
8 considerable mixing of fall-run and spring-run Chinook Salmon stocks (DWR  
9 2009, NMFS 2012a). In 2005, the Feather River Fish Hatchery implemented a  
10 methodology change for distinguishing spring-run Chinook Salmon from fall-run  
11 Chinook Salmon (CHSRG 2012). To maintain genetic integrity, fish entering the  
12 Feather River Fish Hatchery prior to July 1 receive an external tag, and only these  
13 externally tagged fish are used as spring-run Chinook Salmon broodstock  
14 (DWR 2009). Since 2005, the hatchery has attempted to mark 100 percent of  
15 spring-run Chinook Salmon produced at the hatchery with an adipose fin-clip,  
16 coded wire-tag (CHSRG 2012) and race and brood year specific otolith thermal  
17 marks (DWR 2009).

18 The Feather River Fish Hatchery employs best management practices and  
19 protocols to avoid the spread of diseases from the hatchery. The hatchery has  
20 been successful in adaptively managing disease concerns as they arise by the  
21 installing an ultraviolet treatment system, modifying the stocking of Lake  
22 Oroville, conducting periodic testing, and using prescribed therapeutic treatments  
23 (DWR 2004c).

#### 24 **9.3.4.7.5 Disease**

25 Several endemic salmonid pathogens and diseases occur in the Feather River  
26 Basin, including *Ceratomyxa shasta* (salmonid ceratomyxosis), *Flavobacterium*  
27 *columnare* (columnaris), Infectious Hematopoietic Necrosis (IHN) virus,  
28 *Renibacterium salmoninarum* (bacterial kidney disease), and *Flavobacterium*  
29 *psychrophilum* (cold-water disease) (DWR 2004c). Each of these diseases has  
30 been shown to infect stocked and native salmonids in the Feather River; however,  
31 these diseases are not known to infect non-salmonids (FERC 2007b). Whirling  
32 disease has never been detected in the lower Feather River downstream of  
33 Oroville Dam, but has been found in upstream tributaries such as the north and  
34 south forks of the Feather River (DWR 2004c). Of the fish diseases in the Feather  
35 River Basin, IHN and salmonid ceratomyxosis are main contributors to fish  
36 mortality at the Feather River Fish Hatchery and are of highest concern for  
37 fisheries management in the region (DWR 2004c). The Feather River Fish  
38 Hatchery experienced severe IHN outbreaks in 2000 and 2001. A study by the  
39 University of California at Davis and USFWS indicated that although there were  
40 no clinical signs of disease, adult salmonids returning to either the Yuba or the  
41 Feather rivers demonstrated IHN infection rates of 28 percent and 18 percent,  
42 respectively (Brown et al. 2004).

1 Salmonid ceratomyxosis is endemic to the Feather River Basin; local salmonid  
2 stocks have co-evolved with this pathogen and exhibit some natural resistance.  
3 Salmonid ceratomyxosis causes mortality in all ages of anadromous and resident  
4 trout and salmon, although Rainbow Trout and steelhead are more susceptible to  
5 the disease than are Chinook and Coho Salmon (DWR 2004c). Mortality  
6 generally occurs when water temperatures exceed 50°F; however, fish can  
7 become infected at temperatures as low as 39°F (Bartholomew 2012).

#### 8 **9.3.4.7.6 Predation**

9 The FERC (2007b) study suggests that the Fish Barrier Dam, which directs most  
10 anadromous salmonid spawning to occur in the low-flow channel, concentrates  
11 juvenile salmonids within this reach. Counts of known predators on juvenile  
12 anadromous salmonids in the low-flow channel are reported to be low; however,  
13 significant numbers of predators reportedly do exist in the high-flow channel  
14 downstream of Thermalito Afterbay Outlet (Seesholtz et al. 2004). Limited  
15 information is available to estimate the current rate of predation on juvenile  
16 salmonids in the lower Feather River.

#### 17 **9.3.4.8 Yuba River**

18 Portions of the Yuba River watershed along the North Yuba River between New  
19 Bullards Bar Reservoir and Englebright Lake and along the Lower Yuba River  
20 between Englebright Lake and the Feather River could be affected by operation of  
21 the Lower Yuba River Water Accord (DWR et al. 2007), as described in  
22 Chapter 5, Surface Water Resources and Water Supplies.

23 Fish species found in the New Bullards Bar Reservoir include Rainbow Trout,  
24 Brown Trout, Kokanee Salmon, bass, Bluegill, crappie, and bullhead (DWR et al.  
25 2007). A similar mix of species is found in Englebright Reservoir. Fall-run and  
26 spring-run Chinook Salmon and steelhead occur in the Yuba River downstream of  
27 Englebright Dam (YCWA 2009). Sacramento Splittail have been documented  
28 only in the lower Feather River and not in the Yuba River. Low numbers of  
29 Green Sturgeon and White Sturgeon occasionally range into the Yuba River  
30 (Beamesderfer et al. 2004). Other species found in the lower Yuba River include  
31 American Shad, Smallmouth Bass, and Striped Bass (DWR et al. 2007).

#### 32 **9.3.4.9 Bear River**

33 The Bear River flows into the Feather River downstream of the confluence of the  
34 Feather and Yuba rivers. The Bear River includes Nevada Irrigation District's  
35 Rollins and Combie reservoirs along the upper and middle reaches of the Bear  
36 River and South Sutter Water District's Camp Far West Reservoir along the lower  
37 reach of the Bear River (FERC 2013, NID 2005).

38 Fall-run and spring-run Chinook Salmon and steelhead occur in the Bear River  
39 (YCWA 2009). Sacramento Splittail have been documented only in the lower  
40 Feather River and not in the Bear River. Low numbers of Green Sturgeon and  
41 White Sturgeon occasionally range into the Bear River (Beamesderfer et al.  
42 2004). Rollins Reservoir is currently managed as a put-and-take fishery for  
43 rainbow and Brown Trout. Kokanee reproduce naturally in the lake. Gill net

1 surveys from 1970 to 1983 documented numerous other species including bass,  
2 catfish, sunfish, Golden Shiner, Tui Chub, Pond Smelt, crappie, and Bluegill  
3 (DFG 1974-1983 in NID 2008). Native fishes found in Combie Reservoir may  
4 include Sacramento Pikeminnow, Sacramento Sucker, Hardhead, Tui Chub,  
5 Hitch, and Inland Silverside. Nonnative fishes likely include Bluegill, Green  
6 Sunfish, Largemouth Bass, Spotted Bass, Smallmouth Bass, common carp,  
7 Golden Shiner, Threadfin Shad, Black Crappie, Brown Bullhead, White Catfish,  
8 Channel Catfish, Western Mosquitofish, and stocked Rainbow Trout (NID 2009).

9 **9.3.4.10 Folsom Lake and Lake Natoma**

10 The American River watershed encompasses approximately 2,100 square miles  
11 (Reclamation et al. 2006). The three forks of the American River (north, middle,  
12 and south forks) converge upstream of Folsom Dam, with the combined flow  
13 moving through Lake Natoma and the lower American River for about 23 miles  
14 before entering the Sacramento River.

15 Water surface elevations vary annually as a result of seasonal inflow and water  
16 release and are generally the least variable during spring and most variable during  
17 summer (USACE et al. 2012). Thermal stratification of the reservoir generally  
18 begins during April and usually persists throughout summer until November,  
19 when cooler temperatures, winter rains, and high inflows create mixing and result  
20 in “turnover” (Reclamation 2005, USACE et al. 2012). During summer, a  
21 thermocline develops that separates the epilimnion (i.e., upper layer of warm  
22 water) and the hypolimnion (i.e., lower layer of cooler water). This thermal  
23 stratification and segregation of habitats allow for both cold-water and  
24 warm-water species to coexist in Folsom Lake (USACE et al. 2012).

25 Warm-water fish species include native Hardhead, California Roach, Sacramento  
26 Pikeminnow, and Sacramento Sucker, as well as nonnative Largemouth Bass,  
27 Smallmouth Bass, Spotted Bass, sunfish, Black Crappie, and White Crappie  
28 (Reclamation 2007). Cold-water fish species include native Rainbow Trout and  
29 planted Chinook and Kokanee Salmon, as well as nonnative Brown Trout  
30 (Reclamation 2007).

31 Nimbus Dam creates Lake Natoma, which serves as a regulating afterbay to the  
32 Folsom power plant, maintaining more uniform flows in the lower American  
33 River. Lake Natoma is a shallow reservoir with an average depth of about 16 feet  
34 (Reclamation 2005). Surface water elevations in Lake Natoma may fluctuate  
35 between 4 and 7 feet daily (USACE et al. 2012). Lake Natoma has relatively low  
36 productivity as a fishery due to the effects of wide water temperature variability  
37 associated with the lake fluctuating elevation. Reclamation (2007) reports that  
38 fish species found in Lake Natoma are generally the same as those in Folsom  
39 Lake. Although CDFW annually stocks Lake Natoma with hatchery Rainbow  
40 Trout, conditions in Lake Natoma are more favorable for warm-water fish species  
41 (Reclamation 2007).

1 **9.3.4.11 Lower American River between Lake Natoma and the**  
 2 **Sacramento River**

3 The lower American River extends approximately 23 miles from Nimbus Dam  
 4 downstream to the confluence with the Sacramento River. Access to the upper  
 5 reaches of the river by anadromous fish is blocked at Nimbus Dam.

6 **9.3.4.11.1 Fish in the Lower American River**

7 The lower American River system supports numerous resident native and  
 8 introduced species as well as several anadromous species.

9 The analysis is focused on the following species:

- 10 • Fall-run Chinook Salmon
- 11 • Steelhead
- 12 • White Sturgeon
- 13 • Sacramento Splittail
- 14 • Pacific Lamprey
- 15 • Striped Bass
- 16 • American Shad

17 *Fall-run Chinook Salmon*

18 Historically, the American River supported fall-run and perhaps late fall-run  
 19 Chinook Salmon (Williams 2001). Both naturally and hatchery produced  
 20 Chinook Salmon spawn in the lower American River. Recent analysis by DFG  
 21 and USFWS (2010) indicated that approximately 84 percent of the natural fall-run  
 22 Chinook Salmon spawners in the American River are hatchery-origin fish.  
 23 Kormos et al. (2012) reported that 79 percent of the fall-run Chinook Salmon  
 24 entering the Nimbus Fish Hatchery in 2010 and 32 percent of the fish spawning in  
 25 the American River were of hatchery origin.

26 Adult fall-run Chinook Salmon enter the lower American River from about  
 27 mid-September through January, with peak migration from approximately  
 28 mid-October through December (Williams 2001). Spawning occurs from about  
 29 mid-October through early February, with peak spawning from mid-October  
 30 through December. Chinook Salmon spawning occurs within an 18-mile stretch  
 31 from Paradise Beach to Nimbus Dam; however, most spawning occurs in the  
 32 uppermost 3 miles (DFG 2012a). Chinook Salmon egg and alevin incubation  
 33 occurs in the lower American River from about mid-October through April.  
 34 There is high variability from year to year; however, most incubation occurs from  
 35 about mid-October through February. Chinook Salmon fry emergence occurs  
 36 from January through mid-April, and juvenile rearing extends from January to  
 37 about mid-July (Williams 2001). Most Chinook Salmon outmigrate from the  
 38 lower American River as fry between December and July, peaking in February to  
 39 March (Snider and Titus 2002, PSMFC 2014).

1 *Steelhead*

2 Natural spawning by steelhead in the American River occurs (Hannon and  
3 Deason 2008), but the population is supported primarily by the Nimbus Fish  
4 Hatchery. The total estimated steelhead return to the river (spawning naturally  
5 and in the hatchery) has ranged from 946 to 3,426 fish, averaging 2,184 fish per  
6 year from 2002 to 2010 (CHSRG 2012). Steelhead spawning surveys have shown  
7 approximately 300 steelhead spawning in the river each year (Hannon and Deason  
8 2008). Lindley et al. (2007) classifies the listed (i.e., naturally spawning)  
9 population of American River steelhead at a high risk of extinction because it is  
10 reportedly mostly composed of steelhead originating from Nimbus Fish Hatchery.  
11 NMFS views the American River population as important to the survival and  
12 recovery of the species (NMFS 2009a).

13 Nielsen et al. (2005) found steelhead in the American River to be genetically  
14 different from other Central Valley stocks. Eel River steelhead were used to  
15 found the Nimbus Hatchery stock, and steelhead from the American River  
16 (collected from both the Nimbus Fish Hatchery and the American River) are  
17 genetically more similar to Eel River steelhead than other Central Valley  
18 Steelhead stocks. Based on studies by Hallock et al. (1961), Staley (1976), and  
19 Neilsen (2005), Lee and Chilton (2007) reported that American River winter-run  
20 steelhead are genetically and phenotypically different, and demonstrate a later  
21 upstream migration period than Central Valley Steelhead. Zimmerman et al.  
22 (2008) also noted that there remains a strong resident component (i.e., fish that do  
23 not migrate to the ocean) of the *O. mykiss* population that interacts with and  
24 produces anadromous individuals. Steelhead and Rainbow Trout are the same  
25 species and when juveniles of the species are found in fresh water, it is unclear if  
26 they will exhibit an anadromous (steelhead) or resident (Rainbow Trout) life  
27 history strategy. Thus, they are often collectively referred to as *O. mykiss* at this  
28 stage to indicate this uncertainty.

29 Adult steelhead enter the American River from November through April with a  
30 peak occurring from December through March (SWRI 2001). Steelhead have  
31 been trapped at Nimbus Fish Hatchery as early as the first week of October.  
32 Results of a spawning survey conducted from 2001 through 2007 indicate that  
33 steelhead spawning occurs in the lower American River from late December  
34 through early April, with the peak occurring in late February to early March  
35 (Hannon and Deason 2008). Spawning density is highest in the upper 7 miles of  
36 the river, but spawning occurs as far downstream as Paradise Beach. About  
37 90 percent of spawning occurs upstream of the Watt Avenue Bridge (Hannon and  
38 Deason 2008).

39 Embryo incubation begins with the onset of spawning in late December and  
40 generally extends through May, although incubation can occur into June in some  
41 years (SWRI 2001). Steelhead embryo and alevin mortality associated with high  
42 flows in the American River has not been documented, but flows high enough to  
43 mobilize spawning gravels do occur during the spawning and embryo incubation  
44 periods (i.e., late December through early April) (NMFS 2009a).

1 Juvenile *O. mykiss* have been documented year-round throughout the lower  
2 American River, with rearing generally upstream of spawning areas. Juveniles  
3 reportedly can rear in the lower American River for a year or more before  
4 outmigrating as smolts from January through June (Snider and Titus 2000a,  
5 SWRI 2001). However, Snider and Titus (2002) reported only 1 yearling  
6 steelhead capture, and PSMFC (2014) reported capturing primarily YOY fry and  
7 parr. Peak outmigration occurs from March through May (McEwan and Jackson  
8 1996, SWRI 2001, PSMFC 2014).

9 Rearing habitat for juvenile steelhead in the lower American River occurs  
10 throughout the upper reaches downstream to Paradise Beach. In summer,  
11 juveniles occur in most major riffle areas, with the highest concentrations near the  
12 higher density spawning areas (Reclamation 2008a). The number of juveniles in  
13 the American River decreases throughout summer (Reclamation 2008a). Warm  
14 water temperatures stress juvenile steelhead rearing in the American River,  
15 particularly during summer and early fall (LARTF 2002, Water Forum 2005c,  
16 NMFS 2014b). However, laboratory studies suggest that American River  
17 steelhead may be more tolerant of high temperatures than steelhead from regions  
18 farther north (Myrick and Cech 2004).

#### 19 *Pacific Lamprey*

20 The Pacific Lamprey inhabits accessible reaches of the American River.  
21 Information on the status of Pacific Lamprey in the American River is limited, but  
22 the loss of historical habitat and apparent population declines throughout  
23 California indicate populations are greatly decreased compared to historical levels  
24 (Moyle et al. 2009).

25 Hannon and Deason (2008) documented Pacific Lamprey spawning in the  
26 American River between early January and late May, with peak spawning  
27 typically in early April. Pacific Lamprey ammocoetes rear in the American River  
28 for all or part of their 5- to 7-year freshwater residence. Data from rotary screw  
29 trapping in the nearby Feather River suggest that outmigration of Pacific Lamprey  
30 generally occurs from early winter through early summer (Hanni et al. 2006),  
31 although some outmigration likely occurs year-round, as observed at sites on the  
32 mainstem Sacramento River (Hanni et al. 2006) and in other river systems  
33 (Moyle 2002).

34 Because of the parallels in their life cycles, particularly spawning, lampreys may  
35 be affected by many of the same factors as salmon and steelhead. Little  
36 information is available on factors influencing Pacific Lamprey populations in the  
37 American River, but the dams likely play an important role. Moyle et al. (2009)  
38 suggested that in addition to blocking upstream migration, dams may disrupt  
39 upstream sediment inputs required to maintain habitat for ammocoetes and subject  
40 ammocoetes to rapid decreases in stream flow. Moyle et al. (2009) also indicated  
41 that ramping rates sufficient to protect salmonids may not be adequate to prevent  
42 the stranding of ammocoetes and metamorphosing individuals, which are  
43 vulnerable to desiccation and avian predation. Additionally, commercial harvest  
44 of lampreys on the American River (presumably for bait) may reduce spawning  
45 success in some years (Hannon and Deason 2008).

1 *Sacramento Splittail*

2 Splittail likely spawn in the lower reaches of the American River (Sommer et al.  
3 1998, 2008; Moyle et al. 2004). During wet years, upstream migration is more  
4 directed and fish tend to swim farther upstream (Moyle 2002), thus more  
5 individuals are expected to use the American River in wet years. Although  
6 juvenile splittail are known to rear in upstream areas for a year or more (Baxter  
7 1999), most move to the Delta after only a few weeks of rearing on floodplain  
8 habitat (Reclamation 2008a). Most juveniles move downstream into the Delta  
9 from April to August (Meng and Moyle 1995). The primary factor potentially  
10 limiting the American River population of Sacramento Splittail is availability of  
11 inundated floodplains for spawning and rearing habitats (Moyle et al. 2004).

12 *White Sturgeon*

13 Limited quantitative information is available on the distribution and status of  
14 White Sturgeon in the American River; however, small numbers of adults  
15 apparently use the American River, as evidenced by sturgeon report cards  
16 submitted to CDFW by anglers in recent years (e.g., DFG 2012b).

17 *Striped Bass*

18 Striped Bass are found in the American River throughout the year, with the  
19 greatest abundance in summer (SWRI 2001). Although the occurrence of  
20 spawning in the American River is uncertain, the river is believed to serve as a  
21 nursery area for YOY and subadult Striped Bass (SWRI 2001). Striped Bass are  
22 distributed from the confluence with the Sacramento River to Nimbus Dam  
23 (Moyle 2002), and they provide a locally important sportfishing resource.

24 *American Shad*

25 Adult American Shad ascend the lower American River to spawn during the late  
26 spring. During this period, they provide an important sport fishery. The shortage  
27 of adequate attraction flows in major tributaries such as the American River may  
28 be contributing to declines in the population (Moyle 2002).

29 **9.3.4.11.2 Aquatic Habitat**

30 Since 1955, Nimbus Dam has blocked upstream passage by anadromous fish and  
31 restricted available habitat in the lower American River to the approximately  
32 23 river miles between the dam and the confluence with the Sacramento River.  
33 Additionally, Folsom Dam has blocked the downstream transport of sediment that  
34 contributes to the formation and maintenance of habitat for aquatic species.

35 In 2008, Reclamation, in coordination with USFWS and the Sacramento Water  
36 Forum, began implementation of salmonid habitat improvement in the lower  
37 American River. An estimated 5,000 cubic yards of gravel and cobble were  
38 placed just upstream of Nimbus Fish Hatchery in 2008, followed by an estimated  
39 7,000 cubic yards adjacent to the Nimbus Fish Hatchery in fall 2009. In  
40 September 2010, approximately 11,688 cubic yards (approximately 16,200 tons)  
41 of gravel and cobble were placed at Sailor Bar to enhance spawning habitat for  
42 Chinook Salmon and steelhead in the lower American River (Merz et al. 2012).  
43 Additionally, the 2010 augmentation site contained a constructed cobble island

1 and “scallop” in the substrate designed to add habitat heterogeneity to the main  
2 channel and rearing habitat for juvenile Chinook Salmon and steelhead.  
3 Additionally, approximately 5,500 tons of cleaned cobble were placed  
4 downstream of the 2010 augmentation site. The specific purpose of this  
5 placement was to divert flow into an adjacent, perched side channel, thereby  
6 preventing the dewatering of salmonid redds in a historically important spawning  
7 and rearing area during low-flow conditions.

8 During higher flows, channel geomorphology in the lower American River is  
9 characterized by bar complexes and side channel areas, which may become  
10 limited at lower flows (NMFS 2009a). Spawning bed materials in the lower  
11 American River may begin to mobilize at flows of 30,000 cfs, with more  
12 substantial mobilization at flows of 50,000 cfs or greater (Reclamation 2008a).  
13 At 115,000 cfs (the highest flow modeled), particles up to 70 mm median  
14 diameter would be moved in the high-density spawning areas around Sailor Bar  
15 and Sunrise Avenue. Flood frequency analysis for the American River at Fair  
16 Oaks gage shows that, on average, flood control releases exceed 30,000 cfs about  
17 once every 4 years and exceed 50,000 cfs about once every 5 years  
18 (Reclamation 2008a).

19 In 2008, Reclamation began implementing floodplain and spawning habitat  
20 restoration projects in the American River to assist in meeting the requirements of  
21 the 1992 CVPIA, Section 3406 (b)(13). The side channel at Upper Sunrise was  
22 identified as a suitable site for steelhead spawning habitat restoration. In 2008,  
23 the CVPIA (b)(13) program cut and widened the side channel so that it inundated  
24 at a greater range of flows. The project reduced steelhead stranding, but also  
25 inadvertently reduced Chinook Salmon and steelhead spawning and rearing  
26 habitat (AFRP 2012). Consequently, the main channel was filled at the head-cut  
27 to create greater head pressure, thereby allowing flow once again through the side  
28 channel. Monitoring at the Upper Sunrise project revealed immediate response  
29 from Chinook Salmon and steelhead moving up into the side channel to spawn  
30 after completion of the project. Spawning and rearing habitat enhancement  
31 projects occurred each year from 2008 through 2014 in the reach from Nimbus  
32 Dam down to River Bend Park. These annual projects are planned to continue.

### 33 **9.3.4.11.3 Fish Passage**

34 Including the mainstem, north, middle, and south forks, more than 125 miles of  
35 riverine habitat historically were available for anadromous salmonids in the  
36 American River watershed (Yoshiyama et al. 1996). Access to the upper reaches  
37 of the river has been blocked by a series of impassable dams, including Old  
38 Folsom Dam, first constructed in the American River between 1895 and 1939.

39 Reclamation operates a fish diversion weir approximately 0.25 mile downstream  
40 of Nimbus Dam, which functions to divert adult steelhead and Chinook Salmon  
41 into Nimbus Fish Hatchery. The weir is annually installed during September  
42 prior to the arrival of fall-run Chinook Salmon and steelhead and is removed at  
43 the conclusion of fall-run Chinook Salmon immigration in early January  
44 (Reclamation and DFG 2011). Some steelhead may be trapped prior to weir

1 removal, but they are returned to the river. A new fish passageway is being  
2 implemented in the Nimbus Dam stilling basin, commonly referred to as Nimbus  
3 Shoals. The passageway will replace the existing fish diversion weir with a new  
4 flume and fish ladder that will connect to the existing fish ladder near Nimbus  
5 Fish Hatchery.

#### 6 **9.3.4.11.4 Hatcheries**

7 CDFW operates the Nimbus Salmon and Steelhead Hatchery and American River  
8 Trout Hatchery, located immediately downstream from Nimbus Dam. Facilities  
9 associated with Nimbus Fish Hatchery include a fish weir, fish ladder, gathering  
10 and handling tanks, hatchery-specific buildings, and rearing ponds. Nimbus Fish  
11 Hatchery was constructed primarily to mitigate the loss of spawning habitat for  
12 Chinook Salmon and Central Valley Steelhead that were blocked by the  
13 construction of Nimbus Dam (Reclamation and DFG 2011); it does not address  
14 lost habitat upstream from Folsom Dam (CHSRG 2012). The hatchery operations  
15 include the trapping, artificial spawning, rearing, and release of steelhead and fall-  
16 /late fall-run Chinook Salmon. Propagation programs for American River winter-  
17 run steelhead and Central Valley fall/ late fall-run Chinook Salmon are operated  
18 by CDFW under contract with Reclamation (Lee and Chilton 2007). The Nimbus  
19 Fish Hatchery Winter-run Steelhead Program is an isolated-harvest program  
20 (i.e., it does not include natural-origin steelhead in the broodstock), designed and  
21 implemented to artificially spawn the adipose fin-clipped adult steelhead that  
22 seasonally enter the trapping facilities (CHSRG 2012). These fin-clipped fish are  
23 not part of the Central Valley Steelhead DPS. The Nimbus Fish Hatchery  
24 Winter-run Steelhead Program propagates fish for recreational fishing  
25 opportunities and harvest (CHSRG 2012).

26 Steelhead have been trapped at Nimbus Fish Hatchery as early as the first week of  
27 October; however, since 2000, the ladder has been opened in early November.  
28 Trapping of steelhead has continued to occur as late as the second week of March.  
29 Presently, winter-run steelhead are trapped at Nimbus Fish Hatchery, and  
30 artificially spawned adults are marked with an adipose fin clip (CHSRG 2012).  
31 Unmarked steelhead adults are not retained at Nimbus Fish Hatchery for use in  
32 the annual broodstock and are released back to the river (CHSRG 2012). In  
33 addition, marked or unmarked *O. mykiss* that are less than 16 inches long may be  
34 resident hatchery-origin trout and are returned to the river (CHSRG 2012).

35 On average, the program has raised and released approximately 422,000 yearling  
36 steelhead since brood year 1999 (CHSRG 2012). Since 1998, all  
37 steelhead/Rainbow Trout produced in Nimbus Fish Hatchery have been marked  
38 with an adipose fin-clip to aid in subsequently identifying hatchery-origin fish.

39 Juvenile steelhead yearlings are not held past March 30 because of increasing  
40 hatchery water temperatures and to encourage outmigration during spring. If  
41 releases occur during periods of low flows in the Sacramento River and possibly  
42 the American River, some released fish migrate back to Nimbus Fish Hatchery  
43 and may take up residency rather than migrating downstream (Lee and Chilton  
44 2007). Additionally, juvenile fish are released in February and early March to

1 coincide with State Water Resources Control Board (SWRCB) D-1641 closures  
2 of the DCC gates from February 1 through May 20 to reduce straying into the  
3 Delta. Reclamation determines the exact timing and duration of the gate closures  
4 after discussion with USFWS, CDFW, and NMFS.

5 Reclamation is implementing a genetic screening study of Nimbus Fish Hatchery  
6 steelhead. Reclamation, in contract with NMFS, is conducting a parental-based  
7 tagging study of American River steelhead and continuing a study to determine a  
8 more genetically appropriate stock.

9 CDFW releases all hatchery-produced steelhead juveniles into the American  
10 River at boat ramps on the American River or at the confluence of the Sacramento  
11 and American rivers and releases all unclipped steelhead adults returning to  
12 Nimbus Fish Hatchery into the lower American River via the river return tube that  
13 is just downstream of the fish ladder. In accordance with California law, the  
14 current protocol of Nimbus Fish Hatchery is to destroy all surplus eggs to prevent  
15 inter-basin transfer of eggs or juveniles to other hatcheries or waters.

16 The goal of the Nimbus Fish Hatchery Integrated Fall/Late Fall-run Chinook  
17 Salmon Program is to release 4 million smolts. Each fall, Nimbus Hatchery staff  
18 collect approximately 10,000 adult fall-run Chinook Salmon, with an annual goal  
19 of harvesting 8,000,000 eggs and releasing the 4,000,000 smolts. All adult  
20 fall-run Chinook Salmon collected at the hatchery are euthanized, and no trapped  
21 salmon are returned to the American River (Reclamation 2008a).

#### 22 **9.3.4.11.5 Disease**

23 The occurrence of a bacterial-caused inflammation of the anal vent (commonly  
24 referred to as “rosy anus”) of steelhead in the lower American River has been  
25 reported by CDFW to be associated with relatively warm water temperatures  
26 (Water Forum 2005b). Anal vent inflammation of steelhead in the lower  
27 American River was observed in 2004 during periods when water temperatures  
28 were measured between 65°F and 68°F (Water Forum 2005a, 2005b). The Water  
29 Forum (2005b) suggested that, in addition to possible diminished immune system  
30 responses and incidences of diseases associated with elevated water temperatures,  
31 disease transmission may be exacerbated by crowding under conditions when  
32 water flows are reduced.

#### 33 **9.3.4.11.6 Predation**

34 Reduced cold-water storage in Folsom Lake and using Folsom Lake to meet Delta  
35 water quality objectives and demands influence habitat conditions in the lower  
36 American River for warm-water predator species that feed on juvenile salmonids  
37 and potentially alter predation pressure (Water Forum 2005b). Additionally,  
38 isolation of redds in side channels resulting from fluctuations in Folsom Lake  
39 releases may increase predation of emergent fry (Water Forum 2005b).

1     **9.3.4.12   Delta**

2     Ecologically, the Delta consists of three major landscapes and geographic regions:  
3     (1) the north Delta freshwater flood basins composed primarily of freshwater  
4     inflow from the Sacramento River system; (2) the south Delta distributary  
5     channels composed of predominantly San Joaquin River system inflow; and  
6     (3) the central Delta tidal islands landscape wherein the Sacramento, San Joaquin,  
7     and east side tributary flows converge and tidal influences from San Francisco  
8     Bay are greater.

9     **9.3.4.12.1 Fish in the Delta**

10    The Delta provides unique and, in some places, highly productive habitats for a  
11    variety of fish species, including euryhaline and oligohaline resident species and  
12    anadromous species. For anadromous species, the Delta is used by adult fish  
13    during upstream migration and by rearing juvenile fish that are feeding and  
14    growing as they migrate downstream to the ocean. Conditions in the Delta  
15    influence the abundance and productivity of all fish populations that use the  
16    system. Fish communities currently in the Delta include a mix of native species,  
17    some with low abundance, and a variety of introduced fish, some with high  
18    abundance (Matern et al. 2002, Feyrer and Healey 2003, Nobriga et al. 2005,  
19    Brown and May 2006, Moyle and Bennett 2008, Grimaldo et al. 2012).

20    The analysis is focused on the following species:

- 21    • Chinook Salmon (winter-, spring-, and fall-/late fall-run)
- 22    • Steelhead
- 23    • Green Sturgeon
- 24    • White Sturgeon
- 25    • Sacramento Splittail
- 26    • Pacific Lamprey
- 27    • Striped Bass
- 28    • American Shad
- 29    • Delta Smelt
- 30    • Longfin Smelt
- 31    • Sacramento Splittail

32    The Interagency Ecological Program (IEP) has been monitoring fish populations  
33    in the San Francisco Estuary for decades. Survey methods have included beach  
34    seining, midwater trawls, Kodiak trawls, otter trawls, and other methods (Honey  
35    et al. 2004) to sample the pelagic fish assemblage throughout the estuary. Three  
36    of the most prominent resident pelagic fishes captured in the surveys (Delta  
37    Smelt, Longfin Smelt, and Striped Bass) have shown substantial long-term  
38    population declines (Kimmerer et al. 2000, Bennett 2005, Rosenfield and  
39    Baxter 2007). Reductions in pelagic fish abundance since 2002 have been  
40    recognized as a serious water and fish management issue and have become known  
41    as the Pelagic Organism Decline (POD) (Sommer et al. 2007a).

1 In response to the POD, the IEP formed a study team in 2005 to evaluate the  
2 potential causes of the decline. Since completion of the first set of studies in late  
3 2005, alternative models have been developed based on the available data and at  
4 professional judgment of the POD-Modeling Team regarding the extent to which  
5 individual drivers are likely to affect each species-life stage. The nine drivers  
6 identified (Baxter et al. 2010) were: (1) mismatch of larvae and food; (2) reduced  
7 habitat space; (3) adverse water movement/transport; (4) entrainment; (5) toxic  
8 effects on fish; (6) toxic effects on fish food items; (7) harmful *Microcystis*  
9 *aeruginosa* blooms; (8) *Potamocorbula amurensis* effects on food availability;  
10 and (9) disease and parasites.

11 An overall negative trend in habitat quality has occurred for Delta Smelt and  
12 Striped Bass (and potentially other fish species) as measured by water quality  
13 attributes and midwater trawl catch data since 1967, with Delta Smelt and Striped  
14 Bass experiencing the most apparent declines in abundance, distribution, and a  
15 related index of environmental quality (Feyrer et al. 2007, 2010). More  
16 specifically, the position of X2 and water clarity may be important factors  
17 influencing the quality of habitat for these species (McNally et al. 2010). Other  
18 factors, such as the introduction of nonnative clam species, also contribute to  
19 reducing habitat quality. Pelagic habitat suitability in the San Francisco Estuary  
20 has been characterized by changes in X2 (Feyrer et al. 2007, 2010). The  
21 abundance of several taxa increases in years when flows into the estuary are high  
22 and X2 is pushed seaward (Jassby et al. 1995; Kimmerer 2002a, b), implying that  
23 the quantity or suitability of estuarine habitat increases when outflows are high.  
24 Recent analyses by Kimmerer et al. (2009) indicated that neither changes in area  
25 or volume of low salinity water (habitat) account for this relationship, except for  
26 striped bass and American shad. This suggests that X2 is indexing other  
27 environmental variables or processes rather than simple extent of habitat (Baxter  
28 et al. 2010).

### 29 *Winter-run Chinook Salmon*

30 Winter-run Chinook Salmon use the Delta for upstream migration as adults and  
31 for downstream migration and rearing as juveniles (del Rosario et al. 2013).  
32 Adults migrate through the Delta during winter and into late spring (May/June)  
33 enroute to their spawning grounds in the mainstem Sacramento River downstream  
34 of Keswick Dam (USFWS 2001b, 2003b). Adults are believed to primarily use  
35 the mainstem Sacramento River for passage through the Delta (NMFS 2009a).  
36 After entry into the Delta, juvenile winter-run Chinook Salmon remain and rear in  
37 the Delta until they are 5 to 10 months of age (based on scale analysis) (Fisher  
38 1994, Myers et al. 1998). Although the duration of residence in the Delta is not  
39 precisely known, del Rosario et al. (2013) suggested that it can be up to several  
40 months. Winter-run Chinook Salmon juveniles have been documented in the  
41 north Delta (e.g., Sacramento River, Steamboat Slough, Sutter Slough, Miner  
42 Slough, Yolo Bypass, and Cache Slough complex); the central Delta  
43 (e.g., Georgiana Slough, DCC, Snodgrass Slough, and Mokelumne River complex  
44 below Dead Horse Island); south Delta channels, including Old and Middle rivers,  
45 and the joining waterways between Old and Middle rivers (e.g., Victoria Canal,

1 Woodward Canal, and Connection Slough); and the western central Delta,  
2 including the mainstem channels of the Sacramento and San Joaquin rivers and  
3 Threemile Slough (NMFS 2009a).  
4 Sampling at Chipps Island in the western Delta suggests that winter-run Chinook  
5 Salmon exit the Delta as early as December and as late as May, with a peak in  
6 March (Brandes and McLain 2001, del Rosario et al. 2013). The peak timing of  
7 the outmigration of juvenile winter-run Chinook Salmon through the Delta is  
8 corroborated by recoveries of winter-run-sized juvenile Chinook Salmon from the  
9 SWP Skinner Delta Fish Protection Facility and the CVP Tracy Fish Collection  
10 Facility in the south Delta (NMFS 2009a).

#### 11 *Spring-run Chinook Salmon*

12 The Delta is an important migratory route for all remaining populations of spring-  
13 run Chinook Salmon. Like all salmonids migrating up through the Delta, adult  
14 spring-run Chinook Salmon must navigate the many channels and avoid direct  
15 sources of mortality (e.g., fishing and predation), but also must minimize  
16 exposure to sources of nonlethal stress (e.g., high temperatures) that can  
17 contribute to prespawn mortality in adult salmonids (Budy et al. 2002, Naughton  
18 et al. 2005, Cooke et al. 2006, NMFS 2009a). Habitat degradation in the Delta  
19 caused by factors such as channelization and changes in water quality can present  
20 challenges for outmigrating juveniles. Additionally, outmigrating juveniles are  
21 subjected to predation and entrapment in the project export facilities and smaller  
22 diversions (NMFS 2009a). Further detail is provided later in this section.

23 Spring-run Chinook Salmon returning to spawn in the Sacramento River system  
24 enter the San Francisco Estuary from the ocean in January to late February and  
25 move through the Delta prior to entering the Sacramento River. Several  
26 populations of spring-run Chinook Salmon occur in the Sacramento River Basin,  
27 but historical populations that occurred in the San Joaquin River and tributaries  
28 have been extirpated. The Sacramento River channel is the main spring-run  
29 Chinook Salmon migration route through the Delta. However, adult spring-run  
30 Chinook Salmon may stray into the San Joaquin River side of the Delta in  
31 response to water from the Sacramento River Basin flowing into the  
32 interconnecting waterways that join the San Joaquin River channel through the  
33 DCC, Georgiana Slough, and Threemile Slough. Closure of the DCC radial gates  
34 is intended to minimize straying, but some southward net flow still occurs  
35 naturally in Georgiana and Threemile sloughs.

36 Juvenile spring-run Chinook Salmon show two distinct outmigration patterns in  
37 the Central Valley: outmigrating to the Delta and ocean during their first year of  
38 life as YOY, or holding over in their natal streams and outmigrating the following  
39 fall/winter as yearlings. Peak movement of juvenile spring-run Chinook Salmon  
40 in the Sacramento River at Knights Landing generally occurs in December, and  
41 again in March. However, juveniles also have been observed migrating between  
42 November and the end of May (Snider and Titus 1998, 2000b, c, d; Vincik et al.  
43 2006; Roberts 2007).

1 YOY spring-run Chinook Salmon presence in the Delta peaks during April and  
2 May, as suggested by the recoveries of Chinook Salmon in the CVP and SWP  
3 salvage operations and the Chipps Island trawls of a size consistent with the  
4 predicted size of spring-run fish at that time of year. However, it is difficult to  
5 distinguish the YOY spring-run Chinook Salmon outmigration from that of the  
6 fall-run due to the similarity in their spawning and emergence times and size.  
7 Together, these two runs generate an extended pulse of Chinook Salmon smolts  
8 outmigrating through the Delta throughout spring, frequently lasting into June.  
9 Spring-run Chinook Salmon juveniles also overlap spatially with juvenile winter-  
10 run Chinook Salmon in the Delta (NMFS 2009a). Typically, juvenile spring-run  
11 Chinook Salmon are not found in the channels of the eastern side of the Delta or  
12 the mainstem of the San Joaquin River upstream of Columbia and Turner Cuts.

### 13 *Fall-/Late fall-run Chinook Salmon*

14 Central Valley fall- and late fall-run Chinook Salmon pass through the Delta as  
15 adults migrating upstream and juveniles outmigrating downstream. Adult fall-  
16 and late fall-run Chinook Salmon migrating through the Delta must navigate the  
17 many channels and avoid direct sources of mortality and minimize exposure to  
18 sources of nonlethal stress. Additionally, outmigrating juveniles are subject to  
19 predation and entrainment in the project export facilities and smaller diversions.

20 Adult fall-run Chinook Salmon migrate through the Delta and into Central Valley  
21 rivers from June through December. Adult late fall-run Chinook Salmon migrate  
22 through the Delta and into the Sacramento River from October through April.  
23 Adult Central Valley fall- and late fall-run Chinook Salmon migrating into the  
24 Sacramento River and its tributaries primarily use the western and northern  
25 portions of the Delta, whereas adults entering the San Joaquin River system to  
26 spawn use the western, central, and southern Delta as a migration pathway.

27 Most fall-run Chinook Salmon fry rear in fresh water from December through  
28 June, with outmigration as smolts primarily from January through June. In  
29 general, fall-run Chinook Salmon fry abundance in the Delta increases following  
30 high winter flows. Smolts that arrive in the estuary after rearing upstream migrate  
31 quickly through the Delta and Suisun and San Pablo bays. A small number of  
32 juvenile fall-run Chinook Salmon spend over a year in fresh water and outmigrate  
33 as yearling smolts the following November through April. Late fall-run fry rear  
34 in fresh water from April through the following April and outmigrate as smolts  
35 from October through February (Snider and Titus 2000b). Juvenile Chinook  
36 Salmon were found to spend about 40 days migrating through the Delta to the  
37 mouth of San Francisco Bay (MacFarlane and Norton 2002).

38 Results of mark-recapture studies conducted using juvenile Chinook Salmon  
39 released into both the Sacramento and San Joaquin rivers have shown high  
40 mortality during passage downstream through the rivers and Delta (Brandes and  
41 McLain 2001, Newman and Rice 2002, Buchanan et al. 2013). Juvenile salmon  
42 migrating from the San Joaquin River generally experience greater mortality than  
43 fish outmigrating from the Sacramento River. In years when spring flows are  
44 reduced and water temperatures are increased, mortality is typically higher in both  
45 rivers. Closing the DCC gates and installation of the Head of Old River Barrier to

1 reduce the movement of juvenile salmon into the south Delta from the  
2 Sacramento and San Joaquin rivers, respectively, may contribute to improved  
3 survival of outmigrating juvenile Chinook Salmon from these watersheds (see  
4 Section 9.3.4.12.6).

5 Although not directly comparable to these previous coded-wire tag studies in the  
6 San Joaquin River, Buchanan et al. (2013, 2015) found that survival of  
7 acoustically tagged hatchery-origin (Feather River) juvenile Chinook Salmon was  
8 either not statistically different between routes (2009) or was higher through the  
9 south Delta via the Old River route than via the San Joaquin River (2010).  
10 Additionally, most fish in the Old River that survived to the end of the Delta had  
11 been salvaged from the federal water export facility on the Old River and trucked  
12 around the remainder of the Delta (Buchanan et al. 2013, SJRGA 2013).  
13 Buchanan et al. 2013 indicated that the differences in their results compared to  
14 past CWT studies may reflect that an alternative non-physical barrier was being  
15 used during their investigation to examine its ability to keep fish out of the Old  
16 River instead of the HORB which is a physical barrier that reduces not only the  
17 number of fish, but also the majority of flows, from entering the Old River.  
18 Nonphysical barriers may deprive smolts routed to the San Joaquin River of the  
19 increased flows needed for improved survival and created habitat for increased  
20 predation at the site (Buchanan et al. 2013).

21 Juvenile fall- and late fall-run Chinook Salmon migrating through the Delta  
22 toward the Pacific Ocean use the Delta, Suisun Marsh, and the Yolo Bypass for  
23 rearing to varying degrees, depending on their life stage (fry versus juvenile),  
24 size, river flows, and time of year. Movement of juvenile Chinook Salmon in the  
25 estuarine environment is driven by the interaction between tidally influenced  
26 saltwater intrusion through San Francisco Bay and freshwater outflow from the  
27 Sacramento and San Joaquin rivers (Healey 1991).

28 In the Delta, tidal and floodplain habitat areas provide important rearing habitat  
29 for foraging juvenile salmonids, including fall-run Chinook Salmon. Studies have  
30 shown that juvenile salmon may spend 2 to 3 months rearing in these habitat  
31 areas, and losses resulting from land reclamation and levee construction are  
32 considered to be major stressors (Williams 2010). The channeled, leveed, and  
33 riprapped river reaches and sloughs common in the Delta typically have low  
34 habitat diversity and complexity, have low abundance of food organisms, and  
35 offer little protection from predation by fish and birds.

### 36 *Steelhead*

37 Upstream migration of steelhead begins with estuarine entry from the ocean as  
38 early as July and continues through February or March in most years (McEwan  
39 and Jackson 1996, NMFS 2009a). Populations of steelhead occur primarily  
40 within the watersheds of the Sacramento River Basin, although not exclusively.  
41 Steelhead can spawn more than once, with postspawn adults (typically females)  
42 potentially moving back downstream through the Delta after completion of  
43 spawning in their natal streams.

1 Adult steelhead can be present in portions of the Delta with suitable conditions  
2 during any month of the year. Upstream migrating adult steelhead enter the  
3 Sacramento and San Joaquin River basins through their respective mainstem river  
4 channels. Steelhead entering the Mokelumne River system (including Dry Creek  
5 and the Cosumnes River) and the Calaveras River system to spawn are likely to  
6 move up the mainstem San Joaquin River channel before branching off into the  
7 channels of their natal rivers, although some may detour through the South Delta  
8 waterways and enter the San Joaquin River through the Head of Old River.

9 Steelhead entering the San Joaquin River Basin appear to have a later spawning  
10 run, with adults entering the system starting in late October through December,  
11 indicating that migration up through the Delta may begin a few weeks earlier.  
12 During fall, warm water temperatures in the south Delta waterways and water  
13 quality impairment because of low dissolved oxygen at Stockton have been  
14 suggested as potential barriers to upstream migration (NMFS 2009a). Reduced  
15 water temperatures, as well as rainfall runoff and flood control release flows,  
16 provide the stimulus to adult steelhead holding in the Delta to move upriver  
17 toward their spawning reaches in the San Joaquin River tributaries. Adult  
18 steelhead may continue entering the San Joaquin River Basin through winter.

19 Juvenile steelhead can be found in all waterways of the Delta, but particularly in  
20 the main channels leading from their natal river systems (NMFS 2009a). Juvenile  
21 steelhead are recovered in trawls from October through July at Chipps Island and  
22 at Mossdale. Chipps Island catch data indicate there is a difference in the  
23 outmigration timing between wild and hatchery-reared steelhead smolts from the  
24 Sacramento and eastside tributaries. Hatchery fish are typically recovered at  
25 Chipps Island from January through March, with a peak in February and March  
26 corresponding to the schedule of hatchery releases of steelhead smolts from the  
27 Central Valley hatcheries (Nobriga and Cadrett 2001, Reclamation 2008a). The  
28 timing of wild (unmarked) steelhead outmigration is more spread out, and based  
29 on salvage records at the CVP and SWP fish collection facilities, outmigration  
30 occurs over approximately 6 months with the highest levels of recovery in  
31 February through June (Aasen 2011, 2012). Steelhead are salvaged annually at  
32 the project export facilities (e.g., 4,631 fish were salvaged in 2010, and 1,648 in  
33 2011) (Aasen 2011, 2012).

34 Outmigrating steelhead smolts enter the Delta primarily from the Sacramento or  
35 San Joaquin River. Mokelumne River steelhead smolts can either follow the  
36 north or south branches of the Mokelumne River through the central Delta before  
37 entering the San Joaquin River, although some fish may enter farther upstream if  
38 they diverge from the south branch of the Mokelumne River into Little Potato  
39 Slough. Calaveras River steelhead smolts enter the San Joaquin River  
40 downstream of the Port of Stockton. Although steelhead have been routinely  
41 documented by CDFW in trawls at Mossdale since 1988 (SJRG 2011), it is  
42 unknown whether successful outmigration occurs outside the seasonal installation  
43 of the barrier at the Head of Old River (between April 15 and May 15 in most  
44 years). Prior to the installation of the Head of Old River barrier, steelhead smolts  
45 exiting the San Joaquin River Basin could follow one of two routes to the ocean,

1 either staying in the mainstem San Joaquin River through the central Delta, or  
2 entering the Head of Old River and migrating through the south Delta and its  
3 associated network of channels and waterways.

4 *Green Sturgeon*

5 Green Sturgeon reach maturity around 14 to 16 years of age and can live to be  
6 70 years old, returning to their natal rivers every 3 to 5 years for spawning  
7 (Van Eenennaam et al. 2005). Adult Green Sturgeon move through the Delta  
8 from February through April, arriving at holding and spawning locations the  
9 upper Sacramento River between April and June (Heublein 2006, Kelly et al.  
10 2007). Following their initial spawning run upriver, adults may hold for a few  
11 weeks to months in the upper river before moving back downstream in fall  
12 (Vogel 2008, Heublein et al. 2009), or they may migrate immediately back  
13 downstream through the Delta. Radio-tagged adult Green Sturgeon have been  
14 tracked moving downstream past Knights Landing during summer and fall,  
15 typically in association with pulses of flow in the river (Heublein et al. 2009),  
16 similar to behavior exhibited by adult Green Sturgeon on the Rogue River and  
17 Klamath River systems (Erickson et al. 2002, Benson et al. 2007).

18 Similar to other estuaries along the west coast of North America, adult and sub-  
19 adult Green Sturgeon frequently congregate in the San Francisco Estuary during  
20 summer and fall (Lindley et al. 2008). Specifically, adults and subadults may  
21 reside for extended periods in the central Delta as well as in Suisun and San Pablo  
22 bays, presumably for feeding, because bays and estuaries are preferred feeding  
23 habitat rich in benthic invertebrates (e.g., amphipods, bivalves, and insect larvae).  
24 In part because of their bottom-oriented feeding habits, sturgeon are at risk of  
25 harmful accumulations of toxic pollutants in their tissues, especially pesticides  
26 such as pyrethroids and heavy metals such as selenium and mercury (Israel and  
27 Klimley 2008, Stewart et al. 2004).

28 Juvenile Green Sturgeon and White Sturgeon are periodically (although rarely)  
29 collected from the lower San Joaquin River at south Delta water diversion  
30 facilities and other sites (NMFS 2009a; Aasen 2011, 2012). Green Sturgeon are  
31 salvaged from the south Delta Project diversion facilities and are generally  
32 juveniles greater than 10 months but less than 3 years old (Reclamation 2008a).  
33 NMFS (2005b) suggested that the high percentage of San Joaquin River flows  
34 contributing to the Tracy Fish Collection Facility could mean that some entrained  
35 Green Sturgeon originated in the San Joaquin River Basin. Jackson (2013)  
36 reported spawning by White Sturgeon in the San Joaquin River, and anglers have  
37 reported catching a few Green Sturgeon in recent years in the San Joaquin River  
38 (DFG 2012b).

39 After hatching, larvae and juveniles migrate downstream toward the Delta.  
40 Juveniles are believed to use the Delta for rearing for the first 1 to 3 years of their  
41 lives before moving out to the ocean and are likely to be found in the main  
42 channels of the Delta and the larger interconnecting sloughs and waterways,  
43 especially within the central Delta and Suisun Bay/Marsh. Project operations at  
44 the DCC have the potential to reroute Green Sturgeon as they outmigrate through  
45 the lower Sacramento River to the Delta (Israel and Klimley 2008, Vogel 2011).

1 When the DCC is open, there is no passage delay for adults, but juveniles could  
2 be diverted from the Sacramento River into the interior Delta. This has been  
3 shown to reduce the survival of juvenile Chinook Salmon (Brandes and McLain  
4 2001, Newman and Brandes 2010, Perry et al. 2012), but it is unknown whether it  
5 has similar effects on Green Sturgeon.

#### 6 *White Sturgeon*

7 White Sturgeon are similar to Green Sturgeon in terms of their biology and life  
8 history. Like Green Sturgeon and other sturgeon species, White Sturgeon are  
9 late-maturing and infrequent spawners, which makes them vulnerable to  
10 overexploitation and other sources of adult mortality. White Sturgeon are  
11 believed to be most abundant within the San Francisco Bay-Delta region  
12 (Moyle 2002). Both nonspawning adults and juveniles can be found throughout  
13 the Delta year-round (Radtke 1966, Kohlhorst et al. 1991, Moyle 2002,  
14 DWR et al. 2013). When not undergoing spawning or ocean migrations, adults  
15 and subadults are usually most abundant in brackish portions of the Bay-Delta  
16 (Kohlhorst et al. 1991). The population status of White Sturgeon in the Delta is  
17 unclear, but it is not presently listed. Overall, information on trends in adults and  
18 juveniles suggests that numbers are declining (Moyle 2002, NMFS 2009a).

19 The Delta population of White Sturgeon spawns mainly in the Sacramento and  
20 Feather rivers, with occasional spawning in the San Joaquin River (Moyle 2002,  
21 Jackson 2013). Spawning-stage adults generally move into the lower reaches of  
22 rivers during winter prior to spawning and migrate upstream in response to higher  
23 flows to spawn from February to early June (McCabe and Tracy 1994,  
24 Schaffter 1997).

25 After absorbing yolk sacs and initiating feeding, YOY White Sturgeon make an  
26 active downstream migration that disperses them widely to rearing habitat  
27 throughout the lower rivers and the Delta (McCabe and Tracy 1994). White  
28 Sturgeon larvae have been observed to be flushed farther downstream in the Delta  
29 and Suisun Bay in high outflow years, but are restricted to more interior locations  
30 in low outflow years (Stevens and Miller 1970).

31 Salinity tolerance increases with increasing age and size (McEnroe and Cech  
32 1985), allowing White Sturgeon to access a broader range of habitat in the San  
33 Francisco Estuary (Israel et al. 2008). During dry years, White Sturgeon have  
34 been observed following brackish waters farther upstream, while the opposite  
35 occurs in wet years (Kohlhorst et al. 1991). Adult White Sturgeon tend to  
36 concentrate in deeper areas and tidal channels with soft bottoms, especially during  
37 low tides, and typically move into intertidal or shallow subtidal areas to feed  
38 during high tides (Moyle 2002). These shallow water habitats provide  
39 opportunities for feeding on benthic organisms, such as opossum shrimp,  
40 amphipods, and even invasive overbite clams, and small fishes (Israel et al. 2008,  
41 Kogut 2008). White Sturgeon also have been found in tidal habitats of  
42 medium-sized tributary streams to the San Francisco Estuary, such as Coyote  
43 Creek and Guadalupe River in the south bay and Napa and Petaluma rivers and  
44 Sonoma Creek in the north bay (Leidy 2007).

1 Numerous factors likely affect the White Sturgeon population in the Delta, similar  
2 to those for Green Sturgeon. Survival during early life history stages may be  
3 adversely affected by insufficient flows, lack of rearing habitat, predation, warm  
4 water temperatures, decreased dissolved oxygen, chemical toxicants in the water,  
5 and entrainment at diversions (Cech et al. 1984, Israel et al. 2008). Historical  
6 habitats, including shallow intertidal feeding habitats, have been lost in the Delta  
7 because of channelization. Over-exploitation by recreational fishing and  
8 poaching also likely has been an important factor adversely affecting numbers of  
9 adult sturgeon (Moyle 2002), although new regulations were implemented in  
10 2007 by CDFW to reduce harvest. Like Green Sturgeon, there are substantial  
11 passage problems for White Sturgeon such as the Fremont Weir  
12 (Sommer et al. 2014).

### 13 *Delta Smelt*

14 Delta Smelt are endemic to the Delta (Moyle et al. 1992, Bennett 2005). Delta  
15 Smelt were once regarded as one of the most common pelagic fish in the Delta,  
16 but declines in their population led to their listing under the ESA as threatened in  
17 1993 (USFWS 2008a). Delta Smelt are one of four pelagic fish species (including  
18 Longfin Smelt, Threadfin Shad, and juvenile Striped Bass) documented to be in  
19 decline based on fall midwater trawl abundance indices (Sommer et al. 2007a).  
20 The causes of the declines have been extensively studied and are thought to  
21 include a combination of factors, such as decreased habitat quantity and quality,  
22 increased mortality rates, and reduced food availability (Feyrer et al. 2007,  
23 Sommer et al. 2007a, Moyle and Bennett 2008, Baxter et al. 2010, MacNally et al.  
24 2010, Rose et al. 2013a, b, Sommer and Mejia 2013). Two statistical analyses  
25 that used similar data but different statistical methods, (MacNally et al. 2010;  
26 Thomson et al. 2010) examined the dynamics of the four fish species. Both  
27 analyses identified several covariates that were related to abundance of the fish,  
28 but they could not resolve the cause of the recent declines. The analysis of model  
29 results and data for 1995–2005 conducted by Rose et al. (2013a) indicated that it  
30 has been difficult to ascribe the Delta Smelt’s decline to a single cause, either  
31 over the long term or as part of the recent 2002 decline.

32 The status of the Delta Smelt is uncertain, as indicators of Delta Smelt abundance  
33 have continued to decline and the number of fish collected in sampling programs,  
34 such as the trawl surveys conducted by the IEP, have dropped even lower in  
35 recent years. The Fall Midwater Trawl (FMWT) Survey is recognized by some as  
36 the best available long-term index of Delta Smelt relative abundance  
37 (USFWS 2008). Figure 9.1 presents the FMWT abundance indices for Delta  
38 Smelt from 1967 to 2013 (CDFW 2014b). Fewer than 10 Delta Smelt were  
39 collected in these surveys in 2014; the 2014 Delta Smelt index was 9, making it  
40 the lowest in FMWT history (CDFW 2014a, 2015). Results for Delta Smelt from  
41 the 2015 spring Kodiak trawl, 20-mm survey, and summer townet survey reported  
42 in the June 2015 Smelt Working Group meeting summary were similarly low  
43 (Smelt Working Group 2015).

1

2 **Figure 9.1 Fall Midwater Trawl Abundance Indices for Delta Smelt from 1967**  
 3 **to 2013**

4 Source: California Department of Fish and Wildlife, Trends in Abundance of Selected  
 5 Species, January 15, 2014. <http://www.dfg.ca.gov/delta/data/fmwt/Indices/>

6 Studies conducted to synthesize available information about Delta Smelt indicate  
 7 that Delta Smelt have been documented throughout their geographic range during  
 8 much of the year (Merz et al. 2011, Sommer and Mejia 2013, Brown et al. 2014).  
 9 Studies indicate that in fall, prior to spawning, Delta Smelt are found in the Delta,  
 10 Suisun and San Pablo bays, the Sacramento River and San Joaquin River  
 11 confluence, Cache Slough, and the lower Sacramento River (Murphy and  
 12 Hamilton 2013). By spring, they move to freshwater areas of the Delta region,  
 13 including the Sacramento River and San Joaquin River confluence, the Upper  
 14 Sacramento River, and Cache Slough (Brown et al. 2014, Murphy and  
 15 Hamilton 2013).

16 Sommer et al. 2011 described that during winter, adult Delta Smelt initiate  
 17 upstream spawning migrations in association with “first flush” freshets. Others  
 18 report this seasonal change as a multi-directional and more circumscribed  
 19 dispersal movement to freshwater areas throughout the Delta region (Murphy and  
 20 Hamilton 2013). After arriving in freshwater staging habitats, adult Delta Smelt  
 21 hold until spawning commences during favorable water temperatures in the late  
 22 winter-spring (Bennett 2005, Grimaldo et al. 2009, Sommer et al. 2011). Delta  
 23 Smelt spawn over a wide area throughout much of the Delta, including some areas  
 24 downstream and upstream as conditions allow. Although the specific substrates  
 25 or habitats used for spawning by Delta Smelt are not known, spawning habitat  
 26 preferences of closely related species (Bennett 2005) suggest that spawning may  
 27 occur in shallow areas over sandy substrates. The nonpelagic habitats used by  
 28 larval Delta Smelt before they move into the pelagic areas also are not known  
 29 (Swanson et al. 1998, Sommer et al. 2011).

1 During and after larval rearing in fresh water, many young Delta Smelt move with  
2 river and tidal currents to remain in favorable rearing habitats, often moving  
3 increasingly into the low salinity zone to avoid seasonally warm and highly  
4 transparent waters that typify many areas in the central Delta (Nobriga et al.  
5 2008). Bennett and Burau (2014) showed that during winter, delta smelt  
6 aggregate near frontal zones at the shoal-channel interface moving laterally into  
7 the shoals on ebb tides and back into the channel on flood tides. They suggest  
8 that this migration strategy can minimize the energy spent swimming against  
9 strong river and tidal currents, as well as predation risks by remaining in  
10 turbid water.

11 During summer and fall, many juvenile Delta Smelt continue to grow and rear in  
12 the low salinity zone until maturing the following winter (Bennett 2005). Some  
13 Delta Smelt also rear in upstream areas such as the Cache Slough complex and  
14 Sacramento Deepwater Ship Channel, depending on habitat conditions (Sommer  
15 and Mejia 2013).

16 During summer and fall, the distribution of juvenile Delta Smelt rearing is  
17 influenced by the position of the low salinity zone (as indexed by the position of  
18 X2), although their distribution can also be influenced by temperature and  
19 turbidity (Bennett 2005; Feyrer et al. 2007, 2010; Kimmerer et al. 2009; Sommer  
20 and Mejia 2013). The geographical position of the low salinity zone varies  
21 primarily as a function of freshwater outflow; thus, X2 typically lies farther east  
22 in summer and fall during low outflow conditions and drier water years and  
23 farther west during high outflow conditions (Jassby et al. 1995).

24 Higher outflow causes X2 and the low salinity zone to more frequently overlap  
25 with the Suisun Bay/Marsh region, which is broader and shallower and typically  
26 has greater turbidity than the mainstem Sacramento and San Joaquin rivers. The  
27 overlap of the low salinity zone (or X2) with the Suisun Bay/Marsh results in a  
28 dramatic increase in the habitat index (Feyrer et al. 2010); however others (see  
29 Manly et al. 2015) have questioned the use by Feyrer et al. (2010) of outflow and  
30 X2 location as an indicator of Delta Smelt habitat because other factors may be  
31 influencing survival.

32 In addition to salinity, turbidity is an important factor associated with habitat use;  
33 Delta Smelt show a strong preference for higher turbidity water (Feyrer et al.  
34 2007, 2010; Sommer and Mejia 2013) and turbidity may be a key habitat feature  
35 and cue initiating the delta smelt spawning migration (Bennett and Burau 2014).  
36 Turbidity has decreased in recent decades within the Delta (Kimmerer 2004,  
37 Schoellhamer 2011), which has likely contributed to declines in environmental  
38 quality of Delta Smelt habitat (Feyrer et al. 2007, 2010). Higher turbidities are  
39 believed to allow Delta Smelt to hide from open-water predators, such as Striped  
40 Bass (Gregory and Levings 1998, Nobriga et al. 2005), and contribute to feeding  
41 success (Lindberg et al. 2000, IEP 2015).

42 Water temperature is another important environmental factor that affects Delta  
43 Smelt habitat and population dynamics (Sommer and Mejia 2013). A longer  
44 period of optimal water temperatures in cooler years increases the number of

1 spawning events and cohorts produced (Bennett 2005). During rearing, summer  
2 water temperatures also have been shown to be an important predictor of Delta  
3 Smelt occurrence, based on multi-decadal analyses of summer tow net survey data  
4 (Nobriga et al. 2008).

5 The quality and availability of food also have important effects on the abundance  
6 and distribution of Delta Smelt (Sommer and Mejia 2013, Kimmerer 2008). Delta  
7 Smelt feed primarily on zooplankton, and Nobriga (2002) showed that Delta  
8 Smelt larvae with food in their guts typically co-occurred with higher calanoid  
9 copepod densities. Food quality and availability have varied substantially, largely  
10 because of the history of nonnative species introduction into the San Francisco  
11 Estuary (Baxter et al. 2008, Winder and Jassby 2011). The decline of  
12 zooplankton in the western Delta has been hypothesized to be related to several  
13 factors, including increased ammonium concentrations from wastewater effluent  
14 and agricultural runoff (Wilkerson et al. 2006; Dugdale et al. 2007; Miller et al.  
15 2012; Glibert 2010; Glibert et al. 2011, 2014).

16 In 2011 and 2012, an unanticipated change in water management operations led to  
17 relatively large phytoplankton blooms in the western Delta, including in the  
18 Sacramento River near Rio Vista. Historically, rice fields along the Colusa Basin  
19 Drain are flooded in fall to decompose the rice stubble, and the water is released  
20 through the Knights Landing Outfall gates into the Sacramento River. In 2011  
21 and 2012, construction at the outfall gates required the water to be diverted into  
22 the Yolo Bypass, resulting in higher than normal flows. These events temporarily  
23 resulted in a fall pulse flow in the Yolo Bypass that increased the volume of flow  
24 by more than 300 to 900 percent (Frantzich 2014). Concurrently, a substantial  
25 increase in nutrients, phytoplankton, and zooplankton was observed in the Yolo  
26 Bypass and Cache Slough. In 2013, the fall pulse flow of rice drainage water did  
27 not occur in the Yolo Bypass, and nutrient concentrations did not increase. These  
28 nutrient inputs, when they occur, and corresponding increases in phytoplankton  
29 and zooplankton production, could contribute to improved foraging opportunities  
30 for Delta Smelt.

31 Results in prior years indicate that entrainment and salvage-related mortality of  
32 Delta Smelt associated with water pumping and CVP/SWP exports from the Delta  
33 occur primarily from December to July (Kimmerer 2008, Grimaldo et al. 2009,  
34 Baxter et al. 2010). Entrainment occurs when migrating and spawning adult Delta  
35 Smelt and their larvae overlap in time and space with reverse (southward, or  
36 upstream) flows in the Old and Middle river channels (Kimmerer 2008, Grimaldo  
37 et al. 2009, Baxter et al. 2010).

38 In January 2015, the IEP Management Analysis and Synthesis Team (MAST)  
39 published a report to provide an assessment and conceptual model of factors  
40 affecting Delta Smelt throughout its life cycle. One focus of the report was an  
41 evaluation of a notable increase in abundance of all Delta Smelt life stages in  
42 2011, which indicated that the Delta Smelt population could potentially rebound  
43 when conditions are favorable for spawning, growth, and survival.

1 The IEP MAST updated conceptual model described the habitat conditions and  
2 ecosystem drivers affecting each Delta Smelt life stage, across seasons and how  
3 the seasonal effects contributed to the annual success of the species. The  
4 conclusions of the report highlighted some key points about Delta Smelt and their  
5 habitat, using 2011 as the example year. In summary, the report concluded that  
6 Delta Smelt likely benefitted from the following favorable habitat conditions  
7 in 2011:

- 8 1) Adults and larvae benefitted from high winter 2010 and spring 2011 outflows,  
9 which reduced entrainment risk and possibly improved other habitat  
10 conditions, prolonged cool spring water temperatures, and possibly good food  
11 availability in late spring.
- 12 2) Juvenile Delta Smelt benefitted from cool water temperatures in late spring  
13 and early summer as well as from relatively good food availability and low  
14 levels of harmful *Microcystis*.
- 15 3) Subadults benefitted from good food availability and from favorable habitat  
16 conditions in the large low salinity zone, located more toward Suisun Bay in  
17 2010.

#### 18 *Longfin Smelt*

19 Longfin Smelt populations occur along the Pacific Coast of North America, and  
20 the San Francisco Estuary represents the southernmost population. Longfin Smelt  
21 generally occur in the Delta; Suisun, San Pablo, and San Francisco bays; and the  
22 Gulf of the Farallones, just outside San Francisco Bay. Longfin Smelt are not a  
23 focus of any specific RPA actions. However, RPA actions that benefit Delta  
24 Smelt, salmonids, and sturgeon, including increasing Delta outflow, have the  
25 potential to benefit other fish, including Longfin Smelt, given their similar habitat  
26 requirements and trophic feeding levels.

27 Longfin Smelt are anadromous and spawn in fresh water in the Delta, generally at  
28 2 years of age (Moyle 2002). They migrate upstream to spawn during late fall  
29 through winter, with most spawning from November through April (DFG 2009a).  
30 Spawning in the Sacramento River is believed to occur from just downstream of  
31 the confluence of the Sacramento and San Joaquin rivers upstream to about Rio  
32 Vista. Spawning on the San Joaquin River extends from the confluence upstream  
33 to about Medford Island (Moyle 2002). Spawning likely also occurs in Suisun  
34 Marsh and the Napa River (DFG 2009a).

35 Longfin Smelt larvae are most abundant in the water column usually from January  
36 through April (Reclamation 2008a). The geographic distribution of Longfin  
37 Smelt larvae is closely associated with the position of X2; the center of  
38 distribution varies with outflow conditions, but not with respect to X2 (Dege and  
39 Brown 2004). This pattern is consistent with juveniles migrating downstream to  
40 low salinity, brackish habitats for growth and rearing. Larger Longfin Smelt feed  
41 primarily on opossum shrimps and other invertebrates (Feyrer et al. 2003).  
42 Copepods and other crustaceans also can be important food items, especially for  
43 smaller fish (Reclamation 2008a).

1 Longfin Smelt in the San Francisco Estuary are broadly distributed in both time  
2 and space, and interannual distribution patterns are relatively consistent  
3 (Rosenfield and Baxter 2007). Seasonal patterns in abundance indicate that the  
4 population is at least partially anadromous (Rosenfield and Baxter 2007), and the  
5 detection of Longfin Smelt within the estuary throughout the year suggests that,  
6 similar to Striped Bass, anadromy is one of several life history strategies or  
7 contingents in this population.

8 The relative population size of Longfin Smelt in the San Francisco Estuary is  
9 measured by indices of abundance generated from different sampling programs.  
10 The abundance of age 0 and older fish is best indexed by the Fall Midwater Trawl  
11 and Bay Study, while the abundance of larvae and young juveniles is best indexed  
12 by the 20-mm survey. The relationship between these indices and actual  
13 population sizes is unknown. Although the Fall Midwater Trawl data suggest a  
14 sharp decline in Longfin Smelt abundance during the last decade, some of that  
15 decline might be attributable to a downstream movement in the longfin  
16 distribution into regions better covered by the Bay Study fish survey. The Bay  
17 Study uses two types of trawls, an otter trawl and a midwater Trawl. The Longfin  
18 Smelt abundance index created from the Fall Midwater Trawl is consistent with  
19 the trend in the Bay Study midwater trawl but not the Bay Study otter Trawl. In  
20 addition, there have been an increasing proportion of false zeros in the survey data  
21 where the Bay Study midwater trawl failed to detect any Longfin Smelt when  
22 they were detected in the otter trawl.

23 The abundance of Longfin Smelt in the estuary has fluctuated over time but has  
24 exhibited statistically significant step-declines around 1989 to 1991 and in 2004  
25 (Thomson et al. 2010). A synthesis of prior studies conducted by USFWS in its  
26 12-Month Finding on a Petition to List the San Francisco Bay-Delta Population of  
27 the Longfin Smelt as Endangered or Threatened (USFWS 2012) reported that  
28 increased Delta outflow in winter and spring is the largest factor possibly  
29 affecting Longfin Smelt abundance. The trend in Longfin Smelt abundance from  
30 1967 through 2013 is presented on Figure 9.2.

1

2 **Figure 9.2 Fall Midwater Trawl Abundance Indices for Longfin Smelt from 1967 to**  
 3 **2013**

4 Source: California Department of Fish and Wildlife, Trends in Abundance of Selected  
 5 Species, January 15, 2014. <http://www.dfg.ca.gov/delta/data/fmwt/Indices/>

6 Habitat for Longfin Smelt is open water, largely away from shorelines and  
 7 vegetated inshore areas except perhaps during spawning. This includes all of the  
 8 large embayments in the estuary and the deeper areas of many of the larger  
 9 channels in the western Delta; habitat suitability in these areas for Longfin Smelt  
 10 can be strongly influenced by variation in freshwater flow (Jassby et al. 1995,  
 11 Bennett and Moyle 1996, Kimmerer 2004, Kimmerer et al. 2009).

12 Water exports and inadvertent entrainment at the SWP and CVP export facilities  
 13 are anthropogenic sources of mortality for Longfin Smelt. The export facilities  
 14 are known to entrain most species of fish in the Delta (Brown et al. 1996).  
 15 Longfin Smelt entrainment mainly occurs from December to May, with peak  
 16 adult entrainment from December to February (Grimaldo et al. 2009). In water  
 17 year 2011, Aasen (2012) reported four adult Longfin Smelt were salvaged at the  
 18 project export facilities, compared with much higher numbers in the early 2000s  
 19 and late 1980s. The entrainment of Longfin Smelt in recent years has been  
 20 reduced likely because of changes in export operations and a decline in  
 21 abundance.

22 *Sacramento Splittail*

23 Sacramento Splittail are found primarily in marshes, turbid sloughs, and slow-  
 24 moving river reaches throughout the Delta subregion (Sommer et al. 1997, 2008).  
 25 Sacramento Splittail are most abundant in moderately shallow, brackish tidal  
 26 sloughs and adjacent open-water areas, but they also can be found in freshwater  
 27 areas with tidal or riverine flow (Moyle et al. 2004).

28 Adult Sacramento Splittail typically migrate upstream from brackish areas in  
 29 January and February and spawn in fresh water, particularly on inundated  
 30 floodplains when they are available, in March and April (Sommer et al. 1997,  
 31 Moyle et al. 2004, Sommer et al. 2008). A substantial amount of splittail

1 spawning occurs in the Yolo and Sutter bypasses and the Cosumnes River area of  
2 the Delta (Moyle et al. 2004). Spawning also can occur in the San Joaquin River  
3 during high-flow events (Sommer et al. 1997, 2008). However, not all adults  
4 migrate significant distances to spawn as evidenced by spawning in the Napa and  
5 Petaluma rivers (Feyrer et al. 2005).

6 Although juvenile Sacramento Splittail are known to rear in upstream areas for a  
7 year or more (Baxter 1999), most move to the Delta after only a few weeks or  
8 months of rearing in floodplain habitats along the rivers (Feyrer et al. 2006).  
9 Juveniles move downstream into the Delta from April to August (Meng and  
10 Moyle 1995, Feyrer et al. 2005). Sacramento Splittail recruitment is largely  
11 limited by extent and period of inundation of floodplain spawning habitats, with  
12 abundance observed to spike following wet years and dip after dry years  
13 (Moyle et al. 2004). However, the 5- to 7-year life span buffers the adult  
14 population abundance (Sommer et al. 1997, Moyle et al. 2004). Other factors that  
15 may adversely affect the splittail population in the Delta include entrainment,  
16 predation, changed estuarine hydraulics, nonnative species (Moyle et al. 2004),  
17 pollutants (Greenfield et al. 2008), and limited food.

#### 18 *American Shad*

19 American Shad is a recreationally important anadromous species introduced into  
20 the Sacramento-San Joaquin River Basin in the 1870s (Moyle 2002). American  
21 Shad spend most of their adult life at sea and may make extensive migrations  
22 along the coast. American Shad become sexually mature while in the ocean and  
23 migrate through the Delta to spawning areas in the Sacramento, Feather,  
24 American, and Yuba rivers. Some spawning also takes place in the lower San  
25 Joaquin, Mokelumne, and Stanislaus rivers (USFWS 1995). The spawning  
26 migration may begin as early as February, but most adults migrate into the Delta  
27 in March and early April (Skinner 1962). Migrating adults generally take 2 to  
28 3 months to pass through the Sacramento-San Joaquin estuary (Painter et al.  
29 1979).

30 Fertilized eggs are slightly negative buoyant, are not adhesive, and drift in the  
31 current. Newly hatched larvae are found downstream of spawning areas and can  
32 be rapidly transported downstream by river currents because of their small size.  
33 Juvenile shad rear in the Sacramento River below Knights Landing, the Feather  
34 River below Yuba City, and the Delta; rearing also takes place in the Mokelumne  
35 River near the DCC to the San Joaquin River. No rearing occurs in the American  
36 and Yuba rivers (Painter et al. 1979). Some juvenile shad may rear in the Delta  
37 for up to a year before outmigrating to the ocean (USFWS 1995). Outmigration  
38 from the Delta begins in late June and continues through November  
39 (Painter et al. 1979).

40 Juvenile American Shad are frequently encountered in the Delta during the  
41 FMWT Survey and in fish salvage monitoring at the south Delta SWP and CVP  
42 fish facilities (DWR et al. 2013). American Shad use of the Delta has been  
43 observed to vary with salinity (e.g., X2 position) and outflows (Kimmerer 2002).

1 American Shad are entrained at the Tracy Fish Collection Facility (Bowen et al.  
2 1998) and in the Clifton Court Forebay, mostly during May through December  
3 when young American Shad migrate downstream. The American Shad  
4 population in the Sacramento-San Joaquin River Basin has declined since the late  
5 1970s, most likely because of increased diversion of water from rivers and the  
6 Delta, combined with changing ocean conditions, and possibly pesticides  
7 (Moyle 2002). Salvage of American Shad at project export facilities in water year  
8 2011 represented nearly 659,000 fish (Aasen 2012), with similar but slightly  
9 lower salvage in 2010 (545,125 fish) (Aasen 2011).

10 *Striped Bass*

11 Striped Bass is a recreationally important anadromous species introduced into the  
12 Sacramento-San Joaquin River Basin between 1879 and 1882 (Moyle 2002).  
13 Despite their nonnative status and piscivorous feeding habits, Striped Bass are  
14 considered important because they are a major game fish in the Delta. Striped  
15 Bass use the Delta as a migratory route and for rearing and seasonal foraging.  
16 Striped Bass spend the majority of their lives in salt water, returning to fresh  
17 water to spawn. When not migrating for spawning, adult Striped Bass in the San  
18 Francisco Bay-Delta are found in San Pablo Bay, San Francisco Bay, and the  
19 Pacific Ocean (Moyle 2002). Adult Striped Bass spend about 6 to 9 months of the  
20 year in San Francisco and San Pablo bays (Hassler 1988). Striped Bass also use  
21 deeper areas of many of the larger channels in the Delta, in addition to large  
22 embayments such as Suisun Bay.

23 Spawning occurs in spring, primarily in the Sacramento River between  
24 Sacramento and Colusa and in the San Joaquin River between Antioch and  
25 Venice Island (Farley 1966). Eggs are free-floating and negatively buoyant and  
26 hatch as they drift downstream, with larvae occurring in shallow and open waters  
27 of the lower reaches of the Sacramento-San Joaquin rivers, the Delta, Suisun Bay,  
28 Montezuma Slough, and Carquinez Strait. According to Hassler (1988), the  
29 distribution of larvae in the estuary depends on river flow. In low-flow years, all  
30 Striped Bass eggs and larvae are found in the Delta, while in high-flow years, the  
31 majority of eggs and larvae are transported downstream into Suisun Bay.

32 YOY Striped Bass distribute themselves in accordance with the estuarine salinity  
33 gradient (Kimmerer 2002, Feyrer et al. 2007), indicating that salinity is a major  
34 factor affecting their habitat use and geographic distributions. Kimmerer (2002)  
35 found that distributions of fish species, including Striped Bass, substantially  
36 overlapped with the low salinity zone. Older Striped Bass are increasingly  
37 flexible about their distribution relative to salinity (Moyle 2002).

38 The entrainment of Striped Bass has been observed at the project export facilities,  
39 including Clifton Court Forebay (Stevens et al. 1985, Bowen et al. 1998,  
40 Aasen 2012). In water year 2011, salvage of Striped Bass at export facilities  
41 (approximately 550,000 fish) continued a generally low trend observed since the  
42 mid-1990s. Prior to 1995, annual Striped Bass salvage was generally above  
43 1 million fish (Aasen 2012). DWR et al. (2013) reported that Striped Bass longer  
44 than 24 mm were effectively screened at Tracy Fish Collection Facility and

1 bypassed the pumps. However, planktonic eggs, larvae, and juveniles smaller  
2 than 24 mm in length received no protection from entrainment.

3 Striped Bass, primarily YOY, are one of the pelagic fish of the upper estuary that  
4 have shown substantial variability in their populations, with evidence of long-  
5 term declines (Kimmerer et al. 2000, Sommer et al. 2007a). As discussed earlier  
6 for Delta Smelt, a substantial portion of the abundance patterns has been  
7 associated with variation of outflow in the estuary (Jassby et al. 1995, Kimmerer  
8 et al. 2001, Loboschefskey et al. 2012), although this is disputed by some  
9 stakeholders (Bourez 2011). However, surveys showed that population levels for  
10 YOY Striped Bass began to decline sharply around 1987 and 2002  
11 (Thomson et al. 2010), despite relatively moderate hydrology, which typically  
12 supports at least modest fish production (Sommer et al. 2007a). Moyle (2002)  
13 cites causes of decline in Striped Bass to include climatic factors, entrainment at  
14 project export facilities in the south Delta, other diversions, pollutants, reduced  
15 estuarine productivity, invasions by alien species, and human exploitation.  
16 Kimmerer et al. (2000, 2001) attribute the decline in juvenile YOY Striped Bass  
17 to declining carrying capacity, likely related to food limitation. Loboschefskey  
18 et al. (2012) showed that there had been no long-term decline for age 1 and older  
19 Striped Bass as of 2004.

#### 20 *Pacific Lamprey*

21 The Pacific Lamprey is a widely distributed species that uses the Delta for  
22 upstream migration as adults, for downstream migration as juveniles, and for  
23 rearing as ammocoetes (larval form) (Hanni et al. 2006, Moyle et al. 2009).  
24 Pacific Lampreys are present in the north, central, and south Delta, and  
25 ammocoetes are present year-round in all of the regions (DWR et al. 2013).  
26 Limited information on status of Pacific Lamprey in the Delta exists, but the  
27 number of lampreys inhabiting the Delta is likely greatly suppressed compared  
28 with historical levels, as suggested by the loss of access to historical habitat and  
29 apparent population declines throughout California and the Sacramento-San  
30 Joaquin River Basin (Moyle et al. 2009).

31 Limited data indicate most adult Pacific Lamprey migrate through the Delta  
32 enroute to upstream holding and spawning grounds in the early spring through  
33 early summer (Hanni et al. 2006). As documented in other large river systems, it  
34 is likely that some adult migration through the Delta occurs from late fall and  
35 winter through summer and possibly over an even broader period (Robinson and  
36 Bayer 2005, Hanni et al. 2006, Moyle et al. 2009, Clemens et al. 2012, Lampman  
37 2011). Data from the FMWT Survey in the lower Sacramento and San Joaquin  
38 rivers and Suisun Bay suggest that peak outmigration of Pacific Lamprey through  
39 the Delta coincides with high-flow events from fall through spring (Hanni et al.  
40 2006). Some outmigration likely occurs year-round, as observed at sites farther  
41 upstream (Hanni et al. 2006), and in other river systems (Moyle 2002). Some  
42 Pacific Lamprey ammocoetes likely spend part of their extended (5 to 7 years)  
43 freshwater residence rearing in the Delta, particularly in the upstream, freshwater  
44 portions (DWR et al. 2013).

1 **9.3.4.12.2 Aquatic Habitat**

2 Flow management in the Delta has created stress on aquatic resources by  
3 (1) changing aspects of the historical flow regime (timing, magnitude, duration)  
4 that supported life history traits of native species; (2) limiting access to or quality  
5 of habitat; (3) contributing to conditions better suited to invasive, nonnative  
6 species (reduced spring flows, increased summer inflows and exports, and low  
7 and less-variable interior Delta salinity [Moyle and Bennett 2008]); and  
8 (4) causing reverse flows in channels leading to project export facilities that can  
9 entrain fish (Mount et al. 2012). Native species of the Delta are adapted to and  
10 depend on variable flow conditions at multiple scales as influenced by the  
11 region's dramatic seasonal and interannual climatic variation. In particular, most  
12 native fishes evolved reproductive or outmigration timing associated with  
13 historical peak flows during spring (Moyle 2002).

14 Water temperatures in the Delta follow a seasonal pattern of winter cold-water  
15 conditions and summer warm-water conditions, largely because of the region's  
16 Mediterranean climate, with alternating cool-wet and hot-dry seasons. Currently  
17 in the Delta, the most significant changes in water temperatures have been in the  
18 form of increased summer water temperatures over large areas of the Delta  
19 because of high summer ambient air temperatures, the increased temperature of  
20 river inflows, and to a lesser extent, reduced quantities of freshwater inflow and  
21 modified tidal and groundwater hydraulics (Kimmerer 2004, Mount et al. 2012,  
22 NRC 2012, Wagner et al. 2011). Water temperatures in summer now approach or  
23 exceed the upper thermal tolerances (e.g., 20 to 25° Centigrade [C]) for  
24 cold-water fish species such as salmonids and Delta-dependent species such as  
25 Delta Smelt. This is especially true in parts of the south Delta and San Joaquin  
26 River, potentially restricting the distribution of these species and precluding  
27 previously important rearing areas (NRC 2012).

28 Landscape-scale changes resulting from flood management infrastructure, along  
29 with flow modification, have eliminated most of the historical hydrologic  
30 connectivity of floodplains and aquatic ecosystems in the Delta and its tributaries,  
31 thereby degrading and diminishing Delta habitat for native plant and animal  
32 communities (Mount et al. 2012). The large reduction of hydrologic variability  
33 and landscape complexity, coupled with degradation of water quality, has  
34 supported invasive aquatic species that have further degraded conditions for  
35 native species. Due to the combination of these factors, the Delta appears to have  
36 undergone an ecological regime shift unfavorable to many native species (Moyle  
37 and Bennett 2008, Baxter et al. 2010). The major species influenced by current  
38 Delta hydrology include Delta Smelt, Longfin Smelt, Sacramento Splittail, White  
39 Sturgeon, juvenile Chinook Salmon, and Striped Bass (Jassby et al. 1995,  
40 Kimmerer 2002, Rosenfield and Baxter 2007, Kimmerer et al. 2009, Fish 2010,  
41 Perry et al. 2012, Thomson et al. 2010, Feyrer et al. 2010, Loboschefskey et al.  
42 2012, Mount et al. 2012).

43 Salinity is a critical factor influencing plant and animal communities in the Delta.  
44 Although estuarine fish species are generally tolerant of a range of salinity, this  
45 varies by species and lifestage. Some species can be highly sensitive to

1 excessively low or high salinity during physiologically vulnerable periods, such  
2 as reproductive and early life history stages. Although the Delta is tidally  
3 influenced, most of the Delta is fresh water year-round, due to inflows from  
4 rivers. The south Delta can have low salinity because of agricultural return water.  
5 The tidally influenced low salinity zone can move upstream into the central Delta.

6 An important measure of the spatial geography of salinity in the western Delta is  
7 X2. The X2 has also been correlated with the amount of suitable habitat for Delta  
8 Smelt in fall (Feyrer et al. 2007, 2010; USFWS 2008a). It is also helps define the  
9 extent of habitat available for oligohaline pelagic organisms and their prey. An  
10 analysis of historical monitoring data by Feyrer et al. (2007) revealed that the  
11 abiotic habitat of Delta Smelt can be defined as a specific envelope of salinity and  
12 turbidity that changes over the course of the species' life cycle. Project operations  
13 and other potential factors (e.g., lower outflows) have tended to shift the X2  
14 position in fall farther upstream out of the wide expanse of Suisun Bay into the  
15 much narrower channels near the confluence of the Sacramento and San Joaquin  
16 rivers (near Collinsville), reducing the spatial extent of low salinity habitat  
17 important for relevant species such as Delta Smelt (USFWS 2008a, 2011a;  
18 Kimmerer et al. 2009; Baxter et al. 2010). However, there is emerging  
19 information suggesting that a comparison of the Delta outflow during pre-project  
20 and post-project time periods do not support the conclusion that project operations  
21 have significantly moved X2 more easterly in September and October compared  
22 to pre-project conditions and project operations have only potentially impacted  
23 X2 location in November (Hutton et al. in press).

#### 24 **9.3.4.12.3 Nutrients and Food Web Support**

25 Nutrients are essential components of terrestrial and aquatic environments  
26 because they provide a resource base for primary producers. Typically in  
27 freshwater aquatic environments, phosphorous is the primary limiting  
28 macronutrient, whereas in marine aquatic environments, nitrogen tends to be  
29 limiting. A balanced range of abundant nutrients provides optimal conditions for  
30 maximum primary production, a robust food web, and productive fish  
31 populations. However, changes in nutrient loadings and forms, excessive  
32 amounts of nutrients, and altered nutrient ratios can lead to eutrophication and a  
33 suite of problems in aquatic ecosystems, such as low dissolved oxygen  
34 concentrations, un-ionized ammonia, excessive growth of toxic forms of  
35 cyanobacteria, and changes in components of the food web. Nutrient  
36 concentrations in the Delta have been well studied (Jassby et al. 2002;  
37 Kimmerer 2004; Van Nieuwenhuysse 2007; Glibert 2010; Glibert et al. 2011,  
38 2014).

39 Estuaries are commonly characterized as highly productive nursery areas for  
40 numerous aquatic organisms. Nixon (1988) noted that there is a broad continuum  
41 of primary productivity levels in different estuaries, which in turn affects fish  
42 production and abundance. Compared to other estuaries, pelagic primary  
43 productivity in the upper San Francisco Estuary is relatively poor, and a relatively  
44 low fish yield is expected (Wilkerson et al. 2006). In the Delta and Suisun Marsh,  
45 this appears to result from turbidity, clam grazing (Jassby et al. 2002), and

1 nitrogen and phosphorus dynamics (Wilkerson et al. 2006, Van Nieuwenhuysen  
2 2007, Glibert 2010, Glibert et al. 2014).

3 There has been a significant long-term decline in phytoplankton biomass  
4 (chlorophyll a) and primary productivity to low levels in the Suisun Bay region  
5 and the Delta (Jassby et al. 2002). Shifts in nutrient concentrations such as high  
6 levels of ammonium and nitrogen to phosphorus ratio may contribute to the  
7 phytoplankton reduction and to changes in algal species composition in the San  
8 Francisco Estuary (Wilkerson et al. 2006; Dugdale et al. 2007; Lehman et al.  
9 2005, 2008b, 2010; Glibert 2010; Glibert et al. 2014). Low and declining primary  
10 productivity in the estuary may be contributing to the long-term pattern of  
11 relatively low and declining biomass of pelagic fishes (Jassby et al. 2002).

12 The introductions of two clams from Asia have led to major alterations in the food  
13 web in the Delta. *Potamocorbula* is most abundant in the brackish and saline  
14 water of Suisun Bay and the western Delta, and *Corbicula* is most abundant in the  
15 fresh water of the central Delta. These filter feeders significantly reduce the  
16 phytoplankton and zooplankton concentrations in the water column, reducing  
17 food availability for native fishes, such as Delta Smelt and young Chinook  
18 Salmon (Feyrer et al. 2007, Kimmerer 2002).

19 Additionally, introduction of the clams led to the decline of higher-food-quality  
20 native copepods and the establishment of poorer quality nonnative copepods.  
21 More recently, the cyclopoid copepod, *Limnoithona*, has rapidly become the most  
22 abundant copepod in the Delta after its introduction in 1993 (Hennessy and  
23 Enderlein 2013). This species is hypothesized to be a low-quality food source and  
24 intraguild predator of native and nonnative calanoid copepods (CRA 2005). The  
25 clam *Potamocorbula* also has been implicated in the reduction of the native  
26 opossum shrimp, a preferred food of Delta native fishes such as Sacramento  
27 Splittail and Longfin Smelt (Feyrer et al. 2003). Reductions in food availability  
28 and food quality have led to lower fish foraging efficiency and reduced growth  
29 rates (Moyle 2002).

30 Studies on food quality have been relatively limited in the San Francisco Estuary,  
31 with even less information on long-term trends. Nonetheless, several studies have  
32 documented or suggested the food limitations for aquatic species in the estuary,  
33 including zooplankton (Mueller-Solger et al. 2002, Kimmerer et al. 2005), Delta  
34 Smelt (Bennett 2005, Bennett et al. 2008), Chinook Salmon (Sommer et al.  
35 2001a), Sacramento Splittail (Greenfield et al. 2008), Striped Bass  
36 (Loboschewsky et al. 2012), and Largemouth Bass (Nobriga 2009).

#### 37 **9.3.4.12.4 Turbidity**

38 Turbidity is an important water quality component in the Delta that affects  
39 physical habitat through sedimentation and food web dynamics through  
40 attenuation of light in the water column. Light attenuation, in turn, affects the  
41 extent of the photic zone where primary production can occur and the ability of  
42 predators to locate prey and for prey to escape predation.

1 Turbidity has been declining in the Delta, as indicated by sediment data collected  
2 by the U.S. Geological Survey since the 1950s (Wright and Schoellhamer 2004),  
3 with important implications for food web dynamics and predation. Higher water  
4 clarity is at least partially caused by increased water filtration and plankton  
5 grazing by highly abundant overbite clams (*Potamocorbula amurensis*) and other  
6 benthic organisms (Kimmerer 2004, Greene et al. 2011). High nutrient loads,  
7 coupled with reduced sediment loads and higher water clarity, could contribute to  
8 plankton and algal blooms and overall increased eutrophic conditions in some  
9 areas (Kimmerer 2004).

10 The first high-flow events of winter create turbid conditions in the Delta, which  
11 can be drawn into the south Delta during reverse flow conditions in the Old and  
12 Middle rivers. Delta Smelt may follow turbid waters into the southern Delta,  
13 increasing their proximity to project export facilities and, therefore, their  
14 entrainment risk (USFWS 2008a).

#### 15 **9.3.4.12.5 Contaminants**

16 Contaminants can change ecosystem functions and productivity through  
17 numerous pathways. Trends in contaminant loadings and their ecosystem effects  
18 are not well understood. Efforts are underway to evaluate direct and indirect toxic  
19 effects on the POD fishes of manmade contaminants and natural toxins associated  
20 with blooms of *Microcystis aeruginosa*, a cyanobacterium or blue-green alga that  
21 releases a potent toxin known as microcystin. Toxic microcystins cause food web  
22 impacts at multiple trophic levels, and histopathological studies of fish liver tissue  
23 suggest that fish exposed to elevated concentrations of microcystins have  
24 developed liver damage and tumors (Lehman et al. 2005, 2008b, 2010.)

25 There are longstanding concerns related to mercury and selenium in the  
26 Sacramento and San Joaquin watersheds, the Delta, and San Francisco Bay (see  
27 Chapter 6, Surface Water Quality, for additional detail on these constituents).  
28 Additional study is needed to avoid increases in mercury exposure resulting from  
29 tidal wetlands restoration; methylmercury is produced at a relatively high rate in  
30 wetlands and newly flooded aquatic habitats (Davis et al. 2003). Methylmercury  
31 increases in concentration at each level in the food chain and can cause concern  
32 for people and birds that eat piscivorous fish (bass) and sturgeon, as described in  
33 Chapter 6, Surface Water Quality. It has not been shown to be a direct problem  
34 for fish in the Delta, but studies of other fish summarized by Alpers et al. (2008)  
35 indicate that mercury in fish has been linked to hormonal and reproductive  
36 effects, liver necrosis, and altered behavior in fish. With regard to selenium,  
37 benthic foragers like diving ducks, sturgeon, and splittail have the greatest risk of  
38 selenium toxicity; the invasion of the nonnative bivalves (e.g., *P. amurensis*) has  
39 resulted in increased bioavailability of selenium to benthivores in San Francisco  
40 Bay (Linville et al. 2002).

41 Baxter et al. (2008) prepared a 2007 synthesis of results as part of a POD Progress  
42 Report, including a summary of prior studies of contaminants in the Delta. The  
43 summary included studies that suggested that phytoplankton growth rates may be  
44 inhibited by localized high concentrations of herbicides (Edmunds et al. 1999).

1 Toxicity to invertebrates has been noted in water and sediments from the Delta  
2 and associated watersheds (Kuivila and Foe 1995, Weston et al. 2004). The 2004  
3 Weston study of sediment toxicity recommended additional study of the effects of  
4 the pyrethroid insecticides on benthic organisms. Undiluted drainwater from  
5 agricultural drains in the San Joaquin River watershed can be acutely toxic  
6 (quickly lethal) to fish (Chinook Salmon and Striped Bass) and have chronic  
7 effects on growth, likely because of high concentrations of major ions  
8 (e.g., sodium and sulfates) and trace elements (e.g., chromium, mercury, and  
9 selenium) (Saiki et al. 1992).

#### 10 **9.3.4.12.6 Fish Passage and Entrainment**

11 The Delta presents a challenge for anadromous and resident fish during upstream  
12 and downstream migration, with its complex network of channels, low eastern  
13 and southern tributary inflows, and reverse currents created by pumping for water  
14 exports. These complex conditions can lead to straying, extended exposure to  
15 predators, and entrainment during outmigration. Tidal elevations, salinity,  
16 turbidity, in-flow, meteorological conditions, season, habitat conditions, and  
17 project exports all have the potential to influence fish movement, currents, and  
18 ultimately the level of entrainment and fish passage success and survival, which is  
19 the subject of extensive research and adaptive management efforts (IRP 2010,  
20 2011). Michel et al. (2010, 2015) used acoustic telemetry to examine survival of  
21 late fall-run Chinook Salmon smolts outmigrating from the Sacramento River  
22 through the Delta and San Francisco Estuary. Survival was lowest in the  
23 freshwater portion (Delta) and the brackish portion of the estuary relative to  
24 survival in the riverine portion of the migration route.

#### 25 *North Delta Fish Passage and Entrainment*

26 In the north Delta, migrating fish have multiple potential pathways as they move  
27 upstream into the Sacramento or Mokelumne river systems. Marston et al. (2012)  
28 studied stray rates for in-migrating San Joaquin River Basin adult salmon that  
29 stray into the Sacramento River Basin. Results indicated that it was unclear  
30 whether reduced San Joaquin River pulse flows or elevated exports caused  
31 increased stray rates. The DCC, when open, can divert fish as they outmigrate  
32 along this route. The opening of the DCC when salmon are returning to spawn to  
33 the Mokelumne and Cosumnes rivers is believed to lead to increased straying of  
34 these fish into the American and Sacramento rivers because of confusion over  
35 olfactory cues. In recent years, experimental DCC closures have been scheduled  
36 during the fall-run Chinook Salmon migration season for selected days, coupled  
37 with pulsed flow releases from reservoirs on the Mokelumne River, in an attempt  
38 to reduce straying rates of returning adults. These closures have corresponded  
39 with reduced recoveries of Mokelumne River hatchery fish in the American River  
40 system and increased returns to the Mokelumne River hatchery (EBMUD 2012).

41 Outmigrating juvenile fish moving down the mainstem Sacramento River also can  
42 enter the DCC when the gates are open and travel through the Delta via the  
43 Mokelumne and San Joaquin river channels. In the case of juvenile salmonids,  
44 this shifted route from the north Delta to the central Delta increases their mortality

1 rate (Kjelson and Brandes 1989, Brandes and McLain 2001, Newman and  
2 Brandes 2010, Perry et al. 2010, 2012). Steel et al. (2012) found that the best  
3 predictor of which route was selected was the ratio of mean water velocity  
4 between the two routes. Salmon migration studies show losses of approximately  
5 65 percent for groups of outmigrating fish that are diverted from the mainstem  
6 Sacramento River into the waterways of the central and southern Delta (Brandes  
7 and McLain 2001; Vogel 2004, 2008; Perry and Skalski 2008). Perry and Skalski  
8 (2008) found that, by closing the DCC gates, total through-Delta survival of  
9 marked fish to Chipps Island increased by nearly 50 percent for fish moving  
10 downstream in the Sacramento River system. Closing the DCC gates appears to  
11 redirect the migratory path of outmigrating fish into Sutter and Steamboat sloughs  
12 and away from Georgiana Slough, resulting in higher survival rates. Species that  
13 may be affected include juvenile Green Sturgeon, steelhead, and winter and  
14 spring-run Chinook Salmon (NMFS 2009a).

15 However, analysis by Perry et al. (2015) suggests that the mechanisms governing  
16 route selection are more complex. Their analysis revealed the strong influence of  
17 tidal forcing on the probability of fish entrainment into the interior Delta. The  
18 probability of entrainment into both Georgiana Slough and the Delta Cross  
19 Channel was highest during reverse-flow flood tides, and the probability of fish  
20 remaining in the Sacramento River was near zero during flow reversals (Perry  
21 et al. 2015). The magnitude and duration of reverse flows at this river junction  
22 decrease as inflow of the Sacramento River increases. Consequently, reduced  
23 Sacramento River inflow increases the frequency of reverse flows at this junction,  
24 thereby increasing the proportion of fish that are entrained into the interior Delta,  
25 where mortality is high (Perry 2010).

26 Fish passage in the north Delta also can be affected by water quality. Water  
27 quality in the mainstem Sacramento River and its distributary sloughs can be poor  
28 at times during summer, creating conditions that may stress migrating fish or even  
29 impede migration. These conditions include dissolved oxygen, water  
30 temperatures, and, for some species, salinity (e.g., Delta Smelt). For adult  
31 Chinook Salmon, dissolved oxygen concentration less than 3 to 5 milligrams per  
32 liter (mg/L) can impede migration (Hallock et al. 1970) as can mean daily water  
33 temperatures of 21 to 23°C, depending on whether water temperatures are rising  
34 or falling (Strange 2010). Dissolved oxygen levels are generally >5 mg/L  
35 throughout the Delta, but water temperatures can exceed these thresholds during  
36 summer and fall.

37 The SWP Barker Slough Pumping Plant, located on a tributary to Cache Slough,  
38 may cause larval fish entrainment. The intake is equipped with a positive barrier  
39 fish screen to prevent fish at least 25 mm in size from being entrained. CDFW  
40 has monitored entrainment of larval Delta Smelt less than 20 mm at Barker  
41 Slough since 1995. When the presence of Delta Smelt larvae is indicated,  
42 pumping rates from Barker Slough are reduced to a 5-day running average rate of  
43 65 cfs, not to exceed a 75-cfs daily average for any day, for a minimum of 5 days  
44 and until monitoring shows no Delta Smelt are present.

1 *Central and South Delta Fish Passage and Entrainment*

2 The south Delta intake facilities include the CVP and SWP export facilities; local  
3 agency intakes, including Contra Costa Water District intakes; and agricultural  
4 intakes. Contra Costa Water District intakes and the CVP Contra Costa Canal  
5 Pumping Plant include fish screens; however, most of the remaining intakes do  
6 not include fish screens. Water flow patterns in the south Delta are influenced by  
7 the water diversion actions and operations of the south Delta seasonal temporary  
8 barriers and tides and river inflows to the Delta (Kimmerer and Nobriga 2008).  
9 Delta diversions can create reverse flows, drawing fish toward project facilities  
10 (Arthur et al. 1996, Kimmerer 2008, Grimaldo et al. 2009). While swimming  
11 through southern Delta channels, fish can be subjected to stress from poor water  
12 quality (seasonally high temperatures, low dissolved oxygen, high water  
13 transparency, and *Microcystis* blooms) and slow water velocities in lake-like  
14 habitats. Any of these factors can cause elevated mortality rates by weakening or  
15 disorienting the fish and increasing their vulnerability to predators (Vogel 2011).

16 Cunningham et al. (2015) found a negative influence of the export/inflow ratio on  
17 the survival of fall-run Chinook populations and a negative influence of increased  
18 total Delta exports on the survival of spring-run Chinook populations. An  
19 increase in total exports of 1 standard deviation (SD) from the 1967 to 2010  
20 average was predicted to result in a 68.1 percent reduction in the survival of Deer,  
21 Mill, and Butte Creek spring-run Chinook. Similarly, an increase in the ratio of  
22 Delta water exports to Delta inflow of 1 SD was expected to reduce survival of  
23 the four fall-run populations by 57.8 percent (Cunningham et al. 2015). Although  
24 a mechanistic explanation for the reduction in survival remains elusive, "*direct*  
25 *entrainment mortality seems an unlikely mechanism given the success of*  
26 *reclamation and transport procedures, even given increased predation potential*  
27 *at the release site. Changes to water routing may provide a more reasonable*  
28 *explanation for the estimated survival influence of Delta water exports"*  
29 (Cunningham et al. 2015). Although not directly comparable, this contrasts with  
30 the results of Zeug and Cavallo (2012) that found there was little evidence that  
31 large-scale water exports or inflows influenced CWT recovery rates in the ocean  
32 from 1993 to 2003.

33 Delaney et al. (2014) reported on a mark-recapture experiment examining the  
34 survival and movement patterns of acoustically tagged juvenile steelhead  
35 emigrating through the central and southern Delta. Their results indicated that  
36 most tagged steelhead remained in the mainstem San Joaquin River  
37 (77.6 percent); however, approximately one quarter (22.4 percent) of them  
38 entered Turner Cut. Route-specific survival probability for tagged steelhead  
39 using the Turner Cut route was 27.0 percent. The survival probability for tagged  
40 steelhead using the Mainstem route was 56.7 percent (Delaney et al. 2014).  
41 Travel times for tagged steelhead also differed between these two routes with  
42 steelhead using the mainstem route reaching Chipps Island significantly sooner  
43 than those that used the Turner Cut route. Travel time was not significantly  
44 affected by the limited OMR flow treatments examined in their study. While not  
45 significant, there was some evidence that fish movement toward each export

1 facility could be influenced by relative flow entering the export facility (Delaney  
2 et al. 2014).

3 Water from the San Joaquin River mainly moves downstream through the Head of  
4 Old River and through the channels of Old and Middle rivers and Grant Line and  
5 Fabian-Bell canals toward the south Delta intake facilities. Conversely, when  
6 water to the north of the diversion points for the two facilities moves southward  
7 (upstream), the net flow is negative (toward) the pumps. When the temporary  
8 barriers are installed from April through November, internal reverse circulation is  
9 created within the channels isolated by the barriers from other portions of the  
10 south Delta. These conditions are most pronounced during late spring through  
11 fall when San Joaquin River inflows are low and water diversion rates are  
12 typically high. Drier hydrologic years also reduce the frequency of net  
13 downstream flows in the south Delta and mainstem San Joaquin River.

14 A portion of fish that enter the CVP Jones Pumping Plant approach channel and  
15 the SWP Clifton Court Forebay are salvaged at screening and fish salvage  
16 facilities, transported downstream by trucks, and released. NMFS (2009a)  
17 estimates that the direct loss of fish from the screening and salvage process is in  
18 the range of 65 to 83.5 percent for fish from the point they enter Clifton Court  
19 Forebay or encounter the trash racks at the CVP facilities. Additionally, mark-  
20 recapture experiments indicate that most fish are probably subject to predation  
21 prior to reaching the fish salvage facilities (e.g., in Clifton Court Forebay)  
22 (Gingras 1997, Clark et al. 2009, Castillo et al. 2012). Aquatic organisms  
23 (e.g., phytoplankton and zooplankton) that serve as food for fish also are  
24 entrained and removed from the Delta (Jassby et al. 2002, Kimmerer et al. 2008,  
25 Brown et al. 1996). Fish entrainment and salvage are particular concerns during  
26 dry years when the distributions of young Striped Bass, Delta Smelt, Longfin  
27 Smelt, and other migratory fish species shift closer to the project facilities  
28 (Stevens et al. 1985, Sommer et al. 1997).

29 Salvage estimates reflect the number of fish entrained by project exports, but  
30 these numbers alone do not account for other sources of mortality related to the  
31 export facilities. These numbers do not include prescreen losses that occur in the  
32 waterways leading to the diversion facilities, which may in some cases reduce the  
33 number of salvageable fish (Gingras 1997, Clark et al. 2009, Castillo et al. 2012).  
34 For Delta Smelt, prescreen losses appear to be where most mortality occurs  
35 (Castillo et al. 2012). In addition, actual salvage numbers do not include the  
36 entrainment of fish larvae, which cannot be collected by the fish screens. The  
37 number of fish salvaged also does not include losses of fish that pass through the  
38 louvers intended to guide fish into the fish collection facilities or the losses during  
39 collection, handling, transport, and release back into the Delta.

40 The life stage of the fish at which entrainment occurs may be important for  
41 population dynamics (IRP 2011). For example, winter entrainment of Delta  
42 Smelt, Longfin Smelt, and Threadfin Shad may correspond to migration and  
43 spawning of adult fish, and spring and summer exports may overlap with  
44 development of larvae and juveniles. The loss of prespawning adults and all their  
45 potential progeny may have greater consequences than entrainment of the same

1 number of larvae or juvenile fish. Entrainment risk for fish tends to increase with  
2 increased reverse flows in Old and Middle rivers (Kimmerer 2008, Grimaldo  
3 et al. 2009).

4 Research conducted during 2010 and 2011 showed that upriver movements of  
5 adult Delta Smelt are achieved through a form of tidal rectification or active tidal  
6 transport by using lateral movement to shallow edges of channels on ebb tides to  
7 maintain their position (IRP 2010, 2011). Turbidity gradients could be involved  
8 in the lateral positioning of Delta Smelt within the channels, but large-scale  
9 turbidity pulses through the system may not be necessary to trigger upriver  
10 migrations of Delta Smelt if they are already occupying sufficiently turbid water  
11 (IRP 2011). The new understanding of potential tidal and turbidity effects on  
12 Delta Smelt behavior may have important implications for the Delta Smelt  
13 monitoring programs that are the basis for biological triggers for RPA Actions  
14 1 and 2 by understanding the catch efficiency of mid-water trawl data in relation  
15 to the lateral positioning of Delta Smelt within channels.

16 There are more than 2,200 diversions in the Delta (Herren and Kawasaki 2001).  
17 These irrigation diversion pipes are shore-based, typically small (30 to  
18 60 centimeter pipe diameter), and operated via pumps or gravity flow, and most  
19 lack fish screens. These diversions increase total fish entrainment and losses and  
20 alter local fish movement patterns (Kimmerer and Nobriga 2008). Delta Smelt  
21 have been found in samples of Delta irrigation diversions, as well as larger  
22 wetland management diversions downstream. However, Nobriga et al. (2004)  
23 found that the low and inconsistent entrainment of Delta Smelt measured in the  
24 study reflected habitat use by Delta Smelt and relatively small hydrodynamic  
25 influence of the diversion.

#### 26 **9.3.4.12.7 Disease**

27 Preliminary results of several histopathological studies have found evidence of  
28 significant disease in Delta fish species (Reclamation 2008a). For example,  
29 massive intestinal infections with an unidentified myxosporean were found in  
30 yellowfin goby collected from Suisun Marsh (Baxa et al. 2013). Studies by  
31 Bennett (2005) and Bennett et al. (2008) show that exposure to toxic chemicals  
32 may cause liver abnormalities and cancerous cells in Delta Smelt, and stressful  
33 summer conditions, warm water, and lack of food may result in liver glycogen  
34 depletion and liver damage. Studies of Sacramento Splittail suggest that liver  
35 abnormalities in this species are more linked to health and nutritional status than  
36 to pollutant exposure (Greenfield et al. 2008).

37 Additionally, preliminary evidence suggests that contaminants and disease may  
38 impair Striped Bass. Studies by Lehman et al. (2010) suggest that the liver tissue  
39 and health of Striped Bass and Mississippi Silverside were adversely affected by  
40 tumors, particularly at sampling stations where concentrations of tumor-  
41 promoting microcystins were elevated. Exposure of Sacramento Splittail and  
42 Threadfin Shad to microcystins in experimental diets resulted in severe liver  
43 damage; shad also exhibited ovarian necrosis, indicating impairment of health and  
44 reproductive potential (Acuna et al. 2012).

1 In contrast, histopathological and viral evaluation of juvenile Longfin Smelt and  
2 Threadfin Shad collected in 2006 indicated no histological abnormalities and no  
3 evidence of viral infections or high parasite loads (Foott et al. 2006). Parasites  
4 were noted in Threadfin Shad gills at a high frequency, but the infections were not  
5 considered severe. Thus, both Longfin Smelt and Threadfin Shad were  
6 considered healthy in 2006 (a high-flow year). Adult Delta Smelt collected from  
7 the Delta during winter 2005 also were considered healthy, showing little  
8 histopathological evidence for starvation or disease (Reclamation 2008a).  
9 However, there was some evidence of low frequency endocrine disruption. In  
10 2005, 9 of 144 (6 percent) of adult Delta Smelt males were intersex, having  
11 immature oocytes in their testes (Reclamation 2008a).

#### 12 **9.3.4.12.8 Nonnative Invasive Species**

13 Nonnative invasive species influence the Delta ecosystem by increasing  
14 competition and predation on native species, reducing habitat quality (as result of  
15 invasive aquatic macrophyte growth), and reducing food supplies by altering the  
16 aquatic food web. Not all nonnative species are considered invasive<sup>2</sup>. Some  
17 introduced species have minimal ability to spread or increase in abundance.  
18 Others have commercial or recreational value (e.g., Striped Bass, American Shad,  
19 and Largemouth Bass).

20 Many nonnative fishes have been introduced into the Delta for sport fishing  
21 (game fish such as Striped Bass, Largemouth Bass, Smallmouth Bass, Bluegill,  
22 and other sunfish), as forage for game fish (Threadfin Shad, Golden Shiner, and  
23 Fathead Minnow), for vector control (Inland Silverside, Western Mosquitofish),  
24 for human food use (Common Carp, Brown Bullhead, and White Catfish), and  
25 from accidental releases (Yellowfin Goby, Shimofuri Goby, and Shokihaze Goby)  
26 (Moyle 2002). Introduced fish may compete with native fish for resources and, in  
27 some cases, prey on native species.

28 Because of invasive species and other environmental stressors, native fishes have  
29 declined in abundance throughout the region during the period of monitoring  
30 (Matern et al. 2002, Brown and Michniuk 2007, Sommer et al. 2007a,  
31 Mount et al. 2012). Habitat degradation, changes in hydrology and water quality,  
32 and stabilization of natural environmental variability are all factors that generally  
33 favor nonnative, invasive species (Mount et al. 2012, Moyle et al. 2012).

#### 34 **9.3.4.12.9 Predation**

35 Predation is an important factor that influences the behavior, distribution, and  
36 abundance of prey species in aquatic communities to varying degrees. Predation  
37 can have differing effects on a population of fish depending on the size or age  
38 selectivity, mode of capture, mortality rates, and other factors. Predation is a part  
39 of every food web, and native Delta fishes were part of the historical Delta food  
40 web. Because of the magnitude of change in the Delta from historical times and

---

<sup>2</sup> DFG (2008) defines "invasive species" as "species that establish and reproduce rapidly outside of their native range and may threaten the diversity or abundance of native species through competition for resources, predation, parasitism, hybridization with native populations, introduction of pathogens, or physical or chemical alteration of the invaded habitat."

1 the introduction of nonnative predators, it is logical to conclude that predation  
2 may have increased in importance as a mortality factor for Delta fishes, with some  
3 observers suggesting that it is likely the primary source of mortality for juvenile  
4 salmonids in the Delta (Vogel 2011). Predation occurs by fish, birds, and  
5 mammals, including sea lions. The alternatives considered in this EIS are not  
6 anticipated to modify predatory actions of birds and mammals on the focal  
7 species. Therefore, the predation discussion is focused on fish predators.

8 A panel of experts recently convened to review data on predation in the Delta and  
9 draw preliminary conclusions on the effects of predation on salmonids. The panel  
10 acknowledged that the system supports large populations of fish predators that  
11 consume juvenile salmonids (Grossman et al. 2013). However, the panel  
12 concluded that because of extensive flow modification, altered habitat conditions,  
13 native and nonnative fish and avian predators, temperature and dissolved oxygen  
14 limitations, and the overall reduction in salmon population size, it was unclear  
15 what proportion of the juvenile salmonid mortality could be attributed to  
16 predation. The panel further indicated that predation, while the proximate cause  
17 of mortality, may be influenced by a combination of other stressors that make fish  
18 more vulnerable to predation.

19 Striped Bass, White Catfish, Largemouth Bass and other centrarchids, and  
20 silversides are among the introduced, nonnative species that are notable predators  
21 of smaller-bodied fish species and juveniles of larger species in the Delta. Along  
22 with Largemouth Bass, Striped Bass are believed to be major predators on larger-  
23 bodied fish in the Delta. In open-water habitats, Striped Bass are most likely the  
24 primary predator of juvenile and adult Delta Smelt (DWR et al. 2013) and can be  
25 an important open-water predator on juvenile salmonids (Johnston and Kumagai  
26 2012). Native Sacramento Pikeminnow may also prey on juvenile salmonids and  
27 other fishes. Limited sampling of smaller pikeminnows did not find evidence of  
28 salmonids in the foregut of Sacramento Pikeminnow (Nobriga and Feyrer 2007),  
29 but this does not mean that Sacramento Pikeminnow do not prey on salmonids in  
30 the Delta.

31 Largemouth Bass abundance has increased in the Delta over the past few decades  
32 (Brown and Michniuk 2007). Although Largemouth Bass are not pelagic, their  
33 presence at the boundary between the littoral and pelagic zones makes it probable  
34 that they opportunistically consume pelagic fishes. The increase in salvage of  
35 Largemouth Bass occurred during the time period when Brazilian waterweed was  
36 expanding its range in the Delta (Brown and Michniuk 2007). The beds of  
37 Brazilian waterweed provide good habitat for Largemouth Bass and other species  
38 of centrarchids. Largemouth Bass have a much more limited distribution in the  
39 estuary than Striped Bass, but a higher per-capita impact on small fishes (Nobriga  
40 and Feyrer 2007). Increases in Largemouth Bass may have had a particularly  
41 important effect on Threadfin Shad and Striped Bass, whose earlier life stages  
42 occur in littoral habitat (Grimaldo et al. 2004, Nobriga and Feyrer 2007).

43 Invasive Mississippi silversides are another potentially important predator of  
44 larval and pelagic fishes in the Delta. This introduced species was not believed to  
45 be an important predator on Delta Smelt, but recent studies using DNA techniques

1 detected the presence of Delta Smelt in the guts of 41 percent of Mississippi  
2 silversides sampled in mid-channel trawls (Baerwald et al. 2012). This finding  
3 may suggest that predation impacts could be significant, given the increasing  
4 numbers of Mississippi silversides in the Delta.

5 Predation of fish in the Delta is known to occur in specific areas, for example at  
6 channel junctions and areas that constrict flow or confuse migrating fish and  
7 provide cover for predatory fish (Vogel 2011). Sabal (2014) found similar results  
8 at Woodbridge Dam on the Mokelumne River where the dam was associated with  
9 increased Striped Bass per capita salmon consumption and attracted larger  
10 numbers of Striped Bass, decreasing migrating juvenile salmon survival by 10 to  
11 29 percent. DFG (1992) identified subadult Striped Bass as the major predatory  
12 fish in Clifton Court Forebay. In 1993, for example, Striped Bass made up  
13 96 percent of the predators removed (Vogel 2011). Cavallo et al. (2012) studied  
14 tagged salmon smolts to test the effects of predator removal on outmigrating  
15 juvenile Chinook Salmon in the south Delta. Their results suggested that predator  
16 abundance and migration rates strongly influenced survival of salmon smolts.  
17 Exposure time to predators has been found to be important for influencing  
18 survival of outmigrating salmon in other studies in the Delta (Perry et al. 2012).

#### 19 **9.3.4.12.10 Aquatic Macrophytes**

20 Aquatic macrophytes are an important component of the biotic community of  
21 Delta wetlands and can provide habitat for aquatic species, serve as food, produce  
22 detritus, and influence water quality through nutrient cycling and dissolved  
23 oxygen fluctuations. Whipple et al. (2012) described likely historical conditions  
24 in the Delta, which have been modified extensively, with major impacts on the  
25 aquatic macrophyte community composition and distribution. The primary  
26 change has been a shift from a high percentage of emergent aquatic macrophyte  
27 wetlands to open water and hardened channels.

28 The introduction of two nonnative invasive aquatic plants, water hyacinth and  
29 Brazilian waterweed, has reduced habitat quantity and value for many native  
30 fishes. Water hyacinth forms floating mats that greatly reduce light penetration  
31 into the water column, which can significantly reduce primary productivity and  
32 available food for fish in the underlying water column. Brazilian waterweed  
33 grows along the margins of channels in dense stands that prohibit access by native  
34 juvenile fish to shallow water habitat. Additionally, the thick cover of these two  
35 invasive plants provides excellent habitat for nonnative ambush predators, such as  
36 bass, which prey on native fish species. Studies indicate low abundance of native  
37 fish, such as Delta Smelt, Chinook Salmon, and Sacramento Splittail, in areas of  
38 the Delta where submerged aquatic vegetation infestations are thick (Grimaldo  
39 et al. 2004, 2012; Nobriga et al. 2005).

40 Invasive aquatic macrophytes are still equilibrating within the Delta and resulting  
41 habitat changes are ongoing, with negative impacts on habitats and food webs of  
42 native fish species (Toft et al. 2003, Grimaldo et al. 2009). Concerns about  
43 invasive aquatic macrophytes are centered on their ability to form large, dense

1 growth that can clog waterways, block fish passage, increase water clarity,  
2 provide cover for predatory fish, and cause high biological oxygen demand.

3 **9.3.4.13 Yolo Bypass**

4 The Yolo Bypass conveys flood flows from the Sacramento Valley, including the  
5 Sacramento River, Feather River, American River, Sutter Bypass, and west side  
6 streams

7 The Yolo Bypass provides habitat for a wide variety of fish and aquatic species,  
8 including temporary migration corridors and juvenile rearing habitat for  
9 anadromous salmonids and other native and anadromous fishes. Species captured  
10 as adults and subsequently collected as YOY suggest that the Yolo Bypass  
11 provides spawning habitat for these species, including splittail, American Shad,  
12 Striped Bass, Threadfin Shad, Largemouth Bass and carp (Harrell and Sommer  
13 2003, Sommer et al. 2014). The Yolo Bypass lacks suitable gravel substrate that  
14 would support salmon spawning.

15 **9.3.4.13.1 Aquatic Habitat**

16 Aquatic habitats in the Yolo Basin include stream and slough channels for fish  
17 migration, and when flooded, seasonal spawning habitat and productive rearing  
18 habitat (Sommer et al. 2001a; CALFED 2000a, 2000b). During years when the  
19 Yolo Bypass is flooded, it serves as an important migratory route for juvenile  
20 Chinook Salmon and other native migratory and anadromous fishes moving  
21 downstream. During these times, it provides juvenile anadromous salmonids an  
22 alternative migration corridor to the lower Sacramento River (Sommer et al.  
23 2003) and, sometimes, better rearing conditions than the adjacent Sacramento  
24 River channel (Sommer et al. 2001a, 2005). When the floodplain is activated,  
25 juvenile salmon can rear for weeks to months in the Yolo Bypass floodplain  
26 before migrating to the estuary (Sommer et al. 2001a). Research on the Yolo  
27 Bypass has found that juvenile salmon grow substantially faster in the Yolo  
28 Bypass floodplain than in the adjacent Sacramento River, primarily because of  
29 greater availability of invertebrate prey in the floodplain (Sommer et al. 2001a,  
30 2005). When not flooded, the lower Yolo Bypass provides tidal habitat for young  
31 fish that enter from the lower Sacramento River via Cache Slough Complex  
32 (McLain and Castillo; DWR, unpublished data).

33 Sommer et al. (1997) demonstrated that the Yolo Bypass is one of the single most  
34 important habitats for Sacramento Splittail. Because the Yolo Bypass is dry  
35 during summer and fall, nonnative species (e.g., predatory fishes) generally are  
36 not present year-round except in perennial water sources (Sommer et al. 2003). In  
37 addition to providing important fish habitat, seasonal inundation of the Yolo  
38 Bypass supplies phytoplankton and detritus that may benefit aquatic organisms  
39 downstream in the brackish portion of the San Francisco Estuary (Sommer et al.  
40 2004, Lehman et al. 2008a).

#### 1 **9.3.4.13.2 Fish Passage**

2 The Fremont Weir is a major impediment to fish passage and a source of  
3 migratory delay and loss of adult Chinook Salmon, steelhead, and sturgeon  
4 (NMFS 2009a, Sommer et al. 2014). The Fremont Weir creates a migration  
5 barrier for a variety of species, although fish with strong jumping capabilities  
6 such as salmonids may be able to pass the weir at higher flows. Although there is  
7 a fish ladder maintained by CDFW at the center of the weir, the ladder is small,  
8 outdated, and inefficient. Additionally, there are no facilities at the weir to pass  
9 upstream migrants at lower flows. Some adult winter-run, spring-run, and fall-run  
10 Chinook Salmon and White Sturgeon migrate into Yolo Bypass when there is no  
11 flow into the floodplain via the Fremont Weir. Therefore, these fish are often  
12 unable to reach upstream spawning habitat in the Sacramento River and its  
13 tributaries (Harrell and Sommer 2003, Sommer et al. 2014). Other structures in  
14 the Yolo Bypass, such as the Toe Drain, Lisbon Weir, and irrigation dams in the  
15 northern end of the Tule Canal, also may impede upstream passage of adult  
16 anadromous fish (NMFS 2009a).

17 Fish are also attracted into the bypass during periods when water is not flowing  
18 over the Fremont Weir. Fyke trap monitoring by DWR has shown that adult  
19 salmon and steelhead migrate up the Toe Drain in autumn and winter regardless  
20 of whether the Fremont Weir spills (Harrell and Sommer 2003, Sommer et al.  
21 2014). The Toe Drain does not extend to the Fremont Weir because the channel  
22 is blocked by roads or other higher ground at several locations. Sturgeon and  
23 salmonids attracted by high flows into the basin become concentrated behind the  
24 Fremont Weir, where they are subject to heavy legal and illegal fishing pressure.

25 Stranding of juvenile salmonids and sturgeon has been reported in the Yolo  
26 Bypass in scoured areas behind the weir and in other areas as floodwaters recede  
27 (NMFS 2009a, Sommer et al. 2005). However, Sommer et al. (2005) found most  
28 juvenile salmon outmigrated off the floodplain as it drained.

#### 29 **9.3.4.14 Suisun Marsh**

30 Suisun Bay and Marsh are ecologically linked with the central Delta, although  
31 with different tidal and salinity conditions than found upstream. Suisun Bay and  
32 Marsh are the largest expanse of remaining tidal marsh habitat within the greater  
33 San Francisco Bay-Delta ecosystem and include Honker, Suisun, and Grizzly  
34 bays; Montezuma and Suisun sloughs; and numerous other smaller channels  
35 and sloughs.

#### 36 **9.3.4.14.1 Aquatic Habitat**

37 Suisun Marsh is a brackish-water marsh bordering the northern edge of Suisun  
38 Bay. Most of its marsh area consists of diked wetlands managed for waterfowl,  
39 with the rest of the acreage consisting of tidally influenced sloughs (Suisun  
40 Ecological Workgroup 2001). The central latitudinal location of Suisun Marsh  
41 within the San Francisco Estuary makes it an important rearing area for  
42 euryhaline freshwater, estuarine, and marine fishes. Many fish species that  
43 migrate or use Delta habitats also are found in the waters of Suisun Bay.

1 Tides reach Suisun Bay and Marsh through the Carquinez Strait, and most  
2 freshwater flows enter at the southeast border of Suisun Marsh at the confluence  
3 of the Sacramento and San Joaquin rivers. The mixing of freshwater outflows  
4 from the Central Valley with saline tidal water in Suisun Bay and Suisun Marsh  
5 results in brackish water with strong salinity gradients, complex patterns of flow  
6 interactions, and generally the highest biomass productivity in the entire estuary  
7 (Siegel et al. 2010).

8 Although the fish assemblages in Suisun Bay and Marsh can differ substantially  
9 from the fish assemblages in the Delta, all the species that use the Delta also use  
10 Suisun Bay and Marsh.

11 Flow, turbidity, and salinity are important factors influencing the location and  
12 abundance of zooplankton and small prey organisms used by Delta species  
13 (Kimmerer et al. 1998). The location where net current flowing inland along the  
14 bottom reverses direction and sinking particles are trapped in suspension is  
15 associated with higher turbidity known as the estuarine turbidity maximum.  
16 Burau et al. (2000) reports that the estuarine turbidity maximum occurs near the  
17 Benicia Bridge and in Suisun Bay near Garnet Point on Ryer Island.  
18 Zooplanktonic organisms maintain position in this region of historically high  
19 productivity in the estuary through vertical movements (Kimmerer et al. 1998).

20 Salinity in the Suisun Bay and Marsh system is a major water quality  
21 characteristic that strongly influences physical and ecological processes. Fish  
22 species native to Suisun Marsh require low salinities during the spawning and  
23 rearing periods (Suisun Ecological Workgroup 2001; Kimmerer 2004;  
24 Feyrer et al. 2007, 2010; Nobriga et al. 2008). The Suisun Bay and Marsh usually  
25 contain both the maximum estuarine salinity gradient and the low salinity zone.  
26 The overall estuarine salinity gradient trends from west (higher) to east (lower) in  
27 Suisun Bay and Marsh. The location of the low salinity zone gradient and X2 can  
28 be influenced by outflow. Suisun Marsh also exhibits a persistent north-south  
29 salinity gradient. Despite low and seasonal flows, the surrounding watersheds  
30 have a significant water freshening effect because of the long residence times of  
31 freshwater discharges from the upper sloughs and wastewater effluent.

32 The Suisun Bay and Marsh system contains a wide variety of habitats such as  
33 marsh plains, tidal creeks, sloughs, channels, cuts, mudflats, and bays. These  
34 features and the complex hydrodynamics and water quality of the system have  
35 historically fostered significant biodiversity within Suisun tidal aquatic habitats,  
36 but, like the Delta, these habitats also have been significantly altered and  
37 degraded by human activities over the decades.

38 Categories of tidal aquatic habitat were identified as part of the Suisun Marsh  
39 Plan development process and were defined using physical boundaries; habitats  
40 include bays, major sloughs, minor sloughs, and the intertidal mudflats in those  
41 areas (Engle et al. 2010). These tidal habitats total approximately 26,000 acres,  
42 with the various embayments totaling about 22,350 acres. Tidal slough habitat is  
43 composed of major and minor sloughs, with major sloughs of Suisun Marsh  
44 having a combined acreage of about 2,200 acres consisting of both shallow and

1 deep channels. Minor sloughs are made up of shallow channel habitat and have a  
 2 combined acreage of about 1,100 acres. Habitats in Suisun Marsh bays and  
 3 sloughs support a diverse assemblage of aquatic species that typically use  
 4 open-water tidal areas for breeding, foraging, rearing, or migrating.

#### 5 **9.3.4.14.2 Fish Entrainment**

6 Several facilities have been constructed by DWR and Reclamation to provide  
 7 lower-salinity water to managed wetlands in the Suisun Marsh, including the  
 8 Roaring River Distribution System, Morrow Island Distribution System, and  
 9 Goodyear Slough Outfall. Other facilities constructed under the Suisun Marsh  
 10 Preservation Agreement that could entrain fish include the Lower Joice Island and  
 11 Cygnus Drain diversions.

12 The intake to the Roaring River Distribution System is screened to prevent  
 13 entrainment of fish larger than approximately 25 mm (approximately 1 inch).  
 14 DWR monitored fish entrainment from September 2004 to June 2006 at the  
 15 Morrow Island Distribution System to evaluate entrainment losses at the facility.  
 16 Monitoring took place over several months under various operational  
 17 configurations and focused on Delta Smelt and salmonids. Over 20 species were  
 18 identified during the sampling, but only 2 fall-run-sized Chinook Salmon (at the  
 19 South Intake in 2006) and no Delta Smelt from entrained water were caught  
 20 (Reclamation 2008a). The Goodyear Slough Outfall system is open for free fish  
 21 movement except near the outfall when flap gates are closed during flood tides  
 22 (Reclamation 2008a). Conical fish screen have been installed on the Lower Joice  
 23 Island diversion on Montezuma Slough.

#### 24 **9.3.4.15 San Joaquin River from Confluence of the Stanislaus River to** 25 **the Delta**

26 Since the construction of Friant Dam, significant changes in physical (fluvial  
 27 geomorphic) processes and substantial reductions in streamflows in the San  
 28 Joaquin River have occurred, resulting in large-scale alterations to the river  
 29 channel and associated aquatic, riparian, and floodplain habitats. Throughout the  
 30 area, there are physical barriers, reaches with poor water quality or no surface  
 31 flow, and false migration pathways that have reduced habitat connectivity for  
 32 anadromous and resident native fishes (Reclamation and DWR 2011). As a  
 33 result, there has been a general decline in both the abundance and distribution of  
 34 native fishes, with several species extirpated from the system (Moyle 2002).

35 Moyle (2002) reported that of the 21 native fish species historically present in the  
 36 San Joaquin River, at least 8 are now uncommon, rare, or extinct. The deep-  
 37 bodied fish assemblage (e.g., Sacramento Splittail, Sacramento Blackfish) has  
 38 been replaced by nonnative species like carp and catfish.

39 The San Joaquin River from the Stanislaus River to the Delta is dominated by  
 40 nonnative species such as Largemouth Bass, Inland Silverside, carp, and several  
 41 species of sunfish and catfish (Moyle 2002). Anadromous species include fall-run  
 42 Chinook Salmon, steelhead, Striped Bass, American Shad, White Sturgeon, and  
 43 several species of lamprey (Reclamation et al. 2003). The fall-run Chinook

1 Salmon population is supported in part by hatchery stock in the Merced River.  
2 Spawning by anadromous salmonids in the San Joaquin River Basin occurs only  
3 in the tributaries to the San Joaquin River, including the Merced, Tuolumne, and  
4 Stanislaus rivers (Brown and Moyle 1993). Spring-run Chinook Salmon no  
5 longer exist in the San Joaquin River, but are targeted for restoration in this  
6 system under Reclamation's San Joaquin River Restoration Program. In early  
7 2015, the program experimentally released juvenile spring-run Chinook Salmon  
8 into the San Joaquin River near the Merced River. Surviving adults may return to  
9 the San Joaquin River as early as spring 2017. Because of the uncertainty of  
10 future restoration success and the current lack of natural presence in the San  
11 Joaquin River, spring-run Chinook Salmon is not included in the analysis of San  
12 Joaquin River fish.

### 13 **9.3.4.15.1 Fish in the San Joaquin River**

14 The analysis is focused on the following species:

- 15 • Fall-run Chinook Salmon
- 16 • Steelhead
- 17 • White Sturgeon
- 18 • Sacramento Splittail
- 19 • Pacific Lamprey
- 20 • Striped Bass
- 21 • American Shad

#### 22 *Fall-run Chinook Salmon*

23 Fall-run Chinook Salmon are present in the San Joaquin River and its major  
24 tributaries upstream to and including the Merced River. Spawning and rearing  
25 occur in the major tributaries (Merced, Tuolumne, and Stanislaus rivers)  
26 downstream of the mainstem dams. Weir counts in the Stanislaus River suggest  
27 that adult fall-run Chinook Salmon in the San Joaquin River Basin typically  
28 migrate into the upper rivers between late September and mid-November and  
29 spawn shortly thereafter (Pyper et al. 2006; Anderson et al. 2007;  
30 FISHBIO 2010a, 2011).

31 The San Joaquin River downstream of the Stanislaus River primarily provides  
32 upstream passage for adult fall-run Chinook Salmon and downstream passage for  
33 juveniles and smolts as they outmigrate from the tributary spawning and rearing  
34 areas to the Delta to the Pacific Ocean. The juvenile fall-run Chinook Salmon  
35 outmigration in the San Joaquin River Basin typically occurs during winter and  
36 spring, extending primarily from January through May. The outmigration  
37 consists primarily of fry in winter and smolts in spring (FISHBIO 2007, 2013).  
38 Trawl sampling in the lower San Joaquin River from Mossdale to the Head of Old  
39 River (the Mossdale Trawl) captures Chinook Salmon from February into July,  
40 with peak catches generally during April and May (Speegle et al. 2013).

1 *Steelhead*

2 Steelhead were historically present in the San Joaquin River, though data on their  
3 population levels are lacking (McEwan 2001). The current steelhead population  
4 in the San Joaquin River is substantially reduced compared with historical levels,  
5 although resident Rainbow Trout occur throughout the major San Joaquin River  
6 tributaries. Additionally, small populations of steelhead persist in the lower San  
7 Joaquin River and tributaries (e.g., Stanislaus, Tuolumne, and possibly the  
8 Merced rivers) (Zimmerman et al. 2009, McEwan 2001). Steelhead/Rainbow  
9 Trout of anadromous parentage occur at low numbers in all three major San  
10 Joaquin River tributaries. These tributaries have a higher percentage of resident  
11 Rainbow Trout compared to the Sacramento River and its tributaries  
12 (Zimmerman et al. 2009).

13 Presence of steelhead smolts from the San Joaquin River Basin is estimated  
14 annually by CDFW based on the Mossdale Trawl (SJRGGA 2011). The sampling  
15 trawls capture steelhead smolts, although usually in small numbers. One  
16 steelhead smolt was captured and returned to the river during the 2009 sampling  
17 period (SJRGGA 2010), and three steelhead were captured and returned in both  
18 2010 and 2011 (Speegle et al. 2013).

19 *Sacramento Splittail*

20 Historically, Sacramento Splittail were widespread in the San Joaquin River and  
21 found upstream to Tulare and Buena Vista lakes, where they were harvested by  
22 native peoples (Moyle et al. 2004). Today, Sacramento Splittail likely ascend the  
23 San Joaquin River to Salt Slough during wet years (Baxter 1999). During dry  
24 years, Sacramento Splittail are uncommon in the San Joaquin River downstream  
25 of the Tuolumne River (Moyle et al. 2004). Most spawning takes place in the  
26 flood bypasses, along the lower reaches of the Sacramento and San Joaquin rivers  
27 and major tributaries, and lower Cosumnes River and similar areas in the  
28 western Delta.

29 Most juveniles apparently move downstream into the Delta from April to August  
30 (Meng and Moyle 1995). Factors influencing the Sacramento Splittail population  
31 are unclear, but the population is largely influenced by extent and period of  
32 inundation of floodplain spawning habitats, with abundance spiking following wet  
33 years and declining after dry years (Moyle et al. 2004). Other factors that may  
34 influence the San Joaquin River portion of the population include flood control,  
35 entrainment by diversion, recreational fishing, pollutants, and nonnative species  
36 (Moyle et al. 2004).

37 *Pacific Lamprey*

38 The Pacific Lamprey is a widely distributed anadromous species found in  
39 accessible reaches of the San Joaquin River and many of its tributaries.

40 Data from mid-water trawls in the lower San Joaquin River near Mossdale  
41 indicate that adults likely migrate into the San Joaquin River in spring and early  
42 summer (Hanni et al. 2006). In other large river systems, the initial adult  
43 migration from the ocean generally stops in summer, and Pacific Lampreys hold  
44 until the following winter or spring before undergoing a secondary migration to

1 spawning grounds (Robinson and Bayer 2005, Clemens et al. 2012). Midwater  
2 trawl surveys in the San Joaquin River suggest that peak ammocoete outmigration  
3 occurs in January and February (Hanni et al. 2006).

4 Little information is available on factors influencing Pacific Lamprey in the San  
5 Joaquin River, but they are likely affected by many of the same factors as salmon  
6 and steelhead because of parallels in their life cycles. Lack of access to historical  
7 spawning habitats because of the mainstem dams and other migration barriers,  
8 modification of spawning and rearing habitats, altered hydrology, entrainment by  
9 water diversions, and predation by nonnative invasive species such as Striped  
10 Bass all likely influence Pacific Lamprey in the San Joaquin River and tributaries.

#### 11 *Striped Bass*

12 Striped Bass are regularly found in San Joaquin River tributaries, including in  
13 lower mainstem deep pools of the Stanislaus and Tuolumne rivers (e.g., Anderson  
14 et al. 2007). Ainsley et al. (2013) reported that Striped Bass were collected at two  
15 locations between the Head of the Old River and the mouth of the Stanislaus  
16 River on the mainstem San Joaquin River in May.

#### 17 *American Shad*

18 Little is known about American Shad populations inhabiting the San Joaquin  
19 River. American Shad may spawn in the San Joaquin River system, but their  
20 abundance is unknown. Sport fishing for American Shad occurs seasonally in the  
21 San Joaquin River.

#### 22 *Sturgeon*

23 Little is known about White Sturgeon populations inhabiting the San Joaquin  
24 River. Spawning-stage adults generally move into the lower reaches of rivers  
25 during winter prior to spawning, then migrate upstream to spawn in response to  
26 higher flows (Schaffter 1997, McCabe and Tracy 1994). Based on tag returns  
27 from White Sturgeon tagged in the Sacramento-San Joaquin Estuary and  
28 recovered by anglers, Kohlhorst et al. (1991) estimated that over 10 times as  
29 many White Sturgeon spawn in the Sacramento River as in the San Joaquin River.

30 CDFW fisheries catch information for the San Joaquin River obtained from  
31 fishery report cards (DFG 2008b, 2009b, 2010, 2011, 2012b; CDFW 2013, 2014)  
32 documented that anglers upstream of Highway 140 caught between 8 and  
33 25 mature White Sturgeon annually between 2007 and 2013. Below Highway  
34 140 downstream to Stockton, anglers caught between 2 and 35 mature White  
35 Sturgeon annually over the same time period; most of the White Sturgeon caught  
36 were released.

37 White Sturgeon spawning in the San Joaquin River was documented for the first  
38 time in 2011 and confirmed in 2012. Viable White Sturgeon eggs were collected  
39 in 2011 at one sampling location downstream of Laird Park (Gruber et al. 2012)  
40 and in 2012 at four sampling locations generally between Laird Park and the  
41 Stanislaus River confluence (Jackson and Van Eenennaam 2013). Although the  
42 majority of sturgeon likely spawn in the Sacramento River, the results of these  
43 surveys confirm that White Sturgeon do spawn in the San Joaquin River in both

1 wet- and dry-year conditions and may be an important source of production for  
2 the White Sturgeon population in the Sacramento-San Joaquin river system.

3 Green Sturgeon are also present in the San Joaquin River, but at considerably  
4 lower numbers than White Sturgeon. Between 2007 and 2012, anglers reported  
5 catching six Green Sturgeon in the San Joaquin River (Jackson and Van  
6 Eenennaam 2013). Although the reported presence of Green Sturgeon in the  
7 San Joaquin River coincides with the spawning migration period of Green  
8 Sturgeon within the Sacramento River, no evidence of spawning has been  
9 detected (Jackson and Van Eenennaam 2013).

#### 10 **9.3.4.15.2 Aquatic Habitat**

11 Aquatic habitat conditions vary spatially and temporally throughout the lower San  
12 Joaquin River because of differences in habitat availability and connectivity,  
13 water quantity and quality (including water temperature), and channel  
14 morphology.

15 Downstream of the Stanislaus River confluence, the San Joaquin River is more  
16 sinuous than upstream reaches and contains oxbows, side channels, and remnant  
17 channels. It conveys the combined flows of the major tributaries, including the  
18 Merced, Tuolumne, Stanislaus, and Calaveras rivers. Flood control levees closely  
19 border much of the river but are set back in places, creating some off-channel  
20 aquatic habitat areas when inundated (Reclamation and DWR 2011). The channel  
21 gradient in this portion of the San Joaquin River is low, and the lack of gravel or  
22 coarser substrate precludes spawning by salmonids.

#### 23 **9.3.4.15.3 Fish Passage**

24 In the reach of the river downstream of the confluence of the Stanislaus River,  
25 fish encounter passage challenges associated with water diversions, and adult  
26 salmon migrating upstream from the Delta also may encounter prohibitively high  
27 stream temperatures that delay migration until temperatures decline (McBain and  
28 Trush 2002). Installation of seasonal barriers in the Delta also can impair fish  
29 passage.

#### 30 **9.3.4.15.4 Hatcheries**

31 No hatcheries in the San Joaquin River Basin are affected by CVP or SWP  
32 operations. The Merced River Hatchery, located on the Merced River, is operated  
33 by CDFW to supplement the fall-run Chinook Salmon population. It is not  
34 included in the CVP or SWP service areas. As part of the San Joaquin River  
35 Restoration Program, CDFW has begun operation of a conservation hatchery  
36 downstream of Friant Dam to produce spring-run Chinook Salmon (Reclamation  
37 and DWR 2010).

#### 38 **9.3.4.15.5 Predation**

39 Recent studies of predation in the San Joaquin River are limited to the major  
40 tributaries, where largemouth and Smallmouth Bass have been identified as the  
41 most important predators of juvenile Chinook Salmon (McBain and Trush and

1 Stillwater Sciences 2006). Striped Bass also have been identified as salmon  
2 predators, though recent evidence for the San Joaquin River is lacking.

3 **9.3.4.16 New Melones Reservoir, Tulloch Reservoir, and Goodwin Dam**

4 The north, middle, and south forks of the Stanislaus River converge upstream of  
5 the CVP New Melones Reservoir. Water from New Melones Reservoir flows  
6 into Tulloch Reservoir (Reclamation 2010b). Downstream of Tulloch Reservoir,  
7 the Stanislaus River flows through the reservoir formed by Goodwin Dam and  
8 then approximately 40 miles to the confluence with the San Joaquin River.

9 New Melones Reservoir is located approximately 60 miles upstream from the  
10 confluence of the Stanislaus and San Joaquin rivers and is operated by  
11 Reclamation. New Melones Reservoir is an artificial environment and does not  
12 support a naturally evolved aquatic community. Most of the species in the  
13 reservoir were introduced, although a few native species may still be present.  
14 From a fisheries perspective, recreational fishing is the most important use of  
15 New Melones Reservoir. Fish species in New Melones Reservoir include  
16 Rainbow Trout, Brown Trout, Largemouth Bass, sunfishes such as Black Crappie  
17 and Bluegill, and three species of catfish (Reclamation 2010b). Rainbow Trout,  
18 Brown Trout, and large Channel Catfish are generally restricted to colder, deeper  
19 water during summer, when New Melones Reservoir has two distinct thermal  
20 layers of water, although large Brown Trout and Channel Catfish are found in  
21 shallow water near steep banks at night when they ascend to feed.

22 Tulloch Reservoir is operated as an afterbay for the New Melones Reservoir and  
23 is subject to fluctuating water levels that occur on a daily and seasonal basis.  
24 Tulloch Reservoir stratifies weakly during summer and contains a reserve of  
25 relatively cold, well-oxygenated water that is released downstream. Tulloch  
26 Reservoir supports both warm and cold freshwater habitat. Goodwin Power  
27 (2013) reported that DFG captured 15 species in Tulloch Reservoir from  
28 1969 through 1998. Five dominant species made up almost 80 percent of the  
29 catch; White Catfish (31 percent of the total), Bluegill (20 percent), Sacramento  
30 Sucker (11 percent), Smallmouth Bass (10 percent), and Black Crappie  
31 (7 percent). Of these, only the Sacramento Sucker is native. Other native species  
32 in the catch were Sacramento Hitch, Hardhead, Sacramento Pikeminnow, and  
33 Rainbow Trout (now stocked). Other nonnative fish found in Tulloch reservoir  
34 include Largemouth Bass and Threadfin Shad (DFG 2002b).

35 Little information exists regarding aquatic resources in the reservoir formed by  
36 Goodwin Dam. It is assumed that fish assemblies are similar to those described  
37 for Tulloch Reservoir.

38 **9.3.4.17 Stanislaus River from Goodwin Dam to the San Joaquin River**

39 **9.3.4.17.1 Fish in the Stanislaus River**

40 Steelhead and fall-run Chinook Salmon currently occur in the lower Stanislaus  
41 River. Historically, spring-run Chinook Salmon were believed to be the primary  
42 salmon run in the Stanislaus River. Native spring-run Chinook salmon have been

1 extirpated from all tributaries in the San Joaquin River Basin, which represents a  
 2 large portion of their historic range and abundance (NMFS 2014b). Other  
 3 anadromous fish species that occur in the lower Stanislaus River include Striped  
 4 Bass, American Shad, and an unidentified species of lamprey (SRFG 2003). The  
 5 analysis is focused on the following species:

- 6 • Fall-run Chinook Salmon
- 7 • Steelhead
- 8 • Pacific Lamprey
- 9 • Striped Bass
- 10 • American Shad

#### 11 *Fall-run Chinook Salmon*

12 Data collected by private fishery consultants, nonprofit organizations, and DFG  
 13 demonstrate the majority of fall-run Chinook Salmon adults migrate upstream  
 14 from late September through December with peak migration from late October  
 15 through early November. Most Chinook Salmon spawning occurs between  
 16 Riverbank (River Mile 33) and Goodwin Dam (River Mile 58.4) (Reclamation  
 17 2012b). Based on redd surveys conducted by FISHBIO, peak spawning typically  
 18 occurs in November with roughly 7 percent of spawning occurring prior to  
 19 November 1, and 2 percent prior to October 15. The few redds created during late  
 20 September and early October are typically in the reach just below Goodwin Dam.  
 21 By late October, the amount of spawning in downstream locations increases as  
 22 water temperatures decrease, and the median redd location is typically around  
 23 Knights Ferry (SWRCB 2015).

24 In 2010, over 20 percent of the fall-run Chinook Salmon observed passing the  
 25 Stanislaus River weir had adipose fin clips, indicating the presence of a coded-  
 26 wire-tag (CWT) in their snout. Since there is no hatchery on the Stanislaus River  
 27 and no hatchery releases have been conducted into this tributary since 2006, it is  
 28 apparent that straying from other rivers is occurring (FISHBIO 2010b).

29 Rotary screw trap data indicate that about 99 percent of salmon juveniles migrate  
 30 out of the Stanislaus River from January through May (SRFG 2004). Fry  
 31 migration generally occurs from January through March, followed by smolt  
 32 migration from April through May (Reclamation 2012). Watry et al. (2012)  
 33 found that in both 2010 and 2011, peak passage during the pre-smolt period  
 34 generally corresponded with flow pulses. Zeug et al. (2014) examined 14 years of  
 35 rotary screw trap data on the lower Stanislaus River and found a strong positive  
 36 response in survival, the proportion of pre-smolt migrants and the size of smolts  
 37 when cumulative flow and flow variance were greater and concluded that the data  
 38 suggested that periods of high discharge in combination with high discharge  
 39 variance are important for successful emigration as well as migrant size and the  
 40 maintenance of diverse migration strategies.

41 Mesick (2001) surmised that when water exports are high relative to San Joaquin  
 42 River flows, little, if any, San Joaquin River water reaches San Francisco Bay  
 43 where it may be needed to help attract the salmon back to the Stanislaus River.  
 44 During mid-October from 1987 through 1989, when export rates exceeded

1 400 percent of Vernalis flows, Mesick (2001) found that straying rates ranged  
2 between 11 and 17 percent. In contrast, straying rates were estimated to be less  
3 than 3 percent when Delta export rates were less than about 300 percent of  
4 San Joaquin River flow at Vernalis during mid-October.

5 One of the limiting factors appears to be the high rates of mortality for juveniles  
6 migrating through dredged channels in the Stanislaus River and Delta, particularly  
7 the Stockton Deep Water Ship Channel (Newcomb and Pierce 2010). Pickard  
8 et al. (1982) reported that the survival of juvenile fish in the deep-water ship  
9 channel is highest during flood flows or when a barrier is placed at the head of the  
10 Old River that more than doubles the flow in the ship channel. The Stanislaus  
11 River Fish Group (SRFG) (2004) noted that escapement is also directly correlated  
12 with springtime flows when each brood migrates downstream as smolts.  
13 However, the cause of the mortality in the ship channel has not been studied. It is  
14 possible that mortality results from the combined effects of warm water  
15 temperatures, low dissolved oxygen concentrations, ammonia toxicity, and  
16 predation.

17 As discussed earlier, dredging for gravel and gold, regulated flows, and the diking  
18 of floodplains for agriculture have substantially limited the availability of  
19 spawning and rearing habitat for fall-run Chinook Salmon. Reclamation has  
20 conducted spawning gravel augmentation to improve spawning and rearing  
21 habitats in the reach between Goodwin Dam and Knights Ferry most years since  
22 1999. The dredged areas also contain an abundance of large predatory fish,  
23 although the SRFG concluded that there is uncertainty about whether predation is  
24 a substantial source of mortality for juvenile salmon.

25 The SRFG also concluded that water diversions for urban and agricultural use in  
26 all three San Joaquin River tributaries, which reduce flows and potentially result  
27 in unsuitably warm water temperatures during spring and fall, affect fall-run  
28 Chinook Salmon juvenile rearing and adult and juvenile migration in the lower  
29 San Joaquin River and Delta.

### 30 *Steelhead*

31 Steelhead were thought to be extirpated from the San Joaquin River system  
32 (NMFS 2009a). However, monitoring has detected small self-sustaining  
33 (i.e., non-hatchery origin) populations of steelhead in the Stanislaus River and  
34 other streams previously thought to be devoid of steelhead (SRFG 2003, McEwan  
35 2001). There is a catch-and-release steelhead fishery in the lower Stanislaus  
36 River between January 1 and October 15. Surveys of *O. mykiss* (resident trout  
37 and the anadromous steelhead) abundance and distribution conducted annually  
38 since 2009 have documented a relatively stable population. River-wide  
39 abundance estimates from 2009 to 2014 have averaged just over 20,220 (all life  
40 stages combined) and have never been estimated to be less than about 14,000  
41 (2009). The highest densities and abundances of *O. mykiss* are consistently found  
42 in Goodwin Canyon. Key factors that may contribute to higher-than average  
43 abundances in the Stanislaus River (relative to other San Joaquin River  
44 tributaries) include high gradient reaches that are typically associated with higher  
45 amount of fast-water habitats, particularly in Goodwin Canyon (SWRCB 2015).

1 Historically, the distribution of steelhead extended into the headwaters of the  
 2 Stanislaus River (Yoshiyama et al. 1996). Steelhead currently can migrate more  
 3 than 58 miles up the Stanislaus River to the base of Goodwin Dam. In the  
 4 Stanislaus River, there is little data regarding the migration patterns of adult  
 5 steelhead since adults generally migrate during periods when river flows and  
 6 turbidity are high making fish difficult to observe with standard adult monitoring  
 7 techniques. Stanislaus River weir data indicate that steelhead migrate upstream,  
 8 through the South Delta and lower San Joaquin river, between September and  
 9 March with numbers ranging from 6 to 85<sup>3</sup> between 2008-2011 and 2013  
 10 (Reclamation 2014e). High Delta export rates relative to San Joaquin River flows  
 11 at Vernalis, when adults are migrating through the Delta (presumably December  
 12 through May), may result in adults straying to the Sacramento River Basin.

13 It is believed that steelhead spawn primarily between December and March in the  
 14 Stanislaus River. Although steelhead few steelhead spawning surveys have been  
 15 conducted in the Stanislaus, spawning *O. mykiss* were documented between  
 16 Goodwin Dam and Horseshoe Bar in a 2014 spawning survey (Reclamation and  
 17 DWR 2015). The spawning adults require holding and feeding habitat with cover  
 18 adjacent to suitable spawning habitat. These habitat features are relatively rare in  
 19 the lower Stanislaus River because of in-river gravel mining and the scouring of  
 20 gravel from riffles in Goodwin Canyon.

21 Juvenile steelhead rear in the Stanislaus River for at least 1 year, and usually  
 22 2 years, before migrating to the ocean. As a result, flow, water temperature, and  
 23 dissolved oxygen concentration in the reach between Goodwin Dam and the  
 24 Orange Blossom Bridge (their primary rearing habitat) are critical during summer  
 25 (Reclamation 2012b).

26 Small numbers of steelhead smolts have been captured in rotary screw traps at  
 27 Caswell State Park and near Oakdale (FISHBIO 2007; Watry et al. 2007, 2012),  
 28 and data indicate that steelhead outmigrate primarily from February through May.  
 29 Rotary screw traps are generally not considered efficient at catching fish as large  
 30 as steelhead smolts, and the number captured is too small to estimate capture  
 31 efficiency, so no steelhead smolt outmigration population estimate has been  
 32 calculated. The capture of these fish in downstream migrant traps and the  
 33 advanced smolting characteristics exhibited by many of the fish indicate that  
 34 some steelhead/rainbow juveniles might migrate to the ocean in spring. However,  
 35 it is not known whether the parents of these fish were anadromous or fluvial (they  
 36 migrate within fresh water). Resident populations of steelhead/rainbow in large  
 37 streams are typically fluvial, and migratory juveniles look much like smolts.

### 38 *Pacific Lamprey*

39 The Pacific Lamprey is a widely distributed anadromous species that inhabits  
 40 accessible reaches of the Stanislaus River (SRFG 2003). Limited information on  
 41 Pacific Lamprey status in the Stanislaus River exists, but the species has

---

<sup>3</sup> Numbers presented are for all *O. mykiss* passing upstream of the Stanislaus Weir and do not differentiate between adult steelhead and resident rainbow trout that are moving within the river; therefore, actual numbers of steelhead may be lower than those presented.

1 experienced loss of access to historical habitat and apparent population declines  
2 throughout California and the Sacramento and San Joaquin River basins  
3 (Moyle et al. 2009). Little information is available on factors influencing  
4 Pacific Lamprey populations in the Stanislaus River, but they are likely affected  
5 by many of the same factors as salmon and steelhead because of parallels in their  
6 life cycles.

7 Ocean stage adults likely migrate into the Stanislaus River in spring and early  
8 summer, where they hold for approximately 1 year before spawning (Hanni et al.  
9 2006). Hannon and Deason (2008) have documented Pacific Lampreys spawning  
10 in the American River from between early January and late May, with peak  
11 spawning typically in early April. Spawning time is presumably similar in the  
12 Stanislaus River. Pacific Lamprey ammocoetes are expected to rear in the  
13 Stanislaus River for all or part of their 5- to 7-year freshwater residence. Data  
14 from rotary screw trapping in the nearby Mokelumne and Tuolumne rivers  
15 suggest that outmigration of Pacific Lamprey generally occurs from early winter  
16 through early summer (Hanni et al. 2006). Catches of juvenile Pacific Lampreys  
17 in trawl surveys of the mainstem San Joaquin River, near the mouth of the  
18 Stanislaus River at Mossdale, occurred during winter and spring. Some  
19 outmigration likely occurs year-round, as observed at sites on the mainstem  
20 Sacramento River (Hanni et al. 2006). Significant numbers of lampreys of  
21 unknown species and unspecified life stage have been captured during rotary  
22 screw trapping on the Stanislaus River at Oakdale (FISHBIO 2007) and Caswell  
23 (Watry et al. 2007).

#### 24 *Striped Bass*

25 Striped Bass occur in the Stanislaus River, and they support a sport fishery when  
26 adult fish migrate upstream to spawn. Striped Bass have been observed at Lovers  
27 Leap and at Knights Ferry from May through the end of June. These adult fish  
28 were observed in all habitats (USFWS 2002, Kennedy and Cannon 2005). The  
29 distribution of Striped Bass in the Stanislaus River is thought to be limited to  
30 downstream of the historic Knights Ferry Bridge due to a set of falls about 3 feet  
31 tall in the area (USFWS 2002).

#### 32 *American Shad*

33 American Shad migrate up the Stanislaus River to spawn in the late spring and  
34 support a sport fishery during that period. American Shad have been observed on  
35 occasion from June through July at Lovers Leap (USFWS 2002, Kennedy and  
36 Cannon 2005). American Shad were found primarily in the faster habitats and  
37 were observed in schools of 20 or more (USFWS 2002).

#### 38 **9.3.4.17.2 Aquatic Habitat**

39 Schneider et al. (2003) conducted hydrologic analysis of the Stanislaus River and  
40 found that New Melones Dam (built in 1979) and more than 30 smaller dams  
41 cumulatively impound 240 percent of average annual unimpaired runoff.  
42 Schneider et al. (2003) concluded that this has reduced winter floods and spring  
43 snow melt runoff, and increased summer base flows to supply irrigation demand.  
44 As a result, the frequency and extent of overbank flooding has been reduced.

1 Based on historical data and field measurements, Schneider et al. (2003)  
2 suggested that the channel had incised approximately 1 to 3 feet since dam  
3 construction, and that the discharge needed for overbank flows has approximately  
4 doubled.

5 With respect to the related need for geomorphic flows, Kondolf et al. (2001)  
6 estimated bedload mobilization flows in the Stanislaus River to be around  
7 5,000 to 8,000 cfs to mobilize the median particle size of the channel bed  
8 material. Flows necessary to mobilize the bed material increased downstream  
9 from a minimal 280 cfs where gravel had been recently added near Goodwin Dam  
10 to about 5,800 cfs at Oakdale Recreation Area (Reclamation 2008a). Before  
11 construction of New Melones Dam, a bed-mobilizing flow of 5,000 to 8,000 cfs  
12 was equivalent to a 1.5- to 1.8-year return interval flow. Following construction  
13 of the dam, 5,000 cfs represents approximately a 5-year return interval flow, and  
14 8,000 cfs exceeds all flows within the 21-year study period, 1979 to 1999  
15 (maximum flow = 7,350 cfs on January 3, 1997). The probability of occurrence  
16 for a daily average flow exceeding 5,330 cfs (the pre-dam bankfull discharge) is  
17 0.01 per year.

18 Low dissolved oxygen (DO) levels have been measured in the San Joaquin River,  
19 in particular in the Deep Water Ship Channel (DWSC) from the Port of Stockton  
20 seven miles downstream to Turner Cut (Lee and Jones-Lee 2003). These  
21 conditions are the result of increased residence time of water combined with high  
22 oxygen demand in the anthropogenically modified channel, which leads to DO  
23 depletion, particularly near the sediment-water interface (SJTA 2012). Despite  
24 these conditions, adult salmon and steelhead migration does not appear to be  
25 adversely impacted (Pyper et. al 2006). However, during the 1960s, Hallock et al.  
26 (1970) found that adult radio-tagged Chinook Salmon delayed their upstream  
27 migration whenever dissolved oxygen concentrations were less than 5 mg/L at  
28 Stockton. SWRCB D-1422 requires water to be released from New Melones  
29 Reservoir to maintain dissolved oxygen standards in the Stanislaus River, as  
30 described in Chapter 6, Surface Water Quality. It has been shown that low DO  
31 conditions in the San Joaquin River can be ameliorated somewhat through  
32 installation of the Head of the Old River Barrier which increases San Joaquin  
33 River flows (SJTA 2012).

#### 34 *Spawning and Rearing Habitat*

35 Upstream dams have suppressed channel-forming flows that replenish spawning  
36 beds in the Stanislaus River (Kondolf et al. 1996). The physical presence of the  
37 dams impedes normal sediment transportation processes. Kondolf (et al. 2001)  
38 identified levels of sediment depletion at 20,000 cubic yards per year as a result of  
39 a variety of factors, including mining, and geomorphic processes associated with  
40 past and ongoing dam operations. In 2011, 5,000 tons of gravel were placed in  
41 Goodwin Canyon downstream of Goodwin Dam, of which around 70 percent was  
42 transported into nearby downstream areas during high flows (SOG 2012).

43 Extensive instream gravel mining removed large quantities of spawning habitat  
44 (Kondolf et al. 2001). Gravel mining also has resulted in instream mine pits that  
45 occur in the primary salmonid spawning areas, including a large, approximately

1 1-mile-long pit called the Oakdale Recreation Pond. Instream mine pits trap  
2 bedload sediment, store large volumes of sand and silt, and pass sediment-starved  
3 water downstream, where it typically erodes the channel bed and banks to regain  
4 its sediment load (Kondolf et al. 2001). Reclamation restores and replenishes  
5 spawning gravel and rearing habitat lost from the construction and operation of  
6 dams in the Stanislaus River to restore spawning habitat and remediate sediment  
7 related loss of geomorphic function, such as channel incision.

#### 8 *Floodplain Habitat*

9 Kondolf et al. (2001) identified that floodplain terraces and point bars inundated  
10 before operation of New Melones Reservoir have become fossilized with fine  
11 material and thick riparian vegetation that is never rejuvenated by scouring flows.  
12 Channel forming flows in the 8,000-cfs range have occurred only twice since  
13 New Melones Reservoir began operation 28 years ago.

14 Based on historical data and field measurements, Schneider et al. (2003)  
15 suggested that the channel incised approximately 1 to 3 feet since dam  
16 construction, and that the discharge needed for overbank flows has approximately  
17 doubled. Without inundation, the floodplains cannot provide terrestrial food for  
18 juvenile salmon or organic matter that helps produce more food within the river.  
19 Increased flows required for inundation also have had the effect of further  
20 isolating floodplains from the channel, leading to the loss of floodplain habitats.

21 In 2011, a habitat restoration project to increase spawning habitat also restored  
22 640 feet of remnant side channel habitat, allowing water to flow at the current  
23 1.5-year return interval (575 cfs), in addition to three cross channels designed to  
24 inundate at higher flows (SOG 2011).

#### 25 **9.3.4.17.3 Fish Passage and Entrainment**

26 Constructed in 1913, Goodwin Dam was probably the first permanent barrier to  
27 significantly affect anadromous fish access to upstream habitat in the Stanislaus  
28 River. Goodwin Dam had a fishway, but Chinook Salmon could seldom pass it,  
29 and other salmonids may have been similarly affected. Yoshiyama et al. (1996)  
30 estimated that historically Chinook Salmon and other salmonids had access to  
31 113 miles of habitat, compared with 58 miles under current conditions.

32 There are numerous small, unscreened diversions on the lower Stanislaus River  
33 (Herren and Kawasaki 2001). The effects of these diversions on fish is not clear;  
34 however, in tracking the fate of 49 radio tagged fish, S.P. Cramer and Associates  
35 (1998) did not detect any entrainment at several moderately sized unscreened  
36 pumps in the lower Stanislaus River.

#### 37 **9.3.4.17.4 Predation**

38 Areas of the Stanislaus River, including spawning riffles in the active channel,  
39 were mined for gravel and gold primarily between 1940 and 1970. The mined  
40 areas consist of long, deep ditches and large ponds that provide habitat for  
41 predators, such as Striped Bass, Sacramento Pikeminnow, Largemouth Bass, and  
42 Smallmouth Bass (Mesick 2002). Studies by S.P. Cramer and Associates (1998)

1 documented predation on juvenile salmonids by bass in the Tuolumne and  
2 Stanislaus rivers. However, in its review of information, the SRFG (2004)  
3 concluded that the available studies and observations suggest that fish predators in  
4 the Stanislaus River may be limited to adult pikeminnow and Riffle Sculpin  
5 feeding on newly emerged fry, whereas Smallmouth Bass, Largemouth Bass, and  
6 possibly American Shad probably feed on relatively few parr that remain in the  
7 river during late spring and summer when water temperatures are high.

8 It is possible that predation is high for juveniles rearing in the deep-water ship  
9 channel in the Delta as observed by Pickard et al. (1982). Predation rates on  
10 hatchery-reared juveniles and tagged juveniles may be higher than those for  
11 naturally produced fish. TID/MID (1992, 2013), and TRTAC et al. (2006), have  
12 documented predation on salmonids by nonnative predatory fishes in the  
13 Tuolumne River, primarily in run-of-river gravel mining ponds and dredged areas.  
14 Sonke and Fuller (2012) reported the number of juvenile Chinook Salmon passing  
15 the rotary screw traps at Waterford (2006 to 2012) and Grayson (1995 to 2012) on  
16 the Tuolumne River. FISHBIO (2013) calculated the potential consumption of  
17 juvenile Chinook Salmon by predators in the reach between the Waterford and  
18 Grayson rotary screw traps in 2012 and found that consumption of juvenile  
19 Chinook Salmon in this reach could equal or exceed the number passing the  
20 Waterford trap. Based on their consumption calculations and the difference in  
21 estimated numbers of juvenile Chinook Salmon passing the Waterford and  
22 Grayson rotary screw traps, FISHBIO (2013) concluded that it is plausible that  
23 the majority of juvenile Chinook Salmon losses in this reach are due to predation.  
24 NMFS (2009a) noted that losses on the Stanislaus River have not been similarly  
25 quantified, but predation on fall-run Chinook Salmon smolts and steelhead by  
26 Striped Bass and Largemouth Bass has been documented.

#### 27 **9.3.4.18 San Luis Reservoir**

28 San Luis Reservoir is located at the base of the foothills on the west side of the  
29 San Joaquin Valley in Merced County, as described in Chapter 5, Surface Water  
30 Resources and Water Supplies. Water from the Delta is delivered to San Luis  
31 Reservoir via the California Aqueduct and Delta-Mendota Canal for storage.

32 San Luis Reservoir and O'Neill Forebay support several species of fish that have  
33 become established within the system, either by direct introduction or from the  
34 Delta system via pumping from the California Aqueduct and Delta-Mendota  
35 Canal. Striped Bass are the predominant species in San Luis Reservoir  
36 (DWR 1987) and support a recreational fishery. Other species include  
37 Sacramento Blackfish, American Shad, Threadfin Shad, Largemouth Bass,  
38 Kokanee Salmon, Green Sunfish, Bluegill, White Sturgeon, and White Crappie.

39 There are no sensitive fish species in the San Luis Reservoir except, possibly,  
40 individuals entrained by the CVP and SWP projects in the Delta. These  
41 individuals have already been lost to their populations, as they cannot return to the  
42 Delta once entrained. Potentially occurring fish species with special status that  
43 may have been imported from the Delta include Chinook Salmon, Delta Smelt,  
44 Hardhead, and Sacramento Splittail (Reclamation and CSP 2013).

1 **9.3.5 San Francisco Bay Area Region**

2 Fish and aquatic habitat resources in the San Francisco Bay Area Region include  
3 habitat through San Francisco Bay and along the Pacific Ocean coast. The  
4 anadromous fish species discussed above use the Pacific Ocean as part of their  
5 life cycles. In addition, the Pacific Ocean supports the killer whale which relies  
6 upon Chinook Salmon (e.g., fall-run Chinook Salmon) for food.

7 The San Francisco Bay Area Region also includes fish habitat within reservoirs  
8 that store CVP and SWP water. CVP and SWP water supplies are stored in  
9 Contra Loma and San Justo reservoirs; the SWP Bethany Reservoir and Lake  
10 Del Valle; the Contra Costa Water District Los Vaqueros Reservoir; and the East  
11 Bay Municipal Utility District (EBMUD) Upper San Leandro, San Pablo,  
12 Briones, and Lafayette reservoirs and Lake Chabot. Many of these reservoirs also  
13 store water from local and regional water supplies. CVP and SWP water is  
14 generally not stored in reservoirs within Santa Clara County (SCVWD 2010).

15 **9.3.5.1 Pacific Ocean Habitat of the Killer Whale**

16 The Pacific Ocean along the coast of California is included in this description of  
17 the affected environment because of it provides habitat for the Southern Resident  
18 killer whale population. The effect of the action, however, is limited to changes  
19 in the number of Chinook Salmon produced in the Central Valley entering the  
20 Pacific Ocean, which contribute an important component of the killer whale diet.

21 Southern Resident killer whales are found primarily in the coastal waters offshore  
22 of British Columbia and Washington and Oregon in summer and fall (NMFS  
23 2008). During winter, killer whales are sometimes found off the coast of central  
24 California and more frequently off the Washington coast (Independent  
25 Hilborn et al. 2012).

26 The 2005 NMFS endangerment listing (70 FR 69903) for the Southern Resident  
27 killer whale distinct population segment lists several factors that may be limiting  
28 the recovery of killer whales, including the quantity and quality of prey,  
29 accumulation of toxic contaminants, and sound and vessel disturbance. In the  
30 Recovery Plan for Southern Resident Killer Whales (*Orcinus orca*), NMFS  
31 (2008) posits that reduced prey availability forces whales to spend more time  
32 foraging, which may lead to reduced reproductive rates and higher mortality rates.  
33 Reduced food availability may lead to mobilization of fat stores, which can  
34 release stored contaminants and adversely affect reproduction or immune function  
35 (NMFS 2008).

36 The Independent Science Panel reported that Southern Resident killer whales  
37 depend on Chinook Salmon as a critical food resource (Independent Science  
38 Panel and ESSA Technologies 2012). Hanson et al. (2010) analyzed tissues from  
39 predation events and feces to confirm that Chinook Salmon were the most  
40 frequent prey item for killer whales in two regions of the whale's summer range  
41 off the coast of British Columbia and Washington state, representing over  
42 90 percent of the diet in July and August. Samples indicated that when Southern  
43 Residents are in inland waters from May to September, they consume Chinook  
44 Salmon stocks that originate from regions including the Fraser River, Puget

1 Sound, the Central British Columbia Coast, West and East Vancouver Island, and  
2 Central Valley California (Hanson et al. 2010).

3 Significant changes in food availability for killer whales have occurred over the  
4 past 150 years, largely due to human impacts on prey species. Salmon abundance  
5 has been reduced over the entire range of the Southern Resident killer whales,  
6 from British Columbia to California. The Recovery Plan for Southern Resident  
7 Killer Whales (*Orcinus orca*) (NMFS 2008) indicates that wild salmon have  
8 declined primarily due to degraded aquatic ecosystems, overharvesting, and  
9 production of fish in hatcheries. The recovery plan supports restoration efforts to  
10 rebuild depleted salmon populations and other prey to ensure an adequate food  
11 base for Southern Resident killer whales.

12 Central Valley streams produce Chinook Salmon that contribute to the diet of  
13 Southern Resident killer whales. The number of Central Valley salmon that  
14 annually enter the ocean and survive to a size susceptible to predation by killer  
15 whales is not known. However, estimates of total Chinook Salmon production  
16 produced by the Comprehensive Assessment and Monitoring Program,  
17 administered by USFWS and Reclamation, provide an approximation of the size  
18 of the ocean population of Central Valley Chinook Salmon potentially available  
19 to killer whales. Since 1992, total production of fall-run Chinook Salmon ranged  
20 from 53,129 in 2009 to 1,436,928 in 2002 (Table 9.2). The term “total  
21 production” here represents the number of fish that returned from the ocean plus  
22 those that were taken as part of the commercial and sport fishery. It does not  
23 include natural mortality in the ocean, including salmon taken by killer whales.

1 **Table 9.2 Total Production (Number of Individuals) of Central Valley Fall-run**  
 2 **Chinook Salmon in the Pacific Ocean and Ocean Harvest 1992-2011**

Year	Total Production	Ocean Harvest
1992	333,087	203,318
1993	553,617	352,913
1994	711,654	449,060
1995	1,391,357	994,194
1996	891,739	471,865
1997	1,146,471	679,151
1998	557,433	263,935
1999	795,768	316,873
2000	1,156,596	571,829
2001	976,034	218,424
2002	1,436,928	418,785
2003	1,019,686	297,140
2004	977,463	500,929
2005	874,670	356,514
2006	453,274	110,540
2007	202,311	87,528
2008	71,870	0
2009	53,129	0
2010	208,050	13,851
2011	329,092	57,224

3 Source: DOI 2012

4 **9.3.5.2 Contra Loma Reservoir**

5 The Contra Loma Reservoir is a CVP facility in Contra Costa County that  
 6 provides offstream storage along the Contra Costa Canal. The 80-acre reservoir is  
 7 part of 661-acre Contra Loma Regional Park and Antioch Community Park  
 8 (Reclamation 2014b). There are currently 20 known fish species, including  
 9 8 species of game fish, in Contra Loma Reservoir. The East Bay Parks and  
 10 Recreation District (EBRPD) and CDFW stock Rainbow Trout and Channel  
 11 Catfish in the reservoir. The reservoir also supports self-sustaining populations of  
 12 Largemouth Bass, crappie, Redear Sunfish, and Bluegill, which are also popular  
 13 with anglers (Reclamation 2014b). Other species found include White Catfish,  
 14 Threadfin Shad, Bigscale Logperch, Common Carp, Sacramento Blackfish,  
 15 Warmouth, Green Sunfish, Goldfish, Prickly Sculpin, and Inland Silversides  
 16 (Reclamation 2014b).

1 Many of the fish species present have been unintentionally introduced from the  
 2 Delta via the Contra Costa Canal. Recently, the Rock Slough Fish Screen at the  
 3 head of Contra Costa Canal was constructed to prevent the entrainment of  
 4 federally protected species such as Delta Smelt at the Rock Slough Intake of the  
 5 Contra Costa Canal. The new screen also minimizes fish entrainment and  
 6 significantly reduces the potential for fish introductions into Contra Loma  
 7 Reservoir from the Contra Costa Canal (Reclamation 2014b).

#### 8 **9.3.5.3 San Justo Reservoir**

9 The San Justo Reservoir is a CVP facility in San Benito County that provides  
 10 offstream storage as part of the San Felipe Division, as described in Chapter 5,  
 11 Surface Water Resources and Water Supplies. Other than stocked Rainbow  
 12 Trout, all of the fish and other aquatic organisms that have been observed in  
 13 San Justo Reservoir are nonnative species (SBCWD 2012).

#### 14 **9.3.5.4 South Bay Aqueduct Reservoirs**

15 Bethany Reservoir, Patterson Reservoir, and Lake Del Valle are SWP facilities  
 16 associated with the South Bay Aqueduct in Alameda County, as described in  
 17 Chapter 5, Surface Water Resources and Water Supplies. At Bethany Reservoir,  
 18 anglers catch five types of bass (Spotted, White, Largemouth, Smallmouth, and  
 19 Striped), crappie, catfish, and trout (CSP 2013). Presumably, many of the same  
 20 species would be found in Patterson Reservoir. Lake Del Valle is stocked  
 21 regularly with trout and catfish. Largemouth and Smallmouth Bass, Striped Bass,  
 22 and panfish are also caught (EBPRD 2014).

#### 23 **9.3.5.5 Los Vaqueros Reservoir**

24 Los Vaqueros Reservoir is a Contra Costa Water District offstream storage  
 25 facility in Contra Costa County, as described in Chapter 5, Surface Water  
 26 Resources and Water Supplies. Aquatic habitat quality for fish is low to moderate  
 27 due to poorly developed cover vegetation along the shoreline. The reservoir has  
 28 been stocked with more than 300,000 game fish, primarily Rainbow Trout and  
 29 Kokanee Salmon. Other fish introduced to the reservoir include Striped Bass,  
 30 Largemouth Bass, sunfish, Brown Bullhead, and Channel Catfish (Reclamation  
 31 and CCWD 2011).

#### 32 **9.3.5.6 East Bay Municipal Utility District Reservoirs**

33 The EBMUD reservoirs in Alameda and Contra Costa County used to store water  
 34 within and near the EBMUD service area include Briones Reservoir, San Pablo  
 35 Reservoir, Lafayette Reservoir, Upper San Leandro Reservoir, and Lake Chabot.  
 36 Water stored in these reservoirs includes water from local watersheds, the  
 37 Mokelumne River watershed, and CVP water supplies, as described in Chapter 5,  
 38 Surface Water Resources and Water Supplies. San Pablo Reservoir is regularly  
 39 stocked with trout and catfish (EBMUD 2014). Other species caught in the  
 40 reservoir include crappie, Largemouth Bass, Smallmouth Bass, Spotted Bass, and  
 41 carp (OEHHA 2009).

1 CDFW annually stocks trout in Lafayette Reservoir. Other species found in the  
2 reservoir include Bluegill, black bass, Black Crappie, and several species of  
3 catfish (Lafayette Chamber of Commerce 2014).

4 Lake Chabot is stocked with hatchery-raised Rainbow Trout and Channel Catfish  
5 by EBRPD and CDFW for recreational fishing. The lake also supports a popular  
6 nonnative, warm-water recreational fishery for Largemouth Bass, Bluegill, and  
7 Black Crappie. Some native trout escape from the Upper San Leandro Reservoir  
8 during spill events and likely end up in Lake Chabot (EBMUD 2013).

### 9 **9.3.6 Central Coast Region**

10 The Central Coast Region includes portions of San Luis Obispo and Santa  
11 Barbara counties served by the SWP. SWP water is delivered to southern Santa  
12 Barbara County communities through Cachuma Lake.

#### 13 **9.3.6.1 Cachuma Lake**

14 Cachuma Lake is a facility owned and operated by Reclamation in Santa Barbara  
15 County. Cachuma Lake provides a variety of habitats for fish species, including  
16 deep-water areas, rocky drop-offs, shallow areas, and weed beds (wetland areas).  
17 Cachuma Lake and the upper Santa Ynez River are popular fishing areas that  
18 have been stocked with game fish by CDFW and the County of Santa Barbara.  
19 Native fish species in Cachuma Lake include steelhead/Rainbow Trout, Armored  
20 Three-Spine Stickleback, and Prickly Sculpin. Key game fish include  
21 Largemouth Bass, Smallmouth Bass, Bluegill, Green Sunfish, Redear Sunfish,  
22 Black Crappie, and White Crappie. Other species that have been identified in the  
23 lake include Channel Catfish, Black Bullhead, Threadfin Shad, goldfish, carp, and  
24 Mosquitofish (Reclamation 2010c).

### 25 **9.3.7 Southern California Region**

26 The Southern California Region includes portions of Ventura, Los Angeles,  
27 Orange, San Diego, Riverside, and San Bernardino counties served by the SWP.  
28 There are six SWP reservoirs along the main canal, West Branch, and East  
29 Branch of the California Aqueduct and many other reservoirs owned and operated  
30 by regional and local agencies. The Metropolitan Water District of Southern  
31 California's Diamond Valley Lake and Lake Skinner primarily store water from  
32 the SWP. Other reservoirs store SWP water, including United Water  
33 Conservation District's Lake Piru; City of Escondido's Dixon Lake; City of San  
34 Diego's San Vicente Reservoir and Lower Otay Reservoir; Helix Water District's  
35 Lake Jennings; and Sweetwater Authority's Sweetwater Reservoir.

#### 36 **9.3.7.1 State Water Project Reservoirs**

37 The SWP reservoirs include Quail Lake, Pyramid Lake, and Castaic Lake in Los  
38 Angeles County; Silverwood Lake and Crafton Hills Reservoir in San Bernardino  
39 County; and Lake Perris in Riverside County.

1 Although small compared to nearby Pyramid and Castaic lakes, Quail Lake's  
 2 290 acres and 3 miles of shoreline offer shoreline fishing. Striped Bass, Channel  
 3 Catfish, Blackfish, Tule Perch, Threadfin Shad, and Hitch have been found at  
 4 Quail Lake (DWR 1997).

5 Pyramid Lake is located in the Angeles and Los Padres National Forests, about  
 6 60 miles northwest of downtown Los Angeles. Largemouth Bass, Smallmouth  
 7 Bass, and Striped Bass as well as Bluegill, crappie, Brown Bullhead, Channel  
 8 Catfish, and trout are caught by anglers in Pyramid Lake (OEHHA 2013a).  
 9 Rainbow Trout, Bluegill, Green Sunfish, Largemouth Bass, catfish, and Prickly  
 10 Sculpin are found in Piru Creek below the dam (DWR 2004d).

11 Castaic Lake supports a warm-water fishery for Striped Bass and Largemouth  
 12 Bass. Bluegill and assorted minnows provide a forage base for the bass as well as  
 13 being caught by anglers. CDFW maintains a Rainbow Trout fishery in Castaic  
 14 Lake through stocking (DWR 2007).

15 Silverwood Lake is located in the San Bernardino National Forest and surrounded  
 16 by the Silverwood Lake State Recreation Area at the edge of the Mojave Desert  
 17 and at the base of the San Bernardino Mountains. Common sport fish caught in  
 18 Silverwood Lake include stocked Rainbow Trout, Largemouth Bass, Bluegill,  
 19 carp, crappie, catfish, and Striped Bass (CSP 2010, OEHHA 2013b). Other  
 20 species found in the lake include blackfish, Brown Bullhead, Tui Chub, and Tule  
 21 Perch (OEHHA 2013b).

22 The Crafton Hills Reservoir area includes 4.5 acres of open water and 1.9 acres of  
 23 open space. One fish species, Mosquitofish, was observed in the reservoir  
 24 (DWR 2009b).

25 Lake Perris is located within the Lake Perris State Recreation Area, which  
 26 provides extensive recreational opportunities, as described in Chapter 15,  
 27 Recreation Resources. Lake Perris is stocked with Rainbow Trout and managed  
 28 as a recreational fishery. Common fish species in the lake include Largemouth  
 29 Bass, Channel Catfish, Bluegill, Spotted Bass, Flathead Catfish, Green Sunfish,  
 30 Redear Sunfish, and Black Crappie (DWR 2010). Other species found in the lake  
 31 include Inland Silversides and Threadfin Shad (DWR 2007).

### 32 **9.3.7.2 Non-SWP Reservoirs in Riverside County**

33 Diamond Valley Lake and Lake Skinner in Riverside County are offstream  
 34 storage facilities owned and operated by Metropolitan Water District of Southern  
 35 California. These lakes are major reservoirs used to store SWP water. Diamond  
 36 Valley Lake supports Largemouth Bass, Striped Bass, catfish, Redear Sunfish,  
 37 Bluegill, and stocked Rainbow Trout (DVM 2014). Fish species found in Lake  
 38 Skinner include Striped Bass, Largemouth Bass, carp, and Bluegill. The  
 39 Metropolitan Water District also stocks catfish in summer and trout in winter  
 40 (Riverside County 2014).

1     **9.3.7.3     Non-SWP Reservoir in Ventura County**

2     Lake Piru, located in Ventura County, is used to store SWP water by United  
3     Water Conservation District. Like Pyramid Lake upstream on Piru Creek, sport  
4     fish species in Lake Piru include trout, Largemouth Bass, catfish, crappie,  
5     Bluegill, and Redear Sunfish (CA Lakes 2014). Other species found there include  
6     Bigscale Logperch, Black Bullhead, carp, goldfish, Golden Shiner, Green  
7     Sunfish, and Inland Silversides (CalFish 2014).

8     **9.3.7.4     Non-SWP Reservoirs in San Diego County**

9     Reservoirs in San Diego County that are used to store SWP water include the City  
10    of Escondido's Dixon Lake; City of San Diego's San Vicente, El Capitan, and  
11    Lower Otay reservoirs; Helix Water District's Lake Jennings; and Sweetwater  
12    Authority's Sweetwater Reservoir.

13    Dixon Lake is located in the hills above the City of Escondido within the  
14    Escondido Multiple Habitat Conservation Plan area (City of Escondido 2012).  
15    Fish species found in Dixon Lake include Rainbow Trout, Channel Catfish,  
16    Bluegill, Largemouth Bass, Striped Bass, and Black Crappie (SDFish 2014).

17    San Vicente Reservoir has been stocked with various sport fish including sunfish,  
18    Largemouth Bass, Black Crappie, catfish, and Rainbow Trout. Other species  
19    found in the reservoir include Threadfin Shad and Prickly Sculpin (SDCWA and  
20    USACE 2008). El Capitan reservoir is stocked with Largemouth Bass, crappie,  
21    Bluegill, Channel Catfish, Blue Catfish, Green Sunfish, and Common Carp (City  
22    of San Diego 2014a). Fish species in Lower Otay Reservoir include Largemouth  
23    Bass, Bluegill, Black Crappie, White Crappie, Channel Catfish, Blue Catfish,  
24    White Catfish, and bullheads (City of San Diego 2014b).

25    Lake Jennings is regularly stocked with trout and Channel Catfish. Other species  
26    found in the lake are Bluegill, Largemouth Bass and Blue Catfish (SDFish 2015).

27    Eleven fish species were observed in Sweetwater Reservoir during biological  
28    surveys for the wetlands habitat recovery project, all of which were nonnative and  
29    typical of southern California warm-water lakes. Species observed include  
30    Channel Catfish, Threadfin Shad, Bluegill, and Largemouth Bass (Sweetwater  
31    Authority 2013).

32    **9.3.7.5     Non-SWP Reservoir in San Bernardino County**

33    Lake Arrowhead, in San Bernardino County, is used to store SWP water by the  
34    Lake Arrowhead Community Services District (County of San Bernardino 2011;  
35    LACSD 2014a, 2014b). Lake Arrowhead is a private lake, and its use is restricted  
36    to homeowners in a tract of land roughly 1 mile around the perimeter of the lake,  
37    known as Arrowhead Woods. Fish species found in the lake include trout,  
38    Kokanee Salmon, bass, catfish, crappie, sunfish, and carp.

39    **9.3.7.6     Fish and Aquatic Resources During Drought**

40    California is contending with its fourth consecutive year of drought where  
41    significant shortages in water supplies have profoundly influenced water use in  
42    the state, including environmental uses. The reduced water availability has

1 depleted reservoir storage and the ability for operations to provide flow levels  
2 needed to support fish habitat within the river systems. In addition, the limited  
3 cold water held in CVP and SWP reservoirs has impaired the ability to manage  
4 water temperatures downstream. Similarly, the reduced flows in the Delta have  
5 resulted in shifts in salinity and water quality that influence the availability and  
6 quality of habitat for pelagic fishes as well as the factors that influence  
7 entrainment. As a consequence, the reduction in runoff and available water has  
8 likely compromised an already stressed aquatic ecosystem and may have further  
9 imperiled species that are threatened with or in danger of extinction.

10 As described in the sections above, many fish populations have been in decline  
11 over the last several years. There are undoubtedly multiple factors influencing  
12 this decline; however, the recent drought and actions taken to address the drought  
13 are clearly contributors. In the recent conditional approval by the SWRCB of  
14 Reclamation's Temporary Urgency Change Petition (SWRCB 2015), the SWRCB  
15 summarized the effects of the recent drought conditions on aquatic resources  
16 based on a biological review conducted for the purposes of consultation with  
17 NMFS and USFWS. The summaries from that document (SWRCB 2015) for  
18 several key species are paraphrased below.

19 The population of winter-run Chinook salmon is currently at extreme risk. In  
20 2014, due to a lack of ability to regulate water temperatures in September and  
21 October, high water temperatures in the Sacramento River reduced early life stage  
22 survival from Keswick to Red Bluff from a recent average of approximately  
23 27 percent down to 5 percent in 2014. Consequently, 95 percent of the year class  
24 of wild winter-run Chinook was lost last year (Reclamation and DWR 2015).  
25 Temperature management was difficult again in 2015, which reduces this  
26 population's ability to withstand environmental perturbations, especially during a  
27 prolonged drought when each of the existing brood years has been already  
28 negatively affected by drought conditions.

29 The 2014 spawning run of spring-run Chinook Salmon returning to the upper  
30 Sacramento River system also experienced significant impacts due to drought  
31 conditions as well as elevated temperatures on the Sacramento River and other  
32 tributaries. Similar to winter-run, spring-run Chinook Salmon eggs in the  
33 Sacramento River experienced significant and potentially complete mortality  
34 starting in early September 2014 due to high water temperatures downstream of  
35 Keswick. Extremely few juvenile spring-run Chinook Salmon were observed  
36 migrating downstream of the Sacramento River during high winter flows in 2015,  
37 when spring-run originating from the upper Sacramento River, Clear Creek, and  
38 other northern tributaries are typically observed, indicating that the population  
39 was significantly impacted. Similar concerns for spring-run Chinook Salmon exist  
40 this year as for winter-run. While spring-run have greater distribution and inhabit  
41 locations in addition to the Sacramento River, conditions on those streams are  
42 also expected to be poor due to the drought.

43 Steelhead have also likely been affected by the drought, but given the difficulty in  
44 sampling for these fish it is difficult to determine exactly how the species have  
45 been affected. Adult steelhead abundance is not estimated in the mainstem

1 Sacramento River or any waterways of the Central Valley. The drought conditions  
2 are causing increased stress to steelhead populations (with or without water  
3 project operations) from low flows causing reduced rearing and migratory habitat,  
4 increased water temperatures affecting survival, and likely higher than normal  
5 juvenile predation.

6 The effects of the drought are also reflected in Delta species. For example, recent  
7 population indices for Delta Smelt are at record low numbers. This is of  
8 particular concern given that most Delta Smelt do not survive to spawn more than  
9 one season and are thus for the most part an annual species. The fifth Spring  
10 Kodiak Trawl survey conducted the week of May 4, 2015, identified 4 adults in  
11 the Sacramento Deep Water Ship Channel, and one in Cache Slough. The fourth  
12 Spring Kodiak Trawl survey, conducted during the week of April 6, 2015,  
13 identified one adult, which was a record low for that survey (Smelt Working  
14 Group (SWG); 4 May 13 notes). According to the SWG, it appears fish density  
15 has become so low that the Spring Kodiak Trawl has reached or gone below its  
16 minimum effective detection ability (SWG; April 13 Notes). Additionally, in the  
17 final week (March 30) of supplemental USFWS sampling in the lower San  
18 Joaquin River, catch of adult Delta Smelt declined precipitously to zero in the  
19 final month of sampling.

20 In response to the drought and its adverse effects on aquatic resources,  
21 Reclamation is currently conditionally operating under the terms of a temporary  
22 urgency change petition that allows temporary changes to license and permit  
23 requirements imposed pursuant to SWRCB D-1641 to meet flow-dependent and  
24 water quality objectives to protect fish and wildlife beneficial uses. In  
25 compliance with the provisions of the BOs, Reclamation and the SWRCB have  
26 received concurrence on the changes from USFWS and NMFS (USFWS 2015,  
27 NMFS 2015).<sup>4</sup>

## 28 **9.4 Impact Analysis**

29 This section describes the potential mechanisms and analytical methods; results of  
30 the impact analyses; potential mitigation measures; and cumulative effects.

### 31 **9.4.1 Potential Mechanisms and Analytical Methods**

32 The impact analysis considers changes in the ecological attributes that affect fish  
33 and aquatic resources related to changes in CVP and SWP operations under the  
34 alternatives as compared to the No Action Alternative and the Second Basis of  
35 Comparison.

---

<sup>4</sup> Additional information regarding CVP and SWP operations under a TUC Order issued on July 3, 2015, by the State Water Resources Control Board is provided at: [http://www.waterboards.ca.gov/waterrights/water\\_issues/programs/drought/docs/tucp/2015/tucp\\_order070315.pdf](http://www.waterboards.ca.gov/waterrights/water_issues/programs/drought/docs/tucp/2015/tucp_order070315.pdf).

#### 1 **9.4.1.1 CVP and SWP Reservoirs**

2 Changes in CVP and SWP operations under the alternatives could result in  
3 changes in reservoir storage volumes, elevations, and water temperatures in the  
4 primary water supply reservoirs (i.e., Trinity Lake, Shasta Lake, Lake Oroville,  
5 Folsom Lake, New Melones Lake, and San Luis Reservoir). Variation in  
6 reservoir storage, elevation, and temperature is a function of water demand, water  
7 quality requirements, and inflow; these attributes also change based on the  
8 water-year type.

9 The downstream reservoirs (i.e., Lewiston Lake, Keswick Reservoir, Thermalito  
10 Forebay and Afterbay, Lake Natoma, and Tulloch Reservoir) are operated to  
11 maintain relatively stable water elevations. These types of operations would  
12 result in similar conditions in the No Action Alternative, Alternatives 1 through 5,  
13 and the Second Basis of Comparison. Therefore, changes at these reservoirs are  
14 not evaluated in this EIS.

##### 15 **9.4.1.1.1 Changes in CVP and SWP Reservoir Storage Volume**

16 To evaluate changes in operation, changes in reservoir storage and elevation were  
17 estimated based upon modeled monthly average storage and reservoir elevation  
18 output from CalSim II for the entire 82-year period under the operations defined  
19 for each alternative, as described in Appendix 5A, CalSim II and DSM2  
20 Modeling. The output of CalSim II served as input to the quantitative procedures  
21 described below for evaluation of changes in fish habitat and bass nesting success  
22 in CVP and SWP reservoirs.

23 The effects analysis in Chapter 5, Surface Water Resources and Water Supplies,  
24 includes a summary of the monthly storage in each major upstream reservoir in  
25 combination with a frequency of exceedance analysis for each month. Reservoir  
26 storage values are characterized based on results of CalSim II hydrologic  
27 modeling and presented as average monthly storage by water year type. Although  
28 aquatic habitat within the CVP and SWP water supply reservoirs is not thought to  
29 be limiting, storage volume is used as an indicator of how much habitat is  
30 available to fish species inhabiting these reservoirs.

##### 31 **9.4.1.1.2 Changes in CVP and SWP Reservoir Elevation**

32 Seasonal temperature stratification is a dominant feature of these reservoirs.  
33 There are relatively distinct fish assemblages within the upper (warm water) and  
34 lower (cold water) habitat zones, with different feeding and reproductive  
35 behaviors. Flood control, water storage, and water delivery operations typically  
36 result in declining water elevations during the summer through the fall months,  
37 rising or stable elevations during the winter months, and rising elevations during  
38 the spring months, while storing precipitation and snowmelt runoff. During  
39 summer months, the relatively warm surface layer favors warm water fishes such  
40 as bass and catfish. Deeper layers are cooler and are suitable for cold water  
41 species. Drawdown of reservoir storage from June through October can diminish  
42 the volume of cold water, thereby reducing the amount of habitat for cold water  
43 fish species within these reservoirs during these months.

1 Reservoir storage and surface water elevations in the reservoirs from the  
2 CalSim II model were used to analyze potential effects on reservoir fishes. Water  
3 surface elevation in each reservoir was calculated from storage values and is  
4 presented as average end-of-month elevation by water year type.

5 Warm water fish species that inhabit the upper layer of these reservoirs may be  
6 affected by fluctuations in storage through changes in reservoir water surface  
7 elevations (WSELs). Stable or increasing WSEL during spring months (March  
8 through June) can contribute to increased reproductive success, young-of-the-year  
9 production, and juvenile growth rate of several warm water species, including the  
10 black basses. Conversely, reduced or variable WSEL due to reservoir drawdown  
11 during spring spawning months can cause reduced spawning success for warm  
12 water fishes through nest dewatering, egg desiccation, and physical disruption of  
13 spawning or nest guarding behaviors. Increases in WSEL are not thought to result  
14 in adverse effects on these species unless there is a corresponding decrease in  
15 water temperatures that can result in nest abandonment.

16 A conceptual approach was used to evaluate the effects of water surface elevation  
17 fluctuations on bass nests, based upon a relationship between black bass nest  
18 success and water surface elevation reductions developed by CDFW (Lee 1999)  
19 from research conducted on five California reservoirs. Lee (1999) examined the  
20 relationship between water surface elevation fluctuation rates and nesting success  
21 for black bass, and developed nest survival curves for Largemouth, Smallmouth,  
22 and Spotted bass. The equations corresponding to the curves are the following:

23           Largemouth Bass  $Y = -56.378 \cdot \ln(X) - 102.59$

24           Smallmouth Bass  $Y = -46.466 \cdot \ln(X) - 83.34$

25           Spotted Bass  $Y = -79.095 \cdot \ln(X) - 94.162$

26 Where: X is the fluctuation rate (m/day) and Y is the percentage of successful  
27 nests.

28 Based on the work by Lee (1999), the maximum receding water level rate  
29 providing 100 percent successful nesting varied among species, with receding  
30 water level rates of <0.02, <0.01, and <0.065 meters per day providing successful  
31 nesting of 100 percent of the Largemouth, Smallmouth, and Spotted bass nests,  
32 respectively. For this analysis, water surface elevations at the end of each month  
33 from the CalSim II model were used to calculate the monthly fluctuation rates,  
34 and derive the daily fluctuation rates used to compute the percentage of successful  
35 nests using the equations from Lee (1999).

36 CalSim II reports end-of-month (EOM) water surface elevations; therefore, water  
37 surface elevations from February to June were used in this analysis (i.e., March  
38 fluctuation rate = March EOM elevation – February EOM elevation). It was  
39 further assumed that the monthly change in elevation divided by the number of  
40 days in that month reflected the average daily fluctuation rate that was used as  
41 “X” in the above equations to compute the percentage of successful nests during  
42 that month. The percentages of successful bass nests were computed based on the

1 equations from Lee (1999) for each month of the potential spawning season for  
2 these species.

3 Review of the available literature suggests that bass nest failure is highly variable  
4 between water bodies and between years but it is not uncommon to have up to  
5 40 percent of bass nests fail (approximately 60 percent survival) (Scott and  
6 Crossman 1973). Many self-sustaining black bass populations in North America  
7 experience a nest success (i.e., the nest produces swim-up fry) rate of 21 to  
8 96 percent, with many reporting survival rates in the 40 to 60 percent range  
9 (Forbes 1981; Hunt and Annett 2002; Steinhart 2004). This would suggest that  
10 much less than 100 percent survival is required to have a self-sustaining  
11 population. Based on the literature review, bass nest survival probability in  
12 excess of 40 percent is assumed to be sufficient to provide for a self-sustaining  
13 bass fishery. For this analysis, differences between alternatives were evaluated  
14 using the exceedance probability corresponding to the 40 percent level of survival  
15 based on the probability of exceedance over the 82-year CalSim II modeling time  
16 period.

#### 17 **9.4.1.2 Rivers**

18 By altering reservoir storage and releases, changes in CVP and SWP operations  
19 under the alternatives would change flow and temperature regimes in downstream  
20 waterways. In turn, these alterations could affect fishery resources and important  
21 ecological processes on which the fish community depends.

##### 22 **9.4.1.2.1 Changes in Flows**

23 Changes in flows, in and of themselves, do not constitute an effect on aquatic  
24 resources. However, changes in flow can affect the quantity and quality of  
25 aquatic habitats in rivers and have direct effects on fish species through stranding  
26 or dewatering events that occur when flows are reduced. In addition, changes in  
27 flows can result in a reduction in ecologically important geomorphic processes  
28 resulting from reduced frequency and magnitude of intermediate to high flows.

29 Changes in flow also can influence the frequency and duration of inundated  
30 floodplains (e.g., Yolo Bypass) that support salmonid rearing and conditions for  
31 other native fish species. With implementation of the physical actions under  
32 NMFS RPA Action I.6.1, the inundation regime in the Yolo Bypass will be  
33 modified and managed to better coincide with the presence of juvenile salmonids  
34 and with a greater frequency. While this action is included in every alternative,  
35 changes in flows in the Sacramento River at the Freemont Weir associated with  
36 the various alternatives could result in slight differences in the flows entering the  
37 bypass and changes in the amount of habitat available to rearing salmonids and  
38 other native fish species.

39 The effects analysis in Chapter 5, Surface Water Resources and Water Supplies,  
40 includes a summary of the monthly flows at various points downstream of the  
41 reservoirs in each major stream affected by project operations. Instream flows are  
42 characterized based on results of CalSim II hydrologic modeling and presented as  
43 both average monthly flows by month and water year type and monthly frequency

1 of exceedance plots to allow examination of the entire range of simulation results  
2 for each of the alternatives as a means of evaluating differences among  
3 alternatives. Because the CalSim II model uses a monthly time step, it was  
4 determined that incremental changes of 5 percent or less were related to the  
5 uncertainties in the model processing. Therefore, flow changes of 5 percent or  
6 less are considered to be not substantially different, or “similar” in this  
7 comparative analysis.

8 To compare the operational flow regime and evaluate the potential effects on  
9 habitat for anadromous species inhabiting streams, it was necessary to determine  
10 the relationships between streamflow and habitat availability for each life stage of  
11 these species in the rivers in which flows may be altered by CVP and SWP  
12 operations.

13 A number of studies have been conducted using the models and techniques  
14 contained within the Instream Flow Incremental Methodology (IFIM) to establish  
15 these relationships in streams within the study area. The analytic variable  
16 provided by the IFIM is total habitat, in units of Weighted Useable Area (WUA),  
17 for each life stage (fry, juvenile and spawning) of each evaluation species (or race  
18 as applied to Chinook Salmon). Habitat (WUA) incorporates both macro- and  
19 microhabitat features. Macrohabitat features include changes in flow, and  
20 microhabitat features include the hydraulic and structural conditions (depth,  
21 velocity, substrate or cover) affected by flow which define the actual living space  
22 of the organisms. The total habitat available to a species/life stage at any  
23 streamflow is the area of overlap between available microhabitat and  
24 macrohabitat conditions. Because the combination of depths, velocities, and  
25 substrates preferred by species and life stages varies, WUA values at a given flow  
26 differ substantially for the species and life stages evaluated.

27 WUA-flow relationships were available only for some rivers for which simulated  
28 flows were available. Therefore, flow dependent habitat availability was  
29 evaluated quantitatively only for Clear Creek and the Sacramento, Feather, and  
30 American rivers, and was not reported for other rivers evaluated in this Draft EIS.  
31 Tables of the spawning habitat-discharge relationships used in the calculations of  
32 spawning WUA for these rivers are provided in Appendix 9E, Weighted Useable  
33 Area Analysis. Because the WUA-flow relationships developed by the most  
34 recent IFIM studies present WUA values within particular flow ranges at  
35 particular variable steps, it was often the case that the monthly flow for a  
36 particular reach fell between two flows for which there were WUA values. In  
37 these cases, the value was determined by linear interpolation between the  
38 available WUA values for the flows immediately below and above the target  
39 flow. When the target flow was lower than the lowermost flow for which a WUA  
40 value exists, the corresponding WUA value was determined by linear  
41 interpolation between a flow of zero and the lowermost flow for which a WUA  
42 value exists. When the target flow was higher than the highest flow for which a  
43 WUA value exists, the corresponding WUA value was determined by assuming  
44 the WUA value for the highest flow.

1 WUA values are calculated and presented only on a monthly time-step, and not as  
2 seasonal or annual values. WUA values based on the monthly CalSim II flows  
3 were prepared for detailed evaluation of the alternatives. Monthly WUA values  
4 are presented as the average total WUA in each river segment, for the entire  
5 82-year simulation period and the average total WUA in each of five water year  
6 types for each alternative. Differences between the alternatives and the two bases  
7 of comparison (No Action Alternative and Second Basis of Comparison) are used  
8 to identify the effects of each alternative on habitat availability (WUA) for each  
9 species and life stage in each river. These comparisons were made only for the  
10 months in which the species and life stage are anticipated to be present in each  
11 river/reach based on the life history timing presented in Appendix 9B.

12 The ability to estimate sub-monthly WUA values is limited due to the monthly  
13 time-step of the CalSim II results. The monthly time-step is most limiting during  
14 the fall through spring seasons in areas downstream of tributaries, when flows can  
15 vary significantly on a daily basis due to hydrologic conditions. Hydrologic  
16 variability in the runoff and tributary flows cause significant variability of flows  
17 in the areas of interest for the WUA computations. During the periods of low  
18 flows, regulated flows from reservoir releases dampen the impact of daily  
19 variability of flows on WUA estimates. Because the WUA analysis uses output  
20 from the monthly time step CalSim II model, it was determined that incremental  
21 changes of 5 percent or less were related to the uncertainties in the model  
22 processing. Therefore, changes in WUA values of 5 percent or less are  
23 considered to be not substantially different, or “similar” in this comparative  
24 analysis.

#### 25 **9.4.1.2.2 Changes in Water Temperatures**

26 Water temperatures in the rivers and streams downstream of the CVP and SWP  
27 reservoirs are influenced by factors such as reservoir cold water pool, elevation of  
28 reservoir release outlets, and seasonal atmospheric conditions. The level of water  
29 storage in a reservoir has a strong effect on the volume of cold water (cold water  
30 pool) in the reservoir and, in combination with the elevation of reservoir release  
31 outlets, the temperature of water released downstream. Storage levels are often  
32 lowest in the late summer and early fall, resulting in warmer waters released from  
33 the reservoir. During this time of year, ambient air temperatures contribute  
34 substantially to warming instream flows downstream of reservoirs. The summer  
35 and early fall are the times of year when river temperatures are most likely to rise  
36 above tolerance thresholds for steelhead and salmon.

37 The analysis of the effects of water temperature changes on fish was conducted  
38 using two approaches: 1) a comparison of average monthly water temperatures  
39 between the alternatives and the two bases of comparison (No Action  
40 Alternative and Second Basis), and 2) a comparison of average monthly water  
41 temperatures to established temperature objectives intended to be protective of  
42 fish. In addition, Reclamation’s salmon mortality model was applied in certain  
43 water bodies to examine the effects of temperature on salmon spawning and  
44 incubation. These approaches are described below.

1 *Comparison of Average Monthly Water Temperatures between Alternatives*

2 The analysis uses average water monthly temperatures to provide a comparison of  
3 the ability of operations considered under alternatives to meet water temperature  
4 objectives for various species. As described in Appendix 5A, Section 5A.A.3.6,  
5 water temperature modeling is subsequent to CalSim II modeling that simulates  
6 operations on a monthly basis; there are certain components in the temperature  
7 models that are downscaled to a daily time step (simulated or approximated  
8 hydrology). The results of those daily conditions are averaged to a monthly  
9 time step.

10 The effects analysis in Chapter 6, Surface Water Quality, includes a summary of  
11 the average monthly water temperature in each major stream downstream of CVP  
12 and SWP reservoirs in combination with a frequency of temperature exceedance  
13 analysis (see below) for each month. Water temperatures at various locations in  
14 each river were compared to determine whether mean monthly temperatures by  
15 water-year type were different between the alternatives and the two bases of  
16 comparison (No Action Alternative and Second Basis). Because the temperature  
17 models use inputs from the monthly-time-step CalSim II model, effects of real-  
18 time daily temperature management cannot be captured, even though the  
19 temperature models are capable of simulating on a sub-monthly timestep.  
20 Therefore, the analysis is based on monthly average temperature results. For this  
21 monthly analysis that uses two cascading models, it was determined that  
22 incremental changes of 0.5°F or less in mean monthly water temperatures would  
23 be within the model uncertainty. Therefore, changes of 0.5°F or less are  
24 considered to be not substantially different, or “similar” in this comparative  
25 analysis.

26 *Comparison to Established Water Temperature Thresholds*

27 The average monthly water temperature output from CalSim II does not allow a  
28 direct comparison to the temperature objectives identified in Table 9.3, and the  
29 effects of daily (or hourly) temperature swings are likely masked by the averaging  
30 process. Nonetheless, the average monthly water temperatures provide the basis  
31 for a coarse evaluation of the likelihood that temperature objectives (Table 9.3)  
32 would be exceeded. These objectives are used as thresholds in the temperature  
33 exceedance analysis where the frequency of exceedance (percent of years) is  
34 calculated over the 82-year CalSim II modeling period (Appendix 9N). Because  
35 average monthly water temperatures likely mask daily temperatures that could  
36 exceed important thresholds, any difference in the frequency of threshold  
37 exceedance was considered important and could be indicative of a biological  
38 effect on the species/life stage for which the objective was established. While  
39 likely effects from temperature on early life stages occur at a shorter temporal  
40 scale than can be captured in these models, comparative analyses are useful for  
41 looking at long term impacts over numerous water years and types.

1 **Table 9.3 Water Temperature Objectives**

Compliance Location	Year Types	Dates	Temperature Objective (°F)	Purpose
<b>Trinity River</b>				
Lewiston Dam Release	All Year Types	July–Sep	< 60	Spring-run Chinook Salmon holding
		Sep	< 56	Spring-run Chinook Salmon spawning
Lewiston Dam Release	All Year Types	Oct–Dec	< 56	Chinook Salmon, Coho Salmon, and steelhead spawning
<b>Clear Creek</b>				
Igo W	All Year Types	June–Sep 15	60	Spring-run Chinook Salmon holding and rearing
		Sep 15-Oct	56	Spring-run and fall-run Chinook Salmon spawning and egg incubation
<b>Sacramento River</b>				
Keswick Release	All Year Types	May–Sep	56	Winter- and spring-run Chinook Salmon spawning and egg incubation
Balls Ferry	All Year Types	May–Sep	56	Winter- and spring-run Chinook Salmon spawning and egg incubation
Bend Bridge	All Year Types	May–Sep	56	Winter- and spring-run Chinook Salmon spawning and egg incubation
			63	Green sturgeon spawning, incubation, and rearing
Red Bluff	All Year Types	Oct–Apr	56	Spring-, fall-, and late fall–run Chinook Salmon spawning and egg incubation
Hamilton City	All Year Types	Mar–Jun	61 (optimal), 68 (lethal)	White Sturgeon spawning and egg incubation
<b>Feather River</b>				
Robinson Riffle	All Year Types	Sep–Apr	56	Spring-run Chinook Salmon and steelhead spawning and incubation
		May–Aug	63	Spring-run Chinook Salmon and steelhead rearing

Compliance Location	Year Types	Dates	Temperature Objective (°F)	Purpose
Gridley Bridge	All Year Types	Oct–Apr	56	Fall- and late fall–run Chinook Salmon spawning and steelhead rearing
		May–Sep	64	Green sturgeon spawning, incubation, and rearing
<b>American River</b>				
Watt Avenue Bridge	All Year Types	May–Oct	65	Juvenile steelhead rearing
<b>Stanislaus River</b>				
Orange Blossom Bridge	All Year Types	Oct–Dec	56	Adult steelhead migration
		Jan– May	57	Steelhead smoltification
		Jan-May	55	Steelhead spawning and incubation
		Jun-Sep	65	Juvenile steelhead rearing
Knights Ferry	All Year Types	Jan-May	52	Steelhead smoltification

1 *Changes in Egg Mortality*

2 Water temperatures also affect the survival of various life stages of the focal  
3 species. Reclamation’s salmon mortality model (Appendix 9C, Reclamation  
4 Salmon Mortality Model Analysis Documentation) was used to estimate water  
5 temperature induced mortality in the early life stages (pre-spawned eggs,  
6 fertilized eggs, and pre-emergent fry) of salmonids in five rivers: Trinity,  
7 Sacramento, Feather, American, and Stanislaus, based on output from the  
8 temperature models. The salmon mortality model is limited to temperature effects  
9 on early life stages of Chinook Salmon. It does not evaluate potential direct or  
10 indirect temperature impacts on later life stages, such as emergent fry, smolts,  
11 juvenile out-migrants, or adults. Also, it does not consider other factors that may  
12 affect salmon mortality, such as in-stream flows, gravel sedimentation, diversion  
13 structures, predation, and ocean harvest. Differences between alternatives are  
14 assessed based on changes in the percent egg mortality by river over the entire  
15 82-year CalSim II simulation period and by water year type (based on 40-30-30  
16 indexing). Because the salmon mortality model uses output from the temperature  
17 models that are downscaled from the monthly time step CalSim II model, it was  
18 determined that incremental changes in egg mortality of 5 percent or less were  
19 related to the uncertainties in the model processing. Therefore, changes in egg

1 mortality of 5 percent or less are considered to be not substantially different, or  
2 “similar” in this comparative analysis.

### 3 **9.4.1.3 Delta**

4 Changes in CVP and SWP operations under the alternatives would affect Delta  
5 conditions primarily through changes in volume and timing of upstream storage  
6 releases and diversions, Delta exports and diversions, and DCC operations.  
7 Environmental conditions such as water temperature, predation, food production  
8 and availability, competition with introduced exotic fish and invertebrate species,  
9 and pollutant concentrations all contribute to interactive, cumulative conditions  
10 that have substantial effects on aquatic resources in the Delta.

#### 11 **9.4.1.3.1 Changes in Volume and Timing of Flows through the Delta**

12 Operations of the CVP DCC and intake facilities owned by the CVP, SWP, local  
13 agencies, and private parties affect Delta hydrologic flow regimes. The largest  
14 effects of flow management in the Delta related to aquatic resources are the  
15 modification of winter and spring inflows and outflows of the Delta, and the  
16 introduction of net cross-Delta and net reverse flows in some Delta channels that  
17 can alter fish movement patterns. Seasonal flows play an especially important  
18 role in determining the reproductive success and survival of many estuarine  
19 species including salmon, Striped Bass, American Shad, Delta Smelt, Longfin  
20 Smelt, and Sacramento Splittail. In addition, changes in Delta outflow influence  
21 the abundance and distribution of fish and invertebrates in the bay through  
22 changes in salinity, currents, nutrient levels, and pollutant concentrations. Altered  
23 flows through the Delta as a result of changes in CVP and SWP operations affect  
24 water residence time, an important physical property that can influence the ability  
25 of phytoplankton biomass to build up over time, with implications for higher  
26 trophic level consumers such as fish.

#### 27 **9.4.1.3.2 Changes in Water Quality**

28 Changes in water quality due to CVP and SWP operations under the alternatives  
29 would affect aquatic resources in the Delta primarily through changes in water  
30 temperatures, salinity, nutrient levels, pollutant concentrations and turbidity.  
31 Changes in CVP and SWP operations can increase Delta water temperatures by  
32 warmer reservoir releases and to a lesser extent, by reducing quantities of  
33 freshwater inflow and by modifying tidal and ground water hydraulics. Changes  
34 in CVP and SWP operations also can affect the location of the low salinity zone  
35 (position of X2), especially during periods of low inflows and high water exports  
36 (i.e., low outflow conditions) in drier water years. Nutrients, essential  
37 components of terrestrial and aquatic environments because they provide a  
38 resource base for primary producers, and pollutants such as selenium and mercury  
39 could be affected by changes in CVP and SWP operations. Turbidity is an  
40 important water quality component in the Delta that could be affected by changes  
41 in operation. Changes in turbidity affect food web dynamics through attenuation  
42 of light in the water column and altering predation success.

1 The DSM2, a one-dimensional hydrodynamic and water quality simulation  
2 model, is used to evaluate changes in salinity (as represented by EC) in the Delta  
3 and at the CVP/SWP export locations. CalSim II outputs are used to evaluate  
4 changes in location of X2 in the Delta. A more detailed overview of the DSM2  
5 model and input assumptions is presented in Appendix 5A, CalSim II and DSM2  
6 Modeling.

7 The Delta boundary flows and exports from CalSim II are used as input to the  
8 DSM2 Delta hydrodynamic and water quality models to estimate tidally-based  
9 flows, stage, velocity, and salt transport within the estuary. Because CalSim II  
10 operations are simulated on a monthly basis, the DSM2 model would not be able  
11 to capture daily operations and therefore the DSM2 outputs are presented on a  
12 monthly basis, as described in Appendix 5A, CalSim II and DSM2 Modeling.

13 DSM2 HYDRO outputs are used to predict changes in flow rates and depths. The  
14 QUAL module of DSM2 simulates fate and transport of conservative and non-  
15 conservative water quality constituents, including salts, given a flow field  
16 simulated by HYDRO. Chloride and bromide concentrations are estimated using  
17 relationships based on DSM2 EC results, as described in Appendix 6E, Analysis  
18 of Delta Salinity Indicators.

19 The CalSim II outputs described above that estimate the position X2 were used  
20 along with temperature to generally assess effects on Striped Bass and American  
21 Shad. Kimmerer (2002) noted that Striped Bass survival is negatively correlated  
22 with April – June X2 values, although the analysis was inconclusive on the  
23 mechanisms contributing to this relationship. Kimmerer (2009) noted that Delta  
24 Smelt and Striped Bass had more negative slopes in the habitat-X2 relationship  
25 for surveys conducted in spring to early summer months than other surveys. They  
26 also noted that the slopes for abundance-X2 and habitat-X2 were similar for  
27 American Shad and for Striped Bass, and that the habitat relationships to X2  
28 appeared consistent with their relationships of abundance (or survival) to X2.  
29 Thus, Kimmerer et al. (2009) contended that this similarity provides some support  
30 for the notion that increasing habitat quantity as defined by salinity could be one  
31 mechanism to explain the X2 relationship for these species. Based on this  
32 relationship, the position of X2 was used as general indicator of habitat for  
33 Striped Bass and American Shad. Alternatives that resulted in a more westerly  
34 position of X2 relative to the bases of comparison were considered to have less  
35 potential for adverse effect, whereas those with a more easterly position would  
36 have a greater potential for adverse effect.

### 37 **9.4.1.3.3 Changes in Fish Entrainment**

38 Changes in CVP and SWP operations can affect through-Delta survival of  
39 migratory (e.g., salmonids) and resident (e.g., Delta and Longfin smelt) fish  
40 species through changes in the level of entrainment at CVP and SWP export  
41 pumping facilities. The south Delta CVP and SWP facilities are the largest water  
42 diversions in the Delta and in the past, have entrained large numbers of Delta fish  
43 species. Tides, salinity, turbidity, in-flow, meteorological conditions, season,  
44 habitat conditions, and project exports all have the potential to influence fish

1 movement, currents, and ultimately the level of entrainment and fish passage  
2 success and survival. Entrainment risk for fish also tends to increase with  
3 increased reverse flows in Old and Middle rivers.

4 The potential for entrainment of salmonids migrating through the Delta was  
5 analyzed using predicted monthly salvage of salmonids from January through  
6 June using statistical relationships reported in Zeug and Cavallo (2014). In that  
7 analysis, salvage at the State Water Project and Central Valley Project was  
8 modeled as a function of physical, biological and hydrologic variables (see  
9 Appendix 9M for additional detail).

10 Results of the analysis are presented in box-whisker plots showing the median,  
11 central 50 percent probability, and range of simulated data. The comparison  
12 between alternatives relied on interpretation of these plots to distinguish  
13 differences in the median values as follows: (1) when the medians are nearly  
14 identical or the central 50 percent probabilities (i.e., the boxes) overlap  
15 completely, the medians were considered “similar;” (2) when the medians and  
16 box were offset, but the median values were within the range represented by the  
17 contrasting alternative’s box, the medians were considered “slightly” different;  
18 (3) when the median of one alternative was outside of the contrasting alternative’s  
19 box, but the boxes overlapped, the alternatives were considered “moderately”  
20 different; and (4) when the median of one alternative was outside of the  
21 contrasting alternative’s box, and the boxes did not overlap, the medians were  
22 considered “substantially” different.

23 In evaluating the potential for entrainment of Delta Smelt, as influenced by OMR  
24 flows under the alternatives, the USFWS (2008) regression model based on  
25 Kimmerer (2008) was used to estimate potential entrainment of Delta Smelt. The  
26 equation developed by Kimmerer (2008) is based on the average December  
27 through March OMR flow (in units of cfs) as predicted by the CalSim II model,  
28 and yields the percentage of adult Delta Smelt that may become entrained in the  
29 pumps. Further review by Kimmerer (2011) determined that the above equation  
30 has an upward bias, such that the results were reduced by 24 percent to correct  
31 this bias. In the event that a negative entrainment percentage was calculated, the  
32 result was changed to zero.

33 Changes in CVP and SWP operations under the alternatives could also change  
34 entrainment of larvae and early juvenile Delta Smelt. Larvae and early juvenile  
35 Delta Smelt are most prevalent in the Delta in the spring months of March  
36 through June. The USFWS (2008) regression model based on Kimmerer (2008)  
37 was used to calculate the percentage entrainment of larval and early juvenile Delta  
38 Smelt in Banks and Jones Pumping Plants. This regression is dependent on two  
39 variables: March through June average OMR flow (in cfs) and March through  
40 June average X2 position (in km). OMR and X2 values predicted by the  
41 CalSim II model for each alternative were used in estimating the entrainment loss.  
42 In the event that a negative entrainment percentage was calculated, the result was  
43 changed to zero.

1 In this study, the percent entrainment values estimated for Delta Smelt are used as  
2 a tool to compare the alternatives, as one of the factors that would indicate  
3 conditions that might benefit or contribute to adverse effects on Delta Smelt.  
4 Because the regression analysis uses flow output from the monthly time step  
5 CalSim II model and the confidence intervals on the regression parameters are  
6 somewhat broad, it was determined that incremental changes in entrainment  
7 estimates of 5 percent or less were within the model uncertainty. Therefore,  
8 changes in entrainment of less than 5 percent are considered to be not  
9 substantially different, or “similar” in this comparative analysis. One limitation  
10 of this approach is that it does not reflect the benefit that some of the alternatives  
11 might realize through adaptive management of OMR flows to further reduce  
12 potential entrainment, based on input from the Smelt Working Group.

#### 13 **9.4.1.3.4 Changes in Fish Passage and Routing**

14 Changes in CVP and SWP operations can affect through-Delta survival of  
15 migratory (e.g., salmonids) and resident (e.g., Delta and Longfin smelt) fish  
16 species through changes in passage conditions and routing. For example, changes  
17 in operation of the DCC affects the volume of water diverted into the Mokelumne  
18 River distributary channels toward the central and south Delta. Operation of the  
19 south Delta intake facilities, including facilities owned by the CVP and SWP and  
20 Contra Costa Water District, contribute to reverse flow conditions in Old and  
21 Middle rivers.

22 Changes in salmonid passage and routing were evaluated using the Delta Passage  
23 Model (DPM) and an analysis of Delta hydrodynamics and junction entrainment,  
24 as described below. The DPM is based on a detailed accounting of migratory  
25 pathways and reach-specific mortality as Chinook salmon smolts travel through a  
26 simplified network of reaches and junctions (see Appendix 9J for additional  
27 detail). Model output is expressed as through Delta survival of salmon smolts.

28 The key assumption in the Delta Hydrodynamic analysis is that the proportion of  
29 positive velocities in a channel, measured at a monthly time step, is an indicator  
30 of the likelihood that juvenile anadromous fish will successfully migrate through  
31 that channel towards the ocean (see Appendix 9K for additional detail). The  
32 analysis of junction entrainment used a regression based on predicted entrainment  
33 into a distributary and the proportion of flow into the distributary to predict the  
34 daily probability of fish entrainment (see Appendix 9L for additional detail).

35 Results of the Delta hydrodynamics and junction entrainment analysis are  
36 presented in box-whisker plots showing the median, central 50 percent  
37 probability, and range of simulated data. The comparison between alternatives  
38 relied on interpretation of these plots to distinguish differences in the median  
39 values as described above for changes in fish entrainment.

#### 40 **9.4.1.3.5 Changes in Delta Smelt Habitat (X2 Location)**

41 Changes in CVP and SWP operations under the alternatives could change the  
42 location of Fall X2 position (in September through December) as an indicator of  
43 available habitat for Delta Smelt. Feyrer et al. (2010) used X2 location as an

1 indicator of the extent of habitat available with suitable salinity and water  
 2 transparency for the rearing of older juvenile Delta Smelt. Feyrer et al. (2010)  
 3 concluded that when X2 is located downstream (west) of the confluence of the  
 4 Sacramento and San Joaquin Rivers, at a distance of 70 to 80 km from the Golden  
 5 Gate Bridge, there is a larger area of suitable habitat. The overlap of the low  
 6 salinity zone (or X2) with the Suisun Bay/Marsh results in a two-fold increase in  
 7 the habitat index (Feyrer et al 2010); however others (see Manly et al. 2015) have  
 8 questioned the use of outflow and X2 location as an indicator of Delta Smelt  
 9 habitat because other factors may be influencing survival.

10 To evaluate fall abiotic habitat availability for Delta Smelt under the alternatives,  
 11 X2 values (in km) simulated in the CalSim II model for each alternative were  
 12 averaged over September to December, and compared for differences. There are  
 13 uncertainties and limitations associated with this approach, e.g., it does not  
 14 evaluate other factors that influence the quality or quantity of habitat available for  
 15 Delta Smelt (e.g., turbidity, temperature, food availability), nor does it take into  
 16 account the relative abundance of Delta Smelt that might benefit from the  
 17 available habitat in the simulated X2 areas, in any given year. Other scientists  
 18 have developed and described life cycle models to evaluate Delta Smelt  
 19 population responses to changes in flow-related variables (e.g., Maunder and  
 20 Deriso 2011; Rose et al. 2013 a, b), but these life cycle modeling approaches were  
 21 not selected for use in the current study. The life cycle model developed by Rose  
 22 et al. (2013a, b) could not be used in this analysis because it uses a wide array of  
 23 daily data, many of the assumptions and parameter values were based on  
 24 judgment, and the model was not designed for forecasting future Delta Smelt  
 25 population abundances. The model was designed mostly for exploring hypothesis  
 26 about factors affecting Delta smelt populations dynamics, which is not suitable for  
 27 a comparative analysis of operational scenarios under the alternatives. Moreover,  
 28 Reed et al. (2014) noted that *“To date, these models have not been fully vetted and*  
 29 *evaluated sufficiently to be used for direct management applications.”* In this  
 30 study, simulated fall X2 values are used as a tool to compare the alternatives, as  
 31 one of the factors that would indicate available suitable habitat to benefit  
 32 Delta Smelt.

#### 33 **9.4.1.3.6 Changes in Salmonid Production**

34 Collectively, factors such as flow, temperature, and habitat availability affect the  
 35 population dynamics of anadromous fish species during their freshwater life  
 36 stages. Three different models were used to assess changes in salmonid  
 37 production potential: 1) SALMOD; 2) the Interactive Object-Oriented Simulation  
 38 (IOS) model for winter-run Chinook Salmon; and 3) the Oncorhynchus Bayesian  
 39 Analysis (OBAN) model for winter-run Chinook Salmon.

#### 40 *Comparison of Annual Production Using SALMOD*

41 The SALMOD model (Appendix 9D, SALMOD Analysis Documentation) was  
 42 used to assess changes in the annual production potential of four races of Chinook  
 43 Salmon in the Sacramento River. The primary assumption of the model is that  
 44 egg and fish mortality is directly proportional to spatially and temporally variable

1 habitat limitations, such as water temperatures, which themselves are functions of  
2 operational variables (timing and quantity of flow) and meteorological variables,  
3 such as air temperature. SALMOD is a spatially explicit model that characterizes  
4 habitat value and carrying capacity using the hydraulic and thermal properties of  
5 individual habitat units. Inputs to SALMOD include flow, water temperature,  
6 spawning distributions, spawn timing by salmon race, and the number of  
7 spawners provided by the user (e.g., recent average escapement).

8 Annual production potential or the number of outmigrants, annual mortality,  
9 length, and weight of the smolts are some of the reporting metrics available from  
10 SALMOD. The production numbers obtained from SALMOD are best used as an  
11 index in comparing to a specified baseline condition rather than absolute values.  
12 Differences between alternatives are assessed based on changes in the annual  
13 production potential for each species by river by water year type. Because  
14 SALMOD uses flows and output from the water temperature models that are  
15 downscaled from the monthly time step CalSim II model, it was determined that  
16 incremental changes in production of 5 percent or less were related to the  
17 uncertainties in the model processing. Therefore, changes in production of  
18 5 percent or less are considered to be not substantially different, or “similar” in  
19 this comparative analysis.

#### 20 *Comparison of Annual Winter-run Chinook Salmon Escapement Using IOS*

21 IOS is a stochastic life cycle simulation model for winter run Chinook Salmon in  
22 the Sacramento River. The IOS model is composed of six model stages that are  
23 arranged sequentially to account for the entire life cycle of winter run, from eggs  
24 to returning spawners. The primary output from the IOS model is escapement,  
25 the total number of winter-run Chinook Salmon that leave the ocean and return to  
26 the Sacramento River to spawn. Differences between alternatives are assessed  
27 based on changes in the median annual escapement and the range of escapement  
28 values encompassed in the first and second quartiles (25 to 75 percent of years)  
29 over the 82-year CalSim II simulation period. The IOS model uses scenario-  
30 specific daily DSM2, CalSim II, and Sacramento River Basin Water Temperature  
31 Model (HEC-5Q) data as model input. Because IOS uses output from the  
32 monthly time step CalSim II model, or other models downscaled from CalSim II,  
33 as input, it was determined that incremental changes in escapement estimates of  
34 5 percent or less in were related to the uncertainties in the model processing.  
35 Therefore, changes in escapement of 5 percent or less are considered to be not  
36 substantially different, or “similar” in this comparative analysis.

#### 37 *Comparison of Annual Winter-run Chinook Salmon Escapement Using OBAN*

38 The Oncorhynchus Bayesian Analysis (OBAN) is a model that uses statistical  
39 relationships between historical patterns in winter-run Chinook salmon abundance  
40 and a number of other parameters that covary with abundance to predict future  
41 population abundance. The model determines the effects of water temperature,  
42 harvest, exports, striped bass abundance, and offshore upwelling using historical  
43 abundance data. The set of parameters, called covariates, that provided the best  
44 model fit was retained for the full model. The model then uses predicted future  
45 values of these parameters, primarily from CalSim II and temperature model

1 outputs, to predict future patterns in Chinook salmon population abundance  
2 (escapement). Because OBAN uses output from the monthly time step CalSim II  
3 model, or other models downscaled from CalSim II, as input, it was determined  
4 that incremental changes in escapement estimates of 5 percent or less were related  
5 to the uncertainties in the model processing. Therefore, changes in escapement of  
6 5 percent or less are considered to be not substantially different, or “similar” in  
7 this comparative analysis.

#### 8 **9.4.1.3.7 Changes in Sturgeon Year Class Strength**

9 Changes in CVP and SWP operations can affect sturgeon species through changes  
10 in flows through the Delta that, in turn, affect the year class strength of both  
11 Green Sturgeon and White Sturgeon. Estimated Delta outflow from the CalSim II  
12 model was used to analyze the potential effects on sturgeon using the  
13 hypothesized relationship between Delta outflow and the age-0 Year Class Index  
14 (YCI) from the Bay Study in the presentation by Gingras et al. (2014). For this  
15 analysis, the mean Delta outflow during the March to July period for each year  
16 was calculated from the CalSim II output and used as an indicator of potential  
17 year class strength. Because the sturgeon analysis uses flow output from the  
18 monthly time step CalSim II model, it was determined that incremental changes in  
19 mean (March to July) Delta outflow of 5 percent or less were related to the  
20 uncertainties in the model processing. Therefore, changes in Delta outflow of less  
21 than 5 percent are considered to be not substantially different, or “similar” in this  
22 comparative analysis.

23 Mean (March to July) Delta outflow was also used as an indicator of the  
24 likelihood of producing a strong year class of sturgeon by examining the number  
25 of years (over the 82-year CalSim II simulation) that mean (March-July) Delta  
26 outflow would exceed a threshold of 50,000 cfs. Changes in the number of years  
27 exceeding the threshold was considered to have a potential effect on sturgeon.

#### 28 **9.4.1.4 Constructed Water Supply Facilities that Convey and Store CVP 29 and SWP Water**

30 The distribution system for water exported by CVP and SWP includes hundreds  
31 of miles of canals and numerous reservoirs designed to help regulate the flow of  
32 water to the areas where the water is used. Many of these canals and reservoirs  
33 support fish that were entrained into the system or intentionally stocked for  
34 recreational purposes, and changes in export deliveries could influence the quality  
35 of the aquatic habitat in these constructed water bodies. These constructed water  
36 bodies do not support important populations of native fish species and the  
37 management of flows is under the control of the entities that receive the water.  
38 Because many of the reservoirs also store water from non-CVP and SWP water  
39 supplies; it is difficult to predict changes in the aquatic habitat related to changes  
40 in CVP and SWP water supplies. Therefore, the potential effects of operation of  
41 these facilities on fish and aquatic resources are not addressed further in this EIS.

1     **9.4.1.5     Analysis of Provision of Fish Passage**

2     As described previously in the Affected Environment section, Shasta, Folsom,  
3     and New Melones dams and their associated downstream re-regulating reservoirs  
4     permanently blocked salmonid access to upper watersheds and effectively  
5     removed many miles of suitable habitat. These barriers particularly influenced  
6     populations of winter-run and spring-run Chinook Salmon and steelhead because  
7     their life history strategies are adapted to accessing higher elevation river reaches  
8     and tributaries to successfully spawn and rear, as well as for oversummering.  
9     Improving passage would increase the amount of available habitat, including  
10    access to colder headwaters, which would be particularly important considering  
11    anticipated climate change scenarios. Improved fish passage is not included  
12    under the Second Basin of Comparison or Alternative 2.

13    **9.4.1.6     Analysis of Trap and Haul Program**

14    Poor survival of juvenile salmonids in the Sacramento-San Joaquin Delta has  
15    been hypothesized as a major contributor to declines in the number of returning  
16    adults and may be a significant impediment to the recovery of threatened or  
17    endangered populations (NOAA 2009). Alternative 3 and Alternative 4 contain a  
18    trap and haul program for juvenile salmonids entering the Delta from the San  
19    Joaquin River, similar to the program in place on the Columbia River in Oregon.  
20    This action would not be implemented under the No Action Alternative, Second  
21    Basis of Comparison, or other action alternatives, with the exception of  
22    Alternatives 3 and 4. Background information on the trap and haul program  
23    associated with Alternatives 3 and 4 is provided in Appendix 9O and was used in  
24    the qualitative assessment of the trap and haul program under Alternatives 3  
25    and 4.

26    **9.4.1.7     Analysis of Predator Control Programs**

27    As described in Chapter 3, Description of Alternatives, Alternatives 3 and 4  
28    include predator control actions designed to reduce predation on salmonids and  
29    Delta Smelt, primarily within the Delta. Predator control measures are included  
30    in Alternatives 3 and 4, including an increased bag limit and minimum size limit  
31    for Striped Bass and black bass. The proposed bag and size limits are intended  
32    and expected to encourage more fishing effort for and greater harvest of Striped  
33    Bass and black bass, resulting in a reduction in the Striped Bass and black bass  
34    populations throughout the Delta. In addition, a sport reward program for  
35    Sacramento Pikeminnow would be implemented to encourage fishing for and  
36    removal of this predatory species. These two actions would not be implemented  
37    under the No Action Alternative, Second Basis of Comparison, or other action  
38    alternatives, with the exception of Alternatives 3 and 4.

39    **9.4.1.8     Analysis of Ocean Salmon Harvest Restrictions**

40    As described in Chapter 3, Description of Alternatives, Alternatives 3 and 4  
41    include restrictions on the annual ocean Chinook Salmon harvest, which is  
42    intended to minimize harvest mortality of natural origin Central Valley Chinook  
43    Salmon, including fall-run Chinook Salmon, by evaluating and modifying ocean

1 harvest for consistency with Viable Salmonid Population<sup>5</sup> standards. This would  
 2 include working with the Pacific Fisheries Management Council (PFMC),  
 3 CDFW, and NMFS to impose salmon harvest restrictions to reduce by-catch of  
 4 winter-run and spring-run Chinook Salmon to less than 10 percent of age-3 cohort  
 5 in all years.

6 The salmon ocean fishery off the coast of California is regulated by the PFMC,  
 7 which establishes the annual catch limit to optimize overall benefits, particularly  
 8 with regard to food production, recreation, and ecosystem protection. An annual  
 9 catch limit generally is based on achieving the maximum sustained yield from the  
 10 fishery, but also takes into account the effects of uncertainty; management  
 11 imprecision; the need to rebuild stocks; and other relevant economic, social, and  
 12 ecological factors. Compliance with the ESA, other laws, and treaties also may  
 13 affect the annual catch limit. Each year, the maximum allowable harvest  
 14 (i.e., maximum number of fish caught) is determined based on the abundance of  
 15 fish spawning in the previous year. Depending on the number of spawning fish,  
 16 different formulas for calculating the maximum allowable harvest (i.e., control  
 17 rules) are used. These rules calculate the maximum allowable harvest as  
 18 a percentage of the number of spawning fish, and are designed to maximize the  
 19 yield of fish from a stock while preventing overfishing. The annual catch limit  
 20 may be set at or below the maximum allowable harvest.

21 Reduction of the annual catch limit could directly influence the number of adult  
 22 salmon reaching their natal streams to spawn, which could affect the number of  
 23 salmon annually produced in Central Valley streams and the Trinity River.  
 24 Harvest restrictions would be implemented under Alternatives 3 and 4, but would  
 25 not be implemented under the No Action Alternative, Second Basis of  
 26 Comparison, or other action alternatives.

#### 27 **9.4.1.9 Approach to Analyzing the Effects of Alternatives on Fish**

28 The analysis of the effects of changes in operation of the CVP and SWP on fish  
 29 and aquatic resources in this EIS is influenced by numerous factors related to the  
 30 complexity of the ecosystem, changes within the system (e.g., climate change and  
 31 species population trends), and the imprecision of operational controls and  
 32 resolution in modeling tools. These factors are further complicated by the  
 33 scientific uncertainty about some fundamental aspects of aquatic species life  
 34 history and how these species respond to changes in the system, as well as  
 35 sometimes competing points of view on the interpretation of biological and  
 36 physical data within the scientific community. In light of these factors, the  
 37 analysis takes an approach that presents available information and model outputs,  
 38 synthesizes the results, and draws logical conclusions on likely effects of the  
 39 various alternatives. Where relevant and appropriate, the analysis attempts to

---

<sup>5</sup> "A viable salmonid population (VSP)<sup>2</sup> is an independent population of any Pacific salmonid (genus *Oncorhynchus*) that has a negligible risk of extinction due to threats from demographic variation (random or directional), local environmental variation, and genetic diversity changes (random or directional) over a 100-year time frame" (McElhany et al. 2000, pg. 2).

1 identify the level of uncertainty and qualify effect conclusions where competing  
2 hypotheses may exist.

3 Many modeling tools have been developed to evaluate changes in CVP and SWP  
4 water management, and as a result, multiple sources of information are available  
5 to characterize conditions (e.g., water temperature, flows, reservoir storage).  
6 Most of these modeling tools explain or provide insight on one or two of the  
7 factors affecting the species, while some tools are more integrative  
8 (e.g., SALMOD) and capture multiple relationships among physical conditions  
9 and biological responses. Where integrative models were available, these were  
10 relied upon more than evaluation of the individual components. For species  
11 where these tools were not available, the analysis used a preponderance of  
12 evidence approach that drew conclusions based on trends indicated by the  
13 majority of the information. This approach assembled the full range of available  
14 information and model outputs and determined the direction (neutral, positive, or  
15 negative) of effect supported by the information.

16 For each focal species where sufficient information was available, the analysis  
17 includes an effects summary that presents the EIS authors' conclusions for that  
18 species and describes the rationale for the conclusion. It also presents a general  
19 indication of the level of uncertainty regarding the conclusion and presents  
20 qualifying information where disagreement in the scientific community may exist  
21 for more complete disclosure.

22 Because of the multiple model outputs, the body of the impact analysis contains a  
23 considerable amount of information, which is intended to summarize for the  
24 benefit of the reader, while leaving most of the detail in the appendices. The  
25 narrative contained in the body of the document and the model results in the  
26 appendices are intended to be used in concert in reviewing this EIS.

#### 27 **9.4.2 Conditions in Year 2030 without Implementation of** 28 **Alternatives 1 through 5**

29 This EIS includes two bases of comparison, as described in Chapter 3,  
30 Description of Alternatives: the No Action Alternative and the Second Basis of  
31 Comparison. Both of these bases are evaluated at 2030 conditions. Changes that  
32 would occur over the next 15 years without implementation of the alternatives are  
33 not analyzed in this EIS. However, the changes to aquatic resources that are  
34 assumed to occur by 2030 under the No Action Alternative and the Second Basis  
35 of Comparison are summarized in this section. Many of the changed conditions  
36 would occur in the same manner under both the No Action Alternative and the  
37 Second Basis of Comparison.

##### 38 **9.4.2.1 Common Changes in Conditions under the No Action** 39 **Alternative and Second Basis of Comparison**

40 Conditions in 2030 would be different than existing conditions due to:

- 41 • Climate change and sea level rise

- 1 • General plan development throughout California, including increased water  
2 demands in portions of Sacramento Valley
- 3 • Implementation of reasonable and foreseeable water resources management  
4 projects to provide water supplies

5 It is anticipated that climate change would result in more short-duration high-  
6 rainfall events and less snowpack in the winter and early spring months. The  
7 reservoirs would be full more frequently by the end of April or May by 2030 than  
8 in recent historical conditions. However, as the water is released in the spring,  
9 there would be less snowpack to refill the reservoirs. This condition would  
10 reduce reservoir storage and available water supplies to downstream uses in the  
11 summer. The reduced end of September storage also would reduce the ability to  
12 release stored water to downstream regional reservoirs. These conditions would  
13 occur for all reservoirs in the California foothills and mountains, including non-  
14 CVP and SWP reservoirs.

15 These changes would result in a decline of the long-term average CVP and SWP  
16 water supply deliveries by 2030 as compared to recent historical long-term  
17 average deliveries under the No Action Alternative and the Second Basis of  
18 Comparison. However, the CVP and SWP water deliveries would be less under  
19 the No Action Alternative as compared to the Second Basis of Comparison, as  
20 described in Chapter 5, Surface Water Resources and Water Supplies, which  
21 could result in more crop idling.

22 Under the No Action Alternative and the Second Basis of Comparison, land uses  
23 in 2030 would occur in accordance with adopted general plans. Development  
24 under the general plans would change aquatic resources, especially near  
25 municipal areas.

26 The No Action Alternative and the Second Basis of Comparison assumes  
27 completion of water resources management and environmental restoration  
28 projects that would have occurred without implementation of Alternatives  
29 1 through 5, including regional and local recycling projects, surface water and  
30 groundwater storage projects, conveyance improvement projects, and desalination  
31 projects, as described in Chapter 3, Description of Alternatives. The No Action  
32 Alternative and the Second Basis of Comparison also assumes implementation of  
33 actions included in the 2008 USFWS BO and 2009 NMFS BO that would have  
34 been implemented without the BOs by 2030, as described in Chapter 3,  
35 Description of Alternatives. These projects would include several projects that  
36 would affect aquatic resources, including:

- 37 • Habitat Restoration includes restoration of more than 10,000 acres of  
38 intertidal and associated subtidal wetlands in Suisun Marsh and Cache Slough;  
39 and at least 17,000 to 20,000 acres of seasonal floodplain restoration in Yolo  
40 Bypass.
- 41 – 2008 USFWS BO RPA Component 4 (Action 6). Habitat Restoration.
- 42 – 2009 NMFS BO RPA Action I.6.1. Restoration of Floodplain Habitat.

- 1       – 2009 NMFS BO RPA Action I.6.2. Near-Term Actions at Liberty  
2       Island/Lower Cache Slough and Lower Yolo Bypass.
- 3       – 2009 NMFS BO RPA Action I.6.3. Lower Putah Creek Enhancements.
- 4       – 2009 NMFS BO RPA Action I.6.4. Improvements to Lisbon Weir.
- 5       – 2009 NMFS BO RPA Action I.7. Reduce Migratory Delays and Loss of  
6       Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in  
7       the Yolo Bypass.
- 8       • 2009 NMFS BO RPA Action I.1.3. Clear Creek Spawning Gravel  
9       Augmentation.
- 10      • 2009 NMFS BO RPA Action I.1.4. Spring Creek Temperature Control  
11      Curtain Replacement.
- 12      • 2009 NMFS BO RPA Action I.2.6. Restore Battle Creek for Winter-Run,  
13      Spring-Run, and Central Valley Steelhead.
- 14      • 2009 NMFS BO RPA Action I.3.1. Operate Red Bluff Diversion Dam with  
15      Gates Out.
- 16      • 2009 NMFS BO RPA Action I.5. Funding for CVPIA Anadromous Fish  
17      Screen Program.
- 18      • 2009 NMFS BO RPA Action II.1. Lower American River Flow Management.
- 19      Implementation of these common actions are described in more detail in this  
20      section under the No Action Alternative and referred under the discussion of the  
21      Second Basis of Comparison.

#### 22      **9.4.2.2    No Action Alternative**

23      As described in Chapter 3, Description of Alternatives, the No Action  
24      Alternative includes implementation of the 2008 USFWS BO and the 2009  
25      NMFS BO Reasonable and Prudent Alternative (RPA) actions. It also includes  
26      changes not related to the coordinated long-term operation of the CVP and SWP,  
27      specifically changes in CVP and SWP operations caused by climate change and  
28      sea level rise, increased CVP and water rights water demand in portions of the  
29      Sacramento Valley, and implementation of reasonable and foreseeable non-CVP  
30      or SWP water resources management projects to provide water supplies. The  
31      resulting changes in ecological attributes and subsequent effects on fish and  
32      aquatic resources would vary geographically, as described below.

33      As described in Chapter 5, Surface Water Resources and Water Supplies, it is  
34      anticipated that climate change would result in more short-duration, high-rainfall  
35      events and less snowpack in the winter and early spring months. By 2030, the  
36      reservoirs would be full more frequently by the end of April or May than in recent  
37      historical conditions. However, as the water is released in the spring, there would  
38      be less snowpack to refill the reservoirs. This condition would reduce reservoir  
39      storage and available water supplies to downstream uses in the summer. The  
40      reduced storage in fall (end of September storage) would reduce the ability to

1 release stored water to downstream regional reservoirs. These conditions would  
 2 occur for all reservoirs in the California foothills and mountains, including non-  
 3 CVP and SWP reservoirs. Sea level rise also would result in reduced CVP and  
 4 SWP reservoir storage because the CVP and SWP must continue to meet the  
 5 salinity criteria to protect Delta water users and Delta aquatic resources, including  
 6 the SWRCB D-1641 and other salinity criteria to protect Delta water users. To  
 7 meet these criteria, the amount of water released from CVP and SWP reservoirs  
 8 must be increased as compared to recent historical conditions.

#### 9 **9.4.2.2.1 Trinity River Region**

##### 10 *Aquatic Habitat Conditions in CVP and SWP Reservoirs*

11 As described in Chapter 5, Surface Water Resources and Water Supplies, end of  
 12 September reservoir storage in Trinity Lake would be lower by 2030 as compared  
 13 to recent historical conditions due to climate change and related lower snowfall.  
 14 Lewiston Reservoir, a regulating reservoir, would be operated with daily changes  
 15 similar to historical conditions. These changes are not anticipated to substantially  
 16 affect aquatic resources in Trinity Lake or Lewiston Reservoir relative to recent  
 17 historical conditions.

##### 18 *Aquatic Habitat Conditions in Trinity and Lower Klamath Rivers*

19 Under the No Action Alternative, flow, water temperature, and aquatic habitat  
 20 conditions in the Trinity River would continue to be influenced by CVP and SWP  
 21 operations as described in the Affected Environment. Due to the increased  
 22 potential for reduced Trinity Lake surface water storage (see above), there could  
 23 be an increased potential for reduced Trinity River flows during the summer and  
 24 fall months under the No Action Alternative as compared to recent historical  
 25 conditions. The influence of climate change could result in higher water  
 26 temperatures in Trinity Lake that could translate to higher release temperatures in  
 27 the flow releases from Lewiston Dam and a reduction in habitat quality within the  
 28 Trinity River for salmonids and other native species.

29 By 2030, implementation of 2009 NMFS BO RPA Action II.6, Preparation of  
 30 Hatchery Genetic Management Plans for spring- and fall-run Chinook Salmon at  
 31 the Trinity River Fish Hatchery, which is not currently being implemented, could  
 32 reduce the adverse influence of recent hatchery operations on naturally produced  
 33 fall-run and spring-run Chinook Salmon, and increase genetic diversity and  
 34 diversity of run timing for these stocks.

##### 35 *Effects Related to Water Transfers*

36 It is not anticipated that water would be transferred to or from the Trinity River  
 37 Region. It also not anticipated that water transfers would result in changes to  
 38 Trinity Lake operations. Therefore, there would be no change in aquatic habitat  
 39 conditions as a result of water transfers.

1 **9.4.2.2.2 Central Valley Region**

2 *Aquatic Habitat Conditions in CVP and SWP Reservoirs*

3 Seasonal changes in reservoir surface elevations, storage volumes, and the volume  
4 of cold water held within the reservoirs would continue under the No Action  
5 Alternative. Conditions for reservoir fishes would continue to change seasonally  
6 in response to inflow and downstream flow releases to meet demand. Recent  
7 historical averages for reservoir storage and surface elevations in Shasta Lake,  
8 Lake Oroville, and Folsom Lake generally show increases in March and April,  
9 with a reduction in storage occurring in many years during May and June in  
10 response to releases to meet downstream demands. Water surface elevations in  
11 New Melones Reservoir generally decline throughout the spring period in many  
12 years, with reductions typically occurring from April through June.

13 As described in Chapter 5, Surface Water Resources and Water Supplies, end of  
14 September reservoir storage would be lower by 2030 as compared to recent  
15 historical conditions in Shasta Lake, Lake Oroville, Folsom Lake, New Melones  
16 Lake, and San Luis Reservoir due to climate change and related lower snowfall.  
17 Whiskeytown Lake, Keswick Reservoir, Thermalito Forebay and Afterbay, and  
18 Lake Natoma are regulating reservoirs and would be operated with daily changes  
19 similar to historical conditions.

20 Under the No Action Alternative, the magnitude of changes in seasonal surface  
21 elevation and reservoir storage could be more pronounced because of changes in  
22 the timing and intensity of storm events due to climate change and an overall  
23 reduction in snow pack. A smaller snowpack could result in less water entering  
24 the reservoirs during the spring months and an increased frequency of reservoir  
25 elevation declines during the spring months. By 2030, fish in these reservoirs that  
26 spawn in shallow water (e.g., various species of black bass) could be subject to a  
27 hydrologic regime that increases the frequency of reductions in surface elevation  
28 during the spring spawning period, reducing spawning success. In addition,  
29 reduced storage volumes and reduction of the cold water pools could reduce the  
30 amount and suitability of habitat for cold water fishes (e.g., trout) within the  
31 reservoirs relative to recent historical conditions.

32 *Aquatic Habitat Conditions in Rivers Downstream of CVP and SWP Facilities*

33 As described in Chapter 5, Surface Water Resources and Water Supplies, surface  
34 water flows are anticipated to increase during the winter months as a result of an  
35 increase in rainfall and decrease in snowfall, and to decrease in other months  
36 because of the diminished snowmelt flows in the spring and early summer  
37 months. In wetter years, fall flows may be increased relative to recent conditions  
38 to meet downstream targets for Fall X2, which would lead to reduced reservoir  
39 storage in the following months and less carryover storage in May of the  
40 following year.

41 As described in Chapter 6, Surface Water Quality, climate change is anticipated to  
42 result in higher water temperatures during portions of the year, with a  
43 corresponding reduction in habitat quality for salmonids and other cold water  
44 fishes. Increased downstream water demands and climate change are anticipated

1 to contribute to an inability to maintain an adequate cold water pool in critical dry  
2 years and extended dry periods in the future.

3 Implementation of the 2008 USFWS BO and the 2009 NMFS BO Reasonable and  
4 Prudent Alternative (RPA) actions under the No Action Alternative are  
5 anticipated to benefit aquatic species. The resulting changes in ecological  
6 attributes and subsequent effects on fish and aquatic resources would vary from  
7 river to river, as described below.

8 *Aquatic Habitat Conditions in the Clear Creek from Whiskeytown Dam to*  
9 *Sacramento River*

10 Under the No Action Alternative, flow, water temperature, and aquatic habitat  
11 conditions in Clear Creek would continue to be influenced by CVP and SWP  
12 operations as described in the Affected Environment. Whiskeytown Reservoir  
13 would continue to be operated to convey water from the Trinity River to the  
14 Sacramento River via the Spring Creek tunnel and to release flows to Clear Creek  
15 to support anadromous fish.

16 The No Action Alternative includes a suite of six 2009 NMFS BO RPA actions,  
17 intended to improve conditions for salmonids. These actions individually or in  
18 combination could influence conditions in Clear Creek by 2030. These include:

- 19 • 2009 NMFS BO RPA Action I.1. Spring Attraction Flows
- 20 • 2009 NMFS BO RPA Action I.2. Channel Maintenance Flows
- 21 • 2009 NMFS BO RPA Action I.3. Spawning Gravel Augmentation
- 22 • 2009 NMFS BO RPA Action I.4. Spring Creek Temperature Control Curtain
- 23 • 2009 NMFS BO RPA Action I.5. Thermal Stress Reduction
- 24 • 2009 NMFS BO RPA Action I.6. Adaptively Manage to Habitat  
25 Suitability/IFIM Study Results

26 Two of the actions involve additional flow releases to Clear Creek. 2009 NMFS  
27 BO RPA Action I.1, requires at least two pulse flows in May and June to attract  
28 adult spring-run Chinook Salmon holding in the Sacramento River. The pulse  
29 flows would be continued annually, and are expected to improve conditions for  
30 spring-run Chinook Salmon into the future. In addition, 2009 NMFS BO RPA  
31 Action I.1.2, requires the release of channel maintenance flows of a minimum of  
32 3,250 cfs into Clear Creek seven times in a ten-year period. These channel  
33 maintenance flows are intended to provide the higher flows necessary to move  
34 spawning gravels downstream from injection sites (locations where gravel  
35 augmentation is implemented) for the purpose of increasing the amount of  
36 spawning habitat available to spring-run Chinook Salmon and steelhead.  
37 However, as described in Chapter 5, Surface Water Resources and Water  
38 Supplies, the feasibility of releasing these flows is influenced by dam safety  
39 considerations and operational constraints, and the delivery of flows of this  
40 frequency may not be possible, thus the movement of gravel through mechanical  
41 means may be required to achieve this objective.

1 2009 NMFS BO RPA Action I.1.3 addresses the limited availability of spawning  
2 habitat in Clear Creek through the placement of gravel in selected sites in the  
3 creek. This program is expected to continue under the No Action Alternative,  
4 with ongoing improvements to spawning habitat for steelhead, and spring-run and  
5 fall-run Chinook Salmon.

6 Water temperatures in Clear Creek are influenced by the temperature of water in  
7 the Whiskeytown Reservoir and, to some extent, the magnitude of the release  
8 flows. As described in the Affected Environment, Reclamation has managed  
9 releases since 2002 to meet a daily average water temperature target of 56°F at the  
10 Igo Gauge (4 miles downstream of Whiskeytown Dam) from September 15  
11 through October 30 to support spring-run Chinook Salmon spawning. Beginning  
12 in 2004, an additional daily average temperature target of 60°F was implemented  
13 from June 1 to September 15 to protect over-summering juvenile steelhead and  
14 holding adult spring-run Chinook Salmon. 2009 NMFS BO RPA Action I.1.5  
15 continues these temperature targets; however, recent real time operations have  
16 experienced difficulty in meeting the temperature objectives, and by 2030, it may  
17 not be possible to meet the temperature targets as often. The Spring Creek  
18 Temperature Control Curtain in Whiskeytown Lake repaired in 2011 (and also  
19 included in the 2009 NMFS BO RPA) improves this condition by retaining cold  
20 water that is released to reduce water temperatures during the summer for over-  
21 summering juvenile steelhead and holding adult spring-run Chinook Salmon and  
22 during the fall for spring- and winter-run Chinook Salmon spawning and  
23 incubation.

24 2009 NMFS BO RPA Action I.1.6 requires adaptive management of flows in  
25 Clear Creek based on results of habitat suitability/IFIM studies. If warranted by  
26 the studies and if sufficient water is available, this action could result in modified  
27 minimum flows in Clear Creek during the fall and winter to improve conditions  
28 for spawning and incubating salmonids. Whether flow requirements would be  
29 modified by 2030 and the extent of any changes are currently unknown.

30 *Aquatic Habitat Conditions in the Sacramento River from Keswick to*  
31 *Freepoint*

32 Under the No Action Alternative, flow, water temperature, and aquatic habitat  
33 conditions in the Sacramento River downstream of Keswick Dam would continue  
34 to be influenced by CVP and SWP operations as described in the Affected  
35 Environment. Shasta Lake would continue to be operated to convey water from  
36 the Sacramento River to the Delta and release flows to the Sacramento River to  
37 support anadromous fish.

38 The No Action Alternative includes a variety of 2009 NMFS BO RPA actions or  
39 action suites intended to improve conditions for salmonids. These actions  
40 individually or in combination could influence conditions in the Sacramento River  
41 (and Battle Creek) by 2030. These include:

- 42 • 2009 NMFS BO RPA Action Suite I.2.1. Shasta Operations
- 43 – 2009 NMFS BO RPA Action Suite I.2.1. Performance Measures

- 1       – 2009 NMFS BO RPA Action I.2.2 (including I.2.2.A–I.2.2.C). November  
2       through February Keswick Release Schedule (Fall Actions)
- 3       – 2009 NMFS BO RPA Action I.2.3 (including I.2.3.A–I.2.3.C). February  
4       Forecast; March – May 14 Keswick Release Schedule (Spring Actions)
- 5       – 2009 NMFS BO RPA Action I.2.4. May 15 Through October Keswick  
6       Release Schedule (Summer Action)
- 7       – 2009 NMFS BO RPA Action I.2.5. Winter-Run Chinook Salmon Passage  
8       and Reintroduction Program at Shasta Dam – See “Conditions for Fish  
9       Passage”
- 10      – 2009 NMFS BO RPA Action I.2.6. Restore Battle Creek for Winter-Run,  
11      Spring-Run, and CV Steelhead
- 12      • 2009 NMFS BO RPA Action Suite I.3. Red Bluff Diversion Dam (RBDD)  
13      Operations
- 14      • 2009 NMFS BO RPA Action I.4. Wilkins Slough Operations
- 15      • 2009 NMFS BO RPA Action I.5. Funding for CVPIA Anadromous Fish  
16      Screen Program

17      Action Suite I.2 (Shasta Operations) was aimed at maintaining suitable  
18      temperatures for egg incubation, fry emergence, and juvenile rearing in the  
19      Sacramento River for the survival and recovery of the winter-run Chinook  
20      Salmon ESU. Spring-run Chinook Salmon and steelhead are also affected by  
21      temperature management actions from Shasta Lake. This suite of actions is  
22      designed to ensure that Reclamation uses maximum discretion to reduce adverse  
23      impacts of the projects to Chinook Salmon and steelhead in the Sacramento River  
24      by maintaining sufficient carryover storage and optimizing use of the cold water  
25      pool. Because Reclamation already operates Shasta Lake to optimize use of the  
26      cold water pool and maintain carryover storage for temperature control in the  
27      Sacramento River downstream of Shasta and Keswick dams, implementation of  
28      this suite of actions would have little effect on habitat conditions for winter-run  
29      Chinook Salmon and other fish species in the Sacramento River under the No  
30      Action Alternative.

31      A temperature control device has been in operation at Shasta Dam since 1998,  
32      with operations capable of maintaining a water temperature of 56°F downstream  
33      to Balls Ferry Bridge in most years through the summer spawning period for  
34      winter-run. Under the No Action Alternative, the ability to control water  
35      temperatures depends on a number of factors and management flexibility usually  
36      ends in October when the cold water pool in Shasta Lake is depleted. With  
37      climate change, cold water storage at the end of May in Shasta Lake is expected  
38      to be reduced under the No Action Alternative for all water year types. This  
39      would further reduce the already limited cold water pool in late summer. With  
40      the anticipated increase in demands for water by 2030 and less water being  
41      diverted from the Trinity River, it is expected that it would become increasingly

1 difficult to meet water temperature targets at the various temperature compliance  
2 points.

3 It is likely that severe temperature-related effects will be unavoidable in some  
4 years under the No Action Alternative. Due to these unavoidable adverse effects,  
5 RPA Action Suite I.2 also specifies other actions that Reclamation must take,  
6 within its existing authority and discretion, to compensate for these periods of  
7 unavoidably high temperatures. These actions include restoration of habitat at  
8 Battle Creek (see below) which may support a second population of winter-run  
9 Chinook Salmon, and a fish passage program at Keswick and Shasta dams to  
10 partially restore winter-run Chinook Salmon to their historical cold water habitat.

11 2009 NMFS BO RPA Action Suite I.3 addresses mortality and delay of adult and  
12 juvenile migration of winter-run, spring-run, steelhead, and green sturgeon caused  
13 by the presence of the RBDD and the configuration of the operable gates. As  
14 described in the Affected Environment, the Red Bluff Pumping Plant and fish  
15 screen, which diverts water to the Tehama Colusa Canal and Corning Canal, was  
16 constructed to allow year-round opening of the gates at the RBDD, and is  
17 included in the 2009 NMFS BO as Action Suite I.3. Allowing the dam gates at  
18 RBDD to remain open allows salmonids, sturgeon, and other fish species to pass  
19 unimpeded all year. These passage improvements are completed and are  
20 anticipated to benefit fish species that migrate upstream of the RBDD location  
21 through improved access to spawning and rearing areas and a reduction in  
22 predation due to dispersal of predator species like Striped Bass and Sacramento  
23 Pikeminnow.

24 Implementation of 2009 NMFS BO RPA Action I.4 is anticipated to enhance the  
25 ability to manage temperatures for anadromous fish downstream of Shasta Dam  
26 through adjusting Wilkins Slough flow criteria in a manner that best conserves the  
27 cold water pool for summer releases. In years other than critical dry years, the  
28 need for a variance from the 5,000 cfs navigation criterion will be considered  
29 during the process of developing the Keswick release schedules (Action I.2.2-4).  
30 Reclamation has stated that it is no longer necessary to maintain 5,000 cfs at  
31 Wilkins Slough for navigation (CVP/SWP operations BA, page 2-39), however,  
32 the 5,000 cfs flow criterion is now used to support long-time water diversions that  
33 have set their intake pumps just below this level. Under the No Action  
34 Alternative, operating to a minimal flow level at Wilkins Slough based on fish  
35 needs, rather than on outdated navigational requirements, could enhance the  
36 ability to use cold water releases to maintain cooler summer temperatures in the  
37 Sacramento River.

38 The No Action Alternative includes implementation of the CVPIA AFSP to  
39 reduce entrainment of juvenile anadromous fish from unscreened diversions. This  
40 program is also addressed in the 2009 NMFS BO RPA Action I.5. By providing  
41 funding to screen priority diversions as identified in the CVPIA AFSP, the loss of  
42 listed fish in water diversion channels by 2030 could be reduced. In addition, if  
43 new fish screens can be constructed so that diversions can occur at low water  
44 surface elevations to allow diversions below a flow of 5,000 cfs at Wilkins  
45 Slough, then cold water at Shasta Lake could be conserved during critical dry

1 years for release to support winter-run and spring-run Chinook Salmon needs  
2 downstream.

3 As described in the Affected Environment, implementation of the Battle Creek  
4 Restoration Program is underway in accordance with implementation of the  
5 CVPIA. This action, also included in the 2009 NMFS BO RPA Action I.2.6, is  
6 being implemented to partially compensate for unavoidable adverse effects of  
7 project operations by restoring winter-run and spring-run Chinook Salmon to the  
8 Battle Creek watershed. Full implementation of the Battle Creek Restoration  
9 Program under the No Action Alternative would substantially improve passage  
10 conditions for adult Chinook Salmon and steelhead by 2030 and would result in  
11 newly accessible anadromous fish habitat and improved water quality for the  
12 Coleman National Fish Hatchery (Reclamation and SWRCB 2003).  
13 Implementation of the RPA helps ensure that the Battle Creek experimental  
14 winter-run Chinook Salmon re-introduction program will proceed in a timely  
15 fashion. The Battle Creek Restoration Program is critical in creating a second  
16 population of winter-run Chinook Salmon. A second population of winter-run  
17 Chinook Salmon would reduce the risk that lost resiliency and increased  
18 vulnerability to catastrophic events might result in extinction of the species.

19 *Aquatic Habitat Conditions in the Feather River from Oroville Dam to*  
20 *Sacramento River*

21 As described in Chapter 5, Surface Water Resources and Water Supplies, and  
22 Chapter 6, Surface Water Quality, the NMFS and 2008 USFWS BO RPAs did not  
23 specifically recommend actions for Feather River operations. However,  
24 Reclamation and DWR operate the Shasta-Oroville-Folsom coordinated releases  
25 pursuant to 2009 NMFS BO RPA Actions 1.2.2C and 1.2.3B. The following two  
26 RPA actions for operations in the Sacramento River influence Feather River  
27 operations required to meet Delta outflow, X2, or other legal requirements:

- 28 • Action I.2.2. (including I.2.2.A–I.2.2.C) November through February  
29 Keswick Release Schedule (Fall Actions)
- 30 • Action I.2.3. (including I.2.3.A–I.2.3.C) February Forecast; March – May 14  
31 Keswick Release Schedule (Spring Actions).

32 Under the No Action Alternative, Feather River flows in the high flow channel  
33 downstream of Thermalito Dam would be influenced by releases for Fall X2  
34 Delta outflow requirements, regulation to meet water temperature criteria, and to  
35 time Lake Oroville releases and Delta export operations as described for the  
36 Affected Environment. Flows in the low flow channel downstream of Lake  
37 Oroville would remain similar to recent conditions. As part of the ongoing FERC  
38 relicensing process for the Oroville facilities, DWR has entered into a Settlement  
39 Agreement (DWR 2006) that includes actions to be implemented and included as  
40 terms of the anticipated FERC license. Depending on the progress of the  
41 relicensing process, these actions could be implemented by 2030 and would  
42 change fish habitat conditions in the Feather River relative to recent conditions.

1 Under the terms of the Settlement Agreement, DWR will develop a  
2 comprehensive Lower Feather River Habitat Improvement Plan. The Plan will  
3 provide an overall strategy for managing the various environmental measures  
4 developed for implementation in the plan area. The following programs and plans  
5 will be included in the comprehensive Lower Feather River Habitat Improvement  
6 Plan:

- 7 1) Gravel Supplementation and Improvement Program
- 8 2) Channel Improvement Program
- 9 3) Structural Habitat Supplementation and Improvement Program
- 10 4) Fish Weir Program
- 11 5) Riparian and Floodplain Improvement Program including the evaluation of  
12 pulse/flood flows
- 13 6) Feather River Fish Hatchery Improvement Program
- 14 7) Comprehensive Water Quality Monitoring Program
- 15 8) Oroville Wildlife Area Management Plan
- 16 9) Instream Flow and Temperature Improvement for Anadromous Fish.

17 Implementation of these programs and plans under the terms of the Settlement  
18 Agreement as incorporated into the new license are anticipated to improve habitat  
19 conditions and water quality for salmonids and other fishes using the channels of  
20 the Feather River above the confluence with the Sacramento River.

21 *Aquatic Habitat Conditions in the American River from Nimbus Dam to*  
22 *Sacramento River*

23 As described in the Affected Environment section, Reclamation releases water to  
24 the lower American River consistent with flood control requirements; existing  
25 water rights; CVP operations; the Lower American River Flow Management  
26 Standard flow recommendations developed by Reclamation, the Sacramento Area  
27 Water Forum, USFWS, NMFS, DFW, and other interested parties; SWRCB  
28 Decision 893 (D-893); and requirements of the 2009 NMFS BO RPA. The  
29 following two RPA actions for operations in the Sacramento River influence  
30 American River operations required to meet Delta outflow, X2, or other legal  
31 requirements:

- 32 • Action I.2.2. (including I.2.2.A–I.2.2.C) November through February  
33 Keswick Release Schedule (Fall Actions)
- 34 • Action I.2.3. (including I.2.3.A–I.2.3.C) February Forecast; March – May 14  
35 Keswick Release Schedule (Spring Actions).

36 The No Action Alternative includes a variety of 2009 NMFS BO RPA actions or  
37 action suites intended to improve conditions for salmonids in the lower American  
38 River. These actions individually or in combination could influence conditions in  
39 the American River by 2030. These include:

- 1 • 2009 NMFS BO RPA Action II.2.1. Lower American River Flow  
2 Management
- 3 • 2009 NMFS BO RPA Action II.2. Lower American River Temperature  
4 Management
- 5 • 2009 NMFS BO RPA Action II.3. Structural Improvements
- 6 • 2009 NMFS BO RPA Action II.4. Minimize Flow Fluctuation Effects
- 7 • 2009 NMFS BO RPA Action II.5. Fish Passage at Nimbus and Folsom dams
- 8 • 2009 NMFS BO RPA Action II.6.1. Preparation of Hatchery Genetic  
9 Management Plan (HGMP) for Steelhead
- 10 • 2009 NMFS BO RPA Action II.6.2. Interim Actions Prior to Submittal of  
11 Draft HGMP for Steelhead.

12 Under the No Action Alternative, American River flows would be influenced by  
13 releases for Fall X2 Delta outflow requirements, regulation to meet water  
14 temperature criteria, and to time Folsom Dam releases and Delta exports.  
15 However, by 2030, increasing water demands and the influence of climate change  
16 could worsen conditions for fish in the lower American River, particularly for  
17 salmonids.

18 Reclamation releases water from Folsom Lake to implement the flow schedule  
19 specified in the American River Flow Management Standard. The flow schedule  
20 was developed and implemented prior to issuance of the 2009 NMFS BO  
21 (Action II.1) to establish required minimum flows for anadromous salmonids in  
22 the lower American River. The flow schedule specifies minimum flows and does  
23 not preclude Reclamation from making higher releases at Nimbus Dam. The flow  
24 schedule was developed to require more protective minimum flows in the lower  
25 American River in consideration of the river's aquatic resources, particularly  
26 steelhead and fall-run.

27 Reclamation manages the Folsom/Nimbus Dam complex and the water  
28 temperature control shutters at Folsom Dam to maintain a daily average water  
29 temperature of 65°F or lower at Watt Avenue Bridge from May 15 through  
30 October 31, to provide suitable conditions for juvenile steelhead rearing in the  
31 lower American River. Water temperature is the physical factor with the greatest  
32 influence on salmonids in the American River. The inability to maintain suitable  
33 water temperatures for all life history stages of steelhead in the American River is  
34 a chronic issue because of operational (e.g., Folsom Lake operations to meet  
35 Delta water quality objectives and demands and deliveries to M&I users in Placer,  
36 El Dorado, and Sacramento County) and structural (e.g., limited reservoir water  
37 storage and cold water pool) factors. Under the No Action Alternative, increased  
38 water demand and climate change are expected to lead to further reductions in  
39 suitable habitat conditions and increased water temperatures.

40 2009 NMFS BO RPA Action II.3 requires Reclamation to evaluate physical and  
41 structural modifications that may improve temperature management capability in  
42 the lower American River. Structural improvements to be further evaluated and

1 potentially implemented include: improvements to the Folsom Dam TCD, cold  
2 water transport through Lake Natoma, installation of a TCD at El Dorado  
3 Irrigation District's intake or its functional equivalent, and improved temperature  
4 management decision-support tools. If one or more of these actions are  
5 implemented by 2030, they could increase the likelihood that water temperatures  
6 would be suitable for steelhead more frequently.

7 2009 NMFS BO RPA Action II.4 addresses stranding and isolation of juvenile  
8 steelhead through implementation of flow ramping protocols. Implementation of  
9 this action, including the continued monitoring for stranding and isolation of  
10 salmonids in conjunction with flow fluctuations under the No Action Alternative,  
11 could help to better predict the potential for steelhead redd dewatering and  
12 isolation, fry stranding, and fry and juvenile isolation and to potentially avoid  
13 adverse effects to salmonids.

14 As described above, temperature-related effects are likely during some years  
15 under the No Action Alternative. Because of these unavoidable effects, RPA  
16 Action II.5 requires Reclamation to evaluate options for providing steelhead  
17 access their historic cold water habitat above Nimbus and Folsom dams and to  
18 provide access if feasible.

19 Under the No Action Alternative, 2009 NMFS BO RPA Action Suite II.6, which  
20 addresses project effects related to the Nimbus Fish Hatchery related to  
21 introgression of out-of-basin hatchery stock with wild steelhead populations in the  
22 Central Valley, would be implemented. Implementation of an HGMP prior to  
23 2030 should minimize the effects of the ongoing steelhead hatchery program on  
24 the Central Valley steelhead DPS.

25 Implementation of the HGMP also would reduce operational effects on Killer  
26 Whale prey over the long term by improving the genetic diversity and diversity of  
27 run timing of Central Valley fall-run Chinook Salmon, decreasing the potential  
28 for localized prey depletions and increasing the likelihood that fall-run Chinook  
29 Salmon could withstand stochastic events, such as poor ocean conditions. By  
30 2030, implementation of this action could begin to contribute to a more consistent  
31 food source for Killer Whales, even in years with overall poor Chinook Salmon  
32 productivity.

33 *Aquatic Habitat Conditions in the San Joaquin River from Friant Dam to the*  
34 *Stanislaus River*

35 Under the No Action Alternative, operations at Friant Dam would remain similar  
36 to those described under the Affected Environment. Therefore, fish and aquatic  
37 habitat conditions in the San Joaquin River downstream of Friant Dam would  
38 remain similar to those described under the Affected Environment, although water  
39 temperatures could increase as a result climate change.

1        *Aquatic Habitat Conditions in the Stanislaus River from Goodwin Dam to San*  
 2        *Joaquin River*

3        Under the No Action Alternative, flow, water temperature, and aquatic habitat  
 4        conditions in the Stanislaus River downstream of Goodwin Dam would continue  
 5        to be influenced by CVP operations as described in Chapter 5, Surface Water  
 6        Resources and Water Supplies. Flows in the lower Stanislaus River are primarily  
 7        controlled by releases from New Melones Lake. Water released from New  
 8        Melones Dam and Powerplant is re-regulated at Tulloch Reservoir and is either  
 9        diverted at Goodwin Dam or released from Goodwin Dam to the lower  
 10       Stanislaus River.

11       The No Action Alternative includes a variety of 2009 NMFS BO RPA actions or  
 12       action suites intended to improve conditions for salmonids in the Stanislaus River.  
 13       These actions individually or in combination could influence conditions in the  
 14       Stanislaus River by 2030. These include:

- 15       • 2009 NMFS BO RPA Action III.1.1. Establish Stanislaus Operations Group  
 16       (SOG) for real-time operational decision-making
- 17       • 2009 NMFS BO RPA Action III.1.2. Provide cold water releases to maintain  
 18       suitable steelhead temperatures
- 19       • 2009 NMFS BO RPA Action III.1.3. Operate the East Side Division dams to  
 20       meet minimum flows
- 21       • 2009 NMFS BO RPA Action Suite III.2. Stanislaus River CV Steelhead  
 22       Habitat Restoration
  - 23       – 2009 NMFS BO RPA Action III.2.1. Increase and improve quality of  
 24       spawning habitat with addition of gravel
  - 25       – 2009 NMFS BO RPA Action III.2.2. Conduct floodplain restoration and  
 26       inundation flows in winter or spring to inundate steelhead juvenile rearing  
 27       habitat
  - 28       – 2009 NMFS BO RPA Action III.2.3. Restore freshwater migratory habitat  
 29       for juvenile steelhead
  - 30       – 2009 NMFS BO RPA Action III.2.4. Evaluate Fish Passage at New  
 31       Melones, Tulloch, and Goodwin dams

32       Under the No Action Alternative, Stanislaus River flows would be influenced by  
 33       regulations to meet water quality and flow criteria. However, by 2030, conditions  
 34       for fish, particularly salmonids, in the Stanislaus River fish are expected to  
 35       worsen because of increased temperatures due to the influence of climate change.

36       In accordance with 2009 NMFS BO RPA Action III.1.1, Reclamation has  
 37       convened a Stanislaus Operations Group (SOG) to provide a forum for real-time  
 38       operational flexibility implementation of the actions defined in the 2009 NMFS  
 39       BO RPA. This group includes representatives from Reclamation, NMFS,  
 40       USFWS, DWR, CDFW, SWRCB, and outside expertise at the discretion of  
 41       NMFS and Reclamation. The SOG provides direction and oversight to ensure

1 that the East Side Division actions are implemented, monitored for effectiveness  
2 and evaluated.

3 Under the No Action Alternative, Reclamation will continue, where feasible, to  
4 manage the cold water supply within New Melones Reservoir as described in  
5 2009 NMFS BO RPA Action III.1.2. The objective of these temperature criteria  
6 is to provide suitable temperatures for Central Valley steelhead rearing, spawning,  
7 egg incubation, smoltification, and adult migration in the Stanislaus River  
8 downstream of Goodwin Dam. There are no temperature control devices at New  
9 Melones, Goodwin, or Tulloch dams; thus, temperature management flexibility is  
10 limited to storage and flow management under certain conditions. Access to  
11 resources to offset operational temperature effects on steelhead in the Stanislaus  
12 River will continue to be limited, particularly in Conference Years and in drier  
13 Mid-Allocation Years. Under the No Action Alternative, steelhead would  
14 continue to be vulnerable to elevated temperatures in dry and critical dry years,  
15 even if actions are taken to improve temperature management. The frequency of  
16 these occurrences is expected to increase with climate change-related temperature  
17 increases.

18 Under the No Action Alternative, Reclamation would continue to meet the  
19 minimum flow schedule, to the best of their ability, as described in 2009 NMFS  
20 BO RPA Action III.1.3. The objective of the minimum flow schedule is to  
21 maintain minimum base flows to provide habitat for all life history stages of  
22 steelhead and to incorporate habitat maintaining geomorphic flows in a flow  
23 pattern that would provide migratory cues to smolts and facilitate out-migrant  
24 smolt movement. The flow schedule specifies minimum flows and does not  
25 preclude higher releases for other operational criteria. However, due to limited  
26 availability of water under the CVP water rights, it would be difficult to fully  
27 implement this action. Therefore, habitat conditions for steelhead and other fish  
28 species in the Stanislaus River would be similar or reduced relative to recent  
29 conditions in the near term. The value of this habitat also may be adversely  
30 influenced by higher temperatures associated with climate change.

31 Ongoing implementation of 2009 NMFS BO RPA Action Suite III.2 through  
32 2030 is anticipated to improve the physical habitat conditions for steelhead,  
33 although climate change may affect the types and cover rates of vegetation  
34 upslope of the river, and potentially increase the rate of fine sediment transport to  
35 the river and to spawning areas.

36 RPA Action III.2.4 requires Reclamation to evaluate options for providing  
37 steelhead access to their historic cold water habitat upstream of New Melones,  
38 Tulloch, and Goodwin dams and to provide access if feasible. As described  
39 above, temperature-related effects will be unavoidable in some years under the No  
40 Action Alternative. Lindley et al. (2007) identified the need for upstream habitat  
41 for salmonids, given predicted climate change in the next century. This may be  
42 particularly relevant for steelhead and salmon in the Stanislaus River where  
43 Goodwin Dam blocks all access to historical spawning and rearing habitat and  
44 where the remaining population survives as a result of dam operations in  
45 downstream reaches that were historically unsuitable habitat because of high

1 summertime temperatures. To the extent that preliminary fish passage efforts are  
2 underway by 2030, this could improve conditions for Stanislaus River salmonids.

3 *Aquatic Habitat Conditions in the Yolo Bypass (including Cache Slough,*  
4 *Lower Putah Creek, and Fremont Weir)*

5 As described in Chapter 5, Surface Water Resources and Water Supplies, climate  
6 change would increase the frequency of high flow events that would result in  
7 flows into the Yolo Bypass by 2030 as compared to recent historical conditions.  
8 Implementation of the operable gates at the Fremont Weir also would increase the  
9 frequency of flows into the Yolo Bypass.

10 Under the No Action Alternative, it is assumed that aquatic habitat conditions in  
11 the Yolo Bypass would improve by 2030 as a result of the following 2009 NMFS  
12 BO RPA actions:

- 13 • 2009 NMFS BO RPA Action I.6.1. Restoration of Floodplain Rearing  
14 Habitat.
- 15 • 2009 NMFS BO RPA Action I.6.2. Near-Term Actions at Liberty  
16 Island/Lower Cache Slough and Lower Yolo Bypass.
- 17 • 2009 NMFS BO RPA Action I.6.3. Lower Putah Creek Enhancements.
- 18 • 2009 NMFS BO RPA Action I.6.4. Improvements to Lisbon Weir.
- 19 • 2009 NMFS BO RPA Action I.7. Reduce Migratory Delays and Loss of  
20 Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the  
21 Yolo Bypass

22 Under the No Action Alternative, it is assumed that the elements of 2009 NMFS  
23 BO RPA Action Suite I.6.1 would be implemented in the Yolo Bypass, including  
24 up to 20,000 acres of shallow, low-velocity inundated floodplain. Actions in the  
25 Yolo Bypass also would include improvements in fish passage at Fremont Weir  
26 for anadromous salmonids, sturgeon, and other native fish species.

27 Passage at Fremont Weir would be facilitated by correcting a variety of passage  
28 issues within the bypass, including modification of agricultural structures in the  
29 northern Tule Canal that impede flow and cause fish passage delays.  
30 Modification of these structures under the No Action Alternative could  
31 substantially reduce fish passage delays through the Tule Canal. Similarly,  
32 replacement or modification of Lisbon Weir could allow unimpeded fish passage,  
33 reduced maintenance of the weir, and at the same time be managed to impound  
34 water for agriculture. In addition, the Knights Landing Ridge Cut could be  
35 modified to provide an exit path for upstream-migrating fish. These actions,  
36 along with the grading of downstream channels to improve connectivity to the  
37 Tule Canal when water levels fall as inundations recede and provide exit points  
38 for fish that would otherwise be stranded when inundations recede, are expected  
39 to improve conditions for salmonid rearing and fish passage by 2030.

40 Implementation of these ecosystem restoration actions and improvements under  
41 the No Action Alternative could increase growth and survival of juvenile Chinook  
42 Salmon, steelhead, and other native fish by providing increased seasonal access to

1 productive foraging and high quality rearing habitat, depending on the extent and  
2 duration of restoration and inundation. These actions may also reduce migratory  
3 delays or losses by reducing predation, straying, and delays for salmonids and  
4 other migratory native fish species.

5 *Aquatic Habitat Conditions in the Delta*

6 Under the No Action Alternative, flows, water quality, and aquatic habitat  
7 conditions in the Delta would continue to be influenced by CVP and SWP  
8 operations as described in Chapter 5, Surface Water Resources and Water  
9 Supplies and Chapter 6, Surface Water Quality. Overall, long-term average CVP  
10 and SWP water supply deliveries in 2030 through the Delta would decline as  
11 compared to historical long-term average deliveries. Because entrainment of fish  
12 in the Delta export facilities is related to the amount of water exported,  
13 entrainment would decline relative to recent conditions as a result of reduced  
14 water supply delivery.

15 Under the No Action Alternative, climate change is anticipated to have more of an  
16 effect on Delta flows during wetter years than during drier years because CVP  
17 and SWP operations occur with more flexibility during wet years, within the  
18 constraints of flood control requirements, compared to drier years when the CVP  
19 and SWP operations may be more frequently constrained to maintain instream  
20 flows and other environmental objectives. Overall, it is anticipated that due to  
21 climate change, sea level rise, and increased water demands in the Sacramento  
22 Valley, there would be less CVP and SWP water available for export in the Delta  
23 and CVP and SWP exports would decline. The reduction in Delta exports would  
24 result in more positive OMR flows by 2030 as compared to recent historical  
25 conditions. In other words, it is expected that fish in the channels surrounding the  
26 CVP and SWP projects will be exposed to lower entrainment risks than under  
27 recent historical conditions as a result of changes in operation due to factors  
28 described above (i.e., climate change, sea level rise, and increased water demands  
29 in the Sacramento Valley) climate change by 2030.

30 The No Action Alternative includes a variety of RPA actions or action suites from  
31 both the USFWS and NMFS biological opinions intended to improve conditions  
32 in the Delta for Delta Smelt, Longfin Smelt, salmonids and sturgeon. These  
33 actions individually or in combination could influence aquatic habitat conditions  
34 in the Delta by 2030. These include:

- 35 • 2008 USFWS BO RPA Component 1 (Actions 1 and 2). Protection of the  
36 Adult Delta Smelt Life Stage.
- 37 • 2008 USFWS BO RPA Component 2 (Actions 3 and 5). Protection of Larval  
38 and Juvenile Delta Smelt.
- 39 • 2008 USFWS BO RPA Component 3 (Action 4). Improve Habitat for Delta  
40 Smelt Growth and Rearing (Fall X2).
- 41 • 2008 USFWS BO RPA Component 4 (Action 6). Habitat Restoration.

- 1 • 2009 NMFS BO RPA Action Suite IV.1. Modify DCC gate operations and  
2 evaluate methods to control access to Georgiana Slough and the Interior Delta  
3 to reduce diversion of listed fish from the Sacramento River into the southern  
4 or central Delta.
- 5 • 2009 NMFS BO RPA Action Suite IV.2. Control the net negative flows  
6 toward the export pumps in Old and Middle rivers to reduce the likelihood  
7 that fish will be diverted from the San Joaquin or Sacramento River into the  
8 southern or central Delta.
- 9 • 2009 NMFS BO RPA Action IV.3. Curtail exports when protected fish are  
10 observed near the export facilities to reduce mortality from entrainment and  
11 salvage.
- 12 • 2009 NMFS BO RPA Action Suite IV.4. Improve fish screening and salvage  
13 operations to reduce mortality from entrainment and salvage.

14 Component 1 of the 2008 USFWS BO RPA is designed to reduce entrainment of  
15 pre-spawning adult Delta Smelt during December to March by controlling OMR  
16 flows during vulnerable periods, including adaptive management of OMR flows  
17 based on input and guidance from the Smelt Working Group to further reduce  
18 entrainment. Action 1 is designed to protect upmigrating Delta Smelt and  
19 Action 2 is designed to protect adult Delta Smelt that have migrated upstream and  
20 are residing in the Delta prior to spawning. Overall, RPA Component 1 is  
21 expected to increase the suitability of spawning habitat for Delta Smelt by  
22 decreasing the amount of Delta habitat affected by export pumping prior to, and  
23 during, the critical spawning period.

24 Component 2 is intended to improve flow conditions in the Central and South  
25 Delta such that larval and juvenile Delta Smelt could successfully rear in the  
26 Central Delta and move downstream when appropriate. The spring HORB would  
27 be installed only if the USFWS determines Delta Smelt entrainment is not a  
28 concern.

29 Implementation of Component 3 of the 2008 USFWS BO RPA requires the  
30 provision of sufficient Delta outflow to maintain a monthly average X2 no greater  
31 than 74 km in Wet water year types and 81 km in Above Normal water years.  
32 The objective of this component is to improve fall habitat for Delta Smelt through  
33 increasing Delta outflow during fall. Increases in fall habitat quality and quantity  
34 are anticipated to improve conditions for Delta Smelt under the No Action  
35 Alternative. However, implementation of this action would result in reduced  
36 storage in upstream reservoirs which could adversely affect temperature  
37 management in the Sacramento, Feather, and American rivers.

38 Component 4 of the 2008 USFWS BO RPA is intended to improve conditions for  
39 Delta Smelt habitat to supplement the improvements resulting from the flow  
40 actions described above. DWR is required to implement a program to create or  
41 restore a minimum of 8,000 acres of intertidal and associated subtidal habitat in  
42 the Delta and Suisun Marsh. It is assumed under the No Action Alternative that  
43 this requirement would be met by the Suisun Marsh Restoration Program and

1 would result in the restoration of more than 10,000 acres of intertidal and  
2 associated subtidal wetlands in Suisun Marsh and Cache Slough.

3 Implementation of the 2008 USFWS BO RPA would increase the likelihood that  
4 Delta Smelt habitat conditions and attributes for migration, spawning,  
5 recruitment, growth, and survival would be provided under the No Action  
6 Alternative. Implementation of actions under the 2008 USFWS BO RPA to  
7 restore tidally influenced habitat also is expected to increase salmonid and  
8 sturgeon rearing habitat and potentially food production for salmonids and Delta  
9 Smelt. Depending on the amount and type of restoration that would occur in  
10 brackish estuarine areas, restoration could increase rearing habitat for Sacramento  
11 Splittail, and alter conditions for predators and non-native fish species. Spawning  
12 habitat for roach, Hardhead, Sacramento Splittail, and Delta Smelt could be  
13 increased depending on whether restoration occurs in freshwater areas or in  
14 brackish estuarine areas. In addition, habitat restoration has the potential to alter  
15 habitat conditions for some invasive aquatic macrophyte species during some  
16 seasons, and in some locations, which could have indirect effects on predation.

17 Action Suite IV.1 of the 2009 NMFS BO RPA requires continued funding of  
18 monitoring programs at the RBDD, in spring-run Chinook Salmon tributaries to  
19 the Sacramento River, on the Sacramento River at Knights Landing and  
20 Sacramento, and sites within the Delta. In addition, salvage and loss of juvenile  
21 Chinook Salmon would be monitored at the Delta fish collection facilities  
22 operated by the CVP and SWP. A working group, composed of representatives  
23 from Reclamation, DWR, NMFS, USFWS, and CDFW, would develop and  
24 evaluate engineering solutions to reduce adverse impacts on listed fish and their  
25 critical habitat.

26 The DCC gate operations would be modified to reduce loss of emigrating  
27 salmonids and green sturgeon. The operating criteria provide for longer periods  
28 of gate closures during the outmigration season to reduce direct and indirect  
29 mortality of yearling spring-run and winter-run Chinook Salmon, and juvenile  
30 steelhead. Although route selection by Chinook Salmon and the mechanisms  
31 governing selection are complex (Perry et al. (2015), the closure of the DCC gates  
32 may increase the survival of salmonid emigrants through the Delta, and the early  
33 closures could reduce loss of fish with unique and valuable life history strategies  
34 in the spring-run Chinook Salmon and Central Valley steelhead populations.

35 Conditions under the No Action Alternative would be influenced by  
36 implementation of Action Suite IV.2 of the 2009 NMFS BO RPA. This action  
37 suite requires the maintenance of adequate flows in both the Sacramento River  
38 and San Joaquin River basins to increase survival of steelhead emigrating to the  
39 estuary from the San Joaquin River, and of Chinook Salmon, steelhead, and  
40 Green Sturgeon emigrating from the Sacramento River through the Delta to  
41 Chipps Island. This action suite includes actions to reduce the vulnerability of  
42 emigrating steelhead within the lower San Joaquin River to entrainment into the  
43 channels of the South Delta and at the export facilities by increasing the inflow to  
44 export ratio. Cunningham et al. (2015) found a negative influence of the  
45 export/inflow ratio on the survival of fall-run Chinook populations and a negative

1 influence of increased total Delta exports on the survival of spring-run Chinook  
2 populations. In addition, there are actions to enhance the likelihood of salmonids  
3 successfully exiting the Delta at Chipps Island by creating more suitable hydraulic  
4 conditions in the main stem of the San Joaquin River for emigrating fish,  
5 including greater net downstream flows. Historical data suggest that high San  
6 Joaquin River flows in the spring result in higher survival of outmigrating  
7 Chinook Salmon smolts and greater returns of adults. The data also suggest that  
8 when the ratio between spring flows and exports increase, Chinook Salmon  
9 production increases. Increased flows within the San Joaquin River portion of the  
10 Delta could also enhance the survival of Sacramento River salmonids. Those fish  
11 from the Sacramento River that have been diverted through the interior Delta to  
12 the San Joaquin River could benefit by the increased net flow towards the ocean  
13 caused by the higher flows in the San Joaquin River from upstream and the  
14 reduced influence of the export pumps.

15 2009 NMFS BO RPA Action Suite IV.2 also includes flow management for the  
16 Old and Middle rivers that would be implemented in conjunction with the  
17 restrictions on exports under the 2008 USFWS BO RPA. Old and Middle river  
18 flow management is designed to ensure that emigrating steelhead from the San  
19 Joaquin Basin and the east-side tributaries remain in the mainstem of the San  
20 Joaquin River to the greatest extent possible and reduce their exposure to the  
21 adverse effects that are present in the channels leading south toward the export  
22 facilities. This is anticipated to increase the likelihood of survival of steelhead  
23 emigrating from the San Joaquin River. Reducing the risk of diversion into the  
24 central and southern Delta waterways also could increase survival of listed  
25 salmonids and Green Sturgeon entering the San Joaquin River via Georgiana  
26 Slough and the lower Mokelumne River. However, recent coded wire tagging  
27 and acoustic studies have shown survival to be reach specific for both Chinook  
28 Salmon and steelhead and that survival of hatchery-origin (Feather River) juvenile  
29 Chinook Salmon was higher through the south Delta via the Old River route than  
30 via the San Joaquin River (Buchanan et al. 2013, 2015). However, most fish in  
31 the Old River that survived to the end of the Delta had been salvaged from the  
32 federal water export facility on the Old River and trucked around the remainder of  
33 the Delta (Buchanan et al. 2013, SJRGA 2013). Zeug and Cavallo (2014) suggest  
34 that entrainment losses at the diversions may be small relative to overall migration  
35 mortality.

36 The 2009 NMFS BO RPA Action IV.3 requires operations of the Tracy and  
37 Skinner Fish Collection Facilities to be modified according to monitoring data  
38 from upstream of the Delta. In conjunction with the two alerts for closure of the  
39 DCC (Action IV.1.1), a third alert would be used to signal that export operations  
40 may need to be altered due to large numbers of juvenile Chinook Salmon  
41 migrating into the upper Delta region, increasing their risk of entrainment into the  
42 central and south Delta and then to the export pumps. When more fish are  
43 present, more fish are at risk of diversion and losses would be higher. The third  
44 alert is important for real-time operation of the export facilities because the  
45 collection and dissemination of field data to the resource agencies and  
46 coordination of response actions could take several days. This action is designed

1 to work in concert with the Old and Middle River flow management in action  
2 suite IV.2. Under the No Action Alternative, implementation of this action is  
3 anticipated to reduce losses of winter-run and spring-run Chinook Salmon,  
4 steelhead, and Green Sturgeon by reducing exports when large numbers of  
5 juvenile Chinook Salmon are migrating into the upper Delta region.

6 Action Suite IV.4 of the 2009 NMFS BO RPA is designed to increase the  
7 efficiency of the Tracy and Skinner Fish Collection Facilities to improve the  
8 overall salvage survival of winter-run and spring-run Chinook Salmon, steelhead,  
9 and Green Sturgeon to achieve a 75 percent performance goal for whole facility  
10 salvage at both state and Federal facilities. Reclamation and DWR will (1)  
11 conduct studies to evaluate current operations and salvage criteria to reduce take  
12 associated with salvage, (2) develop new procedures and modifications to  
13 improve the current operations, and (3) implement changes to the physical  
14 infrastructure of the facilities where information indicates such changes need to  
15 be made. In addition, Reclamation would continue to fund and implement the  
16 CVPIA Tracy Fish Facility Program. Reclamation and DWR would fund quality  
17 control and quality assurance programs, genetic analysis, louver cleaning loss  
18 studies, release site studies and predation studies. Funding would also be  
19 provided for new studies to estimate Green Sturgeon screening efficiency at both  
20 facilities and survival through the trucking and handling process. Under the No  
21 Action Alternative, implementation of measures to fund fish screens, reduce pre-  
22 screen loss, improve screening efficiency, and improve reporting could reduce  
23 entrainment and salvage, and result in improved survival for juvenile Salmonids  
24 migrating downstream through the Delta, as well as for Sacramento Splittail,  
25 Delta Smelt, and other native fish species.

26 Abundance and habitat conditions for Delta Smelt and other fish species in the  
27 Delta under the No Action Alternative in 2030 are difficult to predict. Abundance  
28 levels for Delta Smelt, Longfin Smelt, Striped Bass, Threadfin Shad, and  
29 American Shad under recent conditions are very low compared to pre-POD levels,  
30 as evidenced by the number of fish collected in sampling programs such as the  
31 FMWT surveys conducted by the IEP. Numbers of fish collected have continued  
32 to decline in recent years, even with implementation of the RPAs. Annual  
33 reviews conducted by the Delta Science Program Independent Review Panel  
34 (IRP) for the Long-Term Operations Biological Opinions have called for better  
35 metrics to measure the effects of the BO RPAs on the protected species (IRP  
36 2011, 2013, 2014) to allow more informed decision-making, while  
37 acknowledging challenges, constraints, and the complexity of the issues.

38 Currently low levels of relative abundance do not bode well for the Delta Smelt or  
39 other fish species in the Delta in 2030. Challenges to fish species in the Delta are  
40 many, and would continue in the future under the No Action Alternative,  
41 including high water temperatures, reduced flows, habitat degradation, barriers,  
42 predation, low DO, contamination, entrainment, salvage, poaching, disease,  
43 competition, non-native species, and lack of available food. Use of observations  
44 on current conditions to predict future long-term changes for Delta fish is  
45 especially challenging when combined with other potentially adverse future

1 changes foreseen for the Delta, e.g., altered hydrology due to drought, rising  
2 temperatures, and potential sea level rise (Sommer and Meija, 2013).

### 3 **9.4.2.2.3 Special Status Species and Critical Habitat**

#### 4 *Clear Creek*

5 Clear Creek is designated critical habitat for spring-run Chinook Salmon and  
6 Central Valley steelhead. The Primary Constituent Element (PCEs) of critical  
7 habitat for both species include freshwater spawning sites, freshwater rearing  
8 areas, and freshwater migration corridors. Spawning and rearing habitat for  
9 spring-run Chinook Salmon in Clear Creek has been negatively affected by flow  
10 and water temperature conditions associated with current operations. As  
11 described above, it is anticipated minimum flows in Clear Creek would be  
12 increased during the fall and winter to improve conditions for spawning  
13 salmonids as a result of recently completed IFIM studies. Continuation of spring  
14 pulse flows (RPA Action I.1.1) and implementation of channel maintenance flows  
15 (RPA Action I.1.2), in conjunction with ongoing gravel augmentation in Clear  
16 Creek, is expected to result in improvements in the PCEs of critical habitat for  
17 spring-run Chinook Salmon and steelhead relative to recent conditions.

#### 18 *Sacramento River*

19 The Sacramento River provides three of the six PCEs essential to support one or  
20 more life stages, including freshwater spawning sites, rearing sites, and migration  
21 corridors for winter-run and spring-run Chinook Salmon and steelhead. The  
22 Sacramento River is also designated critical habitat for the Southern DPS of  
23 Green Sturgeon. Flow and temperature changes under the No Action  
24 Alternative and the effects on spawning and rearing habitat quality were described  
25 previously.

26 Climate change is likely to reduce the conservation value of the spawning habitat  
27 PCE of critical habitat by increasing water temperatures, which would reduce the  
28 availability of suitable spawning habitat. Cold water in Shasta Lake is expected  
29 to be depleted sooner in the summer, impacting winter-run and spring-run  
30 Chinook Salmon spawning habitat. This reduction in an essential feature of the  
31 spawning habitat PCE could reduce the spatial structure, abundance, and  
32 productivity of salmonids. Similarly, as described above, climate change is likely  
33 to reduce availability of rearing habitat, and in turn, the value of the rearing  
34 habitat PCE of critical habitat, by increasing water temperatures.

35 The year-round opening of the gates at the RBDD in accordance with Action  
36 Suite I.3 of the 2009 NMFS BO RPA allows salmonids to pass unimpeded,  
37 enhancing the conservation value of the PCE for migration. Critical habitat for  
38 Green Sturgeon would also improve from unimpeded access to suitable spawning  
39 habitat upstream of the RBDD. The improved passage at the RBDD location is  
40 expected to increase the number of deep holding pools that adult Green Sturgeon  
41 can access, thereby increasing the conservation value of the water depth PCE. In  
42 addition, predation on salmon, steelhead, and sturgeon would be reduced relative  
43 to conditions when the RBDD was operational.

1 *American River*

2 The lower American River downstream of Nimbus Dam is designated critical  
3 habitat for Central Valley steelhead. The PCEs of critical habitat in the lower  
4 American River include freshwater spawning sites, freshwater rearing areas, and  
5 freshwater migration corridors. Flow and temperature changes under the No  
6 Action Alternative and the effects on spawning and rearing habitat quality were  
7 described previously. In addition, the influence of climate change is expected to  
8 alter hydrologic and temperature conditions in the region and could adversely  
9 affect the PCEs for Central Valley steelhead critical habitat in the American  
10 River, primarily through increased water temperatures.

11 *Stanislaus River*

12 The lower Stanislaus River downstream of Goodwin Dam is designated critical  
13 habitat for Central Valley steelhead. The PCEs of critical habitat in the Stanislaus  
14 River include freshwater spawning sites, freshwater rearing areas, and freshwater  
15 migration corridors. Flow and temperature changes under the No Action  
16 Alternative and the effects on spawning and rearing habitat quality were described  
17 previously. The PCEs for spawning and rearing habitat have been adversely  
18 affected by elimination of geomorphic processes that replenish and rejuvenate  
19 spawning riffles and inundate floodplain terraces to provide nutrients and rearing  
20 habitat for juvenile salmonids. In addition, moderation of flood events also  
21 eliminates or reduces the intensity and duration of freshets and storm flows,  
22 which adversely affects the PCE for migration corridors. The influence of climate  
23 change could begin to alter hydrologic and temperature conditions in the region  
24 and adversely affect the PCEs for Central Valley steelhead critical habitat in the  
25 Stanislaus River, primarily through increased water temperatures.

26 *Delta*

27 Critical habitat for both winter-run and spring-run Chinook Salmon is designated  
28 in the Sacramento River adjacent to the location of the DCC gates. The DCC is  
29 specifically not included in designated critical habitat for winter-run Chinook  
30 Salmon because the biological opinions issued by NMFS in 1992 and 1993  
31 included measures on the operations of the gates that were designed to exclude  
32 winter-run Chinook Salmon from the channel and the waters of the Central Delta.  
33 However, for spring-run Chinook Salmon, designated critical habitat does include  
34 the DCC from its point of origin on the Sacramento River to its terminus at  
35 Snodgrass Slough, including the location of the gates. Designated critical habitat  
36 for Central Valley steelhead includes most of the Delta and its waterways, but not  
37 the DCC waterway.

38 Operation of the DCC gates affects the PCEs for critical habitat designated for  
39 these species. Primarily, DCC gate operations interfere with the use of the  
40 Sacramento River as a migratory corridor for Chinook Salmon and steelhead  
41 juveniles during their downstream migration from spawning grounds upstream of  
42 the Delta to San Francisco Bay and the Pacific Ocean. The operation of the gates  
43 permits fish to enter habitat and waterways they would not normally access, with  
44 substantially higher predation risks than the migratory corridor available in the  
45 Sacramento River channel. Under the No Action Alternative, operation of the

1 gates could have a direct effect on the entrainment rate and hence the functioning  
2 of the Sacramento River as a migratory corridor.

#### 3 **9.4.2.2.4 Effects Related to Cross Delta Water Transfers**

4 Because all water transfers would be required to avoid adverse impacts to other  
5 water users and biological resources (see Section 3.A.6.3, Transfers), including  
6 impacts associated with changes in reservoir storage and river flow patterns.  
7 Potential effects to aquatic resources could be similar to those identified in a  
8 recent environmental analysis conducted by Reclamation for long-term water  
9 transfers from the Sacramento to San Joaquin valleys (Reclamation 2014d).  
10 Potential effects were identified as changes to fish in the reservoirs and in the  
11 rivers downstream of the reservoirs and the Delta. The analysis indicated that the  
12 reservoirs did not support primary populations of fish species of management  
13 concern, and that the reservoirs would continue to be operated within the  
14 historical range of operations. The analysis also indicated that mean monthly  
15 flows in the major rivers or creeks in the Sacramento and San Joaquin rivers  
16 watersheds would be similar (less than 10 percent change) with water transfers as  
17 compared to without water transfers; and therefore, changes to aquatic resources  
18 would be less than substantial. Delta conditions also would be similar with water  
19 transfers as compared to without water transfers, including less than 5 percent  
20 changes in Delta exports and less than 1.3 percent changes in Delta outflow and  
21 X2 position. Therefore, changes to aquatic resources would be less than  
22 substantial. For the purposes of this EIS, it is anticipated that similar conditions  
23 would occur due to cross Delta water transfers under the No Action  
24 Alternative and the Second Basis of Comparison.

25 Under the No Action Alternative, the timing of cross Delta water transfers would  
26 be limited to July through September in accordance with the 2008 USFWS BO  
27 and 2009 NMFS BO. The maximum amount of water to be transferred would be  
28 600,000 acre-feet/year in critical dry years or in dry years following a dry or  
29 critical dry year. In all other water year types, the maximum amount of water  
30 would be 360,000 acre-feet/year.

#### 31 **9.4.2.2.5 Conditions for Fish Passage**

32 As described in Chapter 3, Description of Alternatives, the No Action  
33 Alternative includes a suite of RPA actions intended to examine the  
34 reintroduction of salmonids into historical habitats upstream of currently  
35 impassable artificial barriers. The actions include consideration for passage of  
36 winter-run and spring-run Chinook Salmon, and steelhead above Shasta Dam on  
37 the Sacramento River, steelhead above Nimbus and Folsom dams on the  
38 American River, and steelhead above Goodwin, Tulloch, and New Melones dams  
39 on the Stanislaus River. The action suite outlines multiple planning and  
40 implementation steps to evaluate the efficacy of passage before long-term fish  
41 passage is provided. However, for the purposes of the describing the No Action  
42 Alternative, fish passage at each of these facilities (likely through interim means)  
43 is assumed to be functional by 2030.

1 As described in the Affected Environment, Reclamation is currently developing  
2 near-term and long-term fish passage solutions to provide access by anadromous  
3 salmonids to habitat upstream of Shasta Lake (2009 NMFS BO RPA  
4 Action I.2.5). The evaluation includes assessments of amount, suitability, and  
5 location of potential habitat, potential risks (e.g., predation by resident fish,  
6 disease transmission), as well as feasibility of providing upstream and  
7 downstream passage. There are approximately 60 mainstem miles and the  
8 McCloud River upstream of Shasta Lake. Reclamation (2014c) estimated  
9 approximately 9 river-miles of suitable winter-run Chinook Salmon spawning  
10 habitat in the upper Sacramento River below Box Canyon Dam, and  
11 approximately 12 river-miles of suitable spawning habitat for winter-run Chinook  
12 Salmon in the McCloud River below McCloud Dam. By 2030, access to this  
13 habitat could not only expand the amount of habitat available for winter-run  
14 Chinook Salmon relative to recent conditions, but provide access to areas of  
15 temperature refuge at a time when water temperatures in the river downstream of  
16 Keswick Dam are anticipated to increase. This could be particularly beneficial as  
17 winter-run Chinook Salmon are currently at high risk of extinction. Extinction  
18 factors include: winter-run Chinook Salmon is composed of only one population,  
19 which has been blocked from all of its historic spawning habitat; the potential for  
20 catastrophic risks associated with proximity to Mt. Lassen and the population's  
21 dependency on the cold water management of Shasta Lake; and the population  
22 has a "high" hatchery influence (Lindley et al. 2007). Combined with  
23 improvements on Battle Creek that are expected to support a second population  
24 component of winter-run Chinook Salmon, the provision for fish passage  
25 upstream of Shasta Dam may support a third population, which is consistent with  
26 the NMFS Recovery Plan for this species (NMFS 2014b).

27 Similarly, conditions for steelhead in the American River could be influenced by  
28 fish passage at Nimbus and Folsom dams afforded by implementation of 2009  
29 NMFS BO RPA Action II.5. As described in the Affected Environment, water  
30 temperature conditions in the lower American River downstream of Nimbus Dam  
31 currently present challenges for steelhead, especially rearing juveniles. Under the  
32 No Action Alternative, anticipated increases in temperature related to climate  
33 change could increase the vulnerability of steelhead to serious effects of elevated  
34 temperatures in most years, particularly in dry and critical dry years, even if  
35 actions are taken to improve temperature management. The provision of passage  
36 to upstream reaches of the American River, including tributaries, would give  
37 steelhead access to former spawning and rearing habitat higher in the system  
38 where water temperatures are cooler and remain cooler during the summer  
39 months. Assuming this action results in fish passage by 2030, conditions for  
40 steelhead are expected to improve because of the increased amount of available  
41 habitat and the ability to access cooler water temperatures.

42 Relative to recent conditions, substantial improvements also would be expected  
43 for steelhead on the Stanislaus River under the No Action Alternative, if 2009  
44 NMFS BO RPA Action II.2.4 is determined feasible and is implemented by 2030.  
45 As described in the Affected Environment, steelhead in the Stanislaus River are  
46 exposed to multiple stressors, including high water temperatures during adult

1 immigration, embryo incubation, juvenile rearing, and smolt outmigration. In  
 2 addition, flow-dependent habitat availability is limited, particularly for the  
 3 spawning, juvenile rearing, and smolt outmigration life stages. Access to former  
 4 habitat in upstream areas under the No Action Alternative are anticipated to  
 5 reduce many of the stressors associated with recent conditions and could provide  
 6 improved resilience to climate change.

#### 7 **9.4.2.2.6 Ocean Conditions**

8 Operation of the CVP and SWP would not directly affect ocean conditions;  
 9 however, operations have the potential to affect Southern Resident Killer Whales  
 10 indirectly by influencing the number of Chinook Salmon (produced in the  
 11 Sacramento-San Joaquin River and associated tributaries) that enter the Pacific  
 12 Ocean and become available as a food supply for the whales. The No Action  
 13 Alternative would not directly affect critical habitat for Killer Whales. However,  
 14 under the No Action Alternative, production of wild Chinook Salmon could  
 15 increase with increased area and quality of habitat for Chinook Salmon, as  
 16 discussed previously. Chinook Salmon from the Central Valley rivers and  
 17 streams likely represent only a very small proportion of the diet of this Killer  
 18 Whale population because most of their feeding is on Fraser River and Puget  
 19 Sound stocks (Hanson et al. 2010). Therefore, any increase in the population of  
 20 Chinook Salmon originating from the Central Valley under the No Action  
 21 Alternative is not expected to substantially influence the Southern Resident Killer  
 22 Whale population.

#### 23 **9.4.2.3 Second Basis of Comparison**

24 As described in Chapter 3, Description of Alternatives, the Second Basis of  
 25 Comparison is based upon:

- 26 • Coordinated long-term operation of the CVP and SWP in 2030 without  
 27 implementation of the 2008 USFWS BO and the 2009 NMFS BO RPAs
- 28 • Changes in CVP and SWP operations due to climate change and sea level rise,  
 29 and increased CVP and water rights water demand in portions of the  
 30 Sacramento Valley
- 31 • Implementation of reasonable and foreseeable non-CVP and -SWP water  
 32 resources projects to provide additional water supplies, as described in  
 33 Section 7.4.3.1, No Action Alternative
- 34 • Implementation of RPA actions that address programs and projects that were  
 35 ongoing prior to issuance of the 2008 USFWS BO and 2009 NMFS BO,  
 36 including restoration of Battle Creek for salmonids; replacement of the Red  
 37 Bluff Diversion Dam; restoration of more than 10,000 acres of intertidal and  
 38 associated subtidal wetlands in Suisun Marsh and Cache Slough; and  
 39 17,000 to 20,000 acres of seasonal floodplain restoration in the Yolo Bypass.

40 Overall, under the Second Basis of Comparison, long-term average CVP and  
 41 SWP water supply deliveries by 2030 through the Delta would increase, and late  
 42 summer and fall reservoir storage probably would decrease as compared to recent

1 historical conditions without consideration for climate change. However, the  
2 Second Basis of Comparison also includes changes not related to the coordinated  
3 long-term operation of the CVP and SWP, including changes in CVP and SWP  
4 operations due to climate change and sea level rise, increased CVP and water  
5 rights water demand in portions of the Sacramento Valley, and implementation of  
6 reasonable and foreseeable non-CVP or SWP water resources management  
7 projects to provide water supplies, as described under the No Action Alternative.  
8 Therefore, primarily due to climate change, both CVP and SWP reservoir storage  
9 and long-term average CVP and SWP water supply deliveries would decrease by  
10 2030 as compared to historical long-term average deliveries.

11 Under the Second Basis of Comparison it is assumed that fish and aquatic  
12 resources in 2030 would continue to be influenced by CVP and SWP operations.  
13 The resulting changes in ecological attributes and subsequent effects on aquatic  
14 resources would vary geographically, as described below.

#### 15 **9.4.2.3.1 Trinity River Region**

##### 16 *Aquatic Habitat Conditions in CVP and SWP Reservoirs*

17 End of September reservoir storage in Trinity Lake would be lower by 2030 as  
18 compared to recent historical conditions due to climate change and related lower  
19 snowfall. Lewiston Reservoir, a regulating reservoir, would be operated with  
20 daily changes similar to historical conditions. These changes are not anticipated  
21 to substantially affect aquatic resources in Trinity Lake or Lewiston Reservoir  
22 relative to recent historical conditions.

##### 23 *Fish Habitat Conditions in Trinity and Lower Klamath Rivers*

24 Under the Second Basis of Comparison, flow, water temperature, and aquatic  
25 habitat conditions in the Trinity River would continue to be influenced by CVP  
26 and SWP operations as described in the Affected Environment. Due to the  
27 increased potential for lower Trinity Lake surface water storage (see above), there  
28 could be an increased potential for reduced Trinity River flows during the summer  
29 and fall months under the Second Basis of Comparison as compared to recent  
30 historical conditions. The influence of climate change could result in higher  
31 water temperatures in Trinity Lake that could translate to higher release  
32 temperatures in the flow releases from Lewiston Dam and a reduction in habitat  
33 quality within the Trinity River for salmonids and other native species.

##### 34 *Effects Related to Water Transfers*

35 It is not anticipated that water would be transferred to or from the Trinity River  
36 Region. It also not anticipated that water transfers would result in changes to  
37 Trinity Lake operations. Therefore, there would be no change in aquatic habitat  
38 conditions as a result of water transfers.

#### 39 **9.4.2.3.2 Central Valley Region**

##### 40 *Aquatic Habitat Conditions in CVP and SWP Reservoirs*

41 Seasonal changes in reservoir surface elevations, storage volumes, and the volume  
42 of cold water held within the reservoirs would continue under the Second Basis of

1 Comparison. Conditions for reservoir fishes would continue to change seasonally  
 2 in response to inflow and downstream flow releases to meet demand. End of  
 3 September reservoir storage would be lower by 2030 as compared to recent  
 4 historical conditions in Shasta Lake, Lake Oroville, Folsom Lake, New Melones  
 5 Reservoir, and San Luis Reservoir due to climate change and related lower  
 6 snowfall. Whiskeytown Lake, Keswick Reservoir, Thermalito Forebay and  
 7 Afterbay, and Lake Natoma are regulating reservoirs and would be operated with  
 8 daily changes similar to historical conditions.

9 Under the Second Basis of Comparison, the magnitude of changes in seasonal  
 10 surface elevation and reservoir storage could be more pronounced because of  
 11 changes in the timing and intensity of storm events due to climate change and an  
 12 overall reduction in snow pack. By 2030, fish in these reservoirs that spawn in  
 13 shallow water (e.g., various species of black bass) could be subject to a  
 14 hydrologic regime that increases the frequency of reductions in surface elevation  
 15 during the spring spawning period, reducing spawning success. In addition,  
 16 reduced storage volumes and reduction of the cold water pools could reduce the  
 17 amount and suitability of habitat for cold water fishes (e.g., trout) within the  
 18 reservoirs relative to recent historical conditions.

19 *Aquatic Habitat Conditions in Rivers Downstream of CVP and SWP Facilities*

20 Surface water flows are anticipated to increase during the winter months as a  
 21 result of an increase in rainfall and decrease in snowfall, and to decrease in other  
 22 months because of the diminished snowmelt flows in the spring and early summer  
 23 months. Climate change is anticipated to result in higher water temperatures  
 24 during portions of the year, with a corresponding reduction in habitat quality for  
 25 salmonids and other cold water fishes. Increased downstream water demands and  
 26 climate change are anticipated to contribute to an inability to maintain an  
 27 adequate cold water pool in critical dry years and extended dry periods in the  
 28 future.

29 *Aquatic Habitat Conditions in Clear Creek from Whiskeytown Dam to*  
 30 *Sacramento River*

31 Under the Second Basis of Comparison, flow, water temperature, and aquatic  
 32 habitat conditions in Clear Creek would continue to be influenced by CVP and  
 33 SWP operations. Whiskeytown Reservoir would continue to be operated to  
 34 convey water from the Trinity River to the Sacramento River via the Spring Creek  
 35 tunnel and to release flows to Clear Creek to support anadromous fish.

36 The Second Basis of Comparison assumes that one of the 2009 NMFS BO RPA  
 37 actions intended to improve conditions for salmonids would be implemented,  
 38 2009 NMFS BO RPA Action I.3 Spawning Gravel Augmentation, which is  
 39 currently being implemented as part of the CVPIA. This action addresses the  
 40 limited availability of spawning habitat in Clear Creek through the placement of  
 41 gravel in selected sites in the creek. The gravel augmentation program is  
 42 expected to continue under the Second Basis of Comparison, resulting in  
 43 continued improvements to physical spawning habitat for steelhead, and spring-  
 44 run and fall-run Chinook Salmon by 2030.

1 Water temperatures in Clear Creek are influenced by the temperature of water in  
2 the Whiskeytown Reservoir, ambient air temperatures, and solar radiation, and to  
3 some extent the magnitude of Whiskeytown Dam release flows. As described  
4 above for the No Action Alternative, Whiskeytown Dam has limited temperature  
5 control capabilities; however, the Spring Creek Temperature Control Curtain  
6 continues to be operated under the Second Basis of Comparison. With increasing  
7 ambient air temperature and changes in precipitation patterns as result of global  
8 warming, it may not be possible to meet the temperature targets as often in 2030  
9 under the Second Basis of Comparison relative to recent conditions.

10 *Aquatic Habitat Conditions in the Sacramento River from Keswick to*  
11 *Freeport*

12 Under the Second Basis of Comparison, flow, water temperature, and aquatic  
13 habitat conditions in the Sacramento River downstream of Keswick Dam would  
14 continue to be influenced by CVP and SWP operations. Shasta Lake would  
15 continue to be operated to convey water from the Sacramento River to the Delta  
16 and release flows to the Sacramento River to support anadromous fish.  
17 Reclamation would continue to operate Shasta Lake to optimize use of the cold  
18 water pool and maintain carryover storage for temperature control in the  
19 Sacramento River downstream of Shasta and Keswick dams. As described above  
20 for the No Action Alternative, it is likely that temperature-related effects in the  
21 Sacramento River under the Second Basis of Comparison also would be  
22 unavoidable in some years; however, restoration of habitat in Battle Creek (see  
23 below) may compensate for these periods of unavoidably high temperatures by  
24 providing passage and habitat conditions to support a second population of  
25 winter-run Chinook Salmon.

26 The Red Bluff Pumping Plant and fish screen, which diverts water to the Tehama  
27 Colusa Canal and Corning Canal, was constructed to allow year-round opening of  
28 the gates at the RBDD. Allowing the dam gates at RBDD to remain open allows  
29 salmonids, sturgeon, and other fish species to pass unimpeded all year. These  
30 passage improvements are anticipated to improve conditions for fish species that  
31 spawn upstream of RBDD through improved access to spawning and rearing  
32 areas and a reduction in predation due to dispersal of predator species like Striped  
33 Bass and Sacramento Pikeminnow.

34 As described above for the No Action Alternative, it is anticipated that worsening  
35 temperature conditions under the Second Basis of Comparison would occur in  
36 some years as a result of increased demands for water by 2030, climate change,  
37 and less water being diverted from the Trinity River. Continued implementation  
38 of the Battle Creek Restoration Program would partially compensate for  
39 unavoidable adverse effects by restoring winter-run and spring-run Chinook  
40 Salmon habitat to the Battle Creek watershed. Full implementation of the Battle  
41 Creek Restoration Program is expected to substantially improve passage  
42 conditions for adult Chinook Salmon and steelhead relative to recent conditions.  
43 The Battle Creek Restoration Program has a goal of improving habitat for a  
44 second population component of winter-run Chinook Salmon, which could reduce

1 the risk of extinction of the species from lost resiliency and increased  
2 vulnerability to catastrophic events.

3 *Aquatic Habitat Conditions in the Feather River from Oroville Dam to*  
4 *Sacramento River*

5 Feather River flows in the high flow channel downstream of Thermalito Dam  
6 under the Second Basis of Comparison would be influenced by regulation to meet  
7 water temperature criteria and to coordinate Lake Oroville releases and Delta  
8 export operations. Flows in the low flow channel downstream of Lake Oroville  
9 would remain similar to recent conditions. As part of the ongoing FERC  
10 relicensing process for the Oroville facilities, DWR has entered into a Settlement  
11 Agreement (DWR 2006) that includes actions to be implemented and included as  
12 terms of the anticipated FERC license. Depending on the progress of the  
13 relicensing process, these actions could be implemented by 2030 under the  
14 Second Basis of Comparison and could improve fish habitat conditions in the  
15 Feather River relative to recent conditions.

16 Under the terms of the Settlement Agreement, DWR will develop a  
17 comprehensive Lower Feather River Habitat Improvement Plan. Implementation  
18 of the habitat improvement plan and other actions under the terms of the  
19 Settlement Agreement is anticipated to improve habitat conditions and water  
20 quality for salmonids and other fishes using the channels of the Feather River  
21 above the confluence with the Sacramento River under the Second Basis of  
22 Comparison.

23 *Aquatic Habitat Conditions in the American River from Nimbus Dam to*  
24 *Sacramento River*

25 Reclamation releases water to the lower American River consistent with flood  
26 control requirements; existing water rights; CVP operations; the Lower American  
27 River Flow Management Standard; and SWRCB Decision 893 (D-893). Under  
28 the Second Basis of Comparison, American River flows would be influenced by  
29 releases for regulation to meet water temperature criteria, and to coordinate timed  
30 Folsom Lake releases and Delta exports. It is anticipated that conditions for fish  
31 in the lower American River under the Second Basis of Comparison would  
32 worsen relative to recent past operations of the American River Division of the  
33 CVP because of continued operation of the American River Division through  
34 2030 to meet increasing water demands. In addition, the influence of climate  
35 change could alter hydrologic conditions in the region and affect habitat  
36 conditions for fish in the American River.

37 Through 2030, Reclamation would implement the flow schedule specified in the  
38 American River Flow Management Standard. The flow schedule specifies  
39 minimum flows and does not preclude Reclamation from making higher releases  
40 at Nimbus Dam. The flow schedule was developed to require more protective  
41 minimum flows in the lower American River in consideration of the river's  
42 aquatic resources, particularly steelhead and fall-run Chinook Salmon.

1        *Aquatic Habitat Conditions in the San Joaquin River from Friant Dam to the*  
2        *Stanislaus River*

3        Under the Second Basis of Comparison, fish and aquatic habitat conditions in the  
4        San Joaquin River downstream of Friant Dam would remain similar to those  
5        described under the Affected Environment, although water temperatures could  
6        increase as a result climate change.

7        *Aquatic Habitat Conditions in the Stanislaus River from Goodwin Dam to San*  
8        *Joaquin River*

9        Under the Second Basis of Comparison, flow, water temperature, and aquatic  
10       habitat conditions in the Stanislaus River downstream of Goodwin Dam would  
11       continue to be influenced by CVP and SWP operations as described in Chapter 5,  
12       Surface Water Resources and Water Supplies. However, by 2030, conditions for  
13       fish in the Stanislaus River fish are expected to worsen relative to recent  
14       conditions because of continued operation to meet increasing water demands.  
15       In addition, the influence of climate change is expected to begin to alter  
16       hydrologic conditions in the region and affect habitat conditions for fish in the  
17       Stanislaus River.

18       Under the Second Basis of Comparison, management of the cold water supply  
19       within New Melones Reservoir would continue, as would cold water releases  
20       from the reservoir to provide suitable temperatures for steelhead rearing,  
21       spawning, egg incubation smoltification, and adult migration in the Stanislaus  
22       River downstream of Goodwin Dam. There are no temperature control devices at  
23       New Melones, Goodwin, or Tulloch dams, so the only mechanism for temperature  
24       management is direct flow management. This has been achieved in the recent  
25       past through a combination of augmenting baseline water operations for meeting  
26       senior water right deliveries and D-1641 water quality standards with additional  
27       flows from: 1) the CDFW fish agreement, and 2) from b(2) or b(3) water  
28       acquisitions. Access to these resources to offset operational temperature effects  
29       on steelhead in the Stanislaus River would continue to be limited, particularly in  
30       Conference Years and in drier Mid-Allocation Years. Under the Second Basis of  
31       Comparison, steelhead would likely continue to be vulnerable to the effects of  
32       elevated temperatures in dry and critical dry years. The frequency of these  
33       occurrences is expected to increase with climate change and increased water  
34       demands.

35       Reclamation would continue to operate releases from the East Side Division  
36       reservoirs to achieve the minimum flow schedule specified in the 1997 New  
37       Melones Interim Plan of Operations as described in Chapter 5, Surface Water  
38       Resources and Water Supplies. Because this flow schedule has been in place for  
39       a number of years, habitat conditions for steelhead and other fish species in the  
40       Stanislaus River are not anticipated to improve under the Second Basis of  
41       Comparison relative to recent conditions.

42       Dam operations would continue to suppress channel-forming flows that replenish  
43       spawning beds. The physical presence of the dams impedes normal sediment  
44       transportation processes. Climate change may affect the types and cover rates of

1 vegetation upslope of the river, potentially increasing the rate of fine sediment  
 2 transport to the river and to spawning areas Ongoing gravel augmentation through  
 3 2030 is anticipated to maintain or improve physical spawning habitat conditions  
 4 for steelhead.

5 *Aquatic Habitat Conditions in the Yolo Bypass (including Cache Slough,*  
 6 *Lower Putah Creek, and Fremont Weir)*

7 Similar to the No Action Alternative, it is assumed under the Second Basis of  
 8 Comparison that restoration of up to 20,000 acres of seasonal floodplain  
 9 restoration in the Yolo Bypass would occur by 2030. Actions in the Yolo Bypass  
 10 also would include improvements in fish passage at Fremont Weir for  
 11 anadromous salmonids, sturgeon, and other native fish species. Implementation  
 12 of these ecosystem restoration actions and improvements could increase winter  
 13 and spring growth and survival (relative to recent conditions) of juvenile Chinook  
 14 Salmon, steelhead, and other native fish by providing increased seasonal access to  
 15 productive foraging and high quality rearing habitat, depending on the extent and  
 16 duration of restoration and inundation. These actions are also expected to reduce  
 17 migratory delays or losses by reducing predation, straying, and delays for  
 18 salmonids and other migratory native fish species.

19 *Aquatic Habitat Conditions in the Delta*

20 As described in Chapter 3, Description of Alternatives, the Second Basis of  
 21 Comparison is based on coordinated long-term operation of the CVP and SWP in  
 22 2030 without implementation of the 2008 USFWS BO and the 2009 NMFS BO  
 23 RPAs. Similar to the No Action Alternative, reasonable and foreseeable non-  
 24 CVP and -SWP water resources projects to provide additional water supplies  
 25 would be implemented, in addition to restoration of more than 10,000 acres of  
 26 intertidal and associated subtidal wetlands in Suisun Marsh and Cache Slough;  
 27 and up to 20,000 acres of seasonal floodplain restoration in the Yolo Bypass.

28 Under the Second Basis of Comparison, flows, water quality, and aquatic habitat  
 29 conditions in the Delta would continue to be influenced by CVP and SWP  
 30 operations. Climate change would result in increased stream flows in the winter  
 31 and spring months during storm events due to precipitation primarily occurring as  
 32 rain instead of snowfall. The increased stream flows also would increase Delta  
 33 outflow. Delta outflow also would be increased in the spring and summer months  
 34 as more water is released from the CVP and SWP reservoirs to maintain salinity  
 35 criteria in the western Delta in response to sea level rise.

36 Under the Second Basis of Comparison in 2030, many years will have passed  
 37 without seasonal limitations on OMR reverse (negative) flow rates, with the  
 38 anticipated result that fish entrainment would occur at levels comparable to recent  
 39 historical conditions. Future pumping operations would continue to expose fish to  
 40 the salvage facilities and entrainment losses into the future. As described above  
 41 for the No Action Alternative, recent coded wire tagging and acoustic studies  
 42 have shown that survival of hatchery-origin juvenile Chinook Salmon was higher  
 43 through the south Delta via the Old River route than via the San Joaquin River  
 44 and that this may be due to increased survival during salvage at the facilities

1 (Buchanan et al. 2013, 2015; SJRGA 2013). Zeug and Cavallo (2014) suggest  
2 that entrainment losses at the diversions may be small relative to overall migration  
3 mortality.

4 Furthermore, operation of the permanent gates would lead to losses associated  
5 with predation at the physical structures and the local and far-field hydraulic  
6 conditions created by the barriers. Under the Second Basis of Comparison,  
7 significant reductions in the abundance of steelhead and fall-run Chinook Salmon  
8 originating in the San Joaquin River basin, (as well as the Calaveras River and  
9 Mokelumne River basins) are likely to continue.

10 As described above for the No Action Alternative, abundance levels for Delta  
11 Smelt, Longfin Smelt, Striped Bass, Threadfin Shad, and American Shad are  
12 currently very low, and abundance and habitat conditions for fish in the Delta in  
13 future years are difficult to predict. It is not likely that operations of the CVP and  
14 SWP under the Second Basis of Comparison would result in improvement of  
15 habitat conditions in the Delta or increases in populations for these fish by 2030,  
16 and the recent trajectory of loss would likely continue.

### 17 **9.4.2.3.3 Special Status Species and Critical Habitat**

#### 18 *Clear Creek*

19 Clear Creek is designated critical habitat for spring-run Chinook Salmon and  
20 Central Valley steelhead. The PCEs of critical habitat for both species include  
21 freshwater spawning sites, freshwater rearing areas, and freshwater migration  
22 corridors. Spawning and rearing habitat for spring-run Chinook Salmon in Clear  
23 Creek has been negatively affected by flow and water temperature conditions  
24 associated with current operations. Under the Second Basis of Comparison, there  
25 would be little change in the PCEs of critical habitat for spring-run Chinook  
26 Salmon and Central Valley steelhead relative to recent conditions. Ongoing  
27 gravel augmentation in Clear Creek will likely result in improvements to Chinook  
28 Salmon and steelhead physical spawning habitat in Clear Creek. However, due to  
29 climate change, the conservation value of critical habitat for these species will  
30 likely be reduced under the Second Basis of Comparison by 2030, particularly in  
31 drier years when cold water releases cannot be maintained from  
32 Whiskeytown Dam.

#### 33 *Sacramento River*

34 The Sacramento River provides three of the six PCEs essential to support one or  
35 more life stages, including freshwater spawning sites, rearing sites, and migration  
36 corridors for winter-run Chinook Salmon, spring-run Chinook Salmon, and  
37 Central Valley steelhead. The Sacramento River is also designated critical habitat  
38 for the Southern DPS of green sturgeon. Flow and temperature changes under the  
39 Second Basis of Comparison and the effects on spawning and rearing habitat  
40 quality were described previously.

41 As described above for the No Action Alternative, climate change is likely to  
42 reduce the conservation value of the spawning and rearing habitat PCEs of critical  
43 habitat by increasing water temperatures. The reduction in essential features of

1 the spawning and rearing habitat PCEs could reduce the spatial structure,  
2 abundance, and productivity of salmonids.

3 The year-round opening of the gates at the RBDD allows salmonids to pass  
4 unimpeded, enhancing the conservation value of the PCE for migration. Critical  
5 habitat for green Sturgeon would also improve from unimpeded access to suitable  
6 spawning habitat upstream of the RBDD. The improved passage at the RBDD  
7 will increase the number of deep holding pools that adult Green Sturgeon can  
8 access, thereby increasing the conservation value of the water depth PCE. In  
9 addition, as described above, predation on salmon, steelhead, and sturgeon would  
10 be reduced relative to recent conditions when the RBDD was operational.

11 The No Action Alternative includes implementation of the CVPIA AFSP to  
12 reduce entrainment of juvenile anadromous fish from unscreened diversions. By  
13 providing funding to screen priority diversions as identified in the CVPIA AFSP,  
14 the loss of listed fish in water diversion channels by 2030 could be reduced. In  
15 addition, if new fish screens can be constructed so that diversions can occur at  
16 low water surface elevations to allow diversions below a flow of 5,000 cfs at  
17 Wilkins Slough, then cold water at Shasta Lake could be conserved during critical  
18 dry years for release to support winter-run and spring-run Chinook Salmon needs  
19 downstream.

#### 20 *American River*

21 The lower American River downstream of Nimbus Dam is designated critical  
22 habitat for Central Valley steelhead. The PCEs of critical habitat in the lower  
23 American River include freshwater spawning sites, freshwater rearing areas, and  
24 freshwater migration corridors. Flow and temperature changes under the Second  
25 Basis of Comparison and the effects on spawning and rearing habitat quality were  
26 described previously. In addition, the influence of climate change is expected to  
27 alter hydrologic and temperature conditions in the region and adversely affect the  
28 PCEs for Central Valley steelhead critical habitat in the American River,  
29 primarily through increased water temperatures.

#### 30 *Stanislaus River*

31 The lower Stanislaus River downstream of Goodwin Dam is designated critical  
32 habitat for Central Valley steelhead. The PCEs of critical habitat in the Stanislaus  
33 River include freshwater spawning sites, freshwater rearing areas, and freshwater  
34 migration corridors. Flow and temperature changes under the Second Basis of  
35 Comparison and the effects on spawning and rearing habitat quality were  
36 described previously. The PCEs for spawning and rearing habitat have been  
37 adversely affected by elimination of geomorphic processes that replenish and  
38 rejuvenate spawning riffles and inundate floodplain terraces to provide nutrients  
39 and rearing habitat for juvenile salmonids. In addition, moderation of flood  
40 events also eliminates or reduces the intensity and duration of freshets and storm  
41 flows, which adversely affects the PCE for migration corridors. The influence of  
42 climate change could begin to alter hydrologic and temperature conditions in the  
43 region and adversely affect the PCEs for Central Valley steelhead critical habitat  
44 in the Stanislaus River, primarily through increased water temperatures.

1 *Delta*

2 As described above for the No Action Alternative, designated critical habitat for  
3 both winter-run and spring-run Chinook Salmon lies adjacent to the location of  
4 the DCC gates and designated critical habitat for spring-run Chinook Salmon  
5 includes the DCC from its point of origin on the Sacramento River to its terminus  
6 at Snodgrass Slough. Designated critical habitat for Central Valley steelhead  
7 includes most of the Delta and its waterways; however, the DCC waterway was  
8 not included in designated critical habitat for this species.

9 Operation of the DCC gates under the Second Basis of Comparison will continue  
10 to affect the PCEs for critical habitat designated for spring-run Chinook Salmon  
11 and steelhead, primarily, the use of the Sacramento River as a migratory corridor.  
12 The operation of the gates permits fish to enter habitat and waterways they would  
13 not normally have access to with substantially higher predation risks than the  
14 migratory corridor available in the Sacramento River channel. Operation of the  
15 gates can have a direct effect on the entrainment rate and hence the functioning of  
16 the Sacramento River as a migratory corridor. Without the modifications to DCC  
17 gate operations to reduce loss of emigrating salmonids and green sturgeon  
18 described for the No Action Alternative, entrainment in the DCC will continue to  
19 be similar to recent historical conditions.

20 **9.4.2.3.4 Effects Related to Cross Delta Water Transfers**

21 As described under the No Action Alternative, all water transfers would be  
22 required to avoid adverse impacts to other water users and biological resources  
23 (see Section 3.A.6.3, Transfers), including impacts associated with changes in  
24 reservoir storage and river flow patterns. Potential effects to aquatic resources  
25 could be similar to those identified in a recent environmental analysis conducted  
26 by Reclamation for long-term water transfers from the Sacramento to San Joaquin  
27 valleys (Reclamation 2014d). Potential effects were identified as changes to fish  
28 in the reservoirs and in the rivers downstream of the reservoirs and the Delta. The  
29 analysis indicated that the reservoirs did not support primary populations of fish  
30 species of management concern, and that the reservoirs would continue to be  
31 operated within the historical range of operations. The analysis also indicated that  
32 mean monthly flows in the major rivers or creeks in the Sacramento and San  
33 Joaquin rivers watersheds would be similar (less than 10 percent change) with  
34 water transfers as compared to without water transfers; and therefore, changes to  
35 aquatic resources would be less than substantial. Delta conditions also would be  
36 similar with water transfers as compared to without water transfers, including less  
37 than 5 percent changes in Delta exports and less than 1.3 percent changes in Delta  
38 outflow and X2 position. Therefore, changes to aquatic resources would be less  
39 than substantial. For the purposes of this EIS, it is anticipated that similar  
40 conditions would occur due to cross Delta water transfers under the No Action  
41 Alternative and the Second Basis of Comparison.

42 Under the Second Basis of Comparison, water transfers could occur throughout  
43 the year depending upon limitations of available conveyance capacity and  
44 regulatory requirements.

1 **9.4.2.3.5 Conditions for Fish Passage**

2 Conditions for fish passage at Shasta, Folsom, and New Melones dams under the  
3 Second Basis of Comparison would be the same as described in the Affected  
4 Environment because passage of fish to river reaches above these dams would not  
5 be provided. Populations of anadromous fish under the Second Basis of  
6 Comparison would continue to be restricted to the river reaches downstream of  
7 these dams and subjected to increasing water temperatures associated primarily  
8 with climate change.

9 **9.4.2.3.6 Ocean Conditions**

10 Conditions for the Southern Resident Killer Whale under the Second Basis of  
11 Comparison would differ from those for the No Action Alternative, but the effects  
12 on Killer Whales would be the same.

13 **9.4.3 Evaluation of Alternatives**

14 Alternatives 1 through 5 have been compared to the No Action Alternative; and  
15 the No Action Alternative and Alternatives 1 through 5 have been compared to  
16 the Second Basis of Comparison.

17 **9.4.3.1 No Action Alternative Compared to the Second Basis of**  
18 **Comparison**

19 The No Action Alternative is compared to the Second Basis of Comparison.

20 **9.4.3.1.1 Trinity River Region**

21 *Coho Salmon*

22 The analysis of effects associated with changes in operation on Coho Salmon was  
23 conducted using temperature model outputs for Lewiston Dam to anticipate the  
24 likely effects on conditions in the Trinity River downstream of Lewiston Dam for  
25 Coho Salmon.

26 Long term average monthly water temperatures in the Trinity River at Lewiston  
27 Dam under No Action Alternative generally would be similar to the temperatures  
28 that would occur under the Second Basis of Comparison (Appendix 6B,  
29 Table B-1-4). Average monthly temperatures under the Second Basis of  
30 Comparison generally would be similar to those predicted under the No Action  
31 Alternative in most water year types, except from November through January in  
32 above- and below-normal water years when water temperatures under the No  
33 Action Alternative could be up to 1.5°F warmer than under the Second Basis of  
34 Comparison. In November of critical years, water temperatures under the No  
35 Action Alternative could be as much as 2.4°F cooler than under the Second Basis  
36 of Comparison (Appendix 6B, Table B-1-4). Average monthly water  
37 temperatures generally would be similar (less than 0.5°F difference) under the No  
38 Action Alternative and Second Basis of Comparison from July through  
39 September, except in September of wet years when temperatures would be  
40 slightly lower (0.6°F) and in August of critical years when temperatures could be

1 slightly (0.7°F) higher under the No Action Alternative (Appendix 6B,  
2 Table B-1-4).

3 Overall, the temperature differences between the No Action Alternative and  
4 Second Basis of Comparison would be relatively minor and likely would have  
5 little effect on Coho Salmon in the Trinity River. The substantially lower water  
6 temperatures in November of critical dry years (and higher temperatures in  
7 December) under the No Action Alternative would likely have little effect on  
8 Coho Salmon as water temperatures in the Trinity River are typically low during  
9 this time period.

10 The USFWS established a water temperature threshold of 56°F for Coho Salmon  
11 spawning in the reach of the Trinity River from Lewiston Dam to the confluence  
12 with the North Fork Trinity River from October through December. Although not  
13 entirely reflective of water temperatures throughout the reach, the temperature  
14 model provides average monthly water temperature outputs for releases from  
15 Lewiston Dam, which may provide perspective on temperature conditions in the  
16 reach below. In October and November, average monthly water temperatures  
17 under both the No Action Alternative and Second Basis of Comparison would  
18 exceed 56°F at Lewiston Dam in some years (Appendix 9N). Under the No  
19 Action Alternative, the threshold would be exceeded about 8 percent of the time  
20 in October, about 1 percent more frequently than under the Second Basis of  
21 Comparison. In November, both scenarios would result in an exceedance  
22 frequency of about 2 percent. There would be no exceedance of the threshold in  
23 December under both the No Action Alternative and the Second Basis of  
24 Comparison.

25 Overall, the temperature model outputs for each of the Coho Salmon life stages  
26 suggest that the temperature of water released at Lewiston Dam generally would  
27 be similar under both scenarios, although the exceedance of water temperature  
28 thresholds would be slightly more frequent (1 percent) under the No Action  
29 Alternative. Given the similarity of the results and the inherent uncertainty  
30 associated with the resolution of the temperature model (average monthly  
31 outputs), it is concluded that the No Action Alternative and Second Basis of  
32 Comparison are likely to have similar effects on the Coho Salmon population in  
33 the Trinity River.

#### 34 *Spring-run Chinook Salmon*

35 As described above for Coho Salmon, the temperature differences between the No  
36 Action Alternative and Second Basis of Comparison (Appendix 6B, Table B-1-4)  
37 would be relatively minor (less than 0.5°F) and likely would have little effect on  
38 spring-run Chinook Salmon in the Trinity River. The lower water temperatures in  
39 November of critical dry years (and higher temperatures in December) under the  
40 No Action Alternative would likely have little effect on spring-run Chinook  
41 Salmon as water temperatures in the Trinity River are typically low during this  
42 time period.

1 Under both the No Action Alternative and the Second Basis of Comparison,  
2 average monthly water temperatures in the Trinity River at Lewiston Dam would  
3 infrequently (1 percent to 2 percent of the time) exceed 60°F (Appendix 9N), the  
4 threshold for spring-run Chinook Salmon holding. There would be no difference  
5 in the frequency of exceedance of the 60°F threshold under the No Action  
6 Alternative as compared to the Second Basis of Comparison. In September,  
7 however, the threshold for spawning (56°F) would be exceeded 9 percent of the  
8 time under the No Action Alternative, which is 2 percent less frequently than  
9 under the Second Basis of Comparison (11 percent).

10 The differences in the frequency of threshold exceedance between the No Action  
11 Alternative and Second Basis of Comparison would be relatively minor, although  
12 temperature conditions under the No Action Alternative could be less likely to  
13 affect spring-run Chinook Salmon spawning than under the Second Basis of  
14 Comparison because of the slightly (2 percent) reduced frequency of exceedance  
15 of the 56°F threshold at Lewiston Dam in September.

16 Overall, water temperature differences could adversely influence spring-run  
17 Chinook Salmon in the Trinity River under the Second Basis of Comparison;  
18 however, these effects would not occur in every year and are not anticipated to be  
19 substantial based on the relatively small differences in water temperatures under  
20 the No Action Alternative as compared to the Second Basis of Comparison. In  
21 addition, the implementation of the Hatchery Management Plan (RPA  
22 Action II.6.3) under the No Action Alternative could reduce the impacts of  
23 hatchery Chinook Salmon on natural spring-run Chinook Salmon in the Trinity  
24 River and increase the genetic diversity and diversity of run-timing for these  
25 stocks relative to the Second Basis of Comparison. However, the potential  
26 magnitude of these benefits is uncertain. Thus, given these relatively minor  
27 changes in temperature and temperature threshold exceedance, the inherent  
28 uncertainty associated with the resolution of the temperature model (average  
29 monthly outputs), and the uncertainty of the hatchery benefits, it is concluded that  
30 the No Action Alternative and Second Basis of Comparison are likely to have  
31 similar effects on the spring-run Chinook Salmon in the Trinity River.

### 32 *Fall-Run Chinook Salmon*

33 The potential effects of operations on fall-run Chinook Salmon were evaluated  
34 based on water temperature differences and threshold comparisons as described  
35 above for Coho and spring-run Chinook Salmon. In addition, the Reclamation  
36 Salmon Mortality Model (Appendix 9C) was applied to examine the anticipated  
37 effects of water temperature on egg mortality.

38 The water temperature differences in the Trinity River at Lewiston Dam between  
39 the No Action Alternative and Second Basis of Comparison (Appendix 6B,  
40 Table B-1-4) would be relatively minor (less than 0.5°F) and likely would have  
41 little effect on fall-run Chinook Salmon. The lower water temperatures in  
42 November of critical years (and higher temperatures in December) under the No  
43 Action Alternative would likely have little effect on fall-run Chinook Salmon as  
44 water temperatures in the Trinity River are typically low during this time period.

1 The temperature threshold and months during which it applies for fall-run  
2 Chinook Salmon are the same as those for Coho Salmon. Under the No Action  
3 Alternative, the threshold would be exceeded about 8 percent of the time in  
4 October, about 1 percent more frequently than under the Second Basis of  
5 Comparison. In November, both conditions would result in an exceedance  
6 frequency of about 2 percent. There would be no exceedance of the threshold in  
7 December under either the No Action Alternative or the Second Basis of  
8 Comparison.

9 The water temperatures in the Trinity River downstream of Lewiston Dam are  
10 reflected in the analysis the Reclamation Salmon Mortality Model. For fall-run  
11 Chinook Salmon in the Trinity River, the long-term average egg mortality rate is  
12 predicted to be relatively low (around 4 percent), with higher mortality rates  
13 (nearly 15 percent) occurring in critical years under the No Action  
14 Alternative (Appendix 9C, Table B-1-1). Overall, egg mortality under the No  
15 Action Alternative and the Second Basis of Comparison would be similar.

16 In summary, the temperature threshold exceedance suggests that temperature  
17 conditions under the No Action Alternative could be slightly more likely to affect  
18 fall-run Chinook Salmon spawning than under the Second Basis of Comparison  
19 because of the slightly (1 percent) increased frequency of exceedance of the 56°F  
20 threshold at Lewiston Dam in October. However, this would occur prior to the  
21 peak spawning period for fall-run Chinook Salmon.

22 Although the combined analysis based on water temperature suggests that  
23 operations under the No Action Alternative could be slightly more adverse than  
24 under the Second Basis of Comparison, these effects would not occur in every  
25 year and are not anticipated to be substantial based on the relatively small  
26 differences in water temperatures (as well as egg mortality) between the No  
27 Action Alternative as compared to the Second Basis of Comparison. In addition,  
28 these potential adverse effects could be offset by implementation of the Hatchery  
29 Management Plan (RPA Action II.6.3) under the No Action Alternative, which  
30 could reduce the impacts of hatchery Chinook Salmon on natural fall-run Chinook  
31 Salmon in the Trinity River, and increase the genetic diversity and diversity of  
32 run-timing for these stocks relative to the Second Basis of Comparison. Overall,  
33 given the small differences in the numerical model results and the inherent  
34 uncertainty in the temperature model, as well as the potential for offsetting  
35 benefits associated with actions that were not modeled, it is concluded that the No  
36 Action Alternative and Second Basis of Comparison are likely to have similar  
37 effects on the fall-run Chinook Salmon population in the Trinity River.

### 38 *Steelhead*

39 The temperature differences between the No Action Alternative and Second Basis  
40 of Comparison (Appendix 6B) would be relatively minor (less than 0.5°F) and  
41 likely would have little effect on steelhead in the Trinity River. The substantially  
42 lower water temperatures in November of critical years (and higher temperatures  
43 in December) under the No Action Alternative would likely have little effect on

1 steelhead as water temperatures in the Trinity River are typically low during this  
2 time period.

3 The temperature threshold for spawning and the months during which it applies  
4 for steelhead are the same as those for Coho Salmon. Thus, the frequency of  
5 average monthly water temperatures in the Trinity River at Lewiston Dam  
6 exceeding the spawning threshold of 56°F for steelhead would be the same as  
7 those described above for Coho Salmon. The differences in the frequency of  
8 threshold exceedance between the No Action Alternative and Second Basis of  
9 Comparison would be relatively minor, although temperature conditions under the  
10 No Action Alternative could be more likely to affect steelhead spawning than  
11 under the Second Basis of Comparison because of the slightly (1 percent)  
12 increased frequency of exceedance of the 56°F threshold at Lewiston Dam in  
13 October.

14 Although the combined analysis based on water temperature suggests that  
15 operations under the No Action Alternative could be slightly more adverse than  
16 under the Second Basis of Comparison, these effects would not occur in every  
17 year and are not anticipated to be substantial based on the relatively small  
18 differences in water temperatures between the No Action Alternative as compared  
19 to the Second Basis of Comparison. Overall, given these small differences and  
20 the inherent uncertainty in the temperature model, the No Action Alternative and  
21 Second Basis of Comparison are likely to have similar effects on the steelhead  
22 population in the Trinity River.

### 23 *Green Sturgeon*

24 As described in the Affected Environment and species accounts (Appendix 9B)  
25 Green Sturgeon spawn in the lower reaches of the Trinity River from April  
26 through June, and water temperatures above about 63°F are believed stressful to  
27 embryos (Van Eenennaam et al. 2005). Average monthly water temperature  
28 conditions from April through June in the Trinity River at Lewiston Dam under  
29 the No Action Alternative would be similar to temperatures under the Second  
30 Basis of Comparison and would not exceed 58°F during this period  
31 (Appendix 6B, Table B-1-4). In addition, water temperatures in the reach of the  
32 river where Green Sturgeon spawn are likely controlled by other factors  
33 (e.g., ambient air temperatures and tributary inflows) more than water operations  
34 at Trinity and Lewiston dams.

35 Overall, given the similarities between average monthly water temperatures at  
36 Lewiston Dam under the No Action Alternative and the Second Basis of  
37 Comparison, it is likely that temperature conditions for Green Sturgeon in the  
38 Trinity River or lower Klamath River and estuary would be similar under both  
39 scenarios.

### 40 *Reservoir Fishes*

41 The analysis of effects associated with changes in operation on reservoir fishes in  
42 Trinity Lake relied on evaluation of changes in available habitat (reservoir  
43 storage) and anticipated changes in black bass nesting success.

1 Changes in CVP water supplies and operations under the No Action  
2 Alternative as compared to the Second Basis of Comparison would result in lower  
3 reservoir storage in Trinity Lake. Storage in Trinity Lake could be reduced up to  
4 around 10 percent in some months of some water year types. Additional  
5 information related to monthly reservoir elevations is provided in Appendix 5A,  
6 CalSim II and DSM2 Modeling. Using storage volume is an indicator of how  
7 much habitat is available to fish species inhabiting these reservoirs, the amount of  
8 habitat for reservoir fishes could be reduced under the No Action Alternative as  
9 compared to the Second Basis of Comparison.

10 As shown in Appendix 9F, bass nest survival in Trinity Lake is near 100 percent  
11 in March and April in response to increasing reservoir elevations. For May, the  
12 likelihood of survival for Largemouth Bass in Trinity Lake being in the 40 to  
13 100 percent range is slightly (about 1-2 percent) lower under the No Action  
14 Alternative as compared to the Second Basis of Comparison. For June, the  
15 likelihood of survival being greater than 40 percent for Largemouth Bass is lower  
16 than in May and is slightly (about 3 percent) higher under the No Action  
17 Alternative than the Second Basis of Comparison. For Spotted Bass, the  
18 likelihood of survival being greater than 40 percent is 100 percent in May and  
19 June under both the No Action Alternative and the Second Basis of Comparison.

20 Overall, the comparison of storage and the analysis of nesting suggest that effects  
21 of the No Action Alternative on reservoir fishes would be similar to those under  
22 the Second Basis of Comparison.

### 23 *Pacific Lamprey*

24 Little information is available on factors that influence populations of Pacific  
25 Lamprey in the Trinity River, but they are likely affected by many of the same  
26 factors as salmon and steelhead because of the parallels in their life cycles. On  
27 average, the temperature of water released at Lewiston Dam under the No Action  
28 Alternative would be similar to (within 0.5°F) water temperatures under the  
29 Second Basis of Comparison. Changes in CVP water supplies and operations  
30 under the No Action Alternative would result in lower reservoir storage in Trinity  
31 Lake and somewhat reduced Trinity River flows in December through February  
32 in wetter years as compared to the Second Basis of Comparison. The highest  
33 reductions in flow would be less than 10 percent in the Trinity River  
34 (Appendix 5A), with a smaller relative reduction in the lower Klamath River  
35 and Klamath River estuary.

36 Overall, given the similarities between average monthly water temperatures at  
37 Lewiston Dam under the No Action Alternative and the Second Basis of  
38 Comparison, it is likely that the No Action Alternative would have a similar  
39 potential to affect Pacific Lamprey in the Trinity River as the Second Basis of  
40 Comparison. This conclusion likely applies to other species of lamprey that  
41 inhabit the Trinity and lower Klamath rivers (e.g., River Lamprey).

1 *Eulachon*

2 As described in the Affected Environment, the last noticeable runs of Eulachon  
3 were observed in 1988 and 1989 by Yurok tribal fishers. It is unclear whether this  
4 species has been extirpated from the Klamath River. Given that the highest  
5 reductions in flow would be less than 10 percent in the Trinity River, which  
6 would represent even a smaller proportion in the lower Klamath River and  
7 Klamath River estuary, and that water temperatures in the Klamath River are  
8 unlikely to be affected by changes upstream at Lewiston Dam, it is likely that the  
9 No Action Alternative would have a similar potential to influence Eulachon in the  
10 Klamath River as would the Second Basis of Comparison.

11 **9.4.3.1.2 Sacramento River System**

12 *Winter-run Chinook Salmon*

13 Changes in operations that influence temperature and flow conditions in the  
14 Sacramento River downstream of Keswick Dam could affect winter-run Chinook  
15 Salmon. The following describes those changes and their potential effects.

16 *Changes in Water Temperature*

17 Long-term average monthly water temperatures in the Sacramento River at  
18 Keswick Dam under the No Action Alternative would generally be similar (less  
19 than 0.5°F difference) to water temperatures under the Second Basis of  
20 Comparison. An exception is during September and October of critical dry years  
21 when water temperatures could be up to 1.1°F and 0.8°F higher, respectively,  
22 under the No Action Alternative as compared to the Second Basis of Comparison  
23 and up to 1°F cooler in September of wetter years (Appendix 6B, Table B-5-4).  
24 A similar temperature pattern generally would be exhibited downstream at Ball's  
25 Ferry, Jelly's Ferry, and Bend Bridge, although average monthly temperatures  
26 would increase with average monthly temperature differences between the  
27 scenarios progressively decreasing, except in September (up to 2.8°F cooler at  
28 Bend Bridge) during wetter years under the No Action Alternative (Appendix 6B,  
29 Table B-8-4).

30 Overall, the temperature differences between the No Action Alternative and  
31 Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
32 likely would have similar effects on winter-run Chinook Salmon in the  
33 Sacramento River. Spawning for winter-run Chinook Salmon in the Sacramento  
34 River takes place from mid-April to mid-August with incubation occurring over  
35 the same time period and extending into October. The somewhat higher water  
36 temperatures in September and October of critical dry years under the No Action  
37 Alternative could increase the likelihood of adverse effects on winter-run Chinook  
38 Salmon egg incubation during this water year type. Whereas, the reduced water  
39 temperatures during September and October under the No Action Alternative in  
40 wetter years could reduce the likelihood of adverse effects on egg incubation  
41 relative to the Second Basis of Comparison.

1            *Changes in Exceedances of Water Temperature Thresholds*

2    With the exception of April, average monthly water temperatures from April to  
3    September under both the No Action Alternative and Second Basis of  
4    Comparison would show exceedances of the water temperature threshold of 56°F  
5    established in the Sacramento River at Ball's Ferry for winter-run Chinook  
6    Salmon spawning and egg incubation (Appendix 9N). Under the No Action  
7    Alternative, the temperature threshold generally would be exceeded more  
8    frequently than under the Second Basis of Comparison (by about 1 percent to  
9    3 percent) in the April through August period, with the temperature threshold in  
10   September exceeded in 42 percent of the simulated years, about 10 percent less  
11   frequently under the No Action Alternative than the Second Basis of Comparison  
12   (52 percent).

13   Farther downstream at Bend Bridge, the frequency of exceedances would  
14   increase, with exceedances under both the No Action Alternative and Second  
15   Basis of Comparison as high as about 90 percent in some months. Under the No  
16   Action Alternative, temperature exceedances generally would be more frequent  
17   (by up to 8 percent) than under the Second Basis of Comparison, with the  
18   exception of September, when threshold exceedances under the No Action  
19   Alternative would be about 29 percent less frequent.

20   Overall, there would be substantial differences in the frequency of threshold  
21   exceedance between the No Action Alternative and Second Basis of Comparison,  
22   particularly in September. Water temperature conditions under the No Action  
23   Alternative could be more likely to result in adverse effects on winter-run  
24   Chinook Salmon spawning than under the Second Basis of Comparison because  
25   of the increased frequency of exceedance of the 56°F threshold from April  
26   through August. However, the substantial reduction in the frequency of  
27   exceedance in September under the No Action Alternative may reduce the  
28   likelihood of adverse effects on winter-run Chinook Salmon egg incubation  
29   during this limited portion of the spawning and egg incubation period.

30            *Changes in Egg Mortality*

31   The temperatures described above for the Sacramento River downstream of  
32   Keswick Dam are reflected in the analysis of egg mortality using the Reclamation  
33   salmon mortality model (Appendix 9C). For winter-run Chinook Salmon in the  
34   Sacramento River, the long-term average temperature induced egg mortality rate  
35   is predicted to be relatively low (around 5 percent), with higher mortality rates  
36   (exceeding 20 percent) occurring in critical dry years under the No Action  
37   Alternative. In critical dry years the average egg mortality rate would be  
38   5.4 percent greater under the No Action Alternative compared to the Second Basis  
39   of Comparison (Appendix 9C, Table B-4). Overall, egg mortality in the  
40   Sacramento River under the No Action Alternative and the Second Basis of  
41   Comparison would be similar, except in critical dry water years.

1        *Changes in Weighted Usable Area*

2    As described above for the assessment methodology, Weighted Usable Area  
3    (WUA) is a function of flow, but the relationship is not linear due to differences  
4    in depths and velocities present in the wetted channel at different flows. Because  
5    the combination of depths, velocities, and substrates preferred by species and life  
6    stages varies, WUA values at a given flow can differ substantially for the life  
7    stages evaluated.

8    As an indicator of the amount of suitable spawning habitat for winter-run Chinook  
9    Salmon between Keswick Dam and Battle Creek, modeling results indicate that,  
10   in general, there would be similar amounts of spawning habitat available from  
11   May through September under the No Action Alternative and the Second Basis of  
12   Comparison (Appendix 9E).

13   Modeling results indicate that, in general, there would be similar amounts of  
14   suitable fry rearing habitat available from June through October under the No  
15   Action Alternative and the Second Basis of Comparison (Appendix 9E).

16   Similar to the results for fry rearing WUA, modeling results indicate that there  
17   would be similar amounts of suitable juvenile rearing habitat available during the  
18   juvenile rearing period from September through August under the No Action  
19   Alternative and the Second Basis of Comparison (Appendix 9E).

20        *Changes in SALMOD Output*

21   SALMOD results indicate that potential juvenile production would be similar  
22   (less than 5 percent differences) under the No Action Alternative and Second  
23   Basis of Comparison in all water year types (Appendix 9D, Table B-4-16).

24        *Changes in Delta Passage Model Output*

25   The Delta Passage Model predicted similar estimates of annual Delta survival  
26   across the 81-year time period for winter-run Chinook Salmon between the No  
27   Action Alternative and the Second Basis of Comparison  
28   Alternative (Appendix 9J). Median Delta survival was 0.349 for the No Action  
29   Alternative and 0.352 for the Second Basis of Comparison  
30   Alternative (Appendix 9J) indicating that Delta survival of winter-run Chinook  
31   Salmon would be similar under the No Action Alternative and the Second Basis  
32   of Comparison.

33        *Changes in Oncorhynchus Bayesian Analysis Output*

34   Escapement of winter-run Chinook Salmon and Delta survival was modeled by  
35   the Oncorhynchus Bayesian Analysis (OBAN) model for winter-run Chinook  
36   salmon. Escapement was generally higher under the No Action Alternative as  
37   compared to the Second Basis alternative (Appendix 9I). The median escapement  
38   under the No Action Alternative was higher in 19 of the 22 years of simulation  
39   (1971 to 2002), and there was typically greater than a 25 percent chance that the  
40   No Action Alternative values would be greater than under the Second Basis of  
41   Comparison. Median delta survival was approximately 12 percent higher under  
42   the No Action Alternative as compared to the Second Basis of Comparison.

1 However, the probability intervals indicated that no difference between scenarios  
2 was a highly probable outcome (Appendix 9I).

3 *Changes in Interactive Object-Oriented Simulation Output*

4 The IOS model predicted similar adult escapement trajectories for winter-run  
5 Chinook Salmon between the No Action Alternative and the Second Basis of  
6 Comparison across the 81 years (Appendix 9H). Under the No Action  
7 Alternative, median adult escapement was 3,935 and under the Second Basis of  
8 Comparison median escapement was 4,042.

9 Similar to adult escapement, the IOS model predicted similar egg survival  
10 trajectories for winter-run Chinook Salmon under the No Action Alternative and  
11 the Second Basis of Comparison Alternative across the 81 water years. Under the  
12 No Action Alternative, median egg survival was 0.990 and under the Second  
13 Basis of Comparison median egg survival was 0.987 (Appendix 9H).

14 *Changes in Delta Hydrodynamics*

15 Winter-run Chinook Salmon smolts are most abundant in the Delta during  
16 January, February, and March. On the Sacramento River near the confluence of  
17 Georgiana Slough, the median proportion of positive velocities under the No  
18 Action Alternative was indistinguishable from the Second Basis of Comparison.  
19 On the San Joaquin River near the Mokelumne River confluence, the  
20 median percent of positive velocities was slightly higher in January and February  
21 but similar in March. In Old River downstream of the facilities, the  
22 median percent of positive velocities was substantially higher under the No  
23 Action Alternative during January, moderately higher in February and slightly  
24 higher in March. On Old River upstream of the facilities, median percent of  
25 positive velocities were moderately lower under No Action Alternative relative to  
26 Second Basis of Comparison in January but similar in February and March. On  
27 the San Joaquin River downstream of Head of Old River, the median percent of  
28 positive velocities was similar for both scenarios in January, February and March.  
29 See Appendix 9K for detailed results.

30 *Changes in Junction Entrainment*

31 Entrainment at Georgiana Slough was similar under both scenarios during  
32 January, February, and March when winter-run Chinook Salmon smolts are most  
33 abundant in the Delta. At the Head of Old River, median entrainment  
34 probabilities were moderately lower under the No Action Alternative during  
35 January, slightly lower during February and similar in March. At the Turner Cut  
36 junction, median entrainment probabilities under the No Action Alternative were  
37 slightly lower than the Second Basis of Comparison in January and February, and  
38 similar in March. Overall, entrainment patterns at the Columbia Cut junction  
39 were similar to those observed at Turner Cut. Patterns at the Middle River and  
40 Old River junctions were similar to those observed at Columbia and Turner Cut  
41 junctions. See Appendix 9L for detailed results.

1            *Changes in Salvage*

2     The median proportion salvaged of Sacramento River-origin Chinook salmon is  
3     predicted to be greater under Second Basis of Comparison relative to No Action  
4     Alternative in every month. Winter-run Chinook Salmon smolts migrating  
5     through the Delta would be most susceptible in the months of January, February,  
6     and March. Predicted values in January and February indicated a moderately  
7     reduced proportion of fish salvaged under the No Action Alternative relative to  
8     the Second Basis of Comparison. See Appendix 9M for detailed results.

9            *Changes in Fish Passage on the Sacramento and American Rivers*

10    The No Action Alternative includes provision for passage of winter-run Chinook  
11    Salmon at Shasta Dam. Similar actions are underway at some locations in the  
12    Pacific Northwest, but none have been attempted for large storage and flood  
13    control reservoirs such as Shasta Lake. There is considerable uncertainty about  
14    whether such a program could be effective. For example, the size of the reservoir  
15    would require that adults be transported not just into the lake, but possibly to the  
16    river many miles upstream. Also because of the size of the reservoir, successful  
17    volitional passage of juveniles through the reservoir is unlikely. Thus, in order  
18    for juvenile salmonid emigrants to contribute to the population, they must be  
19    captured in the river (or at the entrance to the lake) and provided with safe  
20    transport downstream. A high level of capture efficiency for emigrating  
21    juveniles is essential for the program to be successful at generating a self-  
22    sustaining population.

23    If a fish passage program could establish self-sustaining populations of winter-run  
24    Chinook Salmon, spring-run Chinook Salmon, and steelhead, it would contribute  
25    substantially to satisfaction of the spatial diversity viability standard. The passage  
26    program could also contribute to abundance and productivity, if average returns  
27    consistently exceeded approximately 500 individuals. However, the passage  
28    program could also function as a population sink if fish transported above the  
29    reservoir achieved a cohort replacement rate of less than 1.

30    Insufficient information is available currently the on the productivity of habitat  
31    upstream of these impoundments. Given the technical uncertainties discussed  
32    previously, it is not possible to determine if (or how much) fish passage at Shasta  
33    Dam would be likely to affect the status of Central Valley winter-run Chinook  
34    Salmon populations.

35            *Summary of Effects on Winter-Run Chinook Salmon*

36    The multiple model and analysis outputs described above characterize the  
37    anticipated conditions for winter-run Chinook Salmon and their response to  
38    change under the No Action Alternative as compared to the Second Basis of  
39    Comparison. For the purpose of analyzing effects on winter-run Chinook Salmon  
40    and developing conclusions, greater reliance was placed on the outputs from the  
41    two life cycle models, IOS and OBAN because they each integrate the available  
42    information to produce single estimates of winter-run Chinook Salmon  
43    escapement. The output from IOS indicated that winter-run Chinook Salmon  
44    escapement would be similar under both scenarios, whereas the OBAN results

1 indicated that production escapement under the No Action Alternative would be  
2 higher than under the Second Basis of Comparison, although there would be some  
3 chance (less than a 25 percent) that escapement under the Second Basis of  
4 Comparison could be greater than the No Action Alternative in some years.

5 The model results suggest that effects on winter-run Chinook Salmon would be  
6 similar under both the No Action Alternative and Second Basis of Comparison,  
7 with a small likelihood that winter-run Chinook Salmon escapement would be  
8 higher under the No Action Alternative. This distinction, however, likely would  
9 be greater because of the potential benefits of providing fish passage under the  
10 No Action Alternative intended to address the limited availability of suitable  
11 habitat for winter-run Chinook Salmon in the Sacramento River reaches  
12 downstream of Keswick Dam. This potential beneficial effect and its magnitude  
13 would depend on the success of the fish passage program. In addition, benefits to  
14 winter-run Chinook Salmon may accrue under the No Action Alternative as a  
15 result of implementation of the 2009 NMFS BO RPA action suite (IV.4), which is  
16 intended to increase the efficiency of the Tracy and Skinner Fish Collection  
17 Facilities to improve the overall salvage survival of listed salmonids, including  
18 winter-run Chinook Salmon.

19 Overall, the quantitative results from the numerical models suggest that operation  
20 under the No Action Alternative would be less likely to result in adverse effects  
21 on winter-run Chinook Salmon than would operation under the Second Basis of  
22 Comparison. However, in consideration of the potentially beneficial effects  
23 resulting from the RPA actions that are not included in the numerical models (see  
24 Appendix 5A, Section B), the No Action Alternative has a much greater potential  
25 to address the long-term sustainability of winter-run Chinook Salmon than does  
26 the Second Basis of Comparison. The No Action Alternative includes provisions  
27 for fish passage upstream of Shasta Dam to address long-term temperature  
28 increases associated with climate change. The Second Basis of Comparison does  
29 not include fish passage provisions. Even though the success of fish passage is  
30 uncertain, it is concluded that the potential for adverse effects on winter-run  
31 Chinook Salmon under the No Action Alternative would be less than potential  
32 effects under the Second Basis of Comparison, principally because the Second  
33 Basis of Comparison does not include a fish passage strategy to address water  
34 temperatures that NMFS (2009) indicates is critical to winter-run Chinook  
35 Salmon sustainability over the long term with climate change by 2030.

#### 36 *Spring-run Chinook Salmon*

37 Changes in operations that influence temperature and flow conditions in the  
38 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
39 Whiskeytown Dam, and Feather River downstream of Oroville Dam could affect  
40 spring-run Chinook Salmon. The following describes those changes and their  
41 potential effects.

1            *Changes in Water Temperature*

2       Changes in water temperature that could affect spring-run Chinook Salmon could  
3       occur in the Sacramento River, Clear Creek, and Feather River. The following  
4       describes temperature conditions in those water bodies.

5            *Sacramento River*

6       Long-term average monthly water temperatures in the Sacramento River at  
7       Keswick Dam under the No Action Alternative would generally be similar (less  
8       than 0.5°F difference) to water temperatures under the Second Basis of  
9       Comparison. An exception is during September and October of critical dry years  
10      when water temperatures could be up to 1.1°F and 0.8°F higher respectively,  
11      under the No Action Alternative as compared to the Second Basis of Comparison  
12      and up to 1°F cooler in September of wetter years under the No Action  
13      Alternative (Appendix 6B, Table B-5-4). A similar pattern in water temperatures  
14      generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry, Bend  
15      Bridge and Red Bluff, with average monthly temperatures increasing in a  
16      downstream direction and temperature differences between scenarios  
17      progressively decreasing except in September (up to 3.2°F cooler at Red Bluff)  
18      during wetter years under the No Action Alternative (Appendix 6B, Table B-9-4).

19      Overall, the temperature differences between the No Action Alternative and  
20      Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
21      likely would have little effect on spring-run Chinook Salmon in the Sacramento  
22      River. The somewhat lower water temperatures in September of wetter years may  
23      reduce the likelihood of adverse effects on spring-run Chinook Salmon spawning,  
24      although the increased temperatures in September of critical dry years under the  
25      No Action Alternative may increase the likelihood of adverse effects on spring-  
26      run Chinook Salmon spawning in this water year type. There would be little  
27      difference in potential effects on spring-run Chinook Salmon holding over the  
28      summer due to the similar water temperatures during this time period under the  
29      No Action Alternative and the Second Basis of Comparison.

30           *Clear Creek*

31      Average monthly water temperatures in Clear Creek at Igo under the No Action  
32      Alternative relative to the Second Basis of Comparison are generally predicted to  
33      be similar (less than 0.5°F differences) from September through April and June  
34      through August (Appendix 6B, Table B-3-4). Average monthly water  
35      temperatures during May under the No Action Alternative would be lower by up  
36      to 0.8°F compared to the Second Basis of Comparison. The lower water  
37      temperatures in May associated with the No Action Alternative reflect the effects  
38      of additional water discharged from Whiskeytown Dam to meet the spring  
39      attraction flow requirements to promote attraction of spring-run Chinook Salmon  
40      into the creek. While the reduction in May water temperatures indicated by the  
41      modeling could improve thermal conditions for spring-run Chinook Salmon, the  
42      duration of the two pulse flows may not be of sufficient duration (3 days each) to  
43      provide biologically meaningful temperature benefits. Overall, thermal

1 conditions for spring-run Chinook Salmon in Clear Creek would be similar under  
2 the No Action Alternative and the Second Basis of Comparison.

3 *Feather River*

4 Average monthly water temperatures in the Feather River in the low flow channel  
5 generally were predicted to be similar (less than 0.5°F differences) under the No  
6 Action Alternative and Second Basis of Comparison, except during November  
7 and December when average monthly water temperatures could be up to 1.4°F  
8 higher in some water year types (Appendix 6B, Table B-20-4). Average monthly  
9 water temperatures in September under the No Action Alternative could be up to  
10 1.3°F lower than under the Second Basis of Comparison in wetter years.

11 Although temperatures in the river generally become progressively higher in the  
12 downstream direction, the differences between the No Action Alternative and  
13 Second Basis of Comparison exhibit a similar pattern at the downstream locations  
14 (Robinson Riffle and Gridley Bridge), with water temperature differences  
15 between the No Action Alternative and the Second Basis of Comparison generally  
16 decreasing in most water year types. However, water temperatures from July to  
17 September under the No Action Alternative could be somewhat (0.7°F to 1.6°F)  
18 cooler on average and up to 4.0°F cooler at the confluence with Sacramento River  
19 in wetter years (Appendix 6B, Table B-23-4).

20 Overall, the temperature differences in the Feather River between the No Action  
21 Alternative and Second Basis of Comparison would be relatively minor (less than  
22 0.5°F) and likely would have little effect on spring-run Chinook Salmon in the  
23 Feather River. The slightly higher water temperatures in November and  
24 December under the No Action Alternative would likely have little effect on  
25 spring-run Chinook Salmon as water temperatures in the Feather River are  
26 typically low during this time period. The somewhat lower water temperatures in  
27 September of wetter years may reduce the likelihood of adverse effects on  
28 spring-run Chinook Salmon spawning, although the increased temperatures in  
29 September of critical dry years under the No Action Alternative may increase the  
30 likelihood of adverse effects on spring-run Chinook Salmon spawning in this  
31 water year type. There would be little difference in potential effects on spring-run  
32 Chinook Salmon holding over the summer due to the similar water temperatures  
33 during this time period under the No Action Alternative as compared and the  
34 Second Basis of Comparison.

35 *Changes in Exceedances of Water Temperature Thresholds*

36 Changes in water temperature could result in the exceedance of established water  
37 temperature thresholds for spring-run Chinook Salmon in the Sacramento River,  
38 Clear Creek, and Feather River. The following describes the extent of water  
39 temperature threshold exceedances for each of those water bodies.

40 *Sacramento River*

41 Average monthly water temperatures under both the No Action Alternative and  
42 Second Basis of Comparison indicate exceedances of the water temperature  
43 threshold of 56°F established in the Sacramento River at Red Bluff for spring-run  
44 Chinook Salmon (egg incubation) in October, November, and again in April. The

1 exceedances were predicted to occur at the greatest frequency in October  
2 (82 percent of the time under the No action Alternative); the water temperature  
3 threshold would be exceeded more frequently in November (8 percent under the  
4 No Action Alternative) and not exceeded at all from December through March  
5 under the No Action Alternative (Appendix 9N). As water temperatures warm in  
6 the spring, the thresholds were predicted to be exceeded in April by 15 percent  
7 under the No Action Alternative. In the months when the greatest frequency of  
8 exceedances occur (October, November, and April), model results generally  
9 indicate more frequent exceedances (by up to 4 percent in October) under the No  
10 Action Alternative than under the Second Basis of Comparison. Temperature  
11 conditions in the Sacramento River under the No Action Alternative could be  
12 more likely to result in adverse effects on spring-run Chinook Salmon egg  
13 incubation than under the Second Basis of Comparison because of the increased  
14 frequency of exceedance of the 56°F threshold in October, November, and April.  
15 However, this difference may be partially offset if the water temperature  
16 management and fish passage measures associated with 2009 NMFS BO RPA  
17 under the No Action Alternative are successful in improving water temperatures.

#### 18 *Clear Creek*

19 Average monthly water temperatures under both the No Action Alternative and  
20 Second Basis of Comparison would not exceed the water temperature threshold of  
21 60°F established in Clear Creek at Igo for spring-run Chinook Salmon pre-  
22 spawning and rearing in June through August. However, water temperatures  
23 under the No Action Alternative and Second Basis of Comparison would exceed  
24 the water temperature threshold of 56°F established for spawning in September  
25 and October about 10 to 15 percent of the time. Water temperatures under the No  
26 Action Alternative could exceed the threshold about 3 percent more frequently  
27 than under the Second Basis of Comparison in September and about 2 percent  
28 more frequently in October (Appendix 9N). Temperature conditions in Clear  
29 Creek under the No Action Alternative could be more likely to result in adverse  
30 effects on spring-run Chinook Salmon spawning than under the Second Basis of  
31 Comparison because of the increased frequency of exceedance of the 56°F  
32 threshold in September and October. However, this difference may be partially  
33 offset if the thermal stress reduction measures associated with 2009 NMFS BO  
34 RPA Action I.1.5 under the No Action Alternative are successful in improving  
35 water temperatures in Clear Creek.

#### 36 *Feather River*

37 Average monthly water temperatures under both the No Action Alternative and  
38 the Second Basis of Comparison would exceed the water temperature threshold of  
39 56°F established in the Feather River at Robinson Riffle for spring-run Chinook  
40 Salmon egg incubation and rearing during some months, particularly in October  
41 and November, and March and April, when temperature thresholds could be  
42 exceeded frequently (Appendix 9N). The frequency of exceedance was highest in  
43 October, a month in which average monthly water could get as high as about  
44 68°F. Water temperatures under the No Action Alternative would exceed the  
45 spawning temperature threshold about 1 percent more frequently than under the

1 Second Basis of Comparison in October, November, and December, and about  
2 2 percent less frequently in March.

3 The established water temperature threshold of 63°F for rearing from May  
4 through August would be exceeded often under both the No Action  
5 Alternative and Second Basis of Comparison in May and June, but not at all in  
6 July and August. Water temperatures under the No Action Alternative would  
7 exceed the rearing temperature threshold about 9 percent more frequently than  
8 under the Second Basis of Comparison in May. Temperature conditions in the  
9 Feather River under the No Action Alternative could be more likely to result in  
10 adverse effects on spring-run Chinook Salmon spawning and rearing than under  
11 the Second Basis of Comparison because of the increased frequency of  
12 exceedance of the 56°F threshold from October through December.

13 *Changes in Egg Mortality*

14 These temperature differences described above are reflected in the analysis of egg  
15 mortality using the Reclamation salmon mortality model (Appendix 9C). For  
16 spring-run Chinook Salmon in the Sacramento River, the long-term average egg  
17 mortality rate is predicted to be relatively high (exceeding 20 percent), with high  
18 mortality rates (exceeding 70 percent) occurring in critical dry years. In critical  
19 dry years the average egg mortality rate under the No Action Alternative is  
20 predicted to be 10.4 percent greater than under the Second Basis of Comparison  
21 (Appendix 9C, Table B-3). Overall, egg mortality under the No Action  
22 Alternative and the Second Basis of Comparison would be similar, except in  
23 critical dry water years.

24 *Changes in Weighted Usable Area*

25 Weighted usable area curves are available for spring-run Chinook Salmon in  
26 Clear Creek. As described above, flows in Clear Creek downstream of  
27 Whiskeytown Dam are not anticipated to differ under the No Action  
28 Alternative relative to the Second Basis of Comparison except in May due to the  
29 release of spring attraction flows in accordance with the 2009 NMFS BO.  
30 Therefore, there would be no change in the amount of potentially suitable  
31 spawning and rearing habitat for spring-run Chinook Salmon (as indexed by  
32 WUA) available under the No Action Alternative as compared to the Second  
33 Basis of Comparison. However, the results of the habitat suitability/IFIM studies  
34 associated with the 2009 NMFS BO Action I.1.6 could result in changes in  
35 releases from Whiskeytown Reservoir to Clear Creek. Any changes as a result of  
36 these studies would be implemented to improve habitat for fish.

37 *Changes in SALMOD Output*

38 SALMOD results indicate that potential juvenile spring-run production would be  
39 similar under the No Action Alternative and the Second Basis of Comparison,  
40 except in critical dry water years when production under the No Action  
41 Alternative could be 11 percent less than under the Second Basis of Comparison  
42 (Appendix 9D, Table B-3-16).

1        *Changes in Delta Passage Model Output*

2        The Delta Passage Model predicted similar estimates of annual Delta survival  
3        across the 81-year time period for spring-run between the No Action  
4        Alternative and the Second Basis of Comparison (Appendix 9J). Median Delta  
5        survival was 0.296 for the No Action Alternative and 0.286 for the Second Basis  
6        of Comparison.

7        *Changes in Delta Hydrodynamics*

8        Spring-run Chinook Salmon are most abundant in the Delta from March through  
9        May. Near the junction of Georgiana Slough, the median percent of time that  
10       velocity was positive was similar in March, April, and May for both scenarios  
11       (Appendix 9K). Near the confluence of the San Joaquin River and the  
12       Mokelumne River, the median percent of times with positive velocities was  
13       similar in March and slightly greater under the No Action Alternative relative to  
14       the Second Basis of Comparison in April and May. A similar pattern was  
15       observed in the San Joaquin River downstream of the Head of Old River; the  
16       median percent of time that velocity was positive was similar in March, whereas  
17       values for the No Action Alternative were slightly to moderately lower relative to  
18       the Second Basis of Comparison in April and May. In Old River upstream of the  
19       facilities median percent of time with positive velocities was similar in March,  
20       slightly higher in April, and moderately higher in May under the No Action  
21       Alternative relative to the Second Basis of Comparison. In Old River  
22       downstream of the facilities, the median percent of time with positive velocity  
23       was slightly greater in March and increasingly greater in April and May under the  
24       No Action Alternative relative to the Second Basis of Comparison.

25       *Changes in Junction Entrainment*

26       Entrainment at Georgiana Slough was similar under both scenarios during March,  
27       April, and May when spring-run are most abundant in the Delta (Appendix 9L).  
28       At the Head of Old River, median entrainment probabilities were much greater  
29       under the No Action Alternative during April and May, whereas probabilities  
30       were similar in March. At the Turner Cut junction, median entrainment  
31       probabilities under the No Action Alternative and the Second Basis of  
32       Comparison were similar in March. During April and May, median entrainment  
33       probabilities were more divergent with moderately lower values for the No Action  
34       Alternative relative to the Second Basis of Comparison. Overall, entrainment was  
35       slightly lower at the Columbia Cut junction relative to Turner Cut, but patterns of  
36       median entrainment probabilities between the scenarios were similar. Patterns of  
37       entrainment probability at the Middle River and Old River junctions were similar  
38       to those observed at Columbia and Turner Cut junctions.

39       *Changes in Salvage*

40       Salvage of Sacramento River-origin Chinook Salmon is predicted to be lower  
41       under the No Action Alternative relative to the Second Basis of Comparison in  
42       every month (Appendix 9M). Spring-run smolts migrating through the Delta  
43       would be most susceptible in the months of March, April, and May. Predicted  
44       values in April and May indicated a substantially reduced fraction of fish salvaged

1 under the No Action Alternative. Predicted salvage was more similar in March,  
2 but still moderately lower under the No Action Alternative than under the Second  
3 Basis of Comparison.

4 *Summary of Effects on Spring-Run Chinook Salmon*

5 The multiple model and analysis outputs described above characterize the  
6 anticipated conditions for spring-run Chinook Salmon and their response to  
7 change under the No Action Alternative as compared to the Second Basis of  
8 Comparison. For the purpose of analyzing effects on spring-run Chinook Salmon  
9 in the Sacramento River, greater reliance was placed on the outputs from the  
10 SALMOD model because it integrates the available information on temperature  
11 and flows to produce estimates of mortality for each life stage and an overall,  
12 integrated estimate of potential spring-run Chinook Salmon juvenile production.  
13 The output from SALMOD indicated that spring-run Chinook Salmon production  
14 in the Sacramento River would be similar under the No Action Alternative and  
15 the Second Basis of Comparison, although production under the No Action  
16 Alternative could be over 10 percent less than under the Second Basis of  
17 Comparison in critical dry years. The analyses attempting to assess the effects on  
18 routing, entrainment, and salvage of juvenile salmonids in the Delta suggest that  
19 salvage (as an indicator of potential losses of juvenile salmon at the export  
20 facilities) of Sacramento River-origin Chinook Salmon is predicted to be lower  
21 under the No Action Alternative relative to the Second Basis of Comparison in  
22 every month.

23 In Clear Creek and the Feather River, the analysis of the effects of the No Action  
24 Alternative and Second Basis of Comparison for spring-run Chinook Salmon  
25 relied on output from the WUA analysis and water temperature output for Clear  
26 Creek at Igo, and in the Feather River low flow channel and downstream of the  
27 Thermalito complex. The WUA analysis suggests that there would be little  
28 difference in the availability of spawning and rearing habitat in Clear Creek. The  
29 temperature model outputs suggest that thermal conditions and effects on each of  
30 the spring-run Chinook Salmon life stages generally would be similar under both  
31 scenarios in Clear Creek and the Feather River, although water temperatures  
32 could be somewhat less suitable for spring-run Chinook Salmon holding and  
33 spawning/egg incubation in the Feather River under the No Action Alternative.  
34 This conclusion is supported by the water temperature threshold exceedance  
35 analysis that indicated that water temperature thresholds for spawning and egg  
36 incubation would be exceeded slightly more frequently under the No Action  
37 Alternative in Clear Creek and the Feather River. The water temperature  
38 threshold for rearing spring-run Chinook Salmon would also be exceeded slightly  
39 more frequently in the Feather River. Because of the inherent uncertainty  
40 associated with the resolution of the temperature model (average monthly  
41 outputs), the slightly greater likelihood of exceeding water temperature thresholds  
42 under the No Action Alternative could increase the potential for adverse effects  
43 on the spring-run Chinook Salmon populations in the Feather River. Given the  
44 similarity of the results, the No Action Alternative and Second Basis of

1 Comparison are likely to have similar effects on the spring-run Chinook Salmon  
2 population in Clear Creek.

3 The numerical model results suggest that, overall, effects on spring-run Chinook  
4 Salmon could be slightly more adverse under the No Action Alternative than  
5 under the Second Basis of Comparison, and with a small likelihood that spring-  
6 run Chinook Salmon production would be lower under the No Action Alternative.  
7 This potential distinction between the two scenarios, however, may be offset by  
8 the benefits of implementation of fish passage under the No Action  
9 Alternative intended to address the limited availability of suitable habitat for  
10 spring-run Chinook Salmon in the Sacramento River reaches downstream of  
11 Keswick Dam. This beneficial effect and its magnitude would depend on the  
12 success of the fish passage program. In addition, spring-run Chinook Salmon  
13 may benefit under the No Action Alternative by implementation of the 2009  
14 NMFS BO RPA action suite (IV.4), which is intended to increase the efficiency  
15 of the Tracy and Skinner Fish Collection Facilities to improve the overall salvage  
16 survival of listed salmonids, including spring-run Chinook Salmon.

17 Thus, it is concluded that the potential for adverse effects on spring-run Chinook  
18 Salmon under the No Action Alternative suggested by the results of the numerical  
19 models may be offset by the potential benefits of the RPA actions that are not  
20 included in the numerical models, principally because the Second Basis of  
21 Comparison does not include a fish passage strategy to address water  
22 temperatures that NMFS (2009) indicates is critical to spring-run Chinook Salmon  
23 sustainability over the long term with climate change by 2030. On balance and  
24 over the long term, the adverse effects on spring-run Chinook Salmon under the  
25 No Action Alternative would be less than those under the Second Basis of  
26 Comparison.

### 27 *Fall-Run Chinook Salmon*

28 Changes in operations that influence temperature and flow conditions in the  
29 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
30 Whiskeytown Dam, Feather River downstream of Oroville Dam and American  
31 River below Nimbus could affect fall-run Chinook Salmon. The following  
32 describes those changes and their potential effects.

#### 33 *Changes in Water Temperature*

34 Changes in water temperature could affect fall-run Chinook Salmon in the  
35 Sacramento, Feather, and American rivers, and Clear Creek. The following  
36 describes temperature conditions in those water bodies.

#### 37 *Sacramento River*

38 Average monthly water temperatures in the Sacramento River at Keswick Dam  
39 under the No Action Alternative would generally be similar (less than 0.5°F  
40 difference) to water temperatures under the Second Basis of Comparison. An  
41 exception is during September and October of critical dry years when water  
42 temperatures could be up to 1.1°F and 0.8°F higher, respectively, under the No  
43 Action Alternative as compared to the Second Basis of Comparison and up to 1°F

1 cooler in September of wetter years under the No Action  
2 Alternative (Appendix 6B). A similar pattern in temperature differences  
3 generally would be exhibited at downstream locations along the Sacramento River  
4 (i.e., Ball's Ferry Jelly's Ferry, Bend Bridge, Red Bluff, Hamilton City, and  
5 Knights Landing), with average monthly temperatures increasing in a downstream  
6 direction and temperature differences between scenarios at Knights Landing  
7 progressively increasing (up to 0.9°F warmer) in June and up to 4.6°F cooler in  
8 September during the wetter years under the No Action Alternative relative to the  
9 Second Basis of Comparison.

10 Overall, the temperature differences between the No Action Alternative and  
11 Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
12 likely would have little effect on fall-run Chinook Salmon in the Sacramento  
13 River. The somewhat lower water temperatures in September of wetter years may  
14 reduce the likelihood of adverse effects on early spawning fall-run Chinook  
15 Salmon, although the increased water temperatures in September of critical dry  
16 years under the No Action Alternative may increase the likelihood of adverse  
17 effects on fall-run Chinook Salmon spawning in this water year type.

18 *Clear Creek*

19 Long-term average monthly water temperatures in Clear Creek at Igo under the  
20 No Action Alternative and the Second Basis of Comparison generally would be  
21 similar (less than 0.5°F differences) in most months (Appendix 6B, Table B-3-4).  
22 Modeled average monthly water temperatures during May under the No Action  
23 Alternative would be up to 0.8°F lower than under the Second Basis of  
24 Comparison. Fall-run Chinook Salmon spawn and rear in the lower portion of  
25 Clear Creek, generally downstream of Igo. Average monthly temperatures at the  
26 confluence with the Sacramento River would be similar under the No Action  
27 Alternative and the Second Basis of Comparison, except during May. Modeled  
28 average monthly water temperatures at the confluence during May could be 0.9°F  
29 to 1.3°F lower under the No Action Alternative than under the Second Basis of  
30 Comparison.

31 The lower water temperatures in May associated with the No Action  
32 Alternative reflect the effects of the additional water discharged from  
33 Whiskeytown Dam to meet the spring attraction flow requirements to promote  
34 attraction of spring-run Chinook Salmon into Clear Creek. While the reduction in  
35 water temperature indicated by the modeling could improve thermal conditions  
36 for fall-run Chinook Salmon, the duration of the two pulse flows may not be of  
37 sufficient duration (3 days each) to provide biologically meaningful temperature  
38 benefits. Overall, thermal conditions for fall-run Chinook Salmon in Clear Creek  
39 would be similar under the No Action Alternative and the Second Basis of  
40 Comparison.

41 *Feather River*

42 Long-term average monthly water temperatures in the Feather River in the low  
43 flow channel generally are predicted to be similar (less than 0.5°F differences)  
44 under the No Action Alternative and the Second Basis of Comparison, except

1 during November and December when average monthly water temperatures could  
2 be up to 1.4°F higher in some water year types. Average monthly water  
3 temperatures in September under the No Action Alternative could be up to 1.3°F  
4 lower than under the Second Basis of Comparison in wetter years. Although  
5 temperatures in the river generally become progressively higher in the  
6 downstream direction, the differences between the No Action Alternative and  
7 Second Basis of Comparison exhibit a similar pattern at the downstream locations  
8 (Robinson Riffle and Gridley Bridge), with water temperature differences  
9 between the No Action Alternative and Second Basis of Comparison generally  
10 decreasing in most water year types. However water temperatures from July to  
11 September under the No Action Alternative could be somewhat (0.7°F to 1.6°F)  
12 cooler on average and up to 4.0°F cooler at the confluence with Sacramento River  
13 in wetter years.

14 Overall, the temperature differences in the Feather River between the No Action  
15 Alternative and Second Basis of Comparison would be relatively minor (less than  
16 0.5°F) and likely would have little effect on fall-run Chinook Salmon in the  
17 Feather River. The slightly higher water temperatures in November and  
18 December under the No Action Alternative would likely have little effect on  
19 fall-run Chinook Salmon as water temperatures in the Feather River are typically  
20 low during this time period. The somewhat lower water temperatures in  
21 September of wetter years may reduce the likelihood of adverse effects on early  
22 spawning fall-run Chinook Salmon, although the increased temperatures in  
23 September of critical dry years under the No Action Alternative may increase the  
24 likelihood of adverse effects on fall-run Chinook Salmon spawning in this water  
25 year type.

#### 26 *American River*

27 Average monthly water temperatures in the American River at Nimbus Dam  
28 under the No Action Alternative generally would be similar (differences less than  
29 0.5°F) to the Second Basis of Comparison, with the exception of June and  
30 August, when temperatures under the No Action Alternative could be as much as  
31 0.9°F higher in below normal years (Appendix 6B, Table B-12-4). This pattern  
32 generally would persist downstream to Watt Avenue and the mouth, although  
33 temperatures under the No Action Alternative would be up to 1.6°F and 2.0°F  
34 greater, respectively, than under the Second Basis of Comparison in June. In  
35 addition, average monthly water temperatures at the mouth generally would be  
36 lower under the No Action Alternative than the Second Basis of Comparison in  
37 September of wetter years when water temperatures under the No Action  
38 Alternative could be up to 1.7°F cooler (Appendix 6B, Table B-14-4).

39 Overall, the temperature differences in the American River between the No  
40 Action Alternative and Second Basis of Comparison would be relatively minor  
41 (less than 0.5°F) and likely would have little effect on fall-run Chinook Salmon in  
42 the American River. The slightly higher water temperatures in June and August  
43 in some water year types under the No Action Alternative may increase the  
44 likelihood of adverse effects on fall-run Chinook Salmon rearing in the American

1 River if they are present. The slightly lower water temperatures during  
2 September under the No Action Alternative would have little effect on fall-run  
3 Chinook Salmon spawning in the American River because most spawning occurs  
4 later, in November, but conditions for holding would be improved.  
5 Implementation of water temperature management structural improvements (2009  
6 NMFS BO RPA Action II.3) could contribute to better water temperature  
7 conditions for fish in the American River under the No Action Alternative than  
8 under the Second Basis of Comparison.

9 *Changes in Exceedances of Water Temperature Thresholds*

10 Changes in water temperature could result in the exceedance of water  
11 temperatures that are protective of fall-run Chinook Salmon in the Sacramento  
12 River, Clear Creek, Feather River, and American River. The following describes  
13 the extent of those exceedances for each of those water bodies.

14 *Sacramento River*

15 Average monthly water temperatures under both the No Action Alternative and  
16 Second Basis of Comparison indicate exceedances of the water temperature  
17 threshold of 56°F established in the Sacramento River at Red Bluff for Chinook  
18 Salmon spawning and egg incubation in October, November, and again in April.  
19 In the months when the greatest frequency of exceedances occur (October,  
20 November, and April), model results generally indicate more frequent  
21 exceedances (by up to 4 percent in October) under the No Action Alternative than  
22 under the Second Basis of Comparison. Temperature conditions in the  
23 Sacramento River under the No Action Alternative could be more likely to affect  
24 fall-run Chinook Salmon spawning and egg incubation than under the Second  
25 Basis of Comparison because of the increased frequency of exceedance of the  
26 56°F threshold in October, November, and April. However, this difference may  
27 be partially offset if water temperature management and fish passage measures  
28 associated with 2009 NMFS BO RPA under the No Action Alternative are  
29 successful.

30 *Clear Creek*

31 Fall-run Chinook Salmon spawning in lower Clear Creek typically occurs during  
32 October through December (USFWS 2015). Average monthly water  
33 temperatures at Igo during this period are generally below 56°F, except in  
34 October. Under the No Action Alternative, the 56°F threshold would be exceeded  
35 in October about 12 percent of the time as compared to 10 percent under the  
36 Second Basis of Comparison (Appendix 9N). At the confluence with the  
37 Sacramento River, average monthly water temperatures in October would be  
38 warmer, with 56°F exceeded nearly 20 percent of the time under the No Action  
39 Alternative, about 6 percent more frequently than under the Second Basis of  
40 Comparison (Appendix 6B, Figure B-4-1). During November and December,  
41 average monthly water temperatures generally would remain below 56°F at both  
42 locations (Appendix 6B, Figure B-4-2 and B-4-3). Temperature conditions in  
43 Clear Creek under the No Action Alternative could be more likely to result in  
44 adverse effects on fall-run Chinook Salmon spawning and egg incubation than

1 under the Second Basis of Comparison because of the increased frequency of  
2 exceedance of the 56°F threshold in October.

3 For fall-run Chinook Salmon rearing (January through August), the average  
4 monthly temperatures at Igo would likely remain below the 60°F threshold in all  
5 months. Downstream at the mouth of Clear Creek, average monthly water  
6 temperatures would exceed the 60°F threshold often during the summer, but the  
7 frequency of exceedance would be similar under the No Action Alternative and  
8 the Second Basis of Comparison (Appendix 6B). Temperature conditions for  
9 fall-run Chinook Salmon rearing in Clear Creek would be similar under the No  
10 Action Alternative and the Second Basis of Comparison.

#### 11 *Feather River*

12 Average monthly water temperatures under both the No Action Alternative and  
13 Second Basis of Comparison would exceed the water temperature threshold of  
14 56°F established in the Feather River at Gridley Bridge for fall-run Chinook  
15 Salmon spawning and egg incubation during some months, particularly in  
16 October, November, March, and April, when water temperature thresholds would  
17 be exceeded frequently (Appendix 9N). The frequency of exceedance would be  
18 greatest in October, when average monthly temperatures under both the No  
19 Action Alternative and Second Basis of Comparison would be above the  
20 threshold in nearly every year. The magnitude of the exceedances would be high  
21 as well, with average monthly temperatures in October reaching about 68°F. The  
22 threshold would be exceeded under both the No Action Alternative and Second  
23 Basis of Comparison about 75 percent of the time in April. The differences  
24 between the No Action Alternative and Second Basis of Comparison, however,  
25 would be relatively small, with the No Action Alternative generally exceeding  
26 temperature thresholds about 1-2 percent more frequently than the Second Basis  
27 of Comparison during the October through April period. Temperature conditions  
28 in the Feather River under the No Action Alternative could be more likely to  
29 result in adverse effects on fall-run Chinook Salmon spawning and egg incubation  
30 than under the Second Basis of Comparison because of the increased frequency of  
31 exceedance of the 56°F threshold from October through April.

#### 32 *Changes in Egg Mortality*

33 Water temperatures influence the viability of incubating fall-run Chinook Salmon  
34 eggs. The following describes the differences in egg mortality for the  
35 Sacramento, Feather, and American rivers.

#### 36 *Sacramento River*

37 For fall-run Chinook Salmon in the Sacramento River, the long-term average egg  
38 mortality rate is predicted to be around 17 percent, with higher mortality rates (in  
39 excess of 35 percent) occurring in critical dry years under the No Action  
40 Alternative. Predicted egg mortality would be similar under the No Action  
41 Alternative and the Second Basis of Comparison in all water year types  
42 (Appendix 9C, Table B-1).

1            *Feather River*

2 For fall-run Chinook Salmon in the Feather River, the long-term average egg  
3 mortality rate is predicted to be relatively low (around 7 percent), with higher  
4 mortality rates (around 14.5 percent) occurring in critical dry years under the No  
5 Action Alternative. Predicted egg mortality would be similar under the No  
6 Action Alternative and the Second Basis of Comparison in all water year types  
7 (Appendix 9C, Table B-7).

8            *American River*

9 For fall-run Chinook Salmon in the American River, the long-term average egg  
10 mortality rate is predicted to range from approximately 23 to 25 percent in all  
11 water year types under the No Action Alternative. Overall, egg mortality would  
12 be similar under the No Action Alternative and the Second Basis of Comparison  
13 (Appendix 9C, Table B-6).

14           *Changes in Weighted Usable Area*

15 Weighted usable area, which is influenced by flow, is a measure of habitat  
16 suitability. The following describes changes in WUA for fall-run Chinook  
17 Salmon in the Sacramento, Feather, and American rivers and Clear Creek.

18           *Sacramento River*

19 As an indicator of the amount of suitable spawning habitat for fall-run Chinook  
20 Salmon between Keswick Dam and Battle Creek, WUA modeling results indicate  
21 that, in general, there would be lesser amounts of spawning habitat available in  
22 September and November under the No Action Alternative as compared to the  
23 Second Basis of Comparison. Fall-run spawning WUA would be similar in  
24 October and December under the No Action Alternative and the Second Basis of  
25 Comparison (Appendix 9E, Table C-11-4). The long-term average spawning  
26 WUA during September (prior to the peak spawning period) under the No Action  
27 Alternative would be more than 20 percent lower, and around 6 percent lower in  
28 November compared to the Second Basis of Comparison. November is during the  
29 peak spawning period for fall-run Chinook Salmon in the Sacramento River.  
30 Results for the reach from Battle Creek to Deer Creek show the same pattern for  
31 changes in WUA for spawning fall-run Chinook Salmon between the No Action  
32 Alternative and the Second Basis of Comparison (Appendix 9E, Table C-10-4).  
33 Overall, spawning habitat availability would be somewhat lower under the No  
34 Action Alternative relative to the Second Basis of Comparison.

35 Modeling results indicate that, in general, the amount of suitable fry rearing  
36 habitat available from December to March under the No Action Alternative would  
37 be similar to the amount of fry rearing habitat available under the Second Basis of  
38 Comparison (Appendix 9E, Table C-12-4).

39 Similar to the results for fry rearing WUA, modeling results indicate that there  
40 would be similar amounts of suitable juvenile rearing habitat available during the  
41 juvenile rearing period from February to June under the No Action  
42 Alternative and the Second Basis of Comparison. (Appendix 9E, Table C-13-4).

1            *Clear Creek*

2    As described above, flows in Clear Creek downstream of Whiskeytown Dam are  
 3    not anticipated to differ under the No Action Alternative relative to the Second  
 4    Basis of Comparison except in May due to the release of spring attraction flows in  
 5    accordance with the 2009 NMFS BO. Therefore, there would be no change in the  
 6    amount of potentially suitable spawning and rearing habitat for fall-run Chinook  
 7    Salmon (as indexed by WUA) available under the No Action Alternative as  
 8    compared to the Second Basis of Comparison.

9            *Feather River*

10    As described above, flows in the low flow channel of the Feather River are not  
 11    anticipated to differ under the No Action Alternative relative to the Second Basis  
 12    of Comparison. Therefore, there would be no change in the amount of potentially  
 13    suitable spawning habitat for fall-run Chinook Salmon (as indexed by WUA)  
 14    available under the No Action Alternative as compared to the Second Basis of  
 15    Comparison. The majority of spawning activity by fall-run Chinook Salmon in  
 16    the Feather River occurs in this reach with a lesser amount of spawning occurring  
 17    downstream of the Thermalito Complex.

18    Modeling results indicate that, in general, there would be lesser amounts of  
 19    spawning habitat available in the Feather River downstream of the Thermalito  
 20    Complex during September under the No Action Alternative as compared to the  
 21    Second Basis of Comparison. Fall-run Chinook Salmon spawning WUA would  
 22    be similar under the No Action Alternative and Second Basis of Comparison in  
 23    October and November (the peak spawning months) and in December (after the  
 24    peak spawning period) in this reach (Appendix 9E, Table C-24-4). The decrease  
 25    in long-term average spawning WUA during September (prior to the peak  
 26    spawning period) under the No Action Alternative would be relatively large  
 27    (more than 15 percent). Overall, spawning habitat availability would be similar  
 28    under the No Action Alternative and the Second Basis of Comparison.

29           *American River*

30    Modeling results indicate that, in general, there would be similar amounts of  
 31    spawning habitat available for fall-run Chinook Salmon in the American River  
 32    from October through December under the No Action Alternative as compared to  
 33    the Second Basis of Comparison (Appendix 9E, Table C-25-4).

34           *Changes in SALMOD Output – Sacramento River*

35    SALMOD results indicate that potential juvenile production would similar under  
 36    the No Action Alternative and the Second Basis of Comparison, except in critical  
 37    dry water years when production could be 7 percent lower under the No Action  
 38    Alternative than under the Second Basis of Comparison (Appendix 9D,  
 39    Table B-1-16).

40           *Changes in Delta Passage Model Output*

41    The Delta Passage Model predicted similar estimates of annual Delta survival  
 42    across the 81-year time period for fall-run Chinook Salmon between the No Action  
 43    Alternative and the Second Basis of Comparison (Appendix 9J). Median Delta

1 survival was 0.248 for the No Action Alternative and 0.245 for the Second Basis  
2 of Comparison.

3 *Changes in Delta Hydrodynamics*

4 Fall-run Chinook Salmon smolts are most abundant in the Delta during the  
5 months of April, May, and June. At the junction of Georgiana Slough and the  
6 Sacramento River, the median percent of time with positive velocity was similar  
7 under both scenarios in the months of April, May and June (Appendix 9K). Near  
8 the Confluence of the San Joaquin River and the Mokelumne River, the median  
9 proportion of positive velocities was slightly greater under the No Action  
10 Alternative relative to the Second Basis of Comparison in April and May and  
11 similar in June. In Old River downstream of the facilities, the median proportion  
12 of positive velocities was substantially greater in April and May, but became  
13 more similar in June. In Old River upstream of the facilities, the median  
14 proportion of positive velocities was slightly to moderately greater for the No  
15 Action Alternative relative to the Second Basis of Comparison in April and May,  
16 respectively, and slightly lower in June. On the San Joaquin River downstream of  
17 the Head of Old River, the median proportion of positive velocities was slightly  
18 moderately lower under the No Action Alternative relative to the Second Basis of  
19 Comparison in April and May, respectively, whereas the values were similar  
20 in June.

21 *Changes in Junction Entrainment*

22 Entrainment at Georgiana Slough was similar under both scenarios in most  
23 months, but was slightly lower under the No Action Alternative relative to the  
24 Second Basis of Comparison in the month of June (Appendix 9L). Median  
25 entrainment probabilities at the Head of Old River were much greater under the  
26 No Action Alternative relative to the Second Basis of Comparison during April  
27 and May. The median entrainment probability was similar under both scenarios  
28 in the month of June. At the Turner Cut junction, median entrainment  
29 probabilities under the No Action Alternative were slightly lower than the Second  
30 Basis of Comparison in June. During April and May, median entrainment  
31 probabilities were more divergent with moderately lower values for the No Action  
32 Alternative relative to the Second Basis of Comparison. Overall, entrainment was  
33 slightly lower at the Columbia Cut junction relative to Turner Cut, but patterns of  
34 entrainment between the two scenarios were similar. Patterns in entrainment  
35 probabilities at the Middle River and Old River junctions were similar to those  
36 observed at Columbia and Turner Cut junctions.

37 *Changes in Salvage*

38 Salvage of Sacramento River-origin Chinook Salmon is predicted to be lower  
39 under the No Action Alternative relative to the Second Basis of Comparison in  
40 every month (Appendix 9M). Fall-run smolts migrating through the Delta would  
41 be most susceptible in the months of April, May, and June. Predicted values in  
42 April and May indicated a substantially reduced fraction of fish salvaged under  
43 the No Action Alternative relative to the Second Basis of Comparison. Predicted  
44 salvage was more similar in March but still lower under the No Action  
45 Alternative.

1        *Summary of Effects on Fall-Run Chinook Salmon*

2        The multiple model and analysis outputs described above characterize the  
3        anticipated conditions for fall-run Chinook Salmon and their response to change  
4        under the No Action Alternative as compared to the Second Basis of Comparison.  
5        For the purpose of analyzing effects on fall-run Chinook Salmon in the  
6        Sacramento River, greater reliance was placed on the outputs from the SALMOD  
7        model because it integrates the available information on temperature and flows to  
8        produce estimates of mortality for each life stage and an overall, integrated  
9        estimate of potential fall-run Chinook Salmon juvenile production. The output  
10       from SALMOD indicated that fall-run Chinook Salmon production would be  
11       similar in most water year types under the No Action Alternative than under the  
12       Second Basis of Comparison, and up to 7 percent less than under the Second  
13       Basis of Comparison in critical dry years. The analyses attempting to assess the  
14       effects on routing, entrainment, and salvage of juvenile salmonids in the Delta  
15       suggest that salvage (as an indicator of potential losses of juvenile salmon at the  
16       export facilities) of Sacramento River-origin Chinook Salmon is predicted to be  
17       lower under the No Action Alternative relative to the Second Basis of  
18       Comparison in every month.

19       In Clear Creek and the Feather and American rivers, the analysis of the effects of  
20       the No Action Alternative and Second Basis of Comparison for fall-run Chinook  
21       Salmon relied on the WUA analysis for habitat and water temperature model  
22       output for the rivers at various locations downstream of the CVP and SWP  
23       facilities. The WUA analysis indicated that the availability of spawning and  
24       rearing habitat in Clear Creek and spawning habitat in the Feather and American  
25       rivers would be similar under the No Action Alternative and the Second Basis of  
26       Comparison. The temperature model outputs for each of the fall-run Chinook  
27       Salmon life stages suggest that thermal conditions and effects on fall-run Chinook  
28       Salmon in all of these streams generally would be similar under both scenarios.  
29       The water temperature threshold exceedance analysis that indicated that the water  
30       temperature thresholds for fall-run Chinook Salmon spawning and egg incubation  
31       would be exceeded slightly more frequently in the Feather River and Clear Creek  
32       under the No Action Alternative and could increase the potential for adverse  
33       effects on the fall-run Chinook Salmon populations in Clear Creek and the  
34       Feather River. Results of the analysis using Reclamation's salmon mortality  
35       model indicate that there would be little difference in fall-run Chinook Salmon  
36       egg mortality under the No Action Alternative and the Second Basis of  
37       Comparison.

38       These model results suggest that overall, effects on fall-run Chinook Salmon  
39       could be slightly more adverse under the No Action Alternative than under the  
40       Second Basis of Comparison, with a small likelihood that fall-run Chinook  
41       Salmon production would be lower under the No Action Alternative.

42       Additional RPA actions in the 2009 NMFS BO could help improve conditions for  
43       fall-run Chinook Salmon under the No Action Alternative relative to the Second  
44       Basis of Comparison, such as structural improvements for water temperature  
45       management in the American River (NMFS RPA Action II.3), development of a

1 hatchery management plan for the Nimbus Hatchery (NMFS RPA Action II.6.3)  
2 and actions (NMFS RPA Action Suite IV.4) intended to increase the efficiency of  
3 the Tracy and Skinner Fish Collection Facilities to improve the overall salvage  
4 survival of salmonids.

5 The implementation of fish passage under the No Action Alternative intended to  
6 address the limited availability of suitable habitat for winter-run and spring-run  
7 Chinook Salmon in the Sacramento River reaches downstream of Shasta Dam is  
8 unlikely to benefit fall-run Chinook Salmon unless passage is provided to fall-run  
9 Chinook Salmon. It is unlikely that providing similar fish passage at Folsom Dam  
10 for steelhead would benefit fall-run Chinook Salmon for the same reason.

11 Overall, the results of the numerical models suggest the potential for greater  
12 adverse effects on fall-run Chinook Salmon under the No Action Alternative as  
13 compared to the Second Basis of Comparison. However, discerning a meaningful  
14 difference between these two scenarios based on the quantitative results is not  
15 possible because of the similarity in results (generally differences less than  
16 5 percent) and the inherent uncertainty of the models. In addition, any adverse  
17 effect of the No Action Alternative could be offset by the potentially beneficial  
18 effects resulting from the RPA actions evaluated qualitatively for the No Action  
19 Alternative. Thus, it is concluded that the effects on fall-run Chinook Salmon  
20 would be less adverse under the No Action Alternative than under the Second  
21 Basis of Comparison.

#### 22 *Late Fall-Run Chinook Salmon*

23 Changes in operations that influence temperature and flow conditions in the  
24 Sacramento River downstream of Keswick Dam could affect late fall-run Chinook  
25 Salmon. The following describes those changes and their potential effects.

#### 26 *Changes in Water Temperature*

27 As described above, long-term average monthly water temperatures in the  
28 Sacramento River at Keswick Dam under the No Action Alternative would  
29 generally be similar (less than 0.5°F difference) to water temperatures under the  
30 Second Basis of Comparison. An exception is during September and October of  
31 critical dry years when water temperatures could be up to 1.1°F and 0.8°F higher,  
32 respectively, under the No Action Alternative as compared to the Second Basis of  
33 Comparison and up to 1°F cooler in September of wetter years under the No  
34 Action Alternative (Appendix 6B, Table 5-5-4). A similar pattern in temperature  
35 differences generally would be exhibited at downstream locations along the  
36 Sacramento River (i.e., Ball's Ferry Jelly's Ferry, Bend Bridge, Red Bluff,  
37 Hamilton City, and Knights Landing), with average monthly temperatures  
38 increasing and water temperature differences between scenarios progressively  
39 increasing (up to 0.9°F warmer) in June and up to 4.6°F cooler in September  
40 during the wetter years under the No Action Alternative relative to the Second  
41 Basis of Comparison.

42 Overall, the temperature differences between the No Action Alternative and  
43 Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
44 likely would have little effect on late fall-run Chinook Salmon in the Sacramento

1 River. Spawning of late fall-run Chinook Salmon in the Sacramento River takes  
 2 place from December to mid-April with incubation occurring over the same time  
 3 period and extending into June. The likelihood of adverse effects on late fall-run  
 4 Chinook Salmon spawning and egg incubation would be similar under the No  
 5 Action Alternative and the Second Basis of Comparison due to similar water  
 6 temperatures during the January to May time period.

7 Because late fall-run Chinook Salmon have an extended rearing period, the  
 8 similar water temperatures during the summer under the No Action  
 9 Alternative and Second Basis of Comparison would have similar effects on  
 10 rearing fry and juvenile late fall-run Chinook Salmon in the Sacramento River.  
 11 The lower water temperatures under the No Action Alternative in September of  
 12 wetter years may reduce the likelihood of adverse effects on fry and juvenile late  
 13 fall-run Chinook Salmon in the Sacramento River during this limited time period.

#### 14 *Changes in Exceedances of Water Temperature Thresholds*

15 Average monthly water temperatures under both the No Action Alternative and  
 16 Second Basis of Comparison indicate exceedances of the water temperature  
 17 threshold of 56°F established in the Sacramento River at Red Bluff for Chinook  
 18 Salmon spawning and egg incubation in October, November, and again in April.  
 19 There would be no exceedances of the threshold from December to March under  
 20 both the No Action Alternative and the Second Basis of Comparison. In April,  
 21 model results indicate that water temperatures under the No Action  
 22 Alternative could exceed the threshold about 2 percent more frequently than  
 23 under the Second Basis of Comparison. Temperature conditions in the  
 24 Sacramento River under the No Action Alternative could be slightly more likely  
 25 to affect late fall-run Chinook Salmon spawning and egg incubation than under  
 26 the Second Basis of Comparison because of the increased frequency of  
 27 exceedance of the 56°F threshold in April. However, this difference may be  
 28 partially offset if water temperature management and fish passage measures  
 29 associated with 2009 NMFS BO RPA under the No Action Alternative are  
 30 successful.

#### 31 *Changes in Egg Mortality*

32 For late fall-run Chinook Salmon in the Sacramento River, the long-term average  
 33 egg mortality rate is predicted to range from approximately 2.5 to nearly 5 percent  
 34 in all water year types under the No Action Alternative. Overall, egg mortality  
 35 would be similar under the No Action Alternative and the Second Basis of  
 36 Comparison (Appendix 9C, Table B-2).

#### 37 *Changes in Weighted Usable Area*

38 Modeling results indicate that there would be similar amounts of spawning habitat  
 39 available for late fall-run Chinook Salmon in the Sacramento River from January  
 40 through April under the No Action Alternative and the Second Basis of  
 41 Comparison (Appendix 9E, Table C-14-4). Modeling results also indicate that  
 42 there would be similar amounts of suitable late fall-run Chinook Salmon fry  
 43 rearing habitat available in the Sacramento River from April to June under the

1 No Action Alternative and Second Basis of Comparison (Appendix 9E,  
2 Table C-15-4).

3 A substantial fraction of late fall run Chinook Salmon juveniles oversummer in  
4 the Sacramento River before emigrating, which allows them to avoid predation  
5 through both their larger size and greater swimming ability. One implication of  
6 this life history strategy is that rearing habitat is most likely the limiting factor for  
7 late-fall-run Chinook Salmon, especially if availability of cool water determines  
8 the downstream extent of spawning habitat for late-fall-run Chinook Salmon.  
9 Modeling results indicate that, there would generally be similar amounts of  
10 suitable juvenile rearing habitat available from December through August under  
11 the No Action Alternative and Second Basis of Comparison. There could be  
12 decreases in the amount of late fall-run Chinook Salmon juvenile rearing WUA in  
13 September and November of up to 15 percent (Appendix 9E, Table C-16-4).  
14 Overall, late fall-run juvenile rearing habitat availability would be similar under  
15 the No Action Alternative and the Second Basis of Comparison.

16 *Changes in SALMOD Output – Sacramento River*

17 SALMOD results indicate that potential juvenile production would be similar  
18 under the No Action Alternative and the Second Basis of Comparison  
19 (Appendix 9D, Table B-2-16).

20 *Changes in Delta Passage Model Output*

21 For late fall-run Chinook Salmon, through-Delta survival was predicted to be  
22 slightly higher under the No Action Alternative relative to the Second Basis of  
23 Comparison for all 81 years simulated by the Delta Passage Model (Appendix 9J).  
24 Median Delta survival across all years was 0.244 for the No Action  
25 Alternative and 0.199 for the Second Basis of Comparison.

26 *Changes in Hydrodynamics*

27 The late fall-run Chinook Salmon migration period overlaps with winter-run  
28 Chinook Salmon. See the section on hydrodynamic analysis for winter-run  
29 Chinook Salmon for potential effects on late fall-run Chinook Salmon.

30 *Changes in Junction Entrainment*

31 Entrainment probabilities for late fall-run are assumed to mimic that of winter-run  
32 Chinook Salmon due to overlap in timing. See the section on winter-run Chinook  
33 Salmon entrainment for potential effects on late fall-run Chinook Salmon.

34 *Changes in Salvage*

35 Salvage of late fall-run Chinook Salmon is assumed to mimic that of winter-run  
36 Chinook Salmon due to overlap in timing. See the section on winter-run Chinook  
37 Salmon entrainment for potential effects on late fall-run Chinook Salmon.

38 *Summary of Effects on Late Fall-Run Chinook Salmon*

39 The multiple model and analysis outputs described above characterize the  
40 anticipated conditions for late fall-run Chinook Salmon and their response to  
41 change under the No Action Alternative as compared to the Second Basis of  
42 Comparison. For the purpose of analyzing effects on late fall-run Chinook

1 Salmon and developing conclusions, greater reliance was placed on the outputs  
2 from the SALMOD model because it integrates the available information on  
3 temperature and flows to produce estimates of mortality for each life stage and an  
4 overall, integrated estimate of potential fall-run Chinook Salmon juvenile  
5 production. The output from SALMOD indicated that late fall-run Chinook  
6 Salmon production would be similar under the No Action Alternative and the  
7 Second Basis of Comparison. The analyses attempting to assess the effects on  
8 routing, entrainment, and salvage of juvenile salmonids in the Delta suggest that  
9 salvage (as an indicator of potential losses of juvenile salmon at the export  
10 facilities) of Sacramento River-origin Chinook Salmon is predicted to be lower  
11 under the No Action Alternative relative to the Second Basis of Comparison in  
12 every month.

13 These model results suggest that overall, effects on late fall-run Chinook Salmon  
14 could be slightly less adverse under the No Action Alternative than under the  
15 Second Basis of Comparison. In addition, potential adverse effects may be  
16 lessened under the No Action Alternative by actions intended to increase the  
17 efficiency of the Tracy and Skinner Fish Collection Facilities (NMFS RPA Action  
18 Suite IV.4) and improve the overall salvage survival of salmonids, including late  
19 fall-run Chinook Salmon. Thus, it is concluded that the potential for adverse  
20 effects on late fall-run Chinook Salmon would be lower under the No Action  
21 Alternative compared to the Second Basis of Comparison.

## 22 *Steelhead*

23 Changes in operations that influence temperature and flow conditions could affect  
24 steelhead. The following describes those changes and their potential effects.

### 25 *Changes in Water Temperature*

26 Changes in water temperature could affect steelhead in the Sacramento, Feather,  
27 and American rivers, and Clear Creek. The following describes temperature  
28 conditions in those water bodies.

#### 29 *Sacramento River*

30 As described above, long-term average monthly water temperatures in the  
31 Sacramento River at Keswick Dam under the No Action Alternative would  
32 generally be similar (less than 0.5°F difference) to water temperatures under the  
33 Second Basis of Comparison. An exception is during September and October of  
34 critical dry years when water temperatures could be up to 1.1°F and 0.8°F higher,  
35 respectively, under the No Action Alternative as compared to the Second Basis of  
36 Comparison and up to 1°F cooler in September of wetter years under the No  
37 Action Alternative (Appendix 6B, Table 5-5-4). A similar temperature pattern  
38 generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry, Bend  
39 Bridge and Red Bluff, with average monthly temperatures increasing in a  
40 downstream direction and temperature differences between scenarios  
41 progressively decreasing except in September (up to a 3.2°F difference at Red  
42 Bluff) during wetter years (Appendix 6B, Table B-9-4).

1 Overall, the temperature differences between the No Action Alternative and  
2 Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
3 likely would have little effect on steelhead in the Sacramento River. Based on the  
4 life history timing for steelhead, the slightly higher water temperatures in  
5 September of drier years under the No Action Alternative may increase the  
6 likelihood of adverse effects on steelhead adults migrating upstream in the  
7 Sacramento River. The lower water temperatures in September of wetter years  
8 under the No Action Alternative may decrease the likelihood of adverse effects on  
9 steelhead migration compared to the Second Basis of Comparison.

10 *Clear Creek*

11 Long-term average monthly water temperatures in Clear Creek at Igo under the  
12 No Action Alternative and the Second Basis of Comparison generally would be  
13 similar (less than 0.5°F differences) in most months (Appendix 6B, Table B-3-4).  
14 Modeled average monthly water temperatures during May under the No Action  
15 Alternative would be up to 0.8°F lower than under the Second Basis of  
16 Comparison.

17 The lower water temperatures in May associated with the No Action  
18 Alternative reflect the effects of the additional water discharged from  
19 Whiskeytown Dam to meet the spring attraction flow requirements to promote  
20 attraction of spring-run Chinook Salmon into Clear Creek. While the reduction in  
21 water temperature indicated by the modeling could improve thermal conditions  
22 for steelhead, the duration of the two pulse flows may not be of sufficient duration  
23 (3 days each) to provide temperature benefits. Overall, thermal conditions for  
24 steelhead in Clear Creek would be similar under the No Action Alternative and  
25 the Second Basis of Comparison.

26 *Feather River*

27 Long-term average monthly water temperature in the Feather River in the low  
28 flow channel generally are predicted to be similar (less than 0.5°F differences)  
29 under the No Action Alternative and the Second Basis of Comparison, except  
30 during November and December when average monthly water temperatures could  
31 be up to 1.4°F higher in some water year types. Average monthly water  
32 temperatures in September under the No Action Alternative could be up to 1.3°F  
33 lower than the Second Basis of Comparison in wetter years. Although  
34 temperatures in the river generally become progressively higher in the  
35 downstream direction, the differences between the No Action Alternative and  
36 Second Basis of Comparison exhibit a similar pattern at the downstream locations  
37 (Robinson Riffle and Gridley Bridge), with water temperature differences  
38 between the No Action Alternative and Second Basis of Comparison generally  
39 decreasing in most water year types. However, water temperatures from July to  
40 September under the No Action Alternative could be somewhat (0.7°F to 1.6°F)  
41 cooler on average and up to 4.0°F cooler at the confluence with Sacramento River  
42 in wetter years.

43 Overall, the temperature differences in the Feather River between the No Action  
44 Alternative and Second Basis of Comparison would be relatively minor (less than

1 0.5°F) and likely would have little effect on steelhead in the Feather River. The  
 2 slightly higher water temperatures in November and December under the No  
 3 Action Alternative would likely have little effect on adult steelhead migration as  
 4 water temperatures in the Feather River are typically low during this time period.  
 5 The somewhat lower water temperatures in September of wetter years may reduce  
 6 the likelihood of adverse effects on adult steelhead migrating upstream and  
 7 juveniles rearing in the Feather River, although the increased temperatures in  
 8 September of critical dry years under the No Action Alternative may increase the  
 9 likelihood of adverse effects on migrating and rearing steelhead in this water  
 10 year type.

#### 11 *American River*

12 Average monthly water temperatures in the American River at Nimbus Dam  
 13 under the No Action Alternative generally would be similar (differences less than  
 14 0.5°F) to the Second Basis of Comparison, with the exception of June and  
 15 August, when differences under the No Action Alternative could be as much as  
 16 0.9°F higher in below normal years. This pattern generally would persist  
 17 downstream to Watt Avenue and the mouth, although temperatures under the No  
 18 Action Alternative would be up to 1.6°F and 2.0°F greater, respectively, than  
 19 under the Second Basis of Comparison in June. In addition, average monthly  
 20 water temperatures at the mouth generally would be lower under the No Action  
 21 Alternative than the Second Basis of Comparison in September of wetter years  
 22 when water temperatures under the No Action Alternative could be up to 1.7°F  
 23 cooler.

24 Overall, the temperature differences between the No Action Alternative and  
 25 Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
 26 likely would have little effect on steelhead in the American River. The slightly  
 27 warmer water temperatures in June and August under the No Action  
 28 Alternative may increase the likelihood of adverse effects on steelhead rearing in  
 29 the American River compared to the Second Basis of Comparison.

#### 30 *Changes in Exceedances of Water Temperature Thresholds*

31 Changes in water temperature could result in the exceedance of established water  
 32 temperature thresholds for steelhead in the Sacramento River, Clear Creek, and  
 33 Feather River. The following describes the extent of exceedance for each of  
 34 those streams.

#### 35 *Sacramento River*

36 As described in the life history accounts (Appendix), steelhead spawning in the  
 37 mainstem Sacramento River generally occurs in the upper reaches from Keswick  
 38 Dam downstream to near Balls Ferry, with most spawning concentrated near  
 39 Redding. Most steelhead, however, spawn in tributaries to the Sacramento River.  
 40 Spawning generally takes place in the January through March period when water  
 41 temperatures in the river generally do not exceed 52°F under either the No Action  
 42 Alternative or Second Basis of Comparison. While there are no established  
 43 temperature thresholds for steelhead rearing in the mainstem Sacramento River,  
 44 average monthly temperatures when fry and juvenile steelhead are in the river

1 would generally remain below 56°F at Balls Ferry except in August and  
2 September when this temperature would be exceeded 30 to 40 percent of the time  
3 under both the No Action Alternative and Second Basis of Comparison.  
4 However, water temperatures in the Sacramento River at Balls Ferry would  
5 exceed 56°F about 10 percent more often in September under the Second Basis of  
6 Comparison. Overall, thermal conditions for steelhead in the Sacramento River  
7 would be similar under the No Action Alternative and the Second Basis of  
8 Comparison.

9 *Clear Creek*

10 While there are no established temperature thresholds for steelhead spawning in  
11 Clear Creek, average monthly water temperatures in the river generally would not  
12 exceed 48°F during the spawning period (December to April) under either the No  
13 Action Alternative or Second Basis of Comparison. Similarly, while there are no  
14 established temperature thresholds for steelhead rearing in Clear Creek, average  
15 monthly temperatures throughout the year would not exceed 56°F at Igo. Overall,  
16 thermal conditions for steelhead in Clear Creek would be similar under the No  
17 Action Alternative and the Second Basis of Comparison.

18 *Feather River*

19 Average monthly water temperatures under both the No Action Alternative and  
20 the Second Basis of Comparison would on occasion exceed the water temperature  
21 threshold of 56°F established in the Feather River at Robinson Riffle for steelhead  
22 spawning and incubation during some months, particularly in October and  
23 November, and March and April, when temperature thresholds could be exceeded  
24 frequently (Appendix 9N). There would be a 1 percent exceedance of the 56°F  
25 threshold in December under the No Action Alternative and no exceedances of  
26 the 56°F threshold in January and February under both the No Action  
27 Alternative and the Second Basis of Comparison. However, the differences in the  
28 frequency of exceedance between the No Action Alternative and Second Basis of  
29 Comparison during March and April would be relatively small with water  
30 temperatures under the No Action Alternative exceeding the threshold about  
31 2 percent less frequently in March (18 percent) and the same exceedance  
32 frequency (75 percent) as the Second Basis of Comparison in April.

33 The established water temperature threshold of 63°F for rearing from May  
34 through August would be exceeded often under both the No Action  
35 Alternative and Second Basis of Comparison in May and June, but not at all in  
36 July and August. Water temperatures under the No Action Alternative would  
37 exceed the rearing temperature threshold about 9 percent more frequently than  
38 under the Second Basis of Comparison in May, but no more frequently in June.  
39 Temperature conditions in the Feather River under the No Action  
40 Alternative could be more likely to affect steelhead spawning and rearing than  
41 under the Second Basis of Comparison because of the increased frequency of  
42 exceedance of the 56°F spawning threshold in March and the increased frequency  
43 of exceedance of the 63°F rearing threshold in May.

1            *American River*

2    In the American River, the water temperature threshold for steelhead rearing  
3    (May through October) is 65°F at the Watt Avenue Bridge. Average monthly  
4    water temperatures would exceed this threshold often under both the No Action  
5    Alternative and Second Basis of Comparison, especially in the July through  
6    September period when the threshold is exceeded nearly all of the time. In  
7    addition, the magnitude of the exceedance would be high, with average monthly  
8    water temperatures sometimes higher than 76°F. The differences between the No  
9    Action Alternative and Second Basis of Comparison, however, would be  
10   relatively small and occur only in June (1 percent less frequent exceedance under  
11   the No Action Alternative), and in September, when average monthly water  
12   temperatures under the No Action Alternative would exceed 65°F about 7 percent  
13   less frequently than under the Second Basis of Comparison. Temperature  
14   conditions in the American River under the No Action Alternative could be less  
15   likely to result in adverse effects on steelhead rearing than under the Second Basis  
16   of Comparison because of the reduced frequency of exceedance of the 65°F  
17   rearing threshold.

18           *Changes in Weighted Usable Area*

19   The following describes changes in WUA for steelhead in the Sacramento,  
20   Feather, and American rivers and Clear Creek.

21           *Sacramento River*

22   Modeling results indicate that, in general, there would be similar amounts of  
23   suitable steelhead spawning habitat available from December through March  
24   under the No Action Alternative and the Second Basis of Comparison  
25   (Appendix 9E, Table C-20-4).

26           *Clear Creek*

27   As described above, flows in Clear Creek downstream of Whiskeytown Dam are  
28   not anticipated to differ under the No Action Alternative relative to the Second  
29   Basis of Comparison except in May due to the release of spring attraction flows in  
30   accordance with the 2009 NMFS BO. Therefore, there would be no change in the  
31   amount of potentially suitable spawning and rearing habitat for steelhead (as  
32   indexed by WUA) available under the No Action Alternative as compared to the  
33   Second Basis of Comparison.

34           *Feather River*

35   As described above, flows in the low flow channel of the Feather River are not  
36   anticipated to differ under the No Action Alternative relative to the Second Basis  
37   of Comparison. Therefore, there would be no change in the amount of potentially  
38   suitable spawning habitat for steelhead (as indexed by WUA) available under the  
39   No Action Alternative as compared to the Second Basis of Comparison. The  
40   majority of spawning activity by steelhead in the Feather River occurs in this  
41   reach with a lesser amount of spawning occurring downstream of the  
42   Thermalito Complex.

1 Modeling results indicate that, in general, there would be similar amounts of  
2 spawning habitat for steelhead in the Feather River downstream of Thermalito  
3 available from December through April under the No Action Alternative and the  
4 Second Basis of Comparison (Appendix 9E, Table C-22-4).

5 *American River*

6 Modeling results indicate that, in general, there would be similar amounts of  
7 spawning habitat for steelhead in the American River downstream of Nimbus  
8 Dam available from December through April under the No Action Alternative and  
9 the Second Basis of Comparison (Appendix 9E, Table C-26-4).

10 *Changes in Delta Hydrodynamics*

11 Sacramento River-origin steelhead generally move through the Delta during  
12 spring; however, there is less information on their timing than there is for  
13 Chinook Salmon. Thus, hydrodynamics in the entire January through June period  
14 have the potential to affect juvenile steelhead. For a description of potential  
15 hydrodynamic effects on steelhead, see the descriptions for winter-run and  
16 fall-run Chinook Salmon above.

17 *Summary of Effects on Steelhead*

18 The multiple model and analysis outputs described above characterize the  
19 anticipated conditions for steelhead and their response to change under the No  
20 Action Alternative as compared to the Second Basis of Comparison. The analysis  
21 of the effects of the No Action Alternative and Second Basis of Comparison for  
22 steelhead relied on the WUA analysis for habitat and water temperature model  
23 output for the rivers at various locations downstream of the CVP and SWP  
24 facilities. The WUA analysis indicated that the availability of steelhead spawning  
25 and rearing habitat in Clear Creek and steelhead spawning habitat in the  
26 Sacramento, Feather and American rivers would be similar under the No Action  
27 Alternative and the Second Basis of Comparison. The temperature model outputs  
28 for each of the steelhead life stages suggest that thermal conditions and effects on  
29 steelhead in all of these streams generally would be similar under both scenarios.  
30 This conclusion is supported by the water temperature threshold exceedance  
31 analysis that indicated that the water temperature thresholds for steelhead  
32 spawning and egg incubation would be exceeded slightly less frequently in the  
33 Feather River under the No Action Alternative, although water temperature  
34 thresholds for steelhead rearing would be exceeded more frequently during some  
35 months in the Feather River and American River under the No Action Alternative.  
36 The increased frequency of exceedance of rearing temperature thresholds under  
37 the No Action Alternative could increase the potential for adverse effects on the  
38 steelhead population in the Feather and American rivers.

39 These numerical model results suggest that overall, effects on steelhead could be  
40 slightly more adverse under the No Action Alternative than under the Second  
41 Basis of Comparison, particularly in the Feather and American rivers. However,  
42 implementation of a fish passage program under the No Action  
43 Alternative intended to address the limited availability of suitable habitat for  
44 steelhead in the Sacramento River reaches downstream of Keswick Dam and in

1 the American River could provide a benefit to Central Valley steelhead in the  
2 Sacramento and American rivers. This is particularly important in light of  
3 anticipated increases in water temperature associated with climate change in  
4 2030. In addition to fish passage, preparation and implementation of an HGMP  
5 for steelhead at the Nimbus Fish Hatchery (NMFS RPA Action Suite II.6) and  
6 actions under the No Action Alternative intended to increase the efficiency of the  
7 Tracy and Skinner Fish Collection Facilities (NMFS RPA Action Suite IV.4)  
8 could benefit steelhead under the No Action Alternative in comparison to the  
9 Second Basis of Comparison. Thus, it is concluded that the effects on steelhead  
10 would be less adverse under the No Action Alternative than under the Second  
11 Basis of Comparison.

### 12 *Green Sturgeon*

13 Potential effects on Green Sturgeon were evaluated based on anticipated water  
14 temperature conditions and exceedances of established temperature thresholds in  
15 the Sacramento and Feather rivers. In addition, potential effects on Green  
16 Sturgeon during the Delta portion of their life cycle were evaluated based on  
17 changes in Delta outflow. The effects are described and summarized below.

#### 18 *Changes in Water Temperature*

19 The effects of the No Action Alternative compared to the Second Basis of  
20 Comparison on Green Sturgeon were analyzed based on water temperature model  
21 outputs and comparisons of the frequency of water temperature threshold  
22 exceedances in the Sacramento and Feather rivers.

#### 23 *Sacramento River*

24 Long-term average monthly water temperatures in the Sacramento River at  
25 Keswick Dam under the No Action Alternative would generally be similar (less  
26 than 0.5°F difference) to water temperatures under the Second Basis of  
27 Comparison. An exception is during September and October of critical years  
28 when water temperatures could be up to 1.1°F and 0.8°F higher, respectively,  
29 under the No Action Alternative as compared to the Second Basis of Comparison  
30 and up to 1°F cooler in September of wetter years under the No Action  
31 Alternative (Appendix 6B). A similar pattern in temperature differences  
32 generally would be exhibited at downstream locations along the Sacramento River  
33 (i.e., Ball's Ferry Jelly's Ferry, Bend Bridge, Red Bluff, Hamilton City, and  
34 Knights Landing), with average monthly temperatures increasing in a downstream  
35 direction and temperature differences between scenarios at Knights Landing  
36 progressively increasing (up to 0.9°F warmer) in June and up to 4.6°F cooler in  
37 September during the wetter years under the No Action Alternative relative to the  
38 Second Basis of Comparison. Overall, the temperature differences between the  
39 No Action Alternative and Second Basis of Comparison would be relatively  
40 minor (less than 0.5°F) and likely would have little effect on Green Sturgeon in  
41 the Sacramento River.

1            *Feather River*

2 Long-term average monthly water temperatures in the Feather River in the low  
3 flow channel generally are predicted to be similar (less than 0.5°F differences)  
4 under the No Action Alternative and the Second Basis of Comparison, except  
5 during November and December when average monthly water temperatures could  
6 be up to 1.4°F higher in some water year types. Average monthly water  
7 temperatures in September under the No Action Alternative could be up to 1.3°F  
8 lower than the Second Basis of Comparison in wetter years. Although  
9 temperatures in the river would become progressively higher in the downstream  
10 directions, the water temperature differences between the No Action  
11 Alternative and Second Basis of Comparison exhibit a similar pattern at the  
12 downstream locations (Robinson Riffle and Gridley Bridge), with water  
13 temperature differences between the No Action Alternative and Second Basis of  
14 Comparison generally decreasing in most water year types at the confluence with  
15 Sacramento River (Appendix 6B, Table B-23-1). However, water temperatures  
16 from July to September under the No Action Alternative could be somewhat  
17 (0.7°F to 1.6°F) cooler on average and up to 4.0°F cooler at the confluence with  
18 Sacramento River in wetter years. Overall, the temperature differences between  
19 the No Action Alternative and Second Basis of Comparison would be relatively  
20 minor (less than 0.5°F) and likely would have little effect on Green Sturgeon in  
21 the Feather River.

22            *Changes in Exceedances of Water Temperature Thresholds*

23 Changes in water temperature could result in the exceedance of established water  
24 temperature thresholds for Green Sturgeon in the Sacramento and Feather rivers.  
25 The following describes the exceedances for each of those rivers.

26            *Sacramento River*

27 Average monthly water temperatures in the Sacramento River at Bend Bridge  
28 under both the No Action Alternative and Second Basis of Comparison would  
29 exceed the water temperature threshold of 63°F established for Green Sturgeon  
30 larval rearing in August and September, with exceedances under the No Action  
31 Alternative occurring about 7 percent of the time in August and about 12 percent  
32 of the time in September. This is 1 to 2 percent more frequently than under the  
33 Second Basis of Comparison. Average monthly water temperatures at Bend  
34 Bridge could exceed the threshold by up to 10 degrees (reaching 73°F) during this  
35 period. Temperature conditions in the Sacramento River under the No Action  
36 Alternative could be more likely to result in adverse effects on Green Sturgeon  
37 rearing than under the Second Basis of Comparison because of the increased  
38 frequency of exceedance of the 63°F threshold in August and September.

39            *Feather River*

40 Average monthly water temperatures in the Feather River at Gridley Bridge under  
41 both the No Action Alternative and Second Basis of Comparison would exceed  
42 the water temperature threshold of 64°F established for Green Sturgeon spawning,  
43 incubation, and rearing in May, June, and September; no exceedances under either  
44 scenario would occur in July and August. The frequency of exceedances would

1 be high, with both the No Action Alternative and Second Basis of Comparison  
2 exceeding the threshold in June nearly 100 percent of the time. The magnitude of  
3 the exceedance also would be substantial, with average monthly temperatures  
4 higher than 72°F in June, and higher than 75°F in July and August. Average  
5 monthly water temperatures under the No Action Alternative would exceed the  
6 threshold about 9 percent more frequently than under the Second Basis of  
7 Comparison during May and about 35 percent less frequently in September.  
8 Temperature conditions in the Feather River under the No Action  
9 Alternative could be more likely result in adverse effects on Green Sturgeon  
10 spawning and egg incubation than under the Second Basis of Comparison because  
11 of the increased frequency of exceedance of the 64°F threshold in May. The  
12 reduction in exceedance frequency in September may have little effect on rearing  
13 Green Sturgeon as many juvenile sturgeon may have migrated downstream to the  
14 lower Sacramento River and Delta by this time.

#### 15 *Changes in Delta Outflow*

16 As described in Appendix 9P, mean (March to July) Delta outflow was used an  
17 indicator of potential year class strength and the likelihood of producing a strong  
18 year class of sturgeon. The median value over the 82-year CalSim II modeling  
19 period of mean (March to July) Delta outflow was predicted to be 13 percent  
20 higher under the No Action Alternative than under the Second Basis of  
21 Comparison. In addition, the likelihood of mean (March to July) Delta outflow  
22 exceeding the threshold of 50,000 cfs was the same under both alternatives.

#### 23 *Summary of Effects on Green Sturgeon*

24 The analysis of the effects of the No Action Alternative and Second Basis of  
25 Comparison for Green Sturgeon relied on water temperature model output for the  
26 Sacramento and Feather rivers at various locations downstream of Shasta Dam  
27 and the Thermalito complex. The temperature model outputs for each of these  
28 rivers suggest that thermal conditions and effects on Green Sturgeon in the  
29 Sacramento and Feather rivers generally would be slightly more adverse under the  
30 No Action Alternative. This conclusion is supported by the water temperature  
31 threshold exceedance analysis that indicated that the water temperature thresholds  
32 for Green Sturgeon spawning, incubation, and rearing would be exceeded more  
33 frequently under the No Action Alternative in the Sacramento River. The water  
34 temperature threshold for Green Sturgeon spawning, incubation, and rearing  
35 would also be exceeded more frequently during some months in the Feather River  
36 but would be exceeded substantially less frequently in September under the No  
37 Action Alternative.

38 The increased frequency of exceedance of temperature thresholds under the No  
39 Action Alternative could increase the potential for adverse effects on Green  
40 Sturgeon in the Sacramento and Feather rivers relative to the Second Basis of  
41 Comparison. The analysis based on Delta outflows suggests that the No Action  
42 Alternative provides higher mean (March to July) outflows which could result in  
43 stronger year classes of juvenile Green Sturgeon relative to the Second Basis of  
44 Comparison. In addition, actions under the No Action Alternative intended to  
45 increase the efficiency of the Tracy and Skinner Fish Collection Facilities could

1 improve the overall salvage survival of Green Sturgeon. However, early life stage  
2 survival in the natal rivers is crucial in development of a strong year class.  
3 Therefore, based primarily on the analysis of water temperatures, the No Action  
4 Alternative could be more likely to result in adverse effects on Green Sturgeon  
5 than the Second Basis of Comparison.

6 *White Sturgeon*

7 Changes in water temperature conditions in the Sacramento River would be the  
8 same as those described above for Green Sturgeon in the Sacramento River.  
9 Overall, the temperature differences between the No Action Alternative and  
10 Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
11 likely would have little effect on White Sturgeon in the Sacramento River.

12 The water temperature threshold established for White Sturgeon spawning and  
13 egg incubation in the Sacramento River at Hamilton City is 61°F from March  
14 through June. Although there would be no exceedances of the threshold in March  
15 and April, water temperatures under both the No Action Alternative and Second  
16 Basis of Comparison would exceed this threshold in May and June. The average  
17 monthly water temperatures in May under the No Action Alternative would  
18 exceed this threshold about 55 percent of the time (about 6 percent more  
19 frequently than under the Second Basis of Comparison). In June, average  
20 monthly water temperatures under the No Action Alternative would exceed the  
21 threshold about 86 percent of the time (about 13 percent more frequently than  
22 under the Second Basis of Comparison). Average monthly water temperatures  
23 during May and June under the No Action Alternative would as high as about  
24 65°F which is below the 68°F threshold considered lethal for White Sturgeon  
25 eggs and may cause higher growth rates in juvenile white sturgeon. Temperature  
26 conditions in the Sacramento River under the No Action Alternative could be  
27 more likely to result in adverse effects on White Sturgeon rearing than under the  
28 Second Basis of Comparison because of the increased frequency of exceedance of  
29 the 61°F threshold in May and June.

30 The analysis of the effects of the No Action Alternative and Second Basis of  
31 Comparison for White Sturgeon relied on water temperature model output for the  
32 Sacramento River at various locations downstream of Shasta Dam. The  
33 temperature model outputs suggest that thermal conditions and effects on White  
34 Sturgeon in the Sacramento River generally would be slightly more adverse under  
35 the No Action Alternative. This conclusion is supported by the water temperature  
36 threshold exceedance analysis that indicated that the water temperature thresholds  
37 for White Sturgeon spawning, incubation, and rearing would be exceeded more  
38 frequently under the No Action Alternative in the Sacramento River.

39 Changes in Delta outflows would be the same as those described above for Green  
40 Sturgeon. Mean (March to July) Delta outflow was predicted to be 13 percent  
41 higher under the No Action Alternative than under the Second Basis of  
42 Comparison. In addition, the likelihood of mean (March to July) Delta outflow  
43 exceeding the threshold of 50,000 cfs was the same under both alternatives. In  
44 addition, actions under the No Action Alternative intended to increase the

1 efficiency of the Tracy and Skinner Fish Collection Facilities could improve the  
2 overall salvage survival of White Sturgeon.

3 Overall, the increased frequency of exceedance of temperature thresholds in June  
4 under the No Action Alternative could increase the potential for effects on White  
5 Sturgeon in the Sacramento River relative to the Second Basis of Comparison,  
6 however these effects are uncertain and may include reduced spawning and/or  
7 increased growth. The analysis based on Delta outflows suggests that the No  
8 Action Alternative provides higher mean (March to July) outflows which could  
9 result in stronger year classes of juvenile White Sturgeon relative to the Second  
10 Basis of Comparison. However, early life stage survival in the natal rivers is  
11 crucial in development of a strong year class. Therefore, based primarily on the  
12 analysis of water temperatures, the No Action Alternative could be more likely to  
13 result in adverse effects on White Sturgeon than the Second Basis of Comparison.

#### 14 *Delta Smelt*

15 The potential effects of the No Action Alternative as compared to the Second  
16 Basis of Comparison were analyzed based on differences in proportional  
17 entrainment and the fall abiotic index as described below.

18 As described in Appendix 9G, a proportional entrainment regression model  
19 (based on Kimmerer 2008, 2011) was used to simulate adult Delta Smelt  
20 entrainment, as influenced by OMR flow in December through March. Results  
21 indicate that the percentage of entrainment of migrating and spawning adult Delta  
22 Smelt under the No Action Alternative would be 7 to 8.3 percent, depending on  
23 the water year type, with a long-term average percent entrainment of 7.6 percent.  
24 Percent entrainment of adult Delta Smelt under the No Action Alternative would  
25 be similar to results under the Second Basis of Comparison.

26 A proportional entrainment regression model (based on Kimmerer 2008) was also  
27 used to simulate larval and early juvenile Delta Smelt entrainment, as influenced  
28 by OMR flow and location of X2 in March through June (Appendix 9G). Results  
29 indicate that the percentage of entrainment of larval and early juvenile Delta  
30 Smelt under the No Action Alternative would be 1.3 to 19.3 percent, depending  
31 on the water year type, with a long term average percent entrainment of  
32 8.6 percent, and highest entrainment under critical water year conditions. Percent  
33 entrainment of larval and early juvenile Delta Smelt under the No Action  
34 Alternative would be lower than projected entrainment under the Second Basis of  
35 Comparison by up to 9.4 percent. Under the Second Basis of Comparison, the  
36 long-term average percent entrainment would be 15.5 percent, and highest  
37 entrainment would occur under critical water year conditions, at 23.6 percent.

38 The predicted position of Fall X2 (in September through December) is used as an  
39 indicator of fall abiotic habitat index for Delta Smelt. Feyrer et al. (2010) used  
40 X2 location as an indicator of the extent of habitat available with suitable salinity  
41 for the rearing of older juvenile Delta Smelt. Feyrer et al. (2010) concluded that  
42 when X2 is located downstream (west) of the confluence of the Sacramento and  
43 San Joaquin Rivers, at a distance of 70 to 80 km from the Golden Gate Bridge,  
44 there is a larger area of suitable habitat. The overlap of the low salinity zone (or

1 X2) with the Suisun Bay/Marsh results in a two-fold increase in the habitat index  
2 (Feyrer et al. 2010).

3 The average September through December X2 position in km was used to  
4 evaluate the fall abiotic habitat availability for Delta Smelt under the Alternatives.  
5 X2 values simulated in the CalSim II model for each Alternative were averaged  
6 over September through December, and compared. Results indicate that under  
7 the No Action Alternative, the X2 position would range from 75.9 km to 92.4 km,  
8 depending on the water year type, with a long term average X2 position of 84 km.  
9 The most eastward location of X2 is predicted under Critical water year  
10 conditions. The X2 positions predicted under the No Action Alternative would be  
11 similar to results under the Second Basis of Comparison in drier water year types.  
12 In wetter years, the X2 location would be further west under the No Action  
13 Alternative than under the Second Basis of Comparison, by 6.1 to 9.8 km. This  
14 difference is largely due to implementation of 2008 USFWS BO RPA  
15 Component 3 (Action 4), under the No Action Alternative, which requires  
16 Reclamation and DWR to provide sufficient Delta outflow to maintain a monthly  
17 average X2 no more eastward than 74 km in above normal and wet year types.  
18 Under the Second Basis of Comparison, the long-term average X2 position would  
19 be 88.1 km, a location that does not provide for the advantageous overlap of the  
20 low salinity zone with Suisun Bay/Marsh.

21 Overall, the No Action Alternative likely would result in better conditions for  
22 Delta Smelt than would the Second Basis of Comparison, primarily due to  
23 lower percentage entrainment for larval and juvenile life stages, and more  
24 favorable location of Fall X2 in wetter years, and on average. Given the current  
25 condition of the Delta Smelt population, even small differences between  
26 alternatives may be important.

### 27 *Longfin Smelt*

28 The effects of the No Action Alternative as compared to the Second Basis of  
29 Comparison were analyzed based on the direction and magnitude of OMR flows  
30 during the period (December through June) when adult, larvae, and young  
31 juvenile Longfin Smelt are present in the Delta in the vicinity of the export  
32 facilities (Appendix 5A). The analysis was augmented with calculated Longfin  
33 Smelt abundance index values (Appendix 9G) per Kimmerer et al. (2009), which  
34 is based on the assumptions that lower X2 values reflect higher flows and that  
35 transporting Longfin Smelt farther downstream leads to greater Longfin Smelt  
36 survival. The index value indicates the relative abundance of Longfin Smelt and  
37 not the calculated population.

38 As described in Appendix 5A, OMR flows would generally be negative in all  
39 months under the Second Basis of Comparison, with the long-term average  
40 ranging from -3,700 to -7,400 cfs from December through June; whereas the  
41 OMR flows would generally be less negative during this time period under the No  
42 Action Alternative. The greatest differences between alternatives would be in  
43 April and May, where long-term average OMR flows would be positive under the  
44 No Action Alternative (Appendix 5A, Table C-17-4). The decrease in the  
45 magnitude of negative flows, with positive flows in April and May, under the No

1 Action Alternative as compared to the Second Basis of Comparison suggests that  
2 it could reduce the potential for entrainment of Delta Smelt at the export facilities.

3 Under the No Action Alternative, Longfin Smelt abundance index values range  
4 from 1,147, under critical water year conditions, to a high of 16,635 under wet  
5 water year conditions, with a long-term average value of 7,951. Under the  
6 Second Basis of Comparison, Longfin Smelt abundance index values range from  
7 947 during critical water year conditions to a high of 15,822 under wet water year  
8 conditions, with a long-term average value of 7,257. These results suggest that  
9 the Longfin Smelt abundance index values would be higher in every water year  
10 type under the No Action Alternative as compared to the Second Basis of  
11 Comparison, with a long-term average index for the No Action Alternative that is  
12 almost 10 percent higher than the long-term average index for the Second Basis of  
13 Comparison. For below normal, dry, and critical water years, the Longfin Smelt  
14 abundance index values would be over 20 percent higher under the No Action  
15 Alternative than under the Second Basis of Comparison, with the greatest  
16 difference (26.2 percent) predicted under dry conditions.

17 Overall, based on the decrease in frequency and magnitude of negative OMR  
18 flows and the higher Longfin Smelt abundance index values, especially in dry and  
19 critical years, potential adverse effects on the Longfin Smelt population under the  
20 No Action Alternative likely would be less than under the Second Basis of  
21 Comparison.

## 22 *Sacramento Splittail*

23 Sacramento Splittail could benefit from the increase in inundated floodplain  
24 resulting from implementation of 2009 NMFS BO RPA Action I.6.1, Restoration  
25 of Floodplain Rearing Habitat, which would restore 17,000 to 20,000 acres for the  
26 primary purpose of enhancing rearing habitat for juvenile salmonids. The efforts  
27 currently underway in the Yolo Bypass to comply with this action apply to all  
28 alternatives under consideration and it is assumed that a notch in the Fremont  
29 Weir (6,000 cfs capacity) will be constructed and that the inundation objectives  
30 will be met by 2030. It is not currently known if and how the notch would be  
31 operated and how flows entering the bypass would be managed to accommodate  
32 floodplain rearing.

33 While this action is common to all alternatives, changes in operations that  
34 influence the hydrology in the Sacramento River could affect the frequency and  
35 duration of flows available to provide inundation on the bypass. To generally  
36 evaluate the potential influence of these changes in hydrology, the flows entering  
37 the Yolo Bypass during December through April were examined to determine the  
38 differences among alternatives. It was assumed that the magnitude of flow (and  
39 flow change) roughly corresponds to the amount of inundated floodplain.

40 Under the No Action Alternative, flows entering the Yolo Bypass generally would  
41 be lower than under the Second Basis of Comparison from December through  
42 March, especially during wetter years (Appendix 5A, Table C-26-4). These  
43 decreases would occur during periods of relatively high flow in the bypass, and  
44 may only slightly decrease the potential area of inundation.

1 Overall, the slight flow decreases under the No Action Alternative could result in  
2 less spawning habitat for Sacramento Splittail than under the Second Basis of  
3 Comparison because of the decreased area of potential habitat (inundation).  
4 Given the relatively minor changes in flows into the Yolo Bypass, and the  
5 inherent uncertainty associated with the resolution of the CalSim II model  
6 (average monthly outputs), it is concluded that there would be no definitive  
7 difference in effects on Sacramento Splittail between the No Action  
8 Alternative and Second Basis of Comparison.

9 *Reservoir Fishes*

10 The analysis of effects associated with changes in operation on reservoir fishes  
11 relied on evaluation of changes in available habitat (reservoir storage) and  
12 anticipated changes in black bass nesting success.

13 *Changes in Available Habitat (Storage)*

14 As described in Chapter 5, Surface Water Resources and Water Supplies, changes  
15 in CVP and SWP water supplies and operations under the No Action  
16 Alternative as compared to the Second Basis of Comparison generally would  
17 result in lower reservoir storage in CVP and SWP reservoirs in the Central Valley  
18 Region. Storage levels in Shasta Lake, Lake Oroville, and Folsom Lake would be  
19 lower under the No Action Alternative as compared to the Second Basis of  
20 Comparison, as summarized in Tables 5.12 through 5.14, in the fall and winter  
21 months due to the inclusion of Fall X2 criteria under the No Action Alternative.

22 The highest reductions in Shasta Lake and Lake Oroville storage could be in  
23 excess of 20 percent. Storage in Folsom Lake could be reduced up to around  
24 10 percent in some months of some water year types. Additional information  
25 related to monthly reservoir elevations is provided in Appendix 5A, CalSim II and  
26 DSM2 Modeling. It is anticipated that aquatic habitat within the CVP and SWP  
27 water supply reservoirs is not limiting; however, storage volume is an indicator of  
28 how much habitat is available to fish species inhabiting these reservoirs.  
29 Therefore, the amount of habitat for reservoir fishes could be reduced under the  
30 No Action Alternative as compared to the Second Basis of Comparison.

31 *Changes in Black Bass Nesting Success*

32 Black bass nest survival in CVP and SWP reservoirs is anticipated to be near  
33 100 percent in March and April due to increasing reservoir elevations  
34 (Appendix 9F). For May and June, the likelihood of nest survival for Largemouth  
35 Bass in Shasta Lake being in the 40 to 100 percent range is similar under the No  
36 Action Alternative and the Second Basis of Comparison; however, nest survival  
37 of greater than 40 percent in June is likely only in about 20 percent of the years  
38 evaluated. The likelihood of nest survival for Smallmouth Bass in Shasta Lake  
39 exhibits nearly the same pattern. For Spotted Bass, the likelihood of nest survival  
40 being greater than 40 percent is generally high (near 100 percent) from March to  
41 May under both the No Action Alternative and the Second Basis of Comparison.  
42 For June, Spotted Bass nest survival would be less than for May due to greater  
43 daily reductions in water surface elevation as Shasta Lake is drawn down. The

1 likelihood of survival being greater than 40 percent is about 10 percent higher  
2 under the No Action Alternative as compared to the Second Basis of Comparison.

3 For May and June, the likelihood of nest survival for Largemouth Bass in Lake  
4 Oroville being in the 40 to 100 percent range is higher under the No Action  
5 Alternative as compared to the Second Basis of Comparison; about 10 percent  
6 higher in May and 3 percent higher in June. However, June nest survival of  
7 greater than 40 percent is likely only in about 40 percent of the years evaluated.  
8 The likelihood of nest survival for Smallmouth Bass in Lake Oroville exhibits  
9 nearly the same pattern. For Spotted Bass, the likelihood of nest survival being  
10 greater than 40 percent is high (>90 percent) in May under both the No Action  
11 Alternative and the Second Basis of Comparison with the likelihood of greater  
12 than 40 percent survival similar under the No Action Alternative and the Second  
13 Basis of Comparison. For June, Spotted Bass survival would be less than for May  
14 due to greater daily reductions in water surface elevation as Lake Oroville is  
15 drawn down. The likelihood of survival being greater than 40 percent is  
16 substantially (about 20 percent) higher under the No Action Alternative as  
17 compared to the Second Basis of Comparison.

18 Black bass nest survival in Folsom Lake is near 100 percent in March, April, and  
19 May due to increasing reservoir elevations. For June, the likelihood of nest  
20 survival for Largemouth Bass and Smallmouth Bass in Folsom Lake being in the  
21 40 to 100 percent range is around 5 percent higher under the No Action  
22 Alternative than under the Second Basis of Comparison. For Spotted Bass, nest  
23 survival for June would be less than for May due to greater daily reductions in  
24 water surface elevation. However, the likelihood of survival being greater than  
25 40 percent is about 5 percent higher under the No Action Alternative as compared  
26 to the Second Basis of Comparison.

### 27 *Summary of Effects on Reservoir Fishes*

28 Reservoir storage is anticipated to be reduced under the No Action  
29 Alternative relative to the Second Basis of Comparison and this reduction could  
30 affect the amount of warm and cold water habitat available within the reservoirs.  
31 However, it is unlikely that aquatic habitat within the CVP and SWP water supply  
32 reservoirs is limiting.

33 The analysis of black bass nest survival based on changes in water surface  
34 elevation during the spawning period indicated that the likelihood of high  
35 (>40 percent) nest survival in most of the reservoirs under the No Action  
36 Alternative would be similar under the Second Basis of Comparison from March  
37 through May and somewhat higher in June. Most black bass spawning likely  
38 occurs prior to June, such that drawdowns during June would likely affect only a  
39 small proportion of the spawning population. Thus, it is concluded that effects on  
40 black bass nesting success would be similar under the No Action Alternative and  
41 the Second Basis of Comparison.

1 *Pacific Lamprey*

2 Little information is available on factors that influence populations of Pacific  
3 Lamprey in the Sacramento River, but they are likely affected by many of the  
4 same factors as salmon and steelhead because of the parallels in their life cycles.

5 *Changes in Water Temperature*

6 The following describes anticipated changes in average monthly water  
7 temperature in the Sacramento, Feather, and American rivers and the potential for  
8 those changes to affect Pacific Lamprey.

9 *Sacramento River*

10 Long-term average monthly water temperatures in the Sacramento River at  
11 Keswick Dam under the No Action Alternative would generally be similar (less  
12 than 0.5°F difference) to water temperatures under the Second Basis of  
13 Comparison. An exception is during September and October of critical dry years  
14 when water temperatures could be up to 1.1°F and 0.8°F higher, respectively,  
15 under the No Action Alternative as compared to the Second Basis of Comparison  
16 and up to 1°F cooler in September of wetter years under the No Action  
17 Alternative (Appendix 6B, Table 5-5-4). A similar temperature pattern generally  
18 would be exhibited downstream at Ball's Ferry, Jelly's Ferry, and Bend Bridge,  
19 with average monthly temperatures increasing in a downstream direction and  
20 temperature differences between scenarios progressively decreasing except in  
21 September (up to 2.8°F cooler) at Bend Bridge) during wetter years under the No  
22 Action Alternative. Due to the similarity of water temperatures under the No  
23 Action Alternative and Second Basis of Comparison from January through the  
24 summer, there would be little difference in potential effects on Pacific Lamprey  
25 adults during their migration, holding, and spawning periods.

26 *Feather River*

27 Long-term average monthly water temperature in the Feather River in the low  
28 flow channel (downstream of the Thermalito Complex) generally are predicted to  
29 be similar (less than 0.5°F differences) under the No Action Alternative and the  
30 Second Basis of Comparison, except during November and December when  
31 average monthly water temperatures could be up to 1.4°F higher in some water  
32 year types. Average monthly water temperatures in September under the No  
33 Action Alternative could be up to 1.3°F lower than under the Second Basis of  
34 Comparison in wetter years (Appendix 6B, Table B-20-4). Although  
35 temperatures in the river would become progressively higher in the downstream  
36 directions, the differences in water temperatures between the No Action  
37 Alternative and Second Basis of Comparison would exhibit a similar pattern at the  
38 downstream locations (Robinson Riffle and Gridley Bridge), with water  
39 temperature differences between the No Action Alternative and Second Basis of  
40 Comparison generally decreasing in most water year types. However, water  
41 temperatures from July to September under the No Action Alternative could be  
42 somewhat (0.7°F to 1.6°F) cooler on average and up to 4.0°F cooler at the  
43 confluence with Sacramento River in wetter years (Appendix 6B, Table B-23-4).

1 Due to the similarity of water temperatures under the No Action Alternative and  
2 Second Basis of Comparison from January through the summer, there would be  
3 little difference in potential effects on Pacific Lamprey adults during their  
4 migration, holding, and spawning periods.

5 *American River*

6 Average monthly water temperatures in the American River at Nimbus Dam  
7 under the No Action Alternative generally would be similar (differences less than  
8 0.5°F) to the Second Basis of Comparison, with the exception of during June and  
9 August, when differences under the No Action Alternative could be as much as  
10 0.9°F higher in below normal years. This pattern generally would persist  
11 downstream to Watt Avenue and the mouth, although temperatures under the No  
12 Action Alternative would be up to 1.6°F and 2.0°F greater, respectively, than  
13 under the Second Basis of Comparison in June. In addition, average monthly  
14 water temperatures at the mouth generally would be lower under the No Action  
15 Alternative than the Second Basis of Comparison in September of wetter years  
16 when water temperatures under the No Action Alternative could be up to 1.7°F  
17 cooler. Due to the similarity of water temperatures under the No Action  
18 Alternative and Second Basis of Comparison from January through the summer,  
19 there would be little difference in potential effects on Pacific Lamprey adults  
20 during their migration, holding, and spawning periods.

21 *Summary of Effects on Pacific Lamprey*

22 In general, Pacific Lamprey can tolerate higher temperatures than salmonids, up  
23 to around 72°F during their entire life history. Given the relatively minor changes  
24 in water temperature and water temperature threshold exceedance, and the  
25 inherent uncertainty associated with the resolution of the temperature model  
26 (average monthly outputs), it is likely that effects on Pacific Lamprey in the  
27 Sacramento, Feather, and American rivers would be similar under the No Action  
28 Alternative and the Second Basis of Comparison. This conclusion likely applies  
29 to other species of lamprey that inhabit these rivers (e.g., River Lamprey).

30 *Striped Bass, American Shad, and Hardhead*

31 Changes in operations influence temperature and flow conditions that could affect  
32 Striped Bass, American Shad, and Hardhead. The following describes those  
33 changes and their potential effects.

34 *Changes in Water Temperature*

35 The following describes temperature conditions in the Sacramento, Feather, and  
36 American rivers.

37 *Sacramento River*

38 Long-term average monthly water temperatures in the Sacramento River at  
39 Keswick Dam under the No Action Alternative would generally be similar (less  
40 than 0.5°F difference) to water temperatures under the Second Basis of  
41 Comparison. An exception is during September and October of critical dry years  
42 when water temperatures could be up to 1.1°F and 0.8°F higher, respectively,  
43 under the No Action Alternative as compared to the Second Basis of Comparison

1 and up to 1°F cooler in September of wetter years under the No Action  
2 Alternative (Appendix 6B, Table 5-5-4). A similar temperature pattern generally  
3 would be exhibited downstream at Ball's Ferry, Jelly's Ferry, and Bend Bridge,  
4 with average monthly temperatures increasing in a downstream direction and  
5 temperature differences between scenarios progressively increasing (up to 0.9°F  
6 warmer) in June and up to 4.6°F cooler in September during the wetter years  
7 under the No Action Alternative relative to the Second Basis of Comparison. In  
8 general, Striped Bass, American Shad, and Hardhead can tolerate higher  
9 temperatures than salmonids. Therefore, it is unlikely that the slightly increased  
10 temperatures during some months under the No Action Alternative would have  
11 substantial adverse effects on these species.

12 *Feather River*

13 Average monthly water temperature in the Feather River in the low flow channel  
14 (below the Thermalito Complex) generally were predicted to be similar (less than  
15 0.5°F differences) under the No Action Alternative and the Second Basis of  
16 Comparison, except during November and December when average monthly  
17 water temperatures would be up to 1.4°F higher in some water year types  
18 (Appendix 6B, Table B-20-4). Average monthly water temperatures in  
19 September under the No Action Alternative could be up to 1.3°F lower than under  
20 the Second Basis of Comparison in wetter years. Although temperatures in the  
21 river would become progressively higher in the downstream directions, the  
22 differences between the No Action Alternative and Second Basis of Comparison  
23 exhibit a similar pattern at the downstream locations (Appendix 6B,  
24 Table B-23-4). As described above for the Sacramento River, Striped Bass,  
25 American Shad, and Hardhead can tolerate higher temperatures than salmonids.  
26 Therefore, it is unlikely that the slightly increased temperatures during some  
27 months under the No Action Alternative would have substantial adverse effects  
28 on these species in the Feather River.

29 *American River*

30 Average monthly water temperatures in the American River at Nimbus Dam  
31 under the No Action Alternative generally would be similar (differences less than  
32 0.5°F) to the Second Basis of Comparison, with the exception of during June and  
33 August, when differences under the No Action Alternative could be as much as  
34 0.9°F higher in below normal years. This pattern generally would persist  
35 downstream to Watt Avenue and the mouth, although temperatures under the No  
36 Action Alternative would be up to 1.6°F and 2.0°F greater, respectively, than  
37 under the Second Basis of Comparison in June. As described above for the  
38 Sacramento River, Striped Bass, American Shad, and Hardhead can tolerate  
39 higher temperatures than salmonids. Therefore, it is unlikely that the slightly  
40 increased temperatures during some months under the No Action  
41 Alternative would have substantial adverse effects on these species in the  
42 American River.

1        *Changes in Position of X2*

2        The No Action Alternative would result in a more westward X2 position as  
3        compared to the Second Basis of Comparison during April and May, with similar  
4        values in June (Appendix 5A, Section C Table C-16-4). Based on Kimmerer  
5        (2002) and Kimmerer et al. (2009), this change in X2 would likely increase the  
6        survival index and the habitat index as measured by salinity for Striped Bass and  
7        abundance and habitat index for American Shad.

8        *Summary of Effects on Striped Bass, American Shad, and Hardhead*

9        In general, Striped Bass, American Shad, and Hardhead can tolerate higher  
10       temperatures than salmonids. Given the relatively minor changes in temperature  
11       and temperature threshold exceedance, and the inherent uncertainty associated  
12       with the resolution of the temperature model (average monthly outputs), it is  
13       likely that thermal conditions for and effects on Striped Bass, American Shad, and  
14       Hardhead in the Sacramento, Feather, and American rivers would be similar  
15       under the No Action Alternative and the Second Basis of Comparison. Overall,  
16       the No Action Alternative likely would be similar for Hardhead and have a  
17       slightly lower potential for adverse effects on Striped Bass and American Shad as  
18       compared to the Second Basis of Comparison, primarily due to the potential for  
19       increased survival during larval and juvenile life stages, and more favorable  
20       location of Spring X2 on average.

21       **9.4.3.1.3 Stanislaus River/Lower San Joaquin River**

22       *Fall-Run Chinook Salmon*

23       Changes in operations influence temperature and flow conditions that could affect  
24       fall-run Chinook Salmon in the Stanislaus River downstream of Goodwin Dam  
25       and in the San Joaquin River downstream of the Stanislaus River confluence, as  
26       measured at Vernalis. The following describes those changes and their  
27       potential effects.

28       *Changes in Water Temperature (Stanislaus River)*

29       Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
30       under the No Action Alternative and Second Basis of Comparison generally  
31       would be similar (differences less than 0.5°F), with small differences in critical  
32       dry years when the No Action Alternative would 0.8°F and 1.3°F warmer on  
33       average than under the Second Basis of Comparison during June and September,  
34       respectively, and 0.7°F cooler in November (Appendix 6B, Table B-17-4).

35       Downstream at Orange Blossom Bridge, average monthly water temperatures in  
36       October under the No Action Alternative would be lower in all water year types  
37       than the Second Basis of Comparison by as much as 1.9°F. In most other months,  
38       water temperatures under the No Action Alternative and Second Basis of  
39       Comparison generally would be similar. An exception to this pattern occurs in  
40       April when average monthly water temperatures in all but wet water year types  
41       would be lower under the No Action Alternative by as much as about 1.2°F  
42       (Appendix 6B, Table B-18-4).

1 This temperature pattern would continue downstream to the confluence with the  
2 San Joaquin River, although temperatures would progressively increase, as would  
3 the magnitude of difference between the No Action Alternative and Second Basis  
4 of Comparison. Decreases in average monthly water temperatures in October and  
5 April would be more pronounced under the No Action Alternative, with average  
6 differences as much as 2.7°F in October and 2.0°F in April (Appendix 6B,  
7 Table B-19-4) relative to the Second Basis of Comparison. The magnitude of  
8 differences in average monthly water temperatures between the No Action  
9 Alternative and the Second Basis of Comparison in May and June also would  
10 increase relative to the upstream locations with average June water temperatures  
11 reaching 2.4°F warmer under the No Action Alternative in wet years.

12 Based on the life history timing for fall-run Chinook Salmon, the lower  
13 temperatures in October under the No Action Alternative may reduce the  
14 likelihood of adverse to fall-run Chinook Salmon spawning and egg incubation as  
15 compared to the Second Basis of Comparison.

16 *Changes in Exceedance of Water Temperature Thresholds (Stanislaus River)*

17 While specific water temperature thresholds for fall-run Chinook Salmon in the  
18 Stanislaus River are not established, temperatures generally considered suitable  
19 for fall-run Chinook Salmon spawning (56°F) would be exceeded in October and  
20 November approximately 30 percent of the time in the Stanislaus River at  
21 Goodwin Dam under the No Action Alternative (Appendix 6B, Figures B-17-1  
22 and B-17-2). Similar exceedances would occur under the Second Basis of  
23 Comparison, although slightly less frequently in November. Water temperatures  
24 for rearing from January to May generally would be below 56°F, except in May  
25 when average monthly water temperatures would reach about 60°F under both the  
26 No Action Alternative and the Second Basis of Comparison (Appendix 6B,  
27 Figure B-17-8).

28 Downstream at Orange Blossom Bridge, water temperatures suitable for fall-run  
29 Chinook Salmon spawning (56°F) would be exceeded frequently under both the  
30 No Action Alternative and Second Basis of Comparison during October and  
31 November. Under the No Action Alternative, average monthly water  
32 temperatures would exceed 56°F about 57 percent of the time in October  
33 (Appendix 6B, Figure B-18-1). This, however, would be about 28 percent less  
34 frequently than under the Second Basis of Comparison. In November, average  
35 monthly water temperatures would exceed 56°F about 33 percent of the time  
36 under the No Action Alternative, which would be about 5 percent more frequently  
37 than under the Second Basis of Comparison (Appendix 6B, Figure B-18-2).

38 From January through May, rearing fall-run Chinook Salmon would be subjected  
39 to average monthly water temperatures that exceed 56°F in March (less than  
40 10 percent of the time) and May (about 30 percent of the time) under the No  
41 Action Alternative which is about 10 percent more frequently in May than under  
42 the Second Basis of Comparison (Appendix 6B, Figure B-18-8).

1            *Changes in Egg Mortality (Stanislaus River)*

2 For fall-run Chinook Salmon in the Stanislaus River, the long-term average egg  
3 mortality rate is predicted to be around 7 percent, with higher mortality rates (in  
4 excess of 14 percent) occurring in critical dry years under the No Action  
5 Alternative. Overall, egg mortality in the Stanislaus River would be similar under  
6 the No Action Alternative and the Second Basis of Comparison (Appendix 9C,  
7 Table B-8).

8            *Changes in Delta Hydrodynamics*

9 San Joaquin River-origin fall-run Chinook Salmon smolts are most abundant in  
10 the Delta during the months of April, May and June. Near the Confluence of the  
11 San Joaquin River and the Mokelumne River, the median proportion of positive  
12 velocities was slightly greater under the No Action Alternative relative to the  
13 Second Basis of Comparison in April and May and similar in June  
14 (Appendix 9K). In Old River downstream of the facilities, the median proportion  
15 of positive velocities was substantially greater in April and May, but became  
16 more similar in June. In Old River upstream of the facilities, the median  
17 proportion of positive velocities was slightly to moderately greater for the No  
18 Action Alternative relative to the Second Basis of Comparison in April and May,  
19 respectively, and slightly lower in June. On the San Joaquin River downstream of  
20 the Head of Old River, the proportion of positive velocities was slightly to  
21 moderately lower under the No Action Alternative relative to the Second Basis  
22 of Comparison in April and May, respectively, whereas the values were similar  
23 in June.

24           *Changes in Junction Entrainment*

25 Median entrainment probabilities at the Head of Old River were much greater  
26 under the No Action Alternative relative to the Second Basis of Comparison  
27 during April and May. The median entrainment probability was similar under  
28 both scenarios in the month of June (Appendix 9L). At the Turner Cut junction,  
29 median entrainment probabilities under the No Action Alternative were slightly  
30 lower than the Second Basis of Comparison in June. During April and May,  
31 median entrainment probabilities were more divergent with moderately lower  
32 values for the No Action Alternative relative to the Second Basis of Comparison.  
33 Overall, entrainment was slightly lower at the Columbia Cut junction relative to  
34 Turner Cut, but patterns of entrainment between these two scenarios were similar.  
35 Patterns at the Middle River and Old River junctions were similar to those  
36 observed at Columbia and Turner Cut junctions.

37           *Changes in Fish Passage on the Stanislaus River*

38 The No Action Alternative includes the provision of passage at New Melones  
39 Dam for steelhead. The challenges and difficulties associated with providing fish  
40 passage upstream of Shasta and Folsom dams were briefly summarized  
41 previously, and the same considerations apply to passage upstream of New  
42 Melones Dam.

1 If a fish passage program could establish self-sustaining populations of spring-run  
2 Chinook Salmon and steelhead upstream of New Melones, it would contribute  
3 substantially to satisfaction of the spatial diversity viability standard. The passage  
4 program could also contribute to abundance and productivity, if average returns  
5 consistently exceeded 500 individuals. However, the passage program could also  
6 function as a population sink if fish transported above the reservoir achieved a  
7 cohort replacement rate of less than 1.

8 Insufficient information is available currently on the quantity, suitability, and  
9 accessibility of habitat upstream of New Melones. Given poor habitat data and  
10 the considerable technical uncertainties discussed previously, it is not possible to  
11 determine if (or how much) fish passage at New Melones Dam are likely to affect  
12 the status of Central Valley spring-run Chinook Salmon and steelhead  
13 populations.

14 While the purpose of the fish passage action is not intended to benefit fall-run  
15 Chinook Salmon, it could provide benefit if passage is provided for fall-run  
16 Chinook Salmon.

17 *Summary of Effects on Fall-Run Chinook Salmon*

18 The multiple model and analysis outputs described above characterize the  
19 anticipated conditions for fall-run Chinook Salmon and their response to change  
20 under the No Action Alternative as compared to the Second Basis of Comparison.  
21 In the Stanislaus River, the analysis of the effects of the No Action  
22 Alternative and Second Basis of Comparison for fall-run Chinook Salmon relied  
23 on the water temperature model output for the rivers at various locations  
24 downstream of Goodwin Dam. The temperature model outputs for each of the  
25 fall-run Chinook Salmon life stages suggest that thermal conditions and effects on  
26 fall-run Chinook Salmon in the Stanislaus River generally would be similar under  
27 both scenarios, although water temperatures could be somewhat more suitable for  
28 fall-run Chinook Salmon spawning/egg incubation under the No Action  
29 Alternative. This conclusion is supported by the water temperature threshold  
30 exceedance analysis that indicated that suitable water temperatures for fall-run  
31 Chinook Salmon spawning and egg incubation would be exceeded slightly more  
32 frequently in November, but substantially less frequently in October under the No  
33 Action Alternative. Suitable water temperatures for fall-run Chinook Salmon  
34 rearing would be exceeded somewhat more frequently under the No Action  
35 Alternative. Results of the analysis using Reclamation's salmon mortality model  
36 indicate that there would be little difference in fall-run Chinook Salmon egg  
37 mortality under the No Action Alternative and the Second Basis of Comparison.

38 Implementation of a fish passage project under the No Action Alternative,  
39 although intended to address the limited availability of suitable habitat for spring-  
40 run Chinook Salmon and steelhead in the Stanislaus River reaches downstream of  
41 Goodwin Dam, likely would provide some benefit to fall-run Chinook Salmon if  
42 passage for adult fall-run Chinook Salmon was provided and additional habitat  
43 could be accessed. Any potential benefit to fall-run Chinook Salmon is uncertain.  
44 Moreover, RPA actions intended to increase the efficiency of the Tracy and

1 Skinner Fish Collection Facilities could improve the overall salvage survival of  
2 fall-run Chinook Salmon.

3 The numerical model results for effects on fall-run Chinook Salmon under the No  
4 Action Alternative and Second Basis of Comparison do not definitively show  
5 distinct differences. Because the No Action Alternative has the potential for  
6 beneficial effects resulting from the RPA actions, it is concluded that the effects  
7 on fall-run Chinook Salmon would be less adverse under the No Action  
8 Alternative relative to the Second Basis of Comparison.

#### 9 *Steelhead*

10 Changes in operations that influence temperature and flow conditions in the  
11 Stanislaus River downstream of Goodwin Dam and the San Joaquin River  
12 downstream of the Stanislaus River confluence, as measured at Vernalis could  
13 affect steelhead. The following describes those changes and their potential  
14 effects.

#### 15 *Changes in Water Temperature (Stanislaus River)*

16 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
17 under the No Action Alternative and Second Basis of Comparison generally  
18 would be similar (differences less than 0.5°F), with small differences in critical  
19 dry years when water temperatures under the No Action Alternative would 0.8°F  
20 and 1.3°F warmer on average than under the Second Basis of Comparison during  
21 June and September, respectively, and 0.7°F cooler in November (Appendix 6B,  
22 Table B-17-4).

23 Downstream at Orange Blossom Bridge, average monthly water temperatures in  
24 October under the No Action Alternative would be lower than the Second Basis  
25 of Comparison in all water year types by as much as 1.9°F. In most other months,  
26 water temperatures under the No Action Alternative and Second Basis of  
27 Comparison generally would be similar, except in April when average monthly  
28 water temperatures would be lower under the No Action Alternative by as much  
29 as about 1.2°F in the drier years (Appendix 6B, Table B-18-4).

30 This temperature pattern would continue downstream to the confluence with the  
31 San Joaquin River, although temperatures would progressively increase, as would  
32 the magnitude of difference between the No Action Alternative and Second Basis  
33 of Comparison. Decreases in average monthly water temperatures in October and  
34 April would be more pronounced under the No Action Alternative, with average  
35 differences as much as 2.7°F (Appendix 6B, Table B-19-4) relative to the Second  
36 Basis of Comparison. The magnitude of differences in average monthly water  
37 temperatures between the No Action Alternative and the Second Basis of  
38 Comparison in May and June also would increase relative to the upstream  
39 locations with average June water temperatures reaching 2.4°F warmer under the  
40 No Action Alternative in wet years.

41 Overall, the temperature differences between the No Action Alternative and  
42 Second Basis of Comparison would be relatively minor (less than 0.5°F) and  
43 likely would have little effect on steelhead in the Stanislaus River. Based on the

1 life history timing for steelhead, the slightly higher temperatures in June and  
2 September of drier years under the No Action Alternative may increase the  
3 likelihood of adverse effects to steelhead rearing in the Stanislaus River; the lower  
4 temperatures in October under the No Action Alternative may reduce the  
5 likelihood of adverse effects on adult steelhead during their upstream migration.

6 *Changes in Exceedance of Water Temperature Thresholds (Stanislaus River)*

7 Average monthly water temperatures in the Stanislaus River at Orange Blossom  
8 Bridge would frequently exceed the temperature threshold (56°F) established for  
9 adult steelhead migration under both the No Action Alternative and Second Basis  
10 of Comparison during October and November. Under the No Action Alternative,  
11 average monthly water temperatures would exceed 56°F about 57 percent of the  
12 time in October which is about 28 percent less frequently than under the Second  
13 Basis of Comparison (Appendix 6B, Figure B-18-1). In November, average  
14 monthly water temperatures would exceed 56°F about 33 percent of the time  
15 under the No Action Alternative, which would be about 5 percent more frequently  
16 than under the Second Basis of Comparison (Appendix 6B, Figure B-18-2).

17 From January through May, the temperature threshold at Orange Blossom Bridge  
18 is 55°F, which is intended to support steelhead spawning. This threshold would  
19 not be exceeded under either the No Action Alternative or Second Basis of  
20 Comparison during January or February. From March through May, however,  
21 exceedances would occur under both the No action Alternative and Second Basis  
22 of Comparison, with the threshold most frequently exceeded (nearly half the time)  
23 under the No Action Alternative in May (Appendix 9N). Average monthly water  
24 temperatures under the No Action Alternative would exceed the threshold  
25 5 percent more frequently in March, 6 percent more frequently in May, and  
26 17 percent less frequently in April than under the Second Basis of Comparison.

27 From June through November, the temperature threshold of 65°F established to  
28 support steelhead rearing would be exceeded under both the No Action  
29 Alternative and Second Basis of Comparison in all months but November, and  
30 would exceed the threshold about 16 percent of the time in July under both the No  
31 Action Alternative and Second Basis of Comparison. The differences between  
32 the No Action Alternative and Second Basis of Comparison range from 1 percent  
33 less frequent exceedance in October to 4 percent more frequent exceedance in  
34 June under the No Action Alternative.

35 Average monthly water temperatures also would exceed the threshold (52°F)  
36 established for smoltification at Knights Ferry. At Goodwin Dam, about 4 miles  
37 upstream of Knights Ferry, average monthly water temperatures under the No  
38 Action Alternative would exceed 52°F in March, April, and May about 8 percent,  
39 33 percent, and 63 percent of the time, respectively. Water temperatures under  
40 the No Action Alternative would result in exceedances occurring about 1 to  
41 2 percent less frequently during the January through May period. Farther  
42 downstream at Orange Blossom Bridge, the temperature threshold for  
43 smoltification is higher (57°F) and would be exceeded less frequently. The  
44 magnitude of the exceedance also would be less. Average monthly water

1 temperatures under the No Action Alternative and the Second Basis of  
2 Comparison would not exceed the threshold during January through March. In  
3 April and May, exceedances of 2 percent and 18 percent would occur under the  
4 No Action Alternative, which represent a frequency of about 6 percent less than  
5 the Second Basis of Comparison in April and about an 8 percent higher frequency  
6 in May.

7 Overall, the differences in exceedance frequency between the No Action  
8 Alternative and Second Basis of Comparison would be relatively small, with the  
9 exception of substantial differences in the frequency of exceedances in October  
10 when the average monthly water temperatures under the No Action  
11 Alternative would exceed the threshold for adult steelhead migration about  
12 28 percent less frequently and in April during the spawning period when the  
13 exceedance frequency would be about 17 percent less. Given the frequency of  
14 exceedance under both the No Action Alternative and Second Basis of  
15 Comparison and the generally stressful temperature conditions in the river, the  
16 substantial differences (improvements) in October and April under the No Action  
17 Alternative suggest that there would be less potential to for adverse effects on  
18 steelhead under the No Action Alternative than under the Second Basis of  
19 Comparison. Even during months when the differences would be relatively small,  
20 the lower frequency of exceedances under the No Action Alternative suggest that  
21 there would be less potential to result in adverse effects on steelhead under the No  
22 Action Alternative than under the Second Basis of Comparison.

### 23 *Changes in Delta Hydrodynamics*

24 San Joaquin River-origin steelhead generally move through the Delta during  
25 spring; however, there is less information on their timing than there is for  
26 Chinook salmon. Thus, hydrodynamics in the entire January through June period  
27 have the potential to affect juvenile steelhead. For a description of potential  
28 hydrodynamic effects on steelhead, see the descriptions for fall-run Chinook  
29 Salmon in the San Joaquin River basin above.

### 30 *Summary of Effects on Steelhead*

31 The analysis of the effects of the No Action Alternative and Second Basis of  
32 Comparison for steelhead relied on the water temperature model output for the  
33 rivers at various locations downstream of Goodwin Dam. The temperature model  
34 outputs for each of the steelhead life stages suggest that thermal conditions and  
35 effects on steelhead generally would be similar under both scenarios, although  
36 water temperatures could be somewhat more suitable for steelhead rearing under  
37 the No Action Alternative. Water temperatures could be somewhat less suitable  
38 during the adult upstream migration period under the No Action relative to the  
39 Second Basis of Comparison. This conclusion is supported by the water  
40 temperature threshold exceedance analysis that indicated that the water  
41 temperature threshold for steelhead migration would be exceeded less frequently  
42 in October, but more frequently in November under the No Action Alternative.  
43 The water temperature threshold for steelhead spawning would also be exceeded  
44 less frequently under the No Action Alternative. The water temperature threshold  
45 for steelhead rearing generally would be exceeded more frequently under the No

1 Action Alternative, while the temperature thresholds for smoltification would be  
2 exceeded less frequently in most months.

3 Implementation of the fish passage program under the No Action  
4 Alternative intended to address the limited availability of suitable habitat for  
5 steelhead in the Stanislaus River reaches downstream of Goodwin Dam could  
6 provide a benefit to steelhead, however, the extent of benefit is uncertain. In  
7 addition, the potential effects of the No Action Alternative could be offset by the  
8 RPA actions intended to reduce predation risk on steelhead in the Stanislaus  
9 River, provide passage to upstream habitat, and to increase the efficiency of the  
10 Tracy and Skinner Fish Collection Facilities. The actions to augment spawning  
11 gravel in the Stanislaus River under the No Action Alternative also could benefit  
12 steelhead.

13 The numerical model results for effects on steelhead under the No Action  
14 Alternative and Second Basis of Comparison do not definitively show distinct  
15 differences. However, in consideration of the potentially beneficial effects  
16 resulting from the RPA actions under the No Action Alternative that are not  
17 included in the numerical models (see Appendix 5A, Section B), the No Action  
18 Alternative has a much greater potential to address the long-term sustainability of  
19 steelhead than does the Second Basis of Comparison. The No Action  
20 Alternative includes provisions for fish passage upstream of New Melones Dam  
21 to address long-term temperature increases associated with climate change. Even  
22 though the success of fish passage is uncertain, it is concluded that the potential  
23 for adverse effects on steelhead under the No Action Alternative would be clearly  
24 less than those under the Second Basis of Comparison, principally because the  
25 Second Basis of Comparison does not include a strategy to address water  
26 temperatures critical to steelhead sustainability over the long term with climate  
27 change by 2030.

### 28 *Reservoir Fishes*

29 The analysis of effects associated with changes in operation on reservoir fishes  
30 relied on evaluation of changes in available habitat (reservoir storage) and  
31 anticipated changes in black bass nesting success.

32 As described in Chapter 5, Surface Water Resources and Water Supplies, changes  
33 in CVP and SWP water supplies and operations under the No Action  
34 Alternative as compared to the Second Basis of Comparison would result in lower  
35 Storage levels in New Melones Reservoir under the No Action Alternative as  
36 compared to the Second Basis of Comparison, as summarized in Table 5.16, due  
37 to increased instream releases to support fish flows under the 2009 NMFS BO.

38 Storage in New Melones could be reduced up to around 10 percent in some  
39 months of some water year types. Additional information related to monthly  
40 reservoir elevations is provided in Appendix 5A, CalSim II and DSM2 Modeling.  
41 It is anticipated that aquatic habitat within New Melones is not limiting; however,  
42 storage volume is an indicator of how much habitat is available to fish species  
43 inhabiting these reservoirs. Therefore, the amount of habitat for reservoir fishes

1 could be reduced under the No Action Alternative as compared to the Second  
2 Basis of Comparison.

3 As shown in Appendix 9F, predicted survival in New Melones is higher than in  
4 the other reservoirs during May and June. For March, Largemouth Bass and  
5 Smallmouth Bass nest survival is predicted to be above 40 percent in all of the  
6 years simulated. For April, the likelihood that nest survival of Largemouth Bass  
7 and Smallmouth Bass is between 40 and 100 percent would be about 13 percent  
8 lower under the No Action Alternative than under the Second Basis of  
9 Comparison, but still would be relatively high (around 80 percent). For May, this  
10 pattern is reversed with the likelihood of high nest survival being similar under  
11 the No Action Alternative and the Second Basis of Comparison. For June, the  
12 likelihood of survival being greater than 40 percent for Largemouth Bass and  
13 Smallmouth Bass in New Melones is also higher (by about 8 percent) under the  
14 No Action Alternative as compared to the Second Basis of Comparison. For  
15 Spotted Bass, nest survival from March through June is anticipated to be near  
16 100 percent in every year under both the No Action Alternative and Second Basis  
17 of Comparison.

18 The somewhat lower likelihood of high nesting survival for Largemouth and  
19 Smallmouth Bass during April is not expected to adversely affect nesting success  
20 because the likelihood of successful nesting would be relatively high. Thus, it is  
21 concluded that effects on black bass nesting success would be similar under the  
22 No Action Alternative and the Second Basis of Comparison.

### 23 *Other species*

24 Changes in operations that influence temperature and flow conditions in the  
25 Stanislaus River downstream of Goodwin Dam and the San Joaquin River at  
26 Vernalis could affect other species such as lampreys, Hardhead, and Striped Bass.

27 As described above, average monthly water temperatures in the Stanislaus River  
28 at Goodwin Dam under the No Action Alternative and Second Basis of  
29 Comparison generally would be similar. Downstream at Orange Blossom Bridge,  
30 average monthly water temperatures in the November to March period under the  
31 No Action Alternative generally would be similar to, although somewhat higher  
32 than, under the Second Basis of Comparison, except in April when average  
33 monthly water temperatures in all water year types would be lower under the No  
34 Action Alternative. This temperature pattern would continue downstream to the  
35 confluence with the San Joaquin River, although temperatures would  
36 progressively increase, as would the magnitude of difference between the No  
37 Action Alternative and Second Basis of Comparison (Appendix 6B,  
38 Table B-19-1).

39 In general, lamprey species can tolerate higher temperatures than salmonids, up to  
40 around 72°F during their entire life history. Because lamprey ammocoetes remain  
41 in the river for several years, any substantial flow reductions or water temperature  
42 increases could result in adverse effects on larval lamprey. Given the relatively  
43 minor changes in water temperature and water temperature threshold exceedance,  
44 and the inherent uncertainty associated with the resolution of the temperature

1 model (average monthly outputs), it is likely that the potential to affect lamprey  
2 species in the Stanislaus and San Joaquin rivers would be similar under the No  
3 Action Alternative and the Second Basis of Comparison.

4 In general, Striped Bass and Hardhead also can tolerate higher temperatures than  
5 salmonids. Given the relatively minor changes in water temperature and water  
6 temperature threshold exceedance, the inherent uncertainty associated with the  
7 resolution of the temperature model (average monthly outputs), it is likely that the  
8 potential to affect Striped Bass and Hardhead in the Stanislaus and San Joaquin  
9 rivers would be similar under the No Action Alternative and the Second Basis of  
10 Comparison.

#### 11 **9.4.3.2 Alternative 1**

12 As described in Chapter 3, Description of Alternatives, Alternative 1 is identical  
13 to the Second Basis of Comparison. As described in Chapter 4, Approach to  
14 Environmental Analysis, Alternative 1 is compared to the No Action  
15 Alternative and the Second Basis of Comparison. However, because aquatic  
16 resource conditions under Alternative 1 are identical to aquatic resource  
17 conditions under the Second Basis of Comparison; Alternative 1 is only compared  
18 to the No Action Alternative.

#### 19 **9.4.3.2.1 Alternative 1 Compared to the No Action Alternative**

##### 20 *Trinity River Region*

##### 21 *Coho Salmon*

22 The analysis of effects associated with changes in operation on Coho Salmon was  
23 conducted using temperature model outputs for Lewiston Dam to anticipate the  
24 likely effects on conditions in the Trinity River downstream of Lewiston Dam for  
25 Coho Salmon.

26 Long-term average monthly water temperatures in the Trinity River at Lewiston  
27 Dam under Alternative 1 generally would be similar to the water temperatures  
28 that would occur under the No Action Alternative (Appendix 6B, Table B-1-1).  
29 Average monthly temperatures under Alternative 1 generally would be similar to  
30 those predicted under the No Action Alternative in most water year types, except  
31 from November through January in above- and below-normal water years when  
32 water temperatures under Alternative 1 could be up to 1.5°F cooler than under the  
33 No Action Alternative. In November of critical years water temperatures under  
34 Alternative 1 could be as much as 2.4°F warmer than under the No action  
35 Alternative (Appendix 6B, Table B-1-1). Average monthly water temperatures  
36 generally would be similar (less than 0.5°F differences) under Alternative 1 and  
37 the No Action Alternative from July through September, except in September of  
38 wet years when temperatures would be slightly (0.7°F) lower under Alternative 1.

39 The USFWS established a water temperature threshold of 56°F for Coho Salmon  
40 spawning in the reach of the Trinity River from Lewiston to the confluence with  
41 the North Fork Trinity River from October through December. Although not  
42 entirely reflective of water temperatures throughout the reach, the temperature

1 model provides average monthly water temperature outputs for releases from the  
2 Lewiston Dam, which may provide perspective on temperature conditions in the  
3 reach below. In October and November, average monthly water temperatures  
4 under both Alternative 1 and the No Action Alternative would exceed 56°F at  
5 Lewiston Dam in some years (Appendix 9N). Under Alternative 1, the threshold  
6 would be exceeded about 6 percent of the time in October, about 1 percent less  
7 frequently than under the No Action Alternative. In November, both scenarios  
8 would result in an exceedance frequency of about 2 percent. There would be no  
9 exceedance of the threshold in December under both the Alternative 1 and the No  
10 Action Alternative.

11 Overall, the temperature model outputs for each of the Coho Salmon life stages  
12 suggest that the temperature of water released at Lewiston Dam generally would  
13 be similar under both scenarios, although the exceedance of water temperature  
14 thresholds would be slightly less frequent (1 percent) under Alternative 1. The  
15 higher water temperatures in November of critical years (and lower temperatures  
16 in December) under Alternative 1 would likely have little effect on Coho Salmon  
17 as water temperatures in the Trinity River are typically low during this time  
18 period. Given the similarity of the results and the inherent uncertainty associated  
19 with the resolution of the temperature model (average monthly outputs),  
20 Alternative 1 and the No Action Alternative are likely to have similar effects on  
21 the Coho Salmon population in the Trinity River.

#### 22 *Spring-run Chinook Salmon*

23 The analysis of effects associated with changes in operation on spring-run  
24 Chinook Salmon was conducted using temperature model outputs for Lewiston  
25 Dam to anticipate the likely effects on conditions in the Trinity River downstream  
26 of Lewiston Dam.

27 As described above for Coho Salmon, the temperature differences between  
28 Alternative 1 and the No Action Alternative would be relatively minor (less than  
29 0.5°F) and likely would have little effect on spring-run Chinook Salmon in the  
30 Trinity River. The higher average monthly water temperatures (up to 2.4°F) in  
31 November of critical years (and lower temperatures in December) under  
32 Alternative 1 would likely have little effect on spring-run Chinook Salmon as  
33 water temperatures in the Trinity River are typically low during this time period.

34 Under both Alternative 1 and the No Action Alternative, average monthly water  
35 temperatures in the Trinity River at Lewiston Dam would infrequently (1 percent  
36 to 2 percent of the time) exceed 60°F, the threshold for spring-run Chinook  
37 Salmon holding. There would be no difference in the frequency of exceedance of  
38 the 60°F threshold under Alternative 1 as compared to the No Action Alternative.  
39 In September, however, the threshold for spawning (56°F) would be exceeded  
40 11 percent of the time under Alternative 1 which is about 2 percent more  
41 frequently than under the No Action Alternative.

42 Overall, the differences in the frequency of threshold exceedance between  
43 Alternative 1 and the No Action Alternative would be relatively minor, although  
44 temperature conditions under Alternative 1 could be slightly more likely to result

1 in adverse effects on spring-run Chinook Salmon spawning than under the No  
2 Action Alternative because of the increased frequency of exceedance of the 56°F  
3 threshold at Lewiston Dam in September.

4 The majority of spring-run Chinook Salmon in the Trinity River are produced in  
5 the South Fork Trinity watershed. Although the water temperatures under  
6 Alternative 1 could result in adverse effects on spring-run Chinook Salmon in the  
7 Trinity River, these effects would not occur in every year and are not anticipated  
8 to be substantial based on the relatively small differences water temperatures  
9 under Alternative 1 as compared to the No Action Alternative.

10 Overall, Alternative 1 is likely to have similar effects on the spring-run Chinook  
11 Salmon population in the Trinity River as compared to the No Action Alternative.  
12 However, implementation of the Hatchery Management Plan (RPA Action II.6.3)  
13 under the No Action Alternative could reduce the impacts of hatchery Chinook  
14 Salmon on natural spring-run Chinook Salmon in the Trinity River, and increase  
15 the genetic diversity and diversity of run-timing for these stocks relative to  
16 Alternative 1. Thus, given the relatively minor changes in water temperature and  
17 water temperature threshold exceedance, the inherent uncertainty associated with  
18 the resolution of the temperature model (average monthly outputs), and the  
19 uncertainty of the hatchery benefits, it is concluded that Alternative 1 and the No  
20 Action Alternative are likely to have similar effects on the spring-run Chinook  
21 Salmon in the Trinity River.

#### 22 *Fall-Run Chinook Salmon*

23 The analysis of effects associated with changes in operation on fall-run Chinook  
24 Salmon was conducted using temperature model outputs for Lewiston Dam to  
25 anticipate the likely effects on conditions in the Trinity River downstream of  
26 Lewiston Dam. In addition, the Reclamation Salmon Mortality Model was used  
27 to assess egg mortality.

28 As described above for Coho Salmon, the temperature differences between  
29 Alternative 1 and No Action Alternative would be relatively minor (less than  
30 0.5°F) and likely would have little effect on fall-run Chinook Salmon in the  
31 Trinity River. The higher water temperatures (as much as 2.4°F) in November of  
32 critical years (and lower temperatures in December) under Alternative 1 would  
33 likely have little effect on fall-run Chinook Salmon as water temperatures in the  
34 Trinity River are typically low during this time period.

35 The temperature threshold and months during which it applies for fall-run  
36 Chinook Salmon are the same as those for Coho Salmon. Under Alternative 1,  
37 the threshold would be exceeded about 6 percent of the time in October, about  
38 1 percent less frequently than under the No Action Alternative. In November,  
39 both conditions would result in an exceedance frequency of about 2 percent.  
40 There would be no exceedance of the threshold in December under both  
41 Alternative 1 and the No Action Alternative. Overall, the differences in the  
42 frequency of threshold exceedance between Alternative 1 and the No Action  
43 Alternative would be relatively minor. Temperature conditions under the  
44 Alternative 1 could be slightly less likely to result in adverse effects on fall-run

1 Chinook Salmon spawning than under the No Action Alternative because of the  
2 reduced frequency of exceedance of the 56°F threshold at Lewiston Dam in  
3 October. However, this would occur prior to the peak spawning period for  
4 fall-run Chinook Salmon.

5 The temperatures described above for the Trinity River downstream of Lewiston  
6 Dam are reflected in the analysis of egg mortality using the Reclamation salmon  
7 mortality model (Appendix 9C). For fall-run Chinook Salmon in the Trinity  
8 River, the long-term average egg mortality rate is predicted to be relatively low  
9 (around 4 percent), with higher mortality rates (nearly 15 percent) occurring in  
10 critical dry years under the No Action Alternative (Appendix 9C, Table B-1-5).  
11 Overall, egg mortality under Alternative 1 and the No Action Alternative would  
12 be similar in all water year types.

13 Although the combined analysis based on water temperature suggests that  
14 operations under Alternative 1 could be slightly less adverse than under the No  
15 Action Alternative, these effects would not occur in every year and are not  
16 anticipated to be substantial based on the relatively small differences in water  
17 temperatures (and similar egg mortality) between Alternative 1 and the No Action  
18 Alternative. In addition, implementation of the Hatchery Management Plan (RPA  
19 Action II.6.3) under the No Action Alternative could reduce the impacts of  
20 hatchery Chinook Salmon on natural fall-run Chinook Salmon in the Trinity  
21 River, and increase the genetic diversity and diversity of run-timing for these  
22 stocks relative to Alternative 1.

23 Overall, given the small differences in the numerical model results and the  
24 inherent uncertainty in the temperature model, as well as the potential for  
25 offsetting benefits associated with the Hatchery Management Plan, it is concluded  
26 that there would be no definitive difference in effects on fall-run Chinook Salmon  
27 between Alternative 1 and the No Action Alternative.

#### 28 *Steelhead*

29 The analysis of effects associated with changes in operation on steelhead relied on  
30 temperature model outputs for Lewiston Dam to anticipate the likely effects on  
31 conditions in the Trinity River downstream of Lewiston Dam.

32 Temperature differences between Alternative 1 and No Action Alternative would  
33 be relatively minor (less than 0.5°F) and likely would have little effect on  
34 steelhead in the Trinity River. The higher water temperatures (up to 2.4°F) in  
35 November of critical years (and lower temperatures in December) under  
36 Alternative 1 would likely have little effect on steelhead as water temperatures in  
37 the Trinity River are typically low during this time period.

38 The temperature threshold and months during which it applies for steelhead are  
39 the same as those described for Coho Salmon. Thus, the frequency of average  
40 monthly water temperatures in the Trinity River at Lewiston Dam exceeding the  
41 threshold of 56°F for steelhead would be the same as those described above for  
42 Coho Salmon. Water temperature conditions under Alternative 1 could be less  
43 likely to affect steelhead spawning than under the No Action Alternative because

1 of the slightly (1 percent) reduced frequency of exceedance of the 56°F threshold  
2 at Lewiston Dam in October. The biological significance of this difference,  
3 however, is uncertain.

4 Although the combined analysis based on water temperature suggests that  
5 operations under Alternative 1 could be slightly less adverse than under the No  
6 Action Alternative, these effects would not occur in every year and are not  
7 anticipated to be substantial based on the relatively small differences in water  
8 temperatures between Alternative 1 and the No Action Alternative. Overall,  
9 given these small differences in water temperatures and the inherent uncertainty  
10 in the temperature model, Alternative 1 and the No Action Alternative are likely  
11 to have similar effects on steelhead in the Trinity River.

#### 12 *Green Sturgeon*

13 The analysis of effects associated with changes in operation on Green Sturgeon  
14 relied on temperature model outputs for Lewiston Dam to anticipate the likely  
15 effects on conditions in the Trinity River downstream of Lewiston Dam.

16 Green Sturgeon spawn in the lower reaches of the Trinity River during April  
17 through June, and water temperatures above about 63°F are believed stressful to  
18 embryos (Van Eenennaam et al. 2005). Average monthly water temperature  
19 conditions during April through June in the Trinity River at Lewiston Dam under  
20 Alternative 1 would be similar to the temperatures under the No Action  
21 Alternative and would not exceed 58°F during this period. In addition, water  
22 temperatures in the reach of the river where Green Sturgeon spawn are likely  
23 controlled by other factors (e.g., ambient air temperatures and tributary inflows)  
24 more than water operations at Trinity and Lewiston dams.

25 Overall, given the similarities between average monthly water temperatures at  
26 Lewiston Dam under Alternative 1 and the No Action Alternative, it is likely that  
27 water temperature conditions for Green Sturgeon in the Trinity River or lower  
28 Klamath River and estuary would be similar under both scenarios.

#### 29 *Reservoir Fishes*

30 The analysis of effects associated with changes in operation on reservoir fishes  
31 relied on evaluation of changes in available habitat (reservoir storage) and  
32 anticipated changes in black bass nesting success.

33 Changes in CVP water supplies and operations under Alternative 1 as compared  
34 to the No Action Alternative would result in higher reservoir storage in Trinity  
35 Lake. Storage in Trinity Lake could increase by up to about 10 percent in some  
36 months of some water year types. Additional information related to monthly  
37 reservoir elevations is provided in Appendix 5A, CalSim II and DSM2 Modeling.

38 Using Trinity Lake storage as an indicator of habitat available to fish species  
39 inhabiting the reservoir, the amount of habitat for reservoir fishes would not be  
40 reduced under Alternative 1 as compared to the No Action Alternative.

1 As shown in Appendix 9F, nest survival in Trinity Lake is near 100 percent in  
2 March and April due to increasing reservoir elevations. For May, the likelihood  
3 of survival for Largemouth Bass in Trinity Lake being in the 40 to 100 percent  
4 range is slightly (about 2 percent) higher under Alternative 1 as compared to the  
5 No Action Alternative. For June, the likelihood of survival being greater than  
6 40 percent for Largemouth Bass is somewhat lower than in May and is slightly  
7 lower (about 2 percent) under Alternative 1 as compared to the No Action  
8 Alternative. For Spotted Bass, the likelihood of survival being greater than  
9 40 percent would be 100 percent in May under both Alternative 1 and the No  
10 Action Alternative. For June, Spotted Bass survival in Trinity Lake would be less  
11 than for May due to greater daily reductions in water surface elevation. The  
12 likelihood of survival being greater than 40 percent would be similar (near  
13 100 percent) under Alternative 1 and the No Action Alternative.

14 Overall, the comparison of storage and the analysis of nesting suggest that effects  
15 of Alternative 1 on reservoir fishes would be similar to those under the No Action  
16 Alternative.

#### 17 *Pacific Lamprey*

18 Little information is available on factors that influence populations of Pacific  
19 Lamprey in the Trinity River, but they are likely affected by many of the same  
20 factors as salmon and steelhead because of the parallels in their life cycles. On  
21 average, the temperature of water released at Lewiston Dam under Alternative 1  
22 generally would be similar to (less than 0.5°F differences) to those under the No  
23 Action Alternative. Given the similarities in water temperatures, it is likely that  
24 the effects on Pacific Lamprey would be similar under Alternative 1 and the No  
25 Action Alternative. This conclusion likely applies to other species of lamprey  
26 that inhabit the Trinity and lower Klamath rivers (e.g., River Lamprey).

#### 27 *Eulachon*

28 It is unclear whether this species has been extirpated from the Klamath River.  
29 Given that the highest increases in flow under Alternative 1 would be less than  
30 10 percent in the Trinity River (Appendix 5A), with a smaller relative change in  
31 the lower Klamath River and Klamath River estuary, and that water temperatures  
32 in the Klamath River are unlikely to be affected by changes upstream at Lewiston  
33 Dam, it is likely that Alternative 1 would have a similar potential to influence  
34 Eulachon in the Klamath River as the No Action Alternative.

#### 35 *Sacramento River System*

##### 36 *Winter-run Chinook Salmon*

37 Changes in operations that influence temperature and flow conditions in the  
38 Sacramento River downstream of Keswick Dam could affect winter-run Chinook  
39 Salmon. The following describes those changes and their potential effects.

##### 40 *Changes in Water Temperature*

41 Long-term average monthly water temperature in the Sacramento River at  
42 Keswick Dam under Alternative 1 would generally be similar to (less than 0.5°F  
43 difference) to water temperatures under the No Action Alternative. An exception

1 is during September and October of critical dry years when water temperatures  
2 could be up to 1.1°F and 0.8°F lower, respectively, under Alternative 1 as  
3 compared to the No Action Alternative and up to 1°F warmer in September of  
4 wetter years in some water year types(up to 0.3°F) (Appendix 6B, Table B-5-1).  
5 A similar pattern of changes in temperature generally would be exhibited  
6 downstream at Ball's Ferry, Jelly's Ferry, and Bend Bridge, with average monthly  
7 temperatures differences between the scenarios progressively decreasing, except  
8 in September (up to 2.8°F warmer at Bend Bridge) during wetter years under  
9 Alternative 1 (Appendix 6B, Table B-8-1).

10 Overall, the temperature differences between Alternative 1 and the No Action  
11 Alternative would be relatively minor (less than 0.5°F) and likely would have  
12 similar effects on winter-run Chinook Salmon in the Sacramento River.  
13 Spawning for winter-run Chinook Salmon in the Sacramento River takes place  
14 from mid-April to mid-August with incubation occurring over the same time  
15 period and extending into October. The somewhat lower water temperatures in  
16 September and October of critical dry years under the No Action  
17 Alternative could reduce the likelihood of adverse effects on winter-run Chinook  
18 Salmon egg incubation and fry rearing during this water year type. However, the  
19 increased water temperatures during this time period under Alternative 1 in wetter  
20 years could increase the likelihood of adverse effects on egg incubation relative to  
21 the No Action Alternative.

#### 22 *Changes in Exceedances of Water Temperature Thresholds*

23 With the exception of April, average monthly water temperatures from April to  
24 September under both Alternative 1 and the No Action Alternative would show  
25 exceedances of the water temperature threshold of 56°F established in the  
26 Sacramento River at Ball's Ferry for winter-run Chinook Salmon spawning and  
27 egg incubation (Appendix 9N). Under Alternative 1, the temperature threshold  
28 generally would be exceeded less frequently than under the No Action  
29 Alternative (by about 1 percent to 3 percent) in the April through August period,  
30 with the temperature threshold in September exceeded in 52 percent of the  
31 simulated years about 10 percent more frequently under Alternative 1 than the No  
32 Action Alternative (42 percent). Farther downstream at Bend Bridge, the  
33 frequency of exceedances would increase, with exceedances under both  
34 Alternative 1 and the No Action as Alternative as high as about 90 percent in  
35 some months. Under Alternative 1, temperature exceedances generally would be  
36 less frequent (by up to 8 percent) than under the No Action Alternative, with the  
37 exception of September, when threshold exceedances under Alternative 1 would  
38 be about 29 percent more frequent.

39 Overall, there would be substantial differences in the frequency of threshold  
40 exceedance between Alternative 1 and the No Action Alternative, particularly in  
41 September. Temperature conditions under Alternative 1 would reduce the  
42 likelihood of adverse effects on winter-run Chinook Salmon egg incubation than  
43 under the No Action Alternative because of the reduced frequency of exceedance  
44 of the 56°F threshold from April through August. However, the substantial

1 increase in the frequency of exceedance in September under Alternative 1 may  
2 increase the likelihood of adverse effects on winter-run Chinook Salmon egg  
3 incubation during this limited portion of the spawning and egg incubation period.

#### 4 *Changes in Egg Mortality*

5 The temperatures described above for the Sacramento River downstream of  
6 Keswick Dam are reflected in the analysis of egg mortality using the Reclamation  
7 salmon mortality model (Appendix 9C). For winter-run Chinook Salmon in the  
8 Sacramento River, the long-term average egg mortality rate is predicted to be  
9 relatively low (around 4 percent), with higher mortality rates (exceeding  
10 20 percent) occurring in critical dry years under Alternative 1. In critical dry  
11 years the average egg mortality rate would be 5.4 percent lower under  
12 Alternative 1 than under the No Action Alternative (Appendix 9C, Table B-4).  
13 Overall, winter-run Chinook Salmon egg mortality in the Sacramento River under  
14 Alternative 1 and the No Action Alternative would be similar, except in critical  
15 dry water years.

#### 16 *Changes in Weighted Usable Area*

17 As described above for the assessment methodology, Weighted Usable Area  
18 (WUA) is a function of flow, but the relationship is not linear due to differences  
19 in depths and velocities present in the wetted channel at different flows. Because  
20 the combination of depths, velocities, and substrates preferred by species and life  
21 stages varies, WUA values at a given flow can differ substantially for the life  
22 stages evaluated.

23 As an indicator of the amount of suitable spawning habitat for winter-run Chinook  
24 Salmon between Keswick Dam and Battle Creek, modeling results indicate that,  
25 in general, there would be similar amounts of spawning habitat available from  
26 May through September under Alternative 1 and the No Action  
27 Alternative (Appendix 9E).

28 Modeling results indicate that, in general, there would be similar amounts of  
29 suitable fry rearing habitat available from June through October under  
30 Alternative 1 and the No Action Alternative (Appendix 9E).

31 Similar to the results for fry rearing WUA, modeling results indicate that there  
32 would be similar amounts of suitable juvenile rearing habitat available during the  
33 juvenile rearing period from September through August under Alternative 1 and  
34 the No Action Alternative (Appendix 9E).

#### 35 *Changes in SALMOD Output*

36 SALMOD results indicate that potential juvenile production under Alternative 1  
37 would be the similar to the No Action Alternative (Appendix 9D, Table B-4-1).

#### 38 *Changes in Delta Passage Model Output*

39 The Delta Passage Model predicted similar estimates of annual Delta survival  
40 across the 81 water year time period for winter-run Chinook Salmon between  
41 Alternative 1 and the No Action Alternative (Appendix 9J). Median Delta  
42 survival would be 0.352 for Alternative 1 and 0.349 for the No Action  
43 Alternative.

1            *Changes in Oncorhynchus Bayesian Analysis Output*

2 Escapement of winter-run Chinook Salmon and Delta survival was modeled by  
3 the Oncorhynchus Bayesian Analysis (OBAN) model for winter-run Chinook  
4 salmon. Escapement was generally lower under Alternative 1 as compared to the  
5 No Action Alternative (Appendix 9I). The median abundance under Alternative 1  
6 was lower in 19 of the 22 years of simulation (1971 to 2002), and there was  
7 typically greater than a 25 percent chance that Alternative 1 values would be  
8 lower than under the No Action Alternative. Median delta survival was  
9 approximately 12 percent lower under Alternative 1 as compared to the No Action  
10 Alternative. However, the probability intervals indicated that no difference  
11 between scenarios was a likely outcome.

12            *Changes in Interactive Object-Oriented Simulation Output*

13 The IOS model predicted similar adult escapement trajectories for winter-run  
14 Chinook Salmon between Alternative 1 and the No Action Alternative across the  
15 81 water years (Appendix 9H). Under Alternative 1 median adult escapement  
16 was 4,042 and under the No Action Alternative, median escapement was 3,935.

17 Similar to adult escapement, the IOS model predicted similar egg survival time  
18 histories for winter-run Chinook Salmon between Alternative 1 and the No Action  
19 Alternative across the 81 water years (Appendix 9H). Under Alternative 1  
20 median egg survival was 0.987 and under the No Action Alternative median egg  
21 survival was 0.990.

22            *Changes in Delta Hydrodynamics*

23 Winter-run Chinook Salmon smolts are most abundant in the Delta during  
24 January, February and March. On the Sacramento River near the confluence of  
25 Georgiana Slough, the median proportion of positive velocities under  
26 Alternative 1 was indistinguishable from the No Action  
27 Alternative (Appendix 9K).

28            *Changes in Junction Entrainment*

29 Entrainment at Georgiana Slough was similar under both Alternative 1 and No  
30 Action Alternative during January, February and March when winter-run Chinook  
31 Salmon smolts are most abundant in the Delta (Appendix 9L).

32            *Changes in Salvage*

33 Salvage of Sacramento River-origin Chinook Salmon is predicted to be greater  
34 under Alternative 1 relative to No Action Alternative in every month  
35 (Appendix 9M). Winter-run Chinook Salmon smolts migrating through the Delta  
36 would be most susceptible in the months of January, February and March.  
37 Predicted values in January and February indicated a moderate increase in the  
38 proportion of fish salvaged under Alternative 1 relative to the No Action  
39 Alternative.

40            *Summary of Effects on Winter-Run Chinook Salmon*

41 The multiple model and analysis outputs described above characterize the  
42 anticipated conditions for winter-run Chinook Salmon and their response to  
43 change under Alternative 1 as compared to the No Action Alternative. For the

1 purpose of analyzing effects on winter-run Chinook Salmon and developing  
2 conclusions, greater reliance was placed on the outputs from the two life cycle  
3 models, IOS and OBAN because they each integrate the available information to  
4 produce single estimates of winter-run Chinook Salmon escapement. The output  
5 from IOS indicated that winter-run Chinook Salmon escapement would be similar  
6 under both scenarios, whereas the OBAN results indicated that escapement under  
7 Alternative 1 would be lower than under the No Action Alternative, although  
8 there would be some chance (less than a 25 percent) that escapement under the  
9 Alternative 1 could be greater than the No Action Alternative.

10 These model results suggest that effects on winter-run Chinook Salmon would be  
11 similar under both scenarios, with a small likelihood that winter-run Chinook  
12 Salmon escapement would be lower under Alternative 1 than under the No Action  
13 Alternative. This potential distinction between the two scenarios, however, may  
14 be offset or reversed by the benefits of implementation of fish passage under the  
15 No Action Alternative intended to address the limited availability of suitable  
16 habitat for winter-run Chinook Salmon in the Sacramento River reaches  
17 downstream of Keswick Dam. This potential beneficial effect and its magnitude  
18 would depend on the success of the fish passage program. In addition, RPA  
19 actions intended to increase the efficiency of the Tracy and Skinner Fish  
20 Collection Facilities could improve the overall salvage survival of winter-run  
21 Chinook Salmon.

22 Overall, the quantitative results from the numerical models suggest that operation  
23 under the Alternative 1 would be more likely to result in adverse effects on  
24 winter-run Chinook Salmon than would the No Action Alternative. In addition,  
25 the potentially beneficial effects resulting from the RPA actions under the No  
26 Action Alternative that are not included in the numerical models (see  
27 Appendix 5A, Section B) suggest that the No Action Alternative has a much  
28 greater potential to address the long-term sustainability of winter-run Chinook  
29 Salmon than does the Alternative 1. It is concluded that the potential for adverse  
30 effects on winter-run Chinook Salmon under Alternative 1 would be greater than  
31 those under the No Action Alternative, principally because Alternative 1 does not  
32 include fish passage to address water temperatures critical to winter-run Chinook  
33 Salmon sustainability over the long term with climate change by 2030.

#### 34 *Spring-run Chinook Salmon*

35 Changes in operations that influence temperature and flow conditions in the  
36 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
37 Whiskeytown Dam, and Feather River downstream of Oroville Dam could affect  
38 spring-run Chinook Salmon. The following describes those changes and their  
39 potential effects.

#### 40 *Changes in Water Temperature*

41 Changes in water temperature that could affect spring-run Chinook Salmon could  
42 occur in the Sacramento River, Clear Creek, and Feather River. The following  
43 describes temperature conditions in those water bodies.

1                    *Sacramento River*

2 Long-term average monthly water temperature in the Sacramento River at  
3 Keswick Dam under Alternative 1 would generally be similar (less than 0.5°F  
4 difference) to water temperatures under the No Action Alternative. An exception  
5 is during September and October of critical dry years when water temperatures  
6 could be up to 1.1°F and 0.8°F lower, respectively, under Alternative 1 as  
7 compared to the No Action Alternative and up to 1°F warmer in September of  
8 wetter years (Appendix 6B, Table B-5-1). A similar pattern of changes in  
9 temperature generally would be exhibited downstream at Ball's Ferry, Jelly's  
10 Ferry, Bend Bridge and Red Bluff, with average monthly temperature differences  
11 between scenarios progressively decreasing, except in September (up to 3.2°F  
12 warmer at Red Bluff) during wetter years (Appendix 6B, Table B-9-1).

13 Overall, the temperature differences between Alternative 1 and the No Action  
14 Alternative would be relatively minor (less than 0.5°F) and likely would have  
15 little effect on spring-run Chinook Salmon in the Sacramento River. The slightly  
16 lower water temperatures from October to December under Alternative 1 would  
17 likely have little effect on spring-run Chinook Salmon as water temperatures in  
18 the Sacramento River below Keswick Dam are typically low during this time  
19 period. The somewhat higher water temperatures in September of wetter years  
20 may increase the likelihood of adverse effects on spring-run Chinook Salmon  
21 spawning, although the decreased temperatures in September of critical dry years  
22 under Alternative 1 may reduce the likelihood of adverse effects on spring-run  
23 Chinook Salmon spawning in this water year type. There would be little  
24 difference in potential effects on spring-run Chinook Salmon holding over the  
25 summer due to the similar water temperatures during this time period under  
26 Alternative 1 and the No Action Alternative.

27                    *Clear Creek*

28 Average monthly water temperatures in Clear Creek at Igo under Alternative 1  
29 relative to the No Action Alternative are generally predicted to be similar (less  
30 than 0.5°F differences) from September through April and June through August  
31 from September through April and June through August (Appendix 6B,  
32 Table B-3-1). Average monthly water temperatures during May under  
33 Alternative 1 could be higher by up to 0.8°F than under the No Action  
34 Alternative. Overall, thermal conditions for spring-run Chinook Salmon in Clear  
35 Creek would be similar under Alternative 1 and the No Action Alternative.

36                    *Feather River*

37 Average monthly water temperature in the Feather River in the low flow channel  
38 generally were predicted to be similar (less than 0.5°F differences) under  
39 Alternative 1 and the No Action Alternative, except during November and  
40 December when average monthly water temperatures could be up to 1.4°F lower  
41 in some water year types (Appendix 6B, Table B-20-1). Average monthly water  
42 temperatures in September under Alternative 1 could be up to 1.3°F warmer than  
43 under the No Action Alternative in wetter years. Although temperatures in the  
44 river would become progressively higher in the downstream directions, the  
45 differences between Alternative 1 and No Action Alternative would exhibit a

1 similar pattern at the downstream locations (Robinson Riffle and Gridley Bridge),  
 2 with water temperature differences between Alternative 1 and the No Action  
 3 Alternative generally decreasing in most water year types. However, water  
 4 temperatures from July to September under Alternative 1 were predicted to be  
 5 somewhat (0.7°F to 1.6°F) warmer on average and up to 4.0°F warmer at the  
 6 confluence with the Sacramento River in wetter years (Appendix 6B,  
 7 Table B-23-1).

8 Overall, the temperature differences in the Feather River between Alternative 1  
 9 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
 10 likely would have little effect on spring-run Chinook Salmon in the Feather River.  
 11 The slightly lower water temperatures in November and December under  
 12 Alternative 1 would likely have little effect on spring-run Chinook Salmon as  
 13 water temperatures in the Feather River are typically low during this time period.  
 14 The somewhat higher water temperatures in September of wetter years may  
 15 increase the likelihood of adverse effects on spring-run Chinook Salmon  
 16 spawning, although the decreased temperatures in September of critical dry years  
 17 under Alternative 1 may reduce the likelihood of adverse effects on spring-run  
 18 Chinook Salmon spawning in this water year type. There would be little  
 19 difference in potential effects on spring-run Chinook Salmon holding over the  
 20 summer due to the similar water temperatures during this time period under  
 21 Alternative 1 and the No Action Alternative.

#### 22 *Changes in Exceedances of Water Temperature Thresholds*

23 Changes in water temperature could result in the exceedance of established water  
 24 temperature thresholds for spring-run Chinook Salmon in the Sacramento River,  
 25 Clear Creek, and Feather River. The following describes the extent of water  
 26 temperature threshold exceedances for each of those water bodies.

#### 27 *Sacramento River*

28 Average monthly water temperatures under both Alternative 1 and No Action  
 29 Alternative would show exceedances of the water temperature threshold of 56°F  
 30 established in the Sacramento River at Red Bluff for spring-run Chinook Salmon  
 31 (egg incubation) in October, November, and again in April. The exceedances  
 32 would occur at the greatest frequency in October (79 percent of the time under  
 33 Alternative 1); under Alternative 1 the water temperature threshold would be  
 34 exceeded less frequently in November (7 percent of the time under Alternative 1)  
 35 and not exceeded at all from December through March (Appendix 9N). As water  
 36 temperatures warm in the spring, the thresholds would be exceeded in April by  
 37 15 percent under Alternative 1. In the months when the greatest frequency of  
 38 exceedances occur (October, November, and April), model results generally  
 39 indicate less frequent exceedances (by up to 4 percent in October) under  
 40 Alternative 1 than under the No Action Alternative. Temperature conditions in  
 41 the Sacramento River under Alternative 1 could be less likely to affect spring-run  
 42 Chinook Salmon egg incubation than under the No Action Alternative because of  
 43 the decreased frequency of exceedance of the 56°F threshold in October,  
 44 November, and April. However, this difference may be partially offset if water

1 temperature management and fish passage measures associated with 2009 NMFS  
2 BO RPA under the No Action Alternative are successful.

3 *Clear Creek*

4 Average monthly water temperatures under both Alternative 1 and No Action  
5 Alternative would not exceed the water temperature threshold of 60°F established  
6 in Clear Creek at Igo for spring-run Chinook Salmon pre-spawning and rearing in  
7 June through August. However, water temperatures under Alternative 1 and the  
8 No Action Alternative would exceed the water temperature threshold of 56°F  
9 established for spawning in September and October about 10 percent to  
10 15 percent of the time (Appendix 9N). Water temperatures under Alternative 1  
11 could exceed the threshold about 3 percent less frequently than under the No  
12 Action Alternative in September and about 2 percent less frequently in October  
13 (Appendix 9N). Temperature conditions in Clear Creek under Alternative 1 could  
14 be less likely to affect spring-run Chinook Salmon spawning than under the No  
15 Action Alternative because of the decreased frequency of exceedance of the 56°F  
16 threshold in September and October. However, this difference may be partially  
17 offset if the thermal stress reduction measures associated with 2009 NMFS BO  
18 RPA Action I.1.5 under the No Action Alternative are successful in improving  
19 water temperatures in Clear Creek.

20 *Feather River*

21 Average monthly water temperatures under both Alternative 1 and the No Action  
22 Alternative would exceed the water temperature threshold of 56°F established in  
23 the Feather River at Robinson Riffle for spring-run Chinook Salmon egg  
24 incubation and rearing during some months, particularly in October and  
25 November, and March and April, when temperature thresholds could be exceeded  
26 frequently (Appendix 9N). The frequency of exceedance was highest in October,  
27 a month in which average monthly water could get as high as about 68°F.  
28 However, water temperatures under Alternative 1 would exceed the spawning  
29 temperature threshold about 1 percent less frequently than under the No Action  
30 Alternative in October, November, and December, and about 2 percent more  
31 frequently in March.

32 The established water temperature threshold of 63°F for rearing during May  
33 through August would be exceeded often under both Alternative 1 and the No  
34 Action Alternative in May and June, but not at all in July and August. Water  
35 temperatures under Alternative 1 would exceed the rearing temperature threshold  
36 about 9 percent less frequently than under the No Action Alternative in May.  
37 Temperature conditions in the Feather River under Alternative 1 could be less  
38 likely to affect spring-run Chinook Salmon spawning and rearing than under the  
39 No Action Alternative because of the decreased frequency of exceedance of the  
40 water temperature thresholds.

41 *Changes in Egg Mortality*

42 These temperature differences described above are reflected in the analysis of egg  
43 mortality using the Reclamation salmon mortality model (Appendix 9C). For  
44 spring-run Chinook Salmon in the Sacramento River, the long-term average egg

1 mortality rate is predicted to be relatively high (exceeding 20 percent), with high  
2 mortality rates (exceeding 70 percent) occurring in critical dry years. In critical  
3 dry years the average egg mortality rate under Alternative 1 is predicted to be  
4 10.4 percent lower than under the No Action Alternative (Appendix 9C,  
5 Table B-3). Overall, spring-run Chinook Salmon egg mortality in the Sacramento  
6 River under Alternative 1 and the No Action Alternative would be similar, except  
7 in critical dry water years.

#### 8 *Changes in Weighted Usable Area*

9 Weighted usable area curves are available for spring-run Chinook Salmon in  
10 Clear Creek. As described above, flows in Clear Creek downstream of  
11 Whiskeytown Dam are not anticipated to differ under Alternative 1 relative to the  
12 No Action Alternative except in May due to the release of spring attraction flows  
13 in accordance with the 2009 NMFS BO under the No Action Alternative.  
14 Therefore, there would be no change in the amount of potentially suitable  
15 spawning and rearing habitat for spring-run Chinook Salmon (as indexed by  
16 WUA) available under Alternative 1 as compared to the No Action Alternative.

#### 17 *Changes in SALMOD Output*

18 SALMOD results indicate that potential spring-run juvenile production would be  
19 similar under Alternative 1 and the No Action Alternative except that production  
20 under Alternative 1 could be 12 percent higher than under the No Action  
21 Alternative in critical dry years (Appendix 9D, Table B-3-1).

#### 22 *Changes in Delta Passage Model Output*

23 The Delta Passage Model predicted similar estimates of annual Delta survival  
24 across the 81 water year time period for spring-run Chinook Salmon between  
25 Alternative 1 and the No Action Alternative (Appendix 9J). Median Delta  
26 survival was 0.286 for Alternative 1 and 0.296 for the No Action Alternative.

#### 27 *Changes in Delta Hydrodynamics*

28 Spring-run Chinook Salmon are most abundant in the Delta from March through  
29 May. Near the junction of Georgiana Slough, the median percent of time that  
30 velocity was positive was similar in March, April, and May for both scenarios. In  
31 Old River upstream of the facilities, the median percent of time with positive  
32 velocity was similar in March, slightly lower in April, and moderately lower in  
33 May under Alternative 1 relative to the No Action Alternative (Appendix 9K). In  
34 Old River downstream of the facilities the median percent of time with positive  
35 velocity was slightly lower in March and increasingly lower in April and May  
36 under Alternative 1 relative to No Action Alternative.

#### 37 *Changes in Junction Entrainment*

38 Entrainment at Georgiana Slough was similar under both Alternative 1 and No  
39 Action Alternative during March, April and May when spring run are most  
40 abundant in the Delta (Appendix 9L).

1            *Changes in Salvage*

2 Salvage of Sacramento River-origin Chinook Salmon is predicted to be higher  
3 under Alternative 1 relative to No Action Alternative in every month  
4 (Appendix 9M). Spring-run smolts migrating through the Delta would be most  
5 susceptible in the months of March April and May. Predicted values in April and  
6 May indicated a substantially larger fraction of fish salvaged under Alternative 1.  
7 Predicted salvage was more similar in March but still higher under Alternative 1  
8 than under the No Action Alternative.

9            *Summary of Effects on Spring-Run Chinook Salmon*

10 The multiple model and analysis outputs described above characterize the  
11 anticipated conditions for spring-run Chinook Salmon and their response to  
12 change under Alternative 1 and the No Action Alternative. For the purpose of  
13 analyzing effects on spring-run Chinook Salmon in the Sacramento River, greater  
14 reliance was placed on the outputs from the SALMOD model because it integrates  
15 the available information on temperature and flows to produce estimates of  
16 mortality for each life stage and an overall, integrated estimate of potential spring-  
17 run Chinook Salmon juvenile production. The output from SALMOD indicated  
18 that spring-run Chinook Salmon production in the Sacramento River would be  
19 similar under Alternative 1 and the No Action Alternative, although production  
20 under Alternative 1 could be over 10 percent greater than under the No Action  
21 Alternative in critical dry years. The analyses attempting to assess the effects on  
22 routing, entrainment, and salvage of juvenile salmonids in the Delta suggest that  
23 salvage (as an indicator of potential losses of juvenile salmon at the export  
24 facilities) of Sacramento River-origin Chinook Salmon is predicted to be higher  
25 under Alternative 1 relative to No Action Alternative in every month.

26 In Clear Creek and the Feather River, the analysis of the effects of Alternative 1  
27 and the No Action Alternative for spring-run Chinook Salmon relied on output  
28 from the WUA analysis and water temperature output for Clear Creek at Igo, and  
29 in the Feather River low flow channel and downstream of the Thermalito  
30 complex. The WUA analysis suggests that there would be little difference in the  
31 availability of spawning and rearing habitat in Clear Creek. The temperature  
32 model outputs suggest that thermal conditions and effects on each of the spring-  
33 run Chinook Salmon life stages generally would be similar under both scenarios  
34 in Clear Creek and the Feather River, although water temperatures could be  
35 somewhat more suitable for spring-run Chinook Salmon holding and  
36 spawning/egg incubation in the Feather River under Alternative 1. This  
37 conclusion is supported by the water temperature threshold exceedance analysis  
38 that indicated that water temperature thresholds for spawning and egg incubation  
39 would be exceeded slightly less frequently under Alternative 1 than under the No  
40 Action Alternative in Clear Creek and the Feather River. The water temperature  
41 threshold for rearing spring-run Chinook Salmon would also be exceeded slightly  
42 less frequently in the Feather River under Alternative 1. Because of the inherent  
43 uncertainty associated with the resolution of the temperature model (average  
44 monthly outputs), the slightly greater likelihood of exceeding water temperature  
45 thresholds under Alternative 1 could increase the potential for adverse effects on

1 the spring-run Chinook Salmon populations in the Feather River. Given the  
2 similarity of the results, Alternative 1 and the No Action Alternative are likely to  
3 have similar effects on the spring-run Chinook Salmon population in Clear Creek.

4 These model results suggest that overall, effects on spring-run Chinook Salmon  
5 could be slightly less adverse under Alternative 1 than the No Action Alternative.  
6 This potential distinction between the two scenarios, however, may be partially  
7 offset by the benefits of implementation of fish passage under the No Action  
8 Alternative intended to address the limited availability of suitable habitat for  
9 spring-run Chinook Salmon in the Sacramento River reaches downstream of  
10 Keswick Dam. This potential beneficial effect and its magnitude would depend  
11 on the success of the fish passage program. In addition, RPA actions intended to  
12 increase the efficiency of the Tracy and Skinner Fish Collection Facilities could  
13 improve the overall salvage survival of spring-run Chinook Salmon under the No  
14 Action Alternative.

15 Thus, it is concluded that the potential for adverse effects on spring-run Chinook  
16 Salmon under Alternative 1 would be greater than under the No Action  
17 Alternative, principally because Alternative 1 does not include a strategy to  
18 address water temperatures critical to spring-run Chinook Salmon sustainability  
19 over the long term with climate change by 2030.

#### 20 *Fall-Run Chinook Salmon*

21 Changes in operations that influence temperature and flow conditions in the  
22 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
23 Whiskeytown Dam, Feather River downstream of Oroville Dam and American  
24 River downstream of Nimbus could affect fall-run Chinook Salmon. The  
25 following describes those changes and their potential effects.

#### 26 *Changes in Water Temperature*

27 Changes in water temperature could affect fall-run Chinook Salmon in the  
28 Sacramento, Feather, and American rivers, and Clear Creek. The following  
29 describes temperature conditions in those water bodies.

#### 30 *Sacramento River*

31 Long-term average monthly water temperature in the Sacramento River at  
32 Keswick Dam under Alternative 1 would generally be similar (less than 0.5°F  
33 difference) to water temperatures under the No Action Alternative. An exception  
34 is during September and October of critical dry years when water temperatures  
35 could be up to 1.1°F and 0.8°F lower, respectively, under Alternative 1 as  
36 compared to the No Action Alternative and up to 1°F warmer in September of  
37 wetter years (Appendix 6B). A similar pattern in temperature differences  
38 generally would be exhibited at downstream locations along the Sacramento River  
39 (i.e., Ball's Ferry Jelly's Ferry, Bend Bridge, Red Bluff, Hamilton City, and  
40 Knights Landing), with temperature differences between scenarios at Knights  
41 Landing progressively increasing (up to 0.9°F cooler) in June and up to 4.6°F  
42 warmer in September during wetter years under Alternative 1 relative to the No  
43 Action Alternative.

1 Overall, the temperature differences between Alternative 1 and the No Action  
2 Alternative would be relatively minor (less than 0.5°F) and likely would have  
3 little effect on fall-run Chinook Salmon in the Sacramento River. The somewhat  
4 higher water temperatures in September of wetter years may increase the  
5 likelihood of adverse effects on early spawning fall-run Chinook Salmon under  
6 Alternative 1, although the reduced water temperatures in September of critical  
7 dry years under Alternative 1 may decrease the likelihood of adverse effects on  
8 fall-run Chinook Salmon spawning in this water year type.

9 *Clear Creek*

10 Average monthly water temperatures in Clear Creek at Igo under Alternative 1  
11 relative to the No Action Alternative are generally predicted to be similar (less  
12 than 0.5°F) from September through April and June through August  
13 (Appendix 6B, Table B-3-1). Average monthly water temperatures during May  
14 under Alternative 1 would be higher by up to 0.8°F than under the No Action  
15 Alternative. Average monthly temperatures at the confluence with the  
16 Sacramento River would exhibit a similar pattern, although temperatures in the  
17 creek would be slightly higher in general.

18 Under Alternative 1, temperature conditions at Igo would be similar to  
19 temperature conditions under the No Action Alternative. However, these  
20 temperature outputs represent conditions at Igo, a location upstream of most  
21 fall-run Chinook Salmon spawning and rearing. Water temperatures where most  
22 fall-run Chinook Salmon inhabit the creek would be somewhat higher as indicated  
23 by average monthly temperatures at the confluence with the Sacramento River,  
24 although these temperatures would be similar under Alternative 1 and the No  
25 Action Alternative. Overall, thermal conditions for fall-run Chinook Salmon in  
26 Clear Creek would be similar under Alternative 1 and the No Action Alternative.

27 *Feather River*

28 Average monthly water temperature in the Feather River in the low flow channel  
29 generally were predicted to be similar (less than 0.5°F differences) under  
30 Alternative 1 and the No Action Alternative, except during November and  
31 December when average monthly water temperatures could be up to 1.4°F lower  
32 in some water year types (Appendix 6B, Table B-20-1). Average monthly water  
33 temperatures in September under Alternative 1 could be up to 1.3°F warmer than  
34 under the No Action Alternative in wetter years. Although temperatures in the  
35 river would become progressively higher in the downstream directions, the  
36 differences between Alternative 1 and No Action Alternative would exhibit a  
37 similar pattern at the downstream locations (Robinson Riffle and Gridley Bridge),  
38 with water temperatures differences between Alternative 1 and the No Action  
39 Alternative generally decreasing in most water year types. However, water  
40 temperatures under Alternative 1 were predicted to be somewhat (0.7°F to 1.6°F)  
41 warmer on average and up to 4.0°F warmer at the confluence with the Sacramento  
42 River from July to September in wetter years (Appendix 6B, Table B-23-1).

1 Overall, the temperature differences in the Feather River between Alternative 1  
 2 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
 3 likely would have little effect on fall-run Chinook Salmon in the Feather River.  
 4 The slightly lower water temperatures in November and December under  
 5 Alternative 1 would likely have little effect on fall-run Chinook Salmon as water  
 6 temperatures in the Feather River are typically low during this time period. The  
 7 somewhat higher water temperatures in September of wetter years may increase  
 8 the likelihood of adverse effects on early spawning fall-run Chinook Salmon,  
 9 although the decreased temperatures in September of critical dry years under  
 10 Alternative 1 may reduce the likelihood of adverse effects on fall-run Chinook  
 11 Salmon spawning in this water year type.

#### 12 *American River*

13 Long-term average monthly water temperatures in the American River at Nimbus  
 14 Dam under Alternative 1 generally would be similar (differences less than 0.5°F)  
 15 to the No Action Alternative, with the exception of during June and August, when  
 16 temperatures under Alternative 1 could be as much as 0.9°F lower in below  
 17 normal years (Appendix 6B, Table B-12-1). This pattern generally would persist  
 18 downstream to Watt Avenue and the mouth, although temperatures under  
 19 Alternative 1 would be up to 1.6°F and 2.0°F lower, respectively, than under the  
 20 No Action Alternative in June. In addition, average monthly water temperatures  
 21 at the mouth generally would be higher under Alternative 1 than the No Action  
 22 Alternative in September of wetter years when water temperatures under  
 23 Alternative 1 could be up to 1.7°F warmer (Appendix 6B, Table B-14-1).

24 Overall, the temperature differences in the American River between Alternative 1  
 25 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
 26 likely would have little effect on fall-run Chinook Salmon in the American River.  
 27 The slightly lower water temperatures in June and August in some water year  
 28 types under Alternative 1 may decrease the likelihood of adverse effects on  
 29 fall-run Chinook Salmon rearing in the American River if they are present. The  
 30 slightly higher water temperatures during September under Alternative 1 would  
 31 have little effect on fall-run Chinook Salmon spawning in the American River  
 32 because most spawning occurs later in November.

#### 33 *Changes in Exceedances of Water Temperature Thresholds*

34 Changes in water temperature could result in the exceedance of water  
 35 temperatures that are protective of fall-run Chinook Salmon in the Sacramento  
 36 River, Clear Creek, Feather River, and American River. The following describes  
 37 the extent of those exceedances for each of those water bodies.

#### 38 *Sacramento River*

39 Average monthly water temperatures under both Alternative 1 and the No Action  
 40 Alternative indicate exceedances of the water temperature threshold of 56°F  
 41 established in the Sacramento River at Red Bluff for Chinook Salmon spawning  
 42 and egg incubation in October, November, and again in April. There would be no  
 43 exceedances of the threshold from December to March under both Alternative 1  
 44 and the No Action Alternative. In the months when the greatest frequency of

1 exceedances occur (October, November, and April), model results generally  
2 indicate less frequent exceedances (by up to 4 percent in October) under  
3 Alternative 1 than under the No Action Alternative. Temperature conditions in  
4 the Sacramento River under Alternative 1 could be less likely to affect fall-run  
5 Chinook Salmon spawning and egg incubation than under the No Action  
6 Alternative because of the reduced frequency of exceedance of the 56°F threshold  
7 in October, November, and April. However, this difference may be partially  
8 offset if water temperature management and fish passage measures associated  
9 with 2009 NMFS BO RPA under the No Action Alternative are successful.

10 *Clear Creek*

11 Fall-run Chinook Salmon spawning in lower Clear Creek typically occurs during  
12 October through December (USFWS 2015). Average monthly water  
13 temperatures at Igo during this period generally fall below 56°F, except in  
14 October. Under Alternative 1, the 56°F threshold would be exceeded in October  
15 about 10 percent of the time as compared to 12 percent under the No Action  
16 Alternative (Appendix 9N). At the confluence with the Sacramento River,  
17 average monthly water temperatures in October would be warmer, with the 56°F  
18 threshold exceeded slightly less frequently under Alternative 1 compared to the  
19 No Action Alternative (Appendix 6B, Figure B-4-1). During November and  
20 December, average monthly water temperatures generally would remain below  
21 56°F at both locations (Appendix 6B, Figure B-4-2 and B-4-3). Temperature  
22 conditions in Clear Creek under Alternative 1 could be less likely to affect  
23 fall-run Chinook Salmon spawning and egg incubation than under the No Action  
24 Alternative because of the reduced frequency of exceedance of the 56°F threshold  
25 in October.

26 For fall-run Chinook Salmon rearing (January through August), the average  
27 monthly temperatures at Igo would likely remain below the 60°F rearing  
28 threshold in all months. Downstream at the mouth of Clear Creek, average  
29 monthly water temperatures would exceed the 60°F threshold often during the  
30 summer, but the frequency of exceedance would be similar under Alternative 1  
31 and the No Action Alternative (Appendix 6B). Temperature conditions for fall-  
32 run Chinook Salmon rearing in Clear Creek would be similar under Alternative 1  
33 and the No Action Alternative.

34 *Feather River*

35 Average monthly water temperatures under both Alternative 1 and No Action  
36 Alternative would exceed the water temperature threshold of 56°F established in  
37 the Feather River at Gridley Bridge for fall-run Chinook Salmon spawning and  
38 egg incubation during some months, particularly in October, November, March,  
39 and April, when this temperature threshold would be exceeded frequently  
40 (Appendix 6B, Table B-22-4). The frequency of exceedance would be greatest in  
41 October, when average monthly temperatures under both Alternative 1 and the No  
42 Action Alternative would be above the threshold in nearly every year. The  
43 magnitude of the exceedances would be high as well, with average monthly  
44 temperatures in October reaching about 68°F. Similarly, the threshold would be  
45 exceeded under both Alternative 1 and the No Action Alternative about

1 85 percent of the time in April. The differences between Alternative 1 and the No  
 2 Action Alternative, however, would be relatively small, with water temperatures  
 3 under Alternative 1 generally exceeding the spawning temperature threshold  
 4 about 1-2 percent less frequently than under the No Action Alternative during the  
 5 October through April period. Temperature conditions in the Feather River under  
 6 Alternative 1 could be less likely to affect fall-run Chinook Salmon spawning and  
 7 egg incubation than under the No Action Alternative because of the reduced  
 8 frequency of exceedance of the 56°F threshold from October through April.

#### 9 *Changes in Egg Mortality*

10 Water temperatures influence the viability of incubating fall-run Chinook Salmon  
 11 eggs. The following describes the differences in egg mortality for the  
 12 Sacramento, Feather, and American rivers.

#### 13 *Sacramento River*

14 For fall-run Chinook Salmon in the Sacramento River, the long-term average egg  
 15 mortality rate is predicted to be around 17 percent, with higher mortality rates (in  
 16 excess of 35 percent) occurring in critical dry years under Alternative 1.  
 17 Predicted egg mortality would similar under Alternative 1 and the No Action  
 18 Alternative in all water year types (Appendix 9C, Table B-1).

#### 19 *Feather River*

20 For fall-run Chinook Salmon in the Feather River, the long-term average egg  
 21 mortality rate is predicted to be relatively low (around 7 percent), with higher  
 22 mortality rates (around 17 percent) occurring in critical dry years under  
 23 Alternative 1. Predicted egg mortality would similar under Alternative 1 and the  
 24 No Action Alternative in all water year types (Appendix 9C, Table B-7).

#### 25 *American River*

26 For fall-run Chinook Salmon in the American River, the predicted long-term  
 27 average egg mortality rate is predicted to range from approximately 22 to  
 28 25 percent in all water year types under Alternative 1. The predicted egg  
 29 mortality rate would similar under Alternative 1 and the No Action  
 30 Alternative (Appendix 9C, Table B-6).

#### 31 *Changes in Weighted Usable Area*

32 Weighted usable area, which is influenced by flow, is a measure of habitat  
 33 suitability. The following describes changes in WUA for fall-run Chinook  
 34 Salmon in the Sacramento, Feather, and American rivers and Clear Creek.

#### 35 *Sacramento River*

36 As an indicator of the amount of suitable spawning habitat for fall-run Chinook  
 37 Salmon between Keswick Dam and Battle Creek, modeling results indicate that,  
 38 in general, there would be greater amounts of spawning habitat available in  
 39 September and November under Alternative 1 as compared to the No Action  
 40 Alternative. Fall-run spawning WUA would be similar in October and December,  
 41 under Alternative 1 and the No Action Alternative (Appendix 9E, Table C-11-4).  
 42 The increase in long-term average spawning WUA during September (prior to the  
 43 peak spawning period) under Alternative 1 would be relatively large (more than

1 20 percent) and around 6 percent higher in November. November is during the  
2 peak spawning period for fall-run Chinook Salmon in the Sacramento River.  
3 Results for the reach from Battle Creek to Deer Creek show the same pattern for  
4 changes in WUA for spawning fall-run Chinook Salmon between Alternative 1  
5 and the No Action Alternative (Appendix 9E, Table C-10-4). Overall, spawning  
6 habitat availability would be somewhat higher under Alternative 1 relative to the  
7 No Action Alternative.

8 Modeling results indicate that, in general, the amount of suitable fry rearing  
9 habitat available from December to March under Alternative 1 would be similar  
10 to the amount of fry rearing habitat available under the No Action  
11 Alternative (Appendix 9E, Table C-12-4).

12 Similar to the results for fry rearing WUA, modeling results indicate that, there  
13 would be similar amounts of suitable juvenile rearing habitat available during the  
14 juvenile rearing period from February to June under Alternative 1 and the No  
15 Action Alternative (Appendix 9E, Table C-13-4).

16 *Clear Creek*

17 As described above, flows in Clear Creek downstream of Whiskeytown Dam are  
18 not anticipated to differ under Alternative 1 relative to the No Action  
19 Alternative except in May due to the release of spring attraction flows in  
20 accordance with the 2009 NMFS BO under the No Action Alternative. Therefore,  
21 there would be no change in the amount of potentially suitable spawning and  
22 rearing habitat for fall-run Chinook Salmon (as indexed by WUA) available under  
23 Alternative 1 as compared to the No Action Alternative.

24 *Feather River*

25 As described above, Flows in the low flow channel of the Feather River are not  
26 anticipated to differ under Alternative 1 relative to the No Action Alternative.  
27 Therefore, there would be no change in the amount of potentially suitable  
28 spawning habitat for fall-run Chinook Salmon (as indexed by WUA) available  
29 under Alternative 1 as compared to the No Action Alternative. The majority of  
30 spawning activity by fall-run Chinook Salmon in the Feather River occurs in this  
31 reach with a lesser amount of spawning occurring downstream of the  
32 Thermalito Complex.

33 Modeling results indicate that, in general, there would be greater amounts of  
34 spawning habitat available in September under Alternative 1 as compared to the  
35 No Action Alternative; fall-run Chinook Salmon spawning WUA would be  
36 similar in October and November (the peak spawning months) and in December  
37 (after the peak spawning period) for fall-run Chinook Salmon in this reach  
38 (Appendix 9E, Table C-24-4). The increase in long-term average spawning WUA  
39 during September (prior to the peak spawning period) under Alternative 1 would  
40 be relatively large (more than 15 percent). Overall, spawning habitat availability  
41 would be similar under Alternative 1 and the No Action Alternative.

1 *American River*

2 Modeling results indicate that, in general, there would be similar amounts of  
3 spawning habitat available for fall-run Chinook Salmon in the American River  
4 from October through December under Alternative 1 as compared to the No  
5 Action Alternative (Appendix 9E, Table C-25-4).

6 *Changes in SALMOD Output*

7 SALMOD results indicate that pre-spawning mortality of fall-run Chinook  
8 Salmon eggs would be approximately 16 percent lower under Alternative 1,  
9 primarily due to reduced summer temperatures. Flow-related fall-run Chinook  
10 Salmon egg mortality would be increased by 8 percent under Alternative 1  
11 compared to the No Action Alternative. Conversely, temperature-related egg  
12 mortality would be 11 percent lower under Alternative 1 (Appendix 9D,  
13 Table B-1-4). Flow (habitat)-related fry mortality would be similar under  
14 Alternative 1 and the No Action Alternative. Temperature-related juvenile  
15 mortality would be approximately 21 percent lower under Alternative 1, while  
16 flow (habitat)-related mortality would be similar under Alternative 1 and the No  
17 Action Alternative. Overall, potential fall-run juvenile production would be  
18 similar under Alternative 1 and the No Action Alternative, but up to 12 percent  
19 greater than under the No Action Alternative in critical dry years (Appendix 9D,  
20 Table B-1-1).

21 *Changes in Delta Passage Model Output*

22 The Delta Passage Model predicted similar estimates of annual Delta survival  
23 across the 81 water year time period for fall-run between Alternative 1 and the No  
24 Action Alternative (Appendix 9J). Median Delta survival was 0.245 for  
25 Alternative 1 and 0.248 for the No Action Alternative.

26 *Changes in Delta Hydrodynamics*

27 Fall-run Chinook Salmon smolts are most abundant in the Delta during the  
28 months of April, May and June. At the junction of Georgiana Slough and the  
29 Sacramento River, median percent of time with positive velocity was similar  
30 under both Alternative 1 and No Action Alternative in the months of April, May  
31 and June (Appendix 9K). Near the confluence of the San Joaquin River and the  
32 Mokelumne River, the median proportion of positive velocities was slightly lower  
33 under Alternative 1 relative to No Action Alternative in April and May and  
34 similar in June. In Old River downstream of the facilities, the median proportion  
35 of positive velocities was substantially lower in April and May under  
36 Alternative 1 relative to No Action Alternative but became more similar in June  
37 (Appendix 9K). In Old River upstream of the facilities, the median proportion of  
38 positive velocities was slightly to moderately lower for Alternative 1 relative to  
39 No Action Alternative in April and May, respectively and slightly higher in June  
40 (Appendix 9K). On the San Joaquin River downstream of the Head of Old River,  
41 the median proportion of positive velocities was slightly to moderately higher  
42 under Alternative 1 relative to No Action Alternative in April and May,  
43 respectively, whereas the values were similar in June (Appendix 9K).

1                    *Changes in Junction Entrainment*

2    Entrainment at Georgiana Slough was similar under both Alternative 1 and the No  
3    Action Alternative in most months but was slightly higher under Alternative 1 in  
4    the month of June (Appendix 9L). Median entrainment probabilities at the Head  
5    of Old River were much lower under Alternative 1 relative to the No Action  
6    Alternative during April and May. The median entrainment probability was  
7    similar under both alternatives in the month of June. At the Turner Cut junction,  
8    median entrainment probabilities under Alternative 1 were slightly higher than  
9    under the No Action Alternative in June. During April and May, median  
10    entrainment probabilities were more divergent with moderately higher values for  
11    Alternative 1 relative to No Action Alternative. Overall, entrainment was slightly  
12    lower at the Columbia Cut junction relative to Turner Cut but patterns of  
13    entrainment between the two alternatives were similar. Patterns in entrainment  
14    probabilities at the Middle River and Old River junctions were similar to those  
15    observed at Columbia and Turner Cut junctions.

16                    *Changes in Salvage*

17    Salvage of Sacramento River-origin Chinook Salmon is predicted to be greater  
18    under Alternative 1 relative to No Action Alternative in every month  
19    (Appendix 9M). Fall-run smolts migrating through the Delta would be most  
20    susceptible in the months of April, May and June. Predicted values in April and  
21    May indicated a substantially increased fraction of fish salvaged under  
22    Alternative 1 relative to No Action Alternative. Predicted salvage was more  
23    similar in March but still higher under Alternative 1.

24                    *Summary of Effects on Fall-Run Chinook Salmon*

25    The multiple model and analysis outputs described above characterize the  
26    anticipated conditions for fall-run Chinook Salmon and their response to change  
27    under Alternative 1 and the No Action Alternative. For the purpose of analyzing  
28    effects on fall-run Chinook Salmon in the Sacramento River, greater reliance was  
29    placed on the outputs from the SALMOD model because it integrates the  
30    available information on temperature and flows to produce estimates of mortality  
31    for each life stage and an overall, integrated estimate of potential fall-run Chinook  
32    Salmon juvenile production. The output from SALMOD indicated that fall-run  
33    Chinook Salmon production would be similar in most water year types under  
34    Alternative 1 than under the No Action Alternative, and up to 12 percent greater  
35    than under the No Action Alternative in critical dry years.

36    The analyses attempting to assess the effects on routing, entrainment, and salvage  
37    of juvenile salmonids in the Delta suggest that salvage (as an indicator of  
38    potential losses of juvenile salmon at the export facilities) of Sacramento River-  
39    origin Chinook Salmon is predicted to be higher under Alternative 1 relative to  
40    No Action Alternative in every month.

41    In Clear Creek and the Feather and American rivers, the analysis of the effects of  
42    Alternative 1 and the No Action Alternative for fall-run Chinook Salmon relied  
43    on the WUA analysis for habitat and water temperature model output for the  
44    rivers at various locations downstream of the CVP and SWP facilities. The WUA

1 analysis indicated that the availability of spawning and rearing habitat in Clear  
2 Creek and spawning habitat in the Feather and American rivers would be similar  
3 under Alternative 1 and the No Action Alternative. The temperature model  
4 outputs for each of the fall-run Chinook Salmon life stages suggest that thermal  
5 conditions and effects on fall-run Chinook Salmon in all of these streams  
6 generally would be similar under both scenarios. The water temperature threshold  
7 exceedance analysis that indicated that the water temperature thresholds for  
8 fall-run Chinook Salmon spawning and egg incubation would be exceeded  
9 slightly less frequently in the Feather River and Clear Creek under Alternative 1  
10 and could reduce the potential for adverse effects on the fall-run Chinook Salmon  
11 populations in Clear Creek and the Feather River. Results of the analysis using  
12 Reclamation's salmon mortality model indicate that there would be little  
13 difference in fall-run Chinook Salmon egg mortality under Alternative 1 and the  
14 No Action Alternative.

15 These model results suggest that overall, effects on fall-run Chinook Salmon  
16 could be slightly less adverse under Alternative 1 than the No Action Alternative,  
17 with a small likelihood that fall-run Chinook Salmon production would be higher  
18 under Alternative 1 due to increased production potential in critical dry years.  
19 This potential distinction between the two scenarios, however, may be partially  
20 balanced by the benefits of implementation of fish passage under the No Action  
21 Alternative intended to address the limited availability of suitable habitat for  
22 winter-run and spring-run Chinook Salmon in the Sacramento River reaches  
23 downstream of Keswick Dam. This potential benefit, however, would only apply  
24 if passage is provided for adult fall-run Chinook Salmon that allows access to  
25 additional habitat. In addition, RPA actions under the No Action  
26 Alternative intended to increase the efficiency of the Tracy and Skinner Fish  
27 Collection Facilities could improve the overall salvage survival of fall-run  
28 Chinook Salmon.

29 The results of the numerical models suggest that Alternative 1 is less likely to  
30 result in adverse effects on fall-run Chinook Salmon than the No Action  
31 Alternative. However, discerning a meaningful difference between these two  
32 scenarios based on the quantitative results is not possible because of the similarity  
33 in results (generally differences less than 5 percent) and the inherent uncertainty  
34 of the models. In addition, adverse effects of the No Action Alternative could be  
35 balanced by the potentially beneficial effects resulting from the RPA actions  
36 evaluated qualitatively for the No Action Alternative. Overall, given the small  
37 differences in the numerical model results and the inherent uncertainty in the  
38 temperature model, as well as the potential for benefits associated with the RPA  
39 actions under the No Action Alternative, it is concluded that there would be no  
40 definitive difference in effects on fall-run Chinook Salmon between Alternative 1  
41 and the No Action Alternative.

#### 42 *Late Fall-Run Chinook Salmon*

43 Changes in operations that influence temperature and flow conditions in the  
44 Sacramento River downstream of Keswick Dam could affect late fall-run Chinook  
45 Salmon. The following describes those changes and their potential effects.

1                    *Changes in Water Temperature*

2 Long-term average monthly water temperature in the Sacramento River at  
3 Keswick Dam under Alternative 1 would generally be similar (less than 0.5°F  
4 difference) to water temperatures under the No Action Alternative. An exception  
5 is during September and October of critical dry years when water temperatures  
6 could be up to 1.1°F and 0.8°F lower, respectively, under Alternative 1 as  
7 compared to the No Action Alternative and up to 1°F warmer in September of  
8 wetter years (Appendix 6B, Table 5-5-1). A similar pattern in temperature  
9 differences generally would be exhibited at downstream locations along the  
10 Sacramento River (i.e., Ball's Ferry, Jelly's Ferry, Bend Bridge, Red Bluff,  
11 Hamilton City, and Knights Landing), with temperature differences between  
12 scenarios in June at Knights Landing progressively increasing (up to 0.9°F cooler)  
13 in June and up to 4.6°F warmer in September during wetter years under  
14 Alternative 1 relative to the No Action Alternative.

15 Overall, the temperature differences between Alternative 1 and the No Action  
16 Alternative would be relatively minor (less than 0.5°F) and likely would have  
17 little effect on late fall-run Chinook Salmon in the Sacramento River. The  
18 likelihood of adverse effects on late fall-run Chinook Salmon spawning and egg  
19 incubation would be similar under Alternative 1 and the No Action  
20 Alternative due to similar water temperatures during the January to May time  
21 period. Because late fall-run Chinook Salmon have an extended rearing period,  
22 the similar water temperatures during the summer under Alternative 1 and the No  
23 Action Alternative would have similar effects on rearing fry and juvenile late  
24 fall-run Chinook Salmon in the Sacramento River. The higher water temperatures  
25 under Alternative 1 in September of wetter years may increase the likelihood of  
26 adverse effects on fry and juvenile late fall-run Chinook Salmon in the  
27 Sacramento River during this limited time period.

28                    *Changes in Exceedances of Water Temperature Thresholds*

29 Average monthly water temperatures under both Alternative 1 and the No Action  
30 Alternative indicate exceedances of the water temperature threshold of 56°F  
31 established in the Sacramento River at Red Bluff for Chinook Salmon spawning  
32 and egg incubation in October, November, and again in April. There would be no  
33 exceedances of the threshold from December to March under both Alternative 1  
34 and the No Action Alternative. In April, model results indicate that water  
35 temperatures under Alternative 1 would exceed the threshold about 2 percent less  
36 frequently than under the No Action Alternative. Temperature conditions in the  
37 Sacramento River under Alternative 1 could be slightly less likely to result in  
38 adverse effects on late fall-run Chinook Salmon spawning and egg incubation  
39 than under the No Action Alternative because of the reduced frequency of  
40 exceedance of the 56°F threshold in April.

41                    *Changes in Egg Mortality*

42 For late fall-run Chinook Salmon in the Sacramento River, the long-term average  
43 egg mortality rate is predicted to range from approximately 2 to nearly 5 percent  
44 in all water year types under Alternative 1. Overall, egg mortality would be

1 similar under Alternative 1 and the No Action Alternative (Appendix 9C,  
2 Table B-2).

3 *Changes in Weighted Usable Area*

4 Modeling results indicate that there would be similar amounts of spawning habitat  
5 available for late fall-run Chinook Salmon in the Sacramento River from January  
6 through April under Alternative 1 and the No Action Alternative (Appendix 9E,  
7 Table C-14-4). Modeling results also indicate that there would be similar  
8 amounts of suitable late fall-run Chinook Salmon fry rearing habitat available  
9 from April to June under Alternative 1 and the No Action  
10 Alternative (Appendix 9E, Table C-15-4).

11 A substantial fraction of late fall run Chinook Salmon juveniles oversummer in  
12 the Sacramento River before emigrating, which allows them to avoid predation  
13 through both their larger size and greater swimming ability. One implication of  
14 this life history strategy is that rearing habitat is most likely the limiting factor for  
15 late-fall-run Chinook Salmon, especially if availability of cool water determines  
16 the downstream extent of spawning habitat for late-fall-run salmon. Modeling  
17 results indicate that, there would generally be similar amounts of suitable juvenile  
18 rearing habitat available from December through August under Alternative 1 and  
19 the No Action Alternative. There could be an increase in the amount of late fall-  
20 run Chinook Salmon juvenile rearing WUA in September and November of up to  
21 15 percent (Appendix 9E, Table C-16-4). Overall, late fall-run juvenile rearing  
22 habitat availability would be similar under Alternative 1 and the No Action  
23 Alternative.

24 *Changes in SALMOD Output*

25 SALMOD results indicate that potential juvenile production would be similar  
26 under Alternative 1 and the No Action Alternative (Appendix 9D, Table B-2-1).

27 *Changes in Delta Passage Model Output*

28 For late fall-run Chinook Salmon, through-Delta survival was predicted to be  
29 slightly lower under Alternative 1 relative to the No Action Alternative for all  
30 81 years simulated by the Delta Passage Model (Appendix 9J). Median Delta  
31 survival across all years was 0.199 for Alternative 1 and 0.244 for the No Action  
32 Alternative.

33 *Changes in Delta Hydrodynamics*

34 The late fall run Chinook migration period overlaps with winter-run. See the  
35 section on hydrodynamic analysis for winter run Chinook Salmon for potential  
36 effects on late fall-run Chinook Salmon.

37 *Changes in Junction Entrainment*

38 Entrainment probabilities for late fall-run Chinook Salmon are assumed to mimic  
39 that of winter-run Chinook Salmon due to the overlap in timing. See the section  
40 on winter-run Chinook Salmon entrainment for potential effects on late fall-run  
41 Chinook Salmon.

1            *Changes in Salvage*

2 Salvage of late fall-run Chinook Salmon is assumed to mimic that of winter-run  
3 Chinook Salmon due to the overlap in timing. See the section on winter-run  
4 Chinook Salmon entrainment for potential effects on late fall-run Chinook  
5 Salmon.

6            *Summary of Effects on Late Fall-Run Chinook Salmon*

7 The multiple model and analysis outputs described above characterize the  
8 anticipated conditions for late fall-run Chinook Salmon and their response to  
9 change under Alternative 1 and the No Action Alternative. For the purpose of  
10 analyzing effects on late fall-run Chinook Salmon and developing conclusions,  
11 greater reliance was placed on the outputs from the SALMOD model because it  
12 integrates the available information on temperature and flows to produce  
13 estimates of mortality for each life stage and an overall, integrated estimate of  
14 potential fall-run Chinook Salmon juvenile production. The output from  
15 SALMOD indicated that late fall-run Chinook Salmon production would be  
16 similar under Alternative 1 and the No Action Alternative. The analyses  
17 attempting to assess the effects on routing, entrainment, and salvage of juvenile  
18 salmonids in the Delta suggest that salvage (as an indicator of potential losses of  
19 juvenile salmon at the export facilities) of Sacramento River-origin Chinook  
20 Salmon is predicted to be higher under Alternative 1 relative to No Action  
21 Alternative in every month. Actions under the No Action Alternative intended to  
22 increase the efficiency of the Tracy and Skinner Fish Collection Facilities could  
23 improve the overall salvage survival of late fall-run Chinook Salmon.

24 Although survival in the Delta may be lower, given the similarity in the  
25 SALMOD outputs, it is likely that Alternative 1 and the No Action  
26 Alternative would have similar effects on fall-run Chinook Salmon.

27            *Steelhead*

28 Changes in operations that influence temperature and flow conditions that could  
29 affect steelhead. The following describes those changes and their potential  
30 effects.

31            *Changes in Water Temperature*

32 Changes in water temperature could affect steelhead in the Sacramento, Feather,  
33 and American rivers, and Clear Creek. The following describes temperature  
34 conditions in those water bodies.

35            *Sacramento River*

36 Long-term average monthly water temperature in the Sacramento River at  
37 Keswick Dam under Alternative 1 would generally be similar (less than 0.5°F  
38 difference) to water temperatures under the No Action Alternative. An exception  
39 is during September and October of critical dry years when water temperatures  
40 could be up to 1.1°F and 0.8°F lower, respectively, under Alternative 1 as  
41 compared to the No Action Alternative and up to 1°F warmer in September of  
42 wetter years (Appendix 6B, Table 5-5-1). A similar pattern of changes in  
43 temperature generally would be exhibited downstream at Ball's Ferry, Jelly's

1 Ferry, Bend Bridge and Red Bluff, with average monthly temperature differences  
2 between scenarios progressively decreasing, except in September (up to a 3.2°F  
3 warmer at Red Bluff) during wetter years (Appendix 6B, Table B-9-1).

4 Overall, the temperature differences between Alternative 1 and the No Action  
5 Alternative would be relatively minor (less than 0.5°F) and likely would have  
6 little effect on steelhead in the Sacramento River. Based on the life history timing  
7 for steelhead, the slightly lower water temperatures in September and October of  
8 drier years under Alternative 1 may reduce the likelihood of adverse effects on  
9 steelhead adults migrating upstream in the Sacramento River. The higher water  
10 temperatures in September of wetter years under Alternative 1 may increase the  
11 likelihood of adverse effects on steelhead migration compared to the No Action  
12 Alternative.

13 *Clear Creek*

14 Average monthly water temperatures in Clear Creek at Igo under Alternative 1 are  
15 generally predicted to be similar to (less than 0.5°F differences) water  
16 temperatures under the No Action Alternative from September through April and  
17 June through August (Appendix 6B, Table B-3-1). Average monthly water  
18 temperatures during May under Alternative 1 could be higher by up to 0.8°F than  
19 under the No Action Alternative in all water year types. Overall, thermal  
20 conditions for steelhead in Clear Creek would be similar under Alternative 1 and  
21 the No Action Alternative.

22 *Feather River*

23 Average monthly water temperature in the Feather River in the low flow channel  
24 generally were predicted to be similar (less than 0.5°F differences) under  
25 Alternative 1 and the No Action Alternative, except during November and  
26 December when average monthly water temperatures could be up to 1.4°F lower  
27 in some water year types (Appendix 6B, Table B-20-1). Average monthly water  
28 temperatures in September under Alternative 1 could be up to 1.3°F warmer than  
29 under the No Action Alternative in wetter years. Although temperatures in the  
30 river generally become progressively higher in the downstream direction, the  
31 differences between Alternative 1 and the No Action Alternative exhibit a similar  
32 pattern at the downstream locations (Robinson Riffle and Gridley Bridge), with  
33 water temperature differences between Alternative 1 and the No Action  
34 Alternative generally decreasing in most water year types. Water temperatures  
35 under Alternative 1 are predicted to be somewhat (0.7°F to 1.6°F) warmer on  
36 average and up to 4.0°F warmer at the confluence with Sacramento River from  
37 July to September in wetter years than under the No Action Alternative.

38 Overall, the temperature differences in the Feather River between Alternative 1  
39 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
40 likely would have little effect on steelhead in the Feather River. The slightly  
41 lower water temperatures in November and December under Alternative 1 would  
42 likely have little effect on adult steelhead migration as water temperatures in the  
43 Feather River are typically low during this time period. The somewhat higher  
44 water temperatures in September of wetter years may increase the likelihood of

1 adverse effects on adult steelhead migrating upstream and juveniles rearing in the  
2 Feather River, although the decreased temperatures in September of critical dry  
3 years under Alternative 1 may decrease the likelihood of adverse effects on  
4 migrating and rearing steelhead in this water year type.

5 *American River*

6 Average monthly water temperatures in the American River at Nimbus Dam  
7 under Alternative 1 generally would be similar (differences less than 0.5°F) to the  
8 No Action Alternative, with the exception of during June and August, when  
9 temperatures under Alternative 1 could be as much as 0.9°F lower in below  
10 normal years. This pattern generally would persist downstream to Watt Avenue  
11 and the mouth, although temperatures under Alternative 1 would be up to 1.6°F  
12 and 2.0°F lower, respectively, than under the No Action Alternative in June. In  
13 addition, average monthly water temperatures at the mouth generally would be  
14 higher under Alternative 1 than the No Action Alternative in September of wetter  
15 years when water temperatures under Alternative 1 could be up to 1.7°F warmer.

16 Overall, the temperature differences between Alternative 1 and the No Action  
17 Alternative would be relatively minor (less than 0.5°F) and likely would have  
18 little effect on steelhead in the American River. The slightly cooler water  
19 temperatures in June and August under Alternative 1 may reduce the likelihood of  
20 adverse effects on steelhead rearing in the American River compared to the No  
21 Action Alternative.

22 *Changes in Exceedances of Water Temperature Thresholds*

23 Changes in water temperature could result in the exceedance of established water  
24 temperature thresholds for steelhead in the Sacramento River, Clear Creek, and  
25 Feather River. The following describes the extent of those exceedance for each of  
26 those streams.

27 *Sacramento River*

28 Steelhead spawning in the mainstem Sacramento River generally occurs in the  
29 upper reaches from Keswick Dam downstream to near Balls Ferry, with most  
30 spawning concentrated near Redding. Most steelhead, however, spawn in  
31 tributaries to the Sacramento River. Spawning generally takes place in the  
32 January through March period when water temperatures in the river generally do  
33 not exceed 52°F under either Alternative 1 or the No Action Alternative. While  
34 there are no established temperature thresholds for steelhead rearing in the  
35 mainstem Sacramento River, average monthly temperatures when fry and juvenile  
36 steelhead are in the river would generally remain below 56°F at Balls Ferry  
37 except in August and September when this water temperature would be exceeded  
38 30 to 40 percent of the time under both the No Action Alternative and Second  
39 Basis of Comparison. However, water temperatures in the Sacramento River at  
40 Balls Ferry would exceed 56°F about 10 percent more often in September under  
41 Alternative 1. Overall, thermal conditions for steelhead in the Sacramento River  
42 would be similar under Alternative 1 and the No Action Alternative.

1                    *Clear Creek*

2 While there are no established temperature thresholds for steelhead spawning in  
3 Clear Creek, average monthly water temperatures in the river generally would not  
4 exceed 48°F during the spawning period (December to April) under Alternative 1  
5 and the No Action Alternative. Similarly, while there are no established  
6 temperature thresholds for steelhead rearing in Clear Creek, average monthly  
7 temperatures in most months of the year would not exceed 56°F at Igo under both  
8 alternatives. Overall, thermal conditions for steelhead in Clear Creek would be  
9 similar under Alternative 1 and the No Action Alternative.

10                    *Feather River*

11 Average monthly water temperatures under both Alternative 1 and the No Action  
12 Alternative would on occasion exceed the water temperature threshold of 56°F  
13 established in the Feather River at Robinson Riffle for steelhead spawning and  
14 incubation during some months, particularly in October and November, and  
15 March and April, when temperature thresholds could be exceeded frequently  
16 (Appendix 9N). There would be a 1 percent exceedance of the 56°F threshold in  
17 December under the No Action Alternative and no exceedances of the 56°F  
18 threshold from December through February under Alternative 1. However, the  
19 differences in the frequency of exceedance between Alternative 1 and No Action  
20 Alternative during March and April would be relatively small with water  
21 temperatures under Alternative 1 exceeding the threshold about 2 percent more  
22 frequently in March (20 percent) and the same exceedance frequency (75 percent)  
23 as the No Action Alternative in April.

24 The established water temperature threshold of 63°F for rearing from May  
25 through August would be exceeded often under both Alternative 1 and the No  
26 Action Alternative in May and June, but not at all in July and August. Water  
27 temperatures under Alternative 1 would exceed the rearing temperature threshold  
28 about 9 percent less frequently than under the No Action Alternative in May, but  
29 no more frequently in June. Temperature conditions in the Feather River under  
30 Alternative 1 could be less likely to affect steelhead spawning and rearing than  
31 under the No Action Alternative because of the reduced frequency of exceedance  
32 of the 56°F spawning threshold in March and the increased frequency of  
33 exceedance of the 63°F rearing threshold in May.

34                    *American River*

35 In the American River, the water temperature threshold for steelhead rearing  
36 (May through October) is 65°F at the Watt Avenue Bridge. Average monthly  
37 water temperatures would exceed this threshold often under both Alternative 1  
38 and No Action Alternative, especially in the July through September period when  
39 the threshold is exceeded nearly all of the time. In addition, the magnitude of the  
40 exceedance would be high, with average monthly water temperatures sometimes  
41 higher than 76°F. The differences in exceedance frequency between Alternative 1  
42 and No Action Alternative, however, would be relatively small and only occur in  
43 June (1 percent more frequent exceedance under Alternative 1), and in September,  
44 when average monthly water temperatures under Alternative 1 would exceed 65°F

1 about 7 percent more frequently than under the No Action Alternative.  
2 Temperature conditions in the American River under Alternative 1 could be more  
3 likely to result in adverse effects on steelhead rearing than under the No Action  
4 Alternative because of the increased frequency of exceedance of the 65°F rearing  
5 threshold.

6 *Changes in Weighted Usable Area*

7 The following describes changes in WUA for steelhead in the Sacramento,  
8 Feather, and American rivers and Clear Creek.

9 *Sacramento River*

10 Modeling results indicate that, in general, there would be similar amounts of  
11 suitable steelhead spawning habitat available from December through March  
12 under Alternative 1 and the No Action Alternative (Appendix 9E, Table C-20-4).

13 *Clear Creek*

14 As described above, flows in Clear Creek downstream of Whiskeytown Dam are  
15 not anticipated to differ under Alternative 1 relative to the No Action  
16 Alternative except in May due to the release of spring attraction flows in  
17 accordance with the 2009 NMFS BO under the No Action Alternative. Therefore,  
18 there would be no change in the amount of potentially suitable spawning and  
19 rearing habitat for steelhead (as indexed by WUA) available under Alternative 1  
20 as compared to the No Action Alternative.

21 *Feather River*

22 Flows in the low flow channel of the Feather River are not anticipated to differ  
23 under Alternative 1 relative to the No Action Alternative. Therefore, there would  
24 be no change in the amount of potentially suitable spawning habitat for steelhead  
25 (as indexed by WUA) available under Alternative 1 as compared to the No Action  
26 Alternative. The majority of spawning activity by steelhead in the Feather River  
27 occurs in this reach with a lesser amount of spawning occurring downstream of  
28 the Thermalito Complex.

29 Modeling results indicate that, in general, there would be similar amounts of  
30 spawning habitat for steelhead in the Feather River downstream of Thermalito  
31 available from December through April under Alternative 1 and the No Action  
32 Alternative (Appendix 9E, Table C-22-4).

33 *American River*

34 Modeling results indicate that, in general, there would be similar amounts of  
35 spawning habitat for steelhead in the American River downstream of Nimbus  
36 Dam available from December through April under Alternative 1 and the No  
37 Action Alternative.

38 *Summary of Effects on Steelhead*

39 The multiple model and analysis outputs described above characterize the  
40 anticipated conditions for steelhead and their response to change under  
41 Alternative 1 and the No Action Alternative. The analysis of the effects of  
42 Alternative 1 and the No Action Alternative for steelhead relied on the WUA

1 analysis for habitat and water temperature model output for the rivers at various  
2 locations downstream of the CVP and SWP facilities.

3 The WUA analysis indicated that the availability of steelhead spawning and  
4 rearing habitat in Clear Creek and steelhead spawning habitat in the Sacramento,  
5 Feather and American rivers would be similar under Alternative 1 and the No  
6 Action Alternative. The temperature model outputs for each of the steelhead life  
7 stages suggest that thermal conditions and effects on steelhead in all of these  
8 streams generally would be similar under both scenarios. This conclusion is  
9 supported by the water temperature threshold exceedance analysis that indicated  
10 that the water temperature thresholds for steelhead spawning and egg incubation  
11 would be exceeded less frequently in the Feather River under Alternative 1. The  
12 water temperature threshold for steelhead rearing would also be exceeded less  
13 frequently in the Feather River and could reduce the potential for adverse effects  
14 on the steelhead population in the Feather River.

15 The numerical model results suggest that overall, effects on steelhead could be  
16 slightly less adverse under Alternative 1 than the No Action Alternative,  
17 particularly in the Feather River. Implementation of the fish passage program  
18 under the No Action Alternative intended to address the limited availability of  
19 suitable habitat for steelhead in the Sacramento River reaches downstream of  
20 Keswick Dam and in the American River could provide a benefit to Central  
21 Valley steelhead in the Sacramento and American rivers. This is particularly  
22 important in light of anticipated increases in water temperature associated with  
23 climate change in 2030. In addition to fish passage, preparation and  
24 implementation of an HGMP for steelhead at the Nimbus Fish Hatchery and  
25 actions under the No Action Alternative intended to increase the efficiency of the  
26 Tracy and Skinner Fish Collection Facilities could benefit steelhead under the No  
27 Action Alternative in comparison to Alternative 1. Thus, on balance and over the  
28 long term, the adverse effects on steelhead under Alternative 1 would be greater  
29 than those under the No Action Alternative.

### 30 *Green Sturgeon*

31 The effects on Green Sturgeon were analyzed by comparing changes in water  
32 temperature and the frequency of temperature threshold exceedance between  
33 Alternative 1 and the No Action Alternative. In addition, potential effects on  
34 Green Sturgeon during the Delta portion of their life cycle were evaluated based  
35 on changes in Delta outflow. The effects are described and summarized below.

### 36 *Changes in Water Temperature*

37 The effects of Alternative 1 compared to the No Action Alternative on Green  
38 Sturgeon were analyzed based on water temperature model outputs and  
39 comparisons of the frequency of water temperature threshold exceedances in the  
40 Sacramento and Feather rivers.

### 41 *Sacramento River*

42 As described previously, long-term average monthly water temperature in the  
43 Sacramento River at Keswick Dam under Alternative 1 would generally be  
44 similar (less than 0.5°F difference) to water temperatures under the No Action

1 Alternative An exception is during September and October of critical dry years  
2 when water temperatures could be up to 1.1°F and 0.8°F lower, respectively,  
3 under Alternative 1 as compared to the No Action Alternative and up to 1°F  
4 warmer in September of wetter years (Appendix 6B). A similar pattern in  
5 temperature differences generally would be exhibited at downstream locations  
6 along the Sacramento River (i.e., Ball's Ferry Jelly's Ferry, Bend Bridge, Red  
7 Bluff, Hamilton City, and Knights Landing), with temperature differences  
8 between scenarios at Knights Landing progressively increasing (up to 0.9°F  
9 cooler) in June and up to 4.6°F warmer in September during wetter years under  
10 Alternative 1 relative to the No Action Alternative.

11 Overall, the temperature differences between Alternative 1 and the No Action  
12 Alternative would be relatively minor (less than 0.5°F) and likely would have  
13 little effect on Green Sturgeon. Increased temperatures in September are likely  
14 not to be lethal, but may increase growth of juvenile green sturgeon if food was  
15 not limiting.

16 *Feather River*

17 Average monthly water temperature in the Feather River in the low flow channel  
18 generally were predicted to be similar (less than 0.5°F differences) under  
19 Alternative 1 and the No Action Alternative, except during November and  
20 December when average monthly water temperatures would be up to 1.4°F lower  
21 in some water year types (Appendix 6B, Table B-20-1). Average monthly water  
22 temperatures in September under Alternative 1 could be up to 1.3°F warmer than  
23 under the No Action Alternative in wetter years.

24 Although temperatures in the river would become progressively higher in the  
25 downstream directions, the differences between Alternative 1 and the No Action  
26 Alternative would exhibit a similar pattern at the downstream locations (Robinson  
27 Riffle and Gridley Bridge), with temperatures differences between Alternative 1  
28 and the No Action Alternative generally decreasing in most water year types.  
29 However, water temperatures under Alternative 1 were predicted to be somewhat  
30 (0.7°F to 1.6°F) warmer on average and up to 4.0°F warmer at the confluence  
31 with the Sacramento River from July to September in wetter years (Appendix 6B,  
32 Table B-23-1).

33 Overall, the temperature differences between Alternative 1 and the No Action  
34 Alternative would be relatively minor (less than 0.5°F) and likely would have  
35 little effect on Green Sturgeon in the Feather River.

36 *Changes in Exceedances of Water Temperature Thresholds*

37 Changes in water temperature could result in the exceedance of established water  
38 temperature thresholds for Green Sturgeon in the Sacramento and Feather rivers.  
39 The following describes the extent of those exceedance for each of those rivers.

40 *Sacramento River*

41 Average monthly water temperatures in the Sacramento River at Bend Bridge  
42 under both Alternative 1 and the No Action Alternative would exceed the water  
43 temperature threshold of 63°F established for Green Sturgeon larval rearing in

1 August and September, with exceedances under Alternative 1 occurring about  
2 6 percent of the time in August and about 10 percent of the time in September.  
3 This is 1 to 2 percent less frequent than under the No Action Alternative.  
4 Average monthly water temperatures at Bend Bridge could exceed the threshold  
5 by up to 10 degrees (reaching 73°F) during this period. Temperature conditions  
6 in the Sacramento River under Alternative 1 could be less likely to result in  
7 adverse effects on Green Sturgeon rearing than under the No Action  
8 Alternative because of the reduced frequency of exceedance of the 63°F threshold  
9 in August and September.

#### 10 *Feather River*

11 Average monthly water temperatures in the Feather River at Gridley Bridge under  
12 both Alternative 1 and No Action Alternative would exceed the water temperature  
13 threshold of 64°F established for Green Sturgeon spawning, incubation, and  
14 rearing in May, June, and September; no exceedances under either scenarios  
15 would occur in July and August. The frequency of exceedances would be high,  
16 with water temperatures under both Alternative 1 and No Action  
17 Alternative exceeding the threshold in June nearly 100 percent of the time. The  
18 magnitude of the exceedance also would be substantial, with average monthly  
19 water temperatures higher than 72°F in June, and higher than 75°F in July and  
20 August. Water temperatures under Alternative 1 would exceed the threshold  
21 during May about 9 percent less frequently than the No Action Alternative and  
22 about 35 percent more frequently in September. Temperature conditions in the  
23 Feather River under Alternative 1 could be less likely to result in adverse effects  
24 on Green Sturgeon rearing than under the No Action Alternative because of the  
25 reduced frequency of exceedance of the 64°F threshold in May. The increase in  
26 exceedance frequency in September under Alternative 1 may have little effect on  
27 rearing Green Sturgeon as many juvenile sturgeon may have migrated  
28 downstream to the lower Sacramento River and Delta by this time.

#### 29 *Changes in Delta Outflow*

30 As described in Appendix 9P, mean (March to July) Delta outflow was used an  
31 indicator of potential year class strength and the likelihood of producing a strong  
32 year class of sturgeon. The median value over the 82-year CalSim II modeling  
33 period of mean (March to July) Delta outflow was predicted to be 12 percent  
34 lower under Alternative 1 than under the No Action Alternative. In addition, the  
35 likelihood of mean (March to July) Delta outflow exceeding the threshold of  
36 50,000 cfs was the same under both alternatives.

#### 37 *Summary of Effects on Green Sturgeon*

38 The temperature model outputs for the Sacramento and Feather rivers suggest that  
39 thermal conditions and effects on Green Sturgeon in the Sacramento and Feather  
40 rivers generally would be slightly less adverse under Alternative 1. This  
41 conclusion is supported by the water temperature threshold exceedance analysis  
42 that indicated that the water temperature thresholds for Green Sturgeon spawning,  
43 incubation, and rearing would be exceeded less frequently under Alternative 1 in  
44 the Sacramento River. The water temperature threshold for Green Sturgeon

1 spawning, incubation, and rearing would also be exceeded less frequently during  
2 some months in the Feather River, but would be exceeded more frequently in  
3 September under Alternative 1 and could reduce the potential for adverse effects  
4 on Green Sturgeon in the Sacramento and Feather rivers relative to the No Action  
5 Alternative. The analysis based on Delta outflows suggests that Alternative 1  
6 provides lower mean (March to July) outflows which could result in weaker year  
7 classes of juvenile sturgeon relative to the No Action Alternative. In addition,  
8 actions under the No Action Alternative intended to increase the efficiency of the  
9 Tracy and Skinner Fish Collection Facilities could improve the overall salvage  
10 survival of green sturgeon. However, early life stage survival in the natal rivers is  
11 crucial in development of a strong year class. Therefore, based primarily on the  
12 analysis of water temperatures, Alternative 1 could be less likely to result in  
13 adverse effects on Green Sturgeon than the No Action Alternative.

14 *White Sturgeon*

15 Changes in water temperature conditions in the Sacramento River would be the  
16 same as those described above for Green Sturgeon in the Sacramento River.  
17 Overall, the temperature differences between Alternative 1 and the No Action  
18 Alternative would be relatively minor (less than 0.5°F) and likely would have  
19 little effect on White Sturgeon in the Sacramento River.

20 The water temperature threshold established for White Sturgeon spawning and  
21 egg incubation in the Sacramento River at Hamilton City is 61°F from March  
22 through June. Although there would be no exceedances of the threshold in March  
23 and April, water temperatures under both Alternative 1 and No Action  
24 Alternative would exceed this threshold in May and June. The average monthly  
25 water temperatures in May under Alternative 1 would exceed this threshold about  
26 49 percent of the time (about 6 percent less frequently than under the No Action  
27 Alternative). In June, the average monthly water temperature under Alternative 1  
28 would exceed the threshold about 74 percent of the time (about 13 percent less  
29 frequently than under the No Action Alternative). Average monthly water  
30 temperatures during May and June under Alternative 1 would as high as about  
31 64°F, which is below the 68°F threshold considered lethal for White Sturgeon  
32 eggs. Temperature conditions in the Sacramento River under Alternative 1 could  
33 be less likely to result in adverse effects on White Sturgeon rearing than under the  
34 No Action Alternative because of the reduced frequency of exceedance of the  
35 61°F threshold in May and June.

36 Changes in Delta outflows would be the same as those described above for Green  
37 Sturgeon. Mean (March to July) Delta outflow was predicted to be 12 percent  
38 lower under Alternative 1 than under the No Action Alternative. In addition, the  
39 likelihood of mean (March to July) Delta outflow exceeding the threshold of  
40 50,000 cfs was the same under both alternatives.

41 Overall, the temperature model outputs suggest that thermal conditions and  
42 effects on White Sturgeon in the Sacramento River generally would be slightly  
43 less adverse under Alternative 1. The analysis based on Delta outflows suggests  
44 that Alternative 1 provides lower mean (March to July) outflows which could

1 result in weaker year classes of juvenile Green Sturgeon relative to the No Action  
2 Alternative. However, early life stage survival in the natal rivers is crucial in  
3 development of a strong year class. Therefore, based primarily on the analysis of  
4 water temperatures, Alternative 1 could be less likely to result in adverse effects  
5 on White Sturgeon than the No Action Alternative.

#### 6 *Delta Smelt*

7 The potential for effects on Delta Smelt resulting from Alternative 1 as compared  
8 to the No Action Alternative were analyzed using changes in proportional  
9 entrainment and fall abiotic habitat index values.

10 As described in Appendix 9G, a proportional entrainment regression model  
11 (based on Kimmerer 2008, 2011) was used to simulate adult Delta Smelt  
12 entrainment, as influenced by OMR flow in December through March. Results  
13 indicate that the percentage of entrainment of migrating and spawning adult Delta  
14 Smelt under Alternative 1 would be 9 percent (long term average percent  
15 entrainment). Percent entrainment of adult Delta Smelt under Alternative 1 would  
16 be similar to results under the No Action Alternative.

17 As described in Appendix 9G, a proportional entrainment regression model  
18 (based on Kimmerer 2008) was used to simulate larval and early juvenile Delta  
19 Smelt entrainment, as influenced by OMR flow and location of X2 in March  
20 through June. Results indicate that the percentage of entrainment of larval and  
21 early juvenile Delta Smelt under Alternative 1 would be 15.5 percent, long-term  
22 average, and highest entrainment of 23.6 percent under Critical water year  
23 conditions. Percent entrainment of larval and early juvenile Delta Smelt under  
24 Alternative 1 would be higher than results under the No Action Alternative, by up  
25 to 9.4 percent. Under the No Action Alternative, the long term average percent  
26 entrainment would be 8.6 percent, and highest entrainment would occur under  
27 Critical water year conditions, at 19.3 percent.

28 The predicted location of Fall X2 position (in September through December) is  
29 used as an indicator of fall abiotic habitat index for Delta Smelt. Feyrer et al.  
30 (2010) used X2 location as an indicator of the extent of habitat available with  
31 suitable salinity for the rearing of older juvenile delta smelt. Feyrer et al. (2010)  
32 concluded that when X2 is located downstream (west) of the confluence of the  
33 Sacramento and San Joaquin Rivers, at a distance of 70 to 80 km from the Golden  
34 Gate Bridge, there is a larger area of suitable habitat. The overlap of the low  
35 salinity zone (or X2) with the Suisun Bay/Marsh results in a two-fold increase in  
36 the habitat index (Feyrer et al. 2010). The average September through December  
37 X2 position in km was used to evaluate the fall abiotic habitat availability for  
38 delta smelt under the Alternatives. X2 values simulated in the CalSim II model  
39 for each Alternative were averaged over September through December, and  
40 compared.

41 Alternative 1 does not include the operations related to the 2008 USFWS BO  
42 RPA Component 3 (Action 4), Fall X2 requirement while the No Action  
43 Alternative includes it. Therefore, the average September through December X2  
44 position under Alternative 1 would be eastward by over 6 km compared to the No

1 Action Alternative during the wetter years. In the drier years September through  
2 December average X2 position is similar under both scenarios.

3 Overall, Alternative 1 likely would have adverse effects on Delta Smelt, as  
4 compared to the No Action Alternative, primarily due to the potential for  
5 increased percentage entrainment during larval and juvenile life stages, and less  
6 favorable location of Fall X2 in wetter years, and on average. Given the current  
7 condition of the Delta Smelt population, even small differences between  
8 alternatives may be important.

9 *Longfin Smelt*

10 The effects of the Alternative 1 as compared to the No Action Alternative were  
11 analyzed based on the direction and magnitude of OMR flows during the period  
12 (December through June) when adult, larvae, and young juvenile Longfin Smelt  
13 are present in the Delta in the vicinity of the export facilities (Appendix 5A). The  
14 analysis was augmented with calculated Longfin Smelt abundance index values  
15 (Appendix 9G) per Kimmerer et al. (2009), which is based on the assumptions  
16 that lower X2 values reflect higher flows and that transporting Longfin Smelt  
17 farther downstream leads to greater Longfin Smelt survival. The index value  
18 indicates the relative abundance of Longfin Smelt and not the calculated  
19 population.

20 The OMR flows would generally be negative in all months under Alternative 1,  
21 with the long-term average ranging from -3,700 to -7,400 cfs from December  
22 through June (Appendix 5A). The OMR flows generally would be more negative  
23 during this time period under Alternative 1 as compared to the No Action  
24 Alternative. The greatest differences between alternatives would be in April and  
25 May, where long-term average OMR flows would be negative under Alternative 1  
26 and positive under the No Action Alternative (Appendix 5A, Table C-17-4). The  
27 increase in the magnitude of negative flows, with negative flows in April and  
28 May, under Alternative 1 as compared to the No Action Alternative could  
29 increase the potential for entrainment of Longfin Smelt at the export facilities.

30 Under Alternative 1, Longfin Smelt abundance index values range from 947  
31 under critical water year conditions to a high of 15,822 under wet water year  
32 conditions, with a long-term average value of 7,257. Under the No Action  
33 Alternative, Longfin Smelt abundance index values range from 1,147 under  
34 critical water year conditions to a high of 16,635 under wet water year conditions,  
35 with a long-term average value of 7,951.

36 Results indicate that the Longfin Smelt abundance index values would be lower in  
37 every water year type under Alternative 1 than they would be under the No Action  
38 Alternative, with a long-term average index for Alternative 1 that is almost  
39 10 percent lower than the long-term average index for the No Action Alternative.  
40 For below normal, dry, and critical water years, the Longfin Smelt abundance  
41 index values would be over 20 percent lower under Alternative 1 than they would  
42 be under the No Action Alternative, with the greatest difference (26.2 percent)  
43 predicted under dry conditions. Based on the Longfin Smelt abundance indices,

1 Alternative 1 likely would have adverse effects on Longfin Smelt, as compared to  
2 the No Action Alternative.

3 Overall, based on the increase in frequency and magnitude of negative OMR  
4 flows and the lower Longfin Smelt abundance index values, especially in dry and  
5 critical years, potential adverse effects on the Longfin Smelt population under  
6 Alternative 1 likely would be greater than under the No Action Alternative.

#### 7 *Sacramento Splittail*

8 Under Alternative 1, flows entering the Yolo Bypass generally would be higher  
9 than under the No Action Alternative from December through March, especially  
10 during wetter years (Appendix 5A, Table C-26-1). These increases would occur  
11 during periods of relatively high flow in the bypass, and could slightly increase  
12 the area of inundation. Thus, Alternative 1 could result in a slight increase in  
13 spawning habitat for Sacramento Splittail as a result of the increased area of  
14 potential habitat (inundation). Given the relatively minor changes in flows into  
15 the Yolo Bypass, and the inherent uncertainty associated with the resolution of the  
16 CalSim II model (average monthly outputs), it is concluded that there would be no  
17 definitive difference in effects on Sacramento Splittail between Alternative 1 and  
18 the No Action Alternative.

#### 19 *Reservoir Fishes*

20 The analysis of effects associated with changes in operation on reservoir fishes  
21 relied on evaluation of changes in available habitat (reservoir storage) and  
22 anticipated changes in black bass nesting success.

#### 23 *Changes in Available Habitat (Storage)*

24 Changes in CVP and SWP water supplies and operations under Alternative 1 as  
25 compared to the No Action Alternative generally would result in higher reservoir  
26 storage in CVP and SWP reservoirs in the Central Valley Region. Storage levels  
27 in Shasta Lake, Lake Oroville, and Folsom Lake would be higher under  
28 Alternative 1 as compared to the No Action Alternative, as summarized in Tables  
29 5.12 through 5.14, in the fall and winter months due to the inclusion of Fall X2  
30 criteria under the No Action Alternative.

31 The highest increases in Shasta Lake and Lake Oroville storage could be in excess  
32 of 20 percent. Storage in Folsom Lake and New Melones could be increased by  
33 up to around 10 percent in some months of some water year types. Additional  
34 information related to monthly reservoir elevations is provided in Appendix 5A,  
35 CalSim II and DSM2 Modeling. It is anticipated that aquatic habitat within the  
36 CVP and SWP water supply reservoirs is not limiting; however, storage volume is  
37 an indicator of how much habitat is available to fish species inhabiting these  
38 reservoirs. Therefore, the amount of habitat for reservoir fishes could increase  
39 under Alternative 1 as compared to the No Action Alternative.

#### 40 *Changes in Black Bass Nesting Success*

41 As shown in Appendix 9F, black bass nest survival in CVP and SWP reservoirs is  
42 anticipated to be near 100 percent in March and April due to increasing reservoir  
43 elevations. For May and June, the likelihood of nest survival for Largemouth

1 Bass in Shasta Lake being in the 40 to 100 percent range is similar under  
2 Alternative 1 and the No Action Alternative; however, nest survival of greater  
3 than 40 percent is likely only in about 20 percent of the years evaluated. The  
4 likelihood of high nest survival for Smallmouth Bass in Shasta Lake exhibits  
5 nearly the same pattern. For Spotted Bass, the likelihood of nest survival being  
6 greater than 40 percent is high (nearly 100 percent) from March to May under  
7 both Alternative 1 and the No Action Alternative. For June, Spotted Bass nest  
8 survival would be less than for May due to greater daily reductions in water  
9 surface elevation as Shasta Lake is drawn down. The likelihood of nest survival  
10 being greater than 40 percent is about 10 percent less under Alternative 1 as  
11 compared to the No Action Alternative.

12 For May and June, the likelihood of nest survival for Largemouth Bass in Lake  
13 Oroville being in the 40 to 100 percent range is somewhat (4 to 10 percent) lower  
14 under Alternative 1 than under the No Action Alternative. However, in June, nest  
15 survival of greater than 40 percent is likely only in about 35 percent of the years  
16 evaluated under Alternative 1. The likelihood of high nest survival for  
17 Smallmouth Bass in Lake Oroville exhibits nearly the same pattern. For Spotted  
18 Bass, the likelihood of nest survival being greater than 40 percent is high (over  
19 90 percent) in May under both Alternative 1 and the No Action Alternative with  
20 the likelihood of greater than 40 percent survival being similar under  
21 Alternative 1 and the No Action Alternative. For June, Spotted Bass nest survival  
22 would be less than for May due to greater daily reductions in water surface  
23 elevation as Lake Oroville is drawn down. The likelihood of survival being  
24 greater than 40 percent is substantially lower (nearly 20 percent) under  
25 Alternative 1 as compared to the No Action Alternative.

26 Black bass nest survival in Folsom Lake is near 100 percent in March, April, and  
27 May due to increasing reservoir elevations. For June, the likelihood of nest  
28 survival for Largemouth Bass and Smallmouth Bass in Folsom Lake being in the  
29 40 to 100 percent range is about 5 percent lower under Alternative 1 than the No  
30 Action Alternative. For Spotted Bass, nest survival for June would be less than  
31 for May due to greater daily reductions in water surface elevation. However, the  
32 likelihood of survival being greater than 40 percent is around 5 percent lower  
33 under Alternative 1 as compared to the No Action Alternative.

34 *Summary of Effects on Reservoir Fishes*

35 The analysis of the effects of Alternative 1 and the No Action Alternative for  
36 reservoir fish relied on CalSim II output for reservoir storage levels and water  
37 surface elevation changes as described in Appendix 9F. As described above,  
38 reservoir storage is anticipated to be increased under Alternative 1 relative to the  
39 No Action Alternative and this increase could affect the amount of warm and cold  
40 water habitat available within the reservoirs. However, it is unlikely that aquatic  
41 habitat within the CVP and SWP water supply reservoirs is limiting.

42 The analysis of black bass nest survival based on changes in water surface  
43 elevation during the spawning period indicated that the likelihood of high  
44 (>40 percent) nest survival in most of the reservoirs would be similar in March,  
45 April, and May under Alternative 1 and the No Action Alternative, but somewhat

1 lower in June. Most black bass spawning likely occurs prior to June, such that  
2 drawdowns during June would likely affect only a small proportion of the  
3 spawning population. Thus, it is concluded that effects on black bass nesting  
4 success would be similar under Alternative 1 and the No Action Alternative.

#### 5 *Pacific Lamprey*

6 Little information is available on factors that influence populations of Pacific  
7 Lamprey in the Sacramento River, but they are likely affected by many of the  
8 same factors as salmon and steelhead because of the parallels in their life cycles.

#### 9 *Changes in Water Temperature*

10 The following describes anticipated changes in average monthly water  
11 temperature in the Sacramento, Feather, and American rivers and the potential for  
12 those changes to affect Pacific Lamprey.

#### 13 *Sacramento River*

14 Long-term average monthly water temperature in the Sacramento River at  
15 Keswick Dam under Alternative 1 would generally be similar (less than 0.5°F  
16 difference) to water temperatures under the No Action Alternative. An exception  
17 is during September and October of critical dry years when water temperatures  
18 could be up to 1.1°F and 0.8°F lower, respectively, under Alternative 1 as  
19 compared to the No Action Alternative and up to 1°F warmer in September of  
20 wetter years (Appendix 6B, Table 5-5-1). A similar temperature pattern generally  
21 would be exhibited downstream at Ball's Ferry, Jelly's Ferry, and Bend Bridge,  
22 with average monthly temperatures increasing in a downstream direction and  
23 temperature differences between scenarios progressively decreasing except in  
24 September (up to 2.8°F warmer) at Bend Bridge) during wetter years under  
25 Alternative 1. Due to the similarity of water temperatures under Alternative 1 and  
26 the No Action Alternative from January through the summer, there would be little  
27 difference in potential effects on Pacific Lamprey adults during their migration,  
28 holding, and spawning periods.

#### 29 *Feather River*

30 Long-term average monthly water temperature in the Feather River in the low  
31 flow channel generally were predicted to be similar (less than 0.5°F differences)  
32 under Alternative 1 and the No Action Alternative, except during November and  
33 December when average monthly water temperatures would be up to 1.4°F lower  
34 in some water year types (Appendix 6B, Table B-20-1). Average monthly water  
35 temperatures in September under Alternative 1 generally could be up to 1.3°F  
36 higher than under the No Action Alternative in wetter years. Although  
37 temperatures in the river would become progressively higher in the downstream  
38 directions, the differences in water temperatures between Alternative 1 and the No  
39 Action Alternative would exhibit a similar pattern at the downstream locations  
40 (Robinson Riffle and Gridley Bridge), with water temperature differences  
41 between Alternative 1 and the No Action Alternative generally decreasing in most  
42 water year types. However, water temperatures from July to September under  
43 Alternative 1 could be somewhat (0.7°F to 1.6°F) warmer on average and up to  
44 4.0°F warmer at the confluence with Sacramento River in wetter years.

1 Due to the similarity of water temperatures under Alternative 1 and the No Action  
2 Alternative from January through the summer, there would be little difference in  
3 potential effects on Pacific Lamprey adults during their migration, holding, and  
4 spawning periods under Alternative 1 and the No Action Alternative.

5 *American River*

6 Average monthly water temperatures in the American River at Nimbus Dam  
7 under Alternative 1 generally would be similar (differences less than 0.5°F) to the  
8 No Action Alternative, with the exception of during June and August, when water  
9 temperatures under Alternative 1 could be as much as 0.9°F lower in below  
10 normal years. This pattern generally would persist downstream to Watt Avenue  
11 and the mouth, although temperatures under Alternative 1 would be up to 1.6°F  
12 and 2.0°F lower, respectively, than under the No Action Alternative in June. In  
13 addition, average monthly water temperatures at the mouth generally would be  
14 higher under Alternative 1 than the No Action Alternative in September of wetter  
15 years when water temperatures under Alternative 1 could be up to 1.7°F warmer.  
16 Due to the similarity of water temperatures under Alternative 1 and the No Action  
17 Alternative from January through the summer, there would be little difference in  
18 potential effects on Pacific Lamprey adults during their migration, holding, and  
19 spawning periods.

20 *Summary of Effects on Pacific Lamprey*

21 In general, Pacific Lamprey can tolerate higher temperatures than salmonids, up  
22 to around 72°F during their entire life history. Based on the similar water  
23 temperatures during their spawning and incubation period under Alternative 1, it  
24 is likely that conditions for and effects on Pacific Lamprey in the Sacramento,  
25 Feather, and American rivers would be similar under Alternative 1 and the No  
26 Action Alternative. This conclusion likely applies to other species of lamprey  
27 that inhabit these rivers (e.g., River Lamprey).

28 *Striped Bass, American Shad, and Hardhead*

29 Changes in operations influence temperature and flow conditions that could affect  
30 Striped Bass, American Shad, and Hardhead. The following describes those  
31 changes and their potential effects.

32 *Changes in Water Temperature*

33 Changes in water temperature that affect Striped Bass, American Shad, and  
34 Hardhead could occur in the Sacramento, Feather, and American rivers. The  
35 following describes temperature conditions in those water bodies.

36 *Sacramento River*

37 Long-term average monthly water temperatures in the Sacramento River at  
38 Keswick Dam under Alternative 1 would generally be similar (less than 0.5°F  
39 difference) to water temperatures under the No Action Alternative. An exception  
40 is during September and October of critical dry years when water temperatures  
41 could be up to 1.1°F and 0.8°F lower, respectively, under Alternative 1 as  
42 compared to the No Action Alternative and up to 1°F warmer in September of  
43 wetter years (Appendix 6B, Table 5-5-1). A similar water temperature pattern

1 generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry, and Bend  
2 Bridge, with average monthly water temperatures increasing in a downstream  
3 direction and temperature differences between scenarios progressively increasing  
4 (up to 0.9°F cooler) in June and up to 4.6°F warmer in September during the  
5 wetter years under Alternative 1 relative to the No Action Alternative. In general,  
6 Striped Bass, American Shad, and Hardhead can tolerate higher temperatures than  
7 salmonids. Therefore, it is unlikely that the slightly reduced temperatures during  
8 some months would have adverse effects on these species.

#### 9 *Feather River*

10 Average monthly water temperature in the Feather River in the low flow channel  
11 generally were predicted to be similar (less than 0.5°F differences) under  
12 Alternative 1 and the No Action Alternative, except during November and  
13 December when average monthly water temperatures would be up to 1.4°F lower  
14 in some water year types (Appendix 6B, Table B-20-1). Average monthly water  
15 temperatures in September under Alternative 1 could be up to 1.3°F warmer than  
16 under the No Action Alternative in the wetter years. Although temperatures in the  
17 river would become progressively lower in the downstream directions, the  
18 differences between Alternative 1 and No Action Alternative would exhibit a  
19 similar pattern at the downstream locations (Appendix 6B, Table B-23-1). As  
20 described above for the Sacramento River, Striped Bass, American Shad, and  
21 Hardhead can tolerate higher temperatures than salmonids. Therefore, it is  
22 unlikely that the slightly reduced temperatures during some months would have  
23 adverse effects on these species in the Feather River.

#### 24 *American River*

25 Average monthly water temperatures in the American River at Nimbus Dam  
26 under Alternative 1 generally would be similar (differences less than 0.5°F) to the  
27 No Action Alternative, with the exception of during June and August, when  
28 differences under Alternative 1 could be as much as 0.9°F lower in below normal  
29 years. This pattern generally would persist downstream to Watt Avenue and the  
30 mouth, although temperatures under Alternative 1 would be up to 1.6°F and 2.0°F  
31 lower, respectively, than under the No Action Alternative in June. As described  
32 above for the Sacramento River, Striped Bass, American Shad, and Hardhead can  
33 tolerate higher temperatures than salmonids. Therefore, it is unlikely that the  
34 slightly reduced temperatures during some months would have adverse effects on  
35 these species in the American River.

#### 36 *Changes in Position of X2*

37 Alternative 1 would result in a more eastward X2 position as compared to the No  
38 Action Alternative during April and May, with similar values in June  
39 (Appendix 5A, Section C Table C-16-1). Based on Kimmerer (2002) and  
40 Kimmerer et al. (2009), this change in X2 would likely reduce the survival index  
41 and the habitat index as measured by salinity for Striped Bass and abundance and  
42 habitat index for American Shad.

1            *Summary of Effects on Striped Bass, American Shad, and Hardhead*

2 In general, Striped Bass, American Shad, and Hardhead can tolerate higher  
3 temperatures than salmonids. Based on the similar water temperatures during  
4 their spawning and incubation period under Alternative 1, it is likely that thermal  
5 conditions for and effects on Striped Bass, American Shad, and Hardhead in the  
6 Sacramento, Feather, and American rivers would be similar under Alternative 1  
7 and the No Action Alternative. Overall, however, Alternative 1 likely would have  
8 slightly greater potential for adverse effects on Striped Bass and American Shad  
9 as compared to the No Action Alternative, primarily due to the potential for  
10 reduced survival during larval and juvenile life stages, and less favorable location  
11 of Spring X2 on average.

12 *Stanislaus River/Lower San Joaquin River*

13            *Fall-Run Chinook Salmon*

14 Changes in operations influence temperature and flow conditions that could affect  
15 fall-run Chinook Salmon in the Stanislaus River downstream of Goodwin Dam  
16 and in the San Joaquin River below Vernalis. The following describes those  
17 changes and their potential effects.

18            *Changes in Water Temperature (Stanislaus River)*

19 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
20 under Alternative 1 and the No Action Alternative generally would be similar  
21 (differences less than 0.5°F), with small differences in critical dry years when  
22 Alternative 1 would 0.8°F and 1.3°F cooler on average than under the No Action  
23 Alternative during June and September, respectively, and 0.7°F warmer in  
24 November (Appendix 6B, Table B-1-1).

25 Downstream at Orange Blossom Bridge, average monthly water temperatures in  
26 October under Alternative 1 would be higher in all water year types than under  
27 the No Action Alternative by as much as 1.9°F. In most other months, water  
28 temperatures under Alternative 1 and the No Action Alternative generally would  
29 be similar. An exception to this pattern occurs in April when average monthly  
30 water temperatures in all water year types would be higher under Alternative 1 by  
31 as much as about 1.2°F (Appendix 6B, Table B-18-1).

32 This water temperature pattern would continue downstream to the confluence  
33 with the San Joaquin River, although temperatures would progressively increase,  
34 as would the magnitude of difference between Alternative 1 and No Action  
35 Alternative. Increases in average monthly water temperatures in October and  
36 April would be more pronounced under Alternative 1, with average differences as  
37 much as 2.7°F in October and 2.0 F in April (Appendix 6B, Table B-19-1)  
38 relative to the No Action Alternative. The magnitude of differences in average  
39 monthly water temperatures between Alternative 1 and the No Action  
40 Alternative in May and June also would increase relative to the upstream  
41 locations with average June water temperatures being 2.4°F cooler under  
42 Alternative 1 in wet years.

1 Based on the life history timing for fall-run Chinook Salmon, the higher water  
 2 temperatures in October under Alternative 1 may increase the likelihood of  
 3 adverse effects on fall-run Chinook Salmon spawning and egg incubation as  
 4 compared to the No action Alternative.

5 *Changes in Exceedance of Water Temperature Thresholds Appendix*

6 While specific water temperature thresholds for fall-run Chinook Salmon in the  
 7 Stanislaus River are not established, temperatures generally considered suitable  
 8 for fall-run Chinook Salmon spawning (56°F) would be exceeded in October and  
 9 November about 30 and 25 percent of the time, respectively at Goodwin Dam  
 10 under Alternative 1 (Appendix 6B, Figures B-17-1 and B-17-2). Similar  
 11 exceedances would occur under the No Action Alternative, although slightly more  
 12 frequently in November. Water temperatures for rearing generally would be  
 13 below 56°F, except in May when average monthly water temperatures would  
 14 reach about 60°F under both Alternative 1 and the No action  
 15 Alternative (Appendix 6B, Figure B-17-8).

16 Downstream at Orange Blossom Bridge, water temperatures suitable for fall-run  
 17 Chinook Salmon spawning (56°F) would be exceeded frequently under both  
 18 Alternative 1 and the No Action Alternative during October and November.  
 19 Under Alternative 1, average monthly water temperatures would exceed 56°F  
 20 about 85 percent of the time in October. This, would be about 28 percent more  
 21 frequently than under the No Action Alternative. In November, average monthly  
 22 water temperatures would exceed 56°F about 28 percent of the time under  
 23 Alternative 1, which would be about 5 percent less frequent than under the No  
 24 Action Alternative (Appendix 6B, Figure B-18-2).

25 From January through May, rearing fall-run Chinook Salmon would be subjected  
 26 to average monthly water temperatures that exceed 56° in March (less than  
 27 10 percent of the time) and May (about 20 percent of the time) under  
 28 Alternative 1, which is about 10 percent less frequently than under the No Action  
 29 Alternative in May (Appendix 6B, Figure B-18-8).

30 *Changes in Egg Mortality (Stanislaus River)*

31 For fall-run Chinook Salmon in the Stanislaus River, the long-term average egg  
 32 mortality rate is predicted to be around 7 percent, with higher mortality rates (in  
 33 excess of 15 percent) occurring in critical dry years under Alternative 1. Overall,  
 34 egg mortality in the Stanislaus River would be similar under Alternative 1 and the  
 35 No Action Alternative (Appendix 9C, Table B-1).

36 *Changes in Delta Hydrodynamics*

37 San Joaquin River-origin fall-run Chinook Salmon smolts are most abundant in  
 38 the Delta during the months of April, May and June. Near the confluence of the  
 39 San Joaquin River and the Mokelumne River, the median proportion of positive  
 40 velocities was slightly lower under Alternative 1 relative to the No Action  
 41 Alternative in April and May and similar in June (Appendix 9K). In Old River  
 42 downstream of the facilities, the median proportion of positive velocities was  
 43 substantially lower in April and May under Alternative 1 relative to No Action

1 Alternative but became more similar in June. In Old River upstream of the  
2 facilities, the median proportion of positive velocities was slightly to moderately  
3 lower for Alternative 1 relative to No Action Alternative in April and May,  
4 respectively and moderately lower in June. On the San Joaquin River  
5 downstream of the Head of Old River, the median proportion of positive  
6 velocities was slightly to moderately higher under Alternative 1 relative to No  
7 Action Alternative in April and May, respectively, whereas values were similar  
8 in June.

9 *Changes in Junction Entrainment*

10 Median entrainment probabilities at the Head of Old River were much lower  
11 under Alternative 1 relative to the No Action Alternative during April and May.  
12 The median entrainment probability was similar under both alternatives in the  
13 month of June (Appendix 9L). At the Turner Cut junction, median entrainment  
14 probabilities under Alternative 1 were slightly higher than under the No Action  
15 Alternative in June. During April and May, entrainment probabilities were more  
16 divergent with moderately higher values for Alternative 1 relative to No Action  
17 Alternative. Overall, entrainment was slightly lower at the Columbia Cut junction  
18 relative to Turner Cut but patterns of entrainment between these two alternatives  
19 were similar. Patterns at the Middle River and Old River junctions were similar  
20 to those observed at Columbia and Turner Cut junctions.

21 *Summary of Effects on Fall-Run Chinook Salmon*

22 In the Stanislaus River, the analysis of the effects of Alternative 1 and the No  
23 Action Alternative for fall-run Chinook Salmon relied on the water temperature  
24 model output for the rivers at various locations downstream of Goodwin Dam.  
25 The temperature model outputs for each of the fall-run Chinook Salmon life  
26 stages suggest that thermal conditions and effects on fall-run Chinook Salmon in  
27 the Stanislaus River generally would be similar under both scenarios, although  
28 water temperatures could be somewhat less suitable for fall-run Chinook Salmon  
29 spawning/egg incubation under Alternative 1. This conclusion is supported by the  
30 water temperature threshold exceedance analysis that indicated that suitable water  
31 temperatures for fall-run Chinook Salmon spawning and egg incubation would be  
32 exceeded slightly less frequently in November, but substantially more frequently  
33 in October under Alternative 1. Suitable water temperatures for fall-run Chinook  
34 Salmon rearing would be exceeded somewhat less frequently under Alternative 1.  
35 Results of the analysis using Reclamation's salmon mortality model indicate that  
36 there would be little difference in fall-run Chinook Salmon egg mortality under  
37 Alternative 1 and the No Action Alternative.

38 Implementation of a fish passage project under the No Action Alternative,  
39 although intended to address the limited availability of suitable habitat for  
40 steelhead in the Stanislaus River reaches downstream of Goodwin Dam, could  
41 provide some benefit to fall-run Chinook Salmon if passage for adult fall-run  
42 Chinook Salmon was provided and additional habitat could be accessed. Any  
43 potential benefit to fall-run Chinook Salmon under the No Action Alternative  
44 relative to Alternative 1 is uncertain. The potential benefits of actions under the  
45 No Action Alternative intended to increase the efficiency of the Tracy and

1 Skinner Fish Collection Facilities could improve the overall salvage survival of  
2 fall-run Chinook Salmon relative to Alternative 1.

3 The results of the numerical models suggest that Alternative 1 is less likely to  
4 result in adverse effects on fall-run Chinook Salmon than the No Action  
5 Alternative. However, discerning a meaningful difference between these two  
6 scenarios based on the quantitative results is not possible because of the similarity  
7 in results (generally differences less than 5 percent) and the inherent uncertainty  
8 of the models. In addition, adverse effects of the No Action Alternative could be  
9 balanced by the potentially beneficial effects resulting from the RPA actions  
10 evaluated qualitatively for the No Action Alternative. Overall, given the small  
11 differences in the numerical model results and the inherent uncertainty in the  
12 temperature model, as well as the potential for benefits associated with the RPA  
13 actions under the No Action Alternative, it is concluded that there would be no  
14 definitive difference in effects on fall-run Chinook Salmon between Alternative 1  
15 and the No Action Alternative.

### 16 *Steelhead*

17 Changes in operations that influence temperature and flow conditions in the  
18 Stanislaus River downstream of Goodwin Dam and the San Joaquin River below  
19 Vernalis could affect steelhead. The following describes those changes and their  
20 potential effects.

#### 21 *Changes in Water Temperature (Stanislaus River)*

22 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
23 under Alternative 1 and the No Action Alternative generally would be similar  
24 (differences less than 0.5°F), with small differences in critical dry years when  
25 water temperatures under Alternative 1 would 0.8°F and 1.3°F cooler on average  
26 than under the No Action Alternative during June and September, respectively,  
27 and 0.7°F warmer in November (Appendix 6B, Table B-17-1).

28 Downstream at Orange Blossom Bridge, average monthly water temperatures in  
29 October under Alternative 1 would be higher in all water year types than the No  
30 Action Alternative by as much as 1.9°F. In most other months, water  
31 temperatures under Alternative 1 and the No Action Alternative generally would  
32 be similar (less than 0.5°F differences), except in April when average monthly  
33 water temperatures in all water year types would be higher under Alternative 1 by  
34 as much as about 1.2°F in the drier years (Appendix 6B, Table B-18-1).

35 This water temperature pattern would continue downstream to the confluence  
36 with the San Joaquin River, although temperatures would progressively increase,  
37 as would the magnitude of difference between Alternative 1 and the No Action  
38 Alternative. Increases in average monthly water temperatures in October and  
39 April would be more pronounced under Alternative 1, with average differences as  
40 much as 2.7°F (Appendix 6B, Table B-19-1) relative to the No Action  
41 Alternative. The magnitude of differences in average monthly water temperatures  
42 between Alternative 1 and the No Action Alternative in May and June also would

1 increase relative to the upstream locations with average June water temperatures  
2 being 2.4°F cooler under Alternative 1 in wet years.

3 Overall, the water temperature differences between Alternative 1 and the No  
4 Action Alternative would be relatively minor (less than 0.5°F) and likely would  
5 have little effect on steelhead in the Stanislaus River. Based on the life history  
6 timing for steelhead, the slightly lower temperatures in June and September of  
7 drier years under Alternative 1 may decrease the likelihood of adverse effects to  
8 steelhead rearing in the Stanislaus River; the higher temperatures in October  
9 under Alternative 1 may increase the likelihood of adverse effects on adult  
10 steelhead during their upstream migration.

11 *Changes in Exceedance of Water Temperature Thresholds*  
12 *(Stanislaus River)*

13 Average monthly water temperatures in the Stanislaus River at Orange Blossom  
14 Bridge would frequently exceed the temperature threshold (56°F) established for  
15 adult steelhead migration under both Alternative 1 and No Action  
16 Alternative during October and November. Under Alternative 1, average monthly  
17 water temperatures would exceed 56°F about 85 percent of the time in October  
18 which is about 28 percent more frequently than under the No Action  
19 Alternative (Appendix 6B, Figure B-18-1). In November, average monthly water  
20 temperatures would exceed 56°F about 28 percent of the time under Alternative 1,  
21 which would be about 5 percent less frequent than under the No Action  
22 Alternative (Appendix 6B, Figure B-18-2).

23 From January through May, the temperature threshold at Orange Blossom Bridge  
24 is 55°F, which is intended to support steelhead spawning. This threshold would  
25 not be exceeded under either Alternative 1 or No Action Alternative during  
26 January or February. From March through May, however, exceedances would  
27 occur under both Alternative 1 and the No Action Alternative in each month, with  
28 the threshold most frequently exceeded (43 percent) under Alternative 1 in May  
29 (Appendix 9N). Water temperatures under Alternative 1 would exceed the  
30 threshold 5 percent less frequently in March, 6 percent less frequently in May,  
31 and 17 percent more frequently in April than under the No Action Alternative.

32 From June through November, the temperature threshold of 65°F established to  
33 support steelhead rearing would be exceeded by both Alternative 1 and No Action  
34 Alternative in all months but November, and would exceed the threshold by  
35 16 percent of the time in July under both Alternative 1 and the No Action  
36 Alternative. The differences between Alternative 1 and the No Action  
37 Alternative range from 1 percent less frequent exceedance in October to 4 percent  
38 more frequent exceedance in June under the No Action Alternative.

39 Average monthly water temperatures also would exceed the threshold (52°F)  
40 established for smoltification at Knights Ferry. At Goodwin Dam, about 4 miles  
41 upstream of Knights Ferry, average monthly water temperatures under  
42 Alternative 1 would exceed 52°F in March, April, and May about 9 percent,  
43 31 percent, and 66 percent of the time, respectively. Water temperatures under

1 Alternative 1 would result in exceedances occurring about 1 to 2 percent more  
2 frequently during the January through May period. Farther downstream at Orange  
3 Blossom Bridge, the temperature threshold for smoltification is higher (57°F) and  
4 would be exceeded less frequently. The magnitude of the exceedance also would  
5 be less. Average monthly water temperatures under Alternative 1 and the No  
6 Action Alternative would not exceed the threshold during January through March.  
7 In April and May, exceedances of 8 percent and 10 percent would occur under  
8 Alternative 1, which represent a frequency of about 6 percent more than the No  
9 Action Alternative in April and about an 8 percent lower frequency in May.

10 Overall, the differences in exceedance frequency between Alternative 1 and the  
11 No Action Alternative would be relatively small, with the exception of substantial  
12 differences in the frequency of exceedances in October when the average monthly  
13 water temperatures under Alternative 1 would exceed the threshold for adult  
14 steelhead migration about 28 percent more frequently and in April during the  
15 spawning period when the exceedance frequency would be about 17 percent  
16 more. Given the frequency of exceedance under both Alternative 1 and No  
17 Action Alternative and the generally stressful temperature conditions in the river,  
18 the substantial differences in October and April under Alternative 1 suggest that  
19 there would be more potential to result in adverse effects on steelhead under  
20 Alternative 1 than under the No Action Alternative. Even during months when  
21 the differences would be relatively small, the slightly higher frequency of  
22 exceedances under Alternative 1 suggest that there would be more potential to  
23 result in adverse effects on steelhead under Alternative 1 than under the No  
24 Action Alternative.

#### 25 *Changes in Delta Hydrodynamics*

26 San Joaquin River-origin steelhead generally move through the Delta during  
27 spring; however, there is less information on their timing relative to Chinook  
28 Salmon. Thus, hydrodynamics in the entire January through June period have the  
29 potential to affect juvenile steelhead. For a description of potential hydrodynamic  
30 effects on steelhead, see the descriptions for winter-run Chinook Salmon in the  
31 Sacramento Basin and fall-run Chinook Salmon in the San Joaquin River  
32 basin above.

#### 33 *Summary of Effects on Steelhead*

34 The analysis of the effects of Alternative 1 and the No Action Alternative for  
35 steelhead relied on the water temperature model output for the rivers at various  
36 locations downstream of Goodwin Dam. The temperature model outputs for each  
37 of the steelhead life stages suggest that thermal conditions and effects on  
38 steelhead in all of these streams generally would be similar under both scenarios,  
39 although water temperatures could be somewhat less suitable for steelhead rearing  
40 under Alternative 1. Water temperatures could be somewhat more suitable during  
41 the adult upstream migration period under Alternative 1 than the No Action  
42 Alternative. This conclusion is supported by the water temperature threshold  
43 exceedance analysis that indicated that the water temperature threshold for  
44 steelhead migration would be exceeded substantially more frequently on October,  
45 but somewhat more frequently in November under Alternative 1. The water

1 temperature threshold for steelhead spawning would also be exceeded  
2 substantially more frequently in May, but somewhat less frequently in other  
3 months under Alternative 1. The water temperature threshold for steelhead  
4 rearing generally would be exceeded less frequently under Alternative 1 while the  
5 temperature thresholds for smoltification would be exceeded more frequently in  
6 most months.

7 The differences in the magnitude and frequency of exceedance of suitable  
8 temperatures for the various lifestages under Alternative 1 could affect the  
9 potential for adverse effects on the steelhead populations in the Stanislaus River.  
10 However, the direction and magnitude of this effect is uncertain. Implementation  
11 of the fish passage program under the No Action Alternative intended to address  
12 the limited availability of suitable habitat for steelhead in the Stanislaus River  
13 reaches downstream of Goodwin Dam could provide a benefit to Central Valley  
14 steelhead in the Stanislaus River. This is particularly important in light of  
15 anticipated increases in water temperature associated with climate change in  
16 2030. Thus, it is concluded that the potential for adverse effects on steelhead  
17 under Alternative 1 would be greater, principally because Alternative 1 does not  
18 include fish passage to address water temperatures critical to steelhead  
19 sustainability over the long term with climate change by 2030.

#### 20 *White Sturgeon*

21 Evidence of White Sturgeon spawning has been recorded in the San Joaquin River  
22 upstream of the confluence with the Stanislaus River. While flows in the San  
23 Joaquin River upstream of the Stanislaus River are expected to be similar under all  
24 alternatives, flow contributions from the Stanislaus River could influence water  
25 temperatures in the San Joaquin River where White Sturgeon eggs or larvae may  
26 occur during the spring and early summer. The magnitude of influence on water  
27 temperature would depend on the proportional flow contribution of the Stanislaus  
28 River and the temperatures in both the Stanislaus and San Joaquin rivers. The  
29 potential for an effect on White Sturgeon eggs and larvae would be influenced by  
30 the proportion of the population occurring in the San Joaquin River. In  
31 consideration of this uncertainty, it is not possible to distinguish potential effects  
32 on White Sturgeon between alternatives.

#### 33 *Reservoir Fishes*

34 The analysis of effects associated with changes in operation on reservoir fishes  
35 relied on evaluation of changes in available habitat (reservoir storage) and  
36 anticipated changes in black bass nesting success.

37 Changes in CVP and SWP water supplies and operations under Alternative 1 as  
38 compared to the No Action Alternative would result in higher storage levels in  
39 New Melones Reservoir under Alternative 1 as compared to the No Action  
40 Alternative, as summarized in Table 5.16, due to lower instream releases to  
41 support fish flows under Alternative 1.

42 Storage in New Melones could be increased by up to around 10 percent in some  
43 months of some water year types under Alternative 1 compared to the No Action  
44 Alternative. Additional information related to monthly reservoir elevations is

1 provided in Appendix 5A, CalSim II and DSM2 Modeling. Assuming that  
2 storage volume is an indicator of how much habitat is available to fish species  
3 inhabiting the reservoir, the amount of habitat for reservoir fishes could be  
4 increased under Alternative 1 as compared to the No Action Alternative.

5 As shown in Appendix 9F, Largemouth Bass and Smallmouth Bass nest survival  
6 is anticipated to always be above 40 percent under both Alternative 1 and the No  
7 Action Alternative in March. For April, the likelihood that nest survival of  
8 Largemouth Bass and Smallmouth Bass is between 40 and 100 percent is  
9 reasonably high (nearly 80 percent), although about 13 percent higher under  
10 Alternative 1 as compared to the No Action Alternative. For May, nest survival is  
11 anticipated to be similar under Alternative 1 and the No Action Alternative. For  
12 June, the likelihood of survival being greater than 40 percent for Largemouth  
13 Bass and Smallmouth Bass in New Melones Reservoir is about 8 percent lower  
14 under Alternative 1 as compared to the No Action Alternative. For Spotted Bass,  
15 nest survival from March through June is anticipated to be near 100 percent in  
16 every year under both Alternative 1 and No Action Alternative. Most black bass  
17 spawning likely occurs prior to June, such that drawdowns during June would  
18 likely affect only a small proportion of the spawning population. Thus, it is  
19 concluded that effects on black bass nesting success would be similar under  
20 Alternative 1 and the No Action Alternative.

#### 21 *Other species*

22 Changes in operations that influence temperature and flow conditions in the  
23 Stanislaus River downstream of Keswick Dam and the San Joaquin River at  
24 Vernalis could affect other species such as lampreys, Hardhead, and Striped Bass.

25 As described above, average monthly water temperatures in the Stanislaus River  
26 at Goodwin Dam under Alternative 1 and No Action Alternative generally would  
27 be similar. Downstream at Orange Blossom Bridge, average monthly water  
28 temperatures in the November to March period under Alternative 1 generally  
29 would be similar to, although somewhat lower than, under the No Action  
30 Alternative. In April and October, average monthly water temperatures in all  
31 water year types would be higher under Alternative 1 and in September, water  
32 temperatures would be lower under Alternative 1 compared to the No Action  
33 Alternative. This temperature pattern would continue downstream to the  
34 confluence with the San Joaquin River, although temperatures would  
35 progressively increase, as would the magnitude of difference between  
36 Alternative 1 and No Action Alternative (Appendix 6B, Table B-19-1).

37 In general, lamprey species can tolerate higher temperatures than salmonids, up to  
38 around 72°F during their entire life history. Because lamprey ammocoetes remain  
39 in the river for several years, any substantial flow reductions or temperature  
40 increases could result in adverse effects on larval lamprey. Given the similar  
41 flows and temperatures during their spawning and incubation period, it is likely  
42 that the potential to affect lamprey species in the Stanislaus and San Joaquin  
43 rivers would be similar under Alternative 1 and the No Action Alternative.

1 In general, Striped Bass and Hardhead also can tolerate higher temperatures than  
2 salmonids. Given the similar temperatures during their spawning and incubation  
3 period, it is likely that the potential to affect Striped Bass and Hardhead in the  
4 Stanislaus and San Joaquin rivers would be similar under Alternative 1 and the  
5 No Action Alternative.

6 *San Francisco Bay Area Region*

7 *Killer Whale*

8 Southern Resident killer whales (Southern Residents) are thought to rely heavily  
9 upon salmon as their main source of prey (about 96 percent of their diet)  
10 throughout the areas and times for which reliable data on prey consumption are  
11 available (Ford and Ellis 2006). Studies have indicated that Chinook Salmon  
12 generally constitute a large percentage of the Southern Resident salmon diet, with  
13 some indications that Chinook Salmon are strongly preferred at certain times in  
14 comparison to other salmonids (Ford and Ellis 2006; Hanson et al. 2007). Results  
15 have also suggested that Chinook Salmon from ESUs from California to British  
16 Columbia are being consumed by Southern Residents (Hanson et al. 2007).

17 Best available data on the abundance and composition of Central Valley Chinook  
18 Salmon indicates that approximately 75 percent of all Central Valley-origin  
19 Chinook Salmon available for consumption by Southern Residents are produced  
20 by Central Valley fall-run Chinook Salmon hatcheries (Palmer-Zwhalen and  
21 Kormos 2012; Table 9). Most Central Valley hatchery fall-run Chinook Salmon  
22 production is released directly into San Francisco Bay, and thus bypass potential  
23 impacts from water project operations. Even where there might be a nexus with  
24 water project operations, the purpose of Central Valley fall-run Chinook Salmon  
25 hatchery programs is to produce large numbers of fish independent of freshwater  
26 conditions. Since fall-run Chinook Salmon hatcheries came on-line more than  
27 forty years ago, the only period of exceptionally low returns was principally  
28 attributed to unusual ocean conditions (Lindley et al. 2007).

29 Ocean commercial and recreational fisheries annually harvest hundreds of  
30 thousands of Chinook salmon. The Northwest Region of NMFS (NMFS 2009c)  
31 used a model that estimates prey reduction associated with the salmon fishery and  
32 which considers the metabolic requirements of Southern Residents and the  
33 remaining levels of prey availability. Their analysis concluded that the salmon  
34 fishery was not likely to result in jeopardy for Southern Residents. Given  
35 conclusions from NMFS (2009c), and the fact that at least 75 percent of fall-run  
36 Chinook Salmon available for Southern Residents are produced by Central Valley  
37 hatcheries, it is likely that Central Valley fall-run Chinook Salmon as a prey base  
38 for killer whales would not be appreciably affected by any of the alternatives.

39 **9.4.3.2.2 Alternative 1 Compared to the Second Basis of Comparison**

40 As described in Chapter 3, Description of Alternatives, Alternative 1 is identical  
41 to the Second Basis of Comparison.

1    **9.4.3.3    Alternative 2**

2    The CVP and SWP operations under Alternative 2 are identical to the CVP and  
3    SWP operations under the No Action Alternative, as described in Chapter 3,  
4    Description of Alternatives. Alternative 2 would not include implementation of  
5    fish passage actions under the 2009 NMFS BO. As described in Chapter 4,  
6    Approach to Environmental Analysis, Alternative 2 is compared to the No Action  
7    Alternative and the Second Basis of Comparison.

8    **9.4.3.3.1    Alternative 2 Compared to the No Action Alternative**

9    *Trinity River Region*

10   The CVP and SWP operations under Alternative 2 are identical to the CVP and  
11   SWP operations under the No Action Alternative. Therefore, fish and aquatic  
12   resources conditions at Trinity Lake and along the Trinity River and lower  
13   Klamath River under Alternative 2 would be the same as under the No Action  
14   Alternative.

15   *Central Valley Region*

16   The CVP and SWP operations under Alternative 2 are identical to the CVP and  
17   SWP operations under the No Action Alternative. Therefore, physical conditions  
18   that affect aquatic resources under Alternative 2 would be the same as under the  
19   No Action Alternative. However, salmonid survival could be less under  
20   Alternative 2 due to the lack of fish passage actions to move fish to portions of the  
21   Sacramento, American, and Stanislaus rivers that would provide cooler  
22   temperatures for spawning and rearing under the No Action Alternative. In  
23   addition, Alternative 2 would not include various actions that would occur under  
24   the No Action Alternative intended to benefit salmonids and sturgeon, such as  
25   structural improvements for temperature control on the American River; gravel  
26   augmentation, floodplain restoration and inundation flows, and freshwater  
27   migratory habitat restoration in the Stanislaus River; and measures to increase the  
28   efficiency of the Tracy and Skinner Fish Collection Facilities. Thus, it is  
29   concluded that the potential for adverse effects on salmonids and sturgeon under  
30   Alternative 2 would be greater than under the No Action Alternative.

31   *San Francisco Bay Area Region*

32    *Killer Whale*

33   It is unlikely that the Chinook Salmon prey base of killer whales, supported  
34   heavily by hatchery production of fall-run Chinook Salmon, would be appreciably  
35   affected by any of the alternatives.

36   **9.4.3.3.2    Alternative 2 Compared to the Second Basis of Comparison**

37    *Trinity River Region*

38   The CVP and SWP operations under Alternative 2 are identical to the CVP and  
39   SWP operations under the No Action Alternative. Therefore, changes in aquatic  
40   resources at Trinity Lake and along the Trinity River and lower Klamath River  
41   under Alternative 2 as compared to the Second Basis of Comparison would be the

1 same as the impacts described in Section 10.4.4.1, No Action  
2 Alternative Compared to the Second Basis of Comparison.

3 *Central Valley Region*

4 The CVP and SWP operations under Alternative 2 are identical to the CVP and  
5 SWP operations under the No Action Alternative. Therefore, changes in physical  
6 conditions that affect aquatic resources in the Central Valley Region under  
7 Alternative 2 as compared to the Second Basis of Comparison would be the same  
8 as the impacts described for the No Action Alternative Compared to the Second  
9 Basis of Comparison. Actions to provide fish passage to portions of the  
10 Sacramento, American, and Stanislaus rivers upstream of their dams would not be  
11 undertaken under Alternative 2 or the Second Basis of Comparison.

12 *San Francisco Bay Area Region*

13 *Killer Whale*

14 As described above for the comparison of Alternative 1 to the No Action  
15 Alternative, it is unlikely that the Chinook Salmon prey base of killer whales,  
16 supported heavily by hatchery production of fall-run Chinook Salmon, would be  
17 appreciably affected by any of the alternatives.

18 **9.4.3.4 Alternative 3**

19 As described in Chapter 3, Description of Alternatives, CVP and SWP operations  
20 under Alternative 3 are similar to the Second Basis of Comparison with modified  
21 OMR flow criteria and New Melones Reservoir operations. Alternative 3 also  
22 includes the following items that are not included in the No Action Alternative or  
23 the Second Basis of Comparison and would affect fish and aquatic resources.

- 24 • Implement predator control programs for black bass, Striped Bass, and  
25 Sacramento Pikeminnow to protect salmonids and Delta Smelt as follows:
  - 26 – Black bass catch limit changed to allow catch of 12-inch fish with a bag  
27 limit of 10
  - 28 – Striped Bass catch limit changed to allow catch of 12-inch fish with a bag  
29 limit of 5
  - 30 – Establish a Sacramento Pikeminnow sport-fishing reward program with a  
31 8-inch limit at \$2/fish
- 32 • Establish a trap and haul program for juvenile salmonids entering the Delta  
33 from the San Joaquin River in March through June as follows:
  - 34 – Begin operation of downstream migrant fish traps upstream of the Head of  
35 Old River on the San Joaquin River
  - 36 – “Barge” all captured juvenile salmonids through the Delta, release at  
37 Chipps Island.
  - 38 – Tag subset of fish in order to quantify effectiveness of the program
  - 39 – Attempt to capture 10 percent to 20 percent of out-migrating juvenile  
40 salmonids

- 1 • Work with Pacific Fisheries Management Council, CDFW, and NMFS to  
2 minimize harvest mortality of natural origin Central Valley Chinook Salmon,  
3 including fall-run Chinook Salmon, by evaluating and modifying ocean  
4 harvest for consistency with Viable Salmonid Population Standards; including  
5 harvest management plan to show that abundance, productivity, and diversity  
6 (age-composition) are not appreciably reduced.

7 As described in Chapter 4, Approach to Environmental Analysis, Alternative 3 is  
8 compared to the No Action Alternative and the Second Basis of Comparison.

#### 9 **9.4.3.4.1 Alternative 3 Compared to the No Action Alternative**

##### 10 *Trinity River Region*

##### 11 *Coho Salmon*

12 The analysis of effects associated with changes in operation on Coho Salmon was  
13 conducted using temperature model outputs for Lewiston Dam to anticipate the  
14 likely effects on conditions in the Trinity River downstream of Lewiston Dam for  
15 Coho Salmon.

16 Long-term average monthly water temperatures in the Trinity River at Lewiston  
17 Dam under Alternative 3 generally would be similar to the temperatures that  
18 would occur under the No Action Alternative (Appendix 6B, Table B-1-2). An  
19 exception occurs during November when long-term average water temperatures  
20 are increased by 3.3°F under Alternative 3 relative to the No Action Alternative in  
21 critical years. In addition, water temperatures under Alternative 3 could be as  
22 much as 1.5°F cooler than under the No Action Alternative in December of below  
23 normal years. Overall, the temperature differences between Alternative 3 and the  
24 No Action Alternative would be relatively minor and likely would have little  
25 effect on Coho Salmon in the Trinity River. The higher water temperatures in  
26 November of critical years and lower temperatures in December of below normal  
27 years under Alternative 3 would likely have little effect on Coho Salmon as water  
28 temperatures in the Trinity River are typically low during this time period.

29 The USFWS established a water temperature threshold of 56°F for Coho Salmon  
30 spawning in the reach of the Trinity River from Lewiston to the confluence with  
31 the North Fork Trinity River from October through December. Although not  
32 entirely reflective of water temperatures throughout the reach, the temperature  
33 model provides average monthly water temperature outputs for Lewiston Dam,  
34 which may provide perspective on temperature conditions in the reach below.  
35 Under Alternative 3, the spawning temperature threshold would be exceeded  
36 about 6 percent of the time in October, about 2 percent less frequently than under  
37 the No Action Alternative. In November, average water temperatures under  
38 Alternative 3 would not exceed the threshold, whereas average monthly water  
39 temperatures the No Action Alternative would exceed the threshold about  
40 2 percent of the time. The threshold would not be exceeded in December under  
41 either scenario (Appendix 9N).

1 Overall, the temperature model outputs for each of the Coho Salmon life stages  
2 suggest that the temperature of water released at Lewiston Dam generally would  
3 be similar under both scenarios, although the exceedance of water temperature  
4 thresholds would be less frequent under Alternative 3. Given the similarity of the  
5 results and the inherent uncertainty associated with the resolution of the  
6 temperature model (average monthly outputs), it is concluded that Alternative 3  
7 and the No Action Alternative are likely to have similar effects on the Coho  
8 Salmon population in the Trinity River.

9 *Spring-run Chinook Salmon*

10 The analysis of effects associated with changes in operation on spring-run  
11 Chinook Salmon was conducted using temperature model outputs for Lewiston  
12 Dam to anticipate the likely effects on conditions in the Trinity River downstream  
13 of Lewiston Dam.

14 As described above for Coho Salmon, the differences in long-term average  
15 monthly water temperatures between Alternative 3 and the No Action  
16 Alternative would be relatively minor (less than 0.5°F) and likely would have  
17 little effect on spring-run Chinook Salmon in the Trinity River. The substantially  
18 higher (3.3°F) water temperatures in November of critical dry years and lower (by  
19 1.5°F) in December of below normal years under Alternative 3 would likely have  
20 little effect on spring-run Chinook Salmon as water temperatures in the Trinity  
21 River are typically low during this time period.

22 In July, water temperatures in the Trinity River at Lewiston Dam would not  
23 exceed the 60°F threshold for spring-run Chinook Salmon holding under  
24 Alternative 3, although this threshold would be exceeded 1 percent of the time  
25 under the No Action Alternative. Under both Alternative 3 and the No Action  
26 Alternative, average monthly water temperatures in the Trinity River at Lewiston  
27 Dam would exceed 60°F two percent of the time in August. In September, the  
28 threshold for spawning (56°F) would be exceeded under both scenarios about  
29 9 percent of the time. Overall, the differences in the frequency of threshold  
30 exceedance between Alternative 3 and the No Action Alternative would be  
31 relatively minor. However, temperature conditions under Alternative 3 could be  
32 slightly less likely to affect spring-run Chinook Salmon holding than under the No  
33 Action Alternative because of the reduced frequency of exceedance of the 60°F  
34 threshold at Lewiston Dam in July.

35 The majority of spring-run Chinook Salmon in the Trinity River are produced in  
36 the South Fork Trinity watershed. Although the water temperature and flow  
37 changes could have slight beneficial effects on spring-run Chinook Salmon in the  
38 Trinity River, these effects would not occur in every year and are not anticipated  
39 to be substantial based on the relatively small differences in flows and water  
40 temperatures under Alternative 3 as compared to the No Action Alternative.

41 Overall, Alternative 3 is likely to have similar effects on the spring-run Chinook  
42 Salmon population in the Trinity River as compared to the No Action Alternative.  
43 However, the implementation of the Hatchery Management Plan (RPA  
44 Action II.6.3) under the No Action Alternative could reduce the impacts of

1 hatchery Chinook Salmon on natural spring-run Chinook Salmon in the Trinity  
2 River, and increase the genetic diversity and diversity of run-timing for these  
3 stocks relative to Alternative 3.

4 *Fall-Run Chinook Salmon*

5 The analysis of effects associated with changes in operation on fall-run Chinook  
6 Salmon was conducted using temperature model outputs for Lewiston Dam to  
7 anticipate the likely effects on conditions in the Trinity River downstream of  
8 Lewiston Dam. The Reclamation Salmon Survival Model also was applied to  
9 assess changes in egg mortality.

10 As described above for Coho Salmon, the temperature differences between  
11 Alternative 3 and No Action Alternative would be relatively minor (less than  
12 0.5°F) and likely would have little effect on fall-run Chinook Salmon in the  
13 Trinity River. The higher water temperatures (as much as 3.3°F) in November of  
14 critical years (and lower temperatures in December) under Alternative 3 would  
15 likely have little effect on fall-run Chinook Salmon as water temperatures in the  
16 Trinity River are typically low during this time period.

17 The temperature threshold and months during which it applies for fall-run  
18 Chinook Salmon are the same as those for Coho Salmon. Under Alternative 3,  
19 the 56°F threshold for fall-run Chinook Salmon spawning would be exceeded  
20 about 6 percent of the time in October, about 2 percent less frequently than under  
21 the No Action Alternative. In November and December, average water  
22 temperatures under Alternative 3 would not exceed the threshold, whereas  
23 average monthly water temperatures the No Action Alternative would exceed the  
24 threshold about 2 percent of the time in November, with no exceedances in  
25 December. Overall, the differences in the frequency of threshold exceedance  
26 between Alternative 3 and the No Action Alternative would be relatively minor.  
27 Temperature conditions under the Alternative 3 could be slightly less likely to  
28 affect fall-run Chinook Salmon spawning than under the No Action  
29 Alternative because of the slightly reduced frequency of exceedance of the 56°F  
30 threshold at Lewiston Dam in October. However, this would occur prior to the  
31 peak spawning period (November-December) for fall-run Chinook Salmon.

32 The temperatures described above for the Trinity River downstream of Lewiston  
33 Dam are reflected in the analysis of egg mortality using the Reclamation model  
34 (Appendix 9C). For fall-run Chinook Salmon in the Trinity River, the long-term  
35 average egg mortality rate is predicted to be relatively low (around 4 percent),  
36 with higher mortality rates (over 10 percent) occurring in critical dry years under  
37 Alternative 3 (Appendix 9C, Table B-5). Overall, egg mortality under  
38 Alternative 3 and the No Action Alternative would be similar in all water year  
39 types.

40 Although the water temperature and flow changes suggest a lower potential for  
41 adverse effects on fall-run Chinook Salmon in the Trinity River, these effects  
42 would not occur in every year and are not anticipated to be substantial based on  
43 the relatively small differences in flows and water temperatures (and similar egg  
44 mortality) under Alternative 3 as compared to the No Action Alternative.

1 Overall, Alternative 3 is likely to have similar effects on fall-run Chinook Salmon  
2 in the Trinity River as compared to the No Action Alternative. However, the  
3 implementation of the Hatchery Management Plan (RPA Action II.6.3) under the  
4 No Action Alternative could reduce the impacts of hatchery Chinook Salmon on  
5 natural fall-run Chinook Salmon in the Trinity River, and increase the genetic  
6 diversity and diversity of run-timing for these stocks relative to Alternative 3.

7 *Steelhead*

8 The analysis of effects associated with changes in operation on steelhead was  
9 conducted using temperature model outputs for Lewiston Dam to anticipate the  
10 likely effects on conditions in the Trinity River downstream of Lewiston Dam.

11 As described above for Coho Salmon, the temperature differences between  
12 Alternative 3 and No Action Alternative would be relatively minor (less than  
13 0.5°F) and likely would have little effect on steelhead in the Trinity River. In  
14 critical dry years, increased water temperatures in November under Alternative 3  
15 could increase the likelihood of adverse effects on migrating adult steelhead,  
16 although water temperatures are relatively low at this time of year.

17 The temperature threshold and months during which it applies for steelhead are  
18 the same as those for Coho Salmon. Overall, the differences in the frequency of  
19 threshold exceedance between Alternative 3 and the No Action Alternative would  
20 be relatively minor and are unlikely to affect steelhead spawning in the Trinity  
21 River. While average monthly temperatures would be similar overall, the slight  
22 reduction in the frequency of threshold exceedance provided by Alternative 3  
23 during warm periods in October and November suggest that temperature  
24 conditions under Alternative 3 could be slightly less likely to affect steelhead than  
25 under the No Action Alternative.

26 Although water temperatures under Alternative 3 suggest a slightly lower  
27 potential for adverse effects on steelhead in the Trinity River, the relatively small  
28 differences in flows and water temperatures under Alternative 3 as compared to  
29 the No Action Alternative would likely have similar effects on steelhead in the  
30 Trinity River as compared to the No Action Alternative.

31 *Green Sturgeon*

32 Changes in operations that influence temperature and flow conditions in the  
33 Trinity River downstream of Lewiston Dam could influence Green Sturgeon. The  
34 following describes those changes and their potential effects.

35 As described in the Affected Environment, Green Sturgeon spawn in the lower  
36 reaches of the Trinity River during April through June, and water temperatures  
37 above about 63°F are believed stressful to embryos (Van Eenennaam et al. 2005).  
38 Average monthly water temperature conditions during April through June in the  
39 Trinity River at Lewiston Dam under Alternative 3 are similar and do not exceed  
40 58°F during this period. Water temperatures in the downstream reaches where  
41 Green Sturgeon spawn would be higher, although temperature conditions likely  
42 would be controlled by other factors (e.g., ambient air temperatures and tributary  
43 inflows) rather than water operations at Trinity and Lewiston dams. Therefore,

1 given the similarities between average monthly water temperatures at Lewiston  
2 Dam under Alternative 3 and the No Action Alternative, it is likely that  
3 temperature conditions for Green Sturgeon in the Trinity River and lower  
4 Klamath River and estuary would be similar under both scenarios.

#### 5 *Reservoir Fishes*

6 The analysis of effects associated with changes in operation on reservoir fishes  
7 relied on evaluation of changes in available habitat (reservoir storage) and  
8 anticipated changes in black bass nesting success.

9 Changes in CVP water supplies and operations under Alternative 3 as compared  
10 to the No Action Alternative would result in higher reservoir storage in Trinity  
11 Lake. Storage in Trinity Lake could be increased up to around 10 percent in some  
12 months of some water year types. Additional information related to monthly  
13 reservoir elevations is provided in Appendix 5A, CalSim II and DSM2 Modeling.

14 Aquatic habitat in Trinity Lake may not be limiting; however, storage volume is  
15 an indicator of how much habitat is available to fish species inhabiting these  
16 reservoirs. Therefore, the amount of habitat for reservoir fishes could be  
17 increased somewhat under Alternative 3 as compared to the No Action  
18 Alternative.

19 Results of the bass nesting success analysis are presented in Appendix 9F,  
20 Reservoir Fish Analysis Documentation. Bass nest survival in Trinity Lake is  
21 predicted to be near 100 percent in March and April due to increasing reservoir  
22 elevations. For May, the likelihood of survival for Largemouth and Smallmouth  
23 Bass in Trinity Lake being in the 40 to 100 percent range would be similar under  
24 Alternative 3 and the No Action Alternative. For June, the likelihood of survival  
25 being greater than 40 percent for Largemouth and Smallmouth Bass would be  
26 somewhat lower than in May and would be similar under Alternative 3 and the No  
27 Action Alternative. For Spotted Bass, the likelihood of survival being greater  
28 than 40 percent would be 100 percent in May under both Alternative 3 and the No  
29 Action Alternative. For June, Spotted Bass survival in Trinity Lake would be less  
30 than for May due to greater daily reductions in water surface elevation. The  
31 likelihood of survival being greater than 40 percent would be similar (near  
32 100 percent) under Alternative 3 and the No Action Alternative.

33 Overall, the comparison of storage and the analysis of nesting suggest that effects  
34 of Alternative 3 on reservoir fishes would be similar to those under the No Action  
35 Alternative.

#### 36 *Pacific Lamprey*

37 Little information is available on factors that influence populations of Pacific  
38 Lamprey in the Trinity River, but they are likely affected by many of the same  
39 factors as salmon and steelhead because of the parallels in their life cycles. On  
40 average, the temperature of water released at Lewiston Dam under Alternative 3  
41 would be similar to (within 0.5°F) (Appendix 6B). The highest increases in flow  
42 would be less than 10 percent in the Trinity River, with a smaller relative increase  
43 in the lower Klamath River and Klamath River estuary (Appendix 5A).

1 Overall, it is likely that effects on Pacific Lamprey would be similar under both  
2 Alternative 3 and the No Action Alternative. This conclusion likely also applies  
3 to other species of lamprey that inhabit the Trinity and lower Klamath rivers  
4 (e.g., River Lamprey).

5 *Eulachon*

6 It is uncertain whether Eulachon has been extirpated from the Klamath River.  
7 Given that the highest increases in flow would be less than 10 percent in the  
8 Trinity River (Appendix 5A), with a smaller relative increase in the lower  
9 Klamath River and Klamath River estuary, and that water temperatures in the  
10 Klamath River (Appendix 6B) would be unlikely to be affected by changes  
11 upstream at Lewiston Dam, it is likely that Alternative 3 would have a similar  
12 potential to influence Eulachon in the Klamath River as the No Action  
13 Alternative.

14 *Sacramento River System*

15 *Winter-run Chinook Salmon*

16 Changes in operations that influence temperature and flow conditions in the  
17 Sacramento River downstream of Keswick Dam could affect winter-run Chinook  
18 Salmon. The following describes those changes and their potential effects.

19 *Changes in Water Temperature*

20 Average monthly water temperature in the Sacramento River at Keswick Dam  
21 under Alternative 3 generally would be similar to (less than 0.5°F difference)  
22 water temperatures under the No Action Alternative during most months of the  
23 year (Appendix 6B, Table B-5-2). In September, average water temperatures in  
24 wetter years could be increased by up to 0.8°F and decreased by up to 1.2°F in  
25 critical years. A similar temperature pattern generally would be exhibited  
26 downstream at Ball's Ferry, Jelly's Ferry, and Bend Bridge, with average monthly  
27 temperatures progressively increasing in the downstream direction (e.g., average  
28 difference of about 2°F between Keswick Dam and Bend Bridge) (Appendix 6B,  
29 Table B-8-2). The water temperature differences between Alternative 3 and the  
30 No Action Alternative in September of wetter years would increase to as high as  
31 2.6°F warmer under Alternative 3, while the differences in drier years could reach  
32 1.0°F cooler in September of drier years.

33 Overall, the temperature differences between Alternative 3 and the No Action  
34 Alternative would be relatively minor (less than 0.5°F) and likely would have  
35 little effect on winter-run Chinook Salmon in the Sacramento River. The  
36 increased water temperatures in September of wetter years under Alternative 3  
37 could increase the likelihood of adverse effects on winter-run Chinook Salmon  
38 egg incubation and fry rearing during this water year type. The slightly lower  
39 water temperatures in September of drier years under Alternative 3 could reduce  
40 the likelihood of adverse effects on winter-run Chinook Salmon fry rearing in or  
41 outmigrating from the Sacramento River. There would be little difference in  
42 potential effects on spawning of winter-run Chinook Salmon due to the similar

1 water temperatures during the April to June time period under Alternative 3 as  
2 compared to the No Action Alternative.

3 *Changes in Exceedances of Water Temperature Thresholds*

4 With the exception of April, average monthly water temperatures under both  
5 Alternative 3 and the No Action Alternative would show exceedances of the water  
6 temperature threshold of 56°F established in the Sacramento River at Ball's Ferry  
7 for winter-run Chinook Salmon spawning and egg incubation in every month,  
8 with exceedances under both as high as about 49 percent and 42 percent,  
9 respectively, in some months. Under Alternative 3, the temperature threshold  
10 generally would be exceeded less frequently than it would under the No Action  
11 Alternative (by about 2 percent to 4 percent) in June through August, with the  
12 temperature threshold in September exceeded about 6 percent more frequently  
13 under Alternative 3 than the No Action Alternative. Farther downstream at Bend  
14 Bridge, the frequency of exceedances would increase, with exceedances under  
15 both Alternative 3 and the No Action Alternative as high as nearly 90 percent in  
16 some months. Under Alternative 3, temperature exceedances generally would be  
17 less frequent (by up to 8 percent) than under the No Action Alternative, with the  
18 exception of September, when exceedances under Alternative 3 would be about  
19 26 percent more frequent.

20 Overall, there would be substantial differences in the frequency of threshold  
21 exceedance between Alternative 3 and the No Action Alternative, particularly in  
22 September. While temperature conditions under Alternative 3 could be less likely  
23 to affect winter-run Chinook Salmon egg incubation than under the No Action  
24 Alternative because of the reduced frequency of exceedance of the 56°F threshold  
25 from April through August, the substantial increase in the frequency of  
26 exceedance in September under Alternative 3 may increase the likelihood of  
27 adverse effects on winter-run Chinook Salmon egg incubation during this limited  
28 portion of the spawning and egg incubation period.

29 *Changes in Egg Mortality*

30 The temperatures described above for the Sacramento River downstream of  
31 Keswick Dam are reflected in the analysis of egg mortality using Reclamation's  
32 salmon mortality model (Appendix 9C). For winter-run Chinook Salmon in the  
33 Sacramento River, the long-term average egg mortality rate is predicted to be  
34 relatively low (around 5 percent), with higher mortality rates (exceeding  
35 25 percent) occurring in critical dry years under Alternative 3. In critical dry  
36 years the average egg mortality rate would be 6 percent less than under the No  
37 Action Alternative (Appendix 9C, Table B-4). Overall, winter-run Chinook  
38 Salmon egg mortality in the Sacramento River under Alternative 3 and the No  
39 Action Alternative would be similar, except in critical dry water years.

40 *Changes in Weighted Usable Area*

41 As an indicator of the amount of suitable spawning habitat for winter-run Chinook  
42 Salmon between Keswick Dam and Battle Creek, modeling results indicate that,  
43 in general, there would be similar amounts of spawning habitat available from  
44 April through August under Alternative 3 as compared to the No Action

1 Alternative (Appendix 9E, Weighted Usable Area Analysis). Modeling results  
2 also indicate that, in general, there would be similar amounts of suitable fry  
3 rearing habitat available from June through October under Alternative 3. Similar  
4 to the results for fry rearing WUA, modeling results indicate that there would be  
5 similar amounts of suitable juvenile rearing habitat available during the juvenile  
6 rearing period from July to May under Alternative 3 and the No Action  
7 Alternative.

8 *Changes in SALMOD Output*

9 SALMOD results indicate that potential juvenile production would be similar  
10 under Alternative 3 as compared to the No Action Alternative (Appendix 9D,  
11 Table B-4-6).

12 *Changes in Delta Passage Model Output*

13 The Delta Passage Model predicted similar estimates of annual Delta survival  
14 across the 81-year time period for winter-run Chinook Salmon between  
15 Alternative 3 and the No Action Alternative (Appendix 9J). Median Delta  
16 survival would be 0.354 for Alternative 3 and 0.349 for the No Action  
17 Alternative.

18 *Changes in Delta Hydrodynamics*

19 Winter-run Chinook Salmon smolts are most abundant in the Delta during  
20 January, February, and March. On the Sacramento River near the confluence of  
21 Georgiana Slough, the median proportion of positive velocities under  
22 Alternative 3 was indistinguishable from the No Action  
23 Alternative (Appendix 9K). On the San Joaquin River near the Mokelumne River  
24 confluence, the median proportion of positive velocities would be  
25 indistinguishable between these two alternatives. In Old River downstream of the  
26 facilities, the median proportion of positive velocities would be similar under  
27 Alternative 3 and the No Action Alternative in January, February, and March. In  
28 Old River upstream of the facilities, the median proportion of positive velocities  
29 also would be similar under Alternative 3 and the No Action Alternative in these  
30 months. On the San Joaquin River downstream of Head of Old River, the percent  
31 of positive velocities would be similar under both alternatives in January,  
32 February and March.

33 *Changes in Junction Entrainment*

34 For all junctions examined, entrainment probabilities for both scenarios would be  
35 similar under Alternative 3 and the No Action Alternative from January through  
36 March (Appendix 9L).

37 *Changes in Salvage*

38 Salvage of Sacramento River-origin Chinook Salmon is predicted to be similar  
39 under Alternative 3 relative to No Action Alternative during the three months  
40 when winter-run Chinook Salmon are most abundant in the Delta (January,  
41 February, March; (Appendix 9M).

1            *Changes in Oncorhynchus Bayesian Analysis Output*

2    Escapement of winter-run Chinook Salmon and Delta survival was modeled by  
 3    the Oncorhynchus Bayesian Analysis (OBAN) model for winter-run Chinook  
 4    salmon. Escapement was generally lower under Alternative 3 as compared to the  
 5    No Action Alternative (Appendix 9I). The median abundance under Alternative 3  
 6    was higher in only 5 of the 22 years of simulation (1971 to 2002), and there was  
 7    typically greater than a 25 percent chance that Alternative 3 values would be  
 8    lower than under the No Action Alternative. Median delta survival was  
 9    consistently lower (by approximately 7 percent) under Alternative 3 as compared  
 10   to the No Action Alternative. However, the probability intervals indicated that no  
 11   difference between scenarios was a likely outcome. Thus delta survival was not  
 12   responsible for the temporal patterns in relative escapement. Since the ocean  
 13   conditions were equivalent across scenarios, the differences under Alternative 3  
 14   were likely due to differences in survival in the life stages upstream of the delta  
 15   (i.e., due to differences in temperature and flow at Bend Bridge).

16           *Changes in Interactive Object-Oriented Simulation Output*

17    The IOS model predicted similar adult escapement trajectories for winter-run  
 18    Chinook Salmon between Alternative 3 and the No Action Alternative across the  
 19    81 years (Appendix 9H). Under Alternative 3 median adult escapement was  
 20    4,025 and under the No Action Alternative, median escapement was 3,935.

21    Similar to adult escapement, the IOS model predicted similar egg survival time  
 22    trajectories for winter-run Chinook Salmon between Alternative 3 and No Action  
 23    Alternative across the 81 water years. Under Alternative 3 median egg survival  
 24    was 0.987 and under the No Action Alternative median egg survival was 0.990.

25           *Changes in Predator Management*

26    The fish predator assemblage of the Delta is dominated by invasive predators,  
 27    with the exception of the Sacramento Pikeminnow (Brown and Michniuk 2007;  
 28    Nobriga and Feyrer 2007, National Research Council 2010; Cavallo et al. 2012,  
 29    NRC 2012, Brown 2013). With the exception of Striped Bass, there is little  
 30    population-level information for fish predators including Largemouth Bass and  
 31    Sacramento Pikeminnow and there is even less information for Smallmouth Bass  
 32    and White and Channel Catfish (Grossman et al. 2013). It is important to note  
 33    that, in addition to predation by native and non-native fishes, there has been  
 34    extensive modification of the hydrology, loss of tidal freshwater wetlands,  
 35    increases in non-native submerged aquatic vegetation such as *Egeria densa*, and  
 36    other effects of human population growth within the Delta, which also  
 37    undoubtedly influence the survival of salmonids in the Delta (Brown and  
 38    Michniuk 2007; National Research Council 2010, 2012).

39    Bowen et al. (2009 and 2010) describe salmonid behavior in the vicinity of the  
 40    Head of Old River Barrier and predation from the release point upstream at  
 41    Durham Ferry. Predation in this short reach seemed to be increased during the  
 42    lower flows in 2009 and during later release in 2010. While this two year study  
 43    observed a variable and negative relationship between flow and survival past a  
 44    Head of Old River Barrier, there remains uncertainty in this due to the actual

1 barrier structures implemented and how they affected predator habitat in this  
2 reach.

3 Although it is well documented that Striped Bass can feed heavily on juvenile  
4 salmon and steelhead in the rivers, as they migrate seaward, many of the salmon  
5 eaten are likely to be hatchery-reared fish; juveniles from natural spawning may  
6 be more wary and encounter lower predation rates. It is thought that predation on  
7 hatchery-reared juveniles may buffer wild fish from such predation (Moyle and  
8 Bennett 2010). Much of the predation on juvenile salmon seems to take in place  
9 in conjunction with artificial structures and release practices. These include  
10 releases of fish from hatcheries and those trucked to the estuary from the export  
11 facilities in the south Delta (DWR 2010).

12 In general, Striped Bass are opportunistic predators that tend to forage on  
13 whatever prey are most abundant, from benthic invertebrates to their own young  
14 to juvenile salmon and American Shad (Stevens 1966, Moyle 2002, Nobriga and  
15 Feyrer 2008). Striped Bass are unlikely to be a major predator of Delta Smelt  
16 because Delta Smelt are semi-transparent (making them hard to see in turbid  
17 water) and do not school, unlike more favored prey such as Threadfin Shad,  
18 juvenile Striped Bass, and Mississippi Silverside. Delta Smelt were a minor item  
19 in Striped Bass diets when they were highly abundant in the early 1960s  
20 (Stevens 1966), as well as in recent years at record low abundance (Nobriga and  
21 Feyrer 2008).

22 Predator control measures are included in Alternative 3, including an increased  
23 bag limit (10/day) with a minimum size limit of 12 inches on Striped Bass and  
24 black bass. In addition, a sport reward program for Sacramento Pikeminnow  
25 (\$2/fish > 8 inches) would be implemented to encourage fishing for and removal  
26 of this native predatory fish.

27 A number of studies have been conducted on predation effects in the Delta, and a  
28 recent (2013) workshop was held to assess the status of information and  
29 potentially establish conclusions regarding the importance of fish predation on  
30 salmonid populations in the Delta (Grossman et al. 2013). The workshop  
31 concluded that:

32 “Available data and analyses have generated valuable information  
33 regarding aspects of the predation process in the Delta but do not provide  
34 unambiguous and comprehensive estimates of fish predation rates on  
35 juvenile salmon or steelhead nor on population-level effects for these  
36 species in the Delta.”

37 And:

38 “Juvenile salmon are clearly consumed by fish predators and several  
39 studies indicate that the population of predators is large enough to  
40 effectively consume all juvenile salmon production. However, given  
41 extensive flow modification, altered habitat conditions, native and non-  
42 native fish and avian predators, temperature and dissolved oxygen  
43 limitations, and overall reduction in historical salmon population size, it is

1 not clear what proportion of juvenile mortality can be directly attributed to  
2 fish predation. Fish predation may serve as the proximate mechanism of  
3 mortality in a large proportion of the population but the ultimate causes of  
4 mortality and declines in productivity are less clear.”

5 The proposed bag and size limits are intended and expected to encourage more  
6 fishing effort for and greater harvest of Striped Bass and black bass species,  
7 resulting in a reduction in the Striped Bass and black bass populations throughout  
8 the Delta. It is reasonable to assume that removing or relaxing restrictions on the  
9 harvest of these predatory species would lead to a substantial reduction in their  
10 number. However, whether or not this reduction would lead to a substantial  
11 benefit or population-level effect on salmonid populations is unknown  
12 (Moyle and Bennett 2010). For the proposed (under Alternative 3) predator  
13 reduction program to be effective, it must be true that predation by Striped Bass  
14 and black bass regulates populations of salmon, steelhead, and smelt, with  
15 predation by other species (other fish, birds, marine mammals, etc.) playing a  
16 minor role. The program may not be effective, or the effectiveness would be  
17 reduced if other predators exhibit compensatory increases in predation if Striped  
18 Bass and black bass are removed.

19 As noted above, the modification of the hydrology, loss of tidal freshwater  
20 wetlands, increases in non-native submerged aquatic vegetation, and other effects  
21 of human population growth within the Delta play a role in the survival of  
22 salmonids in the Delta and contribute to the uncertainty that any predator  
23 reduction program will have the desired results. It is unknown whether reducing  
24 Striped bass and black bass populations can measurably compensate for the large  
25 changes to the estuary and watershed, which also contribute to reduced  
26 populations of salmon, steelhead and smelt.

27 In addition to the proposed bag and size limits, Alternative 3 includes a proposal  
28 to implement a sport reward program for Sacramento Pikeminnow to encourage  
29 fishing for and removal of predatory Sacramento Pikeminnow. It is unknown  
30 whether a Sacramento Pikeminnow bounty would be feasible under California  
31 regulations. Currently, the Sacramento Pikeminnow is regulated under CCR  
32 Title 14, section 5.95 (no limit or season), sections 2.25 and 2.30 (bow and arrow  
33 and spear fishing) and section 1.87 (no wastage of fish). Therefore, any fishing  
34 practice, derby or bounty program in which the Sacramento Pikeminnow is  
35 wasted would be in violation of the regulations. In addition, Sacramento  
36 Pikeminnow is listed as a "game fish" in commission regulations (CCR Title 14,  
37 section 230) and a permit is required before any prizes can be offered to  
38 take them.

39 Regardless of whether a Sacramento Pikeminnow reward system is feasible to  
40 implement, the effectiveness of such a program is not assured. This same  
41 approach to predator reduction is ongoing in the Columbia River through the  
42 Northern Pikeminnow (*Ptychocheilus oregonensis*) Sport-Reward Program  
43 sponsored by Bonneville Power Administration that began in 1991. The program  
44 seeks to maintain 10 to 20 percent exploitation rate on Northern Pikeminnow  
45 throughout the Columbia River by paying anglers \$4 to \$8 to harvest fish >

1 228 mm (>9 inches) in total length. In 2012, a total of 158,159 fish were  
2 harvested in the sport-reward fishery. Vouchers for 156,837 untagged fish were  
3 submitted for payment totaling rewards of \$1,016,672. System-wide pikeminnow  
4 exploitation efforts suggest that the desired 10 to 20 percent exploitation rate has  
5 been achieved for a number of years (Porter 2012). The program has removed  
6 over 2.2 million fish from 1998-2009 and is believed to have reduced predation  
7 on juvenile salmonids; however, predation estimates have varied widely and  
8 positive effects on salmonid populations have been difficult to detect (Carey et al.  
9 2012).

10 Control of undesired and invasive fishes is a common fishery management  
11 strategy (Kolar et al. 2010). However, changes in predator abundance produced  
12 via removal, augmentation, or invasion can produce unintended consequences  
13 (Polis and Strong 1996). It is possible that other species on which Striped Bass  
14 prey, such as Mississippi Silverside, would increase in abundance, causing harm  
15 by competing with and preying on desired species, particularly Delta Smelt.  
16 Mississippi Silversides are important in the diets of 1 to 3 year old Striped Bass;  
17 predation by Striped Bass could be regulating the silverside population. Reducing  
18 Striped Bass predation pressure on Mississippi Silversides may increase their  
19 numbers, which could have negative effects on Delta Smelt through predation on  
20 eggs and larvae (Bennett and Moyle 2006).

21 The predator reduction program under Alternative 3 is intended to improve the  
22 survival of listed species (e.g., salmonids and Delta Smelt) by reducing predation  
23 on these species. As described above, the program may be difficult to implement,  
24 may not be effective, and may cause unintended harm to other native Delta fish  
25 species. Consequently, the outcome of the predator management program is  
26 highly uncertain. Compared to the No Action Alternative, which does not include  
27 a predator reduction program, Alternative 3 may or may not provide a benefit to  
28 salmonids and may result in an adverse effect on Delta smelt.

### 29 *Changes in Ocean Salmon Harvest*

30 Alternative 3 includes an action to change ocean salmon harvest for the purpose  
31 of increasing escapement of adult winter-run Chinook Salmon as well as other  
32 runs. The following outlines the benefits and challenges associated with such a  
33 program.

34 Central Valley origin Chinook Salmon of all races are harvested in commercial  
35 and recreational fisheries off the coast of California. Central Valley origin fall-  
36 run Chinook Salmon are the primary target of this harvest. Harvested Chinook  
37 Salmon between Point Conception and Bodega Bay were found to be composed  
38 of 89-95 percent Central Valley fall-run Chinook Salmon (Winans et al. 2001).  
39 More recent studies have shown most Central Valley fall-run Chinook Salmon are  
40 produced by hatcheries, and are not of natural origin. Barnett-Johnson et al.  
41 (2007) analyzed otolith microstructure from harvested Chinook Salmon and  
42 estimated 90 percent were of hatchery origin. Palmer-Zwhalen and Kormos  
43 (2012; Table 9) reported data indicating spawning-escapement for Central Valley  
44 fall-run Chinook Salmon was composed of 75 percent hatchery origin fish.

1 Despite the relatively high abundance of hatchery-produced fall-run Chinook  
2 Salmon, ocean fisheries are often constrained to protect ESA-listed Chinook  
3 Salmon stocks (including Sacramento winter-run and spring-run Chinook Salmon,  
4 and Coastal Chinook Salmon), which constitute less than 10 percent of available  
5 Chinook Salmon (Winans et al. 2001). This “mixed-stock” fishery is managed by  
6 using stock-specific differences in ocean distribution, age at maturity, size-at-date,  
7 and/or timing of river entry to help minimize harvest of sensitive stocks.  
8 However, such management strategies are only partially effective.

9 For example, spring-run Chinook Salmon return to freshwater in the spring and  
10 thus avoid most ocean harvest during the year in which they mature. However,  
11 spring-run Chinook Salmon that mature at age 4 (or older) are subjected to a full  
12 season of harvest at “impact levels” comparable to those directed at Central  
13 Valley fall-run Chinook Salmon. Harvest managers define “impact rate” as the  
14 proportion of a particular stock that will suffer mortality associated with the ocean  
15 fishery. Fall-run Chinook Salmon often experience impact rates between 40 and  
16 70 percent.

17 Thus, the impact of ocean harvest varies substantially by stock, but all stocks are  
18 impacted by harvest directed at the most abundant Chinook Salmon population  
19 (typically hatchery origin fall-run Chinook Salmon). Several analyses are  
20 available that provide a basis for assessing how harvest management identified in  
21 Alternative 3 would affect Central Valley Chinook Salmon populations. Though  
22 there are political and societal considerations for changes in ocean harvest  
23 management, there are no technical or scientific constraints. We have the tools,  
24 the knowledge and the ability to manage Chinook ocean harvest in whatever way  
25 is needed. As such, Alternative 3 is, from a technical and scientific level,  
26 entirely feasible.

27 Alternative 3 calls for ocean harvest to be managed with the standard of causing  
28 no appreciable reduction in viability criteria for natural origin Chinook Salmon.  
29 This alternative is addressed separately for Central Valley spring-run, winter-run,  
30 and fall-run Chinook Salmon.

### 31 *Spring-Run Chinook Salmon.*

32 Fifteen years have elapsed since NMFS last updated its spring-run Chinook  
33 Salmon ocean harvest Biological Opinion (NMFS 2000). The 2000 BO did not  
34 report an estimated “impact rate” for the ocean harvest impact on spring-run  
35 Chinook Salmon. The BO reached a non-jeopardy opinion for the impacts of  
36 ocean harvest primarily by referring to the growth in Central Valley spring-run  
37 Chinook Salmon population which was occurring at that time. Though NMFS  
38 (2010) did not provide a quantitative analysis of spring-run Chinook Salmon  
39 harvest, Grover et al. (2004) estimated that two thirds of spring-run Chinook  
40 Salmon matured at age 4, indicating that a large fraction of the spring-run  
41 Chinook Salmon population is annually subject to high impact rates (40 to  
42 70 percent), which would greatly influence population productivity and  
43 abundance. Harvest of age-3 spring-run Chinook Salmon is likely to be  
44 comparable to that experienced by winter-run Chinook Salmon (which also  
45 mature and return to fresh water, missing most of the ocean fishing season).

1 Though a comparable analysis for spring-run Chinook Salmon is not available,  
2 Winship et al. (2013) applied a simulation model that showed a 25 percent impact  
3 rate (much less than that likely experienced by age 4 spring-run Chinook Salmon)  
4 on winter-run Chinook Salmon substantially decreased population abundance and  
5 population resiliency relative to alternatives with less harvest.

6 Harvest pressure of this intensity can also alter diversity in age at-maturity, a  
7 critical factor for population viability (NMFS 2010). The ocean fishery is thought  
8 to select against fish that mature later because fish that would do so are vulnerable  
9 to harvest for more years (Ricker 1981; Hankin and Healey 1986; Sierra and  
10 Lackey 2015), and age at maturity has moderate heritability (Hankin et al. 1993).  
11 As such, reduced ocean harvest would contribute substantially to age at-maturity  
12 diversity (certainly demographically, if not genetically) and thereby enhance  
13 population viability. A downward shift in size and age at maturity also affect  
14 fitness by reducing fecundity and reproductive rates (Calduch-Verdiell et al.  
15 2014). Larger females generally have larger and more numerous eggs  
16 (Wertheimer et al. 2004), both of which provide reproductive advantages. Larger  
17 eggs produce larger juveniles, which tend to have higher survival rates  
18 (Quinn 2005) and are more resistance to temperature extremes. Since size and  
19 age-at-maturity are heritable, selection for earlier adult maturity leads to a  
20 feedback loop in which younger and smaller adults produce offspring that mature  
21 earlier at smaller sizes. Change in body size may also influence spawning habitat  
22 use where larger fish occupy areas with coarser substrate that smaller fish may not  
23 be able to use. Thus, advantages of diversity in age at-maturity could be  
24 especially important in degraded and thermally stressful habitats typical of  
25 Central Valley tributaries.

26 *Winter-Run Chinook Salmon*

27 NMFS updated their winter-run Chinook Salmon ocean harvest BO in 2010  
28 (NMFS 2010) and concluded:

29 *The effect of harvest and indirect mortality associated with the salmon*  
30 *ocean fishery reduces the reproductive capability of this population, and*  
31 *subsequently the entire ESU, by 10-25 percent per brood, when ocean*  
32 *fisheries occur at a level similar to what has been observed for most of the*  
33 *last decade south of Point Arena, California.*

34 *There is concern about the relatively high impact rate for age-4 fish and*  
35 *the consequences of this relative to the genetic diversity of winter-run. If*  
36 *age at maturity is strongly related to a genetic component, the removal of*  
37 *older fish at a high rate before they can return to spawn, however few of*  
38 *these individuals in the population there might be, could theoretically*  
39 *reduce the potential for that trait to pass on to successive generation. The*  
40 *change in an average life history trait over time, such as age at maturity,*  
41 *has been suggested as evidence for fisheries induced evolution in some*  
42 *situations (Law 2000; Kuparinen and Merilä 2007; Hard et al. 2008).*

1 NMFS has since implemented changes in ocean harvest regulations intended to  
 2 reduce impacts, but the effectiveness of those programs is unclear. Winship et al.  
 3 (2013) applied a simulation model and showed that all current winter-run  
 4 Chinook Salmon harvest alternatives substantially decreased population  
 5 abundance and population extinction risk relative to closing recreational and  
 6 commercial fisheries south of Point Arena. While closing these fisheries may not  
 7 be a realistic management alternative, Winship et al. (2013) did not consider  
 8 intermediate harvest management strategies such as a mark-selective fishery  
 9 (Pyper et al. 2012) or quota based fishing seasons. Currently, about 90 percent of  
 10 winter-run Chinook Salmon mature at age-3. As identified in the winter-run  
 11 Chinook Salmon harvest BO (NMFS 2010), diversity in age at maturity is an  
 12 important viability criterion likely to be adversely impacted by current harvest  
 13 management; winter-run Chinook Salmon currently maturing at age-4 are  
 14 subjected to impact rates comparable to those targeting fall-run Chinook Salmon  
 15 (40 to 70 percent). Given information presented in the spring-run Chinook  
 16 Salmon section, it seems likely that in the absence of this harvest, winter-run  
 17 Chinook Salmon would have a larger fraction of their population maturing at  
 18 age-4 or possibly older. Age-4 and older winter-run Chinook Salmon would  
 19 enhance demographic population viability, but also benefit the population by  
 20 more effectively spawning in coarse substrates, and producing more, larger, and  
 21 more thermally tolerant eggs.

22 *Fall-Run Chinook Salmon.*

23 As indicated previously, fall-run Chinook Salmon produced by Central Valley  
 24 hatcheries are the most abundant stock harvested off the coast of California. The  
 25 current management of Central Valley fall-run Chinook Salmon makes no  
 26 distinction between natural and hatchery fish, and, as such, harvest of natural  
 27 origin fall-run Chinook Salmon appears to occur at a much higher rate than  
 28 population productivity can sustain. The recently convened California HSRG  
 29 concluded:

30 *“Fishery harvests that are sustained at high levels by targeting abundant*  
 31 *hatchery-origin fish may over-exploit naturally reproducing salmonids*  
 32 *and may also induce selection on maturation schedule and other traits...*  
 33 *fishery exploitation rates must be in alignment with the productivity of*  
 34 *naturally reproducing salmon stocks for the recommendations in this*  
 35 *report to be successful at conserving natural salmonid populations”*  
 36 *(p. 19)*

37 *“The California HSRG also believes that an aggregate escapement target*  
 38 *for [the Central Valley natural stocks] that includes returns to hatcheries*  
 39 *lacks biological support. The target could theoretically be met if all fish*  
 40 *returned to hatcheries and none returned to natural spawning areas, or if*  
 41 *all fish in natural spawning areas were of hatchery origin” (p. 21).*

42 Quantitative analyses of current ocean harvest impacts to natural origin fall-run  
 43 Chinook Salmon are not currently available. However, impact rates combined  
 44 with relatively low abundances of natural origin fall-run Chinook Salmon indicate  
 45 adverse impacts to population viability are likely severe. Changes in harvest

1 strategies which could more effectively target hatchery origin fall Chinook while  
2 better protecting natural origin fish would yield substantial benefits. Pyper et al.  
3 (2012) analyzed one alternative, a mark-selective fishery, and found that natural  
4 origin spawning escapement would increase from 24 to 48 percent.

5 Managing ocean salmon harvest as described in Alternative 3 would contribute to  
6 the abundance, productivity and diversity viability criteria for natural origin  
7 spring-run, winter-run, and fall-run Chinook Salmon.

8 *Summary of Effects on Winter-Run Chinook Salmon*

9 The multiple model and analysis outputs described above characterize the  
10 anticipated conditions for winter-run Chinook Salmon and their response to  
11 change under Alternative 3 as compared to the No Action Alternative. For the  
12 purpose of analyzing effects on winter-run Chinook Salmon and developing  
13 conclusions, greater reliance was placed on the outputs from the two life cycle  
14 models, IOS and OBAN because they each integrate the available information to  
15 produce single estimates of winter-run Chinook Salmon escapement. The output  
16 from IOS indicated that winter-run Chinook Salmon escapement would be similar  
17 under both scenarios, whereas the OBAN results indicated that escapement under  
18 Alternative 3 would be lower than under the No Action Alternative.

19 These model results suggest that effects on winter-run Chinook Salmon would be  
20 similar under both scenarios, with a small likelihood that winter-run Chinook  
21 Salmon escapement would be lower under Alternative 3 than under the No Action  
22 Alternative. This potential distinction between the two scenarios, however, may  
23 be increased due to the benefits of implementation of fish passage under the No  
24 Action Alternative. This potential beneficial effect and its magnitude would  
25 depend on the success of the fish passage program. In addition, RPA actions  
26 intended to increase the efficiency of the Tracy and Skinner Fish Collection  
27 Facilities could improve the overall salvage survival of winter-run Chinook  
28 Salmon.

29 The ocean harvest restriction component of Alternative 3 could increase winter-  
30 run Chinook Salmon numbers by reducing ocean harvest and the predator control  
31 measures under Alternative 3 could reduce predation on juvenile winter-run  
32 Chinook Salmon and thereby increase survival.

33 Overall, given the small differences, distinguishing a clear difference between  
34 alternatives is difficult. The non-operational components associated with  
35 Alternative 3 could benefit winter-run Chinook Salmon relative to the No Action  
36 Alternative over the short term if successful; however, these measures would not  
37 address the long-term temperature challenges in the river downstream of Shasta  
38 Dam that would be addressed under the No Action Alternative if fish passage is  
39 successful. Even though the success of fish passage is uncertain, it is concluded  
40 that the potential for adverse effects on winter-run Chinook Salmon under  
41 Alternative 3 would be greater than those under the No Action Alternative,  
42 principally because Alternative 3 does not include a strategy to address water  
43 temperatures critical to winter-run Chinook Salmon sustainability over the long  
44 term with climate change by 2030.

1           *Spring-run Chinook Salmon*

2 Changes in operations that influence temperature and flow conditions in the  
3 Sacramento River downstream of Keswick Dam could affect spring-run Chinook  
4 Salmon. The following describes those changes and their potential effects.

5           *Changes in Water Temperature*

6 Changes in water temperature that could affect spring-run Chinook Salmon could  
7 occur in the Sacramento River, Clear Creek, and Feather River. The following  
8 describes temperature conditions in those water bodies.

9           *Sacramento River*

10 Average monthly water temperature in the Sacramento River at Keswick Dam  
11 under Alternative 3 relative to the No Action Alternative generally would be  
12 similar to (less than 0.5°F differences) water temperatures under the No Action  
13 Alternative during most months of the year (Appendix 6B, Table B-5-2). In  
14 September, average water temperatures in wetter years would be increased by up  
15 to 0.8°F and decreased by up to 1.2°F in critical years. A similar temperature  
16 pattern generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry,  
17 Bend Bridge, and Red Bluff, with average monthly temperatures progressively  
18 increasing in the downstream direction (e.g., average difference of about 3°F  
19 between Keswick Dam and Red Bluff). The water temperature differences  
20 between Alternative 3 and the No Action Alternative in September of wetter years  
21 would increase to as high as 3.0°F warmer under Alternative 3 at Red Bluff, while  
22 the differences in water temperatures in September associated with Alternative 3  
23 during drier years would remain similar to the differences at upstream locations.

24 Overall, the temperature differences between Alternative 3 and the No Action  
25 Alternative would be relatively minor (less than 0.5°F) and likely would have  
26 little effect on spring-run Chinook Salmon in the Sacramento River. The  
27 increased water temperatures in September of wetter years under Alternative 3  
28 could increase the likelihood of adverse effects on spring-run Chinook Salmon  
29 spawning and egg incubation during this water year type. The slightly lower  
30 water temperatures in September of drier years under Alternative 3 would reduce  
31 the likelihood of adverse effects on spring-run Chinook Salmon spawning and egg  
32 incubation in the Sacramento River as compared to the No Action Alternative.  
33 There would be little difference in potential effects on spring-run Chinook  
34 Salmon holding in other summer months due to the similar water temperatures  
35 during this time period under Alternative 3 and the No Action Alternative.

36           *Clear Creek*

37 Average monthly water temperatures in Clear Creek at Igo under Alternative 3  
38 would be similar to (less than 0.5°F differences) water temperatures under the No  
39 Action Alternative with the exception of May when average monthly  
40 temperatures under Alternative 3 would be somewhat higher (up to about 0.8°F)  
41 than the No Action Alternative (Appendix 6B, Table B-3-2). The lower water  
42 temperatures in May associated with the No Action Alternative reflect the effects  
43 of the additional water that would be discharged from Whiskeytown Dam to meet  
44 the spring attraction flow requirements to promote attraction of spring-run

1 Chinook Salmon into the creek. Overall, water temperature conditions for  
2 spring-run Chinook Salmon in Clear Creek would be similar under Alternative 3  
3 and the No Action Alternative.

4 *Feather River*

5 Average monthly water temperatures in the Feather River low flow channel under  
6 Alternative 3 generally would be similar (within 0.5°F) to water temperatures  
7 under the No Action Alternative, except in November and December (differences  
8 as much as 1.6°F lower in December in below normal water years) (Appendix 6B,  
9 Table B-20-2). In September average monthly water temperatures under  
10 Alternative 3 could be somewhat higher (up to about 1.5°F) in wetter years than  
11 under the No Action Alternative. Although temperatures in the river would  
12 become progressively higher in the downstream direction, the differences between  
13 Alternative 3 and the No Action Alternative would exhibit a similar pattern at the  
14 downstream locations (Robinson Riffle and Gridley Bridge), with temperatures  
15 under Alternative 3 and the No Action Alternative generally becoming more  
16 similar at the confluence with the Sacramento River, except in September when  
17 the water temperature under Alternative 3 could be up to 4.4 °F higher than under  
18 the No Action Alternative and in June when temperatures under Alternative 3  
19 could be up to 0.8°F cooler in drier years (Appendix 6B, Table B-23-2).

20 Overall, the temperature differences in the Feather River between Alternative 3  
21 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
22 likely would have little effect on spring-run Chinook Salmon in the Feather River.  
23 The somewhat lower water temperatures in November and December under  
24 Alternative 3 would likely have little effect on spring-run Chinook Salmon as  
25 water temperatures in the Feather River are typically low during this time period.  
26 The somewhat higher water temperatures in September of wetter years may  
27 increase the likelihood of adverse effects on spring-run Chinook Salmon egg  
28 incubation and fry rearing in the Feather River. There would be little difference  
29 in potential for adverse effects on spring-run Chinook Salmon holding over the  
30 summer due to the similar water temperatures during this time period under  
31 Alternative 3 and the No Action Alternative.

32 *Changes in Exceedances of Water Temperature Thresholds*

33 Changes in water temperature could result in the exceedance of established water  
34 temperature thresholds for spring-run Chinook Salmon in the Sacramento River,  
35 Clear Creek, and Feather River. The following describes the extent of those  
36 exceedance for each of those water bodies.

37 *Sacramento River*

38 Average monthly water temperatures under both Alternative 3 and the No Action  
39 Alternative would show exceedances of the water temperature threshold of 56°F  
40 established in the Sacramento River at Red Bluff for spring-run Chinook Salmon  
41 (spawning and egg incubation) in October, November, and again in April. The  
42 exceedances would occur at the greatest frequency in October (78 percent of the  
43 time under Alternative 3). The water temperature threshold would be exceeded  
44 less frequently in November (8 percent of the time) and not exceeded at all during

1 December through March under Alternative 3. As water temperatures warm in  
2 the spring, the threshold would be exceeded in April by 14 percent under  
3 Alternative 3. In the months when the greatest frequency of exceedances occur  
4 (October, November, and April), model results generally indicate that the  
5 threshold would be exceeded less frequently (by up to 4 percent in October) under  
6 Alternative 3 than under the No Action Alternative. Temperature conditions in  
7 the Sacramento River under Alternative 3 could be less likely to affect spring-run  
8 Chinook Salmon egg incubation than under the No Action Alternative because of  
9 the decreased frequency of exceedance of the 56°F threshold in October,  
10 November, and April.

11 *Clear Creek*

12 Average monthly water temperatures under both Alternative 3 and the No Action  
13 Alternative would not exceed the water temperature threshold of 60°F established  
14 in Clear Creek at Igo for spring-run Chinook Salmon pre-spawning and rearing in  
15 June through August. However, water temperatures under Alternative 3 would  
16 exceed the water temperature threshold of 56°F established for spawning in  
17 September and October about 12 percent to 11 percent of the time, respectively.  
18 Water temperatures under Alternative 3 could exceed the threshold about  
19 4 percent less frequently than under the No Action Alternative in September and  
20 about 2 percent less frequently in October. Temperature conditions in Clear  
21 Creek under Alternative 3 could be less likely to affect spring-run Chinook  
22 Salmon spawning than under the No Action Alternative because of the decreased  
23 frequency of exceedance of the 56°F threshold in September and October.  
24 However, this difference may be partially offset if the thermal stress reduction  
25 measures associated with 2009 NMFS BO RPA Action I.1.5 under the No Action  
26 Alternative are successful in improving water temperatures in Clear Creek.

27 *Feather River*

28 Average monthly water temperatures under both Alternative 3 and the No Action  
29 Alternative would exceed the water temperature threshold of 56°F established in  
30 the Feather River at Robinson Riffle for spring-run Chinook Salmon egg  
31 incubation and rearing) during some months, particularly in October and  
32 November, and March and April, when temperature thresholds could be exceeded  
33 frequently (Appendix 9N). The frequency of exceedance would be highest  
34 (about 97 percent) in October, a month in which average monthly water could get  
35 as high as about 68°F under Alternative 3. However, water temperatures under  
36 Alternative 3 would exceed the temperature threshold about 1 percent less  
37 frequently than the No Action Alternative from October to December, and  
38 1 percent more frequently in March.

39 The established water temperature threshold of 63°F for rearing during May  
40 through August would be exceeded often under both Alternative 3 and the No  
41 Action Alternative in May and June, but not at all in July and August. Water  
42 temperatures under Alternative 3 would exceed the rearing temperature threshold  
43 about 5 percent less frequently than under the No Action Alternative in May, with  
44 the same likelihood of exceedance in June. Temperature conditions in the Feather  
45 River under Alternative 3 could be less likely to affect spring-run Chinook

1 Salmon spawning and rearing than under the No Action Alternative because of  
2 the decreased frequency of exceedance of the water temperature thresholds.

3 *Changes in Egg Mortality*

4 The temperature differences described above are reflected in the analysis of egg  
5 mortality using the Reclamation model (Appendix 9C). For spring-run Chinook  
6 Salmon in the Sacramento River, the long-term average egg mortality rate is  
7 predicted to be relatively high (exceeding 20 percent), with high mortality rates  
8 (around 80 percent) occurring in critical dry years under Action Alternative 3. In  
9 critical dry years the average egg mortality rate would be 6.6 percent less under  
10 Alternative 3 than under the No Action Alternative (Appendix 9C, Table B-3).  
11 Overall, spring-run Chinook Salmon egg mortality in the Sacramento River under  
12 Alternative 3 and the No Action Alternative would be similar, except in critical  
13 dry water years.

14 *Changes in Weighted Usable Area*

15 Weighted usable area curves are available for spring-run Chinook Salmon in  
16 Clear Creek. As described above, flows in Clear Creek downstream of  
17 Whiskeytown Dam are not anticipated to differ under Alternative 3 relative to the  
18 No Action Alternative except in May due to the release of spring attraction flows  
19 in accordance with the 2009 NMFS BO under the No Action Alternative.  
20 Therefore, there would be no change in the amount of potentially suitable  
21 spawning and rearing habitat for spring-run Chinook Salmon (as indexed by  
22 WUA) available under Alternative 3 as compared to the No Action Alternative.

23 *Changes in SALMOD Output*

24 SALMOD results indicate that potential juvenile production would be similar  
25 under Alternative 3 and the No Action Alternative (Appendix 9D, Table B-3-6).

26 *Changes in Delta Passage Model Output*

27 The Delta Passage Model predicted similar estimates of annual Delta survival  
28 across the 81-year time period for spring-run Chinook Salmon between  
29 Alternative 3 and the No Action Alternative (Appendix 9J). Median Delta survival  
30 was 0.286 for Alternative 3 and 0.296 for the No Action Alternative.

31 *Changes in Delta Hydrodynamics*

32 Spring-run Chinook Salmon are most abundant in the Delta from March through  
33 May. Near the junction of Georgiana Slough, the median proportion of time that  
34 velocity would be positive was similar in March, April, and May under both  
35 alternatives (Appendix 9K). Near the confluence of the San Joaquin River and  
36 the Mokelumne River, the median proportion of positive velocities would be  
37 similar in March and slightly to moderately, lower under Alternative 3 relative to  
38 the No Action Alternative in April and May, respectively. A similar pattern was  
39 observed in the San Joaquin River downstream of the Head of Old River  
40 (Appendix 9K). In Old River upstream of the facilities, the median proportion of  
41 positive velocities would be slightly higher in April and May under Alternative 3  
42 relative to the No Action Alternative and similar in March. In Old River  
43 downstream of the facilities, the median proportion of positive velocities would

1 be similar in March and substantially lower in April and May under Alternative 3  
2 relative to the No Action Alternative.

### 3 *Changes in Junction Entrainment*

4 Entrainment at Georgiana Slough would be similar under both alternatives during  
5 March, April and May, when spring-run Chinook Salmon are most abundant in  
6 the Delta (Appendix 9L). At the Head of Old River, median entrainment  
7 probabilities would be slightly greater under Alternative 3 during April and May,  
8 whereas probabilities would be similar in March. At the Turner Cut junction,  
9 median entrainment probabilities under Alternative 3 and the No Action  
10 Alternative would be similar in March. During April and May, entrainment  
11 probabilities would be more divergent with slightly higher values for  
12 Alternative 3 relative to the No Action Alternative. Overall, entrainment was  
13 slightly lower at the Columbia Cut junction relative to Turner Cut, but patterns of  
14 entrainment between these two alternatives would be similar with moderately  
15 higher values for median entrainment in April and May under Alternative 3.  
16 Patterns at the Middle River and Old River junctions would be similar to those  
17 observed at Columbia and Turner Cut junctions.

### 18 *Changes in Salvage*

19 Salvage of Sacramento River-origin Chinook Salmon is predicted to be similar  
20 under Alternative 3 and the No Action Alternative in every month except during  
21 April, May, and June (Appendix 9M). Spring-run Chinook Salmon smolts  
22 migrating through the Delta would be most susceptible in the months of March,  
23 April, and May. Predicted values in April and May indicated a substantially  
24 larger fraction of fish salvaged under Alternative 3 relative to the No Action  
25 Alternative. Predicted median salvage was similar in March under Alternative 3  
26 and the No Action Alternative.

### 27 *Summary of Effects on Spring-Run Chinook Salmon*

28 The multiple model and analysis outputs described above characterize the  
29 anticipated conditions for spring-run Chinook Salmon and their response to  
30 change under Alternative 3 and the No Action Alternative. For the purpose of  
31 analyzing effects on spring-run Chinook Salmon in the Sacramento River, greater  
32 reliance was placed on the outputs from the SALMOD model because it integrates  
33 the available information on temperature and flows to produce estimates of  
34 mortality for each life stage and an overall, integrated estimate of potential  
35 spring-run Chinook Salmon juvenile production. The output from SALMOD  
36 indicated that spring-run Chinook Salmon production in the Sacramento River  
37 would be similar under Alternative 3 and the No Action Alternative.

38 The analyses attempting to assess the effects on routing, entrainment, and salvage  
39 of juvenile salmonids in the Delta suggest that salvage (as an indicator of  
40 potential losses of juvenile salmon at the export facilities) of Sacramento River-  
41 origin Chinook Salmon is predicted to be greater under Alternative 3 relative to  
42 the No Action Alternative.

43 In Clear Creek and the Feather River, the analysis of the effects of Alternative 3  
44 and the No Action Alternative for spring-run Chinook Salmon relied on output

1 from the WUA analysis and water temperature output for Clear Creek at Igo, and  
2 in the Feather River low flow channel and downstream of the Thermalito  
3 complex. The WUA analysis suggests that there would be little difference in the  
4 availability of spawning and rearing habitat in Clear Creek. The temperature  
5 model outputs suggest that thermal conditions and effects on each of the  
6 spring-run Chinook Salmon life stages generally would be similar under both  
7 scenarios in Clear Creek and the Feather River, although water temperatures  
8 could be somewhat less suitable for spring-run Chinook Salmon holding and  
9 spawning/egg incubation in the Feather River under Alternative 3. This  
10 conclusion is supported by the water temperature threshold exceedance analysis  
11 that indicated that water temperature thresholds for spawning and egg incubation  
12 would be exceeded slightly more frequently under Alternative 3 than under the  
13 No Action Alternative in Clear Creek and the Feather River. Because of the  
14 inherent uncertainty associated with the resolution of the temperature model  
15 (average monthly outputs), the slightly greater likelihood of exceeding water  
16 temperature thresholds under Alternative 3 could increase the potential for  
17 adverse effects on spring-run Chinook Salmon in the Feather River. Given the  
18 similarity of the results, Alternative 3 and the No Action Alternative are likely to  
19 have similar effects on the spring-run Chinook Salmon population in Clear Creek.

20 These model results suggest that overall, effects on spring-run Chinook Salmon  
21 could be slightly more adverse under Alternative 3 than under the No Action  
22 Alternative. The potential differences between the two scenarios, however, may  
23 be even larger due to the benefits of implementation of fish passage under the No  
24 Action Alternative intended to address the limited availability of suitable habitat  
25 for spring-run Chinook Salmon in the Sacramento River reaches downstream of  
26 Shasta Dam. This potential beneficial effect and its magnitude would depend on  
27 the success of the fish passage program. In addition, RPA actions intended to  
28 increase the efficiency of the Tracy and Skinner Fish Collection Facilities could  
29 improve the overall salvage survival of spring-run Chinook Salmon under the No  
30 Action Alternative.

31 The ocean harvest restriction component of Alternative 3 could increase spring-  
32 run Chinook Salmon numbers by reducing ocean harvest and the trap and haul  
33 program and predator control measures under Alternative 3 could reduce  
34 predation on juvenile spring-run Chinook Salmon and thereby increase survival.

35 Although the operational components associated with Alternative 3 could have  
36 greater adverse effects on spring-run Chinook Salmon than the No Action  
37 Alternative, the non-operational components associated with Alternative 3 could  
38 benefit spring-run Chinook Salmon relative to the No Action Alternative over the  
39 short term if successful. However, these measures would not address the long-  
40 term temperature challenges in the river downstream of Shasta Dam that would be  
41 addressed under the No Action Alternative if fish passage is successful. Even  
42 though the success of fish passage is uncertain, it is concluded that the potential  
43 for adverse effects on spring-run Chinook Salmon under Alternative 3 clearly  
44 would be greater than those under the No Action Alternative, principally because  
45 Alternative 3 does not include a strategy to address water temperatures critical to

1 spring-run Chinook Salmon sustainability over the long term with climate change  
2 by 2030.

3 *Fall-Run Chinook Salmon*

4 Changes in operations that influence temperature and flow conditions in the  
5 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
6 Whiskeytown Dam, Feather River downstream of Oroville Dam and American  
7 River downstream of Nimbus could affect fall-run Chinook Salmon. The  
8 following describes those changes and their potential effects.

9 *Changes in Water Temperature*

10 Changes in water temperature could affect fall-run Chinook Salmon in the  
11 Sacramento, Feather, and American rivers, and Clear Creek. The following  
12 describes temperature conditions in those water bodies.

13 *Sacramento River*

14 Average monthly water temperature in the Sacramento River at Keswick Dam  
15 under Alternative 3 relative to the No Action Alternative generally would be  
16 similar (less than 0.5°F differences) water temperatures under the No Action  
17 Alternative during most months of the year (Appendix 6B, Table B-5-2). In  
18 September, average water temperatures in wetter years could be increased by up  
19 to 0.8°F and decreased by up to 1.2°F in critical years. A similar temperature  
20 pattern generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry,  
21 Bend Bridge, Red Bluff, Hamilton City, and Knights Landing, with average  
22 monthly temperatures progressively increasing in the downstream direction  
23 (e.g., average difference in September of about 9°F between Keswick Dam and  
24 Knights Landing). The water temperature differences between Alternative 3 and  
25 the No Action Alternative in September of wetter years would increase to as high  
26 as 4.4°F warmer under Alternative 3 at Knight's Landing, while the differences in  
27 water temperatures in September associated with Alternative 3 during drier years  
28 would remain similar to upstream locations.

29 Overall, the water temperature differences between Alternative 3 and the No  
30 Action Alternative would be relatively minor (less than 0.5°F) and likely would  
31 have little effect on fall-run Chinook Salmon in the Sacramento River. The  
32 increased water temperatures in September of wetter years under Alternative 3  
33 could increase the likelihood of adverse effects on early spawning fall-run  
34 Chinook Salmon during this water year type. The slightly lower water  
35 temperatures in September of drier years under Alternative 3 would reduce the  
36 likelihood of adverse effects on early spawning fall-run Chinook Salmon in the  
37 Sacramento River as compared to the No Action Alternative.

38 *Clear Creek*

39 Average monthly water temperatures in Clear Creek at Igo under Alternative 3  
40 would be similar to (less than 0.5°F differences) water temperatures under the No  
41 Action Alternative with the exception of May when average monthly  
42 temperatures under Alternative 3 would be somewhat higher (up to about 0.8°F)  
43 than the No Action Alternative (Appendix 6B, Table B-3-2). Alternative 32). As

1 described above for spring-run Chinook Salmon, the lower water temperatures in  
2 May associated with the No Action Alternative reflect the effects of the additional  
3 water that would be discharged from Whiskeytown Dam to meet the 2009 NMFS  
4 BO RPA spring attraction flow requirements.

5 Under Alternative 3, temperature conditions at Igo would be similar to water  
6 temperatures under the No Action Alternative. However, these temperature  
7 outputs are at a location upstream of most fall-run Chinook Salmon spawning and  
8 rearing in Clear Creek. Temperatures where fall-run Chinook Salmon inhabit the  
9 creek would be somewhat higher as indicated by average monthly temperatures at  
10 the confluence with the Sacramento River, although these temperatures would be  
11 similar under Alternative 3 and the No Action Alternative. Overall, effects on  
12 fall-run Chinook Salmon in Clear Creek due to temperature differences between  
13 Alternative 3 and the No Action Alternative would be relatively minor.

14 *Feather River*

15 Average monthly water temperatures in the Feather River at the low flow channel  
16 under the Alternative 3 relative generally would be similar (within 0.5°F) to water  
17 temperatures under the No Action Alternative generally would be, except in  
18 November and December (differences as much as 1.6°F lower in December in  
19 below normal water years) (Appendix 6B, Table B-20-2). In September average  
20 monthly water temperatures under Alternative 3 could be somewhat higher (up to  
21 about 1.5°F) in wetter years than under the No Action Alternative. Although  
22 temperatures in the river would become progressively higher in the downstream  
23 direction, the differences between Alternative 3 and the No Action  
24 Alternative would exhibit a similar pattern at the downstream locations (Robinson  
25 Riffle and Gridley Bridge), with temperatures under Alternative 3 and the No  
26 Action Alternative generally becoming more similar at the confluence with the  
27 Sacramento River, except in September when water temperatures under  
28 Alternative 3 could be up to 4.4 °F higher than under the No Action  
29 Alternative and in June when temperatures under Alternative 3 could be up to  
30 0.8°F cooler in drier years.

31 Overall, the temperature differences in the Feather River between Alternative 3  
32 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
33 likely would have little effect on fall-run Chinook Salmon in the Feather River.  
34 The somewhat lower water temperatures in November and December under  
35 Alternative 3 would likely have little effect on fall-run Chinook Salmon as water  
36 temperatures in the Feather River are typically low during this time period. The  
37 somewhat higher water temperatures in September of wetter years may increase  
38 the likelihood of adverse effects on early spawning fall-run Chinook Salmon in  
39 these water year types.

40 *American River*

41 Long term average monthly water temperatures in the American River at Nimbus  
42 Dam under Alternative 3 generally would be similar (differences less than 0.5°F)  
43 to those under the No Action Alternative (Appendix 6B, Table B-12-2). This  
44 pattern generally would persist downstream to Watt Avenue and the mouth

1 although the temperature differences between scenarios would increase in June  
 2 and September (Appendix 6B, Tables b-13-2 and B-13-2 and B-14-2). In June  
 3 water temperatures could be up to 0.7°F lower under Alternative 3 than under the  
 4 No Action Alternative in some water year types. In September, average monthly  
 5 water temperatures at the mouth generally would be higher under Alternative 3  
 6 than under the No Action Alternative, especially in wetter water year types when  
 7 the water temperatures under Alternative 3 could be up to 1.6°F warmer.

8 Overall, the temperature differences in the American River between Alternative 3  
 9 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
 10 likely would have little effect on fall-run Chinook Salmon in the American River.  
 11 The lower water temperatures in June under Alternative 3 may reduce the  
 12 likelihood of adverse effects on fall-run Chinook Salmon rearing in the American  
 13 River if they were present. Higher water temperatures during September under  
 14 Alternative 3 would have little effect on fall-run Chinook Salmon spawning in the  
 15 American River because most spawning occurs later in November.

#### 16 *Changes in Exceedances of Water Temperature Thresholds*

17 Changes in water temperature could result in the exceedance of water  
 18 temperatures that are protective of fall-run Chinook Salmon in the Sacramento  
 19 River, Clear Creek, Feather River, and American River. The following describes  
 20 the extent of those exceedances for each of those water bodies.

#### 21 *Sacramento River*

22 Average monthly water temperatures under both Alternative and the No Action  
 23 Alternative would show exceedances of the water temperature threshold of 56°F  
 24 established in the Sacramento River at Red Bluff for fall-run Chinook Salmon  
 25 (spawning and egg incubation) in October, November, and again in April. The  
 26 exceedances would occur at the greatest frequency in October (78 percent of the  
 27 time under Alternative 3). The water temperature threshold would be exceeded  
 28 less frequently in November (8 percent of the time) and not exceeded at all during  
 29 December through March under Alternative 3. As water temperatures warm in  
 30 the spring, the threshold would be exceeded in April by 14 percent under  
 31 Alternative 3. In the months when the greatest frequency of exceedances occur  
 32 (October, November, and April), model results generally indicate that the  
 33 threshold would be exceeded less frequently (by up to 4 percent in October) under  
 34 Alternative 3 than under the No Action Alternative. Temperature conditions in  
 35 the Sacramento River under Alternative 3 could be less likely to affect fall-run  
 36 Chinook Salmon spawning and egg incubation than under the No Action  
 37 Alternative because of the decreased frequency of exceedance of the 56°F  
 38 threshold in October, November, and April.

#### 39 *Clear Creek*

40 Fall-run Chinook Salmon spawning in lower Clear Creek typically occurs during  
 41 October through December (USFWS 2015). Average monthly water  
 42 temperatures at Igo during this period generally remain below 56°F, except in  
 43 October. Under Alternative 3, 56°F would be exceeded in October about  
 44 10 percent of the time as compared to 12 percent under the No Action Alternative.

1 At the confluence with the Sacramento River, average monthly water  
2 temperatures would be warmer, with 56°F exceeded about 15 percent of the time  
3 under Alternative 3 and slightly more frequently under the No Action  
4 Alternative (Appendix 6B, Figure B-4-1). During November and December,  
5 average monthly water temperatures generally would remain below 56°F at both  
6 locations. Temperature conditions in Clear Creek under Alternative 3 could be  
7 less likely to affect fall-run Chinook Salmon spawning and egg incubation than  
8 under the No Action Alternative because of the reduced frequency of exceedance  
9 of the 56°F threshold in October.

10 For fall-run Chinook Salmon rearing (January through August), the exceedances  
11 described previously for spring-run Chinook Salmon would apply, with the  
12 average monthly temperatures remaining below the 60°F threshold in all months  
13 Downstream at the mouth of Clear Creek, average monthly water temperatures  
14 would exceed the 60°F threshold often during the summer, but the frequency of  
15 exceedance would be similar under Alternative 3 and the No Action  
16 Alternative (Appendix 6B Figures). Temperature conditions for fall-run Chinook  
17 Salmon rearing in Clear Creek would be similar under Alternative 3 and the No  
18 Action Alternative.

19 *Feather River*

20 Average monthly water temperatures under both Alternative 3 and the No Action  
21 Alternative would exceed the water temperature threshold of 56°F established in  
22 the Feather River at Gridley Bridge for fall-run Chinook Salmon spawning and  
23 rearing during some months, particularly in October, November, March, and  
24 April, when temperature thresholds would be exceeded frequently  
25 (Appendix 9N). The frequency of exceedance would be greatest in October,  
26 when average monthly temperatures under both Alternative 3 and the No Action  
27 Alternative would be above the threshold in nearly every year. The magnitude of  
28 the exceedances would be high as well, with average monthly temperatures in  
29 October reaching about 68°F. Similarly, the threshold would be exceeded under  
30 both alternatives about 85 percent of the time in April. However, water  
31 temperatures under Alternative 3 could exceed temperature thresholds about  
32 1-4 percent less frequently than under the No Action Alternative. Temperature  
33 conditions in the Feather River under Alternative 3 could be less likely to affect  
34 fall-run Chinook Salmon spawning and egg incubation than under the No Action  
35 Alternative because of the reduced frequency of exceedance of the 56°F threshold  
36 from October through April.

37 *Changes in Egg Mortality*

38 The analysis of fall-run Chinook Salmon included the application of the  
39 Reclamation Salmon Survival Model. The following describes the differences in  
40 egg mortality for the Sacramento, Feather, and American rivers based on the  
41 model output.

1                    *Sacramento River*

2 For fall-run Chinook Salmon in the Sacramento River, the long-term average egg  
3 mortality rate is predicted to be around 17 percent, with higher mortality rates (in  
4 excess of 35 percent) occurring in critical dry years under Alternative 3. Overall,  
5 egg mortality would similar under Alternative 3 and the No Action Alternative in  
6 all water year types (Appendix 9C, Table B-1).

7                    *Feather River*

8 For fall-run Chinook Salmon in the Feather River, the long-term average egg  
9 mortality rate is predicted to be relatively low (around 6 percent), with higher  
10 mortality rates (around 14.6 percent) occurring in critical dry years under  
11 Alternative 3. Overall, egg mortality would be similar under Alternative 3 and  
12 the No Action Alternative in all water year types (Appendix 9C, Table B-7).

13                    *American River*

14 For fall-run Chinook Salmon in the American River, the long-term average egg  
15 mortality rate is predicted to range from approximately 22 to 25 percent in all  
16 water year types under Alternative 3. Overall, egg mortality would be similar  
17 under Alternative 3 and the No Action Alternative in all water year types  
18 (Appendix 9C, Table B-6).

19                    *Changes in Weighted Usable Area*

20 Weighted usable area, which is influenced by flow, is a measure of habitat  
21 suitability. The following describes changes in WUA for fall-run Chinook  
22 Salmon in the Sacramento, Feather, and American rivers and Clear Creek.

23                    *Sacramento River*

24 As an indicator of the amount of suitable spawning habitat for fall-run Chinook  
25 Salmon between Keswick Dam and Battle Creek, modeling results indicate that,  
26 in general, there would be greater amounts of spawning habitat available from  
27 September and November under Alternative 3 as compared to the No Action  
28 Alternative; fall-run spawning WUA would be similar in October and December  
29 (Appendix 9E, Table C-11-2). The increase in long-term average spawning WUA  
30 in September under Alternative 3 (prior to the peak spawning period) would be  
31 relatively large (around 20 percent), with a smaller increase in November (around  
32 15 percent) which comprises the peak spawning period for fall-run Chinook  
33 Salmon. Results for the reach from Battle Creek to Deer Creek show the same  
34 pattern in changes in WUA for spawning fall-run Chinook Salmon between  
35 Alternative 3 and the No Action Alternative (Appendix 9E, Table C-10-2).  
36 Overall, spawning habitat availability could be increased under Alternative 3  
37 relative to the No Action Alternative.

38 Modeling results indicate that, in general, there would be similar amounts of  
39 suitable fry rearing habitat available from December to March under Alternative 3  
40 (Appendix 9E, Table C-12-2). Similar to the results for fry rearing WUA,  
41 modeling results indicate that, there would be similar amounts of suitable juvenile  
42 rearing habitat available during the juvenile rearing period from February to June  
43 (Appendix 9E, Table C-13-2).

1 *Clear Creek*

2 Flows in Clear Creek below Whiskeytown Dam are not anticipated to differ under  
3 Alternative 3 relative to the No Action Alternative except in May due to the  
4 release of spring attraction flows in accordance with the 2009 NMFS BO under  
5 the No Action Alternative. Therefore, there would be no change in the amount of  
6 potentially suitable spawning and rearing habitat for fall-run Chinook Salmon (as  
7 indexed by WUA) available under Alternative 3 as compared to the No Action  
8 Alternative.

9 *Feather River*

10 Flows in the low flow channel of the Feather River are not anticipated to differ  
11 under Alternative 3 relative to the No Action Alternative. Therefore, there would  
12 be no change in the amount of potentially suitable spawning habitat for fall-run  
13 Chinook Salmon (as indexed by WUA) available under Alternative 3 as compared  
14 to the No Action Alternative. The majority of spawning activity by fall-run  
15 Chinook Salmon in the Feather River occurs in this reach with a lesser amount of  
16 spawning occurring downstream of the Thermalito Complex.

17 Modeling results indicate that, in general, there would be greater amounts of  
18 spawning habitat available in September under Alternative 3 as compared to the  
19 No Action Alternative. The increase in long-term average spawning WUA during  
20 September (prior to the peak spawning period) would be relatively large (around  
21 30 percent), with similar amounts of spawning WUA for fall-run Chinook Salmon  
22 predicted during other months. Overall, spawning habitat availability would be  
23 somewhat similar under Alternative 3 relative to the No Action Alternative.

24 *American River*

25 Modeling results indicate that, in general, there would be similar amounts of  
26 spawning habitat available for fall-run Chinook Salmon in the American River  
27 from October to December under Alternative 3 as compared to the No Action  
28 Alternative (Appendix 9E, Table C-25-2).

29 *Changes in SALMOD Output*

30 SALMOD results indicate that potential juvenile production would be similar  
31 under Alternative 3 and the No Action Alternative, but up to 5 percent greater  
32 under Alternative 3 in critical dry years.

33 *Changes in Delta Passage Model Output*

34 The Delta Passage Model predicted similar estimates of annual Delta survival  
35 across the 81-year time period for fall-run Chinook Salmon between Alternative 3  
36 and the No Action Alternative (Appendix 9J). Median Delta survival was  
37 0.246 for Alternative 3 and 0.245 for the No Action Alternative.

38 *Changes in Delta Hydrodynamics*

39 Fall-run Chinook Salmon smolts are most abundant in the Delta during the  
40 months of April, May and June. At the junction of Georgiana Slough and the  
41 Sacramento River, the median proportion of positive velocities would be similar  
42 in April, May and June under Alternative 3 and the No Action  
43 Alternative (Appendix 9K). Near the confluence of the San Joaquin River and the

1 Mokelumne River, the median proportion of positive velocities would be slightly  
2 lower under Alternative 3 relative to the No Action Alternative in April and May  
3 and similar in June. On Old River downstream of the facilities, the median  
4 proportion of positive velocities would be substantially lower in April and May  
5 under Alternative 3 relative to the No Action Alternative, but would be only  
6 moderately lower in June. In Old River upstream of the facilities, the median  
7 proportion of positive velocities would be similar for Alternative 3 relative to the  
8 No Action Alternative in June. In April and May, values for Alternative 3 would  
9 be slightly higher under Alternative 3 relative to the No Action Alternative. On  
10 the San Joaquin River downstream of the Head of Old River, the median  
11 proportion of positive velocities would be similar under Alternative 3 relative to  
12 the No Action Alternative in April, May, and June.

### 13 *Changes in Junction Entrainment*

14 The median entrainment at Georgiana Slough under Alternative 3 would be  
15 slightly greater in June relative to the No Action Alternative (Appendix 9L). In  
16 April and May, median entrainment would be almost identical under both  
17 alternatives. At the Head of Old River junction, entrainment under Alternative 3  
18 would be slightly higher in April, May, and June relative to the No Action  
19 Alternative. Median entrainment into Turner Cut would be slightly greater under  
20 Alternative 3 during April, and May and similar in June. At the Columbia Cut  
21 junction, entrainment would be moderately higher under Alternative 3 during  
22 April and May, whereas entrainment would be slightly higher in June.  
23 Entrainment probabilities at the Middle River junction from April through June  
24 would be moderately greater under Alternative 3 relative to the No Action  
25 Alternative. A similar pattern would be observed at the Old River junction.

### 26 *Changes in Salvage*

27 Salvage of Sacramento River-origin Chinook Salmon is predicted to be similar  
28 under Alternative 3 and No Action Alternative in every month except April, May,  
29 and June (Appendix 9M). Fall-run Chinook Salmon smolts migrating through the  
30 Delta would be most susceptible in the months of April, May, and June.  
31 Predicted values in April and May indicated a substantially increased fraction of  
32 fish salvaged under Alternative 3 relative to the No Action Alternative and a  
33 moderately increased fraction salvaged in June under Alternative 3.

### 34 *Summary of Effects on Fall-Run Chinook Salmon*

35 The multiple model and analysis outputs described above characterize the  
36 anticipated conditions for fall-run Chinook Salmon and their response to change  
37 under Alternative 3 and the No Action Alternative. For the purpose of analyzing  
38 effects on fall-run Chinook Salmon in the Sacramento River, greater reliance was  
39 placed on the outputs from the SALMOD model because it integrates the  
40 available information on temperature and flows to produce estimates of mortality  
41 for each life stage and an overall, integrated estimate of potential fall-run Chinook  
42 Salmon juvenile production. The output from SALMOD indicated that fall-run  
43 Chinook Salmon production would be similar in most water year types under  
44 Alternative 3 and the No Action Alternative, but up to 5 percent greater under  
45 Alternative 3 than under the No Action Alternative in critical dry years.

1 The analyses attempting to assess the effects on routing, entrainment, and salvage  
2 of juvenile salmonids in the Delta suggest that salvage (as an indicator of  
3 potential losses of juvenile salmon at the export facilities) of Sacramento  
4 River-origin Chinook Salmon is predicted to be greater under Alternative 3  
5 relative to the No Action Alternative.

6 In Clear Creek and the Feather and American rivers, the analysis of the effects of  
7 Alternative 3 and the No Action Alternative for fall-run Chinook Salmon relied  
8 on the WUA analysis for habitat and water temperature model output for the  
9 rivers at various locations downstream of the CVP and SWP facilities. The WUA  
10 analysis indicated that the availability of spawning and rearing habitat in Clear  
11 Creek and spawning habitat in the Feather and American rivers would be similar  
12 under Alternative 3 and the No Action Alternative. The temperature model  
13 outputs for each of the fall-run Chinook Salmon life stages suggest that thermal  
14 conditions and effects on fall-run Chinook Salmon in all of these streams  
15 generally would be similar under both scenarios. The water temperature threshold  
16 exceedance analysis that indicated that the water temperature thresholds for  
17 fall-run Chinook Salmon spawning and egg incubation would be exceeded  
18 slightly less frequently in the Feather River and Clear Creek under Alternative 3  
19 and could reduce the potential for adverse effects on the fall-run Chinook Salmon  
20 populations in Clear Creek and the Feather River. Results of the analysis using  
21 Reclamation's salmon mortality model indicate that there would be slightly  
22 reduced fall-run Chinook Salmon egg mortality in the Feather River under  
23 Alternative 3 compared to the No Action Alternative.

24 These model results suggest that overall, effects on fall-run Chinook Salmon  
25 could be slightly less adverse under Alternative 3 than the No Action Alternative.  
26 This potential distinction between the two scenarios, however, may be partially  
27 offset by the benefits of implementation of fish passage under the No Action  
28 Alternative intended to address the limited availability of suitable habitat for  
29 winter-run and spring-run Chinook Salmon in the Sacramento River reaches  
30 downstream of Keswick Dam. This potential benefit, however, would only apply  
31 if passage is provided for fall-run Chinook Salmon that allows access to  
32 additional habitat. In addition, RPA actions under the No Action  
33 Alternative intended to increase the efficiency of the Tracy and Skinner Fish  
34 Collection Facilities could improve the overall salvage survival of fall-run  
35 Chinook Salmon. The ocean harvest restriction component of Alternative 3 could  
36 increase fall-run Chinook Salmon numbers by reducing ocean harvest and the trap  
37 and haul program and predator control measures under Alternative 3 could reduce  
38 predation on juvenile fall-run Chinook Salmon and thereby increase survival.

39 Overall, the results of the numerical models suggest the potential for less adverse  
40 effects on fall-run Chinook Salmon under Alternative 3 as compared to the No  
41 Action Alternative. However, discerning a meaningful difference between these  
42 two scenarios based on the quantitative results is not possible because of the  
43 similarity in results (generally differences less than 5 percent) and the inherent  
44 uncertainty of the models. In addition, adverse effects of the No Action  
45 Alternative could be offset by the potentially beneficial effects resulting from the

1 RPA actions evaluated qualitatively for the No Action Alternative. Adverse  
2 effects of Alternative 3 could be offset by the potentially beneficial effects  
3 resulting from predator control and ocean harvest restrictions. Thus, it is  
4 concluded that the effects on fall-run Chinook Salmon would be similar under  
5 Alternative 3 and the No Action Alternative.

#### 6 *Late Fall-Run Chinook Salmon*

7 Changes in operations that influence temperature and flow conditions in the  
8 Sacramento River downstream of Keswick Dam could affect late fall-run Chinook  
9 Salmon. The following describes those changes and their potential effects.

#### 10 *Changes in Water Temperature*

11 Average monthly water temperature in the Sacramento River at Keswick Dam  
12 under Alternative 3 relative to the No Action Alternative generally would be  
13 similar to (less than 0.5°F differences) water temperatures under the No Action  
14 Alternative during most months of the year (Appendix 6B, Table B-5-2). In  
15 September, average water temperatures in wetter years could be increased by up  
16 to 0.8°F and decreased by up to 1.2°F in critical years. A similar temperature  
17 pattern generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry,  
18 Bend Bridge, Red Bluff, Hamilton City, and Knights Landing, with average  
19 monthly temperatures progressively increasing in the downstream direction  
20 (e.g., average difference in September of about 9°F between Keswick Dam and  
21 Knights Landing). The temperature differences between Alternative 3 and the No  
22 Action Alternative in September of wetter years would increase to as high as  
23 4.4°F warmer under Alternative 3 at Knight's Landing, while the differences in  
24 water temperatures in September associated with Alternative 3 during drier years  
25 would remain similar to upstream locations.

26 Overall, the temperature differences between Alternative 3 and the No Action  
27 Alternative would be relatively minor (less than 0.5°F) and likely would have  
28 little effect on late fall-run Chinook Salmon in the Sacramento River. The  
29 likelihood of adverse effects on late fall-run Chinook Salmon spawning and egg  
30 incubation would be similar under Alternative 3 and the No Action  
31 Alternative due to similar water temperatures during the January to May time  
32 period. Because late fall-run Chinook Salmon have an extended rearing period,  
33 the similar water temperatures during the summer under Alternative 3 and the No  
34 Action Alternative would have similar effects on rearing fry and juvenile late fall-  
35 run Chinook Salmon in the Sacramento River. The slightly higher water  
36 temperatures under Alternative 3 in September of wetter years may increase the  
37 likelihood of adverse effects on fry and juvenile late fall-run Chinook Salmon  
38 rearing in the Sacramento River during this limited time period.

#### 39 *Changes in Exceedances of Water Temperature Thresholds*

40 Average monthly water temperatures under both Alternative and the No Action  
41 Alternative would show exceedances of the water temperature threshold of 56°F  
42 established in the Sacramento River at Red Bluff for Chinook Salmon (spawning  
43 and egg incubation) in October, November, and again in April. The exceedances  
44 would occur at the greatest frequency in October (78 percent of the time under

1 Alternative 3). The water temperature threshold would be exceeded less  
2 frequently in November (8 percent of the time) and not exceeded at all during  
3 December through March under Alternative 3. As water temperatures warm in  
4 the spring, the threshold would be exceeded in April by 14 percent under  
5 Alternative 3. In the months when the greatest frequency of exceedances occur  
6 (October, November, and April), model results generally indicate that the  
7 threshold would be exceeded less frequently (by up to 4 percent in October) under  
8 Alternative 3 than under the No Action Alternative. Temperature conditions in  
9 the Sacramento River under Alternative 3 could be less likely to affect late fall-  
10 run Chinook Salmon spawning and egg incubation than under the No Action  
11 Alternative because of the decreased frequency of exceedance of the 56°F  
12 threshold in October, November, and April.

13 *Changes in Egg Mortality*

14 For late fall-run Chinook Salmon in the Sacramento River, the long-term average  
15 egg mortality rate is predicted to range from approximately 1.8 to nearly 5 percent  
16 in all water year types under Alternative 3. Overall, egg mortality would be  
17 similar under Alternative 3 and the No Action Alternative (Appendix 9C,  
18 Table B-2) in all water year types.

19 *Changes in Weighted Usable Area*

20 Modeling results indicate that there would be similar amounts of spawning habitat  
21 available for late fall-run Chinook Salmon in the Sacramento River from January  
22 through April under Alternative 3 as compared to the No Action  
23 Alternative (Appendix 9E, Table C-14-4).

24 Modeling results indicate that, in general, there would be similar amounts of  
25 suitable late fall-run Chinook Salmon fry rearing habitat available during April  
26 and May under Alternative 3 and the No Action Alternative (Appendix 9E,  
27 Table C-15-4).

28 A substantial fraction of late fall run Chinook Salmon juveniles overwinter in  
29 the Sacramento River before emigrating, which allows them to avoid predation  
30 through both their larger size and greater swimming ability. One implication of  
31 this life history strategy is that rearing habitat is most likely the limiting factor for  
32 late-fall-run Chinook Salmon, especially if availability of cool water determines  
33 the downstream extent of spawning habitat for late-fall-run salmon. Modeling  
34 results indicate that, there would generally be similar amounts of suitable juvenile  
35 rearing habitat available from December through August under Alternative 3 and  
36 the No Action Alternative. There could an increase in the amount of late fall-run  
37 Chinook Salmon juvenile rearing WUA in September and November of up to  
38 nearly 10 percent (Appendix 9E, Table C-16-4). Overall, late fall-run juvenile  
39 rearing habitat availability would be similar under Alternative 3 and the No  
40 Action Alternative.

41 *Changes in SALMOD Output*

42 SALMOD results indicate that potential juvenile production would be the same  
43 under Alternative 3 and the No Action Alternative (Appendix 9D, Table B-2-6).

1            *Changes in Delta Passage Model Output*

2 For late fall-run Chinook Salmon, Delta survival was predicted to be slightly  
3 lower for Alternative 3 versus the No Action Alternative for all 81 years  
4 simulated by the Delta Passage Model (Appendix 9J). Median Delta survival  
5 across all years was 0.199 for Alternative 3 and 0.244 for the No Action  
6 Alternative.

7            *Changes in Delta Hydrodynamics*

8 The late fall-run Chinook Salmon migration period overlaps with the winter-run.  
9 See the section on hydrodynamic analysis for winter-run Chinook Salmon for  
10 potential effects on late fall-run Chinook Salmon.

11           *Changes in Junction Entrainment*

12 Entrainment probabilities for late fall-run Chinook Salmon are assumed to mimic  
13 that of winter-run Chinook Salmon due to the overlap in timing. See the section  
14 on winter-run Chinook Salmon entrainment for potential effects on late fall-run  
15 Chinook Salmon.

16           *Changes in Salvage*

17 Salvage of late fall-run Chinook Salmon is assumed to mimic that of winter-run  
18 Chinook Salmon due to the overlap in timing. See the section on winter-run  
19 Chinook Salmon entrainment for potential effects on late fall-run Chinook  
20 Salmon.

21           *Summary of Effects on Late Fall-Run Chinook Salmon*

22 The multiple model and analysis outputs described above characterize the  
23 anticipated conditions for late fall-run Chinook Salmon and their response to  
24 change under Alternative 3 and the No Action Alternative. For the purpose of  
25 analyzing effects on late fall-run Chinook Salmon and developing conclusions,  
26 greater reliance was placed on the outputs from the SALMOD model because it  
27 integrates the available information on temperature and flows to produce  
28 estimates of mortality for each life stage and an overall, integrated estimate of  
29 potential fall-run Chinook Salmon juvenile production. The output from  
30 SALMOD indicated that late fall-run Chinook Salmon production would be  
31 similar under Alternative 3 and the No Action Alternative.

32 The analyses attempting to assess the effects on routing, entrainment, and salvage  
33 of juvenile salmonids in the Delta suggest that salvage (as an indicator of  
34 potential losses of juvenile salmon at the export facilities) of Sacramento  
35 River-origin Chinook Salmon is predicted to be similar under Alternative 3  
36 relative to the No Action Alternative. Actions under the No Action  
37 Alternative intended to increase the efficiency of the Tracy and Skinner Fish  
38 Collection Facilities could improve the overall salvage survival of late fall-run  
39 Chinook Salmon.

40 Overall, the results of the numerical models suggest that potential effects on late  
41 fall-run Chinook Salmon would be similar for Alternative 3 and the No Action  
42 Alternative. Discerning a meaningful difference between these two scenarios  
43 based on the quantitative results is not possible because of the similarity in results

1 (generally differences less than 5 percent) and the inherent uncertainty of the  
2 models. Because fish passage under the No Action Alternative is not expected to  
3 directly benefit late fall-run Chinook Salmon, the non-operational actions  
4 intended to benefit salmonids under both alternatives are expected to balance.  
5 Thus, it is concluded that the effects on late fall-run Chinook Salmon would be  
6 similar under Alternative 3 and the No Action Alternative.

7 *Steelhead*

8 Changes in operations that influence temperature and flow conditions that could  
9 affect steelhead. The following describes those changes and their potential  
10 effects.

11 *Changes in Water Temperature*

12 Changes in water temperature could affect steelhead in the Sacramento, Feather,  
13 and American rivers, and Clear Creek. The following describes temperature  
14 conditions in those water bodies.

15 *Sacramento River*

16 Average monthly water temperature in the Sacramento River at Keswick Dam  
17 under Alternative 3 relative to the No Action Alternative generally would be  
18 similar (less than 0.5°F differences) water temperatures under the No Action  
19 Alternative during most months of the year (Appendix 6B, Table B-5-2). In  
20 September, average water temperatures in wetter years could be increased by up  
21 to 0.8°F and decreased by up to 1.2°F in critical years. A similar temperature  
22 pattern generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry,  
23 Bend Bridge, and Red Bluff, with average monthly temperatures progressively  
24 increasing in the downstream direction (e.g., average difference of about 3°F  
25 between Keswick Dam and Red Bluff). The water temperature differences  
26 between Alternative 3 and the No Action Alternative in September of wetter years  
27 would increase to as high as 3.0°F warmer under Alternative 3 at Red Bluff, while  
28 the differences in water temperatures in September associated with Alternative 3  
29 during drier years would remain similar to upstream locations.

30 Overall, the water temperature differences between Alternative 3 and the No  
31 Action Alternative would be relatively (less than 0.5°F) minor and likely would  
32 have little effect on steelhead in the Sacramento River. The increased water  
33 temperatures in September of wetter years under Alternative 3 could increase the  
34 likelihood of adverse effects on migrating adult steelhead during this water year  
35 type. The slightly lower water temperatures in September of drier years under  
36 Alternative 3 could reduce the likelihood of adverse effects on migrating adult  
37 steelhead during drier years as compared to the No Action Alternative.

38 *Clear Creek*

39 Average monthly water temperatures in Clear Creek at Igo under Alternative 3  
40 would be similar to (less than 0.5°F differences) water temperatures under the No  
41 Action Alternative with the exception of May when average monthly  
42 temperatures under Alternative 3 would be somewhat higher (up to about 0.8°F)  
43 than the No Action Alternative. As described above for spring-run Chinook

1 Salmon, the lower water temperatures in May associated with the No Action  
2 Alternative reflect the effects of the additional water that would be discharged  
3 from Whiskeytown Dam to meet the 2009 NMFS BO RPA spring attraction flow  
4 requirements. Overall, thermal conditions for steelhead in Clear Creek would be  
5 similar under Alternative 3 and the No Action Alternative.

#### 6 *Feather River*

7 Average monthly water temperatures in the Feather River at the low flow channel  
8 under the Alternative 3 relative generally would be similar (within 0.5°F) to water  
9 temperatures under the No Action Alternative except in November and December  
10 (differences as much as 1.6°F in December in below normal water years)  
11 (Appendix 6B, Table B-20-2). In September average monthly water temperatures  
12 under Alternative 3 could be somewhat higher (up to about 1.5°F) in wetter years  
13 than under the No Action Alternative. Although temperatures in the river would  
14 become progressively higher in the downstream direction, the differences between  
15 Alternative 3 and the No Action Alternative would exhibit a similar pattern at the  
16 downstream locations (Robinson Riffle and Gridley Bridge), with temperatures  
17 under Alternative 3 and the No Action Alternative generally becoming more  
18 similar among months at the confluence with the Sacramento River, except in  
19 September when water temperatures under Alternative 3 could be up to 4.4 °F  
20 higher than under the No Action Alternative and in June when temperatures under  
21 Alternative 3 could be up to 0.8°F cooler in drier years.

22 Overall, the temperature differences in the Feather River between Alternative 3  
23 and the No Action Alternative would be relatively minor (less than 0.5°F) and  
24 likely would have little effect on steelhead in the Feather River. The somewhat  
25 higher water temperatures in September of wetter years may increase the  
26 likelihood of adverse effects on migrating adult steelhead during this water year  
27 type. The somewhat lower water temperatures in in November and December  
28 under Alternative 3 also could reduce the likelihood of adverse effects on  
29 steelhead adults migrating upstream and juveniles migrating downstream in the  
30 Feather River as compared to the No Action Alternative.

#### 31 *American River*

32 Long term average monthly water temperatures in the American River at Nimbus  
33 Dam under Alternative 3 generally would be similar (differences less than 0.5°F)  
34 to those under the No Action Alternative (Appendix 6B, Table B-12-2). This  
35 pattern generally would persist downstream to Watt Avenue and the mouth,  
36 although the temperature differences between scenarios would increase in June  
37 and September (Appendix 6B, Tables B-13-2 and B-13-2 and B-14-2). In June  
38 water temperatures could be up to 0.7°F lower under Alternative 3 than under the  
39 No Action Alternative in some water year types. In September, average monthly  
40 water temperatures at the mouth generally would be higher under Alternative 3  
41 than under the No Action Alternative, especially in wetter water year types when  
42 the water temperatures under Alternative 3 could be up to 1.6°F warmer.

1 Overall, the temperature differences between Alternative 3 and the No Action  
2 Alternative would be minor (less than 0.5°F) and likely would have little effect on  
3 steelhead in the American River. The somewhat higher water temperatures in  
4 September of wetter years may increase the likelihood of adverse effects on  
5 migrating adult steelhead during this water year type. The cooler water  
6 temperatures in June under Alternative 3 may reduce the likelihood of adverse  
7 effects on steelhead rearing in the American River compared to the No Action  
8 Alternative.

9 *Changes in Exceedances of Water Temperature Thresholds*

10 Changes in water temperature could result in the exceedance of established water  
11 temperature thresholds for steelhead in the Sacramento River, Clear Creek, and  
12 Feather River. The following describes the extent of those exceedance for each of  
13 those streams.

14 *Sacramento River*

15 As described in the life history accounts, steelhead spawning in the mainstem  
16 Sacramento River generally occurs in the upper reaches from Keswick Dam  
17 downstream to near Balls Ferry, with most spawning concentrated near Redding.  
18 Most steelhead, however, spawn in tributaries to the Sacramento River.  
19 Spawning generally takes place in the January through March period when water  
20 temperatures in the river generally do not exceed 52°F under either Alternative 3  
21 or the No Action Alternative. While there are no established temperature  
22 thresholds for steelhead rearing in the mainstem Sacramento River, average  
23 monthly temperatures when fry and juvenile steelhead are in the river would  
24 generally remain below 56°F at Balls Ferry except in August and September  
25 when this temperature would be exceeded 30 to 40 percent of the time under both  
26 Alternative 3 and the No Action Alternative. However, water temperatures in the  
27 Sacramento River at Balls Ferry would exceed 56°F about 10 percent more often  
28 in September under Alternative 3. Overall, thermal conditions for steelhead in the  
29 Sacramento River would be more likely to result in adverse effects on steelhead  
30 under Alternative 3 than under the No Action Alternative because of the increased  
31 frequency of exceedance of 56°F in September.

32 *Clear Creek*

33 While there are no established temperature thresholds for steelhead spawning in  
34 Clear Creek, average monthly water temperatures in the river generally would not  
35 exceed 49°F during the spawning period (December to April) under Alternative 3  
36 and the No Action Alternative. Similarly, while there are no established  
37 temperature thresholds for steelhead rearing in Clear Creek, average monthly  
38 temperatures in most months of the year would not exceed 56°F at Igo under both  
39 alternatives. Overall, thermal conditions for steelhead in Clear Creek would be  
40 similar under Alternative 3 and the No Action Alternative.

41 *Feather River*

42 Average monthly water temperatures in the Feather River at Robinson Riffle  
43 would on occasion exceed the water temperature threshold of 56°F established for  
44 steelhead spawning and incubation during some months, particularly in October

1 and November, and March and April, when temperature thresholds could be  
 2 exceeded frequently (Appendix 9N). There would be a 1 percent exceedance of  
 3 the 56°F threshold in December under the No Action Alternative and no  
 4 exceedances of the 56°F threshold from December through February under  
 5 Alternative 3. However, the differences in the frequency of exceedance between  
 6 Alternative 3 and No Action Alternative during March and April would be  
 7 relatively small with water temperatures under Alternative 3 exceeding the  
 8 threshold about 1 percent more frequently in March (19 percent) and the same  
 9 exceedance frequency (75 percent) as the No Action Alternative in April.

10 The established water temperature threshold of 63°F for rearing during May  
 11 through August would be exceeded often under both Alternative 3 and the No  
 12 Action Alternative in May and June, but not at all in July and August. Water  
 13 temperatures under Alternative 3 would exceed the rearing temperature threshold  
 14 about 5 percent less frequently than under the No Action Alternative in May, but  
 15 no more frequently in June. Temperature conditions in the Feather River under  
 16 Alternative 3 could be less likely to affect steelhead spawning and rearing than  
 17 under the No Action Alternative because of the reduced frequency of exceedance  
 18 of the spawning and rearing thresholds.

#### 19 *American River*

20 In the American River, the water temperature threshold for steelhead rearing  
 21 (May through October) is 65°F at the Watt Avenue Bridge. Average monthly  
 22 water temperatures would exceed this threshold often under both Alternative 3  
 23 and the No Action Alternative, especially in the July through September period  
 24 when the threshold is exceeded nearly all of the time. In addition, the magnitude  
 25 of the exceedance would be high, with average monthly water temperatures  
 26 sometimes higher than 76°F. The differences between Alternative 3 and No  
 27 Action Alternative, however, would be relatively small (differences within  
 28 2 percent), except in September, when water temperatures under Alternative 3  
 29 would exceed 65°F about 7 percent more frequently than under the No Action  
 30 Alternative. Temperature conditions in the American River under Alternative 3  
 31 could be more likely to affect steelhead rearing than under the No Action  
 32 Alternative because of the increased frequency of exceedance of the 65°F rearing  
 33 threshold.

#### 34 *Changes in Weighted Usable Area*

35 The following describes changes in WUA for steelhead in the Sacramento,  
 36 Feather, and American rivers and Clear Creek.

#### 37 *Sacramento River*

38 Modeling results indicate that, in general, there would be similar amounts of  
 39 suitable steelhead spawning habitat available from December through March  
 40 under Alternative 3 as compared to the No Action Alternative (Appendix 9E,  
 41 Table C-20-2).

1 *Clear Creek*

2 Flows in Clear Creek below Whiskeytown Dam are not anticipated to differ under  
3 Alternative 3 relative to the No Action Alternative except in May due to the  
4 release of spring attraction flows in accordance with the 2009 NMFS BO under  
5 the No Action Alternative. Therefore, there would be no change in the amount of  
6 potentially suitable spawning and rearing habitat for steelhead (as indexed by  
7 WUA) available under Alternative 3 as compared to the No Action Alternative.

8 *Feather River*

9 Flows in the low flow channel of the Feather River are not anticipated to differ  
10 under Alternative 3 relative to the No Action Alternative. Therefore, there would  
11 be no change in the amount of potentially suitable spawning habitat for steelhead  
12 (as indexed by WUA) available under Alternative 3 as compared to the No Action  
13 Alternative. The majority of spawning activity by steelhead in the Feather River  
14 occurs in this reach with a lesser amount of spawning occurring downstream of  
15 the Thermalito Complex.

16 Modeling results indicate that, in general, there would be similar amounts of  
17 spawning habitat for steelhead in the Feather River below Thermalito available  
18 from December through April under Alternative 3 and the No Action Alternative.

19 *American River*

20 Modeling results indicate that, in general, there would be similar amounts of  
21 spawning habitat for steelhead in the American River downstream of Nimbus  
22 Dam available from December through April under Alternative 3 and the No  
23 Action Alternative.

24 *Summary of Effects on Steelhead*

25 The multiple model and analysis outputs described above characterize the  
26 anticipated conditions for steelhead and their response to change under  
27 Alternative 3 and the No Action Alternative. The analysis of the effects of  
28 Alternative 3 and the No Action Alternative for steelhead relied on the WUA  
29 analysis for habitat and water temperature model output for the rivers at various  
30 locations downstream of the CVP and SWP facilities. The WUA analysis  
31 indicated that the availability of steelhead spawning and rearing habitat in Clear  
32 Creek and steelhead spawning habitat in the Sacramento, Feather and American  
33 rivers would be similar under Alternative 3 and the No Action Alternative. The  
34 temperature model outputs for each of the steelhead life stages suggest that  
35 thermal conditions and effects on steelhead could be slightly less adverse for  
36 some life stages in various rivers under Alternative 3. This conclusion is  
37 supported by the water temperature threshold exceedance analysis that indicated  
38 that the water temperature thresholds for steelhead spawning and egg incubation  
39 would be exceeded less frequently in the Feather River under Alternative 3. The  
40 water temperature threshold for steelhead rearing would also be exceeded less  
41 frequently in the Feather River. However, the water temperature threshold for  
42 steelhead rearing in the American River would be exceeded more frequently  
43 under Alternative 3 than under the No Action Alternative. The reduced frequency  
44 of exceedance of temperature thresholds under Alternative 3 could reduce the  
45 potential for adverse effects on the steelhead population in the Feather River

1 while the increased frequency of exceedance could increase the likelihood of  
2 adverse effects on steelhead rearing in the American River.

3 These model results suggest that overall, effects on steelhead could be slightly  
4 less adverse under Alternative 3 than the No Action Alternative, particularly in  
5 the Feather River. Implementation of the fish passage program under the No  
6 Action Alternative intended to address the limited availability of suitable habitat  
7 for steelhead in the Sacramento and American river could provide a benefit to  
8 Central Valley steelhead in the Sacramento and American rivers. This is  
9 particularly important in light of anticipated increases in water temperature  
10 associated with climate change in 2030. In addition to fish passage, preparation  
11 and implementation of an HGMP for steelhead at the Nimbus Fish Hatchery and  
12 actions under the No Action Alternative intended to increase the efficiency of the  
13 Tracy and Skinner Fish Collection Facilities could benefit steelhead under the No  
14 Action Alternative in comparison to Alternative 3. Thus, on balance and over the  
15 long term, the adverse effects on steelhead under Alternative 3 would be greater  
16 than those under the No Action Alternative.

#### 17 *Green Sturgeon*

18 The effects on Green Sturgeon were analyzed by comparing changes in water  
19 temperature and the frequency of temperature threshold exceedance between  
20 Alternative 3 and the No Action Alternative. In addition, potential effects on  
21 Green Sturgeon during the Delta portion of their life cycle were evaluated based  
22 on changes in Delta outflow. The effects are described and summarized below.

#### 23 *Changes in Water Temperature*

24 Changes in water temperature could affect Green Sturgeon in the Sacramento and  
25 Feather rivers. The following describes temperature conditions in those water  
26 bodies.

#### 27 *Sacramento River*

28 Average monthly water temperature in the Sacramento River at Keswick Dam  
29 under Alternative 3 relative to the No Action Alternative generally would be  
30 similar (less than 0.5°F differences) water temperatures under the No Action  
31 Alternative during most months of the year (Appendix 6B, Table B-5-2). In  
32 September, average water temperatures in wetter years could be increased by up  
33 to 0.8°F and decreased by up to 1.2°F in critical years. A similar temperature  
34 pattern generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry,  
35 Bend Bridge, and Red Bluff, with average monthly temperatures progressively  
36 increasing in the downstream direction (e.g., average difference of about 3°F  
37 between Keswick Dam and Red Bluff). The temperature differences between  
38 Alternative 3 and the No Action Alternative in September of wetter years would  
39 increase to as high as 3.0°F warmer under Alternative 3 at Red Bluff, while the  
40 differences in water temperatures in September associated with Alternative 3  
41 during drier years would remain similar to upstream locations.

42 Overall, the temperature differences between Alternative 3 and the No Action  
43 Alternative would be relatively minor (less than 0.5°F). The similar water  
44 temperatures during most months suggest that temperature-related effects on

1 Green Sturgeon would likely be similar under Alternative 3 and the No Action  
2 Alternative.

3 *Feather River*

4 Average monthly water temperatures in the Feather River at the low flow channel  
5 under the Alternative 3 relative generally would be similar (within 0.5°F) to water  
6 temperatures under the No Action Alternative except in November and December  
7 (differences as much as 1.6°F in December in below normal water years)  
8 (Appendix 6B, Table B-20-2). In September average monthly water temperatures  
9 under Alternative 3 could be somewhat higher (up to about 1.5°F) in wetter years  
10 than under the No Action Alternative. Although temperatures in the river would  
11 become progressively higher in the downstream direction, the differences between  
12 Alternative 3 and the No Action Alternative would exhibit a similar pattern at the  
13 downstream locations (Robinson Riffle and Gridley Bridge), with temperatures  
14 under Alternative 3 and the No Action Alternative generally becoming more  
15 similar at the confluence with the Sacramento River, except in September when  
16 the water temperature under Alternative 3 could be up to 4.4 °F higher than under  
17 the No Action Alternative and in June when temperatures under Alternative 3  
18 could be up to 0.8°F cooler in drier years.

19 Overall, the temperature differences between Alternative 3 and the No Action  
20 Alternative would be relatively minor (less than 0.5°F). The similar water  
21 temperatures during most months suggest that temperature-related effects on  
22 Green Sturgeon would likely be similar under Alternative 3 and the No Action  
23 Alternative. The somewhat higher water temperatures in September under  
24 Alternative 3 could affect spawning by Green Sturgeon in the Feather River.

25 *Changes in Exceedances of Water Temperature Thresholds*

26 Changes in water temperature could result in the exceedance of established water  
27 temperature thresholds for Green Sturgeon in the Sacramento and Feather rivers.  
28 The following describes the extent of those exceedance for each of those rivers.

29 *Sacramento River*

30 Average monthly water temperatures in the Sacramento River at Bend Bridge  
31 under both Alternative 3 and the No Action Alternative would exceed the water  
32 temperature threshold of 63°F established for Green Sturgeon larval rearing in  
33 August and September, with exceedances under Alternative 3 occurring about  
34 6 percent of the time in August relative the No Action Alternative (7 percent), and  
35 about 9 percent of the time in September relative to 12 percent under the No  
36 Action Alternative. Average monthly water temperatures at Bend Bridge could  
37 be as high as about 73°F during this period. Temperature conditions in the  
38 Sacramento River under Alternative 3 could be less likely to affect Green  
39 Sturgeon rearing than under the No Action Alternative because of the reduced  
40 frequency of exceedance of the 63°F threshold in August and September.

1                    *Feather River*

2 Average monthly water temperatures in the Feather River at Gridley Bridge under  
3 both Alternative 3 and the No Action Alternative would exceed the water  
4 temperature threshold of 64°F established for Green Sturgeon spawning,  
5 incubation, and rearing in May, June, and September; no exceedances under either  
6 condition would occur in July and August. The frequency of exceedances would  
7 be high, with both Alternative 3 and the No Action Alternative exceeding the  
8 threshold in June nearly 100 percent of the time. The magnitude of the  
9 exceedance also would be substantial, with average monthly temperatures higher  
10 than 72°F in June, and higher than 75°F in July and August. Water temperatures  
11 under Alternative 3 would exceed the threshold for May about 7 percent less  
12 frequently than the No Action Alternative and about 33 percent more frequently  
13 in September. Temperature conditions in the Feather River under Alternative 3  
14 could be less likely to result in adverse effects on Green Sturgeon rearing than  
15 under the No Action Alternative because of the reduced frequency of exceedance  
16 of the 64°F threshold in May. The increase in exceedance frequency in  
17 September under Alternative 3 may have little effect on rearing Green Sturgeon as  
18 many juvenile sturgeon may have migrated downstream to the lower Sacramento  
19 River and Delta by this time.

20                    *Changes in Delta Outflow*

21 As described in Appendix 9P, mean (March to July) Delta outflow was used an  
22 indicator of potential year class strength and the likelihood of producing a strong  
23 year class of sturgeon. The median value over the 82-year CalSim II modeling  
24 period of mean (March to July) Delta outflow was predicted to be 9 percent lower  
25 under the Alternative 3 than under the No Action Alternative. In addition, the  
26 likelihood of mean (March to July) Delta outflow exceeding the threshold of  
27 50,000 cfs was the same under both alternatives.

28                    *Summary of Effects on Green Sturgeon*

29 The analysis of the effects of Alternative 3 and the No Action Alternative for  
30 Green Sturgeon relied on water temperature model output for the Sacramento and  
31 Feather rivers at various locations downstream of Shasta Dam and the Thermalito  
32 complex. The temperature model outputs for each of these rivers suggest that  
33 thermal conditions and effects on Green Sturgeon in the Sacramento and Feather  
34 rivers generally would be slightly less adverse under Alternative 3. This  
35 conclusion is supported by the water temperature threshold exceedance analysis  
36 that indicated that the water temperature thresholds for Green Sturgeon spawning,  
37 incubation, and rearing would be exceeded less frequently under Alternative 3 in  
38 the Sacramento River. The water temperature threshold for Green Sturgeon  
39 spawning, incubation, and rearing would also be exceeded less frequently during  
40 some months in the Feather River but would be exceeded substantially more  
41 frequently in September under Alternative 3 and could increase the potential for  
42 adverse effects on Green Sturgeon in the Sacramento and Feather rivers relative to  
43 the No Action Alternative. The analysis based on Delta outflows suggests that  
44 Alternative 3 provides lower mean (March to July) outflows which could result in  
45 weaker year classes of juvenile Green Sturgeon relative to the No Action

1 Alternative. In addition, actions under the No Action Alternative intended to  
2 increase the efficiency of the Tracy and Skinner Fish Collection Facilities could  
3 improve the overall salvage survival of green sturgeon. However, early life stage  
4 survival in the natal rivers is crucial in development of a strong year class.  
5 Therefore, based primarily on the analysis of water temperatures, Alternative 3  
6 could be less likely to result in adverse effects on Green Sturgeon than the No  
7 Action Alternative.

8 *White Sturgeon*

9 Changes in water temperature conditions in the Sacramento and Feather rivers  
10 would be the same as those described above for Green Sturgeon. Overall, the  
11 temperature differences between Alternative 3 and the No Action  
12 Alternative would be relatively minor (less than 0.5°F) and likely would have  
13 little effect on White Sturgeon in the Sacramento and Feather rivers.

14 The water temperature threshold established for White Sturgeon spawning and  
15 egg incubation in the Sacramento River at Hamilton City is 61°F during March  
16 through June. Both Alternative 3 and the No Action Alternative would exceed  
17 this threshold in May and June. The average monthly water temperatures in May  
18 under Alternative 3 would exceed this threshold about 49 percent of the time  
19 (about 6 percent less frequently than the No Action Alternative). In June, the  
20 temperature under Alternative 3 would exceed the threshold about 74 percent of  
21 the time (about 13 percent less frequently than the No Action Alternative).  
22 Average monthly water temperatures during May and June under Alternative 3  
23 would as high as about 65°F, which is below the 68°F threshold considered lethal  
24 for White Sturgeon eggs. Temperature conditions in the Sacramento River under  
25 Alternative 3 could be less likely to result in adverse effects on White Sturgeon  
26 rearing than under the No Action Alternative because of the reduced frequency of  
27 exceedance of the 61°F threshold in May and June.

28 The analysis of the effects of Alternative 3 and the No Action Alternative for  
29 White Sturgeon relied on water temperature model output for the Sacramento  
30 River at various locations downstream of Shasta Dam. The temperature model  
31 outputs suggest that thermal conditions and effects on White Sturgeon in the  
32 Sacramento River generally would be less adverse under Alternative 3. This  
33 conclusion is supported by the water temperature threshold exceedance analysis  
34 that indicated that the water temperature thresholds for White Sturgeon spawning,  
35 incubation, and rearing would be exceeded less frequently under Alternative 3 in  
36 the Sacramento River. The reduced frequency of exceedance of water  
37 temperature thresholds under Alternative 3 could reduce the potential for adverse  
38 effects on White Sturgeon in the Sacramento River relative to the No Action  
39 Alternative.

40 Changes in Delta outflows would be the same as those described above for Green  
41 Sturgeon. Mean (March to July) Delta outflow was predicted to be 9 percent  
42 lower under Alternative 3 than under the No Action Alternative. In addition, the  
43 likelihood of mean (March to July) Delta outflow exceeding the threshold of  
44 50,000 cfs was the same under both alternatives.

1 Overall, the temperature model outputs suggest that thermal conditions and  
2 effects on White Sturgeon in the Sacramento River generally would be slightly  
3 less adverse under Alternative 3. The analysis based on Delta outflows suggests  
4 that Alternative 3 provides lower mean (March to July) outflows which could  
5 result in weaker year classes of juvenile Green Sturgeon relative to the No Action  
6 Alternative. However, early life stage survival in the natal rivers is crucial in  
7 development of a strong year class. Therefore, based primarily on the analysis of  
8 water temperatures, Alternative 3 could be less likely to result in adverse effects  
9 on White Sturgeon than the No Action Alternative.

#### 10 *Delta Smelt*

11 As described in Appendix 9G, a proportional entrainment regression model  
12 (based on Kimmerer 2008, 2011) was used to simulate adult Delta Smelt  
13 entrainment, as influenced by OMR flow in December through March. Results  
14 indicate that the percentage of entrainment of migrating and spawning adult Delta  
15 Smelt under Alternative 3 would be 7.3 to 8.5 percent, depending on the water  
16 year type, with a long term average percent entrainment of 7.9 percent. Percent  
17 entrainment of adult Delta Smelt under Alternative 3 would be similar to results  
18 under the No Action Alternative.

19 As described in Appendix 9G, a proportional entrainment regression model  
20 (based on Kimmerer 2008) was used to simulate larval and early juvenile Delta  
21 Smelt entrainment, as influenced by OMR flow and location of X2 in March  
22 through June. Results indicate that the percentage of entrainment of larval and  
23 early juvenile Delta Smelt under Alternative 3 would be 5.6 to 20.5 percent,  
24 depending on the water year type, with a long term average percent entrainment  
25 of 12.7 percent, and highest entrainment under Critical water year conditions.  
26 Percent entrainment of larval and early juvenile Delta Smelt under Alternative 3  
27 would be similar to results under the No Action Alternative, except in above- and  
28 below-normal years when entrainment would be higher under Alternative 3 by  
29 5 to 6 percent.

30 The average September through December X2 position in km was used to  
31 evaluate the fall abiotic habitat availability for Delta Smelt under the Alternatives.  
32 X2 values simulated in the CalSim II model for each alternative were averaged  
33 over September through December, and compared. Results indicate that under  
34 the No Action Alternative, the X2 position would range from 75.9 km to 92.4 km,  
35 depending on the water year type, with a long term average X2 position of 84 km.  
36 The most eastward location of X2 is predicted under Critical water year  
37 conditions. The X2 positions predicted under Alternative 3 would be similar to  
38 results under the No Action Alternative in drier water year types. In wetter years,  
39 the X2 location would be further east under Alternative 3 than under the No  
40 Action Alternative, by 6.0 to 9.7 km. This difference is largely due to  
41 implementation of 2008 USFWS BO RPA Component 3 (Action 4), under the No  
42 Action Alternative, which requires Reclamation and DWR to provide sufficient  
43 Delta outflow to maintain a monthly average X2 no more eastward than 74 km in  
44 Above Normal and Wet years. Under Alternative 3, the long term average X2

1 position would be 88.1 km, a location that does not provide for the advantageous  
2 overlap of the low salinity zone with Suisun Bay/Marsh.

3 Overall, Alternative 3 likely would have adverse effects on Delta Smelt, as  
4 compared to the No Action Alternative, primarily due to increased percentage  
5 entrainment during larval and juvenile life stages, and less favorable location of  
6 Fall X2 in wetter years, and on average. Given the current condition of the Delta  
7 Smelt population, even small differences between alternatives may be important.

8 *Longfin Smelt*

9 The effects of the Alternative 3 as compared to the No Action Alternative were  
10 analyzed based on the direction and magnitude of OMR flows during the period  
11 (December through June) when adult, larvae, and young juvenile Longfin Smelt  
12 are present in the Delta in the vicinity of the export facilities (Appendix 5A). The  
13 analysis was augmented with calculated Longfin Smelt abundance index values  
14 (Appendix 9G) per Kimmerer et al. (2009), which is based on the assumptions  
15 that lower X2 values reflect higher flows and that transporting Longfin Smelt  
16 farther downstream leads to greater Longfin Smelt survival. The index value  
17 indicates the relative abundance of Longfin Smelt and not the calculated  
18 population.

19 As described in Appendix 5A, OMR flows would generally be negative in all  
20 months, except April and May where OMR flows would be positive, under the No  
21 Action Alternative and the long-term average negative flow ranges from -2,700 to  
22 -6,200 cfs from December through June. Because there would be no restrictions  
23 on export pumping from December 1 to June 15 due to OMR flow criteria under  
24 Alternative 3, OMR flows would generally be more negative during this time  
25 period under Alternative 3 as compared to the No Action Alternative. The  
26 greatest differences between alternatives would be in April and May, where long-  
27 term average OMR flows would be negative under Alternative 3 instead of  
28 positive as under the No Action Alternative. The increase in the magnitude of  
29 negative flows, particularly the negative flows in April and May, under  
30 Alternative 3 as compared to the No Action Alternative could increase the  
31 potential for entrainment of Longfin Smelt at the export facilities.

32 Under Alternative 3, Longfin Smelt abundance index values range from  
33 1,147 under critical water year conditions to a high of 16,635 under wet water  
34 year conditions, with a long-term average value of 7951 (Appendix 9G). Under  
35 the No Action Alternative, Longfin Smelt abundance index values range from  
36 947 under critical water year conditions to a high of 15,822 under wet water year  
37 conditions, with a long-term average value of 7,257.

38 Results indicate that the Longfin Smelt abundance index values would be lower in  
39 every water year type under Alternative 3 than under the No Action Alternative,  
40 with a long-term average index for Alternative 3 that is 7.6 percent lower than the  
41 long-term average index under the No Action Alternative. The greatest decrease  
42 in the Longfin Smelt abundance index occurs in above normal years where the  
43 index value is 12.3 percent less under Alternative 3 than under the No Action  
44 Alternative. For below normal, dry, and critical water years, the Longfin Smelt

1 abundance index values would be 4.6 to 9.9 percent lower under Alternative 3  
2 than under the No Action Alternative.

3 Overall, based on the increase in frequency and magnitude of negative OMR  
4 flows and the lower Longfin Smelt abundance index values, potential adverse  
5 effects on the Longfin Smelt population under Alternative 3 likely would be  
6 greater than under the No Action Alternative. Given the current condition of the  
7 Longfin Smelt population, even small differences between alternatives may be  
8 important.

#### 9 *Sacramento Splittail*

10 Under Alternative 3, flows entering the Yolo Bypass generally would be  
11 somewhat higher than under the No Action Alternative from December through  
12 March, especially during wetter years (Appendix 5A, Table C-26-2), providing  
13 similar value to Sacramento Splittail because of the similar area of potential  
14 habitat (inundation). Given the relatively minor changes in flows into the Yolo  
15 Bypass, and the inherent uncertainty associated with the resolution of the  
16 CalSim II model (average monthly outputs), it is concluded that there would be no  
17 definitive difference in effects on Sacramento Splittail between Alternative 3 and  
18 the No Action Alternative.

#### 19 *Reservoir Fishes*

20 The analysis of effects associated with changes in operation on reservoir fishes  
21 relied on evaluation of changes in available habitat (reservoir storage) and  
22 anticipated changes in black bass nesting success.

23 Changes in CVP and SWP water supplies and operations under Alternative 3 as  
24 compared to the No Action Alternative generally would result in higher reservoir  
25 storage in CVP and SWP reservoirs in the Central Valley Region. Storage levels  
26 in Shasta Lake, Lake Oroville, and Folsom Lake would be higher under  
27 Alternative 3 as compared to the No Action Alternative (Appendix 9F).

28 The greatest increases in Shasta Lake storage could be as high as 15 percent.  
29 Storage in Lake Oroville could be increased by up to 30 percent in some months  
30 under Alternative 3 as compared to the No Action Alternative. Storage in Folsom  
31 Lake could be increased up to around 20 percent in some months of some water  
32 year types and could be reduced by up to 10 percent in July, August, and  
33 September. Additional information related to monthly reservoir elevations is  
34 provided in Appendix 5A, CalSim II and DSM2 Modeling. Although aquatic  
35 habitat within the CVP and SWP water supply reservoirs is not limiting, storage  
36 volume, as an indicator of how much habitat is available to fish species inhabiting  
37 these reservoirs, suggests that the amount of habitat for reservoir fishes could be  
38 higher under Alternative 3 as compared to the No Action Alternative.

39 Results of the bass nesting success analysis are presented in Appendix 9F,  
40 Reservoir Fish Analysis Documentation. Black bass nest survival in CVP and  
41 SWP reservoirs is anticipated to be near 100 percent in March and April due to  
42 increasing reservoir elevations. For May, the likelihood of nest survival for  
43 Largemouth and Smallmouth Bass in Shasta Lake being in the 40 to 100 percent

1 range is similar under Alternative 3 and the No Action Alternative. For June, the  
2 likelihood of nest survival being greater than 40 percent for Largemouth and  
3 Smallmouth Bass is the same under Alternative 3 and the No Action Alternative;  
4 however, nest survival of greater than 40 percent is likely only in about 20 percent  
5 of the years evaluated. For Spotted Bass, the likelihood of nest survival being  
6 greater than 40 percent is high (nearly 100 percent) in May under both  
7 Alternative 3 and the No Action Alternative. For June, Spotted Bass nest survival  
8 would be less than for May due to greater daily reductions in water surface  
9 elevation as Shasta Lake is drawn down. The likelihood of survival being greater  
10 than 40 percent is about 10 percent less under Alternative 3 as compared to the  
11 No Action Alternative.

12 For May and June, the likelihood of nest survival for Largemouth Bass in Lake  
13 Oroville being in the 40 to 100 percent range is somewhat (4 to 10 percent) lower  
14 under Alternative 3 as compared to the No Action Alternative. However, June  
15 nest survival of greater than 40 percent is likely only in about 30 percent of the  
16 years evaluated under Alternative 3. The likelihood of nest survival for  
17 Smallmouth Bass in Lake Oroville exhibits nearly the same pattern. For Spotted  
18 Bass, the likelihood of nest survival being greater than 40 percent is high (over  
19 90 percent) in May under both Alternative 3 and the No Action Alternative with  
20 the likelihood of greater than 40 percent survival being similar under  
21 Alternative 3 as compared to the No Action Alternative. For June, Spotted Bass  
22 survival would be less than for May due to greater daily reductions in water  
23 surface elevation as Lake Oroville is drawn down. The likelihood of survival  
24 being greater than 40 percent is substantially lower (nearly 20 percent) under  
25 Alternative 3 as compared to the No Action Alternative.

26 Black bass nest survival in Folsom Lake is anticipated to be near 100 percent in  
27 March, April, and May due to increasing reservoir elevations. For June, the  
28 likelihood of nest survival for Largemouth Bass and Smallmouth Bass in Folsom  
29 Lake being in the 40 to 100 percent range would be about 5 percent lower under  
30 Alternative 3 than the No Action Alternative. For Spotted Bass, nest survival for  
31 June would be less than for May due to greater daily reductions in water surface  
32 elevation. However, the likelihood of survival being greater than 40 percent is  
33 around 7 percent lower under Alternative 3 as compared to the No Action  
34 Alternative. Most black bass spawning likely occurs prior to June, such that  
35 drawdowns during June would likely affect only a small proportion of the  
36 spawning population. Thus, it is concluded that effects on black bass nesting  
37 success would be similar under Alternative 3 and the No Action Alternative.

#### 38 *Summary of Effects on Reservoir Fishes*

39 The analysis of the effects of Alternative 3 and the No Action Alternative for  
40 reservoir fish relied on CalSim II output for reservoir storage levels and water  
41 surface elevation changes as described in Appendix 9F. As described above,  
42 reservoir storage is anticipated to be increased under Alternative 3 relative to the  
43 No Action Alternative and this increase could affect the amount of warm and cold  
44 water habitat available within the reservoirs. However, it is unlikely that aquatic  
45 habitat within the CVP and SWP water supply reservoirs is limiting.

1 The analysis of black bass nest survival based on changes in water surface  
2 elevation during the spawning period indicated that the likelihood of high  
3 (>40 percent) nest survival in most of the reservoirs would be similar in March,  
4 April, and May under Alternative 3 and the No Action Alternative, but somewhat  
5 lower in June. Most black bass spawning likely occurs prior to June, such that  
6 drawdowns during June would likely affect only a small proportion of the  
7 spawning population. Overall, the results of the habitat and nest survival analysis  
8 suggest that conditions in the reservoirs likely to support self-sustaining  
9 populations of black bass would be similar under Alternative 3 and the No Action  
10 Alternative.

#### 11 *Other Species*

12 Several other fish species could be affected by changes in operations that  
13 influence temperature and flow. The following describes the extent of these  
14 changes and the potential effects on these species.

#### 15 *Pacific Lamprey*

16 Little information is available on factors that influence populations of Pacific  
17 Lamprey in the Sacramento River, but they are likely affected by many of the  
18 same factors as salmon and steelhead because of the parallels in their life cycles.

19 Pacific Lamprey would be subjected to the same temperature conditions described  
20 above for salmonids. Average monthly water temperatures under Alternative 3  
21 and the No Action Alternative would generally be similar. Pacific Lamprey can  
22 tolerate higher temperatures than salmonids, up to around 72°F during their entire  
23 life history. Given the somewhat increased flows and similar temperatures under  
24 Alternative 3 and the No Action Alternative from January through the summer,  
25 there would be little difference in potential effects on Pacific Lamprey in the  
26 Sacramento, Feather, and American rivers under Alternative 3 and the No Action  
27 Alternative. This conclusion likely applies to other species of lamprey that  
28 inhabit these rivers (e.g., River Lamprey).

#### 29 *Striped Bass, American Shad, and Hardhead*

30 Average monthly water temperatures under Alternative 3 and the No Action  
31 Alternative would generally be similar. Striped Bass, American Shad, and  
32 Hardhead can generally tolerate higher temperatures than salmonids. Based on  
33 the similar water temperatures during their spawning and incubation period under  
34 Alternative 3, it is likely that thermal conditions for and effects on Striped Bass,  
35 American Shad, and Hardhead in the Sacramento, Feather, and American rivers  
36 would be similar under Alternative 1 and the No Action Alternative.

37 Alternative 3 would result in a more eastward X2 position as compared to the No  
38 Action Alternative during April and May, with similar values in June  
39 (Appendix 5A, Section C Table C-16-2). Based on Kimmerer (2002) and  
40 Kimmerer et al. (2009), this change in X2 would likely reduce the survival index  
41 and the habitat index as measured by salinity for Striped Bass and abundance and  
42 habitat index for American Shad. In addition, the increased bag limits and ability  
43 of anglers to retain Striped Bass that are 12 inches in length versus 18 inches

1 under Alternative 3 could reduce the ability to meet the doubling goals for Striped  
2 Bass populations under the requirements of Section 3406(b)(1) of CVPIA.

3 Overall, Alternative 3 likely would have similar effects on Hardhead, but slightly  
4 greater potential for adverse effects on Striped Bass and American Shad as  
5 compared to the No Action Alternative, primarily due to the potential for reduced  
6 survival during larval and juvenile life stages, and less favorable location of  
7 Spring X2 on average.

8 *Stanislaus River/Lower San Joaquin River*

9 *Fall-Run Chinook Salmon*

10 Changes in operations influence temperature and flow conditions that could affect  
11 fall-run Chinook Salmon in the Stanislaus River downstream of Goodwin Dam  
12 and in the San Joaquin River below Vernalis. The following describes those  
13 changes and their potential effects.

14 *Changes in Water Temperature (Stanislaus River)*

15 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
16 under Alternative 3 and the No Action Alternative generally would be similar  
17 (differences less than 0.5°F), except from May through October of drier years  
18 when average monthly water temperatures could be up to 2.9°F cooler  
19 (September) under Alternative 3 as compared to the No Action  
20 Alternative (Appendix 6B, Table B-17-2).

21 Downstream at Orange Blossom Bridge, average monthly water temperatures  
22 would be similar (less than 0.5°F differences) under Alternative 3 and the No  
23 Action Alternative, except in October when water temperatures under  
24 Alternative 3 could be higher than water temperatures under the No Action  
25 Alternative by up to 1.5°F in some water year types. Water temperatures in June  
26 under Alternative 3 would be substantially higher (2.3°F on average) and up to  
27 3.7°F warmer in wetter years. In September of drier years, water temperatures  
28 under Alternative 3 could be cooler (by up to 2.1°F in critical years) than under  
29 the No Action Alternative (Appendix 6B, Table B-18-2).

30 This temperature pattern would continue downstream to the confluence with the  
31 San Joaquin River, although temperatures and magnitude of temperature  
32 differences under Alternative 3 compared to the No Action Alternative would  
33 progressively increase in a downstream direction except for in September when  
34 temperature differences would diminish at this location (Appendix 6B,  
35 Table B-19-2).

36 Overall, the temperature differences between Alternative 3 and the No Action  
37 Alternative would be relatively minor (less than 0.5°F) and likely would have  
38 little effect on fall-run Chinook Salmon in the Stanislaus River. Based on the life  
39 history timing for fall-run Chinook Salmon, the lower water temperatures in  
40 September and October below Goodwin Dam under Alternative 3 likely would  
41 have little effect on fall-run Chinook Salmon spawning as the majority of  
42 spawning occurs later, in November. The higher water temperatures in June at  
43 Orange Blossom Bridge and the mouth under Alternative 3 may increase the

1 likelihood of adverse effects on fall-run Chinook Salmon rearing in the Stanislaus  
2 River, if they are present, as compared to the No action Alternative.

3 *Changes in Exceedance of Water Temperature Thresholds*  
4 *(Stanislaus River)*

5 While specific water temperature thresholds for fall-run Chinook Salmon in the  
6 Stanislaus River are not established, temperatures generally suitable for fall-run  
7 Chinook Salmon spawning (56°F) would be exceeded in October (over 30 percent  
8 of the time) and November over 20 percent of the time in the Stanislaus River at  
9 Goodwin Dam under Alternative 3 (Appendix 6B, Table B-17-2). Similar  
10 exceedances would occur under the No Action Alternative, although average  
11 monthly water temperatures under Alternative 3 would remain lower than under  
12 the No Action Alternative during the periods when the threshold is exceeded.  
13 Water temperatures under Alternative 3 also would exceed the threshold about  
14 5 percent less frequently in November than under the No Action Alternative.  
15 Water temperatures for rearing generally would be below 56°F, except in May  
16 and June when average monthly water temperatures would reach about 60°F  
17 under the No Action Alternative (Appendix 6B, Figures B-17-8 and B-17-9).

18 Downstream at Orange Blossom Bridge, water temperatures suitable for fall-run  
19 Chinook Salmon spawning would be exceeded frequently under both  
20 Alternative 3 and the No Action Alternative during October and November.  
21 Under Alternative 3, average monthly water temperatures would exceed 56°F  
22 about 87 percent of the time in October. This would be about 31 percent more  
23 frequently than under the No Action Alternative. In November, average monthly  
24 water temperatures would exceed 56°F about 24 percent of the time under  
25 Alternative 3, which would be about 9 percent less frequent than under the No  
26 Action Alternative (Appendix 6B, Figure B-18-1 and B-18-2).

27 During January through May, rearing fall-run Chinook Salmon under  
28 Alternative 3 would occasionally encounter average monthly water temperatures  
29 that exceed 56°F at Orange Blossom Bridge under both Alternative 3 and the No  
30 Action Alternative (Appendix 6B, Table B-18-2).

31 *Changes in Egg Mortality (Stanislaus River)*

32 For fall-run Chinook Salmon in the Stanislaus River, the long-term average egg  
33 mortality rate is predicted to be around 6 percent, with higher mortality rates (in  
34 excess of 13 percent) occurring in critical dry years under Alternative 3. Overall,  
35 egg mortality would be similar under Alternative 3 and the No Action  
36 Alternative in all water year types (Appendix 9C, Table B-1).

37 *Changes in Delta Hydrodynamics*

38 San Joaquin River-origin Chinook Salmon smolts are most abundant in the Delta  
39 from April through June. Near the confluence of the San Joaquin River and the  
40 Mokelumne River, the median proportion of positive velocities would be slightly  
41 lower under Alternative 3 relative to the No Action Alternative in April and May,  
42 and similar in June (Appendix 9K). On Old River downstream of the facilities,  
43 the median proportion of positive velocities would be substantially lower in April

1 and May under Alternative 3 relative to the No Action Alternative, but would be  
2 only moderately lower in June. In Old River upstream of the facilities, the  
3 median proportion of positive velocities would be similar for Alternative 3  
4 relative to the No Action Alternative in June. In April and May, values for  
5 Alternative 3 would be slightly higher under Alternative 3 relative to the No  
6 Action Alternative. On the San Joaquin River downstream of the Head of Old  
7 River, the median proportion of positive velocities would be similar under  
8 Alternative 3 relative to the No action Alternative in April, May and June.

9 *Changes in Junction Entrainment*

10 At the Head of Old River junction, entrainment under Alternative 3 would be  
11 slightly higher in April, May, and June (Appendix 9L). Median entrainment into  
12 Turner Cut would be slightly greater under Alternative 3 during April and May,  
13 and similar in June. At the Columbia Cut junction, entrainment would be  
14 moderately higher under Alternative 3 during April and May, whereas  
15 entrainment would be slightly higher in June. Entrainment probabilities at the  
16 Middle River junction from April through June would be moderately greater  
17 under Alternative 3 relative to the No action Alternative. A similar pattern would  
18 be observed at the Old River junction.

19 *Changes in Juvenile Salmonid Passage through the Delta (Trap and Haul)*

20 Poor survival of juvenile salmonids in the Sacramento-San Joaquin Delta has  
21 been hypothesized as a major contributor to declines in the number of returning  
22 adults and may be a significant impediment to the recovery of threatened or  
23 endangered populations (NOAA 2009). Under Alternative 3, fish would be  
24 trapped in the San Joaquin River between the mouth of the Stanislaus River and  
25 the Head of Old River to capture juveniles migrating from natal rearing habitat in  
26 the San Joaquin River, Merced River, Tuolumne River and Stanislaus River.  
27 Captured fish would be transported by barge through the Delta and released at  
28 locations within San Francisco Bay. Although trucks are currently used to  
29 transport hatchery reared salmonids and salvaged fishes (including salmonids),  
30 barging results in greater survival benefits (Ward et al. 1997) and may reduce  
31 straying of returning adults.

32 In response to low survival in the Columbia River hydro system, a transportation  
33 program was initiated where migrating salmonids (Chinook salmon and  
34 steelhead) are captured at dams and transported by barge to the lowest dam in the  
35 system before being released (Williams et al. 2004). The effectiveness of the  
36 Columbia River transportation program has been questioned because although  
37 survival of transported Chinook ( $\approx 98$  percent; McMichael et al. 2011) is greater  
38 than in-river migrants ( $\approx 50$  percent; Faulkner et al. 2010), SAR rates have not  
39 been proportional to the increase in hydro system survival. The most recent  
40 evidence suggests that that differences in ocean entry timing that occur due to the  
41 rapid rate of barge transport and the long distances transported are likely  
42 responsible for the lower post-hydro system survival of transported fish (Muir  
43 et al 2006; Rechisky et al 2012). To assess the potential benefits and risks of a  
44 transportation program for salmonids in the San Joaquin River, an analysis of  
45 CWT recovery rates for Chinook Salmon reared at the Feather River Hatchery

1 and the Mokelumne River Hatchery was performed (Appendix 9O). Based on  
 2 this analysis, Alternative 3 is expected to improve the survival of juvenile fall-run  
 3 Chinook Salmon and steelhead smolts originating from the San Joaquin River  
 4 basin in comparison to the No Action Alternative. Previous work on the  
 5 Columbia River suggests that benefits may be greater than demonstrated in  
 6 Appendix 9O if juveniles were transported by barge instead of truck (Ward et al.  
 7 1997). The program would also improve the survival of spring-run Chinook  
 8 Salmon if these fish become established as part of the San Joaquin River  
 9 Restoration Program, or as part of the New Melones fish passage project. As  
 10 indicated in Chapter 3, Description of Alternatives, this action will include  
 11 measures to quantify the benefit.

12 While a trap and haul program may increase survival, it also may result in  
 13 unintended consequences or population impacts. For example, a study of  
 14 returning adult Chinook Salmon and steelhead on the Columbia River following  
 15 transport as juveniles found that the proportion of adults successfully homing was  
 16 significantly lower and that the unaccounted loss and permanent straying into  
 17 non-natal rivers was higher for barged fish of both species (Keefer et al. 2008).  
 18 Increased straying could have consequences for populations in their natal streams,  
 19 but also could adversely influence populations in other streams if those fish breed  
 20 with other wild populations. The conditions and transport distances in the Delta  
 21 differ from those studied on the Columbia River system, thus the overall influence  
 22 on straying is uncertain.

23 However, as indicated in Appendix 9O, straying rates of transported fish are  
 24 anticipated to be greater than fish allowed to migrate within the river system. An  
 25 important consideration for this analysis of straying is that all releases into the bay  
 26 were transported by truck to bypass the Delta. Barge transport where water is  
 27 recirculated may reduce straying by allowing fish to “sample” water along the  
 28 migration route. Additionally, the location of collection on the San Joaquin River  
 29 would be downstream of natal rearing locations allowing fish to experience  
 30 portions of the migration route during rearing. In addition, trapping and hauling  
 31 is inconsistent with CDFW’s goal of achieving volitional fish passage.

32 *Summary of Effects on Fall-Run Chinook Salmon*

33 The analysis of temperatures indicates lower temperatures and a lesser likelihood  
 34 of exceedance of suitable temperatures for spawning and rearing of fall-run  
 35 Chinook Salmon under Alternative 3 as compared to the No Action Alternative in  
 36 the Stanislaus River downstream of Goodwin Dam and in the San Joaquin River  
 37 at Vernalis. The effect of lower temperatures is not reflected in the overall  
 38 mortality of fall-run Chinook Salmon eggs predicted by Reclamation’s salmon  
 39 mortality model for fall-run in the Stanislaus River.

40 Implementation of a fish passage project under the No Action Alternative,  
 41 although intended to address the limited availability of suitable habitat for spring-  
 42 run Chinook Salmon and steelhead in the Stanislaus River reaches downstream of  
 43 Goodwin Dam, likely would provide some benefit to fall-run Chinook Salmon if  
 44 passage for fall-run Chinook Salmon was provided and additional habitat could be  
 45 accessed. Any potential benefit to fall-run Chinook Salmon under the No Action

1 Alternative relative to Alternative 3 is uncertain. The potential benefits of actions  
2 under the No Action Alternative intended to increase the efficiency of the Tracy  
3 and Skinner Fish Collection Facilities could improve the overall salvage survival  
4 of fall-run Chinook Salmon relative to Alternative 3.

5 Overall, Alternative 3 likely would have similar effects on the fall-run Chinook  
6 Salmon population in the San Joaquin River watershed as compared to the No  
7 Action Alternative. Alternative 3 could also provide beneficial effects to juvenile  
8 fall-run Chinook Salmon as a result of trap and haul passage through the Delta  
9 and ocean harvest restrictions. It remains uncertain, however, if predator  
10 management actions under Alternative 3 and fish passage under the No Action  
11 Alternative would benefit fall-run Chinook Salmon.

#### 12 *Steelhead*

13 Changes in operations that influence temperature and flow conditions in the  
14 Stanislaus River downstream of Goodwin Dam and the San Joaquin River  
15 downstream of the Stanislaus River confluence, as measured at Vernalis could  
16 affect steelhead. The following describes those changes and their potential  
17 effects.

#### 18 *Changes in Water Temperature (Stanislaus River)*

19 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
20 under Alternative 3 and the No Action Alternative generally would be similar  
21 (differences less than 0.5°F), except from May through October of drier years  
22 when average monthly water temperatures could be up to 2.9°F cooler  
23 (September) under Alternative 3 than under the No Action Alternative.

24 Downstream at Orange Blossom Bridge, average monthly water temperatures  
25 would be similar (less than 0.5°F differences) under Alternative 3 and the No  
26 Action Alternative, except in October when water temperatures under  
27 Alternative 3 could be higher than water temperatures under the No Action  
28 Alternative by up to 1.5°F in some water year types. Water temperatures in June  
29 under Alternative 3 would be substantially higher (2.3°F on average) and up to  
30 3.7°F warmer in wetter years. In September of drier years, water temperatures  
31 under Alternative 3 could be cooler (by up to 2.1°F in critical years) than under  
32 the No Action Alternative.

33 This temperature pattern would continue downstream to the confluence with the  
34 San Joaquin River, although temperatures and magnitude of temperature  
35 differences under Alternative 3 compared to the No Action Alternative would  
36 progressively increase in a downstream direction except for in September when  
37 temperature differences would diminish at this location (Appendix 6B,  
38 Table B-19-2).

39 Overall, the temperature differences between Alternative 3 and the No Action  
40 Alternative would be relatively minor (less than 0.5°F) and likely would have  
41 little effect on steelhead in the Stanislaus River. The higher water temperatures in  
42 June at Orange Blossom Bridge and the mouth under Alternative 3 may increase  
43 the likelihood of adverse effects on steelhead rearing in the Stanislaus River as

1 compared to the No action Alternative. The lower water temperatures in  
 2 September of drier years under Alternative 3 may decrease the likelihood of  
 3 adverse effects to steelhead rearing in the Stanislaus River during this month.

4 *Changes in Exceedance of Water Temperature Thresholds*  
 5 *(Stanislaus River)*

6 Average monthly water temperatures in the Stanislaus River at Orange Blossom  
 7 Bridge would frequently exceed the temperature threshold (56°F) established for  
 8 adult steelhead migration under both Alternative 3 and the No Action  
 9 Alternative during October and November. Under Alternative 3, average monthly  
 10 water temperatures would exceed 56°F about 87 percent of the time in October  
 11 and about 57 percent of the time under the No Action Alternative. In November,  
 12 average monthly water temperatures would exceed 56°F about 24 percent of the  
 13 time under Alternative 3, which would be about 9 percent less frequent than under  
 14 the No Action Alternative.

15 From January through May, the temperature threshold at Orange Blossom Bridge  
 16 is 55°F, which is intended to support steelhead spawning. This threshold could be  
 17 exceeded about 1 percent of the time under Alternative 3 in February. In March  
 18 through May, exceedances would occur under both alternatives in each month,  
 19 with the threshold most frequently exceeded (nearly half the time) in May.  
 20 Compared to the No Action Alternative, water temperatures under Alternative 3  
 21 would exceed the threshold 3 percent more frequently in March, 1 percent more  
 22 frequently in April, and 4 percent more frequently in May. From June through  
 23 November, the temperature threshold of 65°F established to support steelhead  
 24 rearing would be exceeded by both Alternative 3 and No Action Alternative in all  
 25 months but November, with the highest frequency of exceedance in July  
 26 (19 percent under Alternative 3). The differences between Alternative 3 and No  
 27 Action Alternative, however, would be variable depending on the month, with  
 28 Alternative 3 exceeding the threshold up to about 6 percent less frequently than  
 29 under the No Action Alternative in June and from August through October.  
 30 Under Alternative 3, water temperatures would exceed the rearing temperature  
 31 threshold up to 4 percent more frequently in April, May, and July.

32 Average monthly water temperatures also would exceed the threshold (52°F)  
 33 established for smoltification at Knights Ferry. At Goodwin Dam, about 4 miles  
 34 upstream of Knights Ferry, average monthly water temperatures under  
 35 Alternative 3 would exceed 52°F in March, April, and May about 12 percent,  
 36 30 percent, and 63 percent of the time, respectively and 2 percent of the time in  
 37 January and February. By comparison to the No Action Alternative, Alternative 3  
 38 would result in exceedances occurring about 2 to 4 percent more frequently  
 39 during the January through March period. Farther downstream at Orange  
 40 Blossom Bridge, the temperature threshold for smoltification is higher (57°F) and  
 41 would be exceeded less frequently. The magnitude of the exceedance also would  
 42 be less. Average monthly water temperatures under Alternative 3 and the No  
 43 Action Alternative would not exceed the threshold during January through March.  
 44 In April and May, exceedances of 3 percent and 17 percent would occur under

1 Alternative 3, which would be nearly the same as under the No Action  
2 Alternative.

3 Overall, the differences in exceedance frequency between Alternative 3 and the  
4 No Action Alternative would be relatively small, with the exception of substantial  
5 differences in the frequency of exceedances in October when the average monthly  
6 water temperatures under Alternative 3 would exceed the threshold for adult  
7 steelhead migration about 28 percent less frequently and in April during the  
8 spawning period when the frequency would be about 17 percent less. Given the  
9 frequency of exceedance under both Alternative 3 and the No Action  
10 Alternative and the generally stressful temperature conditions in the river, the  
11 substantial differences (improvements) in October and April under Alternative 3  
12 suggest that there would be less potential to result in adverse effects on steelhead  
13 under Alternative 3 than under the No Action Alternative. Even during months  
14 when the differences would be relatively small, the lower frequency of  
15 exceedances under Alternative 3 suggest that there would be less potential to  
16 result in adverse effects on steelhead under Alternative 3 than under the No  
17 Action Alternative.

18 *Changes in Delta Hydrodynamics*

19 San Joaquin River-origin steelhead generally move through the Delta during  
20 spring; however, there is less information on their timing relative to Chinook  
21 Salmon. Thus, hydrodynamics in the entire January through June period have the  
22 potential to affect juvenile steelhead. For a description of potential hydrodynamic  
23 effects on steelhead, see the descriptions for winter-run Chinook Salmon in the  
24 Sacramento Basin and fall-run Chinook Salmon in the San Joaquin River basin  
25 above.

26 *Summary of Effects on Steelhead*

27 Given the frequency of exceedance under both Alternative 3 and the No Action  
28 Alternative, water temperature conditions for steelhead in the Stanislaus River  
29 would be generally stressful in the fall, late spring, and summer months. The  
30 differences in temperature exceedance (both positive and negative) between  
31 Alternative 3 and the No Action Alternative would be relatively small, with no  
32 clear benefit associated with either alternative. However, because Alternative 3  
33 generally would exceed thresholds less frequently during the warmest months, it  
34 may have slightly less impact than the No Action Alternative. Alternative 3 also  
35 could provide additional beneficial effects to juvenile steelhead as a result of trap  
36 and haul passage through the Delta. It remains uncertain, however, if predator  
37 management actions under Alternative 3 would benefit steelhead.

38 Implementation of the fish passage program under the No Action  
39 Alternative intended to address the limited availability of suitable habitat for  
40 steelhead in the Stanislaus River reaches downstream of Goodwin Dam could  
41 provide a benefit to Central Valley steelhead in the Stanislaus River. This is  
42 particularly important in light of anticipated increases in water temperature  
43 associated with climate change in 2030. In addition, RPA actions intended to  
44 increase the efficiency of the Tracy and Skinner Fish Collection Facilities could

1 improve the overall salvage survival of steelhead under the No Action  
2 Alternative. Thus, it is concluded that the potential for adverse effects on  
3 steelhead under Alternative 3 would be greater, principally because Alternative 3  
4 does not include a strategy to address water temperatures critical to steelhead  
5 sustainability over the long term with climate change by 2030.

#### 6 *White Sturgeon*

7 Evidence of White Sturgeon spawning has been recorded in the San Joaquin River  
8 upstream of the confluence with the Stanislaus River. While flows in the San  
9 Joaquin River upstream of the Stanislaus River are expected to be similar under all  
10 alternatives, flow contributions from the Stanislaus River could influence water  
11 temperatures in the San Joaquin River where White Sturgeon eggs or larvae may  
12 occur during the spring and early summer. The magnitude of influence on water  
13 temperature would depend on the proportional flow contribution of the Stanislaus  
14 River and the temperatures in both the Stanislaus and San Joaquin rivers. The  
15 potential for an effect on White Sturgeon eggs and larvae would be influenced by  
16 the proportion of the population occurring in the San Joaquin River. In  
17 consideration of this uncertainty, it is not possible to distinguish potential effects  
18 on White Sturgeon between alternatives.

#### 19 *Reservoir Fishes*

20 The analysis of effects associated with changes in operation on reservoir fishes  
21 relied on evaluation of changes in available habitat (reservoir storage) and  
22 anticipated changes in black bass nesting success.

23 Under Alternative 3, storage in New Melones could be increased up to around  
24 20 percent in some months of some water year types (Appendix 5A). Additional  
25 information related to monthly reservoir elevations is provided in Appendix 5A,  
26 CalSim II and DSM2 Modeling. It is anticipated that aquatic habitat within New  
27 Melones is not limiting; however, storage volume is an indicator of how much  
28 habitat is available to fish species inhabiting these reservoirs. Therefore, the  
29 amount of habitat for reservoir fishes could be increased under Alternative 3 as  
30 compared to the No Action Alternative.

31 Results of the bass nesting success analysis are presented in Appendix 9F. For  
32 March, the likelihood of Largemouth Bass and Smallmouth Bass nest survival in  
33 New Melones being above 40 percent is 100 percent under Alternative 3 and the  
34 No Action Alternative. For April, the likelihood that nest survival of Largemouth  
35 Bass and Smallmouth Bass is between 40 and 100 percent is reasonably high  
36 (around 80 percent) but is substantially (about 10 percent) higher under  
37 Alternative 3 than under the No Action Alternative. For May, the pattern is  
38 similar with the likelihood of high nest survival being about 6 percent greater  
39 under Alternative 3. For June, the likelihood of survival being greater than  
40 40 percent for Largemouth Bass and Smallmouth Bass in New Melones is similar  
41 under Alternative 3 and the No Action Alternative. For Spotted Bass, nest  
42 survival from March through June is anticipated to be near 100 percent in every  
43 year under both Alternative 3 and the No Action Alternative. Most black bass  
44 spawning likely occurs prior to June, such that drawdowns during June would

1 likely affect only a small proportion of the spawning population. Thus, it is  
2 concluded that effects on black bass nesting success would be similar under  
3 Alternative 3 and the No Action Alternative.

4 *Other Species*

5 Changes in operations that influence temperature and flow conditions in the  
6 Stanislaus River downstream of Keswick Dam and the San Joaquin River at  
7 Vernalis could affect other species such as lampreys, Hardhead, and Striped Bass.

8 As described above, average monthly water temperatures in the Stanislaus River  
9 at Goodwin Dam under Alternative 3 and the No Action Alternative generally  
10 would be similar. Downstream at Orange Blossom Bridge, average monthly  
11 water temperatures under Alternative 3 generally would be similar to water  
12 temperatures under the No Action Alternative except in September when they  
13 could be cooler and October when they could be warmer than under the No  
14 Action Alternative. This temperature pattern would continue downstream to the  
15 confluence with the San Joaquin River, although temperatures would  
16 progressively increase. Water temperatures from May to July may also be  
17 warmer under Alternative 3 compared to the No Action  
18 Alternative (Appendix 6B, Table B-19-2).

19 In general, lamprey species can tolerate higher temperatures than salmonids, up to  
20 around 72°F during their entire life history. Because lamprey ammocoetes remain  
21 in the river for several years, any substantial flow reductions or water temperature  
22 increases could result in adverse effects on larval lamprey. Given the slightly  
23 lower flows and increased water temperatures during portions of their spawning  
24 and incubation period, it is likely that the potential to affect lamprey species in the  
25 Stanislaus and San Joaquin rivers would be somewhat greater under Alternative 3  
26 and the No Action Alternative.

27 In general, Striped Bass and Hardhead also can tolerate higher temperatures than  
28 salmonids. Thus, thermal conditions for these species are expected to be similar  
29 under Alternative 3 and the No Action Alternative. However, implementation of  
30 a predator control program under Alternative 3 could result in adverse effects on  
31 Striped Bass.

32 *San Francisco Bay Area Region*

33 *Killer Whale*

34 As described above for the comparison of Alternative 1 to the No Action  
35 Alternative, it is unlikely that the Chinook Salmon prey base of killer whales,  
36 supported heavily by hatchery production of fall-run Chinook Salmon, would be  
37 appreciably affected by any of the alternatives.

38 **9.4.3.4.2 Alternative 3 Compared to the Second Basis of Comparison**

39 As described in Chapter 3, Description of Alternatives, the CVP and SWP  
40 operations and ongoing operational management policies of the CVP and SWP  
41 under Alternative 3 would be similar to the operational assumptions under the  
42 Second Basis of Comparison except for changes to water demand assumptions,

1 OMR flow criteria, and operations of New Melones Reservoir to meet SWRCB  
2 D-1641 flow requirements on the San Joaquin River at Vernalis. As a  
3 consequence, conditions for fish and aquatic resources would be relatively  
4 unchanged in most of the system under Alternative 3. The following briefly  
5 summarizes these minor changes, but focuses on portions of the CVP and SWP  
6 where changes would occur under Alternative 3 relative to the Second Basis of  
7 Comparison.

#### 8 *Trinity River Region*

##### 9 *Coho Salmon*

10 The analysis of effects associated with changes in operation on Coho Salmon was  
11 conducted using temperature model outputs for Lewiston Dam to anticipate the  
12 likely effects on conditions in the Trinity River downstream of Lewiston Dam for  
13 Coho Salmon.

14 Long-term average monthly water temperature in the Trinity River at Lewiston  
15 Dam under Alternative 3 would be similar (less than 0.5°F) to long-term average  
16 water temperatures under the Second Basis of Comparison in all months. The  
17 greatest differences would occur in critical years when average monthly  
18 temperatures would be 0.6°F lower in September and October and 0.8°F higher in  
19 November under Alternative 3 (Appendix 6B, Table B-1-5). The differences in  
20 the frequency with which Alternative 3 and the Second Basis of Comparison  
21 would exceed established temperature thresholds also would be small, with water  
22 temperatures under Alternative 3 exceeding thresholds about 0-2 percent less  
23 frequently than under the Second Basis of Comparison.

24 Given the similarity of the results and the inherent uncertainty associated with the  
25 resolution of the water temperature model (average monthly outputs), it is  
26 concluded that Alternative 3 and the Second Basis of Comparison are likely to  
27 have similar effects on the Coho Salmon population in the Trinity River.

##### 28 *Spring-run Chinook Salmon*

29 As described above for Coho Salmon, water temperatures would generally be  
30 similar (less than 0.5°F difference) under Alternative 3 and the Second Basis of  
31 Comparison. Similarly, the differences in the frequency with which water  
32 temperatures under Alternative 3 and the Second Basis of Comparison would  
33 exceed established temperature thresholds also would be small, with Alternative 3  
34 exceeding water temperature thresholds about 1 to 2 percent less frequently than  
35 the Second Basis of Comparison.

36 Given the similarity of the results and the inherent uncertainty associated with the  
37 resolution of the temperature model (average monthly outputs), it is concluded  
38 that Alternative 3 and Second Basis of Comparison are likely to have similar  
39 effects on the spring-run Chinook Salmon population in the Trinity River.

##### 40 *Fall-Run Chinook Salmon*

41 As described above for Coho Salmon, water temperatures under Alternative 3 and  
42 the Second Basis of Comparison generally would be similar (Appendix 6B,  
43 Table B-1-5. This is reflected in the egg mortality results, which indicate similar

1 levels of mortality, under Alternative 3 and the Second Basis of Comparison  
2 (Appendix 9C, Table 5-5).

3 Given the similarity of the results and the inherent uncertainty associated with the  
4 resolution of the temperature model (average monthly outputs), it is concluded  
5 that Alternative 3 and Second Basis of Comparison are likely to have similar  
6 effects on the fall-run Chinook Salmon population in the Trinity River.

7 *Steelhead*

8 Differences in water temperature conditions for steelhead in the Trinity River  
9 between Alternative 3 and the Second Basis of Comparison would be minor as  
10 described above for salmon. These results suggest that conditions for steelhead in  
11 the Trinity River generally would be similar under Alternative 3 and the Second  
12 Basis of Comparison.

13 *Green Sturgeon*

14 Green Sturgeon would be subjected to the same water temperature conditions  
15 described above for salmonids. The similarity in temperatures between  
16 Alternative 3 and the Second Basis of Comparison suggest that conditions for  
17 Green Sturgeon in the Trinity River generally would be similar under  
18 Alternative 3 and the Second Basis of Comparison.

19 *Reservoir Fishes*

20 Reservoir fishes in Trinity Lake would be exposed to relatively minor differences  
21 in storage under Alternative 3 as compared to the Second Basis of Comparison  
22 and these relatively small differences would have little effect on the amount of  
23 habitat available for these species. Black bass nesting survival would be similar  
24 under Alternative 3 and the Second Basis of Comparison. Overall, effects on  
25 reservoir fishes in Trinity Lake would be similar under both Alternative 3 and the  
26 Second Basis of Comparison.

27 *Pacific Lamprey and Eulachon*

28 As described above for Coho Salmon, there would be only minor differences in  
29 water temperatures between Alternative 3 and the Second Basis of Comparison.  
30 This suggests that water temperature conditions for Pacific Lamprey and  
31 Eulachon in the Trinity River and Klamath River downstream of the confluence  
32 generally would be similar under Alternative 3 and the Second Basis of  
33 Comparison.

34 *Sacramento River System*

35 *Winter-run Chinook Salmon*

36 Changes in operations that influence temperature and flow conditions in the  
37 Sacramento River downstream of Keswick Dam could affect winter-run Chinook  
38 Salmon. The following describes those changes and their potential effects.

39 *Changes in Water Temperature*

40 Long-term average monthly water temperature in the Sacramento River at  
41 Keswick Dam under Alternative 3 and the Second Basis would be similar  
42 (Appendix 6B, Table B-5-5). There would be slight differences in the frequency

1 of exceeding temperature thresholds under Alternative 3 and the Second Basis of  
 2 Comparison with the frequency of exceedance being up to 4 percent less under  
 3 Alternative 3 at Balls Ferry and up to 4 percent more at Bend Bridge. Egg  
 4 mortality would be similar under Alternative 3 and the Second Basis of  
 5 Comparison (Appendix 9C, Table B-4).

6 *Changes in Weighted Usable Area*

7 The WUA results for winter-run Chinook Salmon spawning habitat between  
 8 Keswick Dam and Battle Creek indicated that the amount of spawning habitat  
 9 would be similar under Alternative 3 and the Second Basis of Comparison  
 10 (Appendix 9E, Table C-17-5). Results were similar for fry rearing,  
 11 (Appendix 9E, Table C-18-5). Results for juvenile rearing also were similar  
 12 under both Alternative 3 and the Second Basis of Comparison (Appendix 9E,  
 13 Table C-19-5).

14 *Changes in SALMOD Output*

15 SALMOD results indicate that potential production of winter-run Chinook  
 16 Salmon under Alternative 3 would be essentially the same as under the Second  
 17 Basis of Comparison. (Appendix 9D, Table B-4-21).

18 *Changes in Delta Passage Model Output*

19 The Delta Passage Model predicted similar estimates of annual Delta survival  
 20 across the 81-year time period for winter-run Chinook Salmon between  
 21 Alternative 3 and the Second Basis of Comparison (Appendix 9J). Median Delta  
 22 survival was 0.354 for Alternative 3 and 0.352 for the Second Basis of  
 23 Comparison.

24 *Changes in Delta Hydrodynamics*

25 Winter-run Chinook Salmon smolts are most abundant in the Delta during  
 26 January, February, and March. On the Sacramento River near the confluence of  
 27 Georgiana Slough, the median proportion of positive velocities under  
 28 Alternative 3 was indistinguishable from the Second Basis of Comparison  
 29 (Appendix 9K). On the San Joaquin River near the Mokelumne River confluence,  
 30 the median proportion of positive velocities would be slightly higher under  
 31 Alternative 3 than under the Second Basis of Comparison. In Old River  
 32 downstream of the facilities, the median proportion of positive velocities would  
 33 be similar under Alternative 3 and the Second Basis of Comparison in March, but  
 34 would be moderately to slightly higher January and February, respectively under  
 35 Alternative 3. In Old River upstream of the facilities, the median proportion of  
 36 positive velocities would be slightly to moderately lower under Alternative 3 and  
 37 the Second Basis of Comparison in these months. On the San Joaquin River  
 38 downstream of Head of Old River, the percent of positive velocities would be  
 39 similar under both alternative in January, February and March.

40 *Changes in Junction Entrainment*

41 Entrainment at the Georgiana Slough Junction under Alternative 3 would be  
 42 almost indistinguishable from the Second Basis of Comparison (Appendix 9L).  
 43 At the Head of Old River junction, median entrainment probability would be

1 slightly lower under Alternative 3 in January and February and similar in March.  
2 At Turner Cut, median entrainment probabilities would be slightly lower under  
3 Alternative 3 relative to the Second Basis of Comparison in January and  
4 February; however, median entrainment probability would be similar in March.  
5 The median entrainment probability under Alternative 3 at Columbia Cut, Middle  
6 River, and Old River would be slightly lower from January to March relative to  
7 the Second Basis of Comparison.

8 *Changes in Salvage*

9 Salvage of Sacramento River-origin Chinook salmon is predicted to be  
10 substantially lower under Alternative 3 relative to the Second Basis of  
11 Comparison in January (Appendix 9M). In February salvage would be only  
12 moderately lower and slightly lower in March.

13 *Changes in Oncorhynchus Bayesian Analysis Output*

14 Escapement of winter-run Chinook Salmon and Delta survival was modeled by  
15 the Oncorhynchus Bayesian Analysis (OBAN) model for winter-run Chinook  
16 salmon. Differences in escapement between Alternative 3 and the Second Basis  
17 scenarios were moderately small (Appendix 9I). Escapement was generally  
18 greater under Alternative 3 relative to Second Basis of Comparison, and it was  
19 consistently greater over the 1986 to 1988 simulation period (dark gray and light  
20 gray areas above the dashed line). In most other years the difference in  
21 escapement estimates included 0 (i.e., dashed line located in the dark gray, central  
22 0.50 probability region) (see Appendix 9I). The median delta survival was  
23 slightly higher under Alternative 3 relative to the Second Basis scenario  
24 (6 percent), although the probability of no difference between alternatives was  
25 generally high throughout the simulation time period.

26 *Changes in Interactive Object-Oriented Simulation Output*

27 The IOS model predicted similar adult escapement trajectories for winter-run  
28 Chinook Salmon between Alternative 3 and the Second Basis of Comparison  
29 across the 81 years (Appendix 9H). Median adult escapement under Alternative 3  
30 was 4,025 and under the Second Basis of Comparison median escapement  
31 was 4,042.

32 Similar to adult escapement, the IOS model predicted similar egg survival for  
33 winter-run Chinook Salmon between Alternative 3 and the Second Basis of  
34 Comparison across the 81 water years. Median egg survival was 0.987 for both  
35 scenarios.

36 *Summary of Effects on Winter-Run Chinook Salmon*

37 The multiple model and analysis outputs described above characterize the  
38 anticipated conditions for winter-run Chinook Salmon and their response to  
39 change under Alternative 3 as compared to the Second Basis of Comparison. For  
40 the purpose of analyzing effects on winter-run Chinook Salmon and developing  
41 conclusions, greater reliance was placed on the outputs from the two life cycle  
42 models, IOS and OBAN because they each integrate the available information to  
43 produce single estimates of winter-run Chinook Salmon escapement. The output

1 from IOS indicated that winter-run Chinook Salmon escapement would be similar  
2 under both scenarios, whereas the OBAN results indicated that escapement under  
3 Alternative 3 could be higher than under the Second Basis of Comparison.

4 These model results suggest that effects on winter-run Chinook Salmon would be  
5 similar under both scenarios, with a small likelihood that winter-run Chinook  
6 Salmon escapement would be higher under Alternative 3 than under the Second  
7 Basis of Comparison. The ocean harvest restrictions under Alternative 3 could  
8 provide additional benefit, although the effects of the predator management  
9 program are uncertain. Overall, given the small differences, distinguishing a clear  
10 difference between alternatives is difficult. The non-operational components  
11 associated with Alternative 3 could benefit winter-run Chinook Salmon relative to  
12 the Second Basis of Comparison over the short term if successful. Thus, it is  
13 concluded that the potential for adverse effects on winter-run Chinook Salmon  
14 would be slightly less under Alternative 3 than under the Second Basis of  
15 Comparison.

#### 16 *Spring-run Chinook Salmon*

17 Operations under Alternative 3 generally would be similar to those for the Second  
18 Basis of Comparison. The following describes those changes and their potential  
19 effects.

#### 20 *Changes in Water Temperature*

21 Long-term average monthly water temperature in the Sacramento River under  
22 Alternative 3 and the Second Basis of Comparison would be similar  
23 (Appendix 6B). Differences in the frequency of exceeding temperature thresholds  
24 under Alternative 3 and the Second Basis of Comparison also would be minor  
25 (differences of about 1 percent), as would egg mortality, which would be similar  
26 under Alternative 3 and the Second Basis of Comparison (Appendix 9C,  
27 Table B-3).

28 In Clear Creek, average monthly water temperature at Igo under Alternative 3  
29 relative to the Second Basis of Comparison would be similar (Appendix 6B,  
30 Table B-3-5). The frequency of exceeding temperature thresholds for spring-run  
31 Chinook Salmon rearing also would be minor (differences of 1 percent).

32 In the Feather River, average monthly water temperature at the low flow channel  
33 under Alternative 3 relative to the Second Basis of Comparison also would be  
34 similar (differences less than 0.5°F), with a slight reduction in temperature (0.7°F)  
35 in August of below normal years (Appendix 6B, Table B-20-5). Water  
36 temperatures at the downstream location also would be similar, with temperatures  
37 under Alternative 3 at Robinson Riffle and Gridley up to 2°F percent cooler in  
38 July and August of some water year types (Appendix 6B, Table B-21-5).  
39 Changes in the frequency of temperature thresholds would be minor (differences  
40 of 1 percent or less), except in May when the temperature threshold for rearing  
41 would be exceeded about 4 percent more frequently than under the Second Basis  
42 of Comparison.

1            *Changes in Weighted Usable Area*

2 Weighted usable area curves are available for spring-run Chinook Salmon in  
3 Clear Creek. Flows in Clear Creek downstream of Whiskeytown Dam are not  
4 anticipated to differ under Alternative 3 relative to the Second Basis of  
5 Comparison. Therefore, there would be no change in the amount of potentially  
6 suitable spawning and rearing habitat for spring-run Chinook Salmon (as indexed  
7 by WUA) available under the Alternative 3 as compared to the Second Basis of  
8 Comparison.

9            *Changes in SALMOD Output*

10 SALMOD results indicate that potential production of spring-run Chinook  
11 Salmon would be essentially the same under Alternative 3 relative to the Second  
12 Basis of Comparison, but could be up to 8 percent less than under the Second  
13 Basis of Comparison in critical dry years (Appendix 9D, Table B-3-21).

14           *Changes in Delta Passage Model Output*

15 The Delta Passage Model predicted similar estimates of annual Delta survival  
16 across the 81-year time period for spring-run Chinook Salmon between  
17 Alternative 3 and the Second Basis of Comparison (Appendix 9J). Median Delta  
18 survival would be 0.286 for both scenarios.

19           *Changes in Delta Hydrodynamics*

20 Spring-run Chinook Salmon are most abundant in the Delta from March through  
21 May. Near the junction of Georgiana Slough, the median proportion of time that  
22 velocity would be positive was similar for both Alternative 3 and the Second  
23 Basis of Comparison in March, April and May (Appendix 9K). Near the  
24 confluence of the San Joaquin River and the Mokelumne River, the median  
25 proportion with positive velocity was similar during these months under  
26 Alternative 3 and the Second Basis of Comparison. In the San Joaquin River  
27 downstream of the Head of Old River, the median proportion of positive  
28 velocities was similar between scenarios in March, whereas values were slightly  
29 to moderately lower under Alternative 3 relative to the Second Basis of  
30 Comparison in April and May, respectively. In Old River upstream of the  
31 facilities, the median proportion with positive velocities was similar between  
32 scenarios in March and moderately higher in April and May under Alternative 3  
33 relative to the Second Basis of Comparison. In Old River downstream of the  
34 facilities, the median proportion with positive velocities was similar between  
35 scenarios in March and slightly higher in April and May under Alternative 3  
36 relative to the Second Basis of Comparison.

37           *Changes in Junction Entrainment*

38 Entrainment at the Georgiana Slough Junction under Alternative 3 would be  
39 almost indistinguishable from the Second Basis of Comparison during March  
40 April and May (Appendix 9L). At the Head of Old River junction, entrainment  
41 would be similar under Alternative 3 and the Second Basis of Comparison in  
42 March, whereas entrainment would be much greater under Alternative 3 relative  
43 to the Second Basis of Comparison in April and May. At Turner Cut, entrainment  
44 would be similar under Alternative 3 relative to the Second Basis of Comparison

1 in March and slightly to moderately lower in April and May, respectively under  
2 Alternative 3. Entrainment at Columbia Cut, Middle River, and Old River would  
3 yield similar patterns as those observed at Turner Cut.

#### 4 *Changes in Salvage*

5 Spring-run Chinook Salmon smolts migrating through the Delta would be most  
6 susceptible in the months of March, April, and May. Salvage of Sacramento  
7 River-origin Chinook salmon is predicted to be similar under Alternative 3 and  
8 the Second Basis of Comparison in March, April, and May (Appendix 9M).

#### 9 *Summary of Effects on Spring-Run Chinook Salmon*

10 The multiple model and analysis outputs described above characterize the  
11 anticipated conditions for spring-run Chinook Salmon and their response to  
12 change under Alternative 3 and the Second Basis of Comparison. For the purpose  
13 of analyzing effects on spring-run Chinook Salmon in the Sacramento River,  
14 greater reliance was placed on the outputs from the SALMOD model because it  
15 integrates the available information on temperature and flows to produce  
16 estimates of mortality for each life stage and an overall, integrated estimate of  
17 potential spring-run Chinook Salmon juvenile production. The output from  
18 SALMOD indicated that spring-run Chinook Salmon production in the  
19 Sacramento River would be similar under Alternative 3 and the Second Basis of  
20 Comparison, although production under Alternative 3 could be up to 8 percent  
21 less than under the Second Basis of Comparison in critical dry years.

22 The analyses attempting to assess the effects on routing, entrainment, and salvage  
23 of juvenile salmonids in the Delta suggest that salvage (as an indicator of  
24 potential losses of juvenile salmon at the export facilities) of Sacramento  
25 River-origin Chinook Salmon generally would be similar under Alternative 3 and  
26 the Second Basis of Comparison.

27 In Clear Creek and the Feather River, the analysis of the effects of Alternative 3  
28 and the Second Basis of Comparison for spring-run Chinook Salmon relied on  
29 output from the WUA analysis and water temperature output for Clear Creek at  
30 Igo, and in the Feather River low flow channel and downstream of the Thermalito  
31 complex. The WUA analysis suggests that there would be little difference in the  
32 availability of spawning and rearing habitat in Clear Creek. The temperature  
33 model outputs suggest that thermal conditions and effects on each of the  
34 spring-run Chinook Salmon life stages generally cannot be fully characterized in  
35 Clear Creek and the Feather River. This conclusion is supported by the water  
36 temperature threshold exceedance analysis that indicated that water temperature  
37 thresholds for spawning and egg incubation in Clear Creek and the Feather River  
38 would be exceeded less frequently in some months and more frequently in others  
39 under Alternative 3 than under the Second Basis of Comparison. The water  
40 temperature threshold for rearing spring-run Chinook Salmon in the Feather River  
41 would also be exceeded less frequently in some months and more frequently in  
42 others under Alternative 3. Because of the inherent uncertainty associated with  
43 the resolution of the temperature model (average monthly outputs), and the  
44 differences in the magnitude and direction of the temperature exceedances under

1 Alternative 3, the extent of temperature-related effects on spring-run Chinook  
2 Salmon in Clear Creek and the Feather River is uncertain.

3 These model results suggest that overall, effects on spring-run Chinook Salmon  
4 could be slightly more adverse under Alternative 3 than the Second Basis of  
5 Comparison, with a small likelihood that spring-run Chinook Salmon production  
6 would be lower under the Second Basis of Comparison. Although the operational  
7 components associated with Alternative 3 could have greater adverse effects on  
8 spring-run Chinook Salmon than the Second Basis of Comparison, the non-  
9 operational components associated with Alternative 3 could benefit spring-run  
10 Chinook Salmon relative to the Second Basis of Comparison over the short term  
11 if successful. The ocean harvest restriction component of Alternative 3 could  
12 increase spring-run Chinook Salmon numbers by reducing ocean harvest and the  
13 trap and haul program and predator control measures under Alternative 3 could  
14 reduce predation on juvenile spring-run Chinook Salmon and thereby increase  
15 survival. The effects of the trap and haul and predator management programs  
16 under Alternative 3 are uncertain. Thus, it is concluded that the potential for  
17 adverse effects on spring-run Chinook Salmon would be slightly less under  
18 Alternative 3 than under the Second Basis of Comparison.

19 *Fall-Run Chinook Salmon*

20 Changes in operations that influence temperature and flow conditions in the  
21 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
22 Whiskeytown Dam, Feather River downstream of Oroville Dam and American  
23 River below Nimbus could affect fall-run Chinook Salmon. The following  
24 describes those changes and their potential effects.

25 *Changes in Water Temperature*

26 Water temperature conditions in the Sacramento River, Clear Creek, and Feather  
27 River under Alternative 3 and the Second Basis of Comparison would be same as  
28 those described above for spring-run Chinook Salmon. Temperature conditions in  
29 the Sacramento River, Clear Creek, Feather River, and American River would  
30 generally be similar (differences less than 0.5°F) under Alternative 3 and the  
31 Second Basis of Comparison (Appendix 6B).

32 The frequency of exceeding established temperature thresholds in the Sacramento  
33 and Feather rivers for fall-run Chinook Salmon would be the same or nearly so  
34 (differences of up to 2 percent) for both Alternative 3 and the Second Basis of  
35 Comparison. Similarly, in the American River (Appendix 9C, Table B-6),  
36 differences in the frequency of temperature threshold exceedance would be minor  
37 (up to about 1 percent).

38 The results from Reclamation's salmon mortality model reflect the similarities in  
39 temperature described above. For fall-run Chinook Salmon in the Sacramento  
40 River, egg mortality would be similar under Alternative 3 and the Second Basis of  
41 Comparison (Appendix 9C, Table B-1). Differences in the Feather and American  
42 rivers would also be similar under Alternative 3 and the Second Basis of  
43 Comparison.

1            *Changes in Weighted Usable Area*

2 Modeling results indicate that, in general, there would be similar amounts (less  
3 than 5 percent differences) of fall-run Chinook Salmon spawning habitat available  
4 in the Sacramento, Feather, and American rivers under Alternative 3 as compared  
5 to the Second Basis of Comparison; fall-run fry and juvenile rearing WUA would  
6 also be similar under Alternative 3 and the Second Basis of Comparison in the  
7 Sacramento River. Overall, spawning and rearing habitat availability for fall-run  
8 Chinook Salmon would be similar under Alternative 3 and the Second Basis of  
9 Comparison.

10           *Changes in SALMOD Output*

11 SALMOD results indicate that production for fall-run Chinook Salmon would be  
12 similar under Alternative 3 and the Second Basis of Comparison (Appendix 9D,  
13 Table B-1-21).

14           *Changes in Delta Passage Model Output*

15 The Delta Passage Model predicted similar estimates of annual Delta survival  
16 across the 8-year time period for fall-run Chinook Salmon between Alternative 3  
17 and the Second Basis of Comparison (Appendix 9J). Median Delta survival was  
18 0.246 for Alternative 3 and 0.245 for the Second Basis of Comparison.

19           *Changes in Delta Hydrodynamics*

20 Fall-run Chinook Salmon smolts are most abundant in the Delta during the  
21 months of April, May and June. At the junction of Georgiana Slough and the  
22 Sacramento River, the median proportion of positive velocities would be similar  
23 in April, May, and June under Alternative 3 and the Second Basis of Comparison  
24 (Appendix 9K). Near the confluence of the San Joaquin River and the  
25 Mokelumne River, the median proportion of positive velocities would be similar  
26 to or slightly lower under Alternative 3 relative to the Second Basis of  
27 Comparison in the months when fall-run Chinook Salmon are most abundant. On  
28 Old River downstream of the facilities, the median proportion of positive  
29 velocities would be slightly higher in April and May, and similar in June under  
30 Alternative 3 relative to the Second Basis of Comparison. In Old River upstream  
31 of the facilities, the median proportion of positive velocities would be moderately  
32 higher under Alternative 3 in April and May and slightly lower in June. On the  
33 San Joaquin River downstream of the Head of Old River, the median proportion  
34 of positive velocities would be slightly to moderately lower under Alternative 3  
35 relative to the Second Basis of Comparison in April and May, respectively, and  
36 slightly lower in June.

37           *Changes in Junction Entrainment*

38 Entrainment at the Georgiana Slough Junction under Alternative 3 would be  
39 almost indistinguishable from the Second Basis of Comparison in April, May, and  
40 June (Appendix 9L). At the Head of Old River junction in April and May,  
41 entrainment would be much greater under Alternative 3 relative to the Second  
42 Basis of Comparison. In June, entrainment would be similar under each scenario.  
43 Patterns of entrainment would be similar at Turner Cut, Columbia Cut, Middle  
44 River, and Old River. At these junctions, median entrainment under Alternative 3

1 would be slightly to moderately lower in April and May, and almost  
2 indistinguishable in June.

3 *Changes in Salvage*

4 Salvage of Sacramento River-origin Chinook Salmon is predicted to be lower  
5 under Alternative 3 relative to the Second Basis of Comparison in every month  
6 except April, May, and June (Appendix 9M). Fall-run Chinook Salmon smolts  
7 migrating through the Delta would be most susceptible in the months of April,  
8 May, and June. Predicted values in April and May indicated a similar fraction of  
9 fish salvaged under Alternative 3 and the Second Basis of Comparison and a  
10 slightly reduce fraction salvaged in June under Alternative 3.

11 *Summary of Effects on Fall-Run Chinook Salmon*

12 The multiple model and analysis outputs described above characterize the  
13 anticipated conditions for fall-run Chinook Salmon and their response to change  
14 under Alternative 3 and the Second Basis of Comparison. For the purpose of  
15 analyzing effects on fall-run Chinook Salmon in the Sacramento River, greater  
16 reliance was placed on the outputs from the SALMOD model because it integrates  
17 the available information on temperature and flows to produce estimates of  
18 mortality for each life stage and an overall, integrated estimate of potential fall-  
19 run Chinook Salmon juvenile production. The output from SALMOD indicated  
20 that fall-run Chinook Salmon production would be similar in all water year types  
21 under Alternative 3 and the Second Basis of Comparison.

22 The analyses attempting to assess the effects on routing, entrainment, and salvage  
23 of juvenile salmonids in the Delta suggest that salvage (as an indicator of  
24 potential losses of juvenile salmon at the export facilities) of Sacramento  
25 River-origin Chinook Salmon generally would be similar under Alternative 3 and  
26 the Second Basis of Comparison.

27 In Clear Creek and the Feather and American rivers, the analysis of the effects of  
28 Alternative 3 and the Second Basis of Comparison for fall-run Chinook Salmon  
29 relied on the WUA analysis for habitat and water temperature model output for  
30 the rivers at various locations downstream of the CVP and SWP facilities. The  
31 WUA analysis indicated that the availability of spawning and rearing habitat in  
32 Clear Creek and spawning habitat in the Feather and American rivers would be  
33 similar under Alternative 3 and the Second Basis of Comparison. The  
34 temperature model outputs for each of the fall-run Chinook Salmon life stages  
35 suggest that thermal conditions and effects on fall-run Chinook Salmon in all of  
36 these streams generally would be similar under both scenarios. The water  
37 temperature threshold exceedance analysis that indicated that the water  
38 temperature thresholds for fall-run Chinook Salmon spawning and egg incubation  
39 would be exceeded slightly less frequently in the Feather River and Clear Creek  
40 under Alternative 3 and could reduce the potential for adverse effects on the fall-  
41 run Chinook Salmon populations in Clear Creek and the Feather River. Results of  
42 the analysis using Reclamation's salmon mortality model indicate that there  
43 would be little difference in fall-run Chinook Salmon egg mortality under  
44 Alternative 3 and the Second Basis of Comparison.

1 Overall, the results of the numerical models suggest the potential for less adverse  
2 effects on fall-run Chinook Salmon under Alternative 3 as compared to the  
3 Second Basis of Comparison. However, discerning a meaningful difference  
4 between these two scenarios based on the quantitative results is not possible  
5 because of the similarity in results (generally differences less than 5 percent) and  
6 the inherent uncertainty of the models. In addition, adverse effects of  
7 Alternative 3 could be offset by the potentially beneficial effects of the predator  
8 control program and ocean harvest restrictions. Thus, it is concluded that the  
9 potential for adverse effects on fall-run Chinook Salmon would be slightly less  
10 under Alternative 3 than under the Second Basis of Comparison.

#### 11 *Late Fall-Run Chinook Salmon*

##### 12 *Changes in Water Temperature*

13 Temperature conditions in the Sacramento River downstream of Keswick Dam  
14 for late fall-run Chinook Salmon under Alternative 3 and the Second Basis of  
15 Comparison generally would be similar, as described above for fall-run Chinook  
16 Salmon. The results from Reclamation's salmon mortality model reflect the  
17 similarities in temperature described above. For late fall-run Chinook Salmon in  
18 the Sacramento River, egg mortality would be similar under Alternative 3 and the  
19 Second Basis of Comparison (Appendix 9C, Table B-1).

##### 20 *Changes in Weighted Usable Area*

21 Modeling results indicate that there would be similar amounts of spawning habitat  
22 available for late fall-run Chinook Salmon in the Sacramento River from January  
23 through April under Alternative 3 as compared to the Second Basis of  
24 Comparison (Appendix 9E, Table C-14-5). There also would be similar amounts  
25 of suitable late fall-run Chinook Salmon fry rearing habitat available during April  
26 and May under Alternative 3 and the Second Basis of Comparison (Appendix 9E,  
27 Table C-15-5). Modeling results indicate that, there would generally be similar  
28 amounts of suitable juvenile rearing habitat available all year long under  
29 Alternative 3 and the Second Basis of Comparison (Appendix 9E, Table C-16-5).

##### 30 *Changes in SALMOD Output*

31 Results from the SALMOD model indicate that potential production under  
32 Alternative 3 would be similar under Alternative 3 and the Second Basis of  
33 Comparison in all water year types (Appendix 9D, Table B-2-21).

##### 34 *Changes in Delta Passage Model Output*

35 The Delta Passage Model predicted similar estimates of annual Delta survival  
36 across the 81-year time period for late fall-run Chinook Salmon between  
37 Alternative 3 and the Second Basis of Comparison (Appendix 9J). Median Delta  
38 survival would be 0.199 for both scenarios.

##### 39 *Changes in Delta Hydrodynamics*

40 The late fall-run Chinook Salmon migration period overlaps with the winter-run.  
41 See the section on hydrodynamic analysis for winter-run Chinook Salmon for  
42 potential effects on late fall-run Chinook Salmon.

1            *Changes in Junction Entrainment*

2    Entrainment probabilities for late fall-run Chinook Salmon are assumed to mimic  
3    that of winter-run Chinook Salmon due to the overlap in timing. See the section  
4    on winter-run Chinook Salmon entrainment for potential effects on late fall-run  
5    Chinook Salmon.

6            *Changes in Salvage*

7    Salvage of late fall-run Chinook Salmon is assumed to mimic that of winter-run  
8    Chinook Salmon due to overlap in timing. See the section on winter-run Chinook  
9    Salmon entrainment for potential effects on the late fall-run Chinook Salmon.

10           *Summary of Effects on Late Fall-Run Chinook Salmon*

11    The multiple model and analysis outputs described above characterize the  
12    anticipated conditions for late fall-run Chinook Salmon and their response to  
13    change under Alternative 3 and the Second Basis of Comparison. For the purpose  
14    of analyzing effects on late fall-run Chinook Salmon and developing conclusions,  
15    greater reliance was placed on the outputs from the SALMOD model because it  
16    integrates the available information on temperature and flows to produce  
17    estimates of mortality for each life stage and an overall, integrated estimate of  
18    potential fall-run Chinook Salmon juvenile production. The output from  
19    SALMOD suggested that late fall-run Chinook Salmon production would be  
20    similar under Alternative 3 and the Second Basis of Comparison.

21    Although, potential losses of juvenile salmon at the export facilities could be  
22    higher under Alternative 3, as suggested by the analysis of salvage, it is likely that  
23    effects on the late fall-run Chinook Salmon population would be similar under  
24    Alternative 3 and the Second Basis of Comparison.

25    Overall, the results of the numerical models suggest the potential for less adverse  
26    effects on late fall-run Chinook Salmon under Alternative 3 as compared to the  
27    Second Basis of Comparison. However, discerning a meaningful difference  
28    between these two scenarios based on the quantitative results is not possible  
29    because of the similarity in results (generally differences less than 5 percent) and  
30    the inherent uncertainty of the models. In addition, any adverse effects of  
31    Alternative 3 could be offset by the potentially beneficial effects resulting from  
32    predator control and ocean harvest restrictions. Thus, it is concluded that the  
33    effects on late fall-run Chinook Salmon would be similar under Alternative 3 and  
34    the Second Basis of Comparison.

35           *Steelhead*

36            *Changes in Water Temperature*

37    Water temperature conditions in the Sacramento River, Clear Creek, Feather  
38    River and American River under Alternative 3 and the Second Basis of  
39    Comparison would be same as those described above for fall-run Chinook  
40    Salmon. Temperature conditions in the Sacramento River, Clear Creek, Feather  
41    River, and American River would generally be similar (differences less than  
42    0.5°F) under Alternative 3 and the Second Basis of Comparison (Appendix 6B).

1 The frequency of exceeding temperature thresholds in the Sacramento, Feather,  
2 and American rivers for steelhead would be the same or nearly so (differences of  
3 up to 2 percent) for both Alternative 3 and the Second Basis of Comparison  
4 Exceedances.

5 *Changes in Weighted Usable Area*

6 Modeling results indicate that, in general, there would be similar amounts (less  
7 than 5 percent differences) of steelhead spawning habitat available in Clear Creek,  
8 and the Sacramento, Feather, and American rivers under Alternative 3 as  
9 compared to the Second Basis of Comparison.

10 *Summary of Effects on Steelhead*

11 The multiple model and analysis outputs described above characterize the  
12 anticipated conditions for steelhead and their response to change under  
13 Alternative 3 and the Second Basis of Comparison. The analysis of the effects of  
14 Alternative 3 and the Second Basis of Comparison for steelhead relied on the  
15 WUA analysis for habitat and water temperature model output for the rivers at  
16 various locations downstream of the CVP and SWP facilities. The WUA analysis  
17 indicated that the availability of steelhead spawning and rearing habitat in Clear  
18 Creek and steelhead spawning habitat in the Sacramento, Feather and American  
19 rivers would be similar under Alternative 3 and the Second Basis of Comparison.  
20 The temperature model outputs for each of the steelhead life stages indicated that  
21 the water temperature thresholds for steelhead spawning and egg incubation  
22 would be exceeded less frequently in the Feather River under Alternative 3.  
23 However, the water temperature threshold for steelhead rearing in the Feather  
24 River would be exceeded less frequently in some months and more frequently in  
25 others under Alternative 3. The water temperature threshold for steelhead rearing  
26 in the American River would also be exceeded more frequently in most months  
27 under Alternative 3. Because of the inherent uncertainty associated with the  
28 resolution of the temperature model (average monthly outputs), and the  
29 differences in the magnitude and direction of the temperature exceedances under  
30 Alternative 3, the extent of temperature-related effects on steelhead in the Feather  
31 and American rivers is uncertain.

32 Overall, the results of the numerical models suggest a slightly greater potential to  
33 result in adverse effects on steelhead under Alternative 3 as compared to the  
34 Second Basis of Comparison. However, discerning a meaningful difference  
35 between these two scenarios based on the quantitative results is not possible  
36 because of the similarity in results (generally differences less than 5 percent) and  
37 the inherent uncertainty of the models. In addition, any adverse effects of  
38 Alternative 3 could be offset by the potentially beneficial effects resulting from  
39 predator control and ocean harvest restrictions. Thus, it is concluded that the  
40 effects on steelhead would be similar under Alternative 3 and the Second Basis of  
41 Comparison.

1        *Sturgeon (green and white)*

2 Changes in operations that influence temperature and flow conditions could affect  
3 Green Sturgeon. The following describes those changes and their potential  
4 effects.

5            *Changes in Water Temperature*

6 The analysis of the effects of Alternative 3 and Second Basis of Comparison for  
7 sturgeon relied on water temperature model output for the Sacramento and  
8 Feather rivers at various locations downstream of Shasta Dam and the Thermalito  
9 complex. The temperature model outputs for each of these rivers suggest that  
10 thermal conditions and effects on sturgeon in the Sacramento and Feather rivers  
11 generally would be similar under both scenarios. This conclusion is supported by  
12 the water temperature threshold exceedance analysis that indicated that the water  
13 temperature thresholds for sturgeon spawning, incubation, and rearing would be  
14 exceeded slightly less frequently under Alternative 3 in the Sacramento River.  
15 The water temperature threshold for sturgeon spawning, incubation, and rearing  
16 also would be exceeded slightly less frequently in the Feather River.

17            *Changes in Delta Outflow*

18 As described in Appendix 9P, mean (March to July) Delta outflow was used an  
19 indicator of potential year class strength and the likelihood of producing a strong  
20 year class of sturgeon. The median value over the 82-year CalSim II modeling  
21 period of mean (March to July) Delta outflow was predicted to similar under the  
22 Alternative 3 and the Second Basis of Comparison. In addition, the likelihood of  
23 mean (March to July) Delta outflow exceeding the threshold of 50,000 cfs was the  
24 same under both alternatives.

25            *Summary of Effects on Sturgeon*

26 The slightly reduced frequency of exceedance of temperature thresholds under  
27 Alternative 3 could reduce the potential for adverse effects on sturgeon in the  
28 Sacramento and Feather rivers relative to the Second Basis of Comparison. The  
29 analysis based on Delta outflows suggests that Alternative 3 provides similar  
30 mean (March to July) outflows which would have similar effects on year class  
31 strength of juvenile sturgeon relative to the Second Basis of Comparison.  
32 Therefore, based primarily on the analysis of water temperatures, Alternative 3  
33 could be less likely to result in adverse effects on White Sturgeon than the Second  
34 Basis of Comparison.

35            *Delta Smelt*

36            *Changes in Proportional Entrainment*

37 As described in Appendix 9G, a proportional entrainment regression model  
38 (based on Kimmerer 2008, 2011) was used to simulate adult Delta Smelt  
39 entrainment, as influenced by OMR flow in December through March. Results  
40 indicate that the percentage of entrainment of migrating and spawning adult Delta  
41 Smelt under Alternative 3 would be 7.3 to 8.5 percent, depending on the water  
42 year type, with a long term average percent entrainment of 7.9 percent. Percent

1 entrainment of adult Delta Smelt under Alternative 3 would be similar to results  
2 under the Second Basis of Comparison.

3 As described in Appendix 9G, a proportional entrainment regression model  
4 (based on Kimmerer 2008) was used to simulate larval and early juvenile Delta  
5 Smelt entrainment, as influenced by OMR flow and location of X2 in March  
6 through June. Results indicate that the percentage of entrainment of larval and  
7 early juvenile Delta Smelt under Alternative 3 would be 5.6 to 20.5 percent,  
8 depending on the water year type, with a long term average percent entrainment  
9 of 12.7 percent, and highest entrainment under Critical water year conditions.  
10 Percent entrainment of larval and early juvenile Delta Smelt under Alternative 3  
11 would be similar to results under the Second Basis of Comparison.

#### 12 *Changes in Fall Abiotic Habitat Index*

13 The average September through December X2 position in km was used to  
14 evaluate the fall abiotic habitat availability for delta smelt under the Alternatives.  
15 X2 values simulated in the CalSim II model for each alternative were averaged  
16 over September through December, and compared. Results indicate that under  
17 the Second Basis of Comparison, the X2 position would range from 85.6 km to  
18 92.3 km, depending on the water year type, with a long term average X2 position  
19 of 88.1 km. The most eastward location of X2 is predicted under Critical water  
20 year conditions. The X2 positions predicted under Alternative 3 would be similar  
21 to predictions under the Second Basis of Comparison (only 0.1 to 0.3 km  
22 difference). Under Alternative 3, the long term average X2 position would be  
23 88.1 km, a location that does not provide for the advantageous overlap of the low  
24 salinity zone with Suisun Bay/Marsh.

#### 25 *Summary of Effects on Delta Smelt*

26 Overall, Alternative 3 likely would have similar effects on Delta Smelt, as  
27 compared to the Second Basis of Comparison with regard to estimated  
28 entrainment and predicted location of Fall X2. However, given the current  
29 condition of the Delta Smelt population, even small differences between  
30 alternatives may be important.

#### 31 *Longfin Smelt*

32 The effects of the Alternative 3 as compared to the Second Basis of Comparison  
33 were analyzed based on the direction and magnitude of OMR flows during the  
34 period (December through June) when adult, larvae, and young juvenile Longfin  
35 Smelt are present in the Delta in the vicinity of the export facilities  
36 (Appendix 5A). The analysis was augmented with calculated Longfin Smelt  
37 abundance index values (Appendix 9G) per Kimmerer et al. (2009), which is  
38 based on the assumptions that lower X2 values reflect higher flows and that  
39 transporting Longfin Smelt farther downstream leads to greater Longfin Smelt  
40 survival. The index value indicates the relative abundance of Longfin Smelt and  
41 not the calculated population.

42 As described in Appendix 5A, OMR flows would be negative in all months under  
43 both Alternative 3 and the Second Basis of Comparison. Flows under  
44 Alternative 3 generally would be less negative than under the Second Basis of

1 Comparison, except in June, July, and August, when OMR flows under  
2 Alternative 3 would be more negative by greater 25 percent in some months and  
3 year types. The increase in the magnitude of negative flows in June, July, and  
4 August under Alternative 3 could increase the likelihood of entrainment of  
5 Longfin Smelt at the export facilities.

6 Under Alternative 3, Longfin Smelt abundance index values range from 1,094  
7 under critical water year conditions to a high of 15,638 under wet water year  
8 conditions, with a long-term average value of 7,345 (see Appendix 9G). Under  
9 the Second Basis of Comparison, Longfin Smelt abundance index values range  
10 from 947 under critical water year conditions to a high of 15,822 under wet water  
11 year conditions, with a long-term average value of 7,257.

12 Results indicate that the Longfin Smelt abundance index values would be similar  
13 in wetter years and higher in drier water year types under Alternative 3 than they  
14 would be under the Second Basis of Comparison, with a long-term average index  
15 for Alternative 3 that is 1 similar to the long-term average index under the Second  
16 Basis of Comparison. The greatest increase in the Longfin Smelt abundance  
17 index occurs in critical years where it is 15.5 percent greater under Alternative 3  
18 than under the Second Basis of Comparison. For below normal, and dry water  
19 years, the Longfin Smelt abundance index values would be 9.7 and 13.8 percent  
20 higher, respectively, under Alternative 3 than under the Second Basis of  
21 Comparison. Based on the Longfin Smelt abundance indices, Alternative 3 likely  
22 would have a lower potential for adverse effects on Longfin Smelt, as compared  
23 to the Second Basis of Comparison. Given the current condition of the Longfin  
24 Smelt population, even these small differences between alternatives may be  
25 important.

#### 26 *Sacramento Splittail*

27 Under Alternative 3, flows entering the Yolo Bypass generally would similar to  
28 flows under the Second Basis of Comparison from December through March  
29 (Appendix 5A, Table C-26-5). Any differences likely would be insufficient to  
30 reduce potential Sacramento Splittail spawning habitat in the bypass. Given the  
31 relatively minor changes in flows into the Yolo Bypass, and the inherent  
32 uncertainty associated with the resolution of the CalSim II model (average  
33 monthly outputs), it is concluded that there would be no definitive difference in  
34 effects on Sacramento Splittail between Alternative 3 and the Second Basis of  
35 Comparison.

#### 36 *Reservoir Fishes*

37 The analysis of effects associated with changes in operation on reservoir fishes  
38 relied on evaluation of changes in available habitat (reservoir storage) and  
39 anticipated changes in black bass nesting success.

40 Alternative 3 as compared to the Second Basis of Comparison generally would  
41 result in similar (differences less than 5 percent) storage levels in CVP and SWP  
42 reservoirs during the March through June period (Appendix 5A).

1 In general, black bass nesting success also would be similar under Alternative 3  
2 and the Second Basis of Comparison. Nesting success of black bass would be  
3 high in March and April due to increasing water surface elevations. During May,  
4 the likelihood of high (>40 percent) nesting success would be similar in most of  
5 the reservoirs under Alternative 3 as compared to the Second Basis of  
6 Comparison. This pattern is reversed in June, with the likelihood of high nesting  
7 success being somewhat (5 to 7 percent) lower under Alternative 3  
8 (Appendix 9F). Most black bass spawning likely occurs prior to June, such that  
9 drawdowns during June would likely affect only a small proportion of the  
10 spawning population. Thus, it is concluded that effects on black bass nesting  
11 success would be similar under Alternative 3 and the Second Basis of  
12 Comparison.

### 13 *Other Species*

14 Several other fish species could be affected by changes in operations that  
15 influence temperature and flow. In general, lampreys, Striped Bass, American  
16 Shad, and Hardhead can tolerate higher temperatures than salmonids. Based on  
17 the similar water temperatures during their spawning and incubation period under  
18 Alternative 3, it is likely that thermal conditions for and effects on these other  
19 species in the Sacramento, Feather, and American rivers would be similar under  
20 Alternative 3 and the Second Basis of Comparison. Alternative 3 would result in  
21 a similar X2 position as compared to the Second Basis of Comparison during  
22 April, May, and June (Appendix 5A, Section C Table C-16-5). This similarity in  
23 the position of X2 would likely result in a similar survival index and habitat index  
24 as measured by salinity for Striped Bass and a similar abundance and habitat  
25 index for American Shad. Alternative 3 likely would have a similar potential for  
26 adverse effects on lampreys, American Shad, and Hardhead as the Second Basis  
27 of Comparison. However, the increased bag limits and ability of anglers to retain  
28 Striped Bass that are 12 inches in length versus 18 inches under Alternative 3  
29 could reduce the ability to meet the doubling goals for Striped Bass populations  
30 under the requirements of Section 3406(b)(1) of CVPIA. Overall, Alternative 3  
31 likely would have slightly greater potential for adverse effects on Striped Bass as  
32 compared to the Second Basis of Comparison, primarily due to the potential for  
33 adverse effects of changing the bag and size limits for Striped Bass under the  
34 predator control program.

### 35 *Stanislaus River/Lower San Joaquin River*

#### 36 *Fall-Run Chinook Salmon*

37 Changes in operations influence temperature and flow conditions that could affect  
38 fall-run Chinook Salmon in the Stanislaus River downstream of Goodwin Dam  
39 and in the San Joaquin River below Vernalis. The following describes those  
40 changes and their potential effects.

#### 41 *Changes in Water Temperature (Stanislaus River)*

42 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
43 under Alternative 3 generally would be similar to the Second Basis of Comparison  
44 but could be lower (up to 1.5°F) than under the Second Basis of Comparison in

1 September, October, and November of drier years (Appendix 6B, Table B-17-5).  
2 Downstream at Orange Blossom Bridge, average monthly water temperatures  
3 under Alternative 3 and the Second Basis of Comparison would generally be  
4 similar except from August through November of drier years when water  
5 temperatures could be up to up to 1.6°F cooler under Alternative 3 and in June  
6 when the average monthly water temperature could be 2.8°F warmer and up to  
7 4.3°F warmer in wet years under Alternative 3 as compared to the Second Basis  
8 of Comparison (Appendix 6B, Table B-18-5). This temperature pattern would  
9 continue downstream to the confluence with the San Joaquin River, although the  
10 magnitude of temperature differences under Alternative 3 (Appendix 6B,  
11 Table B-19-5) would be larger in June and water temperatures could be up to  
12 1.6°F cooler in April under Alternative 3 as compared to the Second Basis of  
13 Comparison. Lower fall water temperatures in drier years would reduce the  
14 likelihood of adverse effects on spawning fall-run Chinook Salmon.

15 *Changes in Exceedance of Water Temperature Thresholds*  
16 *(Stanislaus River)*

17 While specific water temperature thresholds for fall-run Chinook Salmon in the  
18 Stanislaus River are not established, temperatures generally suitable for fall-run  
19 Chinook Salmon spawning (56°F) would be exceeded in October (over 30 percent  
20 of the time) and November over 20 percent of the time in the Stanislaus River at  
21 Goodwin Dam under Alternative 3 (Appendix 6B, Table B-17-1). Similar  
22 exceedances would occur under the Second Basis of Comparison. Water  
23 temperatures for rearing generally would be below 56°F, except in May.

24 Downstream at Orange Blossom Bridge, water temperatures suitable for fall-run  
25 Chinook Salmon spawning would be exceeded frequently under both  
26 Alternative 3 and the Second Basis of Comparison during October and November,  
27 but the 56°F threshold would be exceeded 2 percent more frequently in October  
28 and 4 percent less frequently in November percent.

29 During January through May, rearing fall-run Chinook Salmon under  
30 Alternative 3 and the Second Basis of Comparison would be subjected to average  
31 monthly water temperatures that exceed 56°F, with water temperatures under  
32 Alternative 3 exceeding the threshold in April about 4 percent less frequently and  
33 about 7 percent more frequently in May than under the Second Basis of  
34 Comparison (Appendix 6B, Figure B-18-5).

35 *Changes in Egg Mortality (Stanislaus River)*

36 For fall-run Chinook Salmon in the Stanislaus River, egg mortality rates would be  
37 similar under both scenarios (Appendix 9C, Table B-8).

38 *Changes in Delta Hydrodynamics*

39 San Joaquin River-origin fall-run Chinook Salmon smolts are most abundant in  
40 the Delta during the months of April, May and June. Near the confluence of the  
41 San Joaquin River and the Mokelumne River, the median proportion of positive  
42 velocities would be similar to or slightly lower under Alternative 3 relative to the  
43 Second Basis of Comparison in the months when fall-run would be most abundant

1 (Appendix 9K). On Old River downstream of the facilities, the median  
 2 proportion of positive velocities would be slightly higher in April and May, and  
 3 similar in June under Alternative 3 relative to the Second Basis of Comparison.  
 4 In Old River upstream of the facilities, the median proportion of positive  
 5 velocities would be moderately higher under Alternative 3 in April and May, and  
 6 slightly lower in June. On the San Joaquin River downstream of the Head of Old  
 7 River, the median proportion of positive velocities would be slightly to  
 8 moderately lower under Alternative 3 relative to the Second Basis of Comparison  
 9 in April and May, respectively, and slightly lower in June.

#### 10 *Changes in Junction Entrainment*

11 Entrainment at the Georgiana Slough Junction under Alternative 3 would be  
 12 almost indistinguishable from the Second Basis of Comparison in April, May, and  
 13 June (Appendix 9L). At the Head of Old River junction in April and May,  
 14 entrainment would be much greater under Alternative 3 relative to the Second  
 15 Basis of Comparison (Appendix 9L). In June, entrainment would be similar  
 16 under each scenario. Patterns of entrainment would be similar at Turner Cut,  
 17 Columbia Cut, Middle River, and Old River. At these junctions, median  
 18 entrainment under Alternative 3 would be slightly to moderately lower in April  
 19 and May, and almost indistinguishable in June.

#### 20 *Summary of Effects on Fall-Run Chinook Salmon*

21 The analysis of temperatures indicates somewhat similar temperatures and a  
 22 similar likelihood of exceedance of suitable temperatures for spawning and  
 23 rearing of fall-run Chinook Salmon under Alternative 3 as compared to the  
 24 Second Basis of Comparison in the Stanislaus River below Goodwin Dam and in  
 25 the San Joaquin River at Vernalis. The effect of lower temperatures is reflected in  
 26 the similar overall mortality of fall-run Chinook Salmon eggs predicted by  
 27 Reclamation's salmon mortality model for fall-run in the Stanislaus River.

28 Overall, Alternative 3 likely would have similar effects on the fall-run Chinook  
 29 Salmon population in the San Joaquin River watershed as compared to the Second  
 30 Basis of Comparison. Alternative 3 could also provide beneficial effects to  
 31 juvenile fall-run Chinook Salmon as a result of trap and haul passage through the  
 32 Delta and ocean harvest restrictions. It remains uncertain, however, if predator  
 33 management actions under Alternative 3 would benefit fall-run Chinook Salmon.

#### 34 *Steelhead*

35 Changes in operations that influence temperature and flow conditions in the  
 36 Stanislaus River downstream of Goodwin Dam and the San Joaquin River below  
 37 Vernalis could affect steelhead. The following describes those changes and their  
 38 potential effects.

#### 39 *Changes in Water Temperature (Stanislaus River)*

40 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
 41 under Alternative 3 generally would be similar to the Second Basis of Comparison  
 42 but could be lower (up to 1.5°F) than under the Second Basis of Comparison in  
 43 September, October, and November of drier years. Downstream at Orange

1 Blossom Bridge, average monthly water temperatures under Alternative 3 and the  
2 Second Basis of Comparison would generally be similar except from August  
3 through November of drier years when water temperatures could be up to up to  
4 1.6°F cooler under Alternative 3 and in June when the average monthly water  
5 temperature could be 2.8°F warmer and up to 4.3°F warmer in drier years under  
6 Alternative 3 as compared to the Second Basis of Comparison. This temperature  
7 pattern would continue downstream to the confluence with the San Joaquin River,  
8 although the magnitude of temperature differences under Alternative 3 would be  
9 larger in June and water temperatures could be up to 1.6°F cooler in April under  
10 Alternative 3 as compared to the Second Basis of Comparison.

11 *Changes in Exceedance of Water Temperature Thresholds*  
12 *(Stanislaus River)*

13 Average monthly water temperatures in the Stanislaus River at Orange Blossom  
14 Bridge would frequently exceed the temperature threshold (56°F) established for  
15 adult steelhead migration under both Alternative 3 and the Second Basis of  
16 Comparison during October and November, with the threshold being exceeded  
17 2 percent more frequently in October and 4 percent less frequently in  
18 November percent. In January through May, the temperature threshold at Orange  
19 Blossom Bridge is 55°F, which is intended to support steelhead spawning. Under  
20 Alternative 3, this threshold would be exceeded under Alternative 3 about  
21 8 percent and 10 percent more frequently in March and May, respectively, than  
22 under the Second Basis of Comparison. However, the threshold would be  
23 exceeded 16 percent less frequently under Alternative 3 in April.

24 During June through November, the temperature threshold of 65°F established to  
25 support steelhead rearing would be exceeded under both Alternative 3 and the  
26 Second Basis of Comparison in all months but November, with the highest  
27 frequency of exceedance in July (19 percent under Alternative 3). The  
28 differences between Alternative 3 and the Second Basis of Comparison, however,  
29 would be variable depending on the month, with water temperatures under  
30 Alternative 3 exceeding the threshold 2 percent to 4 percent more frequently than  
31 under the Second Basis of Comparison in June and July and up to 4 percent less  
32 frequently from August to October.

33 Average monthly water temperatures also would exceed the threshold (52°F)  
34 established for smoltification at Knights Ferry from January through May under  
35 both Alternative 3 and the Second Basis of Comparison. Differences in the  
36 likelihood of threshold exceedance between scenarios would be small (up to  
37 3 percent) with the threshold being more likely to be exceeded in March and less  
38 likely to be exceeded in April and May. Farther downstream at Orange Blossom  
39 Bridge, the temperature threshold for smoltification is higher (57°F). Under  
40 Alternative 3, water temperatures would exceed the 57°F threshold about  
41 4 percent less frequently in April and about 7 percent more frequently than under  
42 the Second Basis of Comparison in May.

1                    *Changes in Delta Hydrodynamics*

2 San Joaquin River-origin steelhead generally move through the Delta during  
3 spring; however, there is less information on their timing than there is for  
4 Chinook salmon. Thus, hydrodynamics in the entire January through June period  
5 could have the potential to affect juvenile steelhead. For a description of potential  
6 hydrodynamic effects on steelhead, see the descriptions for winter-run Chinook  
7 Salmon in the Sacramento Basin and fall-run Chinook Salmon in the San Joaquin  
8 River basin, above.

9                    *Summary of Effects on Steelhead*

10 Given the frequency of exceedance under both Alternative 3 and the Second Basis  
11 of Comparison, water temperature conditions for steelhead in the Stanislaus River  
12 would likely be similar. The differences in temperature exceedance would be  
13 variable (both positive and negative) between Alternative 3 and the Second Basis  
14 of Comparison, with no clear benefit associated with either alternative.  
15 Discerning a meaningful difference between these two scenarios based on the  
16 quantitative results is not possible because of the similarity in results (generally  
17 differences less than 5 percent) and the inherent uncertainty of the models. Thus,  
18 it is concluded that the effects on steelhead would be similar under Alternative 3  
19 and the Second Basis of Comparison.

20                    *White Sturgeon*

21 Evidence of White Sturgeon spawning has been recorded in the San Joaquin River  
22 upstream of the confluence with the Stanislaus River. While flows in the San  
23 Joaquin River upstream of the Stanislaus River are expected to be similar under all  
24 alternatives, flow contributions from the Stanislaus River could influence water  
25 temperatures in the San Joaquin River where White Sturgeon eggs or larvae may  
26 occur during the spring and early summer. The magnitude of influence on water  
27 temperature would depend on the proportional flow contribution of the Stanislaus  
28 River and the temperatures in both the Stanislaus and San Joaquin rivers. The  
29 potential for an effect on White Sturgeon eggs and larvae would be influenced by  
30 the proportion of the population occurring in the San Joaquin River. In  
31 consideration of this uncertainty, it is not possible to distinguish potential effects  
32 on White Sturgeon between alternatives.

33                    *Reservoir Fishes*

34                    *Changes in Available Habitat (Storage)*

35 As described in Chapter 5, Surface Water Resources and Water Supplies, storage  
36 levels in New Melones Reservoir would be higher under Alternative 3 as  
37 compared to the Second Basis of Comparison, as summarized in Table 5.38, due  
38 to higher allocations of water supplies to CVP water service contractors, less  
39 fisheries flows, no water quality releases under SWRCB D-1641, and no  
40 Bay-Delta flow releases under SWRCB D-1641.

41 Storage in New Melones could be increased up to around 20 percent in some  
42 months of some water year types. Additional information related to monthly  
43 reservoir elevations is provided in Appendix 5A, CalSim II and DSM2 Modeling.  
44 It is anticipated that aquatic habitat within New Melones is not limiting; however,

1 storage volume is an indicator of how much habitat is available to fish species  
2 inhabiting these reservoirs. Therefore, the amount of habitat for reservoir fishes  
3 could be increased under Alternative 3 as compared to the Second Basis of  
4 Comparison.

5 *Changes in Black Bass Nesting Success*

6 Results of the bass nesting success analysis are presented in Appendix 9F,  
7 Reservoir Fish Analysis Documentation. For March, the likelihood of  
8 Largemouth Bass and Smallmouth Bass nest survival in New Melones being  
9 above 40 percent is similar under Alternative 3 and the Second Basis of  
10 Comparison. For April, the likelihood that nest survival of Largemouth Bass and  
11 Smallmouth Bass is between 40 and 100 percent is reasonably high (around  
12 80 percent) but is about 5 percent lower under Alternative 3 as compared to the  
13 Second Basis of Comparison. For May, the pattern is reversed with the likelihood  
14 of high nest survival being about 7 percent greater under Alternative 3. For June,  
15 the likelihood of survival being greater than 40 percent for Largemouth Bass and  
16 Smallmouth Bass in New Melones is about 38 percent greater under Alternative 3  
17 as compared to the Second Basis of Comparison. For Spotted Bass, nest survival  
18 from March through June is anticipated to be near 100 percent in every year under  
19 both Alternative 3 and the Second Basis of Comparison. Most black bass  
20 spawning likely occurs prior to June, such that drawdowns during June would  
21 likely affect only a small proportion of the spawning population. Thus, it is  
22 concluded that effects on black bass nesting success would be similar under  
23 Alternative 3 and the Second Basis of Comparison.

24 The analysis of black bass nest survival based on changes in water surface  
25 elevation during the spawning period indicated that the likelihood of high  
26 (>40 percent) nest survival in New Melones under Alternative 3 would be similar  
27 to or higher than under the Second Basis of Comparison. This suggests that  
28 conditions in New Melones could be more likely to support self-sustaining  
29 populations of black bass under Alternative 3 than under the Second Basis of  
30 Comparison.

31 *Other Species*

32 Changes in operations that influence temperature and flow conditions in the  
33 Stanislaus River downstream of Goodwin Dam and the San Joaquin River at  
34 Vernalis could affect other species such as lampreys, Hardhead, and Striped Bass.  
35 As described above, water temperatures would generally be similar under  
36 Alternative 3 and the Second Basis of Comparison. In general, lampreys, Striped  
37 Bass and Hardhead can tolerate higher temperatures than salmonids. Given the  
38 similar flows and temperatures during their spawning and incubation period, it is  
39 likely that the potential to affect these species in the Stanislaus and San Joaquin  
40 rivers would be similar under Alternative 3 and the Second Basis of Comparison.  
41 However, the increased bag limits and ability of anglers to retain Striped Bass that  
42 are 12 inches in length versus 18 inches under Alternative 3 could reduce the  
43 ability to meet the doubling goals for Striped Bass populations under the  
44 requirements of Section 3406(b)(1) of CVPIA.

1 *San Francisco Bay Area Region*2 *Killer Whale*

3 As described above for the comparison of Alternative 1 to the No Action  
4 Alternative, it is unlikely that the Chinook Salmon prey base of killer whales,  
5 supported heavily by hatchery production of fall-run Chinook Salmon, would be  
6 appreciably affected by any of the alternatives.

7 **9.4.3.5 Alternative 4**

8 The CVP and SWP operations under Alternative 4 are identical to the CVP and  
9 SWP operations under the Second Basis of Comparison and Alternative 1, as  
10 described in Chapter 3, Description of Alternatives. Alternative 4 also includes  
11 the following items that are not included in the No Action Alternative or the  
12 Second Basis of Comparison and would affect fish and aquatic resources.

- 13 • Implement predator control programs for black bass, Striped Bass, and  
14 Pikeminnow to protect salmonids and Delta Smelt as follows:
  - 15 – Black bass catch limit changed to allow catch of 12-inch fish with a bag  
16 limit of 10
  - 17 – Striped Bass catch limit changed to allow catch of 12-inch fish with a bag  
18 limit of 5
  - 19 – Establish a Pikeminnow sport-fishing reward program with a 8-inch limit  
20 at \$2/fish
- 21 • Establish a trap and haul program for juvenile salmonids entering the Delta  
22 from the San Joaquin River in March through June as follows:
  - 23 – Begin operation of downstream migrant fish traps upstream of the Head of  
24 Old River on the San Joaquin River
  - 25 – “Barge” all captured juvenile salmonids through the Delta, release at  
26 Chipps Island.
  - 27 – Tag subset of fish in order to quantify effectiveness of the program
  - 28 – Attempt to capture 10 percent to 20 percent of outmigrating juvenile  
29 salmonids
- 30 • Work with Pacific Fisheries Management Council, CDFW, and NMFS to  
31 impose salmon harvest restrictions to reduce by-catch of winter-run and  
32 spring-run Chinook Salmon to less than 10 percent of age-3 cohort in all years

33 As described in Chapter 4, Approach to Environmental Analysis, Alternative 4 is  
34 compared to the No Action Alternative and the Second Basis of Comparison.

35 **9.4.3.5.1 Alternative 4 Compared to the No Action Alternative**36 *Trinity River Region*

37 The CVP and SWP operations under Alternative 4 are identical to the CVP and  
38 SWP operations under the Second Basis of Comparison and Alternative 1.  
39 Therefore, changes in aquatic resources at Trinity Lake and along the Trinity

1 River and lower Klamath River under Alternative 4 as compared to the No Action  
2 Alternative would be the same as the impacts described in Section 10.4.4.2.1,  
3 Alternative 1 Compared to the No Action Alternative.

4 *Central Valley Region and Stanislaus River*

5 The CVP and SWP operations under Alternative 4 are identical to the CVP and  
6 SWP operations under the Second Basis of Comparison and Alternative 1.  
7 Therefore, changes in aquatic habitat conditions at CVP and SWP reservoirs, in  
8 the rivers downstream of the reservoirs, and in the Delta under Alternative 4 as  
9 compared to the No Action Alternative would be the same as the impacts  
10 described in Section 9.4.3.2.1, Alternative 1 Compared to the No Action  
11 Alternative.

12 Conditions related to salmonid survival could be improved under Alternative 4 as  
13 compared to the No Action Alternative due to implementation of changes in  
14 Striped Bass bag limits for predator control and changes in PMFC/NMFS harvest  
15 limits. However, these benefits would not likely exceed those described for the  
16 No Action Alternative, particularly in consideration of the provision of fish  
17 passage upstream of Shasta and Folsom dams to address long-term temperature  
18 challenges on listed salmonids caused by climate change.

19 Conditions for Striped Bass under Alternative 4 could be influenced by  
20 implementation of a predator control program that reduces the size restrictions  
21 and increases the catch limit for Striped Bass taken in the sport fishery. This also  
22 could reduce the ability to meet the doubling goals for Striped Bass populations  
23 under the requirements of Section 3406(b)(1) of CVPIA.

24 *San Francisco Bay Area Region*

25 *Killer Whale*

26 As described above the comparison of Alternative 1 to the No Action Alternative,  
27 it is unlikely that the Chinook Salmon prey base of killer whales, supported  
28 heavily by hatchery production of fall-run Chinook Salmon, would be appreciably  
29 affected by any of the alternatives.

30 **9.4.3.5.2 Alternative 4 Compared to the Second Basis of Comparison**

31 *Trinity River Region*

32 The CVP and SWP operations under Alternative 4 are identical to the CVP and  
33 SWP operations under the Second Basis of Comparison and Alternative 1.  
34 Therefore, aquatic resources conditions at Trinity Lake and along the Trinity  
35 River and lower Klamath River under Alternative 4 be the same as under the  
36 Second Basis of Comparison.

37 *Central Valley Region and Stanislaus River*

38 The CVP and SWP operations under Alternative 4 are identical to the CVP and  
39 SWP operations under the Second Basis of Comparison and Alternative 1.  
40 Therefore, changes in aquatic habitat conditions at CVP and SWP reservoirs, in  
41 the rivers downstream of the reservoirs, and in the Delta due to operations under

1 Alternative 4 would be the same as described for the Second Basis of  
2 Comparison.

3 Conditions related to salmonid survival could be improved under Alternative 4 as  
4 compared to the Second Basis of Comparison due to implementation of the Trap  
5 and Haul Program, changes in bag limits, and changes in PMFC/NMFS harvest  
6 limits. Conditions related to year class strength of juvenile sturgeon would be the  
7 same under the Alternative 4 relative to the Second Basis of Comparison due to  
8 similar reductions in mean (March to July) Delta outflow. Conditions for Striped  
9 Bass under Alternative 4 would be the same as those described above for the  
10 comparison to the No Action Alternative.

11 However, it should be noted that the changes in ocean harvest limits under  
12 Alternative 4 could be inconsistent with NMFS' fisheries management framework  
13 for reducing the impact of ocean salmon fishery on winter-run Chinook Salmon  
14 for the Pacific Coast Salmon Fishery Management Plan (National Marine  
15 Fisheries Service 2012). The framework consists of two components. The first  
16 component specifies that the previous standards for winter-run Chinook Salmon  
17 regarding minimum size limits and seasonal windows south of Point Arena for  
18 both the commercial and recreational fisheries will continue to remain in effect at  
19 all times regardless of abundance estimates or impact rate limit. The second  
20 component is based on the population status of winter-run Chinook Salmon  
21 where, during periods of relatively low abundance, the proposed structure of  
22 fishing management measures each year for winter-run Chinook Salmon south of  
23 Point Arena must be equal to or less than the maximum allowable impact rate  
24 (MAIR) specified annually. The fishery control rule and tiered approach for  
25 managing impacts to winter-run Chinook Salmon in the ocean salmon fishery  
26 include: (1) if the geometric mean of the most recent 3 years of spawning return  
27 estimates is less than 500, the MAIR is zero percent; and (2) if the geometric  
28 mean of the most recent 3 years of spawning return estimates is between 500 and  
29 4,000, the MAIR is between 10 percent and 20 percent, increasing linearly.

30 If Alternative 4 were selected, Reclamation would be required to re-consult with  
31 NMFS regarding all aspects of the alternative that could result in the take of listed  
32 salmonids before implementation, including the provisions of the proposed  
33 changes in harvest limits.

#### 34 *Killer Whale*

35 As described above for the comparison of Alternative 1 to the No Action  
36 Alternative, it is unlikely that the Chinook Salmon prey base of killer whales,  
37 supported heavily by hatchery production of fall-run Chinook Salmon, would be  
38 appreciably affected by any of the alternatives.

#### 39 **9.4.3.6 Alternative 5**

40 As described in Chapter 3, Description of Alternatives, CVP and SWP operations  
41 under Alternative 5 are similar to the No Action Alternative with modified OMR  
42 flow criteria and New Melones Reservoir operations. As described in Chapter 4,  
43 Approach to Environmental Analysis, Alternative 5 is compared to the No Action  
44 Alternative and the Second Basis of Comparison.

1 Alternative 5 also includes the Delta Cross Channel Temporary Closure Multi-  
2 year Study. As noted in the Finding of No Significant Impact (FONSI) document  
3 from Reclamation (Reclamation, 2012), this study proposes closing the DCC for  
4 up to 10 days during the first half of October from 2012 through 2016. The  
5 FONSI also notes that the DCC closure would not cause any adverse effects to the  
6 native aquatic and fisheries. Therefore, the effects of this study are not  
7 considered any further in the impact analyses for Alternative 5 below.

#### 8 **9.4.3.6.1 Alternative 5 Compared to the No Action Alternative**

9 Because of the considerable similarities between Alternative 5 and the No Action  
10 Alternative, the analysis below combines species within some regions where to  
11 reduce repetition.

##### 12 *Trinity River Region*

13 *Coho Salmon, Spring-run Chinook Salmon, Fall-run Chinook Salmon,*  
14 *Steelhead, and Green Sturgeon*

15 Average monthly water temperature in the Trinity River at Lewiston Dam under  
16 Alternative 5 would be similar to water temperatures under the No Action  
17 Alternative (less than 0.5°F differences) in all months (Appendix 6B,  
18 Table B-1-3). Similarly, the differences in the frequency with which  
19 Alternative 5 and the No Action Alternative would exceed established  
20 temperature thresholds also would be small (up to 1 or 2 percent) (Appendix 9N).  
21 These temperature results are reflected in the egg mortality results for fall-run  
22 Chinook Salmon in the Trinity River, which indicate similar mortality under  
23 Alternative 5 and the No Action Alternative (Appendix 9C, Table B-5).

24 The minor differences in temperature and mortality results suggest that conditions  
25 for Coho Salmon, spring-run Chinook Salmon, fall-run Chinook Salmon,  
26 steelhead and Green Sturgeon in the Trinity River generally would be similar  
27 under Alternative 5 and the No Action Alternative. Given the similarity of the  
28 results and the inherent uncertainty associated with the resolution of the  
29 temperature model (average monthly outputs), it is concluded that Alternative 5  
30 and the No Action Alternative are likely to have similar effects on salmonids and  
31 sturgeon in the Trinity River.

##### 32 *Reservoir Fishes*

33 Reservoir fishes in Trinity Lake would be exposed to relatively minor differences  
34 in storage (less than 5 percent) under Alternative 5 (Appendix 5A) as compared to  
35 the No Action Alternative and these relatively small differences likely would have  
36 little effect on the amount of habitat available for these species. Black bass  
37 nesting survival would be similar under Alternative 5 and the No Action  
38 Alternative (Appendix 9F). The minor differences in storage and similar nesting  
39 success suggest that effects on reservoir fishes in Trinity Lake would be similar  
40 under Alternative 5 and the No Action Alternative.

1        *Other Species*

2        The minor differences in average monthly water temperatures described above for  
3        salmonids apply to Pacific Lamprey and Eulachon. These minor differences  
4        suggest that conditions for aquatic species in the Trinity River and Klamath River  
5        downstream of the confluence generally would be similar under Alternative 5 and  
6        the No Action Alternative. Given the similarity of the results and the inherent  
7        uncertainty associated with the resolution of the temperature model (average  
8        monthly outputs), it is concluded that Alternative 5 and the No Action  
9        Alternative are likely to have similar effects on the lamprey and Eulachon in the  
10       Trinity River.

11       *Sacramento River System*

12         *Winter-run Chinook Salmon*

13       Changes in operations that influence temperature and flow conditions in the  
14       Sacramento River downstream of Keswick Dam could affect winter-run Chinook  
15       Salmon. The following describes those changes and their potential effects.

16             *Changes in Water Temperature*

17       Monthly water temperature in the Sacramento River at Keswick Dam under  
18       Alternative 5 and the No Action Alternative would be similar (differences of less  
19       than 0.5°F) (Appendix 6B, Table B-5-3). Differences in the frequency of  
20       exceeding temperature thresholds under Alternative 5 and the No Action  
21       Alternative also would be small (less than 3 percent) (Appendix 9N). The  
22       differences in water temperatures and temperature threshold exceedances  
23       predicted at locations in the downstream reaches are similar to those predicted at  
24       Keswick Dam. Egg mortality is anticipated to be similar under Alternative 5 and  
25       the No Action Alternative (Appendix 9C, Table B-4).

26             *Changes in Weighted Usable Area*

27       The WUA results for winter-run Chinook Salmon spawning habitat between  
28       Keswick Dam and Battle Creek indicated that available spawning habitat under  
29       Alternative 5 and the No Action Alternative would be similar (less than 5 percent  
30       difference) (Appendix 9E, Table C-17-3). The results were similar for fry and  
31       juvenile rearing (Appendix 9E, Table C-18-3 and Table C-19-3).

32             *Changes in SALMOD Output*

33       SALMOD results indicated that potential juvenile production under Alternative 5  
34       would be the similar to the No Action Alternative in all water year types  
35       (Appendix 9D, Table B-4-11).

36             *Changes in Delta Passage Model Output*

37       The Delta Passage Model predicted similar estimates of annual Delta survival  
38       across the 81-year time period for winter-run Chinook Salmon between  
39       Alternative 5 and the No Action Alternative (Appendix 9J). Median Delta  
40       survival was 0.35 for Alternative 5 and 0.349 for the No Action Alternative.

1            *Changes in Delta Hydrodynamics*

2 Winter-run Chinook Salmon smolts are most abundant in the Delta during  
3 January, February and March. On the Sacramento River near the confluence of  
4 Georgiana Slough, the median proportion of positive velocities under  
5 Alternative 5 were indistinguishable from the No Action Alternative in January,  
6 February and March (Appendix 9K). On the San Joaquin River near the  
7 Mokelumne River confluence, the median proportion of positive velocities also  
8 was indistinguishable between these two scenarios. In Old River, both upstream  
9 and downstream of the facilities, the median proportion of positive velocities was  
10 indistinguishable in the months when winter run Chinook Salmon are present. On  
11 the San Joaquin River downstream of the Head of Old River, there was no  
12 discernable difference in the median proportion of positive velocities between  
13 these two scenarios.

14            *Changes in Junction Entrainment*

15 For all junctions examined, the median entrainment probabilities under both  
16 Alternative 5 and the No Action Alternative were almost indistinguishable  
17 (Appendix 9L).

18            *Changes in Salvage*

19 There were no discernable differences in predicted salvage between Alternative 5  
20 and No Action Alternative (Appendix 9M).

21            *Changes in Oncorhynchus Bayesian Analysis Output*

22 Escapement and Delta survival was modeled by the OBAN model for winter-run  
23 Chinook salmon. Escapement was similar under Alternative 5 as compared to the  
24 No Action Alternative (Appendix 9I) as was through-Delta survival.

25            *Changes in Interactive Object-Oriented Simulation Output*

26 The IOS model predicted similar adult escapement trajectories for winter-run  
27 Chinook Salmon between Alternative 5 and the No Action Alternative across the  
28 81 water years (Appendix 9H). Alternative 5 median adult escapement was  
29 3,545 and No Action Alternative median escapement was 3,935.

30 Similar to adult escapement, the IOS model predicted similar egg survival for  
31 winter-run Chinook Salmon between Alternative 5 and the No Action  
32 Alternative across the 81 water years (Appendix 9H). Median egg survival was  
33 0.989 for Alternative 5 and 0.990 for the No Action Alternative.

34            *Summary of Effects on Winter-Run Chinook Salmon*

35 The analysis of temperatures suggested that the frequency of temperature  
36 threshold exceedance under Alternative 5 would be similar to the No Action  
37 Alternative. This was reflected in Reclamation's salmon mortality model results,  
38 which predicted egg mortality would be similar under Alternative 5 and the No  
39 Action Alternative. The analysis of flow changes under Alternative 5 suggested  
40 that availability of spawning habitat for winter-run Chinook Salmon would  
41 similar under Alternative 5 and the No Action Alternative; SALMOD also  
42 indicated that there would be similar juvenile production under these two  
43 alternatives. Through Delta survival of juvenile winter-run Chinook Salmon

1 would be the same under both Alternative 5 and the No Action Alternative as  
 2 indicated by the DPM and the OBAN results. Median adult escapement to the  
 3 Sacramento River would be similar under Alternative 5 and the No Action  
 4 Alternative as indicated by the IOS and OBAN model results. Additional  
 5 analyses attempting to assess the effects on routing, entrainment and salvage of  
 6 juvenile salmonids in the Delta all indicate the effects would be similar between  
 7 Alternative 5 and the No Action Alternative.

8 Given the similarity of the results and the inherent uncertainty associated with the  
 9 resolution of the models, it is concluded that Alternative 5 and the No Action  
 10 Alternative are likely to have similar effects on the winter-run Chinook Salmon in  
 11 the Sacramento River and Delta.

12 *Spring-run Chinook Salmon, Fall-run Chinook Salmon, Late Fall-run*  
 13 *Chinook Salmon, Steelhead, Green Sturgeon and White Sturgeon*  
 14 *Changes in Water Temperature*

15 Average monthly water temperatures in the Sacramento River under Alternative 5  
 16 and the No Action Alternative would be similar (differences of less than 0.5°F)  
 17 (Appendix 6B, Table B-5-3). Differences in the frequency of exceeding  
 18 temperature thresholds under Alternative 5 and the No Action Alternative would  
 19 be relatively small (differences less than 2 percent) for the spring-run, fall-run,  
 20 and late fall-run Chinook Salmon, steelhead, and sturgeon in the Sacramento  
 21 River (Appendix 9N).

22 In Clear Creek, average monthly water temperatures at Igo under Alternative 5  
 23 relative to the No Action Alternative would be similar (differences less than  
 24 0.5°F) (Appendix 6B, Table B-3-3). The frequency of exceeding temperature  
 25 thresholds for spring-run Chinook Salmon rearing also would be small  
 26 (differences of up to 1 percent) (Appendix 9N).

27 In the Feather River, average monthly water temperatures in the low flow channel  
 28 under Alternative 5 relative to the No Action Alternative would be similar  
 29 (differences less than 0.5°F) (Appendix 6B, Table B-20-3). Water temperatures at  
 30 the downstream location also would be similar. Changes in the frequency of  
 31 exceeding temperature thresholds would be relatively small (differences of  
 32 2 percent or less) between the two scenarios for the fall-run Chinook Salmon,  
 33 spring-run Chinook Salmon, steelhead, and Green Sturgeon.

34 In the American River at Watt Avenue, average monthly water temperatures  
 35 under Alternative 5 and the No Action Alternative would be similar (differences  
 36 less than 0.5°F) (Appendix 6B, Table B-13-3). Changes in the frequency of  
 37 exceeding temperature thresholds would be small (differences of 1 percent or  
 38 less) between the two scenarios for fall-run Chinook Salmon and steelhead.

39 Egg mortality for all races Chinook Salmon within the Sacramento River system  
 40 was predicted to be similar under Alternative 5 and the No Action  
 41 Alternative (Appendix 9C, Tables B-1, B-6 and B-7).

1            *Changes in SALMOD Output*

2 SALMOD results indicated that potential spring-run Chinook Salmon juvenile  
3 production under Alternative 5 would be the similar to the No Action  
4 Alternative in all water year types (Appendix 9D, Table B-3-11).

5            *Changes in Delta Passage Model Output*

6 The Delta Passage Model predicted similar estimates of annual Delta survival  
7 across the 81-year time period for spring-run, fall-run and late fall-run Chinook  
8 Salmon between Alternative 5 and the No Action Alternative (Appendix 9J).

9            *Changes in Delta Hydrodynamics*

10 As described in Appendix 9K, the median proportion of time that velocity was  
11 positive at various junctions in the Delta were projected to be similar under  
12 Alternative 5 compared to the No Action Alternative.

13           *Changes in Junction Entrainment*

14 As described in Appendix 9L, median entrainment at various junctions is  
15 indistinguishable or lower under Alternative 5 compared to the No Action  
16 Alternative for fall-run, late fall-run, and spring-run Chinook Salmon.

17           *Changes in Salvage*

18 As described in Appendix 9M, salvage of migrating spring-run, late-fall run and  
19 fall-run smolts is similar or lower under Alternative 5 compared to the No Action  
20 Alternative.

21           *Changes in Delta Outflow*

22 As described in Appendix 9P, mean (March to July) Delta outflow was used an  
23 indicator of potential year class strength and the likelihood of producing a strong  
24 year class of sturgeon. The median value over the 82-year CalSim II modeling  
25 period of mean (March to July) Delta outflow was predicted to be similar under  
26 the Alternative 5 and the No Action Alternative. In addition, the likelihood of  
27 mean (March to July) Delta outflow exceeding the threshold of 50,000 cfs was the  
28 same under both alternatives.

29           *Summary of Effects on Spring-run Chinook Salmon, Fall-run Chinook*  
30           *Salmon, Late Fall-run Chinook Salmon, Steelhead, Green Sturgeon and*  
31           *White Sturgeon*

32 The analysis of temperatures indicates similar temperatures and likelihood of  
33 exceedance of temperature thresholds under Alternative 5 as compared to the No  
34 Action Alternative in the Clear Creek, and the Sacramento, Feather, and  
35 American rivers. This was reflected in Reclamation's salmon mortality model  
36 results for the fall-run on the Sacramento, Feather and American rivers which  
37 predicted similar Chinook Salmon mortalities under Alternative 5 and the No  
38 Action Alternative. There would be no change in flows in Clear Creek and  
39 Feather River low flow channel. Flows are expected to be similar in Sacramento  
40 River and American River. Flows in May in the Feather River are reduced  
41 (Appendix 5A). However, most of the spawning habitat in the Feather River is in  
42 the low flow channel; therefore, this reduction in May flow would only have

1 minor effect on the availability of the habitat. SALMOD results indicate that the  
2 potential production for the fall-run, late fall-run and spring-run Chinook Salmon  
3 on the Sacramento River would be similar. Delta survival is expected to be  
4 similar as indicated by the Delta Passage Model and OBAN results, and the  
5 entrainment risk would be lower based on the expected changes in OMR flows  
6 under Alternative 5. Additional analyses attempting to assess the effects on  
7 routing, entrainment and salvage of juvenile salmonids in the Delta all indicate  
8 the effects would be similar under Alternative 5 and the No Action Alternative.  
9 The analysis based on Delta outflows suggests that Alternative 5 provides similar  
10 mean (March to July) outflows which would have similar effects on year class  
11 strength of juvenile sturgeon relative to the No Action Alternative.

12 Given the similarity of the results and the inherent uncertainty associated with the  
13 resolution of the models, it is concluded that Alternative 5 and the No Action  
14 Alternative are likely to have similar effects on salmonids and sturgeon in the  
15 Sacramento River and Delta.

#### 16 *Delta Smelt*

17 A proportional entrainment regression model (based on Kimmerer 2008, 2011)  
18 was used to simulate adult Delta Smelt entrainment, as influenced by OMR flow  
19 in December through March. Results indicate that the percentage of entrainment  
20 of migrating and spawning adult Delta Smelt under Alternative 5 will be nearly  
21 identical to the results estimated for the No Action Alternative in all water  
22 year types.

23 A proportional entrainment regression model (based on Kimmerer 2008) also was  
24 used to simulate larval and early juvenile Delta Smelt entrainment, as influenced  
25 by OMR flow and location of X2 in March through June. Results indicate that  
26 the percentage of entrainment of larval and early juvenile Delta Smelt under  
27 Alternative 5 would be similar to that estimated for the No Action Alternative.

28 The average September through December X2 position in km was used to  
29 evaluate the fall abiotic habitat availability for delta smelt under the Alternatives.  
30 X2 values simulated in the CalSim II model for each alternative were averaged  
31 over September through December, and compared. Results indicate that fall X2  
32 values under Alternative 5 would be nearly identical to the No Action Alternative.

33 Given the similarity of the results and the inherent uncertainty associated with the  
34 resolution of the models, it is concluded that Alternative 5 and the No Action  
35 Alternative are likely to have similar effects on Delta Smelt.

#### 36 *Longfin Smelt*

37 The effects of the Alternative 5 as compared to the No Action Alternative were  
38 analyzed based on the direction and magnitude of OMR flows during the period  
39 (December through June) when adult, larvae, and young juvenile Longfin Smelt  
40 are present in the Delta in the vicinity of the export facilities (Appendix 5A). The  
41 analysis was augmented with calculated Longfin Smelt abundance index values  
42 (Appendix 9G) per Kimmerer et al. (2009), which is based on the assumptions  
43 that lower X2 values reflect higher flows and that transporting Longfin Smelt

1 farther downstream leads to greater Longfin Smelt survival. The index value  
2 indicates the relative abundance of Longfin Smelt and not the calculated  
3 population.

4 OMR flows generally would be negative in all months under both scenarios,  
5 except in April and May when the long-term average would positive. Flows  
6 under Alternative 5 during these two months would be more positive than under  
7 the No Action Alternative, especially in dry and critical years when OMR flows  
8 under Alternative 5 would be positive and flows under the No Action  
9 Alternative would be negative. Differences in OMR flow during April and May  
10 under Alternative 5 would up to about 1,350 cfs more positive than under the No  
11 Action Alternative.

12 Longfin Smelt abundance index values were calculated for long-term average  
13 conditions and for each water year type for the different alternatives (see  
14 Appendix 9G). Under Alternative 5, Longfin Smelt abundance index values  
15 range from 1,204 under critical water year conditions to a high of 16,683 under  
16 wet water year conditions, with a long-term average value of 8,015  
17 (Appendix 9G). Under the No Action Alternative, Longfin Smelt abundance  
18 index values range from 1,147 under critical water year conditions to a high of  
19 16,635 under wet water year conditions, with a long-term average value of 7,951.

20 Results indicate that the Longfin Smelt abundance index values would be similar  
21 in all but critical years under Alternative 5 than they would be under the No  
22 Action Alternative. In critical water years, the Longfin Smelt abundance index  
23 value would be about 5 percent higher under Alternative 5 than it would be under  
24 the No Action Alternative.

25 Given the similarity of the results and the inherent uncertainty associated with the  
26 resolution of the models, it is concluded that Alternative 5 and the No Action  
27 Alternative are likely to have similar effects on Longfin Smelt.

28 *Sacramento Splittail*

29 Under Alternative 5, flows entering the Yolo Bypass over the Fremont Weir  
30 generally would be similar to the No Action Alternative (Appendix 5A,  
31 Table C-26-3), thus providing similar value to Sacramento Splittail because of the  
32 similar area of potential habitat (inundation) and the similar frequency of  
33 inundation. Given the relatively minor changes in flows into the Yolo Bypass,  
34 and the inherent uncertainty associated with the resolution of the CalSim II model  
35 (average monthly outputs), it is concluded that there would be no definitive  
36 difference in effects on Sacramento Splittail between Alternative 5 and the No  
37 Action Alternative.

38 *Reservoir Fishes*

39 The analysis of effects associated with changes in operation on reservoir fishes  
40 relied on evaluation of changes in available habitat (reservoir storage) and  
41 anticipated changes in black bass nesting success.

1 Changes in CVP and SWP water supplies and operations under Alternative 5 as  
2 compared to the No Action Alternative generally would result in similar reservoir  
3 storage in CVP and SWP reservoirs in the Central Valley Region (Appendix 5A).  
4 Storage levels in Shasta Lake, Lake Oroville, and Folsom Lake would be similar  
5 under Alternative 5 as compared to the No Action Alternative. Additional  
6 information related to monthly reservoir elevations is provided in Appendix 5A,  
7 CalSim II and DSM2 Modeling.

8 In general, black bass nesting success would be similar under Alternative 5 and  
9 the No Action Alternative (Appendix 9F). Nesting success of black bass would  
10 be high in March and April due to increasing water surface elevations. During  
11 May and June, the likelihood of high (>40 percent) nesting success would be  
12 similar in most of the reservoirs under Alternative 5 as compared to the No Action  
13 Alternative (Appendix 9F). Therefore, it is concluded that the effects on black  
14 bass species would be similar under both Alternative 5 and the No Action  
15 Alternative.

#### 16 *Other Species*

17 Several other fish species could be affected by changes in operations that  
18 influence temperature and flow. In general, lampreys, Striped Bass, American  
19 Shad, and Hardhead can tolerate higher temperatures than salmonids. Based on  
20 the generally similar water temperatures during their spawning and incubation  
21 period under Alternative 5, it is likely that thermal conditions for and effects on  
22 these other species in the Sacramento, Feather, and American rivers would be  
23 similar under Alternative 5 and the No Action Alternative. Alternative 5 would  
24 result in a similar X2 position as compared to the No Action Alternative during  
25 April, May, and June (Appendix 5A, Section C Table C-16-3). This similarity in  
26 the position of X2 would likely result in a similar survival index and habitat index  
27 as measured by salinity for Striped Bass and a similar abundance and habitat  
28 index for American Shad. Alternative 5 likely would have a similar potential for  
29 adverse effects on lampreys, American Shad, and Hardhead as the Second Basis  
30 of Comparison. Overall, the potential for effects on lamprey, Striped Bass,  
31 American Shad, and Hardhead would be similar under Alternative 5 and the No  
32 Action Alternative.

#### 33 *Stanislaus River/Lower San Joaquin River*

##### 34 *Fall-Run Chinook Salmon and Steelhead*

##### 35 *Changes in Water Temperature*

36 Monthly average temperatures in the Stanislaus River at Goodwin under  
37 Alternative 5 would be similar (less than 0.5°F differences) to the No Action  
38 Alternative in most of the months and water years. From August through  
39 November, water temperatures under Alternative 5 could be somewhat (0.6°F to  
40 1.6°F) warmer, particularly in drier water years. This pattern in temperature  
41 changes under Alternative 5 was also predicted downstream at Orange Blossom  
42 Bridge. However, the differences are smaller at the San Joaquin River confluence  
43 and water temperatures in April and May could be up to 2.1°F cooler under  
44 Alternative 5.

1 The frequency of exceedance of temperature thresholds for steelhead adult  
2 migration in the fall months, steelhead smoltification thresholds in April and May  
3 at Knights Ferry, and steelhead rearing in summer and fall months are higher  
4 under (by up to 8 percent) under Alternative 5 as compared to the No Action  
5 Alternative. Frequency of exceedance of thresholds for steelhead spawning and  
6 smoltification at Orange Blossom Bridge in March through May are lower by up  
7 to 11 percent under Alternative 5 compared to the No Action Alternative.

8 While specific water temperature thresholds for fall-run Chinook Salmon in the  
9 Stanislaus River are not established, temperatures generally suitable for fall-run  
10 Chinook Salmon spawning (56°F) would be exceeded in October and November  
11 up to 3 percent more frequently under Alternative 5 compared to the No Action  
12 Alternative, in the Stanislaus River at Orange Blossom Bridge. During May and  
13 June, the 56°F threshold for fall-run rearing is exceeded less frequently (by up to  
14 10 percent) under Alternative 5 compared to the No Action Alternative.

15 These changes in temperatures are not reflected in Reclamation's salmon  
16 mortality model results for the fall-run Chinook Salmon in the Stanislaus River.  
17 As shown in Appendix 9C, the long-term average egg mortality rate is predicted  
18 to be around 8.5 percent, with higher mortality rates (in excess of 16 percent)  
19 occurring in critical dry years under Alternative 5. Overall, egg mortality is  
20 predicted to be similar under Alternative 5 and the No Action Alternative.

#### 21 *Changes in Delta Hydrodynamics*

22 San Joaquin River-origin fall run Chinook salmon smolts are most abundant in the  
23 Delta during the months of April, May and June. San Joaquin River-origin  
24 steelhead generally move through the Delta during spring however there is less  
25 information on their timing relative to Chinook salmon. Thus, hydrodynamics in  
26 the entire January through June period could have the potential to affect juvenile  
27 steelhead. Near the confluence of the San Joaquin River and the Mokelumne  
28 River, the proportion of positive velocities was slightly higher under Alternative 5  
29 relative to the No Action Alternative in January and February and almost  
30 indistinguishable from March through June (Appendix 9K). On Old River  
31 upstream and downstream of the facilities, the median proportion of positive  
32 velocities was similar under Alternative 5 and the No Action Alternative in all  
33 months. On the San Joaquin River downstream of the Head of Old River, the  
34 median proportion of positive velocities was similar under Alternative 5 and the  
35 No Action Alternative in all months.

#### 36 *Changes in Entrainment at Junctions*

37 As described in Appendix 9L, median entrainment at various junctions is  
38 indistinguishable or lower under Alternative 5 compared to the No Action  
39 Alternative for fall-run Chinook Salmon.

#### 40 *Summary of Effects on Fall-Run Chinook Salmon and Steelhead*

41 The analysis of temperatures indicates somewhat higher temperatures in some  
42 water year types and a higher likelihood of exceedance of suitable temperatures  
43 for spawning, and lower likelihood of exceeding suitable temperature for rearing  
44 of fall-run Chinook Salmon under Alternative 5 as compared to the No Action

1 Alternative in the Stanislaus River below Goodwin Dam. The effect of higher  
2 temperatures is not reflected in overall mortality of fall-run Chinook Salmon eggs  
3 predicted by Reclamation's salmon mortality model for fall-run Chinook Salmon  
4 in the Stanislaus River. The frequency of exceedance of temperature thresholds  
5 for steelhead smoltification and rearing could be more stressful under  
6 Alternative 5 compared to the No Action Alternative. However, the higher flows  
7 in April and May and lower temperatures in April and May under Alternative 5  
8 may benefit steelhead spawning.

9 Given the variability in the results and the inherent uncertainty associated with the  
10 resolution of the models, it is concluded that Alternative 5 and the No Action  
11 Alternative are likely to have similar effects on fall-run Chinook Salmon and  
12 steelhead in the Stanislaus and lower San Joaquin rivers.

### 13 *White Sturgeon*

14 Evidence of White Sturgeon spawning has been recorded in the San Joaquin River  
15 upstream of the confluence with the Stanislaus River. While flows in the San  
16 Joaquin River upstream of the Stanislaus River are expected to be similar under all  
17 alternatives, flow contributions from the Stanislaus River could influence water  
18 temperatures in the San Joaquin River where White Sturgeon eggs or larvae may  
19 occur during the spring and early summer. The magnitude of influence on water  
20 temperature would depend on the proportional flow contribution of the Stanislaus  
21 River and the temperatures in both the Stanislaus and San Joaquin rivers. The  
22 potential for an effect on White Sturgeon eggs and larvae would be influenced by  
23 the proportion of the population occurring in the San Joaquin River. In  
24 consideration of this uncertainty, it is not possible to distinguish potential effects  
25 on White Sturgeon between alternatives.

### 26 *Reservoir Fishes*

27 Storage levels in New Melones Reservoir would be similar (within 5 percent) for  
28 Alternative 5 as compared to the No Action Alternative (Appendix 5A).

29 Results of the bass nesting success analysis indicate that for March, the likelihood  
30 of Largemouth Bass and Smallmouth Bass nest survival in New Melones being  
31 above 40 percent is 100 percent under both Alternative 5 and the No Action  
32 Alternative. For April, the likelihood that nest survival of Largemouth Bass and  
33 Smallmouth Bass is between 40 and 100 percent is predicted to be reasonably  
34 high but is somewhat (about 13 percent) lower under Alternative 5 as compared to  
35 the No Action Alternative. For May, the difference between alternatives is less  
36 with the likelihood of high nest survival being about 5 percent less under  
37 Alternative 5. For June, the likelihood of survival being greater than 40 percent  
38 for Largemouth Bass and Smallmouth Bass in New Melones is similar under  
39 Alternative 5 and the No Action Alternative. For Spotted Bass, nest survival in  
40 March is anticipated to be near 100 percent in every year under both Alternative 5  
41 and the No Action Alternative. The likelihood of Spotted Bass nest survival  
42 being greater than 40 percent is about 7 percent less under Alternative 5 than  
43 under the No Action Alternative in April, but is still reasonably high (greater than  
44 90 percent). During May, the likelihood of high (>40 percent) Spotted Bass nest

1 survival is about 5 percent lower under Alternative 5 as compared to the No  
2 Action Alternative. During June, Spotted Bass nest survival would be greater  
3 than 40 percent in every year under Alternative 5 as compared to approximately  
4 98 percent of the years under the No Action Alternative.

5 Overall, the analysis suggests that conditions under Alternative 5 have the  
6 potential to negatively influence black bass nesting success, especially in April  
7 and May, by comparison to the No Action Alternative. However, nesting success  
8 under Alternative 5 would still exceed 40 percent most of the time under both  
9 alternatives. Therefore, it is concluded that there would be no definitive  
10 difference in effects on reservoir fish between Alternative 5 and the No Action  
11 Alternative.

12 *Other Species*

13 Changes in operations that influence temperature and flow conditions in the  
14 Stanislaus River downstream of Goodwin Dam and the San Joaquin River at  
15 Vernalis could affect other fishes such as lampreys, Hardhead, and Striped Bass.

16 Monthly average temperatures in the Stanislaus River at Goodwin under  
17 Alternative 5 would be similar (less than 0.5°F differences) to the No Action  
18 Alternative in most of the months and water years. From August through  
19 November, water temperatures under Alternative 5 could be somewhat (0.6°F to  
20 1.6°F) warmer, particularly in drier water years. This pattern in temperature  
21 changes under Alternative 5 was also predicted downstream at Orange Blossom  
22 Bridge. However, the differences are smaller at the San Joaquin River confluence  
23 and water temperatures in April and May could be up to 2.1°F cooler under  
24 Alternative 5.

25 In general, lamprey species can tolerate higher temperatures than salmonids, up to  
26 around 72°F during their entire life history. Because lamprey ammocoetes remain  
27 in the river for several years, any substantial flow reductions or temperature  
28 increases could result in adverse effects on larval lamprey.

29 In general, Striped Bass and Hardhead also can tolerate higher temperatures than  
30 salmonids. Given the similar flows and generally similar temperatures during  
31 their spawning and incubation period, it is likely that the potential to affect  
32 Striped Bass and Hardhead in the Stanislaus and San Joaquin rivers would be  
33 similar under Alternative 5 and the No Action Alternative.

34 Given the similarity of the results and the inherent uncertainty associated with the  
35 resolution of the models, it is concluded that Alternative 5 and the No Action  
36 Alternative are likely to have similar effects on lampreys, Hardhead, and Striped  
37 Bass in the Stanislaus and lower San Joaquin rivers. No definitive difference  
38 between Alternative 5 and the No Action Alternative could be discerned.

1 *San Francisco Bay Area Region*

2 *Killer Whale*

3 As described above for the comparison of Alternative 1 to the No Action  
4 Alternative, it is unlikely that the Chinook Salmon prey base of killer whales,  
5 supported heavily by hatchery production of fall-run Chinook Salmon, would be  
6 appreciably affected by any of the alternatives.

7 **9.4.3.6.1 Alternative 5 Compared to the Second Basis of Comparison**

8 As described in Chapter 3, Description of Alternatives, CVP and SWP operations  
9 under Alternative 5 are similar to the No Action Alternative with modified OMR  
10 flow criteria and New Melones Reservoir operations. Therefore, the comparison  
11 of Alternative 5 to the Second Basis of Comparison would be similar to the  
12 comparison of No Action Alternative to Second Basis of Comparison described  
13 above in Section 9.4.4.1, No Action Alternative.

14 *Trinity River Region*

15 *Coho Salmon, Spring-run Chinook Salmon, Fall-run Chinook Salmon, and*  
16 *Steelhead*

17 Monthly water temperature in the Trinity River at Lewiston Dam under  
18 Alternative 5 generally would be similar (less than 0.5°F differences) to the  
19 temperatures that would occur under the Second Basis of Comparison  
20 (Appendix 6B, Table B-1-6), with the exception of drier years when temperatures  
21 under Alternative 5 could be as much as 2.2°F cooler in November and 1.5°F  
22 warmer in December. Average monthly water temperatures could be slightly (up  
23 to 0.6°F) higher under Alternative 5 during July and August and lower (up to  
24 0.7°F) in September in some water year types. The slightly lower September  
25 temperatures under Alternative 5 may result in slightly better conditions than  
26 under the Second Basis of Comparison for spring-run Chinook Salmon spawning.  
27 Similarly, temperature conditions under Alternative 5 could be slightly better than  
28 the Second Basis of Comparison for fall-run Chinook Salmon spawning because  
29 of the reduced temperatures in November during critical dry years.

30 Under Alternative 5, water temperature thresholds for Coho Salmon, fall-run  
31 Chinook Salmon, and steelhead would be exceeded slightly more frequently (less  
32 than 1 percent), whereas thresholds for spring-run Chinook Salmon would be  
33 exceeded less frequently (up to 4 percent) in August in September  
34 (Appendix 9N).

35 These temperature results are not entirely reflected in the egg mortality results for  
36 fall-run Chinook Salmon, which indicate similar levels of egg mortality under  
37 Alternative 5 compared to the Second Basis of Comparison (Appendix 9C,  
38 Table B-5).

39 The minor changes in water temperatures and mortality suggest that conditions  
40 for Coho Salmon, fall-run Chinook Salmon, and steelhead in the Trinity River  
41 would be similar under both Alternative 5 and the Second Basis of Comparison.  
42 However, the slight reduction in threshold exceedances for spring-run Chinook

1 Salmon spawning under Alternative 5, although small, could reduce the potential  
2 for adverse impacts in the Trinity River under Alternative 5.

3 In addition, implementation of a Hatchery Management Plan under Alternative 5  
4 could reduce the impacts of hatchery Chinook Salmon on natural Chinook  
5 Salmon in the Trinity River and increase the genetic diversity and diversity of  
6 run-timing for these stocks relative to the Second Basis of Comparison, but the  
7 potential magnitude of these benefits is uncertain. Thus, given these relatively  
8 minor changes in temperature and temperature threshold exceedance, the inherent  
9 uncertainty associated with the resolution of the temperature model (average  
10 monthly outputs), and the uncertainty of the hatchery benefits, it is concluded that  
11 Alternative 5 and Second Basis of Comparison are likely to have similar effects  
12 on Chinook Salmon and steelhead in the Trinity River.

### 13 *Reservoir Fishes*

14 The analysis of effects associated with changes in operation on reservoir fishes  
15 relied on evaluation of changes in available habitat (reservoir storage) and  
16 anticipated changes in black bass nesting success.

17 Black bass species in Trinity Lake would be exposed to minor differences in  
18 storage under both Alternative 5 and the Second Basis of Comparison, and these  
19 relatively small differences would have negligible effect on nest survival. The  
20 nest survival under Alternative 5 would be generally similar to Second Basis of  
21 Comparison for Largemouth Bass, Smallmouth Bass, and Spotted Bass  
22 (Appendix 9F). These negligible differences in nest survival suggest that  
23 conditions for reservoir species in Trinity Lake would be similar under  
24 Alternative 5 and the Second Basis of Comparison.

### 25 *Other Species*

26 The minor differences in average monthly water temperatures described above for  
27 salmonids apply to Pacific Lamprey, Eulachon, and other aquatic species in the  
28 Trinity River. These minor differences suggest that conditions for aquatic species  
29 in the Trinity River and Klamath River downstream of the confluence generally  
30 would be similar under Alternative 5 and the Second Basis of Comparison.

### 31 *Sacramento River System*

#### 32 *Winter-run Chinook Salmon*

33 Changes in operations that influence temperature and flow conditions in the  
34 Sacramento River downstream of Keswick Dam could affect winter-run Chinook  
35 Salmon. The following describes those changes and their potential effects.

#### 36 *Changes in Water Temperature*

37 Monthly water temperature in the Sacramento River at Keswick Dam under  
38 Alternative 5 and the Second Basis of Comparison generally would be similar  
39 (differences less than 0.5°F). Average monthly water temperatures in September  
40 under Alternative 5 would be lower (up to 0.9°F) in wetter years and higher (up to  
41 1.2°F) in drier years (Appendix 6B). Similarly, water temperatures in October of  
42 critical years could be 0.9°F warmer under Alternative 5. A similar temperature  
43 pattern generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry,

1 and Bend Bridge, with average monthly temperature differences in September  
2 increasing (up to 2.8°F cooler at Bend Bridge) in September during the wetter  
3 years and up to 0.8°F warmer in critical years (Appendix 6B).

#### 4 *Changes in Exceedances of Water Temperature Thresholds*

5 With the exception of April, average monthly water temperatures under both  
6 Alternative 5 and Second Basis of Comparison would show exceedances of the  
7 water temperature threshold of 56°F established in the Sacramento River at Ball's  
8 Ferry for winter-run Chinook Salmon spawning and egg incubation in every  
9 month, with exceedances under both as high as about 41 percent and 54 percent,  
10 respectively, in some months (Appendix 9N). Under Alternative 5, the  
11 temperature threshold generally would be exceeded more frequently than under  
12 the Second Basis of Comparison (by about 1 percent to 3 percent) in the April  
13 through August period, with the temperature threshold in September exceeded  
14 about 11 percent less frequently under Alternative 5 than under the Second Basis  
15 of Comparison. Farther downstream at Bend Bridge, the frequency of  
16 exceedances would increase, with exceedances under both Alternative 5 and the  
17 Second Basis of Comparison as high as about 90 percent in some months. Under  
18 Alternative 5, temperature exceedances generally would be more frequent (by up  
19 to 10 percent) than under the Second Basis of Comparison, with the exception of  
20 September, when exceedances under Alternative 5 would be about 30 percent less  
21 frequent under Alternative 5.

#### 22 *Changes in Egg Mortality*

23 The temperatures described above for the Sacramento River below Keswick Dam  
24 are reflected in the analysis of egg mortality using the Reclamation Salmon  
25 Survival Model (Appendix 9C). For winter-run Chinook Salmon in the  
26 Sacramento River, the long-term average egg mortality rate is predicted to be  
27 relatively low (around 5 percent), with higher mortality rates (exceeding  
28 20 percent) occurring in critical dry years under Alternative 5. Overall, egg  
29 mortality would be similar under Alternative 5 and the Second Basis of  
30 Comparison (Appendix 9C, Table B-4).

#### 31 *Changes in Weighted Usable Area*

32 As an indicator of the amount of suitable spawning habitat for winter-run Chinook  
33 Salmon between Keswick Dam and Battle Creek, modeling results indicate that,  
34 in general, there would be similar amounts of spawning habitat available from  
35 May through September under Alternative 5 as compared to the Second Basis of  
36 Comparison (Appendix 9E, Table C-17-6). Modeling results indicate that, in  
37 general, there would be similar amounts of suitable fry rearing habitat available  
38 from June through October under Alternative 5 and the Second Basis of  
39 Comparison (Appendix 9E, Table C-18-6). Similar to the results for fry rearing  
40 WUA, modeling results indicate that there would be similar amounts of suitable  
41 juvenile rearing habitat available during the juvenile rearing period under  
42 Alternative 5 and the Second Basis of Comparison (Appendix 9E, Table C-19-6).

1            *Changes in SALMOD Output*

2 SALMOD results indicate that potential juvenile production would be the same  
3 under Alternative 5 and the Second Basis of Comparison (Appendix 9D,  
4 Table B-4-26).

5            *Changes in Delta Passage Model Output*

6 The Delta Passage Model predicted similar estimates of annual Delta survival  
7 across the 81 water year time period for winter-run Chinook Salmon between  
8 Alternative 5 and the Second Basis of Comparison Alternative (Appendix 9J).  
9 Median Delta survival was 0.350 for Alternative 5 and 0.352 for the Second Basis  
10 of Comparison Alternative. Overall, there would be little change in through-Delta  
11 survival for emigrating juvenile winter-run Chinook Salmon under Alternative 5  
12 as compared to the Second Basis of Comparison.

13           *Changes in Delta Hydrodynamics*

14 Winter run smolts are most abundant in the Delta during the months of January  
15 February and March. On the Sacramento River near the confluence of Georgiana  
16 Slough, the median proportion of positive velocities under Alternative 5 was  
17 indistinguishable from the Second Basis of Comparison in January, February, and  
18 March (Appendix 9K). On the San Joaquin River near the Mokelumne River  
19 confluence, the median proportion of positive velocities was slightly greater under  
20 Alternative 5 relative to Second Basis of Comparison in January and February and  
21 similar in March. In Old River downstream of the facilities, the median  
22 proportion of positive velocities was substantially higher under Alternative 5  
23 during January and moderately higher in February. Values in March were almost  
24 indistinguishable between scenarios. On Old River upstream of the facilities, the  
25 median proportion of positive velocities was moderately lower in January and  
26 February and slightly lower in March under Alternative 5 relative to Second Basis  
27 of Comparison. On the San Joaquin River downstream of Head of Old River, the  
28 median proportion of positive velocities was similar for both scenarios in January,  
29 February and March.

30           *Changes in Junction Entrainment*

31 At the junction of Georgiana Slough and the Sacramento River, median  
32 entrainment under Alternative 5 and the Second Basis of Comparison was  
33 essentially indistinguishable in January, February and March (Appendix 9L).  
34 Entrainment at the Head of Old River junction was similar to slightly lower under  
35 Alternative 5 relative to Second Basis of Comparison during the period of winter  
36 run Chinook Salmon migration through the Delta (January, February, and March).  
37 For the Turner Cut junction, median entrainment under Alternative 5 was slightly  
38 lower in January and February relative to Second Basis of Comparison. In  
39 March, the difference in entrainment between scenarios was similar. At the  
40 Columbia Cut, Middle River and Old River junctions, patterns in entrainment  
41 between Alternative 5 and Second Basis of Comparison were similar. At these  
42 junctions, median entrainment was slightly to moderately lower under  
43 Alternative 5 during January and February and values were more similar in  
44 March.

1            *Changes in Salvage*

2 Salvage of winter-run Chinook salmon is predicted to be substantially lower  
3 under Alternative 5 relative to the Second Basis of Comparison in January and  
4 February (Appendix 9M). In March, predicted salvage was only moderately  
5 lower under Alternative 5 relative to Second Basis of Comparison.

6            *Changes in Oncorhynchus Bayesian Analysis Output*

7 Escapement of winter-run Chinook Salmon and Delta survival was modeled by  
8 the Oncorhynchus Bayesian Analysis (OBAN) model for winter-run Chinook  
9 salmon. Escapement was generally higher under Alternative 5 as compared to the  
10 Second Basis alternative (Appendix 9I). The median abundance under  
11 Alternative 5 was higher the Second Basis of Comparison. Median delta survival  
12 was approximately 15 percent higher under Alternative 5 as compared to the  
13 Second Basis of Comparison.

14           *Changes in Interactive Object-Oriented Simulation Output*

15 The IOS model predicted similar adult escapement trajectories for Winter-Run  
16 Chinook salmon between Alternative 5 and the Second Basis of Comparison  
17 Alternative across the 81 water years (Appendix 9H). Alternative 5 median adult  
18 escapement was 3,545 and Second Basis of Comparison Alternative median  
19 escapement was 4,042).

20 Similar to adult escapement, the IOS model predicted similar egg survival for  
21 Winter-Run Chinook salmon between Alternative 5 and the Second Basis of  
22 Comparison Alternative across the 81 water years (Appendix 9H). Median egg  
23 survival was 0.989 for Alternative 5 and 0.987 for the Second Basis of  
24 Comparison Alternative).

25           *Summary of Effects on Winter-Run Chinook Salmon*

26 The analysis of temperatures indicates somewhat higher temperatures and greater  
27 likelihood of exceedance of thresholds under Alternative 5 as compared to the  
28 Second Basis of Comparison. This is not reflected in the similar survival of  
29 winter-run Chinook Salmon eggs predicted by Reclamation's salmon mortality  
30 model. Flow changes under Alternative 5 would have small effects on the  
31 availability of spawning and rearing habitat for winter-run Chinook Salmon as  
32 indicated by the WUA analysis and the decrease in flow (habitat)-related  
33 mortality predicted by SALMOD under Alternative 5. Through Delta survival of  
34 juvenile winter-run Chinook Salmon would be the same under both Alternative 5  
35 and Second Basis of Comparison as indicated by the DPM results; the OBAN  
36 results suggest that Delta survival could be higher under Alternative 5.  
37 Entrainment may also be reduced under Alternative 5 as indicated by the salvage  
38 analysis based on OMR flows. Median adult escapement to the Sacramento River  
39 could be reduced slightly under Alternative 5 as indicated by the IOS model  
40 results which incorporate temperature, flow, and mortality effects on each life  
41 stage over the entire life cycle of winter-run Chinook Salmon. However, the  
42 OBAN model results indicate an increase in escapement over a more limited time  
43 period (1971 to 2002).

1 The model results suggest that effects on winter-run Chinook Salmon would be  
2 similar under both Alternative 5 and Second Basis of Comparison, with a small  
3 likelihood that winter-run Chinook Salmon escapement would be higher under the  
4 Alternative 5. Positive effects, however, likely would be greater because of the  
5 potential benefits of providing fish passage under Alternative 5 intended to  
6 address the limited availability of suitable habitat for winter-run Chinook Salmon  
7 in the Sacramento River reaches downstream of Keswick Dam. This potential  
8 beneficial effect and its magnitude would depend on the success of the fish  
9 passage program. In addition, benefits to winter-run Chinook Salmon may accrue  
10 under Alternative 5 as a result actions intended to increase the efficiency of the  
11 Tracy and Skinner Fish Collection Facilities to improve the overall salvage  
12 survival of listed salmonids, including winter-run Chinook Salmon.

13 Overall, the quantitative results from the numerical models suggest that operation  
14 under Alternative 5 would be less likely to result in adverse effects on winter-run  
15 Chinook Salmon than would the Second Basis of Comparison. In consideration  
16 of the potentially beneficial effects resulting from actions under the Alternative 5  
17 that are not included in the numerical models (see Appendix 5A, Section B),  
18 however, Alternative 5 has a much greater potential to address the long-term  
19 sustainability of winter-run Chinook Salmon than does the Second Basis of  
20 Comparison. Alternative 5 includes provisions for fish passage upstream of  
21 Shasta Dam to address long-term temperature increases associated with climate  
22 change; the Second Basis of Comparison does not. Even though the success of  
23 fish passage is uncertain, it is concluded that the potential for adverse effects on  
24 winter-run Chinook Salmon under Alternative 5 would clearly be less than those  
25 under the Second Basis of Comparison, principally because the Second Basis of  
26 Comparison does not include a strategy to address water temperatures critical to  
27 winter-run Chinook Salmon sustainability over the long term with climate change  
28 by 2030.

### 29 *Spring-run Chinook Salmon*

30 Changes in operations that influence temperature and flow conditions in the  
31 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
32 Whiskeytown Dam, and Feather River downstream of Oroville Dam could affect  
33 spring-run Chinook Salmon. The following describes those changes and their  
34 potential effects.

### 35 *Changes in Water Temperature*

36 Changes in water temperature that could affect spring-run Chinook Salmon could  
37 occur in the Sacramento River, Clear Creek, and Feather River. The following  
38 describes temperature conditions in those water bodies.

### 39 *Sacramento River*

40 Monthly water temperature in the Sacramento River at Keswick Dam under  
41 Alternative 5 and the Second Basis of Comparison generally would be similar  
42 (differences less than 0.5°F). Average monthly water temperatures in September  
43 under Alternative 5 would be lower (up to 0.9°F) in wetter years and higher (up to  
44 1.2°F) in drier years. Similarly, water temperatures in October of critical years

1 could be 0.9°F warmer under Alternative 5. A similar temperature pattern  
 2 generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry, Bend  
 3 Bridge and Red Bluff, with average monthly temperature differences in  
 4 September progressively increasing (up to 3.2°F cooler at Red Bluff) during the  
 5 wetter years (Appendix 6B, Table B-9-6).

#### 6 *Clear Creek*

7 Average monthly water temperatures in Clear Creek at Igo under  
 8 Alternative relative to the Second Basis of Comparison are generally predicted to  
 9 be similar (less than 0.5°F differences) (Appendix 6B, Table B-3-6). Average  
 10 monthly water temperatures during May under Alternative 5 would be up to 0.8°F  
 11 lower than under the Second Basis of Comparison in all but critical water years.  
 12 The lower water temperatures in May associated with Alternative 5 reflect the  
 13 effects of additional water discharged from Whiskeytown Dam to meet the spring  
 14 attraction flow requirements to promote attraction of spring-run Chinook Salmon  
 15 into the creek. While the reduction in May water temperatures indicated by the  
 16 modeling could improve thermal conditions for spring-run Chinook Salmon, the  
 17 duration of the two pulse flows may not be of sufficient duration (3 days each) to  
 18 provide temperature benefits.

#### 19 *Feather River*

20 Long-term average monthly water temperature in the Feather River at the low  
 21 flow channel under Alternative 5 relative to the Second Basis of Comparison  
 22 generally would be similar (less than 0.5°F differences). Water temperatures  
 23 could be up to 1.5°F warmer in November and December of some water year  
 24 types and up to 1.2°F cooler in September of wetter years (Appendix 6B,  
 25 Table B-20-6) under Alternative 5. Although temperatures in the river would  
 26 become progressively higher in the downstream direction, the differences between  
 27 Alternative 5 and Second Basis of Comparison exhibit a similar pattern at the  
 28 downstream locations (Robinson Riffle and Gridley Bridge), with water  
 29 temperature differences under Alternative 5 generally increasing in most water  
 30 year types relative to the Second Basis of Comparison at the confluence with  
 31 Sacramento River (Appendix 6B, Table B-23-6). Water temperatures under  
 32 Alternative 5 could be somewhat (0.8°F to 1.6°F) cooler on average and up to  
 33 3.9°F cooler (September) at the confluence with Sacramento River from July to  
 34 September in wetter years.

#### 35 *Changes in Exceedances of Water Temperature Thresholds*

36 Changes in water temperature could result in the exceedance of established water  
 37 temperature thresholds for spring-run Chinook Salmon in the Sacramento River,  
 38 Clear Creek, and Feather River. The following describes the extent of those  
 39 exceedance for each of those water bodies.

#### 40 *Sacramento River*

41 Average monthly water temperatures under both Alternative 5 and Second Basis  
 42 of Comparison would show exceedances of the water temperature threshold of  
 43 56°F established in the Sacramento River at Red Bluff for spring-run Chinook  
 44 Salmon (egg incubation) in October, November, and again in April. The

1 exceedances would occur at the greatest frequency in October, with 80 percent  
2 and 79 percent for Alternative 5 and Second Basis of Comparison, respectively.  
3 Temperature thresholds would be exceeded less frequently in November  
4 (7 percent) and not exceeded at all during December through March. As water  
5 temperatures warm in the spring, the thresholds would be exceeded in April by  
6 14 percent and 13 percent under Alternative 5 and Second Basis of Comparison.  
7 In the warmer months when exceedances occur (October, November, and April),  
8 temperature thresholds generally would be exceeded more frequently (by up to  
9 2 percent in October) under Alternative 5 than under the Second Basis of  
10 Comparison (Appendix 9N, Table 9N.B.1).

11 *Clear Creek*

12 Average monthly water temperatures under both Alternative 5 and Second Basis  
13 of Comparison would not exceed the water temperature threshold of 60°F  
14 established in Clear Creek at Igo for spring-run Chinook Salmon pre-spawning  
15 and rearing in June through August. However, Alternative 5 and Second Basis of  
16 Comparison would exceed the water temperature threshold of 56°F established  
17 for spawning in September and October about 10 percent to 15 percent of the  
18 time. The differences between Alternative 5 and Second Basis of Comparison are  
19 small, with Alternative 5 exceeding thresholds about 1 percent more frequently  
20 than under the Second Basis of Comparison in September and about 2 percent  
21 more frequently in October (Appendix 9N).

22 *Feather River*

23 Average monthly water temperatures under both Alternative 5 and Second Basis  
24 of Comparison would exceed the water temperature threshold of 56°F established  
25 in the Feather River at Robinson Riffle for spring-run Chinook Salmon egg  
26 incubation and rearing (Appendix 9N) during some months, particularly in  
27 October and November, and March and April, when temperature thresholds could  
28 be exceeded frequently. The frequency of exceedance was highest (about  
29 98 percent) in October, a month in which average monthly water could get as high  
30 as about 68°F. However, water temperatures under Alternative 5 would exceed  
31 temperature thresholds less than 2 percent more frequently than the Second Basis  
32 of Comparison in October, November, and December, and about 1 percent less  
33 frequently in March. The established water temperature threshold of 63°F for  
34 rearing during May through August would be exceeded often under both  
35 Alternative 5 and Second Basis of Comparison in May (57 percent and  
36 51 percent, respectively) and June (97 percent for both), but not at all in July and  
37 August.

38 *Changes in Egg Mortality*

39 These temperature differences described above are reflected in the analysis of egg  
40 mortality using the Reclamation salmon mortality model (Appendix 9C). For  
41 spring-run Chinook Salmon in the Sacramento River, the long-term average egg  
42 mortality rate is predicted to be relatively high (exceeding 20 percent), with high  
43 mortality rates (exceeding 80 percent) occurring in critical dry years. In critical  
44 dry years the average egg mortality rate would be 13.1 percent greater under  
45 Alternative 5 than under the Second Basis of Comparison (Appendix 9C,

1 Table B-3). Overall, egg mortality under Alternative 5 and the Second Basis of  
2 Comparison would be similar, except in critical dry water years.

3 *Changes in Weighted Usable Area*

4 Weighted usable area curves are available for spring-run Chinook Salmon in  
5 Clear Creek. As described above, flows in Clear Creek below Whiskeytown Dam  
6 are not anticipated to differ under Alternative 5 relative to the Second Basis of  
7 Comparison except in May due to the release of spring attraction flows in  
8 accordance with the 2009 NMFS BO. Therefore, there would be no change in the  
9 amount of potentially suitable spawning and rearing habitat for spring-run  
10 Chinook Salmon (as indexed by WUA) available under Alternative 5 as compared  
11 to the Second Basis of Comparison.

12 *Changes in SALMOD Output*

13 SALMOD results indicate that potential spring-run juvenile production would be  
14 similar under Alternative 5 and the Second Basis of Comparison, except in critical  
15 dry years when production could be 14 percent lower under Alternative 5 than  
16 under the Second Basis of Comparison (Appendix 9D).

17 *Changes in Delta Passage Model Output*

18 The Delta Passage Model predicted similar estimates of annual Delta survival  
19 across the 81 water year time period for spring-run between Alternative 5 and the  
20 Second Basis of Comparison (Appendix 9J). Median Delta survival was 0.296 for  
21 Alternative 5 and 0.286 for the Second Basis of Comparison. Overall, there  
22 would be little change in through-Delta survival by emigrating juvenile spring-run  
23 Chinook Salmon under Alternative 5 as compared to the Second Basis of  
24 Comparison.

25 *Changes in Delta Hydrodynamics*

26 Spring run Chinook salmon are most abundant in the Delta from March through  
27 May. Near the junction of Georgiana Slough, the median proportion of time that  
28 velocity was positive was similar in March and April and slightly lower in May  
29 under Alternative 5 relative to the Second Basis of Comparison (Appendix 9K).  
30 Near the confluence of the San Joaquin River and the Mokelumne River, the  
31 median proportion of positive velocities was similar in March and slightly to  
32 moderately higher under Alternative 5 relative to the Second Basis of Comparison  
33 in April and May. In the San Joaquin River downstream of the Head of Old River  
34 the median proportion of positive velocities was slightly to moderately higher  
35 under Alternative 5 relative to Second Basis of Comparison in April and May,  
36 respectively, whereas there was little difference between these scenarios in  
37 March. In Old River upstream of the facilities the median proportion of positive  
38 velocities was slightly higher in April and May under Alternative 5 relative to  
39 Second Basis of Comparison and slightly lower in March. In Old River  
40 downstream of the facilities, the median proportion of positive velocities was  
41 substantially higher under Alternative 5 relative to Second Basis of Comparison  
42 in April and May and more similar in March.

1                    *Changes in Junction Entrainment*

2    At the junction of Georgiana Slough and the Sacramento River, median  
3    entrainment under Alternative 5 was slightly lower than under the Second Basis  
4    of Comparison in April and May but essentially indistinguishable in March  
5    (Appendix 9L). Median entrainment at the Head of Old River junction was  
6    substantially higher under Alternative 5 relative to Second Basis of Comparison  
7    during the months of April and May and similar in March. For the Turner Cut  
8    junction, median entrainment under Alternative 5 was moderately lower in April  
9    and May relative to Second Basis of Comparison and more similar in March. At  
10   the Columbia Cut, Middle River and Old River junctions, entrainment under  
11   Alternative 5 was slightly lower than Second Basis of Comparison in March and  
12   became moderately to substantially lower in April and May.

13                   *Changes in Salvage*

14   Salvage of spring run Chinook salmon was predicted to be substantially lower  
15   under Alternative 5 relative the Second Basis of Comparison during April and  
16   May and only slightly lower in the month of March (Appendix 9M).

17                   *Summary of Effects on Spring-Run Chinook Salmon*

18   The multiple model and analysis outputs described above characterize the  
19   anticipated conditions for spring-run Chinook Salmon and their response to  
20   change under Alternative 5 as compared to the Second Basis of Comparison. For  
21   the purpose of analyzing effects on spring-run Chinook Salmon in the Sacramento  
22   River, greater reliance was placed on the outputs from the SALMOD model  
23   because it integrates the available information on temperature and flows to  
24   produce estimates of mortality for each life stage and an overall, integrated  
25   estimate of potential spring-run Chinook Salmon juvenile production. The output  
26   from SALMOD indicated that spring-run Chinook Salmon production in the  
27   Sacramento River would be similar under Alternative 5 and the Second Basis of  
28   Comparison, except in critical dry years. The analyses attempting to assess the  
29   effects on routing, entrainment, and salvage of juvenile salmonids in the Delta  
30   suggest that salvage (as an indicator of potential losses of juvenile salmon at the  
31   export facilities) of Sacramento River-origin Chinook Salmon is predicted to be  
32   lower under Alternative 5 relative to the Second Basis of Comparison in every  
33   month.

34   In Clear Creek and the Feather River, the analysis of the effects of Alternative 5  
35   and Second Basis of Comparison for spring-run Chinook Salmon relied on water  
36   temperature output for Clear Creek at Igo, and in the Feather River low flow  
37   channel and downstream of the Thermalito complex. The analysis of  
38   temperatures indicates somewhat higher temperatures and greater likelihood of  
39   exceedance of thresholds under Alternative 5 as compared to the Second Basis of  
40   Comparison in the Feather River. There would be little change in flows or  
41   temperatures in Clear Creek under Alternative 5 relative to the Second Basis of  
42   Comparison. The effect of slightly increased temperatures is not reflected in the  
43   similar overall survival of spring-run Chinook Salmon eggs predicted by  
44   Reclamation's salmon mortality model for spring-run in the Sacramento River. In

1 drier years, the likelihood of adverse temperature effects would be increased  
2 under Alternative 5 as compared to the Second Basis of Comparison.

3 Flow changes under Alternative 5 would likely have small effects due to changes  
4 in the availability of spawning and rearing habitat for spring-run Chinook Salmon  
5 in the Sacramento River as indicated by the decrease in flow (habitat)-related  
6 mortality predicted by SALMOD under Alternative 5. Through Delta survival of  
7 juvenile spring-run Chinook Salmon would be the same under both Alternative 5  
8 and Second Basis of Comparison as indicated by the DPM results and entrainment  
9 could be reduced as indicated by the salvage analysis.

10 The numerical model results suggest that, overall, Alternative 5 likely would have  
11 similar or somewhat greater adverse effects on the spring-run Chinook Salmon  
12 population in the Sacramento River watershed as compared to the Second Basis of  
13 Comparison, particularly in drier water year types. This potential distinction  
14 between the two scenarios, however, may be offset by the benefits of  
15 implementation of fish passage under Alternative 5 intended to address the  
16 limited availability of suitable habitat for spring-run Chinook Salmon in the  
17 Sacramento River reaches downstream of Keswick Dam. This beneficial effect  
18 and its magnitude would depend on the success of the fish passage program. In  
19 addition, spring-run Chinook Salmon may benefit from actions under  
20 Alternative 5 intended to increase the efficiency of the Tracy and Skinner Fish  
21 Collection Facilities to improve the overall salvage survival of listed salmonids,  
22 including spring-run Chinook Salmon.

23 Thus, it is concluded that the potential for adverse effects on spring-run Chinook  
24 Salmon under Alternative 5 suggested by the results of the numerical models  
25 would likely be offset by the potential benefits of the actions that are not included  
26 in the numerical models, principally because the Second Basis of Comparison  
27 does not include a strategy to address water temperatures critical to spring-run  
28 Chinook Salmon sustainability over the long term with climate change by 2030.  
29 On balance and over the long term, the adverse effects on spring-run Chinook  
30 Salmon under Alternative 5 would be less than those under the Second Basis of  
31 Comparison.

### 32 *Fall-Run Chinook Salmon*

33 Changes in operations that influence temperature and flow conditions in the  
34 Sacramento River downstream of Keswick Dam, Clear Creek downstream of  
35 Whiskeytown Dam, Feather River downstream of Oroville Dam and American  
36 River below Nimbus could affect fall-run Chinook Salmon. The following  
37 describes those changes and their potential effects.

### 38 *Changes in Water Temperature*

39 Changes in water temperature could affect fall-run Chinook Salmon in the  
40 Sacramento, Feather, and American rivers, and Clear Creek. The following  
41 describes temperature conditions in those water bodies.

1                    *Sacramento River*

2 Monthly water temperature in the Sacramento River at Keswick Dam under  
3 Alternative 5 and the Second Basis of Comparison generally would be similar  
4 (differences less than 0.5°F). Average monthly water temperatures in September  
5 under Alternative 5 would be lower (up to 0.9°F) in wetter years and higher (up to  
6 1.2°F) in drier years. Similarly, water temperatures in October of critical years  
7 could be 0.9°F warmer under Alternative 5. A similar pattern in temperatures  
8 generally would be exhibited at downstream locations along the Sacramento River  
9 (i.e., Ball's Ferry Jelly's Ferry, Bend Bridge, Red Bluff, Hamilton City, and  
10 Knights Landing), with differences in average monthly temperatures at Knights  
11 Landing progressively increasing (up to 1.0°F warmer) in June and up to up to  
12 4.6°F cooler in September of wetter years under Alternative 5 relative to the  
13 Second Basis of Comparison.

14                    *Clear Creek*

15 Average monthly water temperatures in Clear Creek at Igo under  
16 Alternative relative to the Second Basis of Comparison are generally predicted to  
17 be similar (less than 0.5°F differences) (Appendix 6B, Table B-3-6). Average  
18 monthly water temperatures during May under Alternative 5 would be up to 0.8°F  
19 lower than under the Second Basis of Comparison in all but critical water years.  
20 The lower water temperatures in May associated with Alternative 5 reflect the  
21 effects of additional water discharged from Whiskeytown Dam to meet the spring  
22 attraction flow requirements to promote attraction of spring-run Chinook Salmon  
23 into the creek. While the reduction in May water temperatures indicated by the  
24 modeling could improve thermal conditions for fall-run Chinook Salmon, the  
25 duration of the two pulse flows may not be of sufficient duration (3 days each) to  
26 provide temperature benefits.

27                    *Feather River*

28 Long-term average monthly water temperature in the Feather River at the low  
29 flow channel under Alternative 5 relative to the Second Basis of Comparison  
30 generally would be similar (less than 0.5°F differences). Water temperatures  
31 could be up to 1.5°F warmer in November and December of some water year  
32 types and up to 1.2°F cooler in September of wetter years. Although temperatures  
33 in the river would become progressively higher in the downstream direction, the  
34 differences between Alternative 5 and Second Basis of Comparison exhibit a  
35 similar pattern at the downstream locations (Robinson Riffle and Gridley Bridge),  
36 with water temperature differences under Alternative 5 generally increasing in  
37 most water year types relative to the Second Basis of Comparison at the  
38 confluence with Sacramento River (Appendix 6B, Table B-23-6). Water  
39 temperatures under Alternative 5 could be somewhat (0.8°F to 1.6°F) cooler on  
40 average and up to 3.9°F cooler (September) at the confluence with Sacramento  
41 River from July to September in wetter years.

1 *American River*

2 Average monthly water temperatures in the American River at Nimbus Dam  
3 under Alternative 5 generally would be similar (differences less than 0.5°F) to the  
4 Second Basis of Comparison, with the exception of during June and August of  
5 below normal water years, when temperatures under Alternative 5 could be as  
6 much as 0.9°F higher. This pattern generally would persist downstream to Watt  
7 Avenue and the mouth, although temperatures under Alternative 5 would be up to  
8 1.6°F and 2.1°F higher, respectively, than under the Second Basis of Comparison  
9 in June. In addition, average monthly water temperatures at the mouth under  
10 Alternative 5 generally would be lower than under the Second Basis of  
11 Comparison in September, especially in wetter water year types when water  
12 temperatures under Alternative 5 could be up to 1.7°F cooler.

13 *Changes in Exceedances of Water Temperature Thresholds*

14 Changes in water temperature could result in the exceedance of water  
15 temperatures that are protective of fall-run Chinook Salmon in the Sacramento  
16 River, Clear Creek, Feather River, and American River. The following describes  
17 the extent of those exceedances for each of those water bodies.

18 *Sacramento River*

19 Average monthly water temperatures under both Alternative 5 and Second Basis  
20 of Comparison would exceed the water temperature threshold of 56°F established  
21 in the Sacramento River at Red Bluff for fall-run Chinook Salmon spawning and  
22 egg incubation (Table temperature targets) during some months, particularly in  
23 October, November, and April, when temperature thresholds would be exceeded.  
24 The frequency of exceedance would be greatest in October, a month in which  
25 average monthly water temperature could get as high as about 64°F. In October,  
26 average monthly water temperatures under Alternative 5 and Second Basis of  
27 Comparison would exceed the threshold 82 percent and 79 percent of the time,  
28 respectively. The differences in the frequency of exceedances between  
29 Alternative 5 and Second Basis of Comparison would be small. Water  
30 temperatures under Alternative 5 would exceed temperature thresholds about  
31 2 percent more frequently than under the Second Basis of Comparison in October,  
32 1 percent less frequently in November, and 1 percent more frequently in April.

33 *Clear Creek*

34 Fall-run Chinook Salmon spawning in lower Clear Creek typically occurs during  
35 October through December (USFWS 2015). Average monthly water  
36 temperatures at Igo during this period generally would be below 56°F, except in  
37 October. Under Alternative 5, the 56°F threshold would be exceeded in October  
38 about 12 percent of the time as compared to 10 percent under the Second Basis of  
39 Comparison. At the confluence with the Sacramento River, average monthly  
40 water temperatures in October would be warmer, with 56°F exceeded nearly  
41 20 percent of the time under Alternative 5 and somewhat (about 8 percent) less  
42 frequently under the Second Basis of Comparison. During November and  
43 December, average monthly water temperatures generally would remain below  
44 56°F at both locations.

1 For fall-run Chinook Salmon rearing (January through September), the  
2 exceedances described previously for spring-run Chinook Salmon would apply,  
3 with the average monthly temperatures remaining below the 60°F threshold  
4 except in September when temperatures could increase to over 60°F. During  
5 September, water temperatures under Alternative 5 would exceed 56°F about  
6 3 percent more frequently than under the Second Basis of Comparison.  
7 Downstream at the mouth, the average monthly temperatures would exceed 56°F  
8 more frequently, especially in July and August, when it always would be  
9 exceeded and average monthly temperatures would approach 64°F under both  
10 scenarios in September.

11 Under Alternative 5, temperature conditions at Igo would be slightly warmer than  
12 under the Second Basis of Comparison. Average monthly water temperatures  
13 likely mask daily temperatures excursions that could exceed important thresholds.  
14 Therefore, while the differences in threshold exceedance are relatively minor, the  
15 likelihood of adverse effects on fall-run Chinook Salmon in Clear Creek under  
16 Alternative 5 would likely be greater than under the Second Basis of Comparison.

17 *Feather River*

18 Average monthly water temperatures under both Alternative 5 and Second Basis  
19 of Comparison would exceed the water temperature threshold of 56°F established  
20 in the Feather River at Gridley Bridge for fall-run Chinook Salmon spawning and  
21 egg incubation during some months, particularly in October, November, March,  
22 and April, when temperature thresholds would be exceeded frequently  
23 (Appendix 9N). The frequency of exceedance would be greatest in October,  
24 when average monthly temperatures under both Alternative 5 and Second Basis of  
25 Comparison would be above the threshold in nearly every year. The magnitude of  
26 the exceedances would be high as well, with average monthly temperatures in  
27 October reaching about 68°F. Similarly, the threshold would be exceeded under  
28 both Alternative 5 and the Second Basis of Comparison about 85 percent of the  
29 time in April. The differences in threshold exceedance between Alternative 5 and  
30 Second Basis of Comparison, would be small, with water temperatures under  
31 Alternative 5 generally exceeding temperature thresholds about 1-2 percent more  
32 frequently than the Second Basis of Comparison during the October through April  
33 period. However, average monthly water temperatures likely mask daily  
34 temperatures excursions that could exceed important thresholds. Therefore, while  
35 the differences in threshold exceedance are relatively minor, the likelihood of  
36 adverse effects on fall-run Chinook Salmon in the Feather River under  
37 Alternative 5 would likely be greater than under the Second Basis of Comparison.

38 *Changes in Egg Mortality*

39 Water temperatures influence the viability of incubating fall-run Chinook Salmon  
40 eggs. The following describes the differences in egg mortality for the  
41 Sacramento, Feather, and American rivers.

1                    *Sacramento River*

2 For fall-run Chinook Salmon in the Sacramento River, the long-term average egg  
3 mortality rate is predicted to be around 17 percent, with higher mortality rates (in  
4 excess of 35 percent) occurring in critical dry years under Alternative 5. Overall,  
5 egg mortality would be similar under Alternative 5 and the Second Basis of  
6 Comparison (Appendix 9C, Table B-1).

7                    *Feather River*

8 For fall-run Chinook Salmon in the Feather River, the long-term average egg  
9 mortality rate is predicted to be relatively low (around 7 percent), with higher  
10 mortality rates (around 14 percent) occurring in critical dry years under  
11 Alternative 5. Overall, egg mortality would be similar under Alternative 5 and  
12 the Second Basis of Comparison (Appendix 9C, Table B-7).

13                    *American River*

14 For fall-run Chinook Salmon in the American River, the long-term average egg  
15 mortality rate is predicted to range from approximately 23 to 25 percent in all  
16 water year types under Alternative 5. Overall, egg mortality would be similar  
17 under Alternative 5 and the Second Basis of Comparison (Appendix 9C,  
18 Table B-6).

19                    *Changes in Weighted Usable Area*

20 Weighted usable area, which is influenced by flow, is a measure of habitat  
21 suitability. The following describes changes in WUA for fall-run Chinook  
22 Salmon in the Sacramento, Feather, and American rivers and Clear Creek.

23                    *Sacramento River*

24 As an indicator of the amount of suitable spawning habitat for fall-run Chinook  
25 Salmon between Keswick Dam and Battle Creek, modeling results indicate that,  
26 in general, there would be lesser amounts of spawning habitat available in  
27 September and November under Alternative 5 as compared to the Second Basis of  
28 Comparison (Appendix 9E, Table C-11-6). The decrease in long-term average  
29 spawning WUA during September (prior to the peak spawning period) would be  
30 relatively large (more than 20 percent), with a smaller decrease in November  
31 (around 6 percent). The latter month is during the peak spawning period for fall-  
32 run Chinook Salmon. Results for the reach from Battle Creek to Deer Creek  
33 show the same pattern for changes in WUA for spawning fall-run Chinook  
34 Salmon between Alternative 5 and the Second Basis of Comparison  
35 (Appendix 9E, Table C-10-6). Overall, spawning habitat availability would be  
36 slightly lower under Alternative 5 relative to the Second Basis of Comparison.

37 Modeling results indicate that, in general, there would be similar amounts of  
38 suitable fry rearing habitat available from December to March under Alternative 5  
39 and the Second Basis of Comparison (Appendix 9E, Table C-12-6). Similar to  
40 the results for fry rearing WUA, modeling results indicate that, there would be  
41 similar amounts of suitable juvenile rearing habitat available during the juvenile  
42 rearing period under Alternative 5 and the Second Basis of Comparison  
43 (Appendix 9E, Table C-13-6).

1 *Clear Creek*

2 As described above, flows in Clear Creek below Whiskeytown Dam are not  
3 anticipated to differ under Alternative 5 relative to the Second Basis of  
4 Comparison except in May due to the release of spring attraction flows in  
5 accordance with the 2009 NMFS BO. Therefore, there would be no change in the  
6 amount of potentially suitable spawning and rearing habitat for fall-run Chinook  
7 Salmon (as indexed by WUA) available under Alternative 5 as compared to the  
8 Second Basis of Comparison.

9 *Feather River*

10 As described above, Flows in the low flow channel of the Feather River are not  
11 anticipated to differ under Alternative 5 relative to the Second Basis of  
12 Comparison. Therefore, there would be no change in the amount of potentially  
13 suitable spawning habitat for fall-run Chinook Salmon (as indexed by WUA)  
14 available under Alternative 5 as compared to the Second Basis of Comparison.  
15 The majority of spawning activity by fall-run Chinook Salmon in the Feather  
16 River occurs in this reach with a lesser amount of spawning occurring  
17 downstream of the Thermalito Complex.

18 Modeling results indicate that, in general, there would be a lesser amount of  
19 spawning habitat available in September (20 percent less) and greater amounts of  
20 incubation habitat available in February (6 percent more) under Alternative 5 as  
21 compared to the Second Basis of Comparison; fall-run spawning WUA may be  
22 slightly (around 5 percent) increased in October (the peak spawning month) for  
23 fall-run Chinook Salmon in this reach (Appendix 9E, Table C-24-6). The  
24 decrease in long-term average spawning WUA during September would occur  
25 prior to the peak spawning period. Overall, spawning and incubation habitat  
26 availability would be similar under Alternative 5 relative to the Second Basis of  
27 Comparison.

28 *American River*

29 Modeling results indicate that, in general, there would be similar amounts of  
30 spawning habitat available for fall-run Chinook Salmon in the American River  
31 from October through December under Alternative 5 and the Second Basis of  
32 Comparison (Appendix 9E, Table C-25-6).

33 *Changes in SALMOD Output*

34 SALMOD results indicate that potential fall-run juvenile production would be  
35 similar under Alternative 5 and the Second Basis of Comparison, except in critical  
36 dry years when production could be 7 percent lower under Alternative 5 than  
37 under the Second Basis of Comparison (Appendix 9D, Table B-1-26).

38 *Changes in Delta Passage Model Output*

39 The Delta Passage Model predicted similar estimates of annual Delta survival  
40 across the 81 water year time period for Fall-run between Alternative 5 and the  
41 Second Basis of Comparison Alternative (Appendix 9J). Median Delta survival  
42 was 0.248 for Alternative 5 and 0.245 for the Second Basis of Comparison.  
43 Overall, there would be little change in through-Delta survival by emigrating

1 juvenile fall-run Chinook Salmon under Alternative 5 as compared to the Second  
2 Basis of Comparison.

3 *Changes in Delta Hydrodynamics*

4 Fall run Chinook salmon smolts are most abundant in the Delta during the months  
5 of April, May and June. At the junction of Georgiana Slough and the Sacramento  
6 River, the median proportion of positive velocities was slightly lower under  
7 Alternative 5 relative to the Second Basis of Comparison in May and June  
8 (Appendix 9K). The median proportion of positive velocities for Alternative 5  
9 was similar in April. Near the confluence of the San Joaquin River and the  
10 Mokelumne River, the median proportion of positive velocities was slightly to  
11 moderately higher under Alternative 5 relative to Second Basis of Comparison in  
12 April and May, respectively, whereas values in June were similar. On Old River  
13 downstream of the facilities, the median proportion of positive velocities was  
14 substantially higher in April and May and slightly higher in June under  
15 Alternative 5 relative to Second Basis of Comparison. In Old River upstream of  
16 the facilities, the median proportion of positive velocities was slightly higher  
17 under Alternative 5 April and May and slightly lower in June. On the San  
18 Joaquin River downstream of the Head of Old River, the median proportion of  
19 positive velocities was slightly to moderately lower under Alternative 5 relative to  
20 Second Basis of Comparison in April and May, respectively, and similar in June.

21 *Changes in Junction Entrainment*

22 At the junction of Georgiana Slough and the Sacramento River, median  
23 entrainment under Alternative 5 was slightly lower than the Second Basis of  
24 Comparison in June but essentially indistinguishable in all other months  
25 (Appendix 9L). Median entrainment at the Head of Old River junction was  
26 considerably higher under Alternative 5 relative to Second Basis of Comparison  
27 during the months of April and May and slightly lower in June. For the Turner  
28 Cut junction, median entrainment under Alternative 5 was moderately lower in  
29 April and May relative to Second Basis of Comparison and slightly lower in June.  
30 At the Columbia Cut junction, median entrainment under Alternative 5 was  
31 slightly lower in June relative to the Second Basis of Comparison. Median  
32 entrainment was substantially lower under Alternative 5 relative to Second Basis  
33 of Comparison in April and May. A similar pattern of entrainment under  
34 Alternative 5 relative to Second Basis of Comparison was observed at the Middle  
35 River and Old River junctions.

36 *Changes in Salvage*

37 Salvage of Sacramento River-origin fall run was predicted to be substantially  
38 lower under Alternative 5 relative to the Second Basis of Comparison in April and  
39 May (Appendix 9M). During the month of June, salvage was moderately lower  
40 under Alternative 5.

41 *Summary of Effects on Fall-Run Chinook Salmon*

42 The multiple model and analysis outputs described above characterize the  
43 anticipated conditions for fall-run Chinook Salmon and their response to change  
44 under Alternative 5 as compared to the Second Basis of Comparison. For the

1 purpose of analyzing effects on fall-run Chinook Salmon in the Sacramento River,  
2 greater reliance was placed on the outputs from the SALMOD model because it  
3 integrates the available information on water temperature and flows to produce  
4 estimates of mortality for each life stage and an overall, integrated estimate of  
5 potential fall-run Chinook Salmon juvenile production. The output from  
6 SALMOD indicated that fall-run Chinook Salmon production would be similar  
7 under Alternative 5 and the Second Basis of Comparison, except in critical  
8 dry years.

9 In Clear Creek and the Feather and American rivers, the analysis of the effects of  
10 Alternative 5 and Second Basis of Comparison for fall-run Chinook Salmon relied  
11 on the water temperature model output for the rivers at various locations  
12 downstream of the CVP and SWP facilities. The analysis of temperatures  
13 indicates similar temperatures and slightly greater likelihood of exceedance of  
14 thresholds under Alternative 5 as compared to the Second Basis of Comparison in  
15 the Feather River. There would be little change in flows or temperatures in Clear  
16 Creek under Alternative 5 relative to the Second Basis of Comparison. The effect  
17 of slightly increased temperatures is not reflected in the similar overall survival of  
18 fall-run Chinook Salmon eggs predicted by Reclamation's salmon mortality  
19 model for fall-run in the Feather and American rivers. In drier years, the  
20 likelihood of adverse temperature effects would be increased under Alternative 5  
21 as compared to the Second Basis of Comparison.

22 Flow changes under Alternative 5 would likely have small effects on the  
23 availability of spawning and rearing habitat for fall-run Chinook Salmon in the  
24 Sacramento River system as indicated by the similarity in spawning WUA in the  
25 Sacramento, Feather, and American rivers under Alternative 5 and the Second  
26 Basis of Comparison. Fry and juvenile rearing WUA would be similar in the  
27 Sacramento River and this is reflected in the similarity in flow (habitat)-related  
28 mortality predicted by SALMOD under Alternative 5.

29 Through-Delta survival of juvenile fall-run Chinook Salmon would be similar  
30 under both Alternative 5 and Second Basis of Comparison as indicated by the  
31 DPM results and entrainment could be reduced as indicated by the OMR flow  
32 analysis. Overall, Alternative 5 likely would have similar or slightly greater  
33 adverse effects on the fall-run Chinook Salmon population in the Sacramento  
34 River watershed as compared to the Second Basis of Comparison, particularly in  
35 drier water year types.

36 Additional actions implemented under Alternative 5 could help improve  
37 conditions for fall-run Chinook Salmon relative to the Second Basis of  
38 Comparison, such as structural improvements for temperature management in the  
39 American River and actions intended to increase the efficiency of the Tracy and  
40 Skinner Fish Collection Facilities to improve the overall salvage survival of  
41 salmonids, including fall-run Chinook Salmon. The implementation of fish  
42 passage under Alternative 5 intended to address the limited availability of suitable  
43 habitat for winter-run and spring-run Chinook Salmon in the Sacramento River  
44 reaches downstream of Shasta Dam is unlikely to benefit fall-run Chinook  
45 Salmon unless passage is provided for adult fall-run Chinook Salmon. The

1 effects of providing similar fish passage at Folsom Dam would also be uncertain  
2 for the same reason.

3 Overall, the results of the numerical models suggest the potential for greater  
4 adverse effects on fall-run Chinook Salmon under Alternative 5 as compared to  
5 the Second Basis of Comparison. However, discerning a meaningful difference  
6 between these two scenarios based on the quantitative results is difficult because  
7 of the similarity in results (generally differences less than 5 percent), the inherent  
8 uncertainty of the models, and the potential for offsetting benefits. Thus, it is  
9 concluded that the effects on fall-run Chinook Salmon would be similar under  
10 Alternative 5 and the Second Basis of Comparison.

#### 11 *Late Fall-Run Chinook Salmon*

12 Changes in operations that influence temperature and flow conditions in the  
13 Sacramento River downstream of Keswick Dam could affect late fall-run Chinook  
14 Salmon. The following describes those changes and their potential effects.

#### 15 *Changes in Water Temperature*

16 Monthly water temperature in the Sacramento River at Keswick Dam under  
17 Alternative and the Second Basis of Comparison generally would be similar  
18 (differences less than 0.5°F). Average monthly water temperatures in September  
19 under Alternative 5 would be lower (up to 0.9°F) in wetter years and higher (up to  
20 1.2°F) in drier years. Similarly, water temperatures in October of critical years  
21 could be 0.9°F warmer under Alternative 5. A similar temperature pattern  
22 generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry, Bend  
23 Bridge and Red Bluff, with average monthly temperatures in September  
24 progressively increasing (up to 3.2°F cooler at Red Bluff) during the wetter years.

#### 25 *Changes in Exceedances of Water Temperature Thresholds*

26 Average monthly water temperatures under both Alternative 5 and Second Basis  
27 of Comparison would exceed the water temperature threshold of 56°F established  
28 in the Sacramento River at Red Bluff during some months, particularly in  
29 October, November, and April. The frequency of exceedance would be greatest  
30 in October, a month in which average monthly water could get as high as about  
31 64°F. In October, average monthly water temperatures under Alternative 5 and  
32 Second Basis of Comparison would exceed the threshold 80 percent and  
33 79 percent of the time, respectively. Water temperatures under Alternative 5  
34 would exceed temperature thresholds about 2 percent more frequently than under  
35 the Second Basis of Comparison in October, 1 percent less frequently in  
36 November, and 1 percent more frequently in April.

#### 37 *Changes in Egg Mortality*

38 For late fall-run Chinook Salmon in the Sacramento River, the long-term average  
39 egg mortality rate is predicted to range from approximately 2.4 to nearly 5 percent  
40 in all water year types under Alternative 5. Overall, egg mortality would be  
41 similar under Alternative 5 and the Second Basis of Comparison (Appendix 9C,  
42 Table B-2).

1            *Changes in Weighted Usable Area*

2     Modeling results indicate that there would be similar amounts of spawning habitat  
3     available for late fall-run Chinook Salmon in the Sacramento River from January  
4     through April under Alternative 5 and the Second Basis of Comparison  
5     (Appendix 9E, Table C-14-6). Modeling results indicate that, in general, there  
6     would be similar amounts of suitable late fall-run Chinook Salmon fry rearing  
7     habitat available under Alternative 5 and the Second Basis of Comparison  
8     (Appendix 9E, Table C-15-6).

9     A substantial fraction of late fall run Chinook Salmon juveniles oversummer in  
10    the Sacramento River before emigrating, which allows them to avoid predation  
11    through both their larger size and greater swimming ability. One implication of  
12    this life history strategy is that rearing habitat is most likely the limiting factor for  
13    late-fall-run Chinook Salmon, especially if availability of cool water determines  
14    the downstream extent of spawning habitat for late-fall-run salmon. Modeling  
15    results indicate that, there would be reduced amounts of suitable juvenile rearing  
16    habitat available in September (12 percent less) and November (8 percent less  
17    under Alternative 5 as compared to the Second Basis of Comparison. In other  
18    months the amount the amount of late fall-run Chinook Salmon juvenile rearing  
19    WUA would be similar under Alternative 5 and the Second Basis of Comparison  
20    (Appendix 9E, Table C-16-6).

21           *Changes in SALMOD Output*

22    SALMOD results indicate that potential juvenile production would be similar  
23    under Alternative 5 and the Second Basis of Comparison (Appendix 9D,  
24    Table B-2-26).

25           *Changes in Delta Passage Model Output*

26    For Late-Fall-Run, Delta survival was predicted to be slightly higher for  
27    Alternative 5 versus the Second Basis of Comparison for all 81 water years  
28    simulated by the Delta Passage Model (Appendix 9J). Median Delta survival  
29    across all years was 0.243 for Alternative 5 and 0.199 for the Second Basis of  
30    Comparison. Overall, there would be a slight increase in through-Delta survival  
31    for emigrating juvenile late fall-run Chinook Salmon under Alternative 5 as  
32    compared to the Second Basis of Comparison.

33           *Changes in Delta Hydrodynamics*

34    The late fall-run Chinook migration period overlaps with that of winter-run  
35    Chinook Salmon and they are most abundant in the Delta during the months of  
36    January February and March. On the Sacramento River near the confluence of  
37    Georgiana Slough, the median proportion of positive velocities under  
38    Alternative 5 was indistinguishable from the Second Basis of Comparison in  
39    January, February and March (Appendix 9K). On the San Joaquin River near the  
40    Mokelumne River confluence, the median proportion of positive velocities was  
41    slightly greater under Alternative 5 relative to Second Basis of Comparison in  
42    January and February and similar in March. In Old River downstream of the  
43    facilities, the median proportion of positive velocities was substantially higher  
44    under Alternative 5 during January and moderately higher in February. Values in

1 March were almost indistinguishable between scenarios. On Old River upstream  
2 of the facilities, the median proportion of positive velocities was moderately  
3 lower in January and February and slightly lower in March under Alternative 5  
4 relative to Second Basis of Comparison. On the San Joaquin River downstream  
5 of Head of Old River, the median proportion of positive velocities was similar for  
6 both scenarios in January, February and March.

#### 7 *Changes in Junction Entrainment*

8 At the junction of Georgiana Slough and the Sacramento River, median  
9 entrainment under Alternative 5 and the Second Basis of Comparison in January  
10 was essentially indistinguishable in January, February and March (Appendix 9L).  
11 Entrainment at the Head of Old River junction was similar to slightly lower under  
12 Alternative 5 relative to Second Basis of Comparison. For the Turner Cut  
13 junction, median entrainment under Alternative 5 was slightly lower in January  
14 and February relative to Second Basis of Comparison. In March, the difference in  
15 entrainment between scenarios was similar. At the Columbia Cut, Middle River  
16 and Old River junctions, patterns in entrainment between Alternative 5 and the  
17 Second Basis of Comparison were similar. At these junctions, entrainment was  
18 moderately lower under Alternative 5 during January and February and values  
19 were more similar in March.

#### 20 *Changes in Salvage*

21 Salvage of late fall-run Chinook salmon is predicted to be substantially lower  
22 under Alternative 5 relative to the Second Basis of Comparison in January and  
23 February (Appendix 9M). In March salvage was only moderately lower under  
24 Alternative 5 relative to Second Basis of Comparison.

#### 25 *Summary of Effects on Late Fall-Run Chinook Salmon*

26 The multiple model and analysis outputs described above characterize the  
27 anticipated conditions for late fall-run Chinook Salmon and their response to  
28 change under Alternative 5 as compared to the Second Basis of Comparison. For  
29 the purpose of analyzing effects on late fall-run Chinook Salmon in the  
30 Sacramento River, greater reliance was placed on the outputs from the SALMOD  
31 model because it integrates the available information on temperature and flows to  
32 produce estimates of mortality for each life stage and an overall, integrated  
33 estimate of potential late fall-run Chinook Salmon juvenile production. The  
34 output from SALMOD indicated that late fall-run Chinook Salmon production  
35 would be similar under Alternative 5 and the Second Basis of Comparison. The  
36 analyses attempting to assess the effects on routing, entrainment, and salvage of  
37 juvenile salmonids in the Delta suggest that salvage (as an indicator of potential  
38 losses of juvenile salmon at the export facilities) of Sacramento River-origin  
39 Chinook Salmon is predicted to be lower under Alternative 5 relative to the  
40 Second Basis of Comparison in every month.

41 These model results suggest that overall, Alternative 5 is likely to have less  
42 adverse effect on late fall-run Chinook Salmon in the Sacramento River as  
43 compared to the Second Basis of Comparison. Potential benefits may be  
44 enhanced under Alternative 5 by actions intended to increase the efficiency of the

1 Tracy and Skinner Fish Collection Facilities to improve the overall salvage  
2 survival of salmonids, including late fall-run Chinook Salmon. Thus, it is  
3 concluded that the potential for adverse effects on late fall-run Chinook Salmon  
4 would be less under Alternative 5 relative to the Second Basis of Comparison.

5 *Steelhead*

6 Changes in operations that influence temperature and flow conditions that could  
7 affect steelhead. The following describes those changes and their potential  
8 effects.

9 *Changes in Water Temperature*

10 Changes in water temperature could affect steelhead in the Sacramento, Feather,  
11 and American rivers, and Clear Creek. The following describes temperature  
12 conditions in those water bodies.

13 *Sacramento River*

14 Monthly water temperature in the Sacramento River at Keswick Dam under  
15 Alternative 5 and the Second Basis of Comparison generally would be similar  
16 (differences less than 0.5°F). Average monthly water temperatures in September  
17 under Alternative 5 would be lower (up to 0.9°F) in wetter years and higher (up to  
18 1.2°F) in drier years. Similarly, water temperatures in October of critical years  
19 could be 0.9°F warmer under Alternative 5. A similar temperature pattern  
20 generally would be exhibited downstream at Ball's Ferry, Jelly's Ferry, Bend  
21 Bridge and Red Bluff, with average monthly temperatures in September  
22 progressively increasing (up to 3.2°F cooler at Red Bluff) during the wetter years  
23 (Appendix 6B, Table B-9-6).

24 *Clear Creek*

25 Average monthly water temperatures in Clear Creek at Igo under  
26 Alternative relative to the Second Basis of Comparison are generally predicted to  
27 be similar (less than 0.5°F differences) (Appendix 6B, Table B-3-6). Average  
28 monthly water temperatures during May under Alternative 5 would be up to 0.8°F  
29 lower than under the Second Basis of Comparison in all but critical water years.

30 *Feather River*

31 Long-term average monthly water temperature in the Feather River at the low  
32 flow channel under Alternative 5 relative to the Second Basis of Comparison  
33 generally would be similar (less than 0.5°F differences). Water temperatures  
34 could be up to 1.5°F warmer in November and December of some water year  
35 types and up to 1.2°F cooler in September of wetter years. Although temperatures  
36 in the river would become progressively higher in the downstream direction, the  
37 differences between Alternative 5 and Second Basis of Comparison exhibit a  
38 similar pattern at the downstream locations (Robinson Riffle and Gridley Bridge),  
39 with water temperature differences under Alternative 5 generally increasing in  
40 most water year types relative to the Second Basis of Comparison at the  
41 confluence with Sacramento. Water temperatures under Alternative 5 could be  
42 somewhat (0.8°F to 1.6°F) cooler on average and up to 3.9°F cooler (September)  
43 at the confluence with Sacramento River from July to September in wetter years.

1 *American River*

2 Average monthly water temperatures in the American River at Nimbus Dam  
 3 under Alternative 5 generally would be similar (differences less than 0.5°F) to the  
 4 Second Basis of Comparison, with the exception of during June and August of  
 5 below normal years, when temperatures under Alternative 5 could be as much as  
 6 0.9°F higher. This pattern generally would persist downstream to Watt Avenue  
 7 and the mouth, although temperatures under Alternative 5 would be up to 1.6°F  
 8 and 2.1°F higher, respectively, than under the Second Basis of Comparison in  
 9 June. In addition, average monthly water temperatures at the mouth generally  
 10 would be lower than the Second Basis of Comparison in September, especially in  
 11 wetter water year types when Alternative 5 could be up to 1.7°F cooler.

12 *Changes in Exceedances of Water Temperature Thresholds*

13 Changes in water temperature could result in the exceedance of established water  
 14 temperature thresholds for steelhead in the Sacramento River, Clear Creek, and  
 15 Feather River. The following describes the extent of those exceedance for each of  
 16 those streams.

17 *Sacramento River*

18 As described in the life history accounts (Appendix), steelhead spawning in the  
 19 mainstem Sacramento River generally occurs in the upper reaches from Keswick  
 20 Dam downstream to near Balls Ferry, with most spawning concentrated near  
 21 Redding. Most steelhead, however, spawn in tributaries to the Sacramento River.  
 22 Spawning generally takes place in the January through March period when water  
 23 temperatures in the river generally do not exceed 52°F under either Alternative 5  
 24 or Second Basis of Comparison. While there are no established temperature  
 25 thresholds for steelhead rearing in the mainstem Sacramento River, average  
 26 monthly temperatures when fry and juvenile steelhead are in the river would  
 27 generally remain below 56°F at Balls Ferry except in August and September  
 28 when this temperature would be exceeded at least 40 percent of the time under  
 29 both the No Action Alternative and Second Basis of Comparison. However,  
 30 water temperatures in the Sacramento River at Balls Ferry would exceed 56°F  
 31 about 10 percent more often in September under the Second Basis of Comparison  
 32 compared to Alternative 5. Overall, thermal conditions for steelhead in the  
 33 Sacramento River would be similar under Alternative 5 and the Second Basis of  
 34 Comparison.

35 *Clear Creek*

36 While there are no established temperature thresholds for steelhead spawning in  
 37 Clear Creek, average monthly water temperatures in the river generally would not  
 38 exceed 48°F during the spawning period (December to April) under either  
 39 Alternative 5 or Second Basis of Comparison. Similarly, while there are no  
 40 established temperature thresholds for steelhead rearing in Clear Creek, average  
 41 monthly temperatures in throughout the year would not exceed 56°F at Igo.  
 42 Overall, thermal conditions for steelhead in Clear Creek would be similar under  
 43 Alternative 5 and the Second Basis of Comparison.

1                    *Feather River*

2 Average monthly water temperatures under both Alternative 5 and the Second  
3 Basis of Comparison would on occasion exceed the water temperature threshold  
4 of 56°F established in the Feather River at Robinson Riffle for steelhead  
5 spawning and incubation during some months, particularly in October and  
6 November, and March and April, when temperature thresholds could be exceeded  
7 frequently (Appendix 9N). There would be a 1 percent exceedance of the 56°F  
8 threshold in December and no exceedances of the 56°F threshold in January and  
9 February under both Alternative 5 and the Second Basis of Comparison.  
10 However, the differences in the frequency of exceedance between Alternative 5  
11 and Second Basis of Comparison during March and April would be relatively  
12 small with water temperatures under Alternative 5 exceeding the threshold about  
13 1 percent more frequently in March and the same exceedance frequency  
14 (75 percent) as the Second Basis of Comparison in April.

15 The established water temperature threshold of 63°F for rearing from May  
16 through August would be exceeded often under both Alternative 5 and Second  
17 Basis of Comparison in May and June, but not at all in July and August. Water  
18 temperatures under Alternative 5 would exceed the rearing temperature threshold  
19 about 6 percent more frequently than under the Second Basis of Comparison in  
20 May, but no more frequently in June. Temperature conditions in the Feather  
21 River under Alternative 5 could be more likely to result in adverse effects on  
22 steelhead spawning and rearing than under the Second Basis of Comparison  
23 because of the slightly increased frequency of exceedance of the 56°F spawning  
24 threshold in March and the somewhat increased frequency of exceedance of the  
25 63°F rearing threshold in May.

26                    *American River*

27 In the American River, the water temperature threshold for steelhead rearing  
28 (May through October) is 65°F at the Watt Avenue Bridge. Average monthly  
29 water temperatures would exceed this threshold often under both Alternative 5  
30 and Second Basis of Comparison, especially in the July through September period  
31 when the threshold is exceeded nearly all of the time. In addition, the magnitude  
32 of the exceedance would be high, with average monthly water temperatures  
33 sometimes higher than 76°F. The differences in exceedance frequency between  
34 Alternative 5 and Second Basis of Comparison, however, would be relatively  
35 small (differences within 1 percent), except in September, when average monthly  
36 water temperatures under Alternative 5 would exceed 65°F about 6 percent less  
37 frequently than under the Second Basis of Comparison. Temperature conditions  
38 in the American River under Alternative 5 could increase the likelihood of  
39 adverse effects on steelhead rearing than under the Second Basis of Comparison  
40 because of the increased frequency of exceedance of the 65°F rearing threshold in  
41 some months.

42                    *Changes in Weighted Usable Area*

43 The following describes changes in WUA for steelhead in the Sacramento,  
44 Feather, and American rivers and Clear Creek.

1 *Sacramento River*

2 Modeling results indicate that, in general, there would be similar amounts of  
3 suitable steelhead spawning habitat available from December through March  
4 under Alternative 5 as compared to the Second Basis of Comparison  
5 (Appendix 9E, Table C-20-6).

6 *Clear Creek*

7 As described above, flows in Clear Creek below Whiskeytown Dam are not  
8 anticipated to differ under Alternative 5 relative to the Second Basis of  
9 Comparison except in May due to the release of spring attraction flows in  
10 accordance with the 2009 NMFS BO. Therefore, there would be no change in the  
11 amount of potentially suitable spawning and rearing habitat for steelhead (as  
12 indexed by WUA) available under Alternative 5 as compared to the Second Basis  
13 of Comparison.

14 *Feather River*

15 As described above, Flows in the low flow channel of the Feather River are not  
16 anticipated to differ under Alternative 5 relative to the Second Basis of  
17 Comparison. Therefore, there would be no change in the amount of potentially  
18 suitable spawning habitat for steelhead (as indexed by WUA) available under  
19 Alternative 5 as compared to the Second Basis of Comparison. The majority of  
20 spawning activity by steelhead in the Feather River occurs in this reach with a  
21 lesser amount of spawning occurring downstream of the Thermalito Complex.

22 Modeling results indicate that, in general, there would be similar amounts of  
23 spawning habitat for steelhead in the Feather River below Thermalito available  
24 from December through April under Alternative 5 and the Second Basis of  
25 Comparison.

26 *American River*

27 Modeling results indicate that, in general, there would be similar amounts of  
28 spawning habitat for steelhead in the American River downstream of Nimbus  
29 Dam available from December through April under Alternative 5 and the Second  
30 Basis of Comparison.

31 *Changes in Delta Hydrodynamics*

32 Sacramento River-origin steelhead generally move through the Delta during  
33 spring however there is less information on their timing relative to Chinook  
34 salmon. Thus, hydrodynamics in the entire January through June period have the  
35 potential to affect juvenile steelhead.

36 On the Sacramento River near the confluence of Georgiana Slough, the median  
37 proportion of positive velocities under Alternative 5 was moderately lower  
38 relative to the Second Basis of Comparison from January to April and slightly  
39 lower in May and June (Appendix 9K). On the San Joaquin River near the  
40 Mokelumne River confluence, the median proportion of positive velocities was  
41 slightly greater under Alternative 5 relative to Second Basis of Comparison in  
42 January, February, April and May and similar in March and June. In Old River  
43 downstream of the facilities, the median proportion of positive velocities was  
44 substantially higher under Alternative 5 during January, April, and May and

1 moderately higher in February. Values in March and June were almost  
2 indistinguishable between scenarios. On Old River upstream of the facilities, the  
3 median proportion of positive velocities was moderately lower in January and  
4 February, slightly lower March and June, and slightly higher in April and May  
5 under Alternative 5 relative to Second Basis of Comparison. On the San Joaquin  
6 River downstream of Head of Old River, the median proportion of positive  
7 velocities was similar for both scenarios in January, February, March and June,  
8 but slightly to moderately lower in April and May.

9 *Summary of Effects on Steelhead*

10 The multiple model and analysis outputs described above characterize the  
11 anticipated conditions for steelhead and their response to change under  
12 Alternative 5 as compared to the Second Basis of Comparison. The analysis of  
13 the effects of Alternative and Second Basis of Comparison for steelhead relied on  
14 the WUA analysis for habitat and water temperature model output for the rivers at  
15 various locations downstream of the CVP and SWP facilities. The WUA analysis  
16 indicated that the availability of steelhead spawning and rearing habitat in Clear  
17 Creek and steelhead spawning habitat in the Sacramento, Feather and American  
18 rivers would be similar under Alternative 5 and the Second Basis of Comparison.  
19 The analysis of temperatures indicates somewhat higher temperatures and greater  
20 likelihood of exceedance of thresholds under Alternative 5 as compared to the  
21 Second Basis of Comparison in the Sacramento and Feather rivers. In drier years,  
22 the likelihood of adverse temperature effects would be increased under  
23 Alternative 5 as compared to the Second Basis of Comparison. There would be  
24 little change in flows or temperatures in Clear Creek under Alternative 5 relative  
25 to the Second Basis of Comparison.

26 These numerical model results suggest that overall, effects on steelhead could be  
27 slightly more adverse under Alternative 5 than under the Second Basis of  
28 Comparison, particularly in the Feather and American rivers. However,  
29 implementation of a fish passage program under Alternative 5 intended to address  
30 the limited availability of suitable habitat for steelhead in the Sacramento River  
31 reaches downstream of Keswick Dam and in the American River could provide a  
32 benefit to Central Valley steelhead in the Sacramento and American rivers. This  
33 is particularly important in light of anticipated increases in water temperature  
34 associated with climate change in 2030. In addition to fish passage, preparation  
35 and implementation of an HGMP for steelhead at the Nimbus Fish Hatchery and  
36 actions under Alternative 5 intended to increase the efficiency of the Tracy and  
37 Skinner Fish Collection Facilities could benefit steelhead under Alternative 5 in  
38 comparison to the Second Basis of Comparison. Thus, on balance and over the  
39 long term, the adverse effects on steelhead under Alternative 5 would be less than  
40 those under the Second Basis of Comparison.

41 *Green Sturgeon*

42 Changes in operations that influence temperature and flow conditions could affect  
43 Green Sturgeon. The following describes those changes and their potential  
44 effects.

1                    *Changes in Water Temperature*

2    Changes in water temperature could affect Green Sturgeon in the Sacramento and  
3    Feather rivers. The following describes temperature conditions in those water  
4    bodies.

5                    *Sacramento River*

6    Monthly water temperature in the Sacramento River at Keswick Dam under  
7    Alternative and the Second Basis of Comparison generally would be similar  
8    (differences less than 0.5°F). Average monthly water temperatures in September  
9    under Alternative 5 would be lower (up to 0.9°F) in wetter years and higher (up to  
10    1.2°F) in drier years. Similarly, water temperatures in October of critical years  
11    could be 0.9°F warmer under Alternative 5. (Appendix 6B). A similar pattern in  
12    temperatures generally would be exhibited at downstream locations along the  
13    Sacramento River (i.e., Ball's Ferry Jelly's Ferry, Bend Bridge, Red Bluff,  
14    Hamilton City, and Knights Landing), with differences in average monthly  
15    temperatures at Knights Landing progressively increasing (up to 1.0°F warmer) in  
16    June and up to up to 4.6°F cooler in September of wetter years under  
17    Alternative 5 relative to the Second Basis of Comparison.

18                   *Feather River*

19    Long-term average monthly water temperature in the Feather River at the low  
20    flow channel under Alternative 5 relative to the Second Basis of Comparison  
21    generally would be similar (less than 0.5°F differences). Water temperatures  
22    could be up to 1.5°F warmer in November and December of some water year  
23    types and up to 1.2°F cooler in September of wetter years. Although temperatures  
24    in the river would become progressively higher in the downstream direction, the  
25    differences between Alternative 5 and Second Basis of Comparison exhibit a  
26    similar pattern at the downstream locations (Robinson Riffle and Gridley Bridge),  
27    with water temperature differences under Alternative 5 generally increasing in  
28    most water year types relative to the Second Basis of Comparison at the  
29    confluence with Sacramento. Water temperatures under Alternative 5 could be  
30    somewhat (0.8°F to 1.6°F) cooler on average and up to 3.9°F cooler (September)  
31    at the confluence with Sacramento River from July to September in wetter years.

32                   *Changes in Exceedances of Water Temperature Thresholds*

33    Changes in water temperature could result in the exceedance of established water  
34    temperature thresholds for Green Sturgeon in the Sacramento and Feather rivers.  
35    The following describes the extent of those exceedance for each of those rivers.

36                   *Sacramento River*

37    Average monthly water temperatures in the Sacramento River at Bend Bridge  
38    under both Alternative 5 and Second Basis of Comparison would exceed the  
39    water temperature threshold of 63°F established for Green Sturgeon larval rearing  
40    in August and September, with exceedances under Alternative 5 occurring about  
41    7 percent of the time in August and about 12 percent of the time in September.  
42    This is 1 to 2 percent more frequently than under the Second Basis of  
43    Comparison. Average monthly water temperatures at Bend Bridge could be as  
44    high as about 73°F during this period. Temperature conditions in the Sacramento

1 River under Alternative 5 could be more likely to result in adverse effects on  
2 Green Sturgeon rearing than under the Second Basis of Comparison because of  
3 the slightly increased frequency of exceedance of the 63°F threshold in August  
4 and September.

5 *Feather River*

6 Average monthly water temperatures in the Feather River at Gridley Bridge under  
7 both Alternative 5 and Second Basis of Comparison would exceed the water  
8 temperature threshold of 64°F established for Green Sturgeon spawning,  
9 incubation, and rearing in May, June, and September; no exceedances under either  
10 scenarios would occur in July and August. The frequency of exceedances would  
11 be high, with both Alternative 5 and Second Basis of Comparison exceeding the  
12 threshold in June nearly 100 percent of the time. The magnitude of the  
13 exceedance also would be substantial, with average monthly temperatures higher  
14 than 72°F in June, and higher than 75°F in July and August. Water temperatures  
15 under Alternative 5 would exceed the threshold about 7 percent more frequently  
16 in May than under the Second Basis of Comparison and about 33 percent less  
17 frequently in September. Temperature conditions in the Feather River under  
18 Alternative 5 could be more likely to result in adverse effects on Green Sturgeon  
19 rearing than under the Second Basis of Comparison because of the increased  
20 frequency of exceedance of the 64°F threshold in May. The reduction in  
21 exceedance frequency in September may have less effect on rearing Green  
22 Sturgeon as many juvenile sturgeon may have migrated downstream to the lower  
23 Sacramento River and Delta by this time.

24 *Changes in Delta Outflow*

25 As described in Appendix 9P, mean (March to July) Delta outflow was used an  
26 indicator of potential year class strength and the likelihood of producing a strong  
27 year class of sturgeon. The median value over the 82-year CalSim II modeling  
28 period of mean (March to July) Delta outflow was predicted to be 16 percent  
29 higher under Alternative 5 than under the Second Basis of Comparison. In  
30 addition, the likelihood of mean (March to July) Delta outflow exceeding the  
31 threshold of 50,000 cfs was the same under both alternatives.

32 *Summary of Effects on Green Sturgeon*

33 The temperature threshold analysis in the Sacramento and Feather rivers both  
34 suggest that average monthly water temperatures under Alternative 5 would  
35 exceed thresholds for Green Sturgeon more frequently than under the Second  
36 Basis of Comparison, although the frequency of exceedance would be relatively  
37 small (1-2 percent). However, average monthly water temperatures likely mask  
38 daily temperatures excursions that could exceed important thresholds. Therefore,  
39 while the differences in threshold exceedance are relatively minor, the likelihood  
40 of adverse effects on Green Sturgeon under Alternative 5 would likely be greater  
41 than under the Second Basis of Comparison. The analysis based on Delta  
42 outflows suggests that Alternative 5 provides higher mean (March to July)  
43 outflows which could result in stronger year classes of juvenile sturgeon relative  
44 to the Second Basis of Comparison. However, early life stage survival in the

1 natal rivers is crucial in development of a strong year class; therefore, based  
2 primarily on the analysis of water temperatures, Alternative 5 could be more  
3 likely to result in adverse effects on Green Sturgeon than the Second Basis of  
4 Comparison.

#### 5 *White Sturgeon*

6 Changes in water temperature conditions in the Sacramento and Feather rivers  
7 would be the same as those described above for Green Sturgeon.

8 The water temperature threshold established for White Sturgeon spawning and  
9 egg incubation in the Sacramento River at Hamilton City is 61°F from March  
10 through June. Although there would be no exceedances of the threshold in March  
11 and April, water temperatures under both Alternative 5 and Second Basis of  
12 Comparison would exceed this threshold in May and June. The average monthly  
13 water temperatures in May under Alternative 5 would exceed this threshold about  
14 56 percent of the time (about 7 percent more frequently than under the Second  
15 Basis of Comparison). In June, the temperature under Alternative 5 would exceed  
16 the threshold about 87 percent of the time (about 13 percent more frequently than  
17 the Second Basis of Comparison). Average monthly water temperatures during  
18 May and June under Alternative 5 would as high as about 65°F.

19 Changes in Delta outflows would be the same as those described above for Green  
20 Sturgeon. Mean (March to July) Delta outflow was predicted to be 13 percent  
21 higher under the No Action Alternative than under the Second Basis of  
22 Comparison. In addition, the likelihood of mean (March to July) Delta outflow  
23 exceeding the threshold of 50,000 cfs was the same under both alternatives.

#### 24 *Summary of Effects on White Sturgeon*

25 The increased frequency of exceedance of water temperature thresholds under  
26 Alternative 5 could increase the potential for adverse effects on White Sturgeon  
27 relative to the Second Basis of Comparison. The analysis based on Delta  
28 outflows suggests that the No Action Alternative provides higher mean (March to  
29 July) outflows which could result in stronger year classes of juvenile sturgeon  
30 relative to the Second Basis of Comparison. However, early life stage survival in  
31 the natal rivers is crucial in development of a strong year class; therefore, based  
32 primarily on the analysis of water temperatures, Alternative could be more likely  
33 to result in adverse effects on White Sturgeon than the Second Basis of  
34 Comparison.

#### 35 *Delta Smelt*

36 The potential effects of the No Action Alternative as compared to the Second  
37 Basis of Comparison were analyzed based on differences in proportional  
38 entrainment and the fall abiotic index as described below.

39 As described in Appendix 9G, a proportional entrainment regression model  
40 (based on Kimmerer 2008, 2011) was used to simulate adult Delta Smelt  
41 entrainment, as influenced by OMR flow in December through March. Results  
42 indicate that the percentage of entrainment of migrating and spawning adult Delta  
43 Smelt under Alternative 5 would be 7 to 8.3 percent, depending on the water year

1 type, with a long-term average percent entrainment of 7.6 percent. Percent  
2 entrainment of adult Delta Smelt under Alternative 5 would be similar to results  
3 under Second Basis of Comparison. Under the Second Basis of Comparison, the  
4 long-term average entrainment would be 9 percent.

5 A proportional entrainment regression model (based on Kimmerer 2008) also was  
6 used to simulate larval and early juvenile Delta Smelt entrainment, as influenced  
7 by OMR flow and location of X2 in March through June. Results indicate that  
8 the percentage of entrainment of larval and early juvenile Delta Smelt under  
9 Alternative 5 would be 1.3 to 19.3 percent, depending on the water year type, with  
10 a long term average percent entrainment of 8.6 percent, and highest entrainment  
11 under Critical water year conditions. Percent entrainment of larval and early  
12 juvenile Delta Smelt under Alternative 5 would be lower than results under the  
13 Second Basis of Comparison by up to 9.4 percent. Under the Second Basis of  
14 Comparison, the long-term average percent entrainment would be 15.5 percent,  
15 and highest entrainment would occur under critical dry water year conditions, at  
16 23.6 percent.

17 The predicted position of Fall X2 (in September through December) is used as an  
18 indicator of fall abiotic habitat index for Delta Smelt. Feyrer et al. (2010) used  
19 X2 location as an indicator of the extent of habitat available with suitable salinity  
20 for the rearing of older juvenile Delta Smelt. Feyrer et al. (2010) concluded that  
21 when X2 is located downstream (west) of the confluence of the Sacramento and  
22 San Joaquin Rivers, at a distance of 70 to 80 km from the Golden Gate Bridge,  
23 there is a larger area of suitable habitat. The overlap of the low salinity zone (or  
24 X2) with the Suisun Bay/Marsh results in a two-fold increase in the habitat index  
25 (Feyrer et al. 2010).

26 The average September through December X2 position in km was used to  
27 evaluate the fall abiotic habitat availability for Delta Smelt under the Alternatives.  
28 X2 values simulated in the CalSim II model for each Alternative were averaged  
29 over September through December, and compared. Results indicate that under  
30 the No Action Alternative, the X2 position would range from 75.8 km to 92.3 km,  
31 depending on the water year type, with a long term average X2 position of 84 km.  
32 The most eastward location of X2 is predicted under Critical water year  
33 conditions. The X2 positions predicted under Alternative 5 would be similar to  
34 results under the Second Basis of Comparison in drier water year types. In wetter  
35 years, the X2 location would be further west under Alternative 5 than under the  
36 Second Basis of Comparison, by 6.1 to 9.8 km.

37 Overall, Alternative 5 likely would result in better conditions for Delta Smelt than  
38 would the Second Basis of Comparison, primarily due to lower percentage  
39 entrainment for larval and juvenile life stages, and more favorable location of Fall  
40 X2 in wetter years, and on average. Given the current condition of the Delta  
41 Smelt population, even small differences between alternatives may be important.

1        *Longfin Smelt*

2        The effects of the Alternative 5 as compared to the Second Basis of Comparison  
3        were analyzed based on the direction and magnitude of OMR flows during the  
4        period (December through June) when adult, larvae, and young juvenile Longfin  
5        Smelt are present in the Delta in the vicinity of the export facilities  
6        (Appendix 5A). The analysis was augmented with calculated Longfin Smelt  
7        abundance index values (Appendix 9G) per Kimmerer et al. (2009), which is  
8        based on the assumptions that lower X2 values reflect higher flows and that  
9        transporting Longfin Smelt farther downstream leads to greater Longfin Smelt  
10       survival. The index value indicates the relative abundance of Longfin Smelt and  
11       not the calculated population.

12       Under Alternative 5, Longfin Smelt abundance index values range from  
13       1,204 under critical water year conditions to a high of 16,683 under wet water  
14       year conditions, with a long-term average value of 8,015. Under the Second Basis  
15       of Comparison, Longfin Smelt abundance index values range from 947 under  
16       critical water year conditions to a high of 15,822 under wet water year conditions,  
17       with a long-term average value of 7,257.

18       Results indicate that the Longfin Smelt abundance index values would be greater  
19       in every water year type under Alternative 5 than under the Second Basis of  
20       Comparison, with a long-term average index for Alternative 5 that is about  
21       10 percent higher than the long term average index for the Second Basis of  
22       Comparison. For below normal, dry, and critical water years, the Longfin Smelt  
23       abundance index values would be over 20 percent greater under Alternative 5 than  
24       under the Second Basis of Comparison, with the greatest difference (30.8 percent)  
25       predicted under dry conditions.

26       Overall, based on the lower frequency and magnitude of negative OMR flows and  
27       the higher Longfin Smelt abundance index values, especially in dry and critical  
28       years, Alternative 5 would be likely have a lower potential for adverse effects on  
29       the Longfin Smelt population as compared to the Second Basis of Comparison.

30       *Sacramento Splittail*

31       Under Alternative 5, flows entering the Yolo Bypass over the Fremont Weir  
32       generally would be slightly lower compared to the Second Basis of Comparison  
33       (Appendix 5A, Table C-26-6), thus potentially providing lower value to  
34       Sacramento Splittail because of the lower area of potential habitat (inundation)  
35       and the lower frequency of inundation. Given the relatively minor changes in  
36       flows into the Yolo Bypass, and the inherent uncertainty associated with the  
37       resolution of the CalSim II model (average monthly outputs), it is concluded that  
38       no definitive difference in effects on Sacramento Splittail between Alternative 5  
39       and the Second Basis of Comparison could be discerned.

1        *Reservoir Fishes*

2            *Changes in Available Habitat (Storage)*

3        As described in Chapter 5, Surface Water Resources and Water Supplies, changes  
4        in CVP and SWP water supplies and operations under Alternative 5 as compared  
5        to the Second Basis of Comparison generally would result in lower reservoir  
6        storage in CVP and SWP reservoirs in the Central Valley Region. Storage levels  
7        in Shasta Lake, Lake Oroville, and Folsom Lake would be lower under  
8        Alternative 5 as compared to the Second Basis of Comparison in the fall and  
9        winter months due to the inclusion of Fall X2 criteria under Alternative 5.

10       The highest reductions in Shasta Lake and Lake Oroville storage could be in  
11       excess of 20 percent. Storage in Folsom Lake could be reduced up to around  
12       10 percent in some months of some water year types. Additional information  
13       related to monthly reservoir elevations is provided in Appendix 5A, CalSim II and  
14       DSM2 Modeling. The reduction in reservoir storage under Alternative 5 may  
15       suggest that the amount of habitat for reservoir fishes could be reduced under  
16       Alternative 5 as compared to the Second Basis of Comparison. However, it is  
17       anticipated that aquatic habitat within the CVP and SWP water supply reservoirs  
18       is not limiting, such that this potential reduction in habitat may have little adverse  
19       effect on reservoir fishes.

20            *Changes in Black Bass Nesting Success*

21       Black bass nest survival in CVP and SWP reservoirs is anticipated to be near  
22       100 percent in March and April due to increasing reservoir elevations. For May,  
23       the likelihood of nest survival for Largemouth Bass in Lake Shasta being in the  
24       40 to 100 percent range is about 2 percent higher under Alternative 5 as compared  
25       to the Second Basis of Comparison. For June, the likelihood of nest survival  
26       being greater than 40 percent for Largemouth Bass is similar (within 1 percent)  
27       under Alternative 5 and Second Basis of Comparison; however, nest survival of  
28       greater than 40 percent is likely only in about 20 percent of the years evaluated.  
29       The likelihood of nest survival for Smallmouth Bass in Lake Shasta exhibits  
30       nearly the same pattern. For Spotted Bass, the likelihood of nest survival being  
31       greater than 40 percent is high (100 percent) in May under both Alternative 5 and  
32       the Second Basis of Comparison. For June, Spotted Bass nest survival would be  
33       less than for May due to greater daily reductions in water surface elevation as  
34       Shasta Lake is drawn down. The likelihood of survival being greater than  
35       40 percent is higher (by about 12 percent) under Alternative 5 as compared to the  
36       Second Basis of Comparison.

37       For May and June, the likelihood of nest survival for Largemouth Bass in Lake  
38       Oroville being in the 40 to 100 percent range is higher under Alternative 5 as  
39       compared to the Second Basis of Comparison, about 13 percent higher in May  
40       and about 4 percent higher in June. However, June nest survival of greater than  
41       40 percent is likely only in about 40 percent of the years evaluated. The  
42       likelihood of nest survival for Smallmouth Bass in Lake Oroville exhibits nearly  
43       the same pattern. For Spotted Bass, the likelihood of nest survival being greater  
44       than 40 percent is 100 percent in May under Alternative 5 as compared to about  
45       94 percent under the Second Basis of Comparison. For June, Spotted Bass

1 survival would be less than for May due to greater daily reductions in water  
 2 surface elevation as Lake Oroville is drawn down. The likelihood of survival  
 3 being greater than 40 percent is substantially higher (on the order of 20 percent)  
 4 under Alternative 5 as compared to the Second Basis of Comparison.

5 Black bass nest survival in Folsom Lake is near 100 percent in March, April, and  
 6 May due to increasing reservoir elevations. For June, the likelihood of nest  
 7 survival for Largemouth Bass and Smallmouth Bass in Folsom Lake being in the  
 8 40 to 100 percent range is somewhat (around 7 percent) higher under  
 9 Alternative 5 than under the Second Basis of Comparison. For Spotted Bass, nest  
 10 survival for June would be less than for May due to greater daily reductions in  
 11 water surface elevation. However, the likelihood of survival being greater than  
 12 40 percent is similar under Alternative 5 as compared to the Second Basis of  
 13 Comparison.

#### 14 *Summary of Effects on Reservoir Fishes*

15 Reservoir storage is anticipated to be reduced under Alternative 5 relative to the  
 16 Second Basis of Comparison and this reduction could affect the amount of warm  
 17 and cold water habitat available within the reservoirs. However, it is unlikely that  
 18 aquatic habitat within the CVP and SWP water supply reservoirs is limiting.

19 The analysis of black bass nest survival based on changes in water surface  
 20 elevation during the spawning period indicated that the likelihood of high  
 21 (>40 percent) nest survival in most of the reservoirs under Alternative 5 would be  
 22 similar under Alternative 5 and the Second Basis of Comparison. Overall, the  
 23 results of the habitat and nest survival analysis suggest that effects on reservoir  
 24 fishes would be similar under the No Action Alternative and the Second Basis of  
 25 Comparison.

#### 26 *Other Species*

27 Several other fish species could be affected by changes in operations that  
 28 influence temperature and flow. The following describes the extent of these  
 29 changes and the potential effects on these species.

#### 30 *Pacific Lamprey*

31 Little information is available on factors that influence populations of Pacific  
 32 Lamprey in the Sacramento River, but they are likely affected by many of the  
 33 same factors as salmon and steelhead because of the parallels in their life cycles.

#### 34 *Changes in Water Temperature*

35 The following describes anticipated changes in average monthly water  
 36 temperature in the Sacramento, Feather, and American rivers and the potential for  
 37 those changes to affect Pacific Lamprey.

#### 38 *Sacramento River*

39 Monthly water temperature in the Sacramento River at Keswick Dam under  
 40 Alternative 5 and the Second Basis of Comparison generally would be similar  
 41 (differences less than 0.5°F). Average monthly water temperatures in September  
 42 under Alternative 5 would be lower (up to 0.9°F) in wetter years and higher (up to  
 43 1.2°F) in drier years. Similarly, water temperatures in October of critical years

1 could be 0.9°F warmer under Alternative 5 (Appendix 6B, Table 5-5-6). A  
2 similar pattern in temperatures generally would be exhibited at downstream  
3 locations along the Sacramento River (i.e., Ball's Ferry Jelly's Ferry, Bend  
4 Bridge, Red Bluff, Hamilton City, and Knights Landing), with differences in  
5 average monthly temperatures at Knights Landing progressively increasing (up to  
6 1.0°F warmer) in June and up to up to 4.6°F cooler in September of wetter years  
7 under Alternative 5 relative to the Second Basis of Comparison. Given the  
8 generally minor differences in flows and water temperatures between  
9 Alternative 5 and the Second Basis of Comparison, it is anticipated that the effect  
10 on Pacific Lamprey in the Sacramento River generally would be the same under  
11 both scenarios.

12 *Feather River*

13 Long-term average monthly water temperature in the Feather River at the low  
14 flow channel under Alternative 5 relative to the Second Basis of Comparison  
15 generally would be similar (less than 0.5°F differences). Water temperatures  
16 could be up to 1.5°F warmer in November and December of some water year  
17 types and up to 1.2°F cooler in September of wetter years. Although temperatures  
18 in the river would become progressively higher in the downstream direction, the  
19 differences between Alternative 5 and Second Basis of Comparison exhibit a  
20 similar pattern at the downstream locations (Robinson Riffle and Gridley Bridge),  
21 with water temperature differences under Alternative 5 generally increasing in  
22 most water year types relative to the Second Basis of Comparison at the  
23 confluence with Sacramento. Water temperatures under Alternative 5 could be  
24 somewhat (0.8°F to 1.6°F) cooler on average and up to 3.9°F cooler (September)  
25 at the confluence with Sacramento River from July to September in wetter years.

26 Due to the similarity of water temperatures under Alternative 5 and Second Basis  
27 of Comparison from January through August, there would be little difference in  
28 potential effects on Pacific Lamprey adults during their upstream migration.

29 *American River*

30 Average monthly water temperatures in the American River at Nimbus Dam  
31 under Alternative 5 generally would be similar (differences less than 0.5°F) to the  
32 Second Basis of Comparison, with the exception of during June and August of  
33 below normal years, when temperatures under Alternative 5 could be as much as  
34 0.9°F higher. This pattern generally would persist downstream to Watt Avenue  
35 and the mouth, although temperatures under Alternative 5 would be up to 1.6°F  
36 and 2.1°F higher, respectively, than under the Second Basis of Comparison in  
37 June. Due to the similarity of water temperatures under Alternative 5 and Second  
38 Basis of Comparison from January through May, there would be little difference  
39 in potential effects on Pacific Lamprey adults during their upstream migration.  
40 The higher water temperatures during June and August may increase the  
41 likelihood of adverse effects on Pacific Lamprey during their holding, and  
42 spawning periods.

1                    *Summary of Effects on Pacific Lamprey*

2 In general, Pacific Lamprey can tolerate higher temperatures than salmonids, up  
3 to around 72°F during their entire life history. Because lamprey ammocoetes  
4 remain in the river for several years, any substantial flow reductions or  
5 temperature increases could result in adverse effects on larval larvae. Given  
6 similarity in water temperatures during their spawning and incubation period, it is  
7 likely that Alternative 5 would have a similar potential to affect Pacific Lamprey  
8 in the Sacramento, Feather, and American rivers than would the Second Basis of  
9 Comparison. This conclusion likely applies to other species of lamprey that  
10 inhabit these rivers (e.g., River Lamprey).

11                    *Striped Bass, American Shad, and Hardhead*

12 Changes in operations influence temperature and flow conditions that could affect  
13 Striped Bass, American Shad, and Hardhead. The following describes those  
14 changes and their potential effects.

15                    *Changes in Water Temperature*

16 Changes in water temperature that affect Striped Bass, American Shad, and  
17 Hardhead could occur in the Sacramento, Feather, and American rivers. The  
18 following describes temperature conditions in those water bodies.

19                    *Sacramento River*

20 As described above for lampreys, monthly water temperature in the Sacramento  
21 River at Keswick Dam under Alternative and the Second Basis of Comparison  
22 generally would be similar (within about 0.5°F). Average monthly water  
23 temperatures in September under Alternative 5 would be lower (up to 0.9°F) in  
24 wetter years and higher (up to 1.2°F) in drier years. Similarly, water temperatures  
25 in October of critical years could be 0.9°F warmer under Alternative 5  
26 (Appendix 6B, Table 5-5-6). A similar temperature pattern generally would be  
27 exhibited downstream at Ball's Ferry, Jelly's Ferry, and Bend Bridge, with  
28 average monthly temperatures in June progressively increasing by a small margin  
29 under Alternative 5 relative to the Second Basis of Comparison.

30                    *Feather River*

31 Long-term average monthly water temperature in the Feather River at the low  
32 flow channel under Alternative 5 relative to the Second Basis of Comparison  
33 generally would be similar (less than 0.5°F differences). Water temperatures  
34 could be up to 1.5°F warmer in November and December of some water year  
35 types and up to 1.2°F cooler in September of wetter years. Although temperatures  
36 in the river would become progressively higher in the downstream direction, the  
37 differences between Alternative 5 and Second Basis of Comparison exhibit a  
38 similar pattern at the downstream locations (Robinson Riffle and Gridley Bridge),  
39 with water temperature differences under Alternative 5 generally increasing in  
40 most water year types relative to the Second Basis of Comparison at the  
41 confluence with the Sacramento River. Water temperatures under Alternative 5  
42 could be somewhat (0.8°F to 1.6°F) cooler on average and up to 3.9°F cooler  
43 (September) at the confluence with Sacramento River from July to September in  
44 wetter years.

1 *American River*

2 Average monthly water temperatures in the American River at Nimbus Dam  
3 under Alternative 5 generally would be similar (differences less than 0.5°F) to the  
4 Second Basis of Comparison, with the exception of during June and August of  
5 below normal years, when differences under Alternative 5 could be as much as  
6 0.9°F higher. This pattern generally would persist downstream to Watt Avenue  
7 and the mouth, although temperatures under Alternative 5 would be up to 1.6°F  
8 and 2.1°F higher, respectively, than under the Second Basis of Comparison in  
9 June.

10 *Changes in Position of X2*

11 Alternative 5 would result in a more westward X2 position as compared to the  
12 Second Basis of Comparison during April and May, with similar values in June  
13 (Appendix 5A, Section C Table C-16-6). Based on Kimmerer (2002) and  
14 Kimmerer et al. (2009), this change in X2 would likely increase the survival index  
15 and the habitat index as measured by salinity for Striped Bass and abundance and  
16 habitat index for American Shad.

17 *Summary of Effects on Striped Bass, American Shad, and Hardhead*

18 Because Striped Bass, American Shad, and Hardhead can tolerate higher  
19 temperatures than salmonids, it is unlikely that the slightly increased temperatures  
20 during some months under Alternative 5 would have substantial adverse effects  
21 on these species in the American River. Given the generally minor differences in  
22 water temperatures between Alternative 5 and the Second Basis of Comparison, it  
23 is anticipated that the effect of water temperatures on Striped Bass, American  
24 Shad, and Hardhead generally would be the same under both scenarios. Overall,  
25 Alternative 5 likely would have similar effects on Hardhead and a slightly lower  
26 potential for adverse effects on Striped Bass and American Shad as compared to  
27 the Second Basis of Comparison, primarily due to the potential for increased  
28 survival for these two species during larval and juvenile life stages, and more  
29 favorable location of Spring X2 on average.

30 *Stanislaus River/Lower San Joaquin River*

31 *Fall-Run Chinook Salmon*

32 Changes in operations influence temperature and flow conditions that could affect  
33 fall-run Chinook Salmon in the Stanislaus River downstream of Goodwin Dam  
34 and in the San Joaquin River below Vernalis. The following describes those  
35 changes and their potential effects.

36 *Changes in Water Temperature (Stanislaus River)*

37 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
38 under Alternative 5 and Second Basis of Comparison generally would be similar  
39 (differences less than 0.5°F), except in August through October when long-term  
40 average monthly temperatures could be up to 1.0°F warmer than under the Second  
41 Basis of Comparison. These differences would be of higher magnitude in drier  
42 years with average monthly water temperatures in September as much as 1.9°F  
43 warmer under Alternative 5 as compared to the Second Basis of Comparison  
44 (Appendix 6B, Table B-17-6).

1 Downstream at Orange Blossom Bridge, average monthly water temperatures in  
 2 October and April under Alternative 5 would be lower in all water year types than  
 3 the Second Basis of Comparison by as much as 1.4°F in October and 1.6°F in  
 4 April. In most other months, long-term average monthly water temperatures  
 5 under Alternative 5 generally would be similar to water temperatures under the  
 6 Second Basis of Comparison. Water temperatures under Alternative 5 could be  
 7 up to 1.3°F warmer in drier years from July to September than under the Second  
 8 Basis of Comparison. (Appendix 6B, Table B-18-6).

9 Downstream at the confluence with the San Joaquin River, average monthly water  
 10 temperatures in October, April and May would be lower by 2.0°F in October,  
 11 1.9°F in April and 0.6°F in May. Differences in water temperatures between  
 12 Alternative 5 and the Second Basis of Comparison would be even greater in these  
 13 months in some water year types. In most other months, long-term average  
 14 monthly water temperatures under Alternative 5 generally would be similar, but  
 15 could be somewhat higher (up to 1.1°F) in June, compared to the Second Basis of  
 16 Comparison (Appendix 6B, Table B-19-6).

17 *Changes in Exceedance of Water Temperature Thresholds*  
 18 *(Stanislaus River)*

19 While specific water temperature thresholds for fall-run Chinook Salmon in the  
 20 Stanislaus River are not established, temperatures generally suitable for fall-run  
 21 Chinook Salmon spawning (56°F) would be exceeded in October and November  
 22 over 30 percent of the time in the Stanislaus River at Goodwin Dam under  
 23 Alternative 5 ((Appendix 6B, Figure B-17-1 and B-17-2)). Similar exceedances  
 24 would occur under the Second Basis of Comparison, although up to 10 percent  
 25 more frequently in November. Water temperatures for rearing from January to  
 26 May generally would be below 56°F, except in May when average monthly water  
 27 temperatures would reach about 60°F under both conditions (Appendix 6B,  
 28 Figure B-17-8).

29 Downstream at Orange Blossom Bridge, water temperatures suitable for fall-run  
 30 Chinook Salmon spawning would be exceeded frequently under both  
 31 Alternative 5 and Second Basis of Comparison during October and November.  
 32 Under Alternative 5, average monthly water temperatures would exceed 56°F  
 33 about 57 percent of the time in October (Appendix 6B, Figure B-18-1). This,  
 34 however, would be about 28 percent less frequently than under the Second Basis  
 35 of Comparison. In November, average monthly water temperatures would exceed  
 36 56°F about 33 percent of the time under Alternative 5, which would be about  
 37 5 percent more frequently than under the Second Basis of Comparison  
 38 (Appendix 6B, Figure B-18-2).

39 During January through May, rearing fall-run Chinook Salmon under  
 40 Alternative 5 would be subjected to average monthly water temperatures that  
 41 exceed 56° in March (less than 10 percent of the time) and May (about 30 percent  
 42 of the time) under Alternative 5 which is about 10 percent more frequently than  
 43 under the Second Basis of Comparison (Appendix 6B, Figure B-18-8).

1            *Changes in Egg Mortality (Stanislaus River)*

2 For fall-run Chinook Salmon in the Stanislaus River, the long-term average egg  
3 mortality rate is predicted to be around 8.5 percent, with higher mortality rates (in  
4 excess of 15 percent) occurring in critical dry years under Alternative 5. Overall,  
5 egg mortality would be similar under Alternative 5 and the Second Basis of  
6 Comparison (Appendix 9C, Table B-8).

7            *Changes in Delta Hydrodynamics*

8 San Joaquin River-origin fall run Chinook salmon smolts are most abundant in the  
9 Delta during the months of April, May and June. Near the confluence of the San  
10 Joaquin River and the Mokelumne River, the median proportion of positive  
11 velocities was slightly to moderately higher under Alternative 5 relative to Second  
12 Basis of Comparison in April and May, respectively whereas values in June were  
13 similar (Appendix 9K). On Old River downstream of the facilities, the median  
14 proportion of positive velocities was substantially higher in April and May and  
15 slightly higher in June under Alternative 5 relative to Second Basis of  
16 Comparison. In Old River upstream of the facilities, the median proportion of  
17 positive velocities was slightly higher under Alternative 5 April and May and  
18 slightly lower in June. On the San Joaquin River downstream of the Head of Old  
19 River, the median proportion of positive velocities was slightly to moderately  
20 lower under Alternative 5 relative to Second Basis of Comparison in April and  
21 May, respectively, and similar in June.

22           *Changes in Junction Entrainment*

23 Entrainment at the Head of Old River junction was substantially higher under  
24 Alternative 5 relative to Second Basis of Comparison during the months of April  
25 and May and slightly lower in June (Appendix 9L). For the Turner Cut junction,  
26 median entrainment under Alternative 5 was moderately lower in April and May  
27 relative to Second Basis of Comparison and slightly lower in June. At the  
28 Columbia Cut junction, median entrainment under Alternative 5 was slightly  
29 lower in June relative to the Second Basis of Comparison. Median entrainment  
30 was substantially lower under Alternative 5 relative to Second Basis of  
31 Comparison in April and May. A similar pattern of entrainment under  
32 Alternative 5 relative to Second Basis of Comparison was observed at the Middle  
33 River and Old River junctions.

34           *Summary of Effects on Fall-Run Chinook Salmon*

35 The multiple model and analysis outputs described above characterize the  
36 anticipated conditions for fall-run Chinook Salmon and their response to change  
37 under the No Action Alternative as compared to the Second Basis of Comparison.  
38 In the Stanislaus River, the analysis of the effects of the No Action  
39 Alternative and Second Basis of Comparison for fall-run Chinook Salmon relied  
40 on the water temperature model output for the rivers at various locations  
41 downstream of Goodwin Dam. The analysis of temperatures indicates lower  
42 temperatures and a slightly lower likelihood of exceedance of suitable  
43 temperatures for spawning and rearing of fall-run Chinook Salmon under  
44 Alternative 5 as compared to the Second Basis of Comparison in the Stanislaus

1 River below Goodwin Dam and in the San Joaquin River at Vernalis. The effect  
2 of lower temperatures is not reflected in the similar overall mortality of fall-run  
3 Chinook Salmon eggs predicted by Reclamation's salmon survival model for fall-  
4 run in the Stanislaus River. As described above, the instream flow patterns under  
5 Alternative 5 are anticipated to benefit fall-run Chinook Salmon in the Stanislaus  
6 River and downstream in the lower San Joaquin River below Vernalis.

7 Implementation of a fish passage project under Alternative 5, primarily intended  
8 to address the limited availability of suitable habitat for steelhead in the Stanislaus  
9 River reaches downstream of Goodwin Dam, is not likely to provide benefit to  
10 fall-run Chinook Salmon unless passage for fall-run Chinook Salmon was  
11 provided and additional habitat could be accessed. Any potential benefit to fall-  
12 run Chinook Salmon is uncertain. However, actions implemented under  
13 Alternative 5 intended to increase the efficiency of the Tracy and Skinner Fish  
14 Collection Facilities could improve the overall salvage survival of fall-run  
15 Chinook Salmon.

16 On balance, given the small differences in the modeling results and the potential  
17 benefits anticipated by actions not captured in the models, it is concluded that  
18 effects on fall-run Chinook Salmon under Alternative 5 and Second Basis of  
19 Comparison would be similar.

#### 20 *Steelhead*

21 Changes in operations that influence temperature and flow conditions in the  
22 Stanislaus River downstream of Goodwin Dam and the San Joaquin River below  
23 Vernalis could affect steelhead. The following describes those changes and their  
24 potential effects.

#### 25 *Changes in Water Temperature (Stanislaus River)*

26 Average monthly water temperatures in the Stanislaus River at Goodwin Dam  
27 under Alternative 5 and Second Basis of Comparison generally would be similar  
28 (differences less than 0.5°F), except in August through October when long-term  
29 average monthly temperatures could be up to 1.0°F warmer than under the Second  
30 Basis of Comparison. These differences would be of higher magnitude in drier  
31 years with average monthly water temperatures in September as much as 1.9°F  
32 warmer under Alternative 5 as compared to the Second Basis of Comparison.

33 Downstream at Orange Blossom Bridge, average monthly water temperatures in  
34 October and April under Alternative 5 would be lower in all water year types than  
35 the Second Basis of Comparison by as much as 1.4°F in October and 1.6°F in  
36 April. In most other months, long-term average monthly water temperatures  
37 under Alternative 5 generally would be similar to water temperatures under the  
38 Second Basis of Comparison. Water temperatures under Alternative 5 could be  
39 up to 1.3°F warmer in drier years from July to September than under the Second  
40 Basis of Comparison. (Appendix 6B, Table B-18-6).

41 Downstream at the confluence with the San Joaquin River, average monthly water  
42 temperatures in October, April and May would be lower by 2.0°F in October,  
43 1.9°F in April and 0.6°F in May. Differences in water temperatures between

1 Alternative 5 and the Second Basis of Comparison would be even greater in these  
2 months in some water year types. In most other months, long-term average  
3 monthly water temperatures under Alternative 5 generally would be similar, but  
4 could be somewhat higher (up to 1.1°F) in June, compared to the Second Basis of  
5 Comparison.

6 *Changes in Exceedance of Water Temperature Thresholds*  
7 *(Stanislaus River)*

8 Average monthly water temperatures in the Stanislaus River at Orange Blossom  
9 Bridge would frequently exceed the temperature threshold (56°F) established for  
10 adult steelhead migration under both Alternative 5 and Second Basis of  
11 Comparison during October and November. Under Alternative 5, average  
12 monthly water temperatures would exceed 56°F about 57 percent of the time in  
13 October which is about 28 percent less frequently than under the Second Basis of  
14 Comparison (Appendix 6B, Figure B-18-1). In November, average monthly  
15 water temperatures would exceed 56°F about 33 percent of the time under  
16 Alternative 5, which would be about 10 percent more frequently than under the  
17 Second Basis of Comparison.

18 In January through May, the temperature threshold at Orange Blossom Bridge is  
19 55°F, which is intended to support steelhead spawning. This threshold would not  
20 be exceeded under either Alternative 5 or Second Basis of Comparison during  
21 January or February. In March through May, however, exceedances would occur  
22 under both Alternative 5 and the Second Basis of Comparison in each month, with  
23 the threshold most frequently exceeded (40 percent) under Alternative 5 in May  
24 (Appendix 9N). Average monthly water temperatures under Alternative 5 would  
25 exceed the threshold 4 percent more frequently in March 26 percent less  
26 frequently in April and 5 percent less frequently in May than under the Second  
27 Basis of Comparison.

28 From June through November, the temperature threshold of 65°F established to  
29 support steelhead rearing would be exceeded by both Alternative 5 and Second  
30 Basis of Comparison in all months but November. The differences between  
31 Alternative 5 and Second Basis of Comparison, however, would be small, with  
32 average monthly water temperatures under Alternative 5 generally exceeding the  
33 threshold by 3 percent to 8 percent more frequently than under the Second Basis  
34 of Comparison.

35 Average monthly water temperatures also would exceed the threshold (52°F)  
36 established for smoltification at Knights Ferry. At Goodwin Dam, about 4 miles  
37 upstream of Knights Ferry, average monthly water temperatures under  
38 Alternative 5 would exceed 52°F in March, April, and May about 8 percent,  
39 37 percent, and 68 percent of the time, respectively. Alternative 5 would result in  
40 exceedances of the smoltification threshold occurring up to 6 percent more  
41 frequently during the January through May period. Farther downstream at Orange  
42 Blossom Bridge, the temperature threshold for smoltification is higher (57°F) and  
43 would be exceeded less frequently. The magnitude of the exceedance also would  
44 be less. Average monthly water temperatures under Alternative 5 and the Second

1 Basis of Comparison would not exceed the threshold during January through  
 2 April. In May, the threshold would be exceeded 8 percent of the time under  
 3 Alternative 5. Compared to the Second Basis of Comparison, the 57°F at Orange  
 4 Blossom Bridge would be exceeded about 8 percent less frequently in April and  
 5 6 percent less frequently in May under Alternative 5.

6 Overall, the temperature differences between Alternative 5 and Second Basis of  
 7 Comparison would be relatively small, with the exception of substantial  
 8 differences in the frequency of exceedances in October when the average monthly  
 9 water temperatures under Alternative 5 would exceed the threshold for adult  
 10 steelhead migration about 28 percent less frequently and in April during the  
 11 spawning period when the frequency would be about 26 percent less. Given the  
 12 frequency of exceedance under both Alternative 5 and Second Basis of  
 13 Comparison and the generally stressful temperature conditions in the river, the  
 14 substantial differences (improvements) in October and April under Alternative 5  
 15 suggest that there would be less potential to result in adverse effects on steelhead  
 16 under Alternative 5 than under the Second Basis of Comparison. Even during  
 17 months when the differences would be relatively small, the lower frequency of  
 18 exceedances under Alternative 5 suggest that there would be less potential to  
 19 result in adverse effects on steelhead under Alternative 5 than under the Second  
 20 Basis of Comparison.

#### 21 *Changes in Delta Hydrodynamics*

22 Stanislaus River-origin steelhead generally move through the Delta during spring  
 23 however there is less information on their timing relative to Chinook salmon.  
 24 Thus, hydrodynamics in the entire January through June period have the potential  
 25 to affect juvenile steelhead.

26 On the San Joaquin River near the Mokelumne River confluence, the median  
 27 proportion of positive velocities was slightly greater under Alternative 5 relative  
 28 to Second Basis of Comparison in January, February, April and May and similar  
 29 in March and June. In Old River downstream of the facilities, the median  
 30 proportion of positive velocities was substantially higher under Alternative 5  
 31 during January, April, and May and moderately higher in February. Values in  
 32 March and June were almost indistinguishable between scenarios. On Old River  
 33 upstream of the facilities, the median proportion of positive velocities was  
 34 moderately lower in January and February, slightly lower in March and June, and  
 35 slightly higher in April and May under Alternative 5 relative to Second Basis of  
 36 Comparison. On the San Joaquin River downstream of Head of Old River, the  
 37 median proportion of positive velocities was similar for both scenarios in January,  
 38 February, March, and June, but slightly to moderately lower in April and May.

#### 39 *Summary of Effects on Steelhead*

40 The analysis of the effects of the No Action Alternative and Second Basis of  
 41 Comparison for steelhead relied on the water temperature model output for the  
 42 rivers at various locations downstream of Goodwin Dam. Given the frequency of  
 43 exceedance under both Alternative 5 and Second Basis of Comparison and the  
 44 generally stressful temperature conditions in the river, the substantial differences

1 (improvements) in October and April under Alternative 5 suggest that there would  
2 be less potential to result in adverse effects on steelhead under Alternative 5 than  
3 under the Second Basis of Comparison.

4 Implementation of a fish passage program under Alternative 5 intended to address  
5 the limited availability of suitable habitat for steelhead in the Stanislaus River  
6 reaches downstream of Goodwin Dam could provide a benefit to steelhead,  
7 however, the extent of benefit is uncertain. In addition, the potential effects of  
8 Alternative 5 could be offset by actions intended to reduce predation risk on  
9 steelhead in the Stanislaus River and increase the efficiency of the Tracy and  
10 Skinner Fish Collection Facilities. The actions to augment spawning gravel in the  
11 Stanislaus River under Alternative 5 also could benefit steelhead.

12 The numerical model results for effects on steelhead under Alternative 5 and  
13 Second Basis of Comparison do not definitively show distinct differences.  
14 However, in consideration of the potentially beneficial effects resulting from the  
15 actions that would be implemented under Alternative 5 that are not included in the  
16 numerical models (see Appendix 5A, Section B), Alternative 5 has a much greater  
17 potential to address the long-term sustainability of steelhead than does the Second  
18 Basis of Comparison. Alternative 5 includes provisions for fish passage upstream  
19 of New Melones Dam to address long-term temperature increases associated with  
20 climate change. Even though the success of fish passage is uncertain, it is  
21 concluded that the potential for adverse effects on steelhead under Alternative 5  
22 would clearly be less than that under the Second Basis of Comparison, principally  
23 because the Second Basis of Comparison does not include a strategy to address  
24 water temperatures critical to steelhead sustainability over the long term with  
25 climate change by 2030.

#### 26 *White Sturgeon*

27 Evidence of White Sturgeon spawning has been recorded in the San Joaquin River  
28 upstream of the confluence with the Stanislaus River. While flows in the San  
29 Joaquin River upstream of the Stanislaus River are expected to be similar under all  
30 alternatives, flow contributions from the Stanislaus River could influence water  
31 temperatures in the San Joaquin River where White Sturgeon eggs or larvae may  
32 occur during the spring and early summer. The magnitude of influence on water  
33 temperature would depend on the proportional flow contribution of the Stanislaus  
34 River and the temperatures in both the Stanislaus and San Joaquin rivers. The  
35 potential for an effect on White Sturgeon eggs and larvae would be influenced by  
36 the proportion of the population occurring in the San Joaquin River. In  
37 consideration of this uncertainty, it is not possible to distinguish potential effects  
38 on White Sturgeon between alternatives.

#### 39 *Reservoir Fishes*

40 As described in Chapter 5, Surface Water Resources and Water Supplies, changes  
41 in CVP and SWP water supplies and operations under Alternative 5 as compared  
42 to the Second Basis of Comparison would result in lower Storage levels in New  
43 Melones Reservoir under Alternative 5 as compared to the Second Basis of

1 Comparison due to increased instream releases to support fish flows under the  
2 2009 NMFS BO.

3 Storage levels in New Melones Reservoir would be lower under Alternative 5 as  
4 compared to the Second Basis of Comparison (Appendix 5A), especially in  
5 critical years when the difference could be as much as 23 percent. Using storage  
6 volume as an indicator of available availability for fish species inhabiting these  
7 reservoirs, these results suggest that the amount of habitat for reservoir fishes  
8 could be decreased under Alternative 5 as compared to the Second Basis of  
9 Comparison. However, it is anticipated that aquatic habitat within the CVP and  
10 SWP water supply reservoirs is not limiting, such that this potential reduction in  
11 habitat may have little adverse effect on reservoir fishes.

12 Nest survival for black bass species in New Melones is higher than in the other  
13 reservoirs during May and June. For March, Largemouth Bass and Smallmouth  
14 Bass nest survival is predicted to be above 40 percent in all of the years simulated.  
15 For April, the likelihood that nest survival of Largemouth Bass and Smallmouth  
16 Bass is between 40 and 100 percent is substantially less (about 25 percent) under  
17 Alternative 5 as compared to the Second Basis of Comparison. For May, the  
18 likelihood of high nest survival is similar under Alternative 5 and the Second  
19 Basis of Comparison. For June, the likelihood of survival being greater than  
20 40 percent for Largemouth Bass and Smallmouth Bass in New Melones is  
21 somewhat (about 10 percent) higher under Alternative 5 as compared to the  
22 Second Basis of Comparison. For Spotted Bass, nest survival in March is  
23 anticipated to be near 100 percent in every year under both Alternative 5 and  
24 Second Basis of Comparison. The likelihood of survival being greater than  
25 40 percent is about 6 percent lower in April under Alternative 5 than under the  
26 Second Basis of Comparison, but is still reasonably high (about 90 percent). For  
27 May, the likelihood of high Spotted Bass nest survival is similar under  
28 Alternative 5 and the Second Basis of Comparison. For June, Spotted Bass nest  
29 survival would be greater than 40 percent in all of the simulation years under both  
30 Alternative 5 and the Second Basis of Comparison. Overall, the analysis suggests  
31 that conditions under Alternative 5 have the potential to influence black bass  
32 nesting success, especially in April and May in comparison to the Second Basis of  
33 Comparison. However, nesting success under Alternative 5 would still exceed  
34 40 percent most of the time under both alternatives. Therefore, it is concluded  
35 that there would be no definitive difference in effects on reservoir fish between  
36 Alternative 5 and the Second Basis of Comparison.

37 *Other species*

38 Changes in operations that influence temperature and flow conditions in the  
39 Stanislaus River downstream of Keswick Dam and the San Joaquin River at  
40 Vernalis could affect other species such as lampreys, Hardhead, and Striped Bass.

41 As described above, average monthly water temperatures in the Stanislaus River  
42 at Goodwin Dam under Alternative 5 and Second Basis of Comparison generally  
43 would be similar (differences less than 0.5°F), except in August through October  
44 when long-term average monthly temperatures could be up to 1.0°F warmer than

1 under the Second Basis of Comparison. These differences would be of higher  
2 magnitude in drier years with average monthly water temperatures in September  
3 as much as 1.9°F warmer under Alternative 5 as compared to the Second Basis of  
4 Comparison.

5 Downstream at Orange Blossom Bridge, average monthly water temperatures in  
6 October and April under Alternative 5 would be lower in all water year types than  
7 the Second Basis of Comparison by as much as 1.4°F in October and 1.6°F in  
8 April. In most other months, long-term average monthly water temperatures  
9 under Alternative 5 generally would be similar to water temperatures under the  
10 Second Basis of Comparison. Water temperatures under Alternative 5 could be  
11 up to 1.3°F warmer in drier years from July to September than under the Second  
12 Basis of Comparison (Appendix 6B, Table B-18-6).

13 Downstream at the confluence with the San Joaquin River, average monthly water  
14 temperatures in October, April and May would be lower by 2.0°F in October,  
15 1.9°F in April and 0.6°F in May. Differences in water temperatures between  
16 Alternative 5 and the Second Basis of Comparison would be even greater in these  
17 months in some water year types. In most other months, long-term average  
18 monthly water temperatures under Alternative 5 generally would be similar, but  
19 could be somewhat higher (up to 1.1°F) in June, compared to the Second Basis of  
20 Comparison.

21 In general, lamprey species can tolerate higher temperatures than salmonids, up to  
22 around 72°F during their entire life history. Because lamprey ammocoetes remain  
23 in the river for several years, any substantial flow reductions or temperature  
24 increases could adversely affect larval lamprey. Given the similar flows and  
25 temperatures during their spawning and incubation period, it is likely that the  
26 potential to affect lamprey species in the Stanislaus and San Joaquin rivers would  
27 be similar under Alternative 5 and the Second Basis of Comparison.

28 In general, Striped Bass and Hardhead also can tolerate higher temperatures than  
29 salmonids. Given the similar flows and temperatures during their spawning and  
30 incubation period, it is likely that the potential to affect Striped Bass and  
31 Hardhead in the Stanislaus and San Joaquin rivers would be similar under  
32 Alternative 5 and the Second Basis of Comparison.

### 33 *San Francisco Bay Area Region*

#### 34 *Killer Whale*

35 As described above for the comparison of Alternative 1 to the No Action  
36 Alternative, it is unlikely that the Chinook Salmon prey base of killer whales,  
37 supported heavily by hatchery production of fall-run Chinook Salmon, would be  
38 appreciably affected by any of the alternatives.

#### 39 **9.4.3.7 Summary of Environmental Consequences**

40 The results of the environmental consequences of implementation of  
41 Alternatives 1 through 5 as compared to the No Action Alternative and the  
42 Second Basis of Comparison are presented in Tables 9.4 and 9.5, respectively.

1 **Table 9.4 Comparison of Alternatives 1 through 5 to No Action Alternative**

Alternative	Potential Change	Consideration for Mitigation Measures
Alternative 1	<p><b>Trinity River Region</b></p> <p><u>Coho Salmon</u></p> <p>Overall, the temperature model outputs for each of the Coho Salmon life stages suggest that the temperature of water released at Lewiston Dam generally would be similar under both scenarios, although the exceedance of water temperature thresholds would be slightly less frequent (1 percent). Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is concluded that Alternative 1 and the No Action Alternative are likely to have similar effects on the Coho Salmon population in the Trinity River.</p> <p><u>Spring-run Chinook Salmon</u></p> <p>Although the water temperatures under Alternative 1 could result in adverse effects on spring-run Chinook Salmon in the Trinity River, these effects would not occur in every year and are not anticipated to be substantial based on the relatively small differences in water temperatures as compared to the No Action Alternative. However, implementation of the Hatchery Management Plan (RPA Action II.6.3) under the No Action Alternative could reduce the impacts of hatchery Chinook Salmon on natural spring-run Chinook Salmon in the Trinity River. Given the relatively minor changes in water temperature and water temperature threshold exceedance, the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), and the uncertainty of the hatchery benefits, Alternative 1 and the No Action Alternative are likely to have similar effects on spring-run Chinook Salmon in the Trinity River.</p> <p><u>Fall-run Chinook Salmon</u></p> <p>Although the combined analysis based on water temperature suggests that operations under Alternative 1 could be slightly less adverse than under the No Action Alternative, these effects would not occur in every year and are not anticipated to be substantial based on the relatively small differences in water temperatures (and similar egg mortality) between Alternative 1 and the No Action Alternative. In addition, the implementation of the Hatchery Management Plan (RPA Action II.6.3) under the No Action Alternative could reduce the impacts of hatchery Chinook Salmon on natural fall-run Chinook Salmon in the Trinity River. Overall, given the small differences in the numerical model results and the inherent uncertainty in the temperature model, as well as the potential for offsetting benefits associated with actions that were not modeled, it is concluded that Alternative 1 and the No Action Alternative are likely to have similar effects on the fall-run Chinook Salmon population in the Trinity River.</p> <p><u>Steelhead</u></p> <p>Although the analysis based on water temperature suggests that operations under Alternative 1 could be slightly less adverse than under the No Action Alternative, these effects would not occur in every year and are not anticipated to be substantial based on the relatively small differences in water temperatures between Alternative 1 and the No Action Alternative. Given these small differences in water temperatures and the inherent uncertainty in the temperature model,</p>	<p>Implement fish passage programs at Shasta, Folsom, and New Melones dams to reduce temperature impacts on Chinook Salmon and steelhead.</p> <p>Mitigation measures for other substantial impacts have not been identified at this time.</p>

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>Alternative 1 and the No Action Alternative are likely to have similar effects on steelhead in the Trinity River.</p> <p><u>Green Sturgeon</u></p> <p>Overall, given the similarities between average monthly water temperatures at Lewiston Dam, it is likely that water temperature conditions for Green Sturgeon in the Trinity River or lower Klamath River and estuary would be similar under Alternative 1 and the No Action Alternative.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, the comparison of storage and the analysis of nesting suggest that effects on reservoir fishes would be similar under Alternative 1 and the No Action Alternative.</p> <p><u>Pacific Lamprey</u></p> <p>On average, the temperature of water released at Lewiston Dam generally would be similar under Alternative 1 and the No Action Alternative. Given the similarities in water temperatures, it is likely that the effects on Pacific Lamprey would be similar.</p> <p><u>Eulachon</u></p> <p>Given that the highest increases in flow under Alternative 1 would be less than 10 percent in the Trinity River, with a smaller relative change in the lower Klamath River and Klamath River estuary, and that water temperatures in the Klamath River are unlikely to be affected by changes upstream at Lewiston Dam, it is likely that Alternative 1 would have a similar potential to influence Eulachon in the Klamath River as the No Action Alternative.</p> <p><b>Sacramento River System</b></p> <p><u>Winter-run Chinook Salmon</u></p> <p>Overall, the quantitative results from the numerical models suggest that operation under the Alternative 1 would be more likely to result in adverse effects on winter-run Chinook Salmon than would the No Action Alternative. In addition, the potentially beneficial effects resulting from the RPA actions under the No Action Alternative that are not included in the numerical suggest that the No Action Alternative has a much greater potential to address the long-term sustainability of winter-run Chinook Salmon than does the Alternative 1. It is concluded that the potential for adverse effects on winter-run Chinook Salmon under Alternative 1 would be greater than those under the No Action Alternative, principally because Alternative 1 does not include fish passage to address water temperatures critical to winter-run Chinook Salmon sustainability over the long term with climate change by 2030.</p> <p><u>Spring-run Chinook Salmon</u></p> <p>Overall, the quantitative results from the numerical models suggest that operation under Alternative 1 would be less likely to result in adverse effects on spring-run Chinook Salmon. However, it is concluded that the potential for adverse effects on spring-run Chinook Salmon under Alternative 1 would be greater, principally because Alternative 1 does not include fish passage to address water temperatures critical to spring-run Chinook Salmon sustainability over the long term with climate change by 2030</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><u>Fall-run Chinook Salmon</u></p> <p>Overall, the quantitative results from the numerical models suggest that operation under Alternative 1 would be less likely to result in adverse effects on fall-run Chinook Salmon. This potential distinction between the two scenarios, however, may be partially balanced by the potentially beneficial effects resulting from the RPA actions evaluated qualitatively for the No Action Alternative. Given the small differences in the numerical model results and the inherent uncertainty in the temperature model, as well as the potential for benefits associated with the RPA actions under the No Action Alternative, it is likely that the effects on fall-run Chinook Salmon would be similar.</p> <p><u>Late Fall-run Chinook Salmon</u></p> <p>The output from SALMOD indicated that late fall-run Chinook Salmon production would be similar. The analyses attempting to assess the effects on routing, entrainment, and salvage of juvenile salmonids in the Delta suggest that salvage (as an indicator of potential losses of juvenile salmon at the export facilities) of Sacramento River-origin Chinook Salmon is predicted to be higher under Alternative 1 in every month.</p> <p>Although survival in the Delta may be lower, given the similarity in the SALMOD outputs, it is likely that the effects on late fall-run Chinook Salmon would be similar.</p> <p><u>Steelhead</u></p> <p>The numerical model results suggest that overall, effects on steelhead could be slightly less adverse, particularly in the Feather River. However, Alternative 1 would not include fish passage and implementation of an HGMP for steelhead at the Nimbus Fish Hatchery that would occur under the No Action Alternative. Therefore, it is concluded that the adverse effects on steelhead under Alternative 1 would be greater than those under the No Action Alternative.</p> <p><u>Green Sturgeon</u></p> <p>Overall, the temperature model outputs suggest that thermal conditions and effects on Green Sturgeon generally would be slightly less adverse under Alternative 1. The analysis based on Delta outflows suggests that Alternative 1 provides lower mean (March to July) outflows which could result in weaker year classes of juvenile Green Sturgeon relative to the No Action Alternative. However, early life stage survival in the natal rivers is crucial in development of a strong year class. Therefore, based primarily on the analysis of water temperatures, Alternative 1 could be less likely to result in adverse effects on Green Sturgeon than the No Action Alternative.</p> <p><u>White Sturgeon</u></p> <p>Overall, the temperature model outputs suggest that thermal conditions and effects on White Sturgeon generally would be slightly less adverse under Alternative 1. The analysis based on Delta outflows suggests that Alternative 1 provides lower mean (March to July) outflows which could result in weaker year classes of juvenile White Sturgeon relative to the No Action Alternative. However, early life stage survival in the natal rivers is crucial in development of a strong year class. Therefore, based primarily on the analysis of water temperatures, Alternative 1 could be less likely to result in adverse effects on White Sturgeon than the No Action Alternative.</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><u>Delta Smelt</u></p> <p>Overall, Alternative 1 is likely to result in increased adverse effects on Delta Smelt primarily due to the potential for increased percentage entrainment during larval and juvenile life stages, and less favorable location of Fall X2 in wetter years, and on average. Given the current condition of the Delta Smelt population, even these small differences between Alternative 1 and the No Action Alternative may be important.</p> <p><u>Longfin Smelt</u></p> <p>Overall, based on the increase in frequency and magnitude of negative OMR flows and the lower Longfin Smelt abundance index values, especially in dry and critical dry years, potential adverse effects on the Longfin Smelt population likely would be greater.</p> <p><u>Sacramento Splittail</u></p> <p>Given the relatively minor changes in flows into the Yolo Bypass, and the inherent uncertainty associated with the resolution of the CalSim II model (average monthly outputs), it is concluded that there would be no definitive difference in effects on Sacramento Splittail between Alternative 1 and the No Action Alternative.</p> <p><u>Reservoir Fishes</u></p> <p>The analysis of black bass nest survival based on changes in water surface elevation during the spawning period indicated that the likelihood of high (&gt;40 percent) nest survival in most of the reservoirs would be similar in March, April, and May under Alternative 1 would be similar to or slightly lower than under and the No Action Alternative, but somewhat lower in June. Most black bass spawning likely occurs prior to June, such that drawdowns during June would likely affect only a small proportion of the spawning population. Thus, it is concluded that effects on black bass nesting success would be similar under Alternative 1 and the No Action Alternative.</p> <p><u>Pacific Lamprey</u></p> <p>Based on the similar water temperatures during their spawning and incubation period, it likely that conditions for and effects on Pacific Lamprey in the Sacramento, Feather, and American rivers would be similar. This conclusion likely applies to other species of lamprey that inhabit these rivers (e.g., River Lamprey).</p> <p><u>Striped Bass, American Shad, and Hardhead</u></p> <p>In general, Striped Bass, American Shad, and Hardhead can tolerate higher temperatures than salmonids. Based on the similar water temperatures during their spawning and incubation period, it is likely that thermal conditions for and effects on Striped Bass, American Shad, and Hardhead in the Sacramento, Feather, and American rivers would be similar. Overall, however, Alternative 1 likely would have slightly greater potential for adverse effects on Striped Bass and American Shad as compared to the No Action Alternative, primarily due to the potential for reduced survival during larval and juvenile life stages, and less favorable location of Spring X2 on average.</p> <p><b>Stanislaus River/Lower San Joaquin River</b></p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, the quantitative results from the numerical models suggest that operation under Alternative 1 would be less likely to result in adverse effects on fall-</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>run Chinook Salmon. This potential distinction between the two scenarios, however, may be partially balanced by the potentially beneficial effects resulting from the RPA actions evaluated qualitatively for the No Action Alternative. Given the small differences in the numerical model results and the inherent uncertainty in the temperature model, as well as the potential for benefits associated with the RPA actions under the No Action Alternative, there would be no definitive difference in effects on fall-run Chinook Salmon between Alternative 1 and the No Action Alternative.</p> <p><u>Steelhead</u></p> <p>The temperature model outputs suggest that the differences in the magnitude and frequency of exceedance of suitable temperatures for the various lifestages have the potential for adverse effects on the steelhead populations in the Stanislaus River under Alternative 1. However, the magnitude of this effect is uncertain. It is concluded that the potential for adverse effects on steelhead would be greater, principally because Alternative 1 does not include fish passage to address water temperatures critical to steelhead sustainability over the long term with climate change by 2030.</p> <p><u>White Sturgeon</u></p> <p>While flows in the San Joaquin River upstream of the Stanislaus River are expected to be similar, flow contributions from the Stanislaus River could influence water temperatures in the San Joaquin River where White Sturgeon eggs or larvae may occur during the spring and early summer. The magnitude of influence on water temperature would depend on the proportional flow contribution of the Stanislaus River and the temperatures in both the Stanislaus and San Joaquin rivers. The potential for an effect on White Sturgeon eggs and larvae would be influenced by the proportion of the population occurring in the San Joaquin River. In consideration of this uncertainty, it is not possible to distinguish potential effects on White Sturgeon between alternatives.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, predicted nest survival is generally above 40 percent in all months evaluated, although survival would vary among months. In June, the likelihood of survival being greater than 40 percent is lower under Alternative 1. Most black bass spawning likely occurs prior to June, such that drawdowns during June would likely affect only a small proportion of the spawning population. Thus, effects on black bass nesting success would be similar.</p> <p><u>Other Species</u></p> <p>In general, lamprey species can tolerate higher temperatures than salmonids, up to around 72°F during their entire life history. Given the similar temperatures during their spawning and incubation period, it is likely that the potential to affect lamprey species in the Stanislaus and San Joaquin rivers would be similar.</p> <p>In general, Striped Bass and Hardhead also can tolerate higher temperatures than salmonids. Given the similar temperatures during their spawning and incubation period, it is likely that the potential to affect Striped Bass and Hardhead in the Stanislaus and San Joaquin rivers would be similar.</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><b>Pacific Ocean</b>  <u>Killer Whale</u>                      Given conclusions from NMFS (2009c), and the fact that at approximately 75 percent of fall-run Chinook Salmon available for Southern Residents are produced by Central Valley hatcheries, it is likely that Central Valley fall-run Chinook Salmon as a prey base for killer whales would not be appreciably affected.</p>	
Alternative 2	<p><b>Trinity River Region</b>  <u>Coho Salmon, spring-run and fall-run Chinook Salmon, steelhead, Green Sturgeon, Reservoir Fishes, Pacific Lamprey, River Lamprey, and Eulachon</u>                      Similar effects.</p> <p><b>Sacramento River System</b>  <u>Winter-run, spring-run, fall-run, and late fall-run Chinook Salmon, and steelhead</u>                      The effects under Alternative 2 may become more adverse due to the lack of fish passage and other actions, such as structural improvements for temperature control on the American River; gravel augmentation, floodplain restoration and pulse flows, in Clear Creek; and measures to increase the efficiency of the Tracy and Skinner Fish Collection Facilities. Thus, it is concluded that the potential for adverse effects on salmonids and sturgeon under Alternative 2 would be greater than under the No Action Alternative.</p> <p><u>Green Sturgeon, White Sturgeon, Delta Smelt, Longfin Smelt, Sacramento Splittail, Reservoir Fishes, Pacific Lamprey, River Lamprey, Striped Bass, American Shad, and Hardhead</u>                      Similar effects.</p> <p><b>Stanislaus River/Lower San Joaquin River</b>  <u>Fall-run Chinook Salmon and Steelhead</u>                      The effects under Alternative 2 may become more pronounced due to the lack of fish passage and other actions that would occur under the No Action Alternative such as gravel augmentation, floodplain restoration and inundation flows, and freshwater migratory habitat restoration in the Stanislaus River; and measures to increase the efficiency of the Tracy and Skinner Fish Collection Facilities.</p> <p><u>White Sturgeon, Reservoir Fishes, and Other Species</u>                      Similar effects.</p> <p><b>Pacific Ocean</b>  <u>Killer Whale</u>                      Similar effects.</p>	<p>Implement fish passage programs at Shasta, Folsom, and New Melones dams to reduce temperature impacts on Chinook Salmon and steelhead.</p>
Alternative 3	<p><b>Trinity River Region</b>  <u>Coho Salmon and Spring-run Chinook Salmon</u>                      Overall, the water temperature model outputs suggest that the temperature of water released at Lewiston Dam generally would be similar under both scenarios, although the exceedance of water temperature thresholds would be less frequent (by 1 to 2 percent) under Alternative 3. Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is concluded that Alternative 3 and the No Action Alternative are likely to have similar effects on the Coho Salmon population in the Trinity River. This conclusion also applies to spring-run Chinook Salmon,</p>	<p>Implement fish passage programs at Shasta, Folsom, and New Melones dams to reduce temperature impacts on Chinook Salmon and steelhead.</p> <p>Mitigation measures for other substantial impacts have not been identified at this time.</p>

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>although the implementation of the Hatchery Management Plan (RPA Action II.6.3) under the No Action Alternative could reduce the impacts of hatchery Chinook Salmon on natural spring-run Chinook Salmon in the Trinity River, and increase the genetic diversity and diversity of run-timing for these stocks relative to Alternative 3.</p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, the temperature model outputs suggest that the temperature of water released at Lewiston Dam generally would be similar under both scenarios, although the exceedance of water temperature thresholds would be less frequent (by up to 2 percent) under Alternative 3. Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), Alternative 3 is likely to have similar effects on the fall-run Chinook Salmon population in the Trinity River as compared to the No Action Alternative. However, the implementation of the Hatchery Management Plan (RPA Action II.6.3) under the No Action Alternative could reduce the impacts of hatchery Chinook Salmon on natural fall-run Chinook Salmon in the Trinity River, and increase the genetic diversity and diversity of run-timing for these stocks relative to Alternative 3.</p> <p><u>Steelhead</u></p> <p>Overall, the differences in the frequency of threshold exceedance between Alternative 3 and the No Action Alternative would be relatively minor and are unlikely to affect steelhead spawning in the Trinity River. This slight reduction in the frequency of threshold exceedance provided by Alternative 3 suggest that temperature conditions under Alternative 3 could be slightly less likely to affect steelhead than under the No Action Alternative. However, the relatively small differences in flows and water temperatures under Alternative 3 as compared to the No Action Alternative would likely have similar effects on steelhead in the Trinity River as compared to the No Action Alternative.</p> <p><u>Green Sturgeon</u></p> <p>Given the similarities between average monthly water temperatures at Lewiston Dam, it is likely that water temperature conditions for Green Sturgeon in the Trinity River or lower Klamath River and estuary would be similar.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, while reservoir storage and nest survival would be slightly higher under Alternative 3, it is uncertain whether these differences would be biologically meaningful. Thus, it is concluded that effects on black bass likely would be similar for Alternative 3 and the No Action Alternative.</p> <p><u>Pacific Lamprey</u></p> <p>Overall, it is likely that effects on Pacific Lamprey would be similar. This conclusion likely also applies to other species of lamprey that inhabit the Trinity and lower Klamath rivers (e.g., River Lamprey).</p> <p><u>Eulachon</u></p> <p>Given that the highest increases in flow would be less than 10 percent in the Trinity River, with a smaller relative increase in the lower Klamath River and</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>Klamath River estuary, and that water temperatures in the Klamath River would unlikely to be affected by changes upstream at Lewiston Dam, it is likely that effects would have a similar potential to influence Eulachon in the Klamath River.</p> <p><b>Sacramento River System</b></p> <p><u>Winter-run Chinook Salmon</u></p> <p>Overall, given the small differences between alternatives and the uncertainty regarding the non-operational components, distinguishing a clear difference between alternatives is difficult. The non-operational components associated with Alternative 3 could benefit winter-run Chinook Salmon over the short term if successful. However, these measures would not address the long-term temperature challenges in the river downstream of Shasta Dam that would be addressed under the No Action Alternative. It is concluded that the potential for adverse effects on winter-run Chinook Salmon under Alternative 3 would be greater, principally because Alternative 3 does not include a strategy to address water temperatures critical to winter-run Chinook Salmon sustainability over the long term.</p> <p><u>Spring-run Chinook Salmon</u></p> <p>The model results suggest that overall, effects on spring-run Chinook Salmon could be slightly more adverse. However, the ocean harvest restriction component and predator control measures could reduce spring-run Chinook Salmon mortality. These non-operational components could benefit spring-run Chinook Salmon over the short term if successful. However, these measures would not address the long-term temperature challenges in the river downstream of Shasta Dam that would be addressed through fish passage under the No Action Alternative. It is concluded that the potential for adverse effects on spring-run Chinook Salmon under Alternative 3 would be greater, principally because Alternative 3 does not include a strategy to address water temperatures critical to spring-run Chinook Salmon sustainability over the long term.</p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, the results of the numerical models suggest the potential for less adverse effects on fall-run Chinook Salmon. However, discerning a meaningful difference between these two scenarios based on the quantitative results is not possible because of the similarity in results (generally differences less than 5 percent) and the inherent uncertainty of the models. Adverse effects of Alternative 3 could be offset by the potentially beneficial effects resulting from predator control and ocean harvest restrictions. However, Alternative 3 does not contain the RPA actions that could provide benefit under the No Action Alternative. Thus, effects on fall-run Chinook Salmon would be similar.</p> <p><u>Late Fall-run Chinook Salmon</u></p> <p>Overall, the results of the numerical models suggest that potential effects on late fall-run Chinook Salmon would be similar. Discerning a meaningful difference between these two scenarios based on the quantitative results is not possible because of the similarity in results (generally differences less than 5 percent) and the inherent uncertainty of the models. Because fish passage under the No Action Alternative is not expected</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>to directly benefit late fall-run Chinook Salmon, the non-operational actions intended to benefit salmonids under both alternatives are expected to balance. Thus, it is concluded that the effects on late fall-run Chinook Salmon would be similar under Alternative 3 and the No Action Alternative.</p> <p><u>Steelhead</u></p> <p>The model results suggest that overall, effects on steelhead could be slightly less adverse, particularly in the Feather River. The ocean harvest restriction component and predator control measures could reduce steelhead mortality. This potential distinction may be partially offset and become more adverse by the lack of the benefits of implementation of fish passage. This is particularly important in light of anticipated increases in water temperature associated with climate change in 2030. Thus, on balance and over the long term, the adverse effects on steelhead under Alternative 3 would be greater than those under the No Action Alternative.</p> <p><u>Green Sturgeon</u></p> <p>The temperature model outputs suggest that thermal conditions and effects on Green Sturgeon in the Sacramento and Feather rivers generally would be slightly less adverse under Alternative 3. By contrast, the analysis based on Delta outflows suggests that Alternative 3 provides lower mean (March to July) outflows which could result in weaker year classes of juvenile sturgeon. However, early life stage survival in the natal rivers is crucial in development of a strong year class, and actions under the No Action Alternative intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities could improve the overall salvage survival of green sturgeon. Therefore, based primarily on the analysis of water temperatures, adverse effects on Green Sturgeon would be less likely.</p> <p><u>White Sturgeon</u></p> <p>Given the general similarity in results and the inherent uncertainty associated with the resolution of the temperature model, the effects likely would be similar. However, the analysis based on Delta outflows suggests that Alternative 3 provides lower mean (March to July) outflows which could result in weaker year classes of juvenile sturgeon. Overall, given the small differences in the numerical model results and the inherent uncertainty in the temperature model, as well as the potential for offsetting effects of increased Delta outflow and improved salvage survival under the No Action Alternative, there would be no definitive difference in effects on White Sturgeon.</p> <p><u>Delta Smelt</u></p> <p>Overall, likely would result in increased adverse effects, primarily due to increased percentage entrainment during larval and juvenile life stages, and less favorable location of Fall X2 in wetter years, and on average. Given the current condition of the Delta Smelt population, even these small differences between alternatives may be important.</p> <p><u>Longfin Smelt</u></p> <p>Overall, based on the increase in frequency and magnitude of negative OMR flows and the lower Longfin Smelt abundance index values, potential adverse effects likely would be greater.</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><u>Sacramento Splittail</u></p> <p>Flows entering the Yolo Bypass generally would be somewhat higher than under the No Action Alternative from December through March, especially during wetter years, providing similar value to Sacramento Splittail because of the similar area of potential habitat (inundation). Given the relatively minor changes in flows into the Yolo Bypass, and the inherent uncertainty associated with the resolution of the CalSim II model (average monthly outputs), it is concluded that there would be no definitive difference in effects on Sacramento Splittail between Alternative 3 and the No Action Alternative.</p> <p><u>Reservoir Fishes</u></p> <p>The analysis of black bass nest survival based on changes in water surface elevation during the spawning period indicated that the likelihood of high (greater than 40 percent) nest survival in most of the reservoirs would be similar in March, April, and May, but somewhat lower in June. Most black bass spawning likely occurs prior to June, such that drawdowns during June would likely affect only a small proportion of the spawning population. Overall, the results of the habitat and nest survival analysis suggest that conditions in the reservoirs likely to support self-sustaining populations of black bass would be similar under Alternative 3 and the No Action Alternative.</p> <p><u>Pacific Lamprey</u></p> <p>Pacific Lamprey would be subjected to the same temperature conditions described above for salmonids. Based on the somewhat increased water temperatures from January through the summer, it is likely that there would be little difference in potential effects on Pacific Lamprey in the Sacramento, Feather, and American rivers. This conclusion likely applies to other species of lamprey that inhabit these rivers (e.g., River Lamprey).</p> <p><u>Other Species</u></p> <p>Based on the similar water temperatures during their spawning and incubation period under Alternative 3, it is likely that thermal conditions for and effects on Striped Bass, American Shad, and Hardhead in the Sacramento, Feather, and American rivers would be similar under Alternative 1 and the No Action Alternative.</p> <p>Alternative 3 would result in a more eastward X2 position as compared to the No Action Alternative during April and May, with similar values in June (Appendix 5A, Section C Table C-16-2). Based on Kimmerer (2002) and Kimmerer et al. (2009), this change in X2 would likely reduce the survival index and the habitat index as measured by salinity for Striped Bass and abundance and habitat index for American Shad.</p> <p>In addition, the increased bag limits and ability of anglers to retain Striped Bass that are 12 inches in length versus 18 inches under Alternative 3 could reduce the ability to meet the doubling goals for Striped Bass populations under the requirements of Section 3406(b)(1) of CVPIA.</p> <p>Overall, Alternative 3 likely would have similar effects on Hardhead, but slightly greater potential for adverse effects on Striped Bass and American Shad as compared to the No Action Alternative, primarily due to the potential for reduced survival during larval and</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>juvenile life stages, and less favorable location of Spring X2 on average.</p> <p><b>Stanislaus River/Lower San Joaquin River</b></p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, likely would have similar effects on the fall-run Chinook Salmon population in the San Joaquin River watershed.</p> <p>Beneficial effects to juvenile fall-run Chinook Salmon could result from implementation of trap and haul passage through the Delta and ocean harvest restrictions. It remains uncertain, however, if predator management actions under Alternative 3 would benefit fall-run Chinook Salmon.</p> <p><u>Steelhead</u></p> <p>Given the frequency of exceedance under both Alternative 3 and the No Action Alternative, water temperature conditions for steelhead in the Stanislaus River would be generally stressful in the fall, late spring, and summer months. The differences in temperature exceedance between Alternative 3 and the No Action Alternative would be relatively small, with no clear benefit associated with either alternative. However, because Alternative 3 generally would exceed thresholds less frequently during the warmest months, it may have slightly less impact than under the No Action Alternative. Alternative 3 also could provide additional beneficial effects to juvenile steelhead as a result of trap and haul passage through the Delta. It remains uncertain, however, if predator management actions under Alternative 3 would benefit steelhead.</p> <p>This potential distinction between the two alternatives, however, may be partially offset by the benefits of implementation of fish passage under the No Action Alternative intended to address the limited availability of suitable habitat for in the Stanislaus River reaches downstream of New Melones Dam. In addition, RPA actions intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities could improve the overall salvage survival of steelhead under the No Action Alternative.</p> <p>Implementation of the fish passage program under the No Action could provide a benefit to Central Valley steelhead in the Stanislaus River. This is particularly important in light of anticipated increases in water temperature associated with climate change in 2030. In addition, RPA actions intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities could improve the overall salvage survival of steelhead under the No Action Alternative. Thus, it is concluded that the potential for adverse effects on steelhead would be greater, principally because Alternative 3 does not include a strategy to address water temperatures critical to steelhead sustainability over the long term with climate change by 2030.</p> <p><u>White Sturgeon</u></p> <p>While flows in the San Joaquin River upstream of the Stanislaus River are expected to be similar, flow contributions from the Stanislaus River could influence water temperatures in the San Joaquin River where White Sturgeon eggs or larvae may occur during the spring and early summer. The magnitude of influence on water temperature would depend on the proportional flow contribution of the Stanislaus River and the temperatures in both the Stanislaus and San Joaquin</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>rivers. The potential for an effect on White Sturgeon eggs and larvae would be influenced by the proportion of the population occurring in the San Joaquin River. In consideration of this uncertainty, it is not possible to distinguish potential effects on White Sturgeon.</p> <p><u>Reservoir Fishes</u></p> <p>While the analyses suggest that the effects could be more adverse, most black bass spawning likely occurs prior to June, such that drawdowns during June would likely affect only a small proportion of the spawning population. Thus, it is concluded that effects on black bass nesting success would be similar under Alternative 3 and the No Action Alternative.</p> <p><u>Other Species</u></p> <p>In general, lampreys, Striped Bass and Hardhead also can tolerate higher water temperatures than salmonids. Thus, temperature effects on these species are expected to be similar under both alternatives.</p> <p>Predator controls related to Striped Bass could result in adverse effects.</p> <p><b>Pacific Ocean</b></p> <p><u>Killer Whale</u></p> <p>It is unlikely that the Chinook Salmon prey base of killer whales, supported heavily by hatchery production of fall-run Chinook Salmon, would be appreciably affected.</p>	
Alternative 4	<p><b>Trinity River Region</b></p> <p><u>Coho Salmon, spring-run and fall-run Chinook Salmon, steelhead, Green Sturgeon, Reservoir Fishes, Pacific Lamprey, River Lamprey, and Eulachon</u></p> <p>The effects are identical as described under Alternative 1 as compared to the No Action Alternative.</p> <p><b>Sacramento River System</b></p> <p><u>Winter-run, spring-run, fall-run, and late fall-run Chinook Salmon, and steelhead</u></p> <p>CVP and SWP operations under Alternative 4 are identical to the CVP and SWP operations under the Second Basis of Comparison and Alternative 1. Therefore the effects in the Sacramento River system would be similar to those described under Alternative 1.</p> <p>Conditions related to salmonid survival could be improved under Alternative 4 by implementation of a trap and haul program, changes in Striped Bass bag limits, and changes in PMFC/NMFS harvest limits. However, these benefits would not likely exceed those described for the No Action Alternative, particularly in consideration of the provision of fish passage to address long-term temperature challenges on listed salmonids caused by climate change.</p> <p><u>Green Sturgeon, White Sturgeon, Delta Smelt, Longfin Smelt, Sacramento Splittail, Reservoir Fishes, Pacific Lamprey, River Lamprey, American Shad, and Hardhead</u></p> <p>The effects in the Sacramento River system would be similar to those described under Alternative 1.</p> <p><u>Striped Bass</u></p> <p>The effects in the Sacramento River system would be similar to those described under Alternative 1.</p> <p>Conditions for Striped Bass could be influenced by implementation of a predator control program that reduces the size restrictions and increases the catch</p>	<p>Implement fish passage programs at Shasta, Folsom, and New Melones dams to reduce temperature impacts on Chinook Salmon and steelhead.</p> <p>Mitigation measures for other substantial impacts have not been identified at this time.</p>

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>limit for Striped Bass taken in the sport fishery. This also could reduce the ability to meet the doubling goals for Striped Bass populations under the requirements of Section 3406(b)(1) of CVPIA.</p> <p><b>Stanislaus River/Lower San Joaquin River</b>  <u>Fall-run Chinook Salmon and Steelhead</u>                      The effects in the Stanislaus River/Lower San Joaquin River system would be similar to those described under Alternative 1.                      Beneficial effects to Chinook Salmon as a result of trap and haul passage through the Delta and ocean harvest restrictions. It remains uncertain, however, if predator management actions would benefit the Chinook Salmon population.</p> <p><u>White Sturgeon, Reservoir Fishes, and Other Species</u>                      The effects in the Stanislaus River/Lower San Joaquin River system would be similar to those described under Alternative 1.</p> <p><u>Striped Bass</u>                      The effects in the Stanislaus River/Lower San Joaquin River system would be similar as described under Alternative 1 as compared to the No Action Alternative. Conditions for Striped Bass could be influenced by implementation of a predator control program that reduces the size restrictions and increases the catch limit for Striped Bass taken in the sport fishery. This also could reduce the ability to meet the doubling goals for Striped Bass populations under the requirements of Section 3406(b)(1) of CVPIA.</p> <p><b>Pacific Ocean</b>  <u>Killer Whale</u>                      It is unlikely that the Chinook Salmon prey base of killer whales, supported heavily by hatchery production of fall-run Chinook Salmon, would be appreciably affected.</p>	
Alternative 5	<p><b>Trinity River Region</b>  <u>Coho Salmon, Spring-run Chinook Salmon, Fall-run Chinook Salmon, Steelhead, and Green Sturgeon</u>                      Effects would be similar.</p> <p><u>Reservoir Fishes</u>                      Effects would be similar.</p> <p><u>Pacific Lamprey</u>                      Effects would be similar.</p> <p><u>Eulachon</u>                      Effects would be similar.</p> <p><b>Sacramento River System</b>  <u>Winter-run Chinook Salmon, Spring-run Chinook Salmon, Fall-run Chinook Salmon, Late Fall-run Chinook Salmon, Steelhead, Green Sturgeon, and White Sturgeon</u>                      Effects would be similar.</p> <p><u>Delta Smelt, Longfin Smelt, and Sacramento Splittail</u>                      Effects would be similar.</p> <p><u>Reservoir Fishes</u>                      Effects would be similar.</p> <p><u>Pacific Lamprey and Other Species</u>                      Effects would be similar.</p>	Mitigation measures for other substantial impacts have not been identified at this time.

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><b>Stanislaus River/Lower San Joaquin River</b></p> <p><u>Fall-run Chinook Salmon and Steelhead</u></p> <p>The analysis of temperatures indicates somewhat higher temperatures in some water year types and a higher likelihood of exceedance of suitable temperatures for spawning, and lower likelihood of exceeding suitable temperature for rearing of fall-run Chinook Salmon. The frequency of exceedance of temperature thresholds for steelhead smoltification and rearing could be more stressful. However, the higher flows in April and May and lower temperatures in April and May could benefit steelhead spawning. Given the variability in the results and the inherent uncertainty associated with the resolution of the models, it is concluded that Alternative 5 is likely to have similar effects on fall-run Chinook Salmon and steelhead in the Stanislaus and lower San Joaquin rivers.</p> <p><u>White Sturgeon</u></p> <p>While flows in the San Joaquin River upstream of the Stanislaus River are expected to be similar, flow contributions from the Stanislaus River could influence water temperatures in the San Joaquin River where White Sturgeon eggs or larvae may occur during the spring and early summer. The magnitude of influence on water temperature would depend on the proportional flow contribution of the Stanislaus River and the temperatures in both the Stanislaus and San Joaquin rivers. The potential for an effect on White Sturgeon eggs and larvae would be influenced by the proportion of the population occurring in the San Joaquin River. In consideration of this uncertainty, it is not possible to distinguish potential effects on White Sturgeon.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, the analysis suggests that conditions under Alternative 5 have the potential to negatively influence black bass nesting success, especially in April and May. However, nesting success under Alternative 5 would still exceed 40 percent most of the time. Therefore, it is likely that the effects on black basses in New Melones Reservoir would be similar.</p> <p><u>Other Species</u></p> <p>Given the similar water temperatures, it is likely that the potential to affect lamprey species in the Stanislaus and San Joaquin rivers would be similar.</p> <p>Striped Bass and Hardhead also can tolerate higher temperatures than salmonids. Given the similar water temperatures, it is likely that the potential effects to affect Striped Bass and Hardhead in the Stanislaus and San Joaquin rivers would be similar.</p> <p><b>Pacific Ocean</b></p> <p><u>Killer Whale</u></p> <p>It is unlikely that the Chinook Salmon prey base of killer whales, supported heavily by hatchery production of fall-run Chinook Salmon, would be appreciably affected.</p>	

1  
2  
3

Note: Due to the limitations and uncertainty in the CalSim II monthly model and other analytical tools, incremental differences of 5 percent or less between alternatives and the Second Basis of Comparison are considered to be "similar."

1 **Table 9.5 Comparison of No Action Alternative and Alternatives 1 through 5 to**  
 2 **Second Basis of Comparison**

Alternative	Potential Change	Consideration for Mitigation Measures
<p>No Action Alternative</p>	<p><b>Trinity River Region</b></p> <p><u>Coho Salmon</u></p> <p>Overall, the temperature model outputs for each of the Coho Salmon life stages suggest that the temperature of water released at Lewiston Dam generally would be similar, although the exceedance of water temperature thresholds would be slightly more frequent (1 percent). Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is concluded that the No Action Alternative and Second Basis of Comparison are likely to have similar effects on the Coho Salmon population in the Trinity River.</p> <p><u>Spring-run Chinook Salmon</u></p> <p>Overall, water temperature could have adverse effects on spring-run Chinook Salmon in the Trinity River; however, these effects would not occur in every year and are not anticipated to be substantial based on the relatively small differences in flows and water temperatures. However, the implementation of the Hatchery Management Plan could reduce the impacts of hatchery Chinook Salmon on natural spring-run Chinook Salmon in the Trinity River. Thus, given these relatively minor changes in temperature and temperature threshold exceedance, the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), and the uncertainty of the hatchery benefits, it is concluded that the No Action Alternative and Second Basis of Comparison are likely to have similar effects on the spring-run Chinook Salmon in the Trinity River.</p> <p><u>Fall-run Chinook Salmon</u></p> <p>Although the combined analysis based on water temperature suggests that operations could be slightly more adverse, these effects would not occur in every year and are not anticipated to be substantial based on the relatively small differences in water temperatures (as well as egg mortality). In addition, these potential adverse effects could be offset by implementation of the Hatchery Management Plan (RPA Action II.6.3), which could reduce the impacts of hatchery Chinook Salmon on natural fall-run Chinook Salmon in the Trinity River, and increase the genetic diversity and diversity of run-timing for these stocks. Overall, given the small differences in the numerical model results and the inherent uncertainty in the temperature model, as well as the potential for offsetting benefits associated with actions that were not modeled, it is concluded that the No Action Alternative is likely to have similar effects on the fall-run Chinook Salmon population in the Trinity River.</p> <p><u>Steelhead</u></p> <p>Although the combined analysis based on water temperature suggests that operations could be slightly more adverse, these effects would not occur in every year and are not anticipated to be substantial based on the relatively small differences in water temperature exceedances. Overall, given these small differences and the inherent uncertainty in the temperature model, these two scenarios are likely to have similar effects on the steelhead population in the Trinity River.</p>	<p>Not considered for this comparison.</p>

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><u>Green Sturgeon</u></p> <p>Overall, given the similarities between average monthly water temperatures at Lewiston Dam, it is likely that temperature conditions for Green Sturgeon in the Trinity River or lower Klamath River and estuary would be similar.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, the comparison of storage and the analysis of black bass nesting suggest that effects would be similar.</p> <p><u>Pacific Lamprey</u></p> <p>Overall, given the similarities between average monthly water temperatures at Lewiston Dam, it is likely that the effects would be similar. This conclusion likely applies to other species of lamprey that inhabit the Trinity and lower Klamath rivers (e.g., River Lamprey).</p> <p><u>Eulachon</u></p> <p>Given that the highest reductions in flow would be less than 10 percent in the Trinity River, which would represent even a smaller proportion in the lower Klamath River and Klamath River estuary, and that water temperatures in the Klamath River are unlikely to be affected by changes upstream at Lewiston Dam, it is likely the conditions would be similar for Eulachon in the Klamath River.</p> <p><b>Sacramento River System</b></p> <p><u>Winter-run Chinook Salmon</u></p> <p>Overall, the quantitative results from the numerical models suggest that the No Action Alternative would be less likely to result in adverse effects on winter-run Chinook Salmon. In consideration of the potentially beneficial effects resulting from the RPA actions that are not included in the numerical models, the No Action Alternative has a much greater potential to address the long-term sustainability of winter-run Chinook Salmon than does the Second Basis of Comparison, principally because the Second Basis of Comparison does not include a strategy to address water temperatures critical to winter-run Chinook Salmon sustainability over the long term with climate change by 2030.</p> <p><u>Spring-run Chinook Salmon</u></p> <p>The model results suggest that overall, effects on spring-run Chinook Salmon could be slightly more adverse with a small likelihood that spring-run Chinook Salmon production would be lower under the No Action Alternative. However, it is concluded that the potential for adverse effects on spring-run Chinook Salmon suggested by the results of the numerical models would likely be offset by the potential benefits of the RPA actions that are not included in the numerical models, principally because the Second Basis of Comparison does not include a strategy to address water temperatures critical to spring-run Chinook Salmon sustainability over the long term with climate change by 2030. On balance and over the long term, the adverse effects on spring-run Chinook Salmon would be less than those under the Second Basis of Comparison.</p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, the results of the numerical models suggest the potential for greater adverse effects on fall-run Chinook Salmon under the No Action Alternative as compared to the Second Basis of Comparison. However, discerning a meaningful difference between these two scenarios based on the quantitative results is not possible</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>because of the similarity in results and the inherent uncertainty of the models. In addition, any adverse effect of the No Action Alternative could be offset by the potentially beneficial effects resulting from the RPA actions evaluated qualitatively for the No Action Alternative. Thus, it is concluded that the effects on fall-run Chinook Salmon would be less adverse under the No Action Alternative than under the Second Basis of Comparison.</p> <p><u>Late Fall-run Chinook Salmon</u></p> <p>The model results suggest that overall, effects on late fall-run Chinook Salmon could be slightly less adverse. Potential effects may be lessened further due to actions intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities to improve the overall salvage survival of salmonids, including late fall-run Chinook Salmon. Thus, it is concluded that the potential for adverse effects on late fall-run Chinook Salmon would be lower under the No Action Alternative compared to the Second Basis of Comparison.</p> <p><u>Steelhead</u></p> <p>The numerical model results suggest that overall, effects on steelhead could be slightly more adverse, particularly in the Feather and American rivers. However, implementation of a fish passage program under the No Action Alternative intended to address the limited availability of suitable habitat for steelhead in the Sacramento River reaches downstream of Keswick Dam and in the American River could provide a benefit to Central Valley steelhead in the Sacramento and American rivers. This is particularly important in light of anticipated increases in water temperature associated with climate change in 2030. In addition to fish passage, preparation and implementation of an HGMP for steelhead at the Nimbus Fish Hatchery and actions under the No Action Alternative intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities could benefit steelhead under the No Action Alternative in comparison to the Second Basis of Comparison. Thus, it is concluded that the effects on steelhead would be less adverse under the No Action Alternative than under the Second Basis of Comparison.</p> <p><u>Green Sturgeon</u></p> <p>The increased frequency of exceedance of temperature thresholds under the No Action Alternative could increase the potential for adverse effects on Green Sturgeon in the Sacramento and Feather rivers relative to the Second Basis of Comparison. However, the analysis based on Delta outflows suggests that the No Action Alternative provides higher mean (March to July) outflows which could result in stronger year classes of juvenile Green Sturgeon relative to the Second Basis of Comparison. In addition, actions under the No Action Alternative intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities could improve the overall salvage survival of Green Sturgeon. However, early life stage survival in the natal rivers is crucial in development of a strong year class. In addition, actions under the No Action Alternative intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities could improve the overall salvage survival of green sturgeon. Therefore, based primarily on the analysis of water temperatures, the No Action Alternative could be more</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>likely to result in adverse effects on Green Sturgeon than the Second Basis of Comparison.</p> <p><u>White Sturgeon</u></p> <p>Overall, the increased frequency of exceedance of temperature thresholds in June under the No Action Alternative could increase the potential for effects on White Sturgeon in the Sacramento River relative to the Second Basis of Comparison, however, these effects are uncertain and may include reduced spawning and/or increased growth. The analysis based on Delta outflows suggests that the No Action Alternative provides higher mean (March to July) outflows which could result in stronger year classes of juvenile White Sturgeon relative to the Second Basis of Comparison. However, early life stage survival in the natal rivers is crucial in development of a strong year class. Therefore, based primarily on the analysis of water temperatures, the No Action Alternative could be more likely to result in adverse effects on White Sturgeon than the Second Basis of Comparison.</p> <p><u>Delta Smelt</u></p> <p>Overall, likely to result in better conditions for Delta Smelt, primarily due to lower percentage entrainment for larval and juvenile life stages, and more favorable location of Fall X2 in wetter years, and on average. Given the current condition of the Delta Smelt population, even these small differences between alternatives may be important.</p> <p><u>Longfin Smelt</u></p> <p>Overall, based on the decrease in frequency and magnitude of negative OMR flows and the higher Longfin Smelt abundance index values, especially in dry and critical dry years, potential adverse effects on the Longfin Smelt population likely would be less.</p> <p><u>Sacramento Splittail</u></p> <p>Overall, the slight flow decreases under the No Action Alternative could result in less spawning habitat for Sacramento Splittail than under the Second Basis of Comparison because of the decreased area of potential habitat (inundation). Given the relatively minor changes in flows into the Yolo Bypass and the inherent uncertainty associated with the resolution of the CalSim II model (average monthly outputs), it is concluded that there would be no definitive difference in effects on Sacramento Splittail between the No Action Alternative and Second Basis of Comparison.</p> <p><u>Reservoir Fishes</u></p> <p>The analysis of black bass nest survival based on changes in water surface elevation during the spawning period indicated that the likelihood of high (greater than 40 percent) nest survival in most of the reservoirs would be similar from March through May and somewhat higher in June. Most black bass spawning likely occurs prior to June, such that drawdowns during June would likely affect only a small proportion of the spawning population. Thus, it is concluded that effects on black bass nesting success would be similar under the No Action Alternative and the Second Basis of Comparison.</p> <p><u>Pacific Lamprey</u></p> <p>Given the relatively minor changes in water temperature and water temperature threshold exceedance, and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>likely that effects on Pacific Lamprey in the Sacramento, Feather, and American rivers would be similar. This conclusion likely applies to other species of lamprey that inhabit these rivers (e.g., River Lamprey).</p> <p><u>Striped Bass, American Shad, and Hardhead</u></p> <p>In general, Striped Bass, American Shad, and Hardhead can tolerate higher temperatures than salmonids. Given the relatively minor changes in temperature and temperature threshold exceedance, and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is likely that conditions for and effects on Striped Bass, American Shad, and Hardhead in the Sacramento, Feather, and American rivers would be similar. Overall, the No Action Alternative likely would be similar for Hardhead and have a slightly lower potential for adverse effects on Striped Bass and American Shad as compared to the Second Basis of Comparison, primarily due to the potential for increased survival during larval and juvenile life stages, and more favorable location of Spring X2 on average.</p> <p><b>Stanislaus River/Lower San Joaquin River</b></p> <p><u>Fall-run Chinook Salmon</u></p> <p>The water temperature model outputs for each of the life stages suggest that thermal conditions and effects on fall-run Chinook Salmon in the Stanislaus River generally would be similar, although water temperatures under the No Action Alternative could be somewhat more suitable for fall-run Chinook Salmon spawning/egg incubation. Because the No Action Alternative has the potential for beneficial effects resulting from the RPA actions, it is concluded that the effects on fall-run Chinook Salmon would be less adverse relative to the Second Basis of Comparison.</p> <p><u>Steelhead</u></p> <p>The water temperature model outputs suggest that the differences in the magnitude and frequency of exceedance of suitable temperatures for the various lifestages could have the potential for adverse effects on steelhead in the Stanislaus River. However, the direction and magnitude of this effect is uncertain. It is concluded that the potential for adverse effects on steelhead would be lower, principally because the Second Basis of Comparison does not include a strategy to address water temperatures critical to steelhead sustainability over the long term with climate change by 2030.</p> <p><u>White Sturgeon</u></p> <p>Evidence of White Sturgeon spawning has been recorded in the San Joaquin River upstream of the confluence with the Stanislaus River. While flows in the San Joaquin River upstream of the Stanislaus River are expected to be similar under all alternatives, flow contributions from the Stanislaus River could influence water temperatures in the San Joaquin River where White Sturgeon eggs or larvae may occur during the spring and early summer. The magnitude of influence on water temperature would depend on the proportional flow contribution of the Stanislaus River and the temperatures in both the Stanislaus and San Joaquin rivers. The potential for an effect on White Sturgeon eggs and larvae would be influenced by the proportion of the population occurring in the San Joaquin River. In consideration of this uncertainty, it is not possible to</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>distinguish potential effects on White Sturgeon between alternatives.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, predicted nest survival is generally above 40 percent in all months evaluated, although survival would vary among months. Given the relatively high survival in general and the uncertainty caused by the inconsistency in changes in survival, it is likely that effects would be similar.</p> <p><u>Other Species</u></p> <p>In general, Pacific Lamprey, Striped Bass, and Hardhead also can tolerate higher temperatures than salmonids. Given the relatively minor changes in temperature and temperature threshold exceedance, the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is likely that the potential to affect these species in the Stanislaus and San Joaquin rivers would be similar.</p> <p><b>Pacific Ocean</b></p> <p><u>Killer Whale</u></p> <p>Given conclusions from NMFS (2009c), and the fact that at least 75 percent of fall-run Chinook Salmon available for Southern Residents are produced by Central Valley hatcheries, it is likely that Central Valley fall-run Chinook Salmon as a prey base for killer whales would not be appreciably affected.</p>	
Alternative 1	No effects on aquatic resources.	Not considered for this comparison.
Alternative 2	<p><b>Trinity River Region</b></p> <p><u>The effects are identical as described under the No Action Alternative as compared to the Second Basis of Comparison.</u></p> <p><b>Sacramento River System</b></p> <p>The CVP and SWP operations under Alternative 2 are identical to the CVP and SWP operations under the No Action Alternative. Therefore, changes in physical conditions that affect aquatic resources in the Central Valley Region would be the same as the impacts described for the No Action Alternative Compared to the Second Basis of Comparison. However, actions to provide fish passage to portions of the Sacramento, American, and Stanislaus rivers upstream of their dams would not be undertaken under Alternative 2 or the Second Basis of Comparison.</p> <p><b>Stanislaus River/Lower San Joaquin River</b></p> <p>The effects are identical as described under the No Action Alternative as compared to the Second Basis of Comparison.</p> <p><b>Pacific Ocean</b></p> <p><u>Killer Whale</u></p> <p>The effects are identical as described under the No Action Alternative as compared to the Second Basis of Comparison.</p>	Not considered for this comparison.
Alternative 3	<p><b>Trinity River Region</b></p> <p><u>Coho Salmon and Chinook Salmon</u></p> <p>Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is concluded that Alternative 3 and the Second Basis of</p>	Not considered for this comparison.

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>Comparison are likely to have similar effects on Coho Salmon and Chinook Salmon in the Trinity River.</p> <p><u>Steelhead</u></p> <p>Differences in water temperature conditions for steelhead in the Trinity River would be minor as described above for salmon. These results suggest that conditions for steelhead in the Trinity River generally would be similar.</p> <p><u>Green Sturgeon</u></p> <p>The results of the water temperature analysis suggests similar effects on Green Sturgeon in the Trinity River and lower Klamath River and estuary.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, reservoir storage and nest survival suggest similar effects on black bass.</p> <p><u>Pacific Lamprey and Eulachon</u></p> <p>Overall, water temperature conditions for Pacific Lamprey and Eulachon in the Trinity River and Klamath River downstream of the confluence generally would be similar. This conclusion likely also applies to other species of lamprey that inhabit the Trinity and lower Klamath rivers (e.g., River Lamprey).</p> <p><b>Sacramento River System</b></p> <p><u>Winter-run Chinook Salmon</u></p> <p>The numerical model results suggest that effects on winter-run Chinook Salmon would be similar, with a small likelihood that winter-run Chinook Salmon escapement would be higher. The ocean harvest restrictions under Alternative 3 could provide a benefit, although the effects of the predator management program are uncertain. Overall, given the small differences, distinguishing a clear difference between alternatives is difficult. The non-operational components could benefit winter-run Chinook Salmon relative to the Second Basis of Comparison over the short term if successful. Thus, the potential for adverse effects on winter-run Chinook Salmon would be slightly less under Alternative 3 than under the Second Basis of Comparison.</p> <p><u>Spring-run Chinook Salmon</u></p> <p>The numerical model results suggest that overall, effects on spring-run Chinook Salmon could be slightly more adverse with a small likelihood that spring-run Chinook Salmon production would be lower. Although the operational components could have greater adverse effects on spring-run Chinook Salmon, the non-operational components could benefit spring-run Chinook Salmon over the short term if successful. The ocean harvest restrictions could increase spring-run Chinook Salmon numbers by reducing ocean harvest and the trap and haul program and predator control measures could reduce predation on juvenile spring-run Chinook Salmon and thereby increase survival. The effects of the trap and haul and predator management programs are uncertain. Thus, the potential for adverse effects on spring-run Chinook Salmon would be slightly less under Alternative 3 than under the Second Basis of Comparison.</p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, the results of the numerical models suggest the potential for less adverse effects on fall-run Chinook Salmon. However, discerning a meaningful difference</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>based on the quantitative results is not possible because of the similarity in results (generally differences less than 5 percent) and the inherent uncertainty of the models. In addition, adverse effects could be offset by the potentially beneficial effects resulting from predator control and ocean harvest restrictions. Thus, the potential for adverse effects on fall-run Chinook Salmon would be slightly less under Alternative 3 than under the Second Basis of Comparison.</p> <p><u>Late Fall-run Chinook Salmon</u></p> <p>Overall, the results of the numerical models suggest the potential for less adverse effects on late fall-run Chinook Salmon. However, discerning meaningful differences based on the quantitative results is not possible because of the similarity in results (generally differences less than 5 percent) and the inherent uncertainty of the models. In addition, any adverse effects could be offset by the potentially beneficial effects resulting from predator control and ocean harvest restrictions. Thus, the effects on late fall-run Chinook Salmon would be similar under Alternative 3 and the Second Basis of Comparison.</p> <p><u>Steelhead</u></p> <p>Overall, the results of the numerical models suggest a slightly greater potential for adverse effects on steelhead. However, discerning a meaningful difference between based on the quantitative results is not possible because of the similarity in results (generally differences less than 5 percent) and the inherent uncertainty of the models. In addition, any adverse effects could be offset by the potentially beneficial effects resulting from predator control. Thus, the effects on steelhead would be similar under Alternative 3 and the Second Basis of Comparison.</p> <p><u>Green and White Sturgeon</u></p> <p>The slightly reduced frequency of exceedance of temperature thresholds could reduce the potential for adverse effects on sturgeon in the Sacramento and Feather rivers. The analysis based on Delta outflows suggests that there would be similar mean (March to July) outflows which would have similar effects on year class strength of juvenile sturgeon. Therefore, based primarily on the analysis of water temperatures, Alternative 3 could be less likely to result in adverse effects on White Sturgeon than the Second Basis of Comparison.</p> <p><u>Delta Smelt</u></p> <p>Overall, effects would be similar with regard to estimated entrainment and predicted location of Fall X2. However, given the current condition of the Delta Smelt population, even small differences between alternatives may be important.</p> <p><u>Longfin Smelt</u></p> <p>Overall, based on the decrease in frequency and magnitude of negative OMR flows and the higher Longfin Smelt abundance index values in drier years, the potential for adverse effects likely to be lower. Given the current condition of the Longfin Smelt population, even these small differences between alternatives may be important.</p> <p><u>Sacramento Splittail</u></p> <p>Flows entering the Yolo Bypass generally would be similar. Given the relatively minor changes in flows into</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>the Yolo Bypass, and the inherent uncertainty associated with the resolution of the CalSim II model (average monthly outputs), there would be no definitive difference in effects on Sacramento Splittail between Alternative 3 and the Second Basis of Comparison.</p> <p><u>Reservoir Fishes</u></p> <p>The analysis of black bass nest survival based on changes in water surface elevation during the spawning period indicated that the likelihood of high (greater than 40 percent) nest survival in most of the reservoirs would be similar. Thus, it is likely that effects on black bass would be similar.</p> <p><u>Other Species</u></p> <p>Changes in average monthly water temperature would be small. In general, lampreys, Striped Bass, American Shad, and Hardhead can tolerate higher temperatures than salmonids. Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), likely to have similar effects on Striped Bass, American Shad, and Hardhead in the Sacramento, Feather, and American rivers.</p> <p>However, the increased bag limits and ability of anglers to retain Striped Bass that are 12 inches in length versus 18 inches could reduce the ability to meet the doubling goals for Striped Bass populations under the requirements of Section 3406(b)(1) of CVPIA.</p> <p><b>Stanislaus River/Lower San Joaquin River</b></p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, likely would have similar effects on the fall-run Chinook Salmon population in the San Joaquin River watershed.</p> <p>Beneficial effects to juvenile fall-run Chinook Salmon as a result of trap and haul passage through the Delta and ocean harvest restrictions. It remains uncertain, however, if predator management actions under fall-run Chinook Salmon would benefit the fall-run Chinook Salmon population.</p> <p><u>Steelhead</u></p> <p>Given the frequency of exceedance under both Alternative 3 and the Second Basis of Comparison, water temperature conditions for steelhead in the Stanislaus River would be generally similar. Discerning a meaningful difference based on the quantitative results is not possible because of the similarity in results (generally differences less than 5 percent) and the inherent uncertainty of the models. Thus, the effects on steelhead would be similar under Alternative 3 and the Second Basis of Comparison.</p> <p><u>White Sturgeon</u></p> <p>While flows in the San Joaquin River upstream of the Stanislaus River are expected to be similar, flow contributions from the Stanislaus River could influence water temperatures in the San Joaquin River where White Sturgeon eggs or larvae may occur during the spring and early summer. The magnitude of influence on water temperature would depend on the proportional flow contribution of the Stanislaus River and the temperatures in both the Stanislaus and San Joaquin rivers. The potential for an effect on White Sturgeon eggs and larvae would be influenced by the proportion of the population occurring in the San Joaquin River. In</p>	

Chapter 9: Fish and Aquatic Resources

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>consideration of this uncertainty, it is not possible to distinguish potential effects on White Sturgeon.</p> <p><u>Reservoir Fishes</u></p> <p>The analysis of black bass nest survival based on changes in water surface elevation during the spawning period indicated that the likelihood of high (&gt;40 percent) nest survival in New Melones would be similar to or higher. This suggests that conditions in New Melones could be more likely to support self-sustaining populations of black bass.</p> <p><u>Other Species</u></p> <p>In general, Striped Bass and Hardhead also can tolerate higher temperatures than salmonids. Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is likely that the potential effects to affect Striped Bass and Hardhead in the Stanislaus and San Joaquin rivers would be similar.</p> <p>However, the increased bag limits and ability of anglers to retain Striped Bass that are 12 inches in length versus 18 inches could reduce the ability to meet the doubling goals for Striped Bass populations under the requirements of Section 3406(b)(1) of CVPIA.</p> <p><b>Pacific Ocean</b></p> <p><u>Killer Whale</u></p> <p>It is unlikely that the Chinook Salmon prey base of killer whales, supported heavily by hatchery production of fall-run Chinook Salmon, would be appreciably affected.</p>	
Alternative 4	<p><b>Trinity River Region</b></p> <p><u>Coho Salmon, spring-run and fall-run Chinook Salmon, steelhead, Green Sturgeon, Reservoir Fishes, Pacific Lamprey, River Lamprey, and Eulachon</u></p> <p>The effects would be identical.</p> <p><b>Sacramento River System</b></p> <p>The CVP and SWP operations under Alternative 4 are identical to the CVP and SWP operations under the Second Basis of Comparison. Therefore, changes in aquatic habitat conditions at CVP and SWP reservoirs, in the rivers downstream of the reservoirs, and in the Delta would be the same as under the Second Basis of Comparison.</p> <p><u>Winter-run, spring-run, fall-run, and late fall-run Chinook Salmon, and steelhead</u></p> <p>The effects in the Sacramento River system would be similar, although Alternative 4 could produce beneficial effects to Chinook Salmon as a result of trap and haul passage through the Delta and ocean harvest restrictions. However, the magnitude of these potential benefits remain uncertain.</p> <p><u>Green Sturgeon, White Sturgeon, Delta Smelt, Longfin Smelt, Sacramento Splittail, Reservoir Fishes, Pacific Lamprey, River Lamprey, American Shad, and Hardhead</u></p> <p>The effects in the Sacramento River system would be identical.</p> <p><u>Striped Bass</u></p> <p>The effects in the Sacramento River system would be similar, although predator control would result in adverse effects on Striped Bass.</p>	Not considered for this comparison.

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><b>Stanislaus River/Lower San Joaquin River</b>  <u>Fall-run Chinook Salmon and Steelhead</u>                      The effects in the Stanislaus River/Lower San Joaquin River system would be similar. Beneficial effects to Chinook Salmon as a result of trap and haul passage through the Delta and ocean harvest restrictions. It remains uncertain, however, if predator management actions would benefit the Chinook Salmon population.</p> <p><u>White Sturgeon, Reservoir Fishes, and Other Species</u>                      The effects in the Stanislaus River/Lower San Joaquin River system would be identical.</p> <p><u>Striped Bass</u>                      The effects in the Stanislaus River/Lower San Joaquin River system would be similar. Predation controls related to Striped Bass would result in adverse effects.</p> <p><b>Pacific Ocean</b>  <u>Killer Whale</u>                      It is unlikely that the Chinook Salmon prey base of killer whales, supported heavily by hatchery production of fall-run Chinook Salmon, would be appreciably affected.</p> <p>Beneficial effects due to benefits to fall-run Chinook Salmon as a result of trap and haul passage through the Delta and ocean harvest restrictions. It remains uncertain, however, if predator management actions would benefit the fall-run Chinook Salmon population.</p>	
<p>Alternative 5</p>	<p><b>Trinity River Region</b>  <u>Coho Salmon, Spring-run Chinook Salmon, Fall-run Chinook Salmon, and Steelhead</u>                      Monthly water temperature generally would be similar (less than 0.5°F differences), with the exception of drier years when temperatures could be as much as 2.2°F cooler in November and 1.5°F warmer in December. Average monthly water temperatures could be slightly (up to 0.6°F) higher during July and August and lower (up to 0.7°F) in September. Lower September temperatures may result in slightly better conditions for spring-run Chinook Salmon spawning. Similarly, temperature conditions could be slightly better for fall-run Chinook Salmon spawning because of the reduced temperatures in November during critical dry years.</p> <p>Water temperature thresholds for Coho Salmon, fall-run Chinook Salmon, and steelhead would be exceeded slightly more frequently (less than 1 percent), whereas thresholds for spring-run Chinook Salmon would be exceeded less frequently (up to 4 percent) in August in September.</p> <p>Discerning a meaningful difference based on the quantitative results is not possible because of the similarity in results (generally differences less than 5 percent) and the inherent uncertainty of the models. In addition, implementation of a Hatchery Management Plan could reduce the impacts of hatchery Chinook Salmon on natural Chinook Salmon in the Trinity River and increase the genetic diversity and diversity of run-timing for these stocks, but the potential magnitude of these benefits is uncertain.</p> <p>Alternative 5 is likely to have similar effects on Chinook Salmon and steelhead in the Trinity River.</p> <p><u>Reservoir Fishes</u>                      Overall, the comparison of storage and the analysis of nesting suggest that effects would be similar.</p>	<p>Not considered for this comparison.</p>

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><u>Other Species</u></p> <p>The minor differences in average monthly water temperatures described above for salmonids apply to Pacific Lamprey, Eulachon, and other aquatic species in the Trinity River. These minor differences suggest that conditions for aquatic species in the Trinity River and Klamath River downstream of the confluence generally would be similar under Alternative 5 and the Second Basis of Comparison.</p> <p><b>Sacramento River System</b></p> <p><u>Winter-run Chinook Salmon</u></p> <p>Overall, the quantitative results from the numerical models suggest that operations would be less likely to result in adverse effects on winter-run Chinook Salmon. In consideration of the potentially beneficial effects resulting from actions that are not included in the numerical models, the potential for adverse effects on winter-run Chinook Salmon under Alternative 5 would clearly be less than those under the Second Basis of Comparison, principally because the Second Basis of Comparison does not include a strategy to address water temperatures critical to winter-run Chinook Salmon sustainability over the long term with climate change by 2030.</p> <p><u>Spring-run Chinook Salmon</u></p> <p>The numerical model results suggest that, overall, Alternative 5 likely would have similar or slightly greater adverse effects on the spring-run Chinook Salmon population in the Sacramento River watershed as compared to the Second Basis of Comparison. The potential for adverse effects on spring-run Chinook Salmon suggested by the results of the numerical models would likely be offset by the potential benefits of the actions that are not included in the numerical models, principally because the Second Basis of Comparison does not include a strategy to address water temperatures critical to spring-run Chinook Salmon sustainability over the long term with climate change by 2030. On balance and over the long term, the adverse effects on spring-run Chinook Salmon under Alternative 5 would be less than those under the Second Basis of Comparison.</p> <p><u>Fall-run Chinook Salmon</u></p> <p>Overall, the results of the numerical models suggest the potential for greater adverse effects on fall-run Chinook Salmon. However, discerning a meaningful difference between these two scenarios based on the quantitative results is difficult because of the similarity in results (generally differences less than 5 percent), the inherent uncertainty of the models, and the potential for offsetting benefits. Thus, the effects on fall-run Chinook Salmon would be similar.</p> <p><u>Late Fall-run Chinook Salmon</u></p> <p>The numerical model results suggest that overall, Alternative 5 is likely to have less adverse effect on late fall-run Chinook Salmon in the Sacramento River. Benefits may be enhanced by actions intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities to improve the overall salvage survival of salmonids, including late fall-run Chinook Salmon. Thus, the potential for adverse effects on late fall-run Chinook Salmon would be less under Alternative 5 relative to the Second Basis of Comparison.</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><u>Steelhead</u></p> <p>The numerical model results suggest that overall, effects on steelhead could be slightly more adverse, particularly in the Feather and American rivers. However, implementation of a fish passage program intended to address the limited availability of suitable habitat for steelhead in the Sacramento River reaches downstream of Keswick Dam and in the American River could provide a benefit to Central Valley steelhead in the Sacramento and American rivers. This is particularly important in light of anticipated increases in water temperature associated with climate change in 2030. In addition to fish passage, preparation and implementation of an HGMP for steelhead at the Nimbus Fish Hatchery and actions intended to increase the efficiency of the Tracy and Skinner Fish Collection Facilities could benefit steelhead. Thus, on balance and over the long term, the adverse effects on steelhead under Alternative 5 would be less than those under the Second Basis of Comparison.</p> <p><u>Green Sturgeon</u></p> <p>Overall, the increased frequency of exceedance of temperature thresholds could increase the potential for adverse effects on Green Sturgeon in the Sacramento and Feather rivers. However, analysis based on Delta outflows suggests that Alternative 5 provides higher mean (March to July) outflows which could result in stronger year classes of juvenile sturgeon relative to the Second Basis of Comparison. However, early life stage survival in the natal rivers is crucial in development of a strong year class; therefore, based primarily on the analysis of water temperatures, Alternative 5 could be more likely to result in adverse effects on Green Sturgeon than the Second Basis of Comparison.</p> <p><u>White Sturgeon</u></p> <p>The increased frequency of exceedance of temperature thresholds under Alternative 5 could increase the potential for adverse effects on White Sturgeon relative to the Second Basis of Comparison. However, the analysis based on Delta outflows suggests that the No Action Alternative provides higher mean (March to July) outflows which could result in stronger year classes of juvenile sturgeon relative to the Second Basis of Comparison. Early life stage survival in the natal rivers is crucial in development of a strong year class; therefore, based primarily on the analysis of water temperatures, Alternative 5 could be more likely to result in adverse effects on White Sturgeon than the Second Basis of Comparison.</p> <p><u>Delta Smelt</u></p> <p>Overall, likely would result in better conditions for Delta Smelt, primarily due to lower percentage entrainment for larval and juvenile life stages, and more favorable location of Fall X2 in wetter years, and on average. Given the current condition of the Delta Smelt population, even small differences between alternatives may be important.</p> <p><u>Longfin Smelt</u></p> <p>Overall, based on the decrease in frequency and magnitude of negative OMR flows and the higher Longfin Smelt abundance index values, especially in dry and critical dry years, potential adverse effects on the Longfin Smelt population likely would be less.</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p><u>Sacramento Splittail</u></p> <p>Overall, the slight adverse effects related to spawning habitat for Sacramento Splittail because of the decreased area of potential habitat (inundation) and the potential for a slight decrease in the frequency of inundation. Given the relatively minor changes in flows into the Yolo Bypass, and the inherent uncertainty associated with the resolution of the CalSim II model, no definitive difference in effects on Sacramento Splittail could be discerned.</p> <p><u>Reservoir Fishes</u></p> <p>The analysis of black bass nest survival based on changes in water surface elevation during the spawning period indicated that the likelihood of high (greater than 40 percent) nest survival in most of the reservoirs would be similar. Overall, the results of the nest survival analysis suggest that effects on reservoir fishes would be similar.</p> <p><u>Pacific Lamprey</u></p> <p>Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model (average monthly outputs), it is likely that conditions for and effects on Pacific Lamprey in the Sacramento, Feather, and American rivers would be similar. This conclusion likely applies to other species of lamprey that inhabit these rivers (e.g., River Lamprey).</p> <p><u>Striped Bass, American Shad, and Hardhead</u></p> <p>In general, Striped Bass, American Shad, and Hardhead can tolerate higher temperatures than salmonids. Given the similarity of the results and the inherent uncertainty associated with the resolution of the temperature model, it is likely that thermal conditions for and effects on Striped Bass, American Shad, and Hardhead in the Sacramento, Feather, and American rivers would be similar. Overall, Alternative 5 likely would have similar effects on Hardhead and a slightly lower potential for adverse effects on Striped Bass, American Shad, and Hardhead as compared to the Second Basis of Comparison, primarily due to the potential for increased survival for these two species during larval and juvenile life stages, and more favorable location of Spring X2 on average.</p> <p><b>Stanislaus River/Lower San Joaquin River</b></p> <p><u>Fall-run Chinook Salmon</u></p> <p>The analysis of temperatures indicates lower temperatures and a lesser likelihood of exceedance of suitable temperatures for spawning and rearing of fall-run Chinook Salmon in the Stanislaus River below Goodwin Dam and in the San Joaquin River at Vernalis. As described above, the instream flow patterns are anticipated to benefit fall-run Chinook Salmon in the Stanislaus River and downstream in the lower San Joaquin River below Vernalis.</p> <p>Implementation of a fish passage project under Alternative 5, intended to address the limited availability of suitable habitat for steelhead in the Stanislaus River reaches downstream of Goodwin Dam, likely would not provide benefit to fall-run Chinook Salmon unless passage was provided and additional habitat could be accessed. Potential benefits to fall-run Chinook Salmon associated with fish passage is nevertheless uncertain. However, actions implemented under Alternative 5 intended to increase the efficiency of the Tracy and</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>Skinner Fish Collection Facilities could improve the overall salvage survival of fall-run Chinook Salmon. Overall, given the small differences in the modeling results and the potential benefits anticipated by actions not captured in the models, effects on fall-run Chinook Salmon would be similar.</p> <p><u>Steelhead</u></p> <p>Given the frequency of exceedance and the generally stressful temperature conditions in the river, the substantial lower temperatures in October and April suggest that there would be less potential to result in adverse effects on steelhead.</p> <p>Implementation of a fish passage program under Alternative 5 intended to address the limited availability of suitable habitat for steelhead in the Stanislaus River reaches downstream of Goodwin Dam could provide a benefit to steelhead. In addition, the potential effects of Alternative 5 could be offset by actions intended to reduce predation risk on steelhead in the Stanislaus River and increase the efficiency of the Tracy and Skinner Fish Collection Facilities. The actions to augment spawning gravel in the Stanislaus River under Alternative 5 also could benefit steelhead.</p> <p>The numerical model results for effects on steelhead under Alternative 5 and Second Basis of Comparison do not definitively show distinct differences. However, in consideration of the potentially beneficial effects resulting from the actions that would be implemented under Alternative 5 that are not included in the numerical models, Alternative 5 has a much greater potential to address the long-term sustainability of steelhead than does the Second Basis of Comparison. Alternative 5 includes provisions for fish passage upstream of New Melones Dam to address long-term temperature increases associated with climate change. Even though the success of fish passage is uncertain, the potential for adverse effects on steelhead under Alternative 5 would clearly be less than that under the Second Basis of Comparison, principally because the Second Basis of Comparison does not include a strategy to address water temperatures critical to steelhead sustainability over the long term with climate change by 2030.</p> <p><u>White Sturgeon</u></p> <p>Evidence of White Sturgeon spawning has been recorded in the San Joaquin River upstream of the confluence with the Stanislaus River. While flows in the San Joaquin River upstream of the Stanislaus River are expected to be similar under all alternatives, flow contributions from the Stanislaus River could influence water temperatures in the San Joaquin River where White Sturgeon eggs or larvae may occur during the spring and early summer. The magnitude of influence on water temperature would depend on the proportional flow contribution of the Stanislaus River and the temperatures in both the Stanislaus and San Joaquin rivers. The potential for an effect on White Sturgeon eggs and larvae would be influenced by the proportion of the population occurring in the San Joaquin River. In consideration of this uncertainty, it is not possible to distinguish potential effects on White Sturgeon between alternatives.</p> <p><u>Reservoir Fishes</u></p> <p>Overall, the analysis suggests that conditions under Alternative 5 have the potential to influence black bass</p>	

Alternative	Potential Change	Consideration for Mitigation Measures
	<p>nesting success, especially in April and May in comparison to the Second Basis of Comparison. However, nesting success under Alternative 5 would still exceed 40 percent most of the time under both alternatives. Therefore, there would be no definitive difference in effects on reservoir fish between Alternative 5 and the Second Basis of Comparison.</p> <p><u>Other Species</u></p> <p>In general, Striped Bass and Hardhead can tolerate higher temperatures than salmonids. Given the similar flows and temperatures during their spawning and incubation period, it is likely that the potential to affect Striped Bass and Hardhead in the Stanislaus and San Joaquin rivers would be similar.</p> <p><b>Pacific Ocean</b></p> <p><u>Killer Whale</u></p> <p>Given conclusions from NMFS (2009c), and the fact that at least 75 percent of fall-run Chinook Salmon available for Southern Residents are produced by Central Valley hatcheries, it is likely that Central Valley fall-run Chinook Salmon as a prey base for killer whales would not be appreciably affected.</p>	

1  
2  
3

Note: Due to the limitations and uncertainty in the CalSim II monthly model and other analytical tools, incremental differences of 5 percent or less between alternatives and the Second Basis of Comparison are considered to be "similar."

4 **9.4.3.8 Potential Mitigation Measures**

5 Mitigation measures are presented in this section to avoid, minimize, rectify,  
6 reduce, eliminate, or compensate for adverse environmental effects of  
7 Alternatives 1 through 5 as compared to the No Action Alternative. Mitigation  
8 measures were not included to address adverse impacts under the alternatives as  
9 compared to the Second Basis of Comparison because this analysis was included  
10 in this EIS for information purposes only.

11 Changes in CVP and SWP operations under Alternatives 1 through 5 as compared  
12 to the No Action Alternative would result in adverse impacts. Potential  
13 mitigation measures that could be considered to reduce the adverse water  
14 temperature impacts include implementation of fish passage programs. Mitigation  
15 measures for other substantial adverse impacts have not been identified at this  
16 time.

17 **9.4.3.8.1 Fish Passage Programs**

18 Implementation of Alternatives 1, 2, 3, and 4 would result in adverse impacts due  
19 to high water temperatures in the streams downstream of the dams. A potential  
20 mitigation measure to reduce these effects would be:

- 21 • Implement fish passage programs at Shasta and Keswick, Oroville and  
22 Thermalito, Folsom and Nimbus, and New Melones dams to reduce  
23 temperature impacts on Chinook Salmon and steelhead under Alternatives 1,  
24 2, 3, and 4.

1 These programs would be similar to programs implemented under the 2009  
 2 NMFS BO, as included in the No Action Alternative and Alternative 5. This  
 3 mitigation measure would be in response to the climate change effects anticipated  
 4 in 2030 in addition to the changes under Alternatives 1, 2, 3, and 4.

5 **9.4.3.9 Cumulative Effects Analysis**

6 As described in Chapter 3, the cumulative effects analysis considers projects,  
 7 programs, and policies that are not speculative; and are based upon known or  
 8 reasonably foreseeable long-range plans, regulations, operating agreements, or  
 9 other information that establishes them as reasonably foreseeable.

10 The cumulative effects analysis under Alternatives 1 through 5 for Fish and  
 11 Aquatic Resources are summarized in Table 9.6.

12 **Table 9.6 Summary of Cumulative Effects on Fish and Aquatic Resources of**  
 13 **Alternatives 1 through 5 as Compared to the No Action Alternative**

Scenarios	Actions	Cumulative Effects of Actions
Past & Present, and Future Actions Included in the No Action Alternative and in All Alternatives in Year 2030	Consistent with Affected Environment conditions plus: Actions in the 2008 USFWS BO and 2009 NMFS BO that would have occurred without implementation of the BOs, as described in Section 3.3.1.2 (of Chapter 3, Descriptions of Alternatives) Actions not included in the 2008 USFWS BO and 2009 NMFS BO that would have occurred without implementation of the BOs, as described in Section 3.3.1.3 (of Chapter 3, Descriptions of Alternatives), including climate change and sea level rise: <ul style="list-style-type: none"> <li>• Implementation of Federal and state policies and programs, including Clean Water Act (e.g. Total Maximum Daily Loads); Safe Drinking Water Act; Clean Air Act; and flood management programs</li> <li>• General plans for 2030.</li> <li>• Trinity River Restoration Program.</li> <li>• Central Valley Project Improvement Act programs</li> <li>• Iron Mountain Mine Superfund Site</li> <li>• Nimbus Fish Hatchery Fish Passage Project</li> <li>• Folsom Dam Water Control Manual Update</li> </ul>	<u>These effects would be the same under all alternatives.</u> Climate change and sea level rise, development under the general plans, FERC relicensing projects, and some future projects to improve water quality and/or habitat are anticipated to reduce carryover storage in reservoirs, stream flows and Delta outflow, and the availability of CVP and SWP water supplies as compared to past conditions. These future actions could modify surface water conditions (e.g., flow) and affect habitat for fish and aquatic resources. However, many of these actions are intended to improve habitat conditions for aquatic resources or water quality, and thus the alternatives would not contribute to an adverse cumulative effect on aquatic resources. In addition, these actions were or would be subject to compliance with ESA, CESA, and other environmental laws and requirements, which serve to reduce the potential for impacts on aquatic resources.

Chapter 9: Fish and Aquatic Resources

Scenarios	Actions	Cumulative Effects of Actions
	<ul style="list-style-type: none"> <li>• FERC Relicensing for the Middle Fork of the American River Project</li> <li>• Lower Mokelumne River Spawning Habitat Improvement Project</li> <li>• Dutch Slough Tidal Marsh Restoration</li> <li>• Suisun Marsh Habitat Management, Preservation, and Restoration Plan Implementation</li> <li>• Tidal Wetland Restoration: Yolo Ranch, Northern Liberty Island Fish Restoration Project, Prospect Island Restoration Project, and Calhoun Cut/Lindsey Slough Tidal Habitat Restoration Project</li> <li>• San Joaquin River Restoration Program</li> <li>• Stockton Deep Water Ship Channel Dissolved Oxygen Project</li> <li>• Grasslands Bypass Project</li> <li>• Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS)</li> </ul>	
<p>Future Actions Considered as Cumulative Effects Actions in All Alternatives in Year 2030</p>	<p>Actions as described in Section 3.5 (of Chapter 3, Descriptions of Alternatives):</p> <ul style="list-style-type: none"> <li>• Bay-Delta Water Quality Control Plan Update</li> <li>• FERC Relicensing Projects</li> <li>• Bay Delta Conservation Plan (including the California WaterFix alternative)</li> <li>• Shasta Lake Water Resources Investigation, North-of-the-Delta Offstream Storage, Los Vaqueros Reservoir Expansion Phase 2, and Upper San Joaquin River Basin Storage Investigations</li> <li>• El Dorado Water and Power Authority Supplemental Water Rights Project</li> <li>• Sacramento River Water Reliability Project</li> <li>• Semitropic Water Storage District Delta Wetlands</li> </ul>	<p><u>These effects would be the same under all alternatives.</u></p> <p>Most of the future reasonably foreseeable actions are anticipated to reduce water supply impacts due to climate change, sea level rise, and increased water allocated to improve habitat conditions. It is unclear how these future reasonably foreseeable actions would influence aquatic resources because project details are not available. However, as described above, these actions would be subject to environmental regulations that avoid or limit the potential for cumulative effects on aquatic resources. Some of these actions (e.g., FERC relicensing projects) could cumulatively contribute to reducing adverse effects of climate change on aquatic resources if fish passage and improved water temperature control result from the FERC process.</p>

Scenarios	Actions	Cumulative Effects of Actions
	<ul style="list-style-type: none"> <li>• North Bay Aqueduct Alternative Intake</li> <li>• Irrigated Lands Regulatory Program</li> <li>• San Luis Reservoir Low Point Improvement Project</li> <li>• <i>Westlands Water District v. United States Settlement</i></li> <li>• Future water supply projects, including water recycling, desalination, groundwater banks and wellfields, and conveyance facilities (projects that did not have completed environmental documents during preparation of the EIS)</li> </ul>	
<p>No Action Alternative with Associated Cumulative Effects in Year 2030</p>	<p>Full implementation of the 2008 USFWS BO and 2009 NMFS BO</p>	<p>Implementation of No Action Alternative would result in changes in stream flows, increased Delta outflow, and reduced CVP and SWP water supplies as compared to conditions prior to the BOs. These RPA actions are intended and anticipated to put fish and aquatic resources on a more favorable trajectory than would occur without these actions.</p>
<p>Alternative 1 with Associated Cumulative Effects in Year 2030</p>	<p>No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant)</p>	<p>Implementation of Alternatives 1 and 4 with reasonably foreseeable actions would result in changes in stream flows, reduced Delta outflows, and increased CVP and SWP water exports as compared to the No Action Alternative with reasonably foreseeable actions. Favorable conditions for listed salmonids could be less available as compared to the No Action Alternative because access to habitat upstream of Shasta, Folsom, and New Melones dams would not be available. In addition, implementation of these alternatives could contribute cumulatively to impacts on listed Delta species by comparison to the No Action Alternative with reasonably foreseeable actions.</p>
<p>Alternative 2 with Associated Cumulative Effects in Year 2030</p>	<p>Full implementation of the 2008 USFWS BO and 2009 NMFS BO CVP and SWP operational actions.</p> <p>No implementation of structural improvements or other actions that require further study to develop a more detailed action description.</p>	<p>The effects of Alternative 2 on water temperature relative to the No Action Alternative could contribute incrementally to the cumulative effects on listed salmonids because the alternative provides no mechanism for addressing long-term temperature increases.</p>

Scenarios	Actions	Cumulative Effects of Actions
Alternative 3 with Associated Cumulative Effects in Year 2030	<p>No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant)</p> <p>Slight increase in positive Old and Middle River flows in the winter and spring months</p> <p>Increased bag limits for Striped Bass and Pikeminnow</p> <p>Increased ocean salmon fishing harvest limitations</p>	<p>Implementation of Alternatives 1 and 4 with reasonably foreseeable actions would result in changes in stream flows, reduced Delta outflows, and increased CVP and SWP water exports as compared to the No Action Alternative with reasonably foreseeable actions. Favorable conditions for listed salmonids could be less available as compared to the No Action Alternative because access to habitat upstream of Shasta, Folsom, and New Melones dams would not be available. In addition, implementation of these alternatives could contribute cumulatively to impacts on listed Delta species by comparison to the No Action Alternative with reasonably foreseeable actions.</p>
Alternative 4 with Associated Cumulative Effects in Year 2030	<p>No implementation of the 2008 USFWS BO and 2009 NMFS BO actions unless the actions would have been implemented without the BO (e.g., Red Bluff Pumping Plant)</p> <p>Increased bag limits for Striped Bass and Pikeminnow</p> <p>Increased ocean salmon fishing harvest limitations</p> <p>No implementation of the USACE vegetation standards for levees</p>	<p>Implementation of Alternatives 1 and 4 with reasonably foreseeable actions would result in changes in stream flows, reduced Delta outflows, and increased CVP and SWP water exports as compared to the No Action Alternative with reasonably foreseeable actions. Favorable conditions for listed salmonids could be less available as compared to the No Action Alternative because access to habitat upstream of Shasta, Folsom, and New Melones dams would not be available. In addition, implementation of these alternatives could contribute cumulatively to impacts on listed Delta species by comparison to the No Action Alternative with reasonably foreseeable actions.</p>
Alternative 5 with Associated Cumulative Effects in Year 2030	<p>Full implementation of the 2008 USFWS BO and 2009 NMFS BO</p> <p>Positive Old and Middle River flows and increased Delta outflow in spring months</p>	<p>Implementation of Alternative 5 with reasonably foreseeable actions would result in changes in stream flows, increased Delta outflows, and reduced CVP and SWP water exports as compared to the No Action Alternative with these added actions.</p>
