Soils are intrinsic features of a landscape. They develop over time through physical, chemical, and biological processes. In the LSJR area of potential effects and SDWQ area of potential effects, the suitability of soils to support agricultural enterprises is classified by NRCS and is based on the soil type, adequate drainage, and the availability of water supply for irrigation. The State of California uses this information to develop maps that identify Prime Farmland, Farmland of Statewide Importance, and Unique Farmland. In addition, counties may identify Farmland of Local Importance. The definitions for each of the land use categories are provided in Section 11.3.1, *State [Regulatory Background]*.

All waters contain soluble salts, collectively referred to as *salinity*. The major components of either water or soil salinity include cations (calcium, sodium, and magnesium) and anions (bicarbonate, chloride, and sulfate) (Ayers and Westcott 1985). With regards to soil, salinity refers to the soluble plus readily dissolvable salts in the soil or in an extract of a soil sample. Salinity is quantified in terms of the total concentration of soluble salts. In practical terms, salinity is measured as electrical conductivity (EC)[5] of the solution (USDA 1954).

Salts in soil are generally at higher concentrations than those found in water. The extent to which salts accumulate in the soil depends on the irrigation water quality, irrigation management, and the adequacy of drainage. Crop water use (evapotranspiration) of irrigation water results in a salt load to the soil because crop evapotranspiration removes water from the soil profile but leaves the salt. Although crops uptake salt, the amount is insignificant. If salts in the soil become excessive, crop yield could be reduced. Certain crops may also have specific ion toxicities, where even relatively low concentrations of the ion could lead to yield reductions. Factors to consider when establishing a salinity standard for irrigated agriculture include plant response to soil salinity, effective rainfall, and irrigation management and method. Another important factor is that a plant's sensitivity to soil

---

[5] In this document, EC is *electrical conductivity*, which is generally expressed in deciSiemens per meter (dS/m). Measurement of EC is a widely accepted indirect method to determine the salinity of water, which is the concentration of dissolved salts (often expressed in parts per thousand or parts per million). EC and salinity are therefore used interchangeably in this document.

salinity changes during plant development. Many crops are most sensitive to soil salinity during emergence and early seedling development (Ayers and Westcott 1985; USSL 2011).

The method of irrigation and water management affects how a plant tolerates water or soil salinity. The main methods of irrigation in the LSJR Watershed and southern Delta include surface (border strip, furrow, and basin), sprinkler, and micro-irrigation (Edinger-Marshall and Letey 1997). In some areas of the southern Delta, subirrigation is also practiced. Poorly managed border and furrow irrigation can cause salt to build up in the soil profile in areas that do not receive adequate irrigation water of sufficient quality. Salt buildup can occur with micro-irrigation if the systems are not properly managed to push salts away from the rootzone. Subirrigation causes salt to build up in the top portion of the soil profile, unless this is flushed with surface irrigation or precipitation (Grattan 2002).

To reduce salinity impacts on crops, a leaching fraction is added to the crop's irrigation water requirement. The amount of water used for leaching is considered a beneficial use and is based on a plant's salinity tolerance and the salinity of the irrigation water. However, depending on the efficiency of the irrigation system being used and the effectiveness of rainfall, the leaching requirement may be inherently satisfied through irrigation inefficiency.

11.2.2 Lower San Joaquin River Watershed and Eastside Tributaries

This section summarizes the types of farmland and recent changes in farmland acreage, land subject to Williamson Act contracts, crop production, and water supply in the LSJR area of potential effects.

Types of Farmland

The LSJR area of potential effects covers more than 1 million acres of agricultural lands in California's San Joaquin Valley. The majority (55 percent) of farms in the San Joaquin Valley are less than 100 acres, while approximately 20 percent of farms are between 100 and 250 acres (Agricultural Water Management Council 2010). Statewide, the average farm size is 312 acres (DFA 2010).

The majority of land (65 percent) in the LSJR area of potential effects is designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Table 11-2). These lands are designated as such because of certain positive qualities, such as good soil characteristics like drainage, and the availability, amount, and frequency of irrigation. The lands must be irrigated 8 out of every 10 years and there must be adequate depth to the water table to support commonly cultivated crops.

Table 11-2 identifies the total acres of the various farmland categories within the LSJR area of potential effects organized by the six geographic areas that receive surface water supplies from the Stanislaus, Tuolumne, and Merced Rivers: SEWD/CSJWCD, SSJID, OID, MID, TID, and Merced ID. Figure 11-1 identifies the location and type of farmland within the LSJR area of potential effects. Although Table 11-2 shows total acres, including nonagricultural land, for the six geographic regions, typically the respective water districts supply only the farmland portion of each region with irrigation water.

Table 11-2. California Department of Conservation's Land Use Classification Acreages in the LSJR Area of Potential Effects

Land Use Category	SEWD and CSJWCD	SSJID	OID	MID	TID	Merced ID	Total Acres
Prime Farmland	79,648	20,021	11,370	50,186	82,466	67,566	311,257

[a] The sum of Prime Farmland, Unique Farmland, and Farmland of Statewide Importance.

The LSJR area of potential effects, like other parts of the Central Valley and California, has generally experienced a decline in agricultural lands in the past 20 years. Table 11-3 identifies the change in the acreages of Prime Farmland, Unique Farmland, Farmland of Statewide Importance, and Farmland of Local Importance in San Joaquin, Stanislaus, and Merced Counties. San Joaquin County had a relatively large reduction of Prime Farmland from 1990 to 2012, resulting in a correspondingly large net loss of farmland overall. Total farmland area in Merced County remained mostly unchanged from 1992 to 2012, but there was still a large reduction of Prime Farmland. On the other hand, from 2004 to 2012, Stanislaus County had a net gain in total farmland area, primarily because lost Prime Farmland was offset by a large increase of Unique Farmland.

Table 11-3. Changes in Prime Farmland, Unique Farmland, and Farmland of Statewide and Local Importance (Acres)

Land Use Category	San Joaquin County (1990–2012)	Stanislaus County (2004–2012)	Merced County (1992–2012)
Prime Farmland	-55,744	-10,321	-17,105
Farmland of Statewide Importance	-18,116	2,017	-8,687
Unique Farmland	25,194	25,053	15,606
Farmland of Local Importance	23,261	-3,719	10,142
Total	-25,405	13,030	-44

Source: DOC 2015a.

Note: Data include the entire counties, and therefore it is assumed that changes in the LSJR area of potential effects are proportional in the LSJR area of potential effects portion of the respective county.

Farmland Conversion

Like many of California's inland areas, the San Joaquin Valley is likely to experience urbanization on an unprecedented scale. As California grows, much of its growth will be accommodated in crowded metropolitan coastal areas and in Southern California's Inland Empire (PPIC 2005). But spillover from the Bay Area is causing growth stress in the San Joaquin Valley as commuters seek affordable housing. Over the past 35 years, the northern San Joaquin Valley, including San Joaquin, Stanislaus and Merced Counties, has experienced explosive growth in the numbers of workers who commute north and west out of the valley each day. By 2010, that was estimated to be about 24 percent of workers working outside their county of residence with about 46,000 heading towards the Bay Area (Stevens 2014). In addition to the Bay Are growth shift, the San Joaquin Valley is experiencing major growth in its own right—doubling in population approximately every 30 years since 1900. To accommodate that growth, the Public Policy Institute of California estimated that an additional 1 million acres or more of land would be converted by 2040, which would triple the current amount of urbanized land to accommodate new development and reduce farmland by at least 15 percent overall (PPIC 2005). Under DWR projections, irrigated acreage in the San Joaquin Valley declines on average from a low of 117,000 acres by year 2050 to a high of approximately 272,000 acres relative to a 2006 base-year footprint of approximately 1.9 million acres. In other words, declines of between 6 percent and 14 percent of the irrigated acreage (DWR 2014).

Historically, in the San Joaquin Valley, more than 60 percent of all land developed is high quality farmland (Prime, Unique, or Farmland of Statewide Importance), even though that land is only 40 percent of all land in the region. In the LSJR area of potential effects for agricultural resources, the impacts are even higher with development in San Joaquin, Stanislaus, and Merced Counties occurring on high-quality farmland at rates of 76 percent, 83 percent, and 63 percent, respectively, of all land urbanized between 1990 and 2004. The disproportionate impact of urbanization on the best farmland is because most California cities were located in areas with good soils and abundant water, and most development occurs in the immediate urban fringe. In addition, while statewide growth has consumed an acre of land for every 9.4 people (and even less in places like Sacramento where it is about 20 people per acre), the San Joaquin Valley has consumed land at the rate of an acre for every 8 people and, if rural residential ranchettes are included, the development efficiency figure drops even lower. This makes rapid city-centered growth and inefficient land use the underlying causes of most farmland conversion (AFT 2007).

While urbanization isn't the only pressure causing conversions to nonagricultural use in the San Joaquin Valley, it is the greatest pressure in the potential area of effects for agricultural resources. Other large scale pressures, such as salt buildup, are occurring outside the potential area of effects. For example, the San Joaquin Valley Drainage Relief Act identifies 75,000 acres of irrigated agricultural lands on the west side of the San Joaquin Valley that should be retired by the year 2040 primarily due to characteristics of low productivity, poor drainability, and high levels of selenium in shallow groundwater. (Wat. Code, § 14900 et seq.)

Williamson Act Contracts

The Land Conservation Act of 1965, commonly referred to as the Williamson Act, provides a statutory framework for local implementation of farm and ranch land preservation, protecting over 16.4 million acres or nearly one-third of all privately owned land in California. The Williamson Act discourages premature and unnecessary conversion of agricultural land to urban uses through an interrelated set of property tax, land use, and conservation measures. Under the Williamson Act, a landowner enters into a contract with the local government wherein he or she foregoes the possibility of development, or converting his or her property into nonagricultural or non-open space use, during the term of the contract. In return he or she receives lower property taxes. A 1989 analysis of the program showed an average tax savings of 44 percent for tree and vine land up to 70 percent for grazing land (DOC 1989). In a 2012 study, 91 percent of the ranchers polled stated Williamson Act tax reductions were either "very important" or "extremely important" for the "long term viability of their cattle and rangeland operations" and that for 71 percent of the Williamson Act-enrolled ranchers, their net annual profit was equal or less than their Williamson Act property tax savings in 2009 (Wetzel 2012). Although local governments forego a portion of property taxes due to Williamson Act valuations, in return they receive planning advantages and values implicit in retaining or open space.

Land Conservation Act contracts are for rolling 10-years terms, meaning they renew automatically each year for another 10 year term. There is also a rolling 20-year contract option called a Farmland Security Zone contract, also known as a "Super Williamson Act" contract. Until 2010, the state made Open Space Subvention payments from the state general fund to local governments to offset a portion of Williamson Act-related reduced revenues. Those payments totaled $863 million between 1971 and 2010, or almost $1.5 billion when adjusted for inflation. Starting fiscal year 2010–11 Open Space Subvention payments were effectively eliminated. In response, the legislature passed Assembly Bill (AB) 1265, which allows participating counties to recapture a portion of foregone property tax revenue by decreasing the duration of contracts to 9 years for regular Land Conservation Act contracts or 18 years for Farmland Security Zone contracts. Also in 2011, the legislature passed Senate Bill (SB) 618, providing an option to rescind Land Conservation Act contracts on land that has been compromised due to chemical, physical, or water-related limitations and replace the contracts with Solar-Use Easements. Within the past decade, the nonrenewal of Williamson Act contracts, often viewed as a precursor to converting farmland to other uses, occurred in response to economic trends with nonrenewal peaking in 2007 at 157,805 acres. Following that period, as the recession slowed the demand for urban expansion, nonrenewal initiation acreages fell sharply to 19,967 acres in 2010. In 2011, the elimination of Open Space Subvention payments led Imperial County to initiate nonrenewal on all 117,246 acres remaining under contract (DOC 2015b).

There are approximately 377,999 acres under Williamson Act contracts in the LSJR area of potential effects (DOC 2009, 2010a) with Merced and Stanislaus Counties participating in the AB 1265 option for reduced contract terms. Table 11-4 identifies the acreages under Williamson Act contracts within each of the six geographic areas.

Crop Production

Farmland in the LSJR area of potential effects is irrigated by surface water diversions from the three eastside tributaries[6] and from groundwater.

Dryland farming, which relies on stored water in the soil, is feasible for some annual crops in the LSJR area of potential effects (Luers 1970). Dryland farming acreage information is not collected by the Farmland Mapping Program (DOC 2009, 2010a) or reported in the agricultural water management plans for the irrigation districts in the LSJR area of potential effects; as a result, the full extent of the practice is unknown. The acreage reported for planted and harvested winter wheat can be used to estimate dryland farming because this type of crop can be dryland farmed in the LSJR area of potential effects. In 2011, Merced County harvested 20,800 acres of 36,000 acres of winter wheat that were planted, San Joaquin County harvested 26,000 acres of the 36,500 acres of winter wheat that were planted, and Stanislaus County harvested 3,200 acres of the 12,000 acres of winter wheat that were planted (USDA 2012). No acreage was planted in any county in 2013 (USDA 2013). While winter wheat acreage is useful to characterize the practice of dryland farming, there is the potential that winter wheat may be irrigated. In such cases, these estimates would potentially overestimate the amount of dryland acres.

On a periodic basis, DWR surveys and catalogs irrigated acreage into 19 crop categories and provides this data organized by DAU. Irrigated crop production within the LSJR area of potential effects is diverse, with a wide variety of crops grown on 516,727 acres (Table 11-5). Table 11-6 shows the percentage of each of the 19 crop categories within each irrigation district and illustrates how cropping patterns differ between districts.

Cultural crop practices in the LSJR area of potential effects include crop rotation and fallowing (Marsh and Jackson 2006). However, the extent of fallowed land and crop rotation cannot be quantified because this type of data is not readily available and is not reported in the irrigation districts' agricultural water management plans. Crop rotation involves the use of the same piece of land cultivated for various crops, such as corn followed by winter wheat. Land fallowing, or removing land from agricultural production for a period of time, is the deliberate idling of land for a cultural crop practice, such as disease control. Fallowed land is typically managed to keep down weed growth (Marsh and Jackson 2006).

Other Agricultural Production

In addition to crop production, the other significant agricultural activity in the LSJR area of potential effects is dairy. In California there are approximately 1,563 dairies, of which 578 are located in Merced, Stanislaus, and San Joaquin Counties. This is approximately 36 percent of the state's total dairy operations (USDA 2015). Confined animal agriculture acreage is approximately 17,675 acres in the LSJR area of potential effects (Table 11-2); however, the breakdown of this acreage into dairy and other feed operations is unknown because the data is collected based on the definition of confined animal agriculture and does not distinguish between dairies and other confined animal operations. The total value of dairy in the LSJR area of potential effects in 2013 was $2.2 billion (USDA 2015).

---

[6] In this document, the term *three eastside tributaries* refers to the Stanislaus, Tuolumne, and Merced Rivers.

Dairies in the LSJR area of potential effects use water for herd and facility management and for waste disposal. Local crop production allows for both feed and waste disposal for dairies within the LSJR area of potential effects. Dairy relies on Alfalfa and Corn for feed and, to some extent, pasture for grazing. Waste disposal is typically on cropland that is adjacent to dairy facilities. Cropland that is used for disposal may be used for production of feed crops such as Corn, Grain, or Pasture. Water used for waste disposal is to help manage the salt and nitrate loading to lands and local groundwater. Dairy operations in the LSJR area of potential effects operate under waste discharge permits issued by the Central Valley Regional Water Quality Control Board (Cady and Francesconi 2010). In 2015, a critically dry year, irrigation water cost for dairy feed in the San Joaquin Valley represent about 9 percent of the cost of farm milk production (Sumner 2016). Although this is a major cost, it is not itself dominant when considering other costs associated with dairies (Sumner 2016).

Beef cattle operations are also located in the LSJR area of potential effects, representing about 11 percent of the state's total beef cattle inventory of 600,000. There are three segments to beef cattle operations: cow-calf, feeder cattle, and feedlot operations. Cow-calf and feeder cattle operations typically rely on winter pasture and some irrigated pasture for grazing in the summer. In contrast, feedlots rely on grains and oilseed from out of state and, therefore, do not rely on feed directly produced in the LSJR area of potential effects (Medellin-Azuara et al. 2016).

Water Supply, Irrigation, and Water Quality

Surface water supply for irrigation in the LSJR area of potential effects is provided to agricultural users by organized irrigation and water (conservation) districts (collectively referred to as the *irrigation districts* throughout the rest of this chapter). These irrigation districts regularly receive surface water from the Stanislaus, Tuolumne, and Merced Rivers. In addition to surface water supply provided by irrigation districts, many growers have access to groundwater. Details on surface water supply availability and groundwater supply to irrigation and water districts are discussed in Chapter 2, *Water Resources,* Chapter 9, *Groundwater Resources*, and Chapter 13, *Service Providers*.

Irrigation district operations are generally based on diverting river flow into open channels that provide service to parcels of various sizes (Merced ID 2013; MID 2012; OID 2012; TID 2012). Typically, surface water irrigation deliveries begin in April and continue through September, with peak delivery in the summer months. Water can be delivered to a farm on various terms – for example, it can be delivered on a rotating schedule with a fixed flow rate and duration or a user-requested schedule with a variable flow rate and duration. In addition, some irrigation districts operate canals and make deliveries in the off-season for groundwater recharge.

In general, irrigation districts state that they emphasize equity and fairness in the distribution of surface water supplies during normal and dry periods (Merced ID 2013; OID 2012, TID 2012). Irrigation districts acknowledge an increase in groundwater pumping by growers during normal and dry periods, as well as some level of groundwater overdraft, to meet on-farm flexibility needs when surface water supplies are not enough (Merced ID 2013; MID 2012; OID 2012; TID 2012). Merced ID reported in its 2012 Agricultural Water Management Plan that it meets shortages in surface water through increased groundwater pumping (Merced ID 2013). TID allows for internal water transfers but does not distinguish between crop types when making surface water supply allocations (TID 2012).

On-farm irrigation methods in the LSJR area of potential effects include surface, sprinkler, drip, and micro-irrigation (Table 11-7) (DWR 2010). Sometimes other methods of irrigation are used, such as subirrigation, in which the water table is controlled (Table 11-7) (DWR 2010). For the most part, higher net value crops, such as Trees and Vines, are irrigated with pressurized systems, such as hand-moved sprinklers or micro-sprayers. Generally, crops that produce lower net revenue per acre, such as Grains and Pasture, are irrigated with surface methods.

Table 11-7. Irrigation Method Types in Merced, San Joaquin, and Stanislaus Counties (Percent)

County	Surface	Sprinkler	Drip and Micro	Other
Merced	57.2	6.2	34.0	2.7
San Joaquin	36.0	14.2	36.6	13.2
Stanislaus	44.1	9.5	44.8	1.6

Source: DWR 2010.

Surface water quality is very good in the three eastside tributaries, with an average salinity (ECw) value of less than 0.1 deciSiemens per meter (dS/m), as discussed in Chapter 5, *Surface Hydrology and Water Quality*. Groundwater quality in the LSJR area of potential effects varies depending on the groundwater basin, hydrogeology, and depth to groundwater, as discussed in Chapter 9, *Groundwater Resources*. In general, groundwater is known to have elevated salt and nitrate concentrations in the LSJR area of potential effects. However, groundwater within the three eastside tributary watersheds is considered to be of higher quality than for other locations because it is recharged by snowmelt from the Sierra Nevada, which has a low concentration of dissolved constituents.

11.2.3 Extended Plan Area

There are limited agricultural resources in the extended plan area and no designated Prime, Unique, or Farmland of Statewide Importance (California Farmland Mapping and Monitoring Program n.d.). Much of the extended plan area is designated as nonagricultural, but there is some acreage in grazing in Mariposa County near Lake McClure (California Farmland Mapping and Monitoring Program webpage). There are individual small water rights used for irrigated pastures, orchards, and occasional vineyards.

11.2.4 Southern Delta

This section summarizes the agricultural features within the SDWQ area of potential effects, including the farmland classification and acreage, the Williamson Act contract acreage, and the total crop production for different crop types. This section also summarizes water supply, irrigation methods, and water quality in the SDWQ area of potential effects within the boundary of the SDWA. Figure 11-2 shows the location of the SDWQ area of potential effects and the SDWA boundary with respect to San Joaquin County and the legal boundary of the Delta.

Prior to development, lands in the SDWQ area of potential effects existed in a natural state with both organic and mineral soils (NRCS 1999). Over many millennia, histosols, commonly known as organic soils, peats, or mucks, developed in the Delta as plants grew and died. Delta reclamation took place between 1900 and 1920 on lands in the Delta's interior. When adequate drainage was provided to these lands, microbial oxidation of the organic material began, resulting in loss of soil volume (subsidence) over time. Soil subsidence is compounded by wind erosion. Depending on the location, subsidence and erosion rates of 0.5–1.5 inches per year can be common in certain areas. Since the early 1900s, as much as half of the original accumulated soil volume has been lost. The result of the reclamation efforts is largely what is seen as the Delta today—approximately 700 miles of waterways and 1,100 miles of levees that protect over 538,000 acres of farmland, homes, and other structures (DWR 2009).

Types of Farmland

As depicted on Figure 11-2 and described in Table 11-8, the majority of agricultural land in the SDWQ area of potential effects is classified as Prime Farmland (DOC 2012).

Table 11-8. California Farmland Mapping Program Land Use Classification for the SDWA (2010)

Land Use Classification	Acres
Prime Farmland	98,563
Unique Farmland	4,890
Farmland of Statewide Importance	8,079
Farmland of Local Importance	9,071
Semi-Agricultural and Rural Commercial Land	1,255
Urban and Built-Up Land	16,186
Rural Residential Land	1,592
Grazing Lands	447
Confined Animal Agriculture	1,213
Nonagricultural and Natural Vegetation	3,942
Vacant or Disturbed Land	1,930
Water	227
Total	147,396

Source: DOC 2012.

SDWA = Southern Delta Water Agency

Some Prime Farmland in San Joaquin County (Table 11-3) has undergone conversion to urban and other lands (California Department of Conservation 2015).

Farmland Conversion

For over 20 years, the Delta has been recognized as an agricultural region and open-space region of great value to the state and nation and that retention and continued cultivation and production of its fertile peatlands and prime soils are of significant value. In response, the Legislature passed the Johnston-Baker-Andal-Boatwright Delta Protection Act of 1992. (Pub. Resources Code, § 29700 et seq.) The act created the Delta Protection Commission and, as updated in 2009, required the commission to adopt a resources management plan for the Delta region by October 1, 1994 that addressed, among its mandatory requirements, how to protect the Delta from any development that results in significant loss of habitat or agricultural land. (Pub. Resources Code, § 29760.) The Delta Protection Act is discussed in more detail below under Section 11.3.1, *State [Regulatory Background]*. However, as no reduction or conversion of agricultural acreage under the SDWQ alternatives is likely, potential farmland conversion pressures in the Delta are not discussed further here.

Williamson Act Contracts

There are approximately 83,614 acres under Williamson Act contracts in the SDWQ area of potential effects (Table 11-4), representing about 84 percent of the total agricultural acreage. Further discussion of the Williamson Act can be found in Section 11.3.1, *State [Regulatory Background]*.

Crop Production

A wide variety of crops are grown on over 100,000 acres in the SDWQ area of potential effects (Table 11-9) (DWR 2005). Agricultural uses in the southern Delta currently divert water from existing waterways, expecting it to be of suitable water quality to irrigate various different crops. About 60 percent of the land is cultivated as annual crops (Truck & Berry, Field Crops, and Grain & Hay). Alfalfa is cultivated on roughly 30 percent of the land. There has been about a 15 percent drop in total cultivated acreage since 1996, as the acreage planted with dry beans and safflower has declined (Field Crops) (Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–San Joaquin Delta*).

Table 11-9. Crop Production in the SDWQ Area of Potential Effects for 2005

Crop Category & Crop	Acres
Fruits & Nuts	
Apples	18
Apricots	204
Olives	77
Peaches & Nectarines	0
Pears	0
Plums	5
Almonds	3,107
Walnuts	2,051
Pistachios	18
Fruit or Nut < 10 acres	56
Subtotal	5,536
Field Crops	
Cotton	34
Safflower	2,684
Sugar Beets	135
Corn	15,481
Grain Sorghum	0
Sudan	1,286
Castor	0
Dry Beans	4,417
Sunflowers	0
Hybrid sorghum/sudan	71
Subtotal	24,108
Grain & Hay	
Wheat & Oat	7,297
Pasture	
Alfalfa	31,342
Clover	0
Turf Farm	324
Pasture	3,148
Subtotal	34,814

Crop Category & Crop	Acres
Truck & Berry	
Asparagus	3,651
Green Beans	24
Cole	257
Carrots	197
Celery	105
Cucurbits	2,628
Onion & Garlic	165
Tomatoes	16,444
Strawberries	4
Peppers	253
Misc.	555
Subtotal	24,283
Vineyards	2,902
Idle	2,114
Total	101,054

Note: Data was adapted from Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–San Joaquin Delta*.

Water Supply, Irrigation, and Water Quality

Although growers have access to groundwater, it is not commonly used as a source of irrigation water. The majority of growers claim riparian or appropriative water rights and obtain their water supply through direct diversion of surface water from the Delta waterways (San Joaquin County 2009). Diversions are performed using pumps, siphons, or subirrigation. The operation of diversion pumps and siphons is dependent upon sufficient water depth and quality. When the depth of water in conveyance canals is too shallow, pumps and siphons cannot operate.

The salinity in the southern Delta is strongly influenced by the concentrations in the SJR at Vernalis. If the salinity of Delta water exceeds a crop's salinity tolerance, it cannot be used to irrigate that crop. Historically, salinity in the southern Delta has generally ranged between 0.2 dS/m and 1.2 dS/m and is suitable for irrigating a wide variety of agricultural crops (Chapter 5, *Surface Hydrology and Water Quality*). Chapter 5 and Appendix F.2, *Evaluation of Historical Flow and Salinity Measurements of the Lower San Joaquin River and Southern Delta,* provide additional information regarding water quality and historical and existing salinity concentrations in the southern Delta.

The primary on-farm irrigation methods include surface methods, sprinklers, and drip or micro-irrigation methods (Table 11-10). For the most part, higher net value crops, such as Trees and Vines, are irrigated with pressurized systems, such as hand-moved sprinklers or micro-sprayers (Edinger-Marshall and Letey 1997). Generally crops with lower net revenue, such as Grains and Pasture, are irrigated with surface methods. There is significant subirrigation in the area, which provides irrigation water by controlling the water table. Dryland cropping is possible on some annual acreage in the SDWQ area of potential effects; however, the vast majority of the crops rely on a supply of irrigation water.

Table 11-10. Irrigation Method Types in San Joaquin County

Surface (%)	Sprinkler (%)	Drip and Micro (%)	Other (%)
36.0	14.2	36.6	13.2

Source: DWR 2010.

Soil salinity for crop lands is managed through the use of a leaching fraction, which is the portion of applied irrigation water that infiltrates past the root zone. The amount of water required for leaching is dependent on the crop being grown and the salinity of the water used for irrigation. Maintaining the leaching fraction is an important management tool in the southern Delta. Over time, the use of irrigation water and water management techniques, particularly leaching, brings soil salinity to equilibrium. In other words, salt introduced in the irrigation water is removed from the rootzone through the additional water supplied for leaching. There are 7,041 acres of saline soils in the SDWQ area of potential effects, or about 5 percent of the total acreage. Several leaching fraction studies examining salt are based on an irrigation water quality of 0.7 dS/m. Among the studies, the leaching fractions averaged between 21 and 27 percent, with a low of 11 percent and a high of 44 percent. Bean and Alfalfa, two crops with significant acreage (Table 11-9) in the SDWQ area of potential effects, have the highest sensitivity to salinity. These crops are successfully grown on lands with low infiltration rates, but maintain leaching fractions that average between 21 percent and 27 percent (Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–San Joaquin Delta*). Further information on soil salinity and leaching fractions within the boundary of the SDWA is provided in Appendix E.

11.3 Regulatory Background

11.3.1 State

Relevant state programs, policies, plans, or regulations related to agricultural resources are described below.

Farmland Mapping and Monitoring Program

Through the DOC, California administers the Farmland Mapping and Monitoring Program (FMMP). This program maps farmland throughout the state (California Department of Conservation 2007). The farmland categories listed under the FMMP are the basis of certain significance thresholds in the State CEQA Guidelines, discussed in Section 11.4.1, *Thresholds of Significance*. The categories are defined based on the U.S. Department of Agriculture's (USDA) land inventory and monitoring criteria and modified for California.

Prime Farmland is land with the best combination of physical and chemical characteristics for the production of crops. It has the soil quality, growing season, and moisture supply needed to produce sustained high yields of crops when treated and managed in accordance with accepted farming methods. In addition, the land must have been used for irrigated agricultural production in the last 4 years to qualify as Prime Farmland. It does not include publicly owned lands for which there is an adopted policy preventing agricultural use. Prime Farmland must meet several criteria, some of which are listed below (DOC 2013a).

(a) Water —The soils have xeric, ustic, or aridic (torric) moisture regimes in which the available water capacity is at least 4.0 inches (10 centimeters) per 40 to 60 inches (1.02 to 1.52 meters) of soil, and a developed irrigation water supply that is dependable and of adequate quality. A dependable water supply is one which is available for the production of the commonly grown crops in 8 out of 10 years.

(d) Water Table—The soils have no water table or have a water table that is maintained at a sufficient depth during the cropping season to allow cultivated crops common to the area to be grown.

(f) Flooding—Flooding of the soil (uncontrolled runoff from natural precipitation) during the growing season occurs infrequently, taking place less often than once every 2 years.

Farmland of Statewide Importance is land other than Prime Farmland that has a good combination of physical and chemical characteristics for the production of crops. It must have been used for the production of irrigated crops at some time during the two update cycles (4 years) prior to the mapping date, and it does not include publicly owned lands for which there is an adopted policy preventing agricultural use (DOC 2013b).

Unique Farmland is land that does not meet the criteria for Prime Farmland or Farmland of Statewide Importance and that has been used for the production of specific high–economic value crops at some time during the two update cycles (4 years) prior to the mapping date (DOC 2013b). This land is usually irrigated, but may include nonirrigated orchards or vineyards. It has the special combination of soil quality, location, growing season, and moisture supply needed to produce sustained high quality or high yields of a specific crop when treated and managed according to current farming methods. Examples of such crops may include oranges, olives, avocados, rice, grapes, and cut flowers. It does not include publicly owned lands for which there is an adopted policy preventing agricultural use.

Williamson Act and Farmland Security Zone Contracts

As discussed above, the Williamson Act recognizes the importance of protecting agricultural land from premature development and provides a tax incentive for the voluntary enrollment of agricultural and open space lands in contracts between local government and landowners. (DOC 2010b; Gov. Code, § 51200 et seq.) Establishment of an agricultural preserve by a city or county is a prerequisite for a landowner to enter into Williamson Act contract, and only land located within the agricultural preserve is eligible. The city or county establishing the agricultural preserve also adopts rules that provide the standards for property eligibility, including minimum parcel sizes, and that determine the land use restrictions within the preserve. Once a landowner enters into a Williamson Act contract, the land is reassessed for tax purposes based upon the restrictions. This assures the landowner that property valuations and taxes will remain at lower stable levels notwithstanding location relative to urban or other developing areas. In exchange for the tax benefits of the program, the landowner agrees to keep the land in agricultural or open space use and in parcel sizes related to the quality of the land or existing use (Merced County 2015).

As was previously noted, the Williamson Act also provides for the establishment of Farmland Security Zone contracts. (Gov. Code, § 51296 et seq.) A Farmland Security Zone is an area created within an agricultural preserve by a board of supervisors upon the request of a landowner or group of landowners. Farmland Security Zone contracts offer landowners greater property tax reduction and have a minimum initial term of 20 years.

Central Valley Water Board Basin Plan Amendment for Control of Salt and Boron Discharges in the Lower San Joaquin River

The Central Valley Regional Water Quality Control Board (Central Valley Water Board) has adopted the *Water Quality Control Plan for the Sacramento River and San Joaquin River Basins* (Basin Plan). In 2004, it adopted a total maximum daily load (TMDL) and Basin Plan amendment that establishes a control program for salt and boron discharges into the LSJR to Vernalis (Central Valley Water Board 2004).

The Delta Protection Act and Delta Reform Act

The California legislature, through various statutes, has established a policy of recognizing, protecting, and preserving Delta resources, including agriculture, in various statutes. These statutes include the Delta Protection Act, referenced under Section 11.2.4, *Southern Delta (Farmland Conversion)* above, and the Delta Reform Act.

The Delta Protection Act created the Delta Protection Commission and required that the commission prepare and adopt a comprehensive long-term resource management plan for land uses within the primary zone of the Delta. The *Land Use and Resource Management Plan for the Primary Zone of the Delta* was prepared and adopted by the Delta Protection Commission in 1995 and revised in 2002. Regarding agriculture, the plan is required to conserve and protect the quality of renewable resources, preserve and protect agricultural viability, preserve and protect the water quality of the Delta, and protect the Delta from any development that results in a significant loss of habitat or agricultural land. This plan identifies nine general policies in support of Delta agriculture. Among these policies are prioritizing lower net revenue lands for conversion to nonagricultural uses, encouraging the acquisition of agricultural conservation easements, managing agricultural lands to maximize wildlife habitat, and supporting efforts to maintain a viable agricultural economy, such as educational programs, ag-tourism, and value-added production activities.

SB 1 passed during the Seventh Extraordinary Session of the Legislature in November 2009, declared that the two coequal goals for the state regarding the Delta are to achieve “a more reliable water supply for California and protecting, restoring, and enhancing the Delta ecosystem.” In addition, the coequal goals are to “be achieved in a manner that protects and enhances the unique cultural, recreational, natural resource, and agricultural values of the Delta as an evolving place.” (Pub. Resources Code, § 29702.) SBX7-1 also revised the membership of the Delta Protection Commission (Pub. Resources Code, § 29735) and included the Sacramento-San Joaquin Delta Reform Act of 2009. (Wat. Code, § 85000 et seq.) The Delta Reform Act established a new legal framework for Delta management, emphasizing the coequal goals as a foundation for state decisions about Delta management and creating the Delta Stewardship Council, which was required to develop and adopt a long-term and enforceable management plan for the Delta. The Delta Stewardship Council unanimously adopted the Delta Plan in 2013. The Delta Plan acknowledges that agriculture dominates the Delta landscape and that “agriculture is among the qualities that define the Delta as a place.” The Delta Plan identifies many challenges for Delta agriculture, including increasing urbanization (DSC 2013). Finally, SBX7-1 also created a new Sacramento–San Joaquin Delta Conservancy to support efforts that advance environmental protection and the economic well-being of Delta residents. (Pub. Resources Code, § 32320, et seq.)

Water Conservation Bill of 2009

The Water Conservation Bill, SB 7 (Steinberg), was also enacted during the Seventh Extraordinary Session in November 2009. SBX7-7 requires all water suppliers to increase efficiency in water use and evaluate additional practices that may conserve water. SBX7-7 requires that agricultural water suppliers providing water to 25,000 irrigated acres or more (excluding acres that receive only recycled water) measure the volume of water delivered to their customers; implement efficient water management practices; submit documentation for agricultural water measurement regulation compliance by preparing and adopting an agricultural water management plan (AWMP); and submit an aggregated farm-gate delivery report. AWMPs that were submitted in 2012 must be updated by December 31, 2015 and every 5 years thereafter.

In response to a continued drought State of Emergency, Governor Brown issued Executive Order B-29-15 on April 1, 2015, requiring agricultural water suppliers that supply water for between 10,000 and 25,000 acres of irrigated land to also develop AWMPs and to submit them to DWR by July 1, 2016. The executive order required plans to include "a detailed drought management plan and quantification of water supplies and demands in 2013, 2014, and 2015, to the extent that data is available." On, May 9, 2016 the governor issued Executive Order B-37-16, *Making Water Conservation a Way of Life*. Executive Order B-37-16 permanently requires the completion of AWMPs by water suppliers with over 10,000 acres of irrigated land. A general description of AWMPs within the LSJR area of potential effects is provided in Section 11.3.2, *Regional or Local [Regulatory Background]*.

11.3.2 Regional or Local

Regional or local programs, policies, plans, and regulations related to agricultural resources are described in this section. Although local policies, plans, and regulations are not binding on the State of California, below is a description of those that are relevant in the LSJR area of potential effects.

General Plans

Local agencies in California have primary responsibility for land use control and regulation within their areas of jurisdiction and, to a lesser extent, for areas within their spheres of influence. State planning and zoning law requires all California counties and incorporated cities to prepare, adopt, and implement a comprehensive general plan to guide the community's growth and development. A general plan may also include optional elements at the discretion of the local agency, such as an agricultural element or a recreation element. The counties and cities in the LSJR area of potential effects have general plans stipulating goals, objectives and policies associated with agricultural land, as described in this section.

Merced County

The *Agricultural Element* of the *2030 Merced County General Plan* (Merced County 2013) provides goals and policies related to the agricultural economy, preservation of agricultural lands, agricultural and urban area compatibility, agricultural research and education, and agricultural recreation.

- Goal AG-2: Ensure the long-term preservation and conservation of land used for productive agriculture, potentially-productive agricultural land, and agricultural-support facilities.

- Policy AG-2.1: Protect agriculturally-designated areas and direct urban growth away from productive agricultural lands into cities, Urban Communities, and New Towns.
- Policy AG-2.2: Protect productive agricultural areas from conversion to nonagricultural residential uses by establishing and implementing an agricultural mitigation program that matches farmland acres to be converted with farmland acres of a similar quality to be preserved at a 1:1 ratio. The plan also requires coordination with the six cities in Merced County and the Merced Local Agency Formation Commission (LAFCo), consistent with LAFCo's statutory mission to preserve agricultural land and open space, to establish consistent standards and mitigation for the loss of farmland. In addition, the Land Evaluation and Site Assessment Model (LESA Model) may be used to determine whether the conservation land is of equal or greater value than the land being converted.
- Policy AG-2.17: Where requested by the water purveyor, when agricultural parcels are subdivided and the original parcel (prior to subdivision) has access to surface water (such as from an irrigation or water district facility), it is required that an easement be provided over the parcel(s) that has/have access to the surface water source to the remaining parcel(s) that will not be adjacent to or near the surface water source. The easement should specify the purpose of the easement and whose responsibility it is to maintain private water conveyance facilities within said easement.

San Joaquin County

The *Resources* chapter of the *San Joaquin County General Plan* (San Joaquin County 2010) describes policies for the protection of the county's natural resources, including agricultural lands. San Joaquin County is in the process of updating its general plan.

- Objective 1: To protect agricultural lands needed for the continuation of commercial agricultural enterprises, small-scale farming operations and the preservation of open space.
- Objective 3: To minimize the impact on agriculture in the transition of agricultural areas to urban development.
- Policy 5: Agricultural areas shall be used principally for crop production, ranching, and grazing.
- Policy 6: All lands designated for agricultural uses and those lands designated for nonagricultural use but not needed for development for 10 years shall be placed in an agricultural preserve and shall be eligible for Williamson Act contracts. Parcels eligible for Williamson Act contracts shall be 20 or more acres in size in the case of prime land, or 40 or more acres in the case of non-prime land.

Stanislaus County

The *Agricultural Element* of the *Stanislaus County General Plan* (Stanislaus County 2012) describes goals, objectives, policies, and implementation measures focused on the protection of the economy of the county by minimizing conflicts between the environment, agriculture, and urban development. Stanislaus County is currently updating its general plan and incorporating a 20-year planning horizon to 2035.

- Goal 1: Strengthen the agricultural sector of the economy.
- Goal 2: Conserve our agricultural lands for agricultural uses.

- Policy 1: Established agricultural land use categories that promote a range of agricultural activities and preserve open space (e.g., general agriculture, limited agriculture, and agriculture-urban reserve).

City of Tracy

The *City of Tracy General Plan's Open Space and Conservation Element* contains an objective (OSC-2.2) and policy (P1) focused on minimizing conflicts between agricultural and urban uses, and the policy establishes buffer zones around development projects to protect agriculture operations from the impacts of incompatible development (City of Tracy 2011).

City of Stockton

The *Land Use Element* of the *2035 Stockton General Plan Goals and Policies Report* discusses the City's goal to promote the protection of agricultural lands outside of the urban service area and to discourage the premature conversion of agricultural lands within the urban service area. Related policies limit urban uses in agricultural land and establish permanent agricultural/open space buffers along the "ultimate edge" of the Urban Service Area (Policies LU-2.1 and LU-2.2, respectively). In addition, The *Natural and Cultural Resources Element* describes the goal and related policies to foster a viable agricultural industry in the city through promoting the continuation of existing agricultural operations; insuring the compatibility of Stockton's Right to Farm ordinance with San Joaquin County's ordinance; supporting an Agricultural Conservation Program; and supporting policies adopted by San Joaquin County to promote agricultural viability (City of Stockton 2007).

City of Modesto

The *Environmental Resources and Open Spaces* element of the City of Modesto's *Final Urban Area General Plan* identifies agricultural resources policies focused on minimizing the loss of agricultural land by maintaining future development such that it is relatively compact and of "reasonable high density." Where necessary to promote planned growth, the City encourages the development of agricultural lands that are already compromised by adjacent urban development (City of Modesto 2008).

City of Merced

Agriculture is a major contributor to the economic viability of the City of Merced. As such, Merced's general plan identifies goals and policies intended to foster the protection of agriculture and the preservation of agriculturally significant areas by directing development away from significant concentrations of Prime agricultural soils, giving priority to the conversion of non-prime agricultural land, and limiting development impacts on agricultural lands along the city's urban fringe (City of Merced 2015).

City of Turlock

In its general plan, the City of Turlock states that one of the eight "General Plan Themes" is the establishment of limits to urban growth to maintain Turlock as a "freestanding city surrounded by agricultural land" (City of Turlock 2012). To that end, policies related to agricultural resources in the *Turlock General Plan* promote continued agricultural activity on lands surrounding the urban areas of the city; encourage infill to protect farmland; minimize conflict between urban and agricultural uses; require participation in county-wide agricultural mitigation; and support participation in the Williamson Act Program (City of Turlock 2012).

City of Riverbank

The *Conservation and Open Space* element of the *City of Riverbank General Plan 2005–2025* addresses the importance of agriculture in the city of Riverbank through policies that focus on sustaining agriculture and resources associated with farming. These policies include developing a sustainable agricultural strategy to conserve agricultural production in the Stanislaus River Watershed and establishing buffers to protecting ongoing agricultural practices in the western portion of the Riverbank planning area from urban encroachment (City of Riverbank 2009).

City of Oakdale

The *Land Use* and *Natural Resources* elements of the *City of Oakdale 2030 General Plan* identify goals and policies related to the preservation of agricultural lands and agricultural operations within and outside of the City of Oakdale's planning area. Policies include supporting the production of existing agricultural properties; preparing and adopting a plan for agricultural preservation; and maintaining agricultural and rural lands outside of urbanized areas (City of Oakdale 2013).

City of Ripon

The *Open Space and Conservation* element of the *City of Ripon General Plan 2040* establishes goals and policies to protect recreational, cultural, and natural resources, including agricultural resources. The general plan identifies policies intended to discourage premature conversion of agricultural lands, reduce the intrusion of urban development in agricultural areas, and prohibit the conversion of agricultural land to urban uses unless the property is contiguous to existing or approved urban uses (City of Ripon 2006).

City of Manteca

The *Resource Conservation Element* of the *City of Manteca General Plan 2023 Policy Document* outlines a goal and related policies to "promote the continuation of agricultural uses in the Manteca area and discourage the premature conversion of agricultural land to nonagricultural uses, while providing for the urban development needs of Manteca" (City of Manteca 2011).

City of Lathrop

The *Comprehensive General Plan for the City of Lathrop* (City of Lathrop 2004) stresses the importance of minimizing the amount of agricultural land converted for urban use and avoiding premature conversion of agricultural land. Agricultural land policies are focused on avoiding urban-agricultural conflicts at the margin of urban areas.

City of Escalon

Select goals and policies identified in the *Urban Boundary Element* and the *Open Space, Conservation and Recreation Element* of the City of Escalon's general plan stress the need to preserve and protect agricultural use on lands in and around the Escalon planning area for open space, and to prohibit the premature conversion of agricultural lands where agricultural preserves are present (City of Escalon 2010).

Zoning

The general plan for counties and cities is commonly implemented through zoning and other local land use and development ordinances that must be consistent with the general plan. City and county zoning ordinances in the LSJR area of potential effects generally allow a variety of agricultural and related uses. In reviewing and making decisions on applications for various land use entitlements and development projects, the local agency must typically make findings that the proposed activity (e.g., a conditional use permit or a subdivision of real property) is consistent with the applicable general plan. If the decision is discretionary and a project could have a potentially significant adverse effect on the physical environment, then the county or city is also obligated to comply with the procedural and documentation requirements of CEQA. Table 11-11 identifies the approximate acres zoned for agriculture or related use (e.g., agricultural residential) in the LSJR area of potential effects according to the six geographic areas, as well as in the SDWQ area of potential effects.

Table 11-11. Acreages Zoned for Agricultural Use in the LSJR and SDWQ Areas of Potential Effects

Areas of Potential Effects	Zoned Agricultural Land [a, b]
LSJR Area of Potential Effects	
SEWD/ CSJWCD	119,000
SSJID	55,000
OID	65,000
TID	161,000
MID	69,000
Merced ID	129,000
Total	598,000 [c]
SDWQ Area of Potential Effects	
Total	113,000 [d]

LSJR	= Lower San Joaquin River
SDWQ	= southern Delta water quality
SEWD	= Stockton East Water District
CSJWCD	= Central San Joaquin Water Conservation District
SSJID	= South San Joaquin Irrigation District
OID	= Oakdale Irrigation District
MID	= Modesto Irrigation District
TID	= Turlock Irrigation District
Merced ID	= Merced Irrigation District

[a] Acreage values are rounded to the nearest thousand and are based on available GIS zoning data for the cities and counties within the areas of potential effects.

[b] *Zoned agricultural land* includes land designations made by the applicable local jurisdictions (i.e., Merced, Stanislaus, and San Joaquin Counties) that are intended to protect farmland and farming activities from incompatible uses.

[c] Approximately 73,000 additional acres lie within the LSJR area of potential effects that could not be identified according to county or city zoning because GIS zoning data was not available.

[d] Approximately 4,000 additional acres lie within the SDWQ area of potential effects that could not be identified according to county or city zoning because GIS zoning data was not available.

Agricultural Water Management Plans or Water Management Plans

Pursuant to the Water Conservation Bill of 2009 (SBX7-7), OID, Merced ID, MID, SSJID, SEWD, and TID have prepared AWMPs. Table 13-10 in Chapter 13, *Service Providers*, describes methods that are common throughout all of the irrigation district AWMPs for addressing surface water shortages. Below is a brief summary of information contained in each district's AWMP regarding water shortage allocation polices and water management.

Oakdale Irrigation District

OID supplies irrigation water and domestic drinking water for subdivisions outside of the City of Oakdale service area.[7] The district's primary water supply comes from surface water diversions on the Stanislaus River at Goodwin Dam. OID's surface water shortage policy "includes suspension of surface water deliveries once available supplies are exhausted, but allows for intra-district water transfers and the use of available groundwater from OID wells" (OID 2012). OID's *Rules and Regulations Governing the Operation and Distribution of Irrigation Water within the Oakdale Irrigation District Service Area* (Rules and Regulations) are occasionally reviewed and revised as needed to address changing conditions and to account for dry periods, most recently in 2005. The rules and regulations prescribe conditions that ensure distribution of irrigation water to users in an orderly, efficient and equitable manner. Depending on the severity of the water shortage the district may suspend out of district agreements, provide irrigation water for agricultural purposes only, and implement a zero discharge policy, with fines for violators. OID's AWMP identifies implemented and planned efficient water management practices (EWMPs), including providing technical assistance for growers implementing on-farm improvements through the Natural Resources Conservation Service Environmental Quality Incentives program; continuing a testing and evaluation program for existing pumps; and implementing OID's water resources plan flow control and measurement structure projects (OID 2012).

Merced Irrigation District

The Merced River is the main source of Merced ID's water supply. During an average wet year, 99 percent of Merced ID's water supply comes from surface water. The remainder of the supply comes from groundwater. Merced ID identifies a conjunctive water management strategy in their AWMP as part of its drought water management approach. This strategy is intended to manage groundwater conditions so that during surface water supply shortages, there will be sufficient water supplies available to meet the district's needs. Furthermore, during years of surface water shortage, Merced ID reduces the allocation to its growers proportioned to its Class I and Class II users. The Merced ID AWMP identifies several EWMPs, such as facilitating financial assistance to support on-farm improvements needed to take surface water from Merced ID during years of available surface water and utilize groundwater wells during years of surface water shortages. Other Merced ID EWMPs include implementing an incentive pricing structure to encourage more efficient water use at the farm level; constructing/operating tailwater and spill recovery systems; and promoting and performing pump testing (Merced ID 2013).

---

[7] OID surface water is provided for agriculture, and OID owns and operates a rural water system that provides groundwater for domestic use.

Modesto Irrigation District

MID supplies groundwater and surface water from the Tuolumne River to agricultural, residential, and municipal customers. Tuolumne River water supplies vary depending on precipitation, snow melt runoff, and the previous year's carryover storage in Don Pedro Reservoir. During dry years, the MID Board of Directors reduces water allocation and may shorten the irrigation season. In addition, MID will also conjunctively use groundwater to supplement surface water and water users may use private irrigation wells to supplement water supplied by the irrigation district. MID has an irrigation water allocation policy, which establishes the allocation and cost of water to landowners. It is adopted by the Board of Directors annually. The allocation is based on factors including the volume of water carried over in storage in Don Pedro Reservoir and the projected runoff from the watershed. The allocation is not finalized and adopted until after the rainy season when runoff information has been made available. Identified in MID's AWMP are several ongoing and planned EWMPs, such as facilitating alternative land uses for lands with high water duties or irrigation problems, including drainage issues; providing financial assistance to water users to replace private ditches and pipelines; and lining approximately 86 percent of the district's delivery canals with concrete (MID 2012).

South San Joaquin Irrigation District

SSJID diverts water from the Stanislaus River at Goodwin Dam into the Joint Main Canal, which is jointly owned and operated by SSJID and OID, with 72 percent of the capacity intended for SSJID. SSJID provides water predominately for irrigation, but also provides treated surface water to the cities of Manteca, Lathrop, and Tracy for domestic use (SSJID 2012). SSJID's surface water shortage contingency actions entail eight operational measures including postponing the start date of the irrigation season; implementing a variable water delivery rotation schedule and maximum time limits for flood irrigation; allowing for inter-parcel transfers/fallowing; and implementing irrigation quantity limits for pressurized systems (SSJID 2012). The SSJID AWMP identifies several ongoing EWMPs and the activities implemented and planned to achieve those EWMPs. Some planned activities include continuing their On-Farm Conservation Program, which provides financial incentives to improve the existing distribution system and enhance farm irrigation practices (SSJID 2013); refining conjunctive management by further evaluating the underlying groundwater system; and continuing and expanding spill site monitoring to reduce spillage and develop representative data (SSJID 2012). SSJID functions in an economical manner to distribute the water equitably and in as satisfactory a manner as possible for all water users.as near as may be satisfactory to all water users. No two individuals have exactly the same requirements, and while these individual requirements will be met as far as possible, there must be general rules and general practices to secure the greatest good to the greatest number.

Stockton East Water District

SEWD serves both urban and agricultural water users. SEWD receives surface water from both the Stanislaus River (within the LSJR area of potential effects) and Calaveras River (outside of the LSJR area of potential effects). SEWD also has a contract to provide water to CSJWCD (within the LSJR area of potential effects) on an annual basis (SEWD 2014). The *Stockton East Water Management Plan* (SEWD 2014) includes information that addresses the AWMP requirements, including the agricultural water allocation policy, as well as an EWMP report and best management practices (BMPs) for agricultural contractors. According to the agricultural water allocation policy, SEWD has sufficient water to withstand 2 to 3 dry years. When a water year has been identified as a dry year, SEWD requests voluntary water use reductions from its agricultural customers. In a subsequent dry year, these voluntary reductions are identified as critical, and in a third subsequent dry year, these reductions may be mandatory (SEWD 2014). In all water years, SEWD customers are asked to call in advance of diverting water so that the district may adjust water releases; this advance notice is mandatory in dry years. SEWD's water management plan identifies several BMPs that the district implements in the context of efficient water management, such as providing evaluation of irrigation practices to its customers; implementing agricultural water management educational programs for farmers and the public; and optimizing conjunctive management of surface and groundwater (SEWD 2014).

Turlock Irrigation District

TID receives its principal water supply from the Tuolumne River. TID supplements surface water releases with drainage wells and rented wells, and also uses supplemental groundwater pumping to help conserve water by reducing canal spillage. TID primarily supplies irrigation water for agriculture in its service area, but also provides drinking water to the community of La Grange, in conjunction with MID. TID's surface water shortage policies include increasing groundwater pumping, implementing a "dry year" rate schedule, and internal transfers (TID 2012). Historically a three-tiered, increasing block rate schedule based on three classes of water deliveries has been used. The first block is the annual allotment that was available equally to each acre of land. The volume of the allotment varied depending upon the available surface water supply. The actual allotment, as well as any additional water available above the allotment, is set each year based on projected runoff including the possibility of the occurrence of consecutive dry years, carryover storage, flows required to be delivered to the lower Tuolumne River and the availability of rented pumps. TID's AWMP also identifies currently implemented and planned EWMPs, such as operating spill and tailwater recovery systems; facilitating the use of available recycled water; implementing a pricing structure that promotes various goals to improve water use efficiency; and converting 90 percent of its conveyance and distribution system to pipeline or concrete lined canals (TID 2012).

11.4 Impact Analysis

This section identifies the thresholds or significance criteria used to evaluate the potential impacts on agricultural resources. It further describes the methods of analysis used to determine significance. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant impacts accompany the impact discussion, if any significant impacts are identified.

11.4.1 Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the State Water Board's Environmental Checklist in Appendix A of the Board's CEQA regulations. (Cal. Code Regs., tit. 23, §§ 3720–3781.) The thresholds derived from the checklist have been modified, as appropriate, to meet the circumstances of the alternatives. (Cal. Code Regs., tit. 23, § 3777, subd. (a)(2).) Agricultural resource impacts were determined to be potentially significant in the State Water Board's Environmental Checklist (see Appendix B, *State Water Board's Environmental Checklist*) and, therefore, are discussed in this analysis as to whether the alternatives could result in the following.

- Potentially convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland) to nonagricultural use.
- Involve other changes in the environment which, due to their location or nature, could result in conversion of farmland to nonagricultural use.
- Conflict with existing zoning for agricultural use or a Williamson Act contract.
- Conflict with any applicable land use plan, policy, or regulation related to agriculture of an agency with jurisdiction over a project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect.

Where appropriate, specific quantitative or qualitative criteria are described in Section 11.4.2, *Methods and Approach*, for evaluating these thresholds.

As described in Appendix B, *State Water Board's Environmental Checklist*, the alternatives would result in either no impact or less-than-significant impacts with regards to the following conditions, and therefore are not discussed further in this chapter.

- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in Pub. Resources Code, § 12220(g)), timberland (as defined by Pub. Resources Code, § 4526), or timberland zoned Timberland Production (as defined by Gov. Code, § 51104(g).)
- Result in the loss of forest land or conversion of forest land to nonforest use.

11.4.2 Methods and Approach

Under the LSJR and SDWQ alternatives, two basic changes could result in significant impacts on agricultural resources: reduction in surface water diversions for crop production in the LSJR area of potential effects or a change in water quality that could result in crop yield reductions in the SWDA. Both of these changes have the potential to affect crop production and lead to conversion of irrigated lands to nonagricultural uses in either the LSJR area of potential effects or the SDWQ area of potential effects.

The methods for analyzing impacts under the LSJR and SDWQ alternatives are described below.

LSJR Alternatives

This chapter evaluates the potential groundwater impacts associated with the LSJR alternatives. Each LSJR alternative includes a February–June unimpaired flow requirement (i.e., 20, 40, or 60 percent) and different methods for adaptive implementation to reasonably protect fish and wildlife beneficial uses, as described in Chapter 3, *Alternatives Description*. The sections below describe steps for processing the WSE model results for the groundwater analysis, methods of analysis for adaptive implementation in this chapter, and baseline results to which the LSJR alternatives are compared to determine the significance of impacts on groundwater. The LSJR alternatives could result in a reduction of surface water diversions currently used to irrigate existing agricultural lands. The WSE and SWAP models are the primary tools used to assess how decreased surface water supplies under the LSJR alternatives could impact irrigated crop land.

Four separate models were used to analyze agricultural impacts. Brief definitions of each model and the manner in which they are used and applied to the analysis are given below. For full descriptions of the models refer to the appendices listed by each model below.

- Water Supply Effects (WSE) Model – Appendix F.1, *Hydrologic and Water Quality Modeling*.
- Statewide Agricultural Production (SWAP) Model – Appendix G, *Agricultural Economic Effects of the Lower San Joaquin River Flow Alternatives: Methodology and Modeling Results.*
- Impact Analysis for Planning (IMPLAN) – Appendix G, *Agricultural Economic Effects of the Lower San Joaquin River Flow Alternatives: Methodology and Modeling Results.*
- Salinity Related Impacts – Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–San Joaquin Delta.*

Water Supply Effects Model

Results from the WSE model were used in the SWAP model to generate annual crop production under each LSJR alternative. The WSE model generated monthly surface water diversion volumes and estimated the availability of water delivery for crop production expected under each LSJR alternative. In addition to surface water, groundwater was assumed to be available (see Appendix G, *Agricultural Economic Effects of the Lower San Joaquin River Flow Alternatives: Methodology and Modeling Results,* and Chapter 9, *Groundwater Resources,* for more information regarding groundwater) and was included in the monthly water amounts available for irrigation. Monthly surface and groundwater values were aggregated to cropping season requirements. Annual crop production under each LSJR alternative is represented as acreage of a given crop category by year for 1922–2003.

Estimates of the total amount of water applied to the irrigated lands of the irrigation districts (applied water) are required for the SWAP analysis. Applied water rates are unique to each crop category and to each geographic area. Applied water demands may be satisfied by surface water and groundwater, or a combination of the two. After the water is applied to the irrigated land, it will either be consumptively used by the crops, return to the river as surface runoff, or percolate into the ground below the fields. However, for the WSE modeling surface runoff from the fields is accounted for separately from applied water, as part of the "spills and returns" of each irrigation district. For more information on applied water see Appendix G, Section G.4.2, *Crop Distribution and Applied Water Inputs for SWAP*.

Some post-processing of the WSE model results is required to generate the applied water input for the SWAP analysis. As part of post-processing, the diversions for each river are partitioned between different types of deliveries and losses. Volumes of water assumed not to be subject to a water shortage (e.g., municipal and industrial water supply, riparian rights) are subtracted from the total diversions for each river to calculate the remaining water. Any water left over is then delivered to the irrigation districts to be used for applied water demands and to account for the operational spills and river returns from the district. In the modeling, operational spills and river returns are assumed to be fully accounted for, even in times of water shortage. In addition, some fraction of the water delivered to the districts will also be lost as seepage or evaporation from the conveyance system. When diversions are less than what is needed to meet full demands (including all categories of deliveries and losses), only the applied water deliveries are assumed to be reduced (which, in turn, will also reduce the conveyance losses). This allows for a conservative estimate of agricultural impacts (i.e., agricultural impacts may be slightly overestimated rather than underestimated).

In the WSE model, SEWD and CSJWCD diversions from the Stanislaus River are calculated separately from the SSJID and OID diversions because they are CVP contractors and only receive water after SSJID and OID water rights have been met. The division of Stanislaus River water between SSJID and OID and Tuolumne River water between MID and TID is calculated as part of post processing. This is based on the assumption that each district receives the same percent of surface water demand for consumptive use, as described in Appendix G.

The capacity of each irrigation district to pump groundwater varies and depends on existing infrastructure (Chapter 9, *Groundwater Resources*, Table 9-6, and Appendix G). Within the districts, there is a minimum amount of groundwater pumping that occurs every year. If the amount of available surface water and minimum groundwater pumping is insufficient to meet the irrigation district's applied water demands, then additional groundwater pumping would occur. In this situation, groundwater pumping would increase either to meet the shortage or until it reaches the maximum amount that the districts could pump. The maximum groundwater pumping capacities are estimated based on best available data as described in Chapter 9 and Appendix G. Agriculture is potentially affected when the additional groundwater pumping is unable to fully meet the shortfall in the applied surface water.

Because baseline is representative of 2009 groundwater infrastructure, the primary agricultural analysis utilizes estimates of maximum groundwater pumping that were possible in 2009. However, as a result of recent drought conditions, more wells have been drilled and, therefore, an assessment using estimates of maximum groundwater pumping for 2014 is also discussed in Section 11.4.3, *Impacts and Mitigation Measures*. All of the 2014 maximum groundwater pumping estimates are greater than the 2009 maximum groundwater estimates, with the exception of Merced ID, for which the two estimates are the same. This is reasonable because Merced ID's 2009 capacity for increased groundwater pumping was almost sufficient to meet full demand in drought years.

Adaptive Implementation

Each LSJR alternative includes a February–June unimpaired flow requirement (i.e., 20, 40, or 60 percent) and methods for adaptive implementation to reasonably protect fish and wildlife beneficial uses, as described in Chapter 3, *Alternatives Description*. In addition, a minimum base flow is required at Vernalis at all times during this period. The base flow may be adaptively implemented as described below and in Chapter 3. State Water Board approval is required before any method can be implemented, as described in Appendix K, *Revised Water Quality Control Plan*. All methods may be implemented individually or in combination with other methods, may be applied differently to each tributary, and could be in effect for varying lengths of time, so long as the flows are coordinated to achieve beneficial results in the LSJR related to the protection of fish and wildlife beneficial uses.

The Stanislaus, Tuolumne, and Merced Working Group (STM Working Group) will assist with implementation, monitoring, and assessment activities for the flow objectives and with developing biological goals to help evaluate the effectiveness of the flow requirements and adaptive implementation actions. The STM Working Group may recommend adjusting the flow requirements through adaptive implementation if scientific information supports such changes to reasonably protect fish and wildlife beneficial uses. Scientific research may also be conducted within the adaptive range to improve scientific understanding of measures needed to protect fish and wildlife and reduce scientific uncertainty through monitoring and evaluation. Further details describing the methods, the STM Working Group, and the approval process are included in Chapter 3 and Appendix K.

Without adaptive implementation, flow must be managed such that it tracks the daily unimpaired flow percentage based on a running average of no more than 7 days. The four methods of adaptive implementation are described briefly below.

1. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the specified annual February–June minimum unimpaired flow requirement may be increased or decreased to a percentage within the ranges listed below. For LSJR Alternative 2 (20 percent unimpaired flow), the percent of unimpaired flow may be increased to a maximum of 30 percent. For LSJR Alternative 3 (40 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 30 percent or increased to a maximum of 50 percent. For LSJR Alternative 4 (60 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 50 percent.
2. Based on best available scientific information indicating a flow pattern different from that which would occur by tracking the unimpaired flow percentage would better protect fish and wildlife beneficial uses, water may be released at varying rates during February–June. The total volume of water released under this adaptive method must be at least equal to the volume of water that would be released by tracking the unimpaired flow percentage from February–June.
3. Based on best available scientific information, release of a portion of the February–June unimpaired flow may be delayed until after June to prevent adverse effects to fisheries, including temperature, which would otherwise result from implementation of the February–June flow requirements. The ability to delay release of flow until after June is only allowed when the unimpaired flow requirement is greater than 30 percent. If the requirement is greater than 30 percent but less than 40 percent, the amount of flow that may be released after June is limited to the portion of the unimpaired flow requirement over 30 percent. For example, if the flow requirement is 35 percent, 5 percent may be released after June. If the requirement is 40 percent or greater, then 25 percent of the total volume of the flow requirement may be released after June. As an example, if the requirement is 50 percent, at least 37.5 percent unimpaired flow must be released in February–June and up to 12.5 percent unimpaired flow may be released after June. If after June the STM Working Group determines that conditions have changed such that water held for release after June should not be released by the fall of that year, the water may be held until the following year. See Chapter 3 and Appendix K for further details.
4. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the February–June Vernalis base flow requirement of 1,000 cubic feet per second (cfs) may be modified to a rate between 800 and 1,200 cfs.

The operational changes made using the adaptive implementation methods above may be approved if the best available scientific information indicates that the changes will be sufficient to support and maintain the natural production of viable native SJR Watershed fish populations migrating through the Delta and meet any biological goals. The changes may take place on either a short-term (e.g., monthly or annually) or longer-term basis. Adaptive implementation is intended to foster coordinated and adaptive management of flows based on best available scientific information in order to protect fish and wildlife beneficial uses. Adaptive implementation could also optimize flows to achieve the objective, while allowing for consideration of other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. While the measures and processes used to decide upon adaptive implementation actions must achieve the narrative objective for the reasonable protection of fish and wildlife beneficial uses, adaptive implementation could result in flows that would benefit or reduce impacts on other beneficial uses that rely on water.

The quantitative results included in the figures, tables, and text of this chapter present WSE modeling results of the specified unimpaired flow requirement for each LSJR alternative (i.e., 20, 40, or 60 percent). However, the modeling does allow some inflows to be retained in the reservoirs after June, as could occur under adaptive implementation method 3, to prevent adverse temperature effects and this is included in the results presented in this chapter. If the percent of unimpaired flow is not specified in this chapter, these are the percentages of unimpaired flow evaluated in the impact analysis. However, as part of adaptive implementation method 1, the required percent of unimpaired flow could change by up to 10 percent if the STM Working Group agrees to adjust it. The highest possible percent of unimpaired flow associated with an LSJR alternative is also evaluated in the impact analysis if long-term implementation of method 1 has the potential to affect a determination of significance. For example, if the determination for LSJR Alternative 2 at 20 percent unimpaired flow is less than significant, but the determination for LSJR Alternative 3 at 40 percent unimpaired flow is significant, then LSJR Alternative 2 is also evaluated at the 30 percent unimpaired flow. This use of modeling provides information to support the analysis and evaluation of the effects of the alternatives and adaptive implementation. For more information regarding the modeling methodology and quantitative flow and temperature modeling results, see Appendix F.1, *Hydrologic and Water Quality Modeling*.

SWAP Model

After the post processing of the WSE model results, as described above, the SWAP model simulates the decisions of growers at a regional level based on the principles of economic optimization. The model assumes that farmers maximize profit subject to resources and market constraints, shifting crop production to favor crop categories that maximize profit subject to given constraints. The model accounts for land and water availability and production prices, while calibrating to observed yearly values of land, labor, and water supplies. The basic model outputs are annual estimates of crop production acreage, water use, and revenue by the 19 crop categories in the DAU survey (Table 11-4) for the LSJR alternatives.

Impact AG-1 uses the quantitative results of the SWAP model to first evaluate if significant reductions in agricultural acreage or significant reductions in crop mix would occur under the LSJR alternatives. This analysis uses cumulative distribution tables since the cumulative distribution of a particular variable (e.g., irrigated acreage) provides a basic summary of the distribution of values. The percentile (percent cumulative distribution) associated with each value indicates the percent of time that the values were less than the specified value. For example, as depicted in Figure 11-3b, for SSJID under baseline conditions, approximately 1,656 acres of Pasture receive irrigation water at the 80th percentile, while approximately 473 acres of Pasture are irrigated at the 90th percentile; and, in all water years (i.e., 100th percentile) there is sufficient supply to irrigate only about 50 acres of Pasture. In other words, the acreage value at the 100th percentile provides an estimate of irrigated acreage that is likely to be exceeded 100 percent of the time, meaning that this fraction of irrigated pasture under baseline conditions would be expected to always be irrigated in SSJID, even under the driest possible conditions. The acreage value at the 0 percentile is an amount of irrigated acreage that would never likely be exceeded, even under the wettest conditions.

The amount of irrigated acreage is central to the analysis of Impact AG-1 because, by definition, Prime Farmland and Farmland of Statewide Importance, as described by the 2006 FMMP, requires a dependable water supply in 8 out of 10 years (DOC 2007). Stated another way, if there is more than a 20 percent reduction in overall irrigated acreage, then the water supply for that crop will be assumed to be inadequate to maintain the Prime Farmland and Farmland of Statewide Importance criteria. For this analysis, annual changes in the amount of irrigated acreage over the 82-year modeling period were averaged by irrigation district,.

The SWAP-generated baseline was the basis for comparison and determination of potential impacts on irrigated cropland for Impact AG-1. However, the SWAP model cannot quantify whether actual conversation of Prime, Farmland of Statewide Importance, and Unique Farmland to nonagricultural uses would result, given numerous factors, including the individual decisions of agricultural producers that influence potential conversion. However, as the amount of irrigated lands that are converted to non-irrigated agriculture increases, the likelihood that *some* of these lands may result in being converted to nonagricultural uses, including urbanization, would be expected to increase.

The 2013 California Water Plan Update for the San Joaquin River Hydrologic Region (DWR 2014) projects that by 2050 urbanization will result in the permanent conversion of between 6 percent and 14 percent of irrigated acreage in the San Joaquin Valley annually. This conversion is dependent on many development pressure factors, such as population growth and the density of development of surrounding lands. Although predicting which irrigation districts would be more likely to be affected by urbanization in the San Joaquin Valley is not possible because it would depend on local land use decisions, a reduction of irrigated lands would be expected to influence where conversions occur. For example, all the irrigation districts presently contain urban and built-up lands, much of it along the Highway 99 corridor, and most conversions of agricultural lands to urban uses happen in the urban fringe area. Therefore, it is reasonable to assume that the amount of land that may actually convert to nonagricultural use in the San Joaquin Valley would include some fraction of the percentage of land that does not receive irrigation in the LSJR area of potential effects for agricultural resources. It is also reasonable to assume that some percentage of the farmland that would be converted to nonagricultural uses has been included as part of recent projections (6–14 percent annually) for urban conversion (although reductions in the availability of irrigation water may have more influence on the ultimate location of development as opposed to the extent of development). Importantly, a presumably large proportion of the farm lands affected by potential reductions of irrigation water supply, as estimated by the SWAP model, is likely to remain either temporarily or permanently in nonirrigated agricultural use (e.g., dryland farming, grazing, and fallowing). Based on consideration of these factors, a predicted reduction of 4 percent or more of irrigated acreage in any one district was adopted as a conservative threshold for determining significance for Impact AG-1.

For Impact AG-2, other changes in the existing environment, as possibly predicted by the SWAP model, are addressed, including seepage effects on agricultural lands and indirect effects of reduced Pasture and Alfalfa on dairies. Information from Chapter 5, *Surface Hydrology and Water Quality*, and Chapter 6, *Flooding, Sediment, and Erosion,* is incorporated to identify Stanislaus River flow levels that may result in elevated seepage in areas previously identified as being affected by Stanislaus River flows. Information from the SWAP model and irrigation district water use are used to qualitatively discuss indirect effects on dairies. To observe impacts that may affect the dairy industry acreage for Alfalfa and Pasture or Corn and Grain from the SWAP model can be combined. The SWAP model has limitations in modeling performance of feed crops as these crop groups usually have lower net returns to land and management. The issue is overcome for dairies by employing minimum silage constraints as silage typically must be produced closed to the dairies. Given the SWAP model uses a simplified assumption that water use would shift from lower net revenue crops to high-value crops, it likely over predicts the shift for other feed crops.

Impacts AG-3 and AG-4 were qualitatively evaluated based on whether the reduced crop production conflict with Williamson Act or zoning policies. The evaluation incorporates the existing setting information identified in Sections 11.2.2, *Lower San Joaquin River Watershed and Eastside Tributaries*, and 11.3, *Regulatory Background*, and the authority of the State Water Board as a state agency under each of the LSJR alternatives.

SWAP Modeled Baseline

Based on the WSE model estimates of allowable surface water diversions and available groundwater for the 1922–2003 period, SWAP model output show the distribution of crop acreage by crop categories for each irrigation district in the area of potential effects (Table 11-12 and Figures 11-3a and 11-3b through Figure 11-8). Crop category groupings are based on similar type crops. These combinations were selected because of similar net revenue by crop category, the ability to observe impacts on specific industries such as dairy and cattle, and where appropriate to reduce the overall number of impact curves. These figures provide examples of how the acreage of different crop types can change in response to water availability. Figure 11-3, for example, shows that the acreage of permanent crops (Almonds, Orchards, Pistachio, Subtropical, and Vine) changes very little. There is only a very small reduction that occurs in less than 10 percent of years, when acreage drops from approximately 41,000 acre to approximately 39,000 acres. The acreage of pasture stays the same, about 2,300 acres, most of the time under baseline. However, unlike for permanent crops, acreage decreases in about 15 percent of years to acreages approaching zero under baseline. This is generally reflective of the response of irrigated agriculture to reduced water availability—limited water supplies are typically directed towards permanent crops and crops with higher net revenue.

Salinity Impacts of LSJR Alternatives

The effects of the LSJR Alternatives on salinity concentrations in the SJR at Vernalis and the southern Delta are evaluated using the WSE model as presented in Appendix F.1, *Hydrologic and Water Quality Modeling*. The impacts of these salinity concentrations relative to baseline are analyzed in Chapter 5, *Surface Hydrology and Water Quality* (Impacts WQ-1 and WQ-2) and determined to be less than significant for all LSJR alternatives. Therefore, the associated salinity impacts on agricultural resources are also considered to be less than significant and are not discussed further in this chapter.

Table 11-12. Average Annual SWAP Baseline Acreage and Percent by Crop Category for Each Irrigation District

	SSJID		OID		SEWD & CSJWCD		MID		TID		Merced ID	
	Acres	% of Total	Acres	% of Total	Acres	% of Total	Acres	% of Total	Acres	% of Total	Acres	% of Total

Extended Plan Area

The analysis of the extended plan area generally identifies how the impacts may be similar to or different from the impacts in the plan area (i.e., downstream of the rim dams) depending on the similarity of the impact mechanism (e.g., changes in reservoir levels, reduced water diversions, and additional flow in the rivers) or location of potential impacts in the extended plan area. Where appropriate, the program of implementation is discussed to help contextualize the potential impacts in the extended plan area.

SDWQ Alternatives

The program of implementation for the numeric salinity objectives contained in SDWQ Alternatives 2 and 3 includes continued USBR compliance with the Vernalis salinity requirement currently established in the 2006 *Water Quality Control Plan for the San Francisco/Sacramento-San Joaquin Delta Estuary* (2006 Bay-Delta Plan) and implemented through the State Water Board's Water Right Decision 1641 (D-1641). Accordingly, it is expected that salinity conditions in the southern Delta would not be degraded and would not result in significant impacts.

SDWQ Alternatives 2 and 3 include numeric salinity objectives of 1.0 dS/m and 1.4 dS/m, respectively, applicable in all months. The program of implementation for these two alternatives would maintain the EC at Vernalis at or below 0.7 dS/m April–August and 1.0 dS/m September-March, as it is under the current objectives. This would provide some assimilative capacity downstream of Vernalis and protect beneficial agricultural uses. The existing salinity objectives are 0.7 dS/m for April-August and 1.0 dS/m for September-March and, as described in Chapter 5, *Surface Hydrology and Water Quality,* and Appendix F.2, *Evaluation of Historical Flow and Salinity Measurements of the Lower San Joaquin River and Southern Delta*, baseline salinity conditions have historically ranged from approximately 0.2 dS/m to 1.2 dS/m. The potential agricultural acreage impact (Impact AG-1 and Impact AG-2 for the SDWQ alternatives) is estimated by assuming year-round irrigation salinity concentrations of 1.0 dS/m and 1.4 dS/m for SDWQ Alternatives 2 and 3, respectively. The analysis compares the associated crop yield impacts for this salinity concentration against crop yields under baseline. Based on the conclusions of Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–San Joaquin Delta,* baseline salinity conditions are suitable for all agricultural crops, so the crop yield and agricultural acreage impacts of Alternatives 2 and 3 would simply be those associated respectively with 1.0 dS/m and 1.4 dS/m irrigation water salinity concentrations.

The potential for salinity-related impacts was evaluated using the information and modeling approaches contained in Appendix E. It is first determined if significant reductions in agricultural acreage or significant reductions in crop mix or crop production would take place under the SDWQ alternatives using the quantitative and qualitative results presented in Appendix E. These results are then qualitatively discussed as to the expected impacts under each SDWQ alternative with respect to conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural uses or conversion of farmland to nonfarmland.

Appendix E describes the models that are commonly used when assessing the suitability of a particular water quality (ECw) for crop production. A summary is provided here. Such models estimate the soil water salinity (ECe) that would result from using a certain quality of ECw under specified irrigation management practices (i.e., leaching fraction) and then uses the relationship between salinity and crop yield to develop an estimate of an associated impact. As recommended in Appendix E, the exponential steady-state model results presented in Appendix E are used in this analysis to determine ECe. ECe threshold levels, and the rates at which increasing levels affect crop production, are unique for each crop, a crop's growth stage, and potentially for a cultivar (Ayers and Westcott 1985).

Maas and Hoffman (1977) developed a relationship (Eqn. 11-1) between rootzone salinity and yield decline using the salinity tolerance of crops. This relationship states that at rootzone salinity (ECe) levels greater than a threshold (salinity tolerance of a crop), yield decline begins and increases based on the percent decline for the given increase in salinity (ECe).

$$\text{Yield} = 100\% - \text{slope}\ (\%) * (\text{measured rootzone ECe} - \text{threshold ECe}) \qquad \text{(Eqn. 11-1)}$$

This equation (Eqn. 11-1) uses quantitative salinity tolerance information available for many of the crops grown in the SDWQ area of potential effects, presented in Table 11-13. Relative salt tolerance, on an annual basis, for each crop group is ranked from *sensitive* (S), *moderately sensitive* (MS), *moderately tolerant* (MT), to *tolerant* (T). Qualitative salinity tolerance information, presented in Table 11-14 is available for crops without quantitative data.

As an example, using Eqn. 11-1 above and information from Table 11-13, the decrease in apricot yield can be calculated. Apricots have an ECe tolerance of 1.6 dS/m with a decline of 24 percent for each unit increase in rootzone salinity (ECe). Therefore, using Eqn. 11-1, if the rootzone salinity (ECe) was 2.6 dS/m, then the yield would be expected to decrease by 24 percent, and the total apricot yield would be 76 percent, as presented below in Eqn. 11-2.

$$\text{Apricot yield} = 100\% - 0.24 * (2.6 - 1.6) = 76\% \qquad \text{(Eqn. 11-2)}$$

The methodology uses the results presented in Appendix E for three crops: alfalfa, almonds, and dry beans. All of these crops are grown on significant acreage in the southern Delta (Table 11-9) and have relatively low thresholds to soil salinity (ECe) (Table 11-13). Crops without specific tolerance are listed in Table 11-14. This information can be compared against crops with quantitative data. For example, there is no specific information on apples, but when comparing apples to another sensitive crop (S), yield decline should not occur unless the salinity of the soil extract (ECe) becomes greater than 1 to about 1.5 dS/m. Appendix E presents estimates of soil water salinity and yield impact estimates for dry beans, alfalfa, and almonds across a range of different irrigation water salinity levels and leaching fractions. The analysis considers both a minimum and median level of precipitation, as precipitation influences the level of salinity in the soil, and higher precipitation can result in lower salinity levels. For the purpose of this analysis, a significant impact would result if the impact on crop yield for salt-sensitive crops is greater than 10 percent. Above this level, it would become more difficult for farmers to mitigate impacts with modified irrigation practices (e.g., increased leaching) and would start to substantially reduce the acreage of these types of crops in the southern Delta.

Central Valley Water Board's TMDLs for salt and boron determined that EC objectives protective of beneficial uses in this part of the watershed also protect those uses from the potential impacts from boron. Therefore, boron toxicity to agricultural resources is not considered in this analysis.

Table 11-13. Available Soil Salinity Threshold, Slope Information, and Relative Salinity Tolerance for Crops Grown in within the SDWQ Area of Potential Effects

Crop Category & Crop	Threshold ECe (dS/m)	Slope %/dS/m	Relative Salt Tolerance
Fruits & Nuts			
Apricots	1.6	24	S
Almonds	1.5	19	S
Field Crops			
Cotton	7.7	5.2	T
Sugar Beets	7	5.9	T
Corn	1.7	12	MS

Notes:

1 dS/m = 1000 microSiemens per centimeter (1000 µS/cm).

There is no quantitative data for the crops with only the relative salt tolerance information; however, these crops can be compared against crops with quantitative data. For example, there is no specific information on apples, but when comparing apples to another sensitive crop (S), yield decline should not occur unless the salinity of the soil extract (ECe) becomes greater than 1 to about 1.5 dS/m.ECe = soil salinity

SDWQ = southern Delta water quality
dS/m = deciSiemens per meter
S = Sensitive
MS = Moderately sensitive
MT = Moderately tolerant
T = Tolerant

11.5 Impacts and Mitigation Measures

Impact AG-1: Potentially convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)* for the No Project Alternative technical analysis.

LSJR Alternatives

The LSJR alternatives would require flows for fish and wildlife beneficial uses in the rivers. As a result, modifications to reservoir operations and reductions in the available surface water supply could result in irrigation diversions. A reduction in water supply availability for irrigation purposes could potentially lead to a reduction in crop acreage and a potential conversion to nonagricultural uses. The precise amount of lands that are designated as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance that could be converted to nonagricultural uses cannot be precisely quantified. However, potential impacts, based on the crop reduction modeling results, can be qualitatively discussed to determine possible conversion to nonagricultural uses. In other words, the analysis uses decreased crop production as a proxy for potential conversion to nonagricultural uses. Although the reduction in water supply is used as a proxy for the conversion of irrigated land to nonagricultural lands, lands that are not irrigated could remain in agricultural use (as discussed in Impact AG-3). Non-irrigated uses that are still considered agricultural use include dry land farming, fallowing, grazing, dairy, and animal husbandry. Figures 11-9 through 11-14 summarize the results of the SWAP analysis for all crops for each LSJR Alternative compared to the baseline in each of the six geographic areas.

These figures show how irrigated acreage in each water district changes in response to changed water availability under baseline and for each of the LSJR alternatives. Figure 11-9, for example shows that irrigated acreage in SSJID stays the same, at approximately 58,500 acres in most years under baseline. Irrigated acreage, however, starts dropping at the 95 percent exceedance probability—this means that irrigated acreage drops below 58,500 acres about once in every 20 years and can be as low as approximately 44,000 acres. Figure 11-9 also shows that reduction in irrigated acreage is bigger and occurs more frequently under the LSJR alternatives. Under LSJR Alternative 3, there would be no reduction in crop acreage about 62 percent of the time, and 80 percent of the time crop acreage would still be approximately 55,000 acres. Although the lowest irrigated acreage under LSJR Alternative 3 is only slightly lower than under baseline (42,000 acres under LSJR Alternative 3 versus 44,000 acres under baseline), crop acreage would be lower than under baseline in about 38 percent of all years.

LSJR Alternative 2 (Less than significant/Significant and unavoidable with adaptive implementation)

Irrigated crop acreage under LSJR Alternative 2 as estimated by the SWAP model for the 1922–2003 period shows minimal reductions when compared to baseline (Figures 11-9 through 11-14). Average crop acreage and acreage reductions are summarized in Table 11-15. Two of the six districts had none or minimal (Merced ID) acreage reductions. Reductions in the remaining districts ranges from 1.5 to 2.6 percent. The impact is less than significant.

Adaptive Implementation

Based on best available scientific information indicating that a change in the percent of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation of method 1 would allow an increase of up to 10 percent over the 20-percent February–June unimpaired flow requirement (to a maximum of 30 percent of unimpaired flow). A change to the percent of unimpaired flow would take place based on required evaluation of current scientific information and would need to be approved as described in Appendix K, *Revised Water Quality Control Plan.* Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. However, an increase of up to 30 percent of unimpaired flow would potentially result in different effects as compared to 20-percent unimpaired flow, depending upon flow conditions and frequency of the adjustment.

Table 11-15. Average Cropped Acreage and Acreage Reduction under LSJR Alternative 2

	Baseline	LSJR Alternative 2		
District	Average Acres		Acre Change	% Reduction
SSJID	58,229	57,372	-857	1.5
OID	54,162	52,767	-1,395	2.6
SEWD + CSJWCD	98,931	98,931	0	0.0
MID	57,354	56,143	-1,211	2.1
TID	143,783	141,183	-2,600	1.8
Merced ID	99,769	99,747	-22	0.0
Total	512,229	506,144	-6,086	1.2

SSJID = South San Joaquin Irrigation District
OID = Oakdale Irrigation District
SEWD = Stockton East Water District
CSJWCD = Central San Joaquin Water Conservation District
MID = Modesto Irrigation District
TID = Turlock Irrigation District
Merced ID = Merced Irrigation District

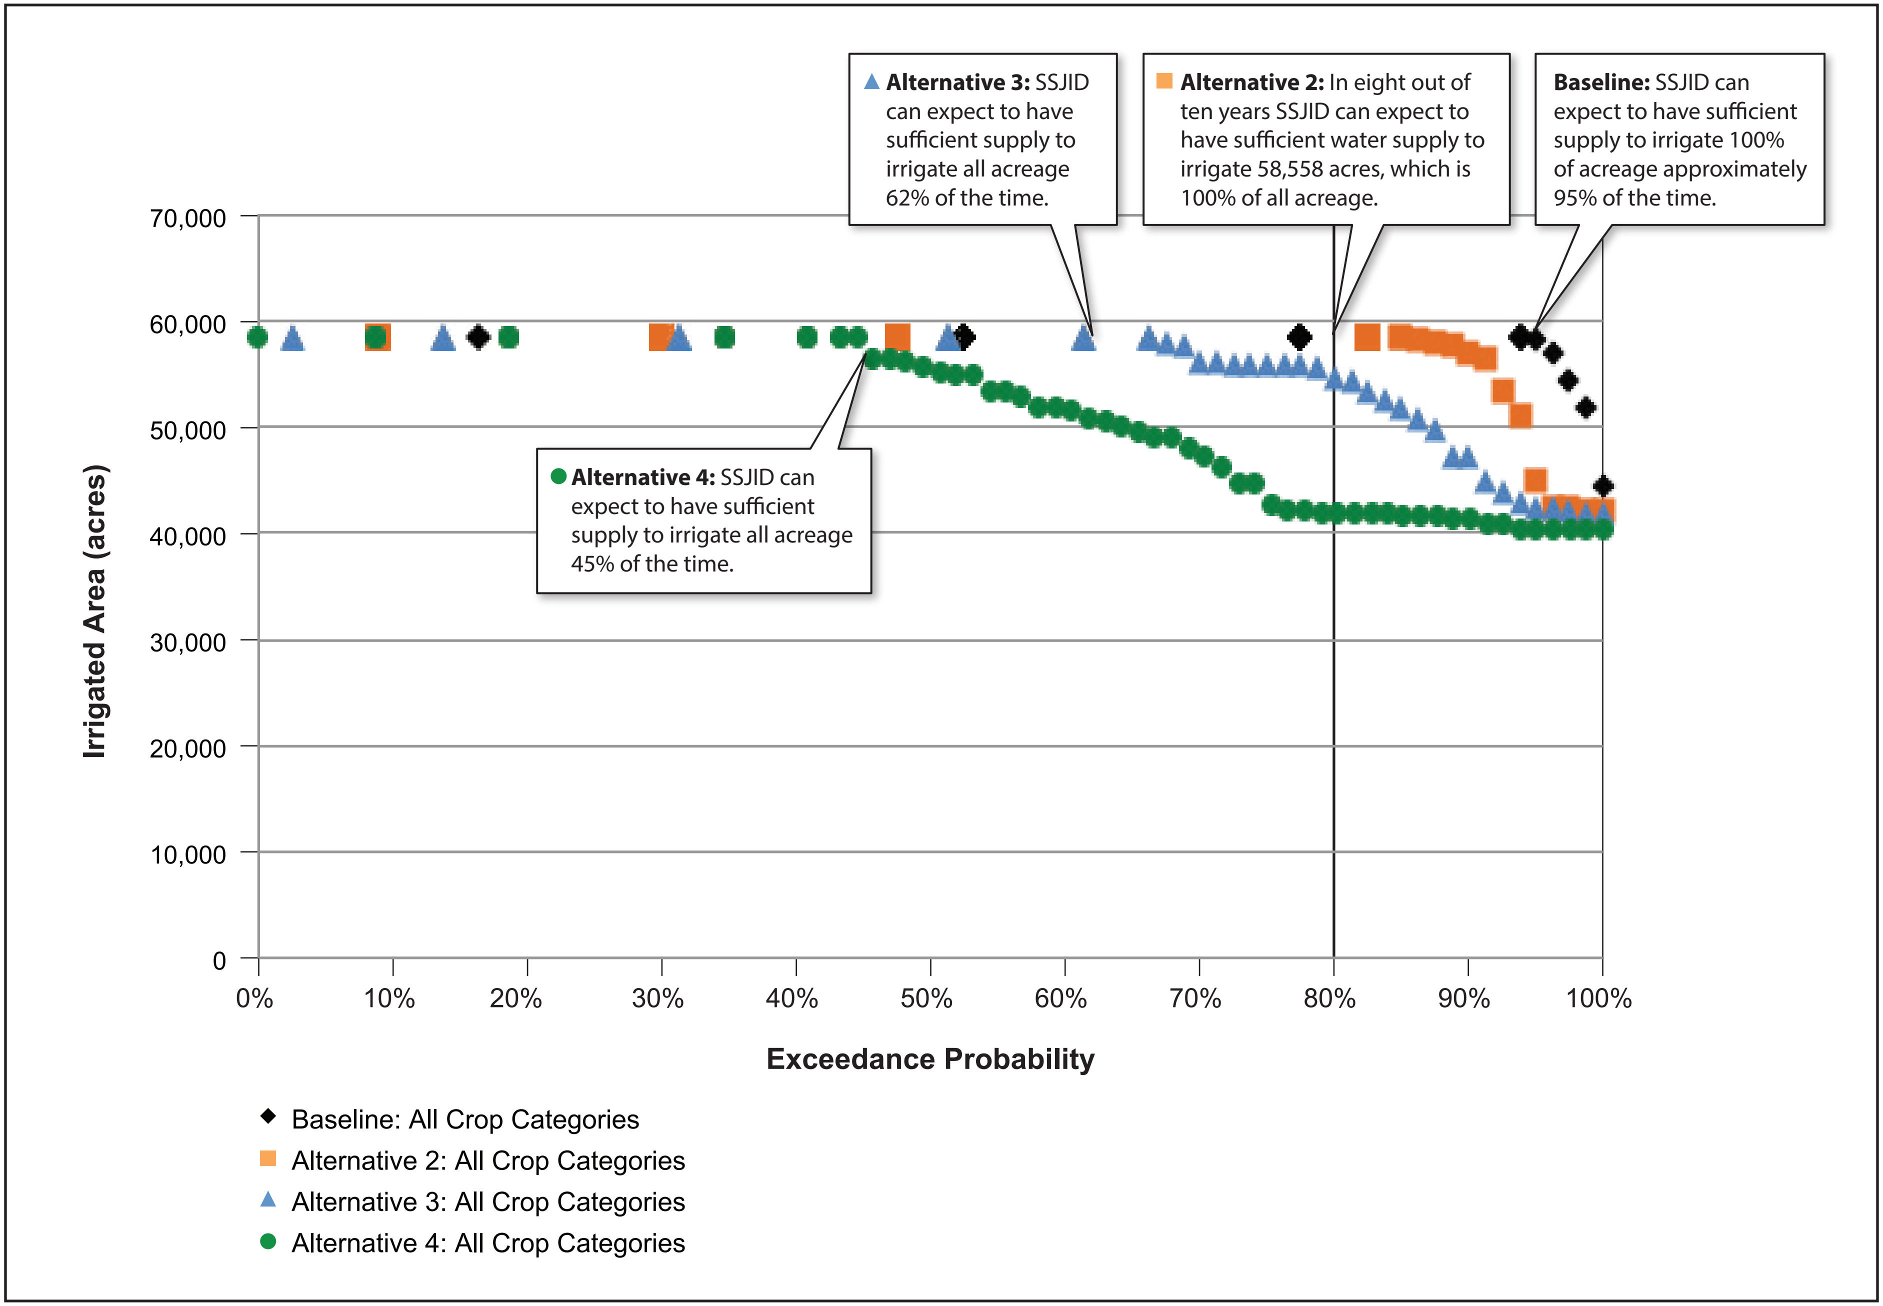
If the adjustment occurs frequently or for extended durations, impacts under LSJR Alternative 2 could become more like the impacts under LSJR Alternative 3. At 30 percent unimpaired flow, the average acreage reduction for all irrigation districts increases from 1.2 percent (Table 11-15) to 2.3 percent (Table 11-16). Reductions in average acreage at the district level ranges from none for SEWD & CSJWCD to 4.5 percent for MID (Table 11-16). When the maximum groundwater pumping capacity for 2014 is used in the analysis instead of the estimates for 2009, the acreage is less affected because increased groundwater pumping can meet the shortfall in the applied surface water needed to meet crop demand.

Table 11-16 Average Baseline and Crop Production 2009 and 2014 Groundwater Pumping under LSJR Alternative 2 with Adaptive Implementation

	2009 Groundwater Pumping			2014 Groundwater Pumping[a]		
	Baseline	30 PCT		Baseline	30 PCT	
District	Acres		% Reduction		Acres	% Reduction
SSJID	58,229	56,806	2.4	58,385	57,367	1.7
OID	54,162	51,806	4.4	54,414	52,865	2.8
SEWD & CSJWSD	98,931	98,931	0.0	98,931	98,931	0.0
MID	57,354	54,765	4.5	58,833	58,584	0.4
Turlock ID	143,783	138,550	3.6	146,006	144,129	1.3
Merced ID	99,769	99,544	0.02	99,769	99,544	0.2
	512,229	500,401	2.3	516,339	511,420	1.0

SSJID = South San Joaquin Irrigation District
OID = Oakdale Irrigation District
SEWD = Stockton East Water District
CSJWCD = Central San Joaquin Water Conservation District
MID = Modesto Irrigation District
TID = Turlock Irrigation District
Merced ID = Merced Irrigation District

[a] TID baseline increased by 182 acres with 2014 groundwater pumping.



▲ **Alternative 3:** SSJID can expect to have sufficient supply to irrigate all acreage 62% of the time.

■ **Alternative 2:** In eight out of ten years SSJID can expect to have sufficient water supply to irrigate 58,558 acres, which is 100% of all acreage.

Baseline: SSJID can expect to have sufficient supply to irrigate 100% of acreage approximately 95% of the time.

● **Alternative 4:** SSJID can expect to have sufficient supply to irrigate all acreage 45% of the time.

Based on best available scientific information indicating that a change in the timing or rate of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation method 2 would allow changing the timing of the release of the volume of water within the February-June timeframe. While the total volume of water released February-June would be the same as LSJR Alternative 2 without adaptive implementation, the rate could vary from the actual (7-day running average) unimpaired flow rate. Method 2 would not authorize a reduction in flows required by other agencies or through other processes, which are incorporated in the modeling of baseline conditions. It is unlikely that alteration of the timing of the river flows under method 2 would result in substantial modification to the April–September (e.g., irrigation season) diversions. Although method 2 could result in a change in flow during April through June, the total volume of water required for river flow would be the same and, therefore, there would be little change in the volume of water available for agriculture. Method 3 would not be authorized under LSJR Alternative 2 since the unimpaired flow percentage would not exceed 30 percent. Adaptive implementation method 4 would allow an adjustment of the Vernalis February–June flow requirement. The WSE model results indicate changes due to method 4 under this alternative would rarely alter the flows in the three eastside tributaries or the LSJR, and thus would not affect agricultural resources. Accordingly, LSJR Alternative 2, with the incorporation of adaptive implementation methods 2, 3, and 4, would not affect agricultural resources, and impacts would be less than significant.

Although adaptive implementation methods 2, 3, and 4 would not cause significant impacts, this impact is still considered to be significant as a result of adaptive implementation method 1. If method 1 is used to increase the required percent of unimpaired flow to 30 percent unimpaired flow on a long-term basis, it is estimated that OID would experience an average decrease in irrigated acreage of 4.4 percent and MID would experience an average reduction in irrigated acres of 4.5 percent under 2009 conditions (Table 11-16). Therefore, impacts would be significant.

Mitigation Measures

A SED must identify feasible mitigation measures for each significant environmental impact identified in the SED. (Cal. Code Regs., tit. 23, § 3777(b)(3).) Local land use agencies can mitigate for the loss of farmland to urban development through development conditions such as in lieu fees for, or direct purchases of, agricultural conservation easements. In addition, local water suppliers, regional groundwater management agencies, and irrigation districts could reduce potential conversion of agricultural land due to reduced surface water availability by requiring modifications to existing agricultural practices that increase irrigation efficiency. To some extent, irrigation efficiencies have already resulted from the implementation of SBX7-7 requirements (see Section 11.3, *Regulatory Background*). Implementing irrigation efficiency measures could reduce the overall amount of irrigation water needed because the water applied to the crops would have fewer losses to deep percolation and surface runoff. The conserved water would then be available for application to additional acreage, thus reducing the likelihood of conversion to nonagricultural use. Increasing the irrigation efficiency could be accomplished with the following methods.

- Increase the use of irrigation management services to better determine how much water is needed by a crop and when to apply it.
- Convert less efficient irrigation systems (e.g., surface irrigation) to more efficient ones (e.g., microirrigation).

- Increase the capability of irrigation water suppliers to provide delivery flexibility, such as the use of irrigation district regulating reservoirs, to allow flexible delivery durations, scheduling, and flow rates.

The measures identified above, such as agricultural conservation easements, could be adopted as project-level measures for project-specific development. Individual projects will be subject to the appropriate level of environmental review at the time they are proposed, and mitigation would have to be identified to avoid or reduce significant effects, prior to any project-level action. Some potential actions, however, may not require discretionary approvals and may not be subject to project-level CEQA review. Nevertheless, local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or under other local authorities, adopt the relevant mitigation measures identified above.

The State Water Board has authority to take action to prevent waste, unreasonable use, unreasonable method of use, and unreasonable method of diversion of water. The State Water Board may exercise this authority through quasi-adjudicative or quasi-legislative proceedings. However, such proceedings are not part of this project. It is also infeasible for the State Water Board to impose mitigation measures at this time because it is undertaking a programmatic analysis of the potential agricultural resource impacts, does not now have specific facts associated with an individual project to legally and technically impose requirements related to waste and unreasonable use, and it is speculative whether these actions would reduce conversions of agricultural lands. In addition, while the State Water Board may impose water conservation or efficiency requirements through the adoption of regulations, the amount of time, high cost, and commitment of staff resources associated with such rule-making proceedings also renders adopting the mitigation measures now infeasible. Adopting regulations right now would require considerable staff time to research, formulate and develop, require extensive stakeholder outreach, and require numerous public meetings before the regulations would take effect. The State Water Board currently has limited resources to pursue adoption of such regulations as most of its budget for the water right program is supported by fees imposed on water right permit and license holders, and is used for program activities related to the diversion and use of water subject to the permit and license system. Only a small amount of funding is available for other regulatory activities and it is speculative to anticipate that additional funding will be made available. Therefore, at this time the imposition of the above mitigation measures is infeasible and impacts under LSJR Alternative 2 with adaptive implementation would remain significant and unavoidable.

While it is possible that some of the water-diversion and use measures, including irrigation efficiency, may have some applicability to reducing impacts or could be implemented as part of the individualized water right proceedings that are expected to take place to implement the flow objectives, any application of these measures at this point by the State Water Board is infeasible for the reasons stated above. Furthermore, it is unknown whether these activities would reduce the significant impacts to less-than-significant levels. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies can and should adopt irrigation efficiencies and local land use authorities can and should impose development conditions and require conservation easements where allowed to mitigate for the loss of agricultural lands to urbanization; however, given the uncertainty of the extent to which these mitigation measures would occur and because they may not fully mitigate impacts, impacts would remain significant. As such, according to the number of acres that would no longer be considered Prime Farmland, Unique Farmland, or Farmland of Statewide Importance as predicted by the SWAP model and the possibility of conversion of these acres to nonagricultural land uses, impacts on agricultural resources under LSJR Alternative 2 with adaptive implementation would remain significant and unavoidable.

LSJR Alternative 3 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

Under LSJR Alternative 3, the average annual reduction in acreage ranges from a low of 0.0 percent for SEWD and CSJWCD to just under 10 percent for MID (Table 11-17). While the SWAP results indicated there would be little to no change in crop acreage for either SEWD/CSJWCD or Merced ID, the remaining irrigation districts could experience change in crop acreage of various crop categories.

Crops categories that would experience greater than 1 percent average acreage reduction are shown in Figures 11-15 through 11-18 for SSJID, OID, MID, and TID, respectively for illustration purposes. These figures illustrate how the acreage of select crops change in response to reduced water availability, under both baseline and Alternative 3. Figure 11-15a, for example, shows the irrigated acreage in SSJID for alfalfa. Under baseline, acreage remains stable, at approximately 3,200 acres, in a little over 95 percent of all years, and then is reduced to less than 200 acres. This is reflective of the response to reduced water availability that occurs about once in every 20 years under baseline. Acreage also remains stable under Alternative 3 in approximately 65 percent of years, but then drops a little in about 10 percent of years, followed by a dramatic drop in acreage to 200 acres or less in approximately 17 percent of years. These figures show how the average reductions in crop acreages are concentrated in years with reduced water availability, and vary depending on crop type. Figures are not shown for crops that are not much affected by reduced water supplies, such as orchards, vines, and truck crops (see Appendix G tables G.4-6a through G.4-6f).

Table 11-17. Average Cropped Acreage and Acreage Reduction under LSJR Alternative 3, by District, Compared to Baseline

	Baseline	LSJR Alternative 3		
District	Average Acres		Acre Change	% Reduction
SSJID	58,229	55,951	-2,277	3.9
OID	54,162	50,184	-3,978	7.3
SEWD + CSJWCD	98,931	98,931	0	0.0
MID	57,354	51,685	-5,670	9.9
TID	143,783	132,830	-10,954	7.6
Merced ID	99,769	98,970	-800	0.8
Total	512,229	488,551	-23,679	4.6

Since the crop categories within the six geographic areas need irrigation in 8 out of 10 years to qualify as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, implementing LSJR Alternative 3 could potentially reduce the total lands classified as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance. When the maximum groundwater pumping capacity scenario for 2014 is used in the analysis instead of the estimates for 2009, the acreage is less affected because there was more groundwater pumping in 2014 to meet the shortfall in the applied surface water needed to meet crop demands. The results show an overall decrease in the reduction of average annual crop acreage for all irrigation districts, but particularly MID (Table 11-18). If the groundwater pumping capabilities of the irrigation districts are closer to the 2014 values, then the crop acreage reductions estimated under 2009 conditions would be smaller; however, it is unlikely this is a sustainable practice given groundwater conditions (Chapter 9, *Groundwater Resources*).

Table 11-18. Percent Average Acreage Reduction from Baseline for Irrigation Districts Impacted under LSJR Alternative 3 for 2009 and 2014 Groundwater Pumping Levels

	Groundwater Pumping Level	
	2009	2014
District	% Reduction	
SSJID	4	3
OID	7	5
MID	9	1
TID	8	3

SSJID = South San Joaquin Irrigation District
OID = Oakdale Irrigation District
MID = Modesto Irrigation District
TID = Turlock Irrigation District

It is unknown whether the reduction in irrigation water would result in a direct conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use, but it is conservative to assume that if irrigation water is unavailable to sustain these specific crop categories identified in Table 11-17, then some of the 22,879 acres affected, on average, in SSJID, OID, MID, and TID (7.3 percent of the total Prime Farmland, Unique Farmland, and Farmland of Statewide Importance within the affected districts) would be converted to nonagricultural uses. While it would be speculative to quantify the amount of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance that might be converted, the substantial reduction in these types of existing irrigated agricultural lands, as a result of LSJR Alternative 3, could result in their conversion to nonagricultural uses, in which case impacts would be significant.

Similar to the availability of feasible mitigation above under LSJR Alternative 2 (20 percent unimpaired flow), while it is possible that some of the water-diversion and use measures, including irrigation efficiency, may have some applicability to reducing impacts or could be implemented as part of the individualized water right proceedings that are expected to take place to implement the flow objectives, any application of these measures at this point by the State Water Board is infeasible as explained in LSJR Alternative 2. Furthermore, it is unknown whether these activities would reduce the significant impacts to less-than-significant levels. Local water districts and suppliers,

regional groundwater agencies, irrigation districts, and local agencies can and should adopt irrigation efficiencies described in LSJR Alternative 2 and local land use authorities can and should impose development conditions and require conservation easements where allowed to mitigate for the loss of agricultural land; however, given the uncertainty of the extent to which these mitigation measures would occur and because they may not fully mitigate impacts, impact would remain significant. While adaptive implementation method 1 could reduce the percent of unimpaired flow to 30 percent and potentially reduce impacts on agricultural resources, it cannot be independently applied as an alternative because it is part of LSJR Alternative 3 and because the purpose of adaptive implementation is to benefit fish. Therefore, according to the number of acres that would no longer be considered Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as predicted by the SWAP model, and the possibility of conversion of these acres to nonagricultural land uses, impacts on agricultural resources would remain significant and unavoidable.

Adaptive Implementation

As discussed under LSJR Alternative 2, adaptive implementation methods 2 and 4 are not expected to result in impacts on agricultural resources. Adaptive implementation method 3 would result in a shift in the volume of February–June water available to other parts of the year, and one potential way to implement this method is included in the modeling results presented for LSJR Alternative 3 in Table 11-17. Because this method would have minimal effect on diversions and the total annual volume of river flow, this method would not affect agricultural resources and it would result in similar impacts to those described above. Adaptive implementation method 1 would allow an increase or decrease of up to 10 percent in the February–June, 40-percent unimpaired flow requirement (with a minimum of 30 percent and maximum of 50 percent) to optimize implementation measures to meet the narrative objective, while considering other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. Adaptive implementation must be approved using the process described in Appendix K. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. If the specified percent of unimpaired flow were changed from 40 percent to 30 percent or 40 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternatives 2 or 4, respectively.

If the adjustment occurs frequently or for extended durations, based on the modeling results for LSJR Alternative 4 and with adaptive implementation method 1 incorporated (i.e., 50 percent unimpaired flow), impacts would still be significant. If the adjustment occurs frequently or for extended durations, based on the modeling results for LSJR Alternative 2 and with adaptive implementation method 1 incorporated (i.e., 30 percent unimpaired flow), impacts on agricultural resources would be less than significant for all districts except for OID, which would experience an average decrease in irrigated acreage of 4.4 percent; and, MID, which would experience an average reduction in irrigated acres of 4.5 percent (Table 11-16) from baseline.

LSJR Alternative 4 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

Under Alternative 4, the average annual reduction in acreage ranges from a low of 0 percent for SEWD and CSJWCD to 27.5 percent for MID (Table 11-19). Figures 11-19 through 11-22 show SWAP-modeled crop changes for all crops as a result of LSJR Alternative 4 compared to baseline for the six geographic areas. While the SWAP results indicated there would be little to no change in crop acreage for either SEWD/CSJWCD or Merced ID, the remaining irrigation districts are predicted to experience change in crop acreage for various crop categories. Crops categories that would experience an average acreage reduction of greater than 4 percent are shown in Figures 11-19 through 11-22 for SSJID, OID, MID, and TID respectively. These figures show how the acreage of select crops change in response to reduced water availability under both baseline and LSJR Alternative 4. Figure 11-19a, for example, shows the irrigated acreage in SSJID for Alfalfa. Under baseline, acreage remains stable, at approximately 3,200 acres, in a little over 95 percent of all years, and then is reduced to less than 200 acres. This is reflective of the response to reduced water availability that occurs about once in every 20 years under baseline. Acreage also remains stable under LSJR Alternative 4 in approximately 45 percent of years, but then is reduced to about 200 acres or less in approximately 42 percent of years. These figures show how the average reductions in crop acreages are concentrated in years with reduced water availability, and vary depending on crop type. Figures are not shown for crops that are not much affected by reduced water supplies, such as Orchards, Vines, and Truck crops (see Appendix G, Tables G.4-6a through G.4-6f).

Table 11-19. Average Cropped Acreage and Acreage Reduction under LSJR Alternative 4, by District, Compared to Baseline

	Baseline	LSJR Alternative 4		
District	Average Acres		Acre Change	% Reduction
SSJID	58,229	52,048	-6,181	10.6
OID	54,162	43,414	-10,748	19.8
SEWD + CSJWCD	98,931	98,931	0	0.0
MID	57,354	41,580	-15,774	27.5
TID	143,783	108,490	-35,294	24.5
Merced ID	99,769	97,126	-2,644	2.6
Total	512,229	441,589	-70,640	13.8

Since the land within the six geographic areas would need irrigation 8 out of 10 years to qualify as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance it is expected the total lands classified as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance would be reduced as a result of LSJR Alternative 4 (Table 11-19). It is unknown whether the reduction in irrigation water would result in a direct conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use, but it is conservative to assume that if irrigation water is unavailable to sustain these acreages identified in Table 11-19, then some of the 70,640 acres affected in SSJID, OID, MID, and TID (17 percent of the total Prime Farmland, Unique Farmland, and Farmland of Statewide Importance within the affected districts) would be converted to nonagricultural uses

When the maximum groundwater pumping capacity for 2014 is used in the analysis instead of the estimates for 2009, the acreage is less affected because there was more groundwater pumping in 2014 to meet the shortfall in the applied surface water needed to meet crop demand. The results show an overall decrease in the reduction of average annual crop acreage for all irrigation districts, but particularly MID (Table 11-20). If the groundwater pumping capabilities of the irrigation districts are closer to the 2014 values, then the crop acreage reductions estimated under 2009 conditions would be smaller; however, it is unlikely this is a sustainable practice given groundwater conditions (Chapter 9, *Groundwater Resources)*.

TID = Turlock Irrigation District

Similar to the availability of feasible mitigation above under LSJR Alternative 2 (20 percent unimpaired flow), while it is possible that some of the water-diversion and use measures, including irrigation efficiency, may have some applicability to reducing impacts or could be implemented as part of the individualized water right proceedings that are expected to take place to implement the flow objectives, any application of these measures at this point by the State Water Board is infeasible, as explained in LSJR Alternative 2. Furthermore, it is unknown whether these activities would reduce the significant impacts to less-than-significant levels. Irrigation efficiency measures could be implemented by local water purveyors, irrigation districts, or groundwater management districts to reduce the amount of water applied to crops while still meeting crop water demands. Irrigation efficiency would serve to keep as much agricultural acreage in production as possible. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies can and should adopt irrigation efficiencies described in LSJR Alternative 2 and local land use authorities can and should impose development conditions and require conservation easements where allowed to mitigate for the loss of agricultural lands; however, given the uncertainty of the extent to which these mitigation measures would occur and because they may not fully mitigate impacts, impacts would remain significant. While adaptive implementation method 1, could reduce the percent of unimpaired flow to 50 percent and potentially reduce impacts on agricultural resources (discussed below), it cannot be independently applied as an alternative because it is part of LSJR Alternative 4 and because the purpose of adaptive implementation is to benefit fish. Therefore, according to the number of acres that would no longer be considered Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as predicted by the SWAP model, and the possibility of conversion of these acres to nonagricultural land uses, impacts on agricultural resources would remain significant and unavoidable.

Adaptive Implementation

As discussed under LSJR Alternative 2, adaptive implementation methods 2 and 4 are not expected to result in impacts on agriculture. For reasons discussed under LSJR Alternative 3, adaptive implementation method 3 would not affect agricultural impacts associated with LSJR Alternative 4. Adaptive implementation method 1 would allow a decrease of up to 10 percent in the February-June, 60-percent unimpaired flow requirement (to 50 percent) to optimize implementation measures to meet the narrative objective, while considering other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. Adaptive implementation must be approved using the process described in Appendix K. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. If the specified percent of unimpaired flow were changed from 60 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternative 3 (i.e., less severe for agricultural resources, but still significant).

Irrigation efficiency measures and adaptive implementation method 1 could potentially reduce impacts, but likely not to a less-than-significant level. Applying adaptive implementation method 1 independent of LSJR Alternative 4 is infeasible given adaptive implementation is for the benefit of fish. Therefore, the significant impacts on agricultural resources are based on the number of acres of crop loss predicted by the model and the unknown ability of pumping groundwater or irrigation efficiencies to offset the loss of crop acreage. Impacts would remain significant and unavoidable.

SDWQ Alternatives

While the SDWQ alternatives are expected to maintain historical salinity concentrations in the southern Delta, the potential crop yield under the SDWQ alternatives is estimated by assuming year-round irrigation salinity concentrations of 1.0 dS/m and 1.4 dS/m for SDWQ Alternatives 2 and 3, respectively. The crop yield estimated under each of the alternatives is then compared with baseline results to determine the associated crop yield impacts of the alternatives. This information is used to qualitatively discuss if conversion to nonagricultural uses would take place.

SDWQ Alternative 2: (Less than significant)

Using the modeling approach described in Section 11.4.2, *Methods and Approach*, with a 20 percent leaching fraction, under either a median or minimum amount of precipitation, there was no yield reduction for dry beans irrigated with water containing a salinity level (ECw) of 1.0 dS/m. In addition, Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–San Joaquin Delta,* reports that studies in the LSJR area of potential effects have shown that the highest soil salinities (ECe) and lowest apparent leaching fractions occurred at locations where water quality was the best and that higher leaching fractions and lower salt accumulations (ECe) were found at the locations where more saline irrigation water was used (1.1 dS/m or more). For this reason, it is reasonable to assume that salt-sensitive crops would not be affected. Since dry bean is the southern Delta crop most sensitive to salinity (Table 11-12), and given that the yield for dry beans is not affected, then the yield of crops with higher salt tolerance would not be affected. Crop production would not be substantially reduced, and Prime Farmland, Unique Farmland or Farmland of Statewide Importance would not be converted to nonagricultural uses. Impacts on agricultural resources would be less than significant.

SDWQ Alternative 3: (Less than significant)

Using the modeling approach described in Section 11.4.2, *Methods and Approach*, there is a 5 percent yield reduction for dry bean irrigated with 1.4 dS/m water, with a minimum amount of precipitation and a leaching fraction of 20 percent. When the median level of precipitation is used, the yield decline is less than 1 percent. For almonds, the yield decline is 3 percent with a leaching fraction of 15 percent and minimal precipitation; with the median level of precipitation the yield decline is less than 1 percent. For alfalfa there was no yield decline under the 15 percent leaching fraction with minimal precipitation. In addition, Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–*

San Joaquin Delta, reports that southern Delta studies have shown that the highest soil salinities (ECe) and lowest apparent leaching fractions occurred at locations where water quality was the best and that higher leaching fractions and lower salt accumulations (ECe) were found at the locations where more saline irrigation water was used (1.1 dS/m or more). Because dry bean is the southern Delta crop most sensitive to salinity (Table 11-12) and given that the reduction in yield for dry beans is less than 10 percent, there is little potential for any yield impacts on crops with higher salt tolerance. Accordingly, a 10 percent yield decline is not expected, and it is reasonable to assume that Prime Farmland, Unique Farmland, or Farmland of Statewide Importance would not be converted to nonagricultural uses. Impacts would be less than significant.

Impact AG-2: Involve other changes in the existing environment which, due to their location or nature, could result in a conversion of farmland to nonagricultural use

Other changes to the existing environment that could result from the LSJR and SDWQ alternatives include changes to the timing and magnitude of flows in the tributaries, the loss of farmland upon which other agricultural production relies, and the amount of farmland in production that could be reduced as a result of these changes.

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)*, for the No Project impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

Agricultural lands along the Stanislaus River include orchard, field, and vegetable crops. An investigation by the U.S. Attorney in Sacramento, California (USDOI 1982) found that when the river is over 1,250 cfs at Ripon, the high water table (i.e., seepage) can affect fields, specifically a 60-acre sugar beet field on the Collier Ranch, and that at flows above 1,500 cfs, the water tables rises sufficiently to damage almond and walnut orchards adjacent to the river. To monitor the water table, auger holes were dug on six properties that were thought to be susceptible under high river flow conditions.

Flows greater than 1,500 cfs currently exist on the Stanislaus River. Such flows typically occur more than 30 percent of the time in March, April, and May and less than 20 percent of the time the remainder of the year (Tables 6-13 and 6-14 in Chapter 6, *Flooding, Sediment, and Erosion)*. Flows greater than 1,500 cfs on the Stanislaus River are not considered to increase in frequency under LSJR Alternative 2 when compared to baseline (Table 6-14 in Chapter 6, *Flooding, Sediment, and Erosion*).

For this analysis, it is assumed that regardless of what crop is grown on the land, a high water table could still impact agricultural production. However, if this land is in sugar beet production, it would represent less than 3 percent of the total sugar beet production in the LSJR area of potential effects and approximately 0.1 percent of the total agricultural production in the LSJR area of potential effects (Table 11-5). Therefore, this would be a localized effect that would have a less-than-significant impact on the overall production of sugar beets in the area and would not substantially reduce crop production.

Six properties of walnut and almond orchards adjacent to the Stanislaus River were also reported as being susceptible to damage at flows above 1,500 cfs (USDOI 1982). As of 2010, there were approximately 2,605 acres of almonds and 1,288 acres of walnuts within the Stanislaus River 100-year floodplain (based on GIS analysis using 2010 CropScape Data published by the USDA (2016), and floodplain area data published by the Federal Emergency Management Agency (2016). The 100-year floodplain is inundated at volumes much greater than 1,500 cfs. For this area, in 2010 the gross annual revenue of orchards ranged from $1,500 to $2,000 per a (from the SWAP model, as described in Medellín-Azuara 2015). If 100 percent of this acreage was affected by seepage the revenue lost could range from $5.8 million to $7.8 million in value. This acreage represents only about 3 percent of baseline Almond and Pistachio (the crop category that most resembles walnuts and almonds) acreage and less than 1 percent of all agricultural production in the LSJR area of potential effects (Table 11-5). There would be no change in the frequency of flows at 1,500 cfs relative to baseline conditions and LSJR Alternative 2 would not increase the likelihood of a 100-year flood (Chapter 6, *Flooding, Sediment, and Erosion*). As such, it is reasonable to assume that a substantial reduction in agricultural production would not occur in the LSJR area of potential effects as a result of seepage when compared to baseline. Because there is no substantial reduction in crop production, acreage impacts would be less than significant.

LSJR Alternative 3 (Less than significant/Less than significant with adaptive implementation)

Flows greater than 1,500 cfs on the Stanislaus River would slightly increase in frequency under LSJR Alternative 3 when compared to baseline. The overall frequency of monthly flows greater than 1,500 cfs would increase from 14 percent to 16 percent at Ripon (Table 6-14 in Chapter 6). However, as described under LSJR Alternative 2, LSJR Alternative 3 would not increase the likelihood of a 100-year flood and effects would occur to less than 1 percent of the total agricultural production in the LSJR area of potential effects. Therefore, it is reasonable to assume that a substantial reduction in agricultural production, and thus acreage, would not occur in the LSJR area of potential effects as a result of seepage when compared to baseline. Impacts would be less than significant.

For economic viability, dairies rely, in part, on the proximity of cropland for feed and waste disposal. If cropland is in close proximity to a dairy or used by a dairy it may be considered a higher net revenue crop when compared to other cropland in the LSJR area of potential effects. Reduction in acreage for feed, particularly Alfalfa, can be offset through purchases of feed from production areas outside of the LSJR area of potential effects. Due to additional transportation costs, feed costs could go up; however, the increase in the cost of feed is not known because it depends on where dairies source feed from and the competition for the feed from other users. As an example of the uncertainty in feed costs, statewide feed costs decreased in 2015 ($10.41/hundredweight [112 pounds]) from 2014 ($11.05/hundredweight) prices (Sumner 2016).

During water-short years, dairy and cattle operations relying on Alfalfa (SSJID, MID, and TID), Grain (MID), and Pasture (SSJID, OID, MID, and TID) production could experience some input cost increases if reductions to these crop types occur. Although SWAP results predict a reduction of lower net revenue crops, such as Alfalfa, under LSJR Alternatives 3, SWAP could be over predicting fallowing from feed crops in particular Alfalfa and Pasture. Considering that Alfalfa and Pasture crops could be associated with dairies (i.e., have higher net revenue), potentially less acreage could actually go out of production. In addition, Alfalfa and Pasture are able to survive without receiving their full water requirements during an irrigation season; however, there could be a decline in yield for these crops or a reduction in the full use of Pasture if the full water requirements were continually restricted (Putnam et al. 2015a, 2015b). Silage corn can only be grown locally for cost effectiveness. Limited substitution of silage corn in dairy cows is considered in SWAP because of the minimum silage constraints in the model and hence less fallow land in silage crops is predicted because of the minimum silage constraints in the model. This is exemplified in the recent drought, as dairy operators obtained water supplies from willing sellers within an irrigation district in order to manage waste disposal and meet minimum dietary requirements of silage corn particularly.

A review of agricultural commodity data shows that dairies either exceed or are competitive with other agricultural commodities in the LSJR area of potential effects (Table 11-21). As such, some commodities, such as field and grain and even higher net value crops in the spectrum, may decrease in production if dairies obtain needed water supplies during drier conditions. Given the gross revenues of different agricultural commodities, it is likely that dairies would be competitive for water supplies (Table 11-21), as they have in the past. For example, irrigation water cost for dairy feed in the San Joaquin Valley represent about 9 percent of the cost of farm milk production in 2015, and is not considered the dominant cost when evaluating all other costs associated with dairies (Sumner 2016).

Table 11-21. Gross Revenue of Agricultural Commodities

Agricultural Commodity	Gross Value ($)
Dairy	2,211,377,149
Hay Alfalfa	50,337,017
Oranges	8,074,381
Almonds	883,756,849
Vegetables (Truck in SWAP)	121,637,329

Source: USDA 2015.

The three sectors of beef cattle operations may adjust differently under LSJR Alternative 3 conditions. Beef cattle feedlot operations rely on grains and oilseeds from out of the state are imported (Medellin-Azuara et al. 2016). As such, the beef cattle feedlot segment is more vulnerable to fluctuations in output commodity prices (e.g., feed and where it is coming from) than water supply conditions and would be unlikely to be affected by reduced surface water conditions (Medellin-Azuara et al. 2016). The cow-calf and feeder cattle segments of the beef cattle industry may be more vulnerable. These two segments rely on pasture and other forages prior to weaning calves and before transitioning to feedlots. Under reduced surface water conditions, summer Pasture (typically irrigated) can become scarce and may limit grazing opportunities. If this is combined with poor winter grass conditions, the size of these operations could be reduced (Medellin-Azuara et al. 2016). Pasture is typically grown on land with soils, slopes or other characteristics support pasture rather than other crops (Cattlemen's Beef Board and Cattlemen's National Beef Association 2009). As such, it is likely these areas would be maintained as Pasture. In addition, these lands can provide Pasture for 4 or 5 months per year during the wet season and so the timing could offset potential effects. Further, cow-calf operations are able to substitute fodder and other food sources for irrigated pasture land, if needed (The Pennsylvania State University

2013). Finally, as discussed above, SWAP is potentially over predicting effects on Pasture and as such, not all of the lands would be reduced under LSJR Alternative 3.

Given cost of feed input compared to other dairy and beef cattle inputs and the availability of the feed input for both dairy and beef cattle, the value of dairy production in the LSJR area of potential effects, and the potential use of equitable distribution of local water suppliers, it is unlikely dairies and beef cattle operations would be converted to nonagricultural uses. Impacts would be less than significant.

LSJR Alternative 4 (Less than significant/Less than significant with adaptive implementation)

Flows greater than 1,500 cfs on the Stanislaus River would increase in frequency under LSJR Alternative 4 when compared to baseline. The overall frequency of monthly flows greater than 1,500 cfs would increase from 14 percent to 22 percent at Ripon (Table 6-14 in Chapter 6). However, as described under LSJR Alternative 2, LSJR Alternative 4 would not increase the likelihood of a 100-year flood and effects would occur to less than 1 percent of the total agricultural production in the LSJR area of potential effects. Therefore, it is reasonable to assume that a substantial reduction in agricultural production, and thus acreage, would not occur in the LSJR area of potential effects as a result of seepage when compared to baseline. Impacts would be less than significant.

Similar to the discussion above under LSJR Alternative 3, dairy and cattle operations that rely on Alfalfa, Corn, Grain, and Pasture production from SSJID, OID, MID, and TID could experience some input cost increases during water-short years. Dry forms of feed crops such as alfalfa can be imported to replace the reduction in locally grown feed crops that may occur when the regional markets for these crops exist. A review of data shows that dairy value either exceeds or is competitive with other crops in the LSJR area of potential effects (Table 11-21). As such, some crops, such as Field and Grain and even higher net value crops in the spectrum, may decrease in production if dairies obtain water supplies. Given the gross revenues of different agricultural commodities, it is likely that dairies would be competitive for water supplies (Table 11-21). Furthermore, because of the equitable distribution policies of local water suppliers described in Section 11.3, *Regulatory Background*, it is anticipated dairy operators could receive water within irrigation districts that apply reductions equally across agricultural uses. Given cost of feed input compared to other dairy and beef cattle inputs and the availability of the feed input for both dairy and beef cattle, the value of dairy production in the LSJR area of potential effects, and the potential use of equitable distribution of local water suppliers, it is unlikely dairies and beef cattle operations would be converted to nonagricultural uses. Impacts would be less than significant. Impacts would be less than significant.

SDWQ Alternatives

SDWQ Alternatives 2 and 3: (Less than significant)

As discussed under Impact AG-1 for SDWQ Alternatives 2 and 3, reductions in crop acreage in the SDWQ area of potential effects are not expected beyond what may typically occur in the area as a result of normal farming practices. Therefore, it is reasonable to assume that a conversion of farmland to nonagricultural uses would not occur in the SDWQ area of potential effects. Impacts would be less than significant.

Impact AG- 3: Conflict with existing zoning for agricultural use or a Williamson Act contract

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)*, for the No Project impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternatives 2, 3, and 4 (Less than significant/Less than significant with adaptive implementation)

Lands under Williamson Act contracts are enforceably restricted to compatible open space or agricultural uses, generally for rolling 10-year or 20-year terms, and the LSJR alternatives do not alter those restrictions. Therefore, any reduction in surface water supplies expected under LSJR Alternatives 2, 3, and 4 would not conflict with Williamson Act provisions because the existing agricultural lands can and must be maintained in compatible open space and agricultural uses, which can include non-irrigated agricultural uses. Specifically, the Williamson Act holds that a reduction in the economic character of existing agricultural land is not a sufficient reason for cancellation of a contract. There is enough annual crop acreage for rotation if the plantings of annual crops such as Corn and Grain were rotated in years with reduced irrigation supply such that all the lands would be irrigated at least once every other year or fallowed in other years. There is enough annual crop acreage for rotation if the plantings of Grain were rotated in years with reduced irrigation supply such that all lands would be irrigated at least once every other year or dryland farmed or fallowed in other years. These practices are all considered agricultural uses. There is potential for Alfalfa and Pasture to survive without receiving their full water requirements during an irrigation season (i.e., deficit irrigation), even though they are permanent-type crops (Putnam et al. 2015a, 2015b). Deficit irrigation would keep this acreage in agricultural use. While cities or counties may designate boundaries for agricultural preserves, create farmland security zones, enter into conservation easements, or enter into Williamson Act contracts, they do not have the authority to require landowners to sparticipate in such measures in the first instance. However, once a land owner has entered into a Williamson Act contract he or she must abide by the contract provisions until he or she chooses to non-renew, cancel, or otherwise withdraw. Cities and counties administering agricultural preserves may enforce existing Williamson Act contracts, but it is speculative and unknown to what extent, if any, contracts covering such lands would be subject to nonrenewal, cancellation, or enforcement. Importantly, there are serious financial disincentives to landowners for each of those outcomes: nonrenewal carries with it significant tax disadvantages; cancellation is at the option of the city or county administering the preserve and can include cancellation fees; and, enforcement can result in financial penalties. Therefore, LSJR Alternatives 2, 3, and 4 would not conflict with the existing Williamson Act, and impacts would be less than significant.

LSJR Alternatives 2, 3, and 4 would not conflict with existing zoning for agricultural use. Only cities and counties enact zone change. The LSJR alternatives would not change zoning and would not require a discretionary action that conflicts with a land zoned for agriculture. LSJR Alternatives 3 and 4 could result in reduced irrigation available to designated prime, unique, and farmland of statewide importance as described above under Impact AG-1; however, if the lands do not receive irrigation, they could be dryland farmed, rotated, deficit irrigated, or fallowed, all of which would be consistent with agricultural zoning. Therefore, a conflict would not occur as a result of LSJR Alternatives 2, 3, and 4, and agricultural land would continue to maintain existing zoning. Impacts would be less than significant.

SDWQ Alternatives

SDWQ Alternatives 2 and 3: (Less than significant)

Williamson Act contracts for lands in the SDWQ area of potential effects total 83,614. While Williamson Act lands do not need to be irrigated to be maintained within Williamson Act contracts, agricultural uses in the southern Delta currently divert surface water from existing waterways, expecting it to be of suitable water quality to irrigate existing crops. SDWQ Alternatives 2 and 3 would not conflict with existing Williamson Act contracts or zoning for agricultural use because they would not result in an action that would change existing zoning or activities consistent with agricultural zoning, and Williamson Act contracts would continue in the southern Delta. Therefore, impacts would be less than significant.

Impact AG- 4: Conflict with any applicable land use plan, policy, or regulation related to agriculture of an agency with jurisdiction over a project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)*, for the No Project impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternative 2, 3, and 4 (Less than significant/Less than significant with adaptive implementation)

Implementation of the LSJR alternatives do not involve general plan amendments to convert currently designated agricultural land to other uses. LSJR Alternatives 2, 3, or 4 would result in a change in the volume of water within existing reservoirs or rivers. This change would not conflict with applicable land use plans, policies, or regulations in the LSJR area of potential effects. LSJR Alternatives 3 or 4 could result in physical environmental effects associated with reducing surface water diversions that primarily serve agricultural lands, as described under Impact AG-1. Some agricultural land could be taken out of use as Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, given reductions in the availability of irrigation water due to reductions in surface water diversions under LSJR Alternatives 3 and 4. However, some of these lands could remain in agricultural use even if they are not irrigated, as described under Impact AG-3. Thus, the reduction in surface water diversions due to implementation of LSJR Alternatives 3 or 4 would not conflict with existing land use plans or policies that protect or preserve agricultural lands. Although LSJR Alternatives 3 and 4 could result in constraints on agricultural use and may limit it in some cases, LSJR Alternatives 2, 3, and 4 would not conflict with any land use plan or policy. Therefore, impacts would be less than significant.

SDWQ Alternatives

SDWQ Alternatives 2 and 3: (No impact)

The SDWQ alternatives do not include general plan amendments or zone changes and would not result in changes to existing land designations or zoning. Furthermore, the agricultural lands would continue to divert water from existing waterways and rely on suitable water quality to irrigate crops. Therefore, there would be no impact.

11.6 Impacts and Mitigation Measures: Extended Plan Area

Bypassing flows, as described in Chapter 5, *Surface Hydrology and Water Quality*, would not cause potentially significant impacts on agricultural resources in the extended plan area. There are limited agricultural resources in the extended plan area and no designated Prime, Unique, or Farmland of Statewide Importance (California Farmland Mapping and Monitoring Program webpage). Much of the extended plan area is designated as nonagricultural with some acreage in grazing in Mariposa County near Lake McClure (California Farmland Mapping and Monitoring Program n.d.) and individual small water rights used for irrigated pastures, orchards, and occasional vineyards. However, these are a small volume with limited or no storage volume that could be affected by bypass flow requirements (State Water Board 2016). Any reduction in surface water supplies that are available for irrigation in the extended plan area would be similar to that described for the plan area, but smaller in magnitude. Therefore, impacts would be less than significant.

11.7 Cumulative Impacts

For the cumulative impact analysis, refer to Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources.*

Chapter 12
Cultural Resources

12.1 Introduction

This chapter describes the environmental setting of cultural resources, including paleontological resources (described in Section 12.2, *Environmental Setting*) and the regulatory background associated with these resources. This chapter evaluates environmental impacts on cultural resources that could result from the Lower San Joaquin River (LSJR) alternatives and, if applicable, it also offers mitigation measures that would reduce significant impacts.

The potential of cultural resources to exist within the plan area is used to determine if flow and reservoir conditions under the LSJR alternatives, when compared to baseline, would impact cultural resources, including paleontological resources. The area of potential effects evaluated in this chapter is primarily the area of fluctuation around the three reservoirs and the channels of the three eastside tributaries[1] and the LSJR within the plan area as, described in Chapter 1, *Introduction*. A broad cultural context for potential impacts in the plan area is provided in this chapter and in Appendix I, *Cultural Resources Overview*.

The extended plan area, also described in Chapter 1, *Introduction*, generally includes the area upstream of the rim dams.[2] The area of potential effects for the extended plan area is similar to that of the plan area and includes the zone of fluctuation around the numerous reservoirs that store water on the Stanislaus and Tuolumne Rivers. (Merced does not have substantial upstream reservoirs that would be affected.) It also includes the upper reaches of the Stanislaus, Tuolumne, and Merced Rivers. Unless otherwise noted, all discussion in this chapter refers to the plan area. Where appropriate, the extended plan area is specifically identified.

In Appendix B, *State Water Board's Environmental Checklist*, the State Water Resources Control Board (State Water Board) determined whether the plan amendments[3] would cause any adverse impact on resources in each of the listed environmental categories and provided a brief explanation for its determination. Impacts in the checklist that are identified as "Potentially Significant Impacts" are discussed in the resource chapters. Appendix B identified the LSJR alternatives as having a potentially significant impact on cultural resources because the project could potentially degrade or destroy existing cultural resources within the plan area. Accordingly, this chapter evaluates the potential of the LSJR alternatives to impact cultural resources by determining whether the alternatives would: (1) cause a substantial adverse change in the significance of a historical or archaeological resource, (2) disturb any human remains, including those interred outside formal cemeteries, or (3) directly or indirectly destroy a unique paleontological resource or site or unique geologic feature.

---

[1] In this document, the term *three eastside tributaries* refers to the Stanislaus, Tuolumne, and Merced Rivers.

[2] In this document, the term *rim dams* is used when referencing the three major dams and reservoirs on each of the eastside tributaries: New Melones Dam and Reservoir on the Stanislaus River; New Don Pedro Dam and Reservoir on the Tuolumne River; and New Exchequer Dam and Lake McClure on the Merced River.

[3] These plan amendments are the *project* as defined in State CEQA Guidelines, Section 15378.

Potential cultural resource impacts were generally evaluated using changes in river flows and changes in reservoir water surface elevations that are expected to result from the implementation of each of the LSJR alternatives. For this evaluation, the potential for known and unknown significant cultural resources to exist at the three reservoirs and along the rivers was determined. Following this determination, a qualitative analysis of the effects of altering reservoir elevations or modifying flows using the results of the State Water Board's Water Supply Effects (WSE) model was performed. Results indicated that LSJR alternatives 2–4 would change the rates of flow of the three eastside tributaries and the LSJR within the plan area, the maximum and minimum surface elevations of the three reservoirs, and the timing that these fluctuations in surface water elevations occur. For the three large reservoirs, the WSE model results were summarized in two ways to characterize the effect of the LSJR alternatives on both high and low reservoir elevations in order to assess changes in reservoir elevation that may: (1) increase inundation of cultural resources that are typically out of the water, or (2) increase exposure of cultural resources that are typically below the water surface. These two assessments also capture the change in the range of reservoir elevations. For the three eastside tributaries and the LSJR, the modeled changes in flow are the primary mechanism for impacts on cultural resources. The comparison of monthly cumulative distributions of flows, in conjunction with the individual monthly average changes in flow, provides an appropriate measure of hydrologic changes resulting from the LSJR alternatives.

A summary of the potential impacts of the LSJR alternatives on cultural resources is provided in Table 12-1. As described in Chapter 3, *Alternatives Description*, LSJR Alternatives 2, 3 and 4 each include four methods of adaptive implementation. This recirculated substitute environmental document (SED) provides an analysis with and without adaptive implementation because the frequency, duration, and extent to which each adaptive implementation method would be used, if at all, within a year or between years under each LSJR alternative is unknown. The analysis, therefore, discloses the full range of impacts that could occur under an LSJR alternative, from no adaptive implementation to full adaptive implementation. As such, Table 12-1 includes impact determinations with and without adaptive implementation.

Any change in salinity in the southern Delta as a result of southern Delta water quality (SDWQ) Alternatives 2 or 3 is expected to be similar to that of the historic range of salinity because Vernalis water quality would be maintained under the SDWQ alternatives through the program of implementation. Since the chemical properties of the baseline water quality conditions would not change, there would be no potential to substantially adversely impact significant cultural resources. Therefore, the SDWQ alternatives are not discussed in this chapter. To comply with specific water quality objectives or the program of implementation under SDWQ Alternatives 2 or 3, construction and operation of different facilities in the southern Delta could occur, which could involve impacts on cultural resources. These impacts are evaluated in Chapter 16, *Evaluation of Other Indirect and Additional Actions.*

Impacts related to the No Project Alternative (LSJR/SDWQ Alternative 1) are presented in Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* and the supporting technical analysis is presented in Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1).* Chapter 16, *Evaluation of Other Indirect and Additional Actions,* includes discussion of impacts related to actions and methods of compliance.

Table 12-1. Summary of Cultural Resource Impact Determinations

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
Impact CUL-1 Cause a substantial adverse change in the significance of a historical or archaeological resource			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note.[b]	Significant	NA
LSJR Alternatives 2, 3, and 4	The expected changes in reservoir elevations are within historical fluctuations, and known or unknown significant cultural resources are expected to continue to be inundated or exposed as usual under current operations. Additionally, historic property management plans at the reservoirs would continue to be implemented Changes in river flows are not expected to alter the low potential for significant cultural resources to remain along rivers due to previous natural and anthropogenic disturbances.	Less than significant	Less than significant
Impact CUL-2 Disturb any human remains, including those interred outside formal cemeteries			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note. [b]	Less than significant	NA
LSJR Alternatives 2, 3, and 4	The expected changes in reservoir elevations are within historical fluctuations and are not expected to affect human remains due to low potential for human remains to exist within the fluctuation zone of the reservoirs. Additionally, historic property management plans at the reservoirs would continue to be implemented Additionally, any human remains would be treated in accordance with existing state and federal regulations. Changes in river flows are not expected to alter the low potential for undocumented human remains to exist along rivers due to previous natural and anthropogenic disturbances.	Less than significant	Less than significant
Impact CUL-3 Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note.[b]	Significant	NA
LSJR Alternatives 2, 3, and 4	The expected changes in reservoir elevations are within historical fluctuations, and unique paleontological or geologic resources, specifically caves, would continue to be inundated and exposed as usual under current	Less than significant	Less than significant

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
	operations. Additionally, the documented caves are managed and protected under a cave management plan. Changes in river flows are not expected to alter the low potential for paleontological resources to exist along rivers due to depth of occurrence of rock units with high paleontological potential.		

[a] Four adaptive implementation methods could occur under the LSJR alternatives, as described in Chapter 3, *Alternatives Description*, and summarized in Section 12.4.2, *Methods and Approach*, of this chapter.

[b] The No Project Alternative (LSJR/SDWQ Alternative 1) would result in the continued implementation of flow objectives and salinity objectives established in the 2006 *Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary* (2006 Bay-Delta Plan). See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

12.2 Environmental Setting

The environmental setting for cultural resources in the plan area is described below according to cultural resources that are historic or archaeological (including sites with human remains), and paleontological in origin. The geographic scope of the plan area potentially affected by cultural resources impacts is defined by the cultural setting and ethnographic territory of the prehistoric, ethnohistoric, and historic peoples who have occupied the northern San Joaquin Valley and adjacent Sierra Nevada foothills region of inland California, as well as by accessible, near-surface areas in this region exhibiting a high paleontological potential (e.g., Calaveras Formation caves). The LSJR alternatives would apply to the LSJR up to its confluence with the Merced River and to the lower portions of the three eastside tributaries to the LSJR (Stanislaus, Tuolumne, and Merced Rivers) upstream to, and including, the reservoirs (New Melones Reservoir, New Don Pedro Reservoir, and Lake McClure), impounded by the three rim dams (New Melones, New Don Pedro, and New Exchequer Dams).

Cultural resources include archaeological sites of prehistoric or historic origin, built or architectural resources older than 50 years (e.g., historical resources), traditional or ethnographic resources, and paleontological resources (e.g., fossil deposits of paleontological importance). A prehistoric or historic archaeological site, district, built environment resource, or traditional cultural resource that is recognized as historically or culturally significant may be determined to be a *historical resource* as defined by state law. (California Public Resources Code [Pub. Resources Code], § 21084.1; California Code of Regulations [Cal. Code Regs.], tit. 14, § 15064.5, subd. (a).)

Archaeological resources include both prehistoric and historic remains of human activity. Built environment resources include an array of historic resources such as buildings, structures, and objects serving as a physical connection to California’s past. Traditional or ethnographic cultural resources may include Native American sacred sites (traditional cultural properties), traditional cultural places, and traditional resources of any ethnic community that are important for maintaining the cultural traditions of any group.

Prehistoric site locations are often predicted using environmental variables, particularly the availability of water and food, because site occupation and exploitation of natural resources were primarily based on subsistence essentials. For historic-era sites, historical settlement in this region was influenced primarily by the growth of mining in the foothills, agriculture in the valley, and the development of a transportation network of rivers, roads, and railroads connecting the valley and foothills. Many archaeological sites in the region, particularly along the river drainages, have been destroyed by mining practices and developments in agriculture and irrigation, or previously have been affected by the construction of dams and reservoirs or other development. Although remnants of sites have been discovered within the region, many have been highly disturbed.

Paleontological resources, including mineralized, partially mineralized, or unmineralized bones and teeth, soft tissues, shells, wood, leaf impressions, footprints, burrows, and microscopic remains, are more than 5,000 years old and occur mainly in Pleistocene or older sedimentary rock units.

The following sections describe the environmental setting for cultural resources in the reservoirs, and rivers in the plan area: Section 12.2.1, *Reservoir Historic or Archaeological and Paleontological Resources,* describes the environmental setting for New Melones, New Don Pedro, and Lake McClure; and Section 12.2.2, *River Historic or Archaeological and Paleontological Resources*, describes the environmental setting for the three eastside tributaries and the LSJR. For additional information see Appendix I, *Cultural Resources Overview,* provides an overview of the prehistoric, historic, and paleontological setting of the northern portion of the San Joaquin Valley and the adjacent foothills.

12.2.1 Reservoir Historic or Archaeological and Paleontological Resources

New Melones Reservoir

Prehistoric and Historic Resources

The U.S. Army Corps of Engineers (USACE) began construction of the New Melones Dam and reservoir, spillway, and powerhouse on the Stanislaus River in 1966 and completed it in 1979. Management of the project was transferred to U.S. Bureau of Reclamation (USBR) in 1979, and the reservoir is now part of the Central Valley Project (CVP). Archaeological survey, excavation, and analysis were conducted for the project between 1968 and 1981, documenting nearly 700 prehistoric and historic-era sites (Moratto 1984:312). The New Melones Archaeological District, comprised of more than 500 archaeological sites, bedrock mortars, and historic-era homestead sites, is eligible for National Register of Historic Places (NRHP) inclusion (USBR 2010:5.90–5.91).
In addition to prehistoric habitation, rock art, and resource processing sites, mortuary chambers used between circa 1000 B.C. and A.D. 700 were identified in numerous caves in the plan area (Moratto 2002:40). The reservoir inundated the Gold Rush era mining towns of Bostwick Bar, Pine Log, and Robinson’s Ferry (later renamed Melones, and now State Historical Landmark #276) (USBR 2007:3.14). Completed in 1988, the 10-volume cultural report on the New Melones project presented the evidence for a local archaeological sequence, with occupation of the area beginning as early as 10,000 years ago (USBR 2010:5.84).

A study completed in 2008 for the *New Melones Lake Area Resource Management Plan and Environmental Impact Statement* (RMP/EIS) identified 643 prehistoric, ethnohistoric, and historic-era cultural resources within the New Melones Lake Area, which includes a total of

23,265 acres administered by USBR and the U.S. Bureau of Land Management (BLM) (USBR 2010:5.82). Prehistoric site types, some of which include lithic scatters, human remains, house depressions and/or shell scatters, bedrock mortar, midden, cave, and rock art. Historic site types are mining, homestead/ranching, water/power systems, transportation, cemetery, and historic feature.

Of the archaeological sites identified within the New Melones Lake Area, 122 sites are located in the permanent pool zone lower than 808 feet (ft) above mean sea level (MSL), 33 sites in the permanent pool/fluctuation pool zone 808–1,088 ft above MSL, 232 sites in the fluctuating pool zone, 24 sites in the fluctuating pool zone/above-pool area, 203 sites above the flood pool zone, and 5 sites that include portions in all zones (USBR 2007:3.1-3.3, Table R-9). The elevation of the remaining sites is uncertain. Of the archaeological resources located in the permanent pool zone, 66 sites are prehistoric and 75 sites are historic sites or features (USBR 2007:3.11–3.12, 3.14–3.15). Ninety-six prehistoric and 226 historic sites or features are located entirely or partially within the fluctuating pool zone; these have been subject to wave action, as well as erosion from cyclical inundation and exposure, and are considered by USBR to be most susceptible to damage from lakeside recreational use and vandalism. Known cultural resources above the flood zone include 69 prehistoric and 147 historic sites or features.

No historic-era built environment resources are referenced in the New Melones Lake Area Final RMP/EIS (USBR 2010:5.82–5.83).

Of the 6,735 total acres of the New Melones Lake Area that has not yet been surveyed for the presence or absence of cultural resources, 2,063 acres are below the maximum pool zone (USBR 2010:5.82–5.83, Table 5-14). The potential for a surface survey to yield newly identified cultural resources varies from low to very high depending on the management area and the density of previously recorded resources within each area. In management areas (USBR 2010: Figure 2-2) that have been completely inventoried (Bowie Flat, Dam and Spillway, Mark Twain) or in those under the maximum pool zone (Middle Bay, North Bay, and South Bay), the discovery of previously unidentified cultural resources is considered unlikely. The potential for surface discovery in nine management areas located under or partially under reservoir waters is considered low to moderate in one (Greenhorn Creek), moderate in two (Bear Creek, Carson), moderate to high in two (Camp Nine, French Flat), high in two (Coyote Creek, Westside), and very high in two (Parrotts Ferry, Stanislaus River Canyon). Four of the designated management areas are outside the reservoir boundary (Bowie Flat, Dam and Spillway, Peoria Wildlife Area, Tuttletown).

No TCPs or sacred lands have been identified as of February, 2010 within the New Melones Lake Area (USBR 2010:5.91). If identified after this date, TCPs are subject to the same impacts as archaeological sites.

All documented or currently undocumented historic properties[4] at New Melones Lake Area would be protected and managed by the *Resource Protection Plan* administered by the USBR at the New Melones Lake Area (USBR 2010:1.5, 5.81) (Section 12.3.1*, Federal [Regulatory Background]*).

---

[4] *Historic property* is a term with defined statutory meaning at 36 CFR Section 800.16, subd. (l)(1), and refers to any cultural resource (i.e., prehistoric or historic district, site, building, structure, or object) included in, or eligible for inclusion in, the NRHP. The term includes properties of traditional religious or cultural importance to an Indian tribe that meet the NRHP criteria listed at 36 CFR Section 60.4.

Paleontological Resources

Geologic formations around the reservoir are pre-Tertiary metamorphic or igneous rocks with low paleontological potential; however, there are Calaveras Formation deposits in proximity to New Melones Reservoir (USBR 2010:5.5-5.8). Caves formed in the Calaveras Formation limestone deposits are unique geologic features, and the formation is also considered to have high paleontological potential because fossilized vertebrate remains have been recovered from its caves (UCMP 2012). Paleontological specimens have been discovered in the New Melones region inside the limestone caves. The caves are managed and protected in accordance with the directives of the *New Melones Lake Revised Cave Management Plan* administered by USBR (Section 12.3.1*, Federal [Regulatory Background]*).

Fossilized remains of Rancholabrean (younger Pleistocene and Holocene fauna) vertebrates recovered from more than a dozen Calaveras Formation caves include ground sloth, horse, deer, rabbit, squirrel, and mole, among others (UCMP 2012). In 1978, before the reservoir was filled, the BLM identified 87 caves within the New Melones Lake Area (USBR 2010:5.10–5.12). The specific location of caves ranked by the BLM as paleontologically significant is confidential, so the following discussion references all 87 caves. Of these, 30 of the 44 caves within the Stanislaus River Canyon are inundated or subject to inundation by the impounded waters. Of the 19 caves in the Coyote Creek Canyon, all but Lower Natural Bridges Cave are above the New Melones Dam spillway elevation of 1,088 ft above MSL. Coyote Creek flows through two caves, Upper and Lower Natural Bridges. In the Skunk Gulch and Grapevine Gulch areas, all 24 caves identified there are above spillway elevation. Five of the caves, including Upper and Lower Natural Bridges, are protected under the Federal Caves Protection Act of 1988. Of these, Lower Natural Bridges (Cave 85) and two others (Caves 25 and 54) are below the 1,088-foot MSL spillway level of New Melones Dam.

New Don Pedro Reservoir

The New Don Pedro Dam and reservoir on the Tuolumne River were completed in 1971. Archaeological investigations were conducted in the late 1960s but were fairly limited and not initiated before many of the archaeological sites already had been inundated or damaged (TID and MID 2011a:5.246). During 1970 and 1971, salvage archaeology in the reservoir basin recorded the remnants of 41 prehistoric sites (Moratto 1984:311). A July 2010 records search identified 61 prehistoric and historic archaeological sites within the boundary for the Federal Energy Regulatory Commission (FERC) New Don Pedro relicensing application (FERC Project No. 2299) (TID and MID 2011a: 5.255, 5.260–5.263). These include 32 prehistoric, 21 historic, and 2 multi-component sites; 6 sites with missing records are of unknown type. Prehistoric site types found at New Don Pedro Reservoir are bedrock mortar, kiln, lithic scatter, midden, and village; a few of these include human remains, shell scatters, house pits, or evidence for cave dwelling. Historic site types found at New Don Pedro Reservoir are foundations, rock walls, mining features, a gravestone, water conveyance systems, rock dam, roadbeds, debris scatters, and the former location of a mining town called Jacksonville. Of the 61 resources that are currently documented, four prehistoric sites have been determined eligible for inclusion in the NRHP and two prehistoric bedrock milling stations, as well as the former location of Jacksonville, which is now a State Historical Landmark (#419), are under the waters of New Don Pedro Reservoir (TID and MID 2011a:5.260–5.263, 2011b:4-5). An inventory and evaluation for NRHP eligibility of historic-era built environment resources is also in progress for the Don Pedro FERC relicensing application (TID and MID 2011b:8). A review of historic maps identified more than 50 locations where unrecorded historic-era sites or features may be present, such as roads, trails, buildings, mines, ditches, and the Hetch Hetchy railroad and aqueduct.

No TCPs or sacred lands have been identified as of November 2011 within the FERC relicensing boundary (TID and MID 2011c:3.5). A TCP study and consultation with local Native American groups or tribes is in the New Don Pedro FERC relicensing application. If identified, TCPs are subject to the same impacts as archaeological sites.

Geologic formations around the reservoir are pre-Tertiary metamorphic or igneous rocks (TID and MID 2011a:5.3) with low paleontological potential. No paleontological resources have been reported at New Don Pedro Reservoir (TID and MID 2011a).

All documented or undocumented cultural resources at New Don Pedro Reservoir would be protected and managed under a Historic Properties Management Plan (HPMP) (Section 12.3.3, *Regional or Local [Regulatory Background]*).

Lake McClure

Construction of the New Exchequer Dam and Lake McClure Reservoir on the Merced River was completed in 1967, prior to the 1972 enactment of the California Environmental Quality Act (CEQA). No cultural resources investigations were conducted in the plan area prior to 1977 (Merced Irrigation District [Merced ID] 2008: 7.12/4-5). Cultural resources surveys of approximately 6,200 acres were conducted for the Merced River Hydroelectric Project (FERC Project No. 2179) July 2008–July 2010 when lands usually inundated by Lake McClure were exposed and accessible due to lower than normal water levels (Merced ID 2012a: Exhibit E, 411-415). Merced ID has identified a total of 203 archaeological sites: 38 prehistoric, 149 historic-era, and 16 with prehistoric and historic-era components (Merced ID 2012b:27). Prehistoric site types that were identified include base and temporary camps, sparse lithic scatter, and milling station; site constituents at the camps include bedrock mortars, rock art, midden, and/or artifact scatters (Merced ID 2012b:28). Historic site types found include mining and mining related, road and trail, railroad element, farming and ranching habitation, industrial foundation, rock walls, water control element, refuse deposit, land survey marker, hydroelectric element, transmission line, and Bagby townsite (Merced ID 2012b:31). Multi-component sites include constituents of both prehistoric and historic period use (e.g., bedrock mortars and lithic scatters with cabin foundations, rock walls, or prospect pits) (Merced ID 2012b:30-31). No evidence of burials was observed at the location of a possible cemetery noted on a U.S. Geological Survey (USGS) quadrangle map, and no human remains were found during the survey (Merced ID 2012b:27, 48).

The 203 documented archaeological sites remain unevaluated for potential listing on the NRHP; all prior eligibility assessments are now considered premature (Merced ID 2012a: Exhibit E, 413–414).[5] Of the 203 sites, more than 45 prehistoric and historic-era sites are at or below the high water level (Merced ID 2011: Exhibit E, 334–335). Siltation was noted at 16 of the 45 sites and was considered a positive effect because it provides site protection. Among the Gold Rush-era mining communities now under the waters of Lake McClure are the town of Benton Mills (later renamed Bagby), the Exchequer mining camp, and the Horseshoe Bend camp (Merced ID 2008: 7.12/12).

---

[5] It is anticipated that concurrence by the State Historic Preservation Officer (SHPO) on NRHP recommendations will be received by the end of 2012.

The archaeological site on the north and south banks of the Merced River comprising the townsite of Bagby/Benton Mills includes artifacts and 31 features (e.g., foundations, structure pads, pits, cisterns, retaining walls) (Merced ID 2012b:30–32). Although normally submerged, portions of the townsite were exposed during low water levels in 2009 (Merced ID 2010b:48). Remnants of Yosemite Valley Railroad elements were exposed during the low water levels in 2008 (Merced ID 2010b:34–38). During the survey within the two drought years (2008–2010), portions of a prehistoric base camp were also noted to extend underwater into the Merced River (Merced ID 2010b:28).

In 2011, Merced ID completed its study of the built environment for the Merced River Hydroelectric Project (FERC Project No. 2179) and determined the New Exchequer and McSwain Dams, powerhouses, and other project features, most of which were constructed in the late 1960s, are not currently eligible for inclusion on the NRHP but will be reevaluated once individual facilities become 50 years old (Merced ID 2012a: Exhibit E, 412–414). Seventeen buildings and structures more than 50 years old, including the original Exchequer Dam and a gauging station, were determined not eligible for NRHP listing. The original Exchequer Dam is normally submerged but was exposed in 2008 during the low water levels (below 720-ft elevation) (Merced ID 2010b:38).

No TCPs or sacred lands have been identified prior to submission of the final license application for the Merced River Hydroelectric Project in February 2012 (Merced ID 2012a: Exhibit E, 412). Ethnographic interviews with the Southern Sierra Miwok Nation (also known as the American Indian Council of Mariposa County, Inc.) may be conducted during the term of the new license and may identify potential TCPs. If identified, TCPs are subject to the same impacts as archaeological sites.

Geologic formations around the reservoir are pre-Tertiary metamorphic or igneous rocks (Merced ID 2012a, b: E3.47, Figure 3.3.1-1) with low paleontological potential. No paleontological resources have been reported within the boundaries of the Merced River Hydroelectric Project (FERC Project No. 2179) (Merced ID 2008, 2012b).

All documented or undocumented cultural resources at Lake McClure would be protected and managed under an HPMP (Section 12.3.3*, Regional or Local [Regulatory Background]*).

12.2.2 River Historic or Archaeological and Paleontological Resources

The potential presence or absence of cultural resources along the LSJR and the Merced, Tuolumne, and Stanislaus Rivers below the major rim dams and reservoirs has been presented in numerous documents. It was most recently summarized in the environmental impact statement/ environmental impact report (EIS/EIR) prepared to meet the flow objectives for the San Joaquin River Agreement (SJRA) (EA Engineering 1999). Due to the extensive reach of the LSJR and its three eastside tributaries, the summary of prehistoric and historic resources was presented in two tables tabulated by the total number of sites recorded in each county (EA Engineering 1999: Tables 3.7-2 and 3.7-3). Because little change is likely in the number of recorded cultural resources between the time that document was prepared and now, the same information is presented in Table 12-2 and Table 12-3 for the six counties traversed by the LSJR and the Stanislaus, Tuolumne, and Merced Rivers. Following Table 12-2 and Table 12-3 is a discussion of anthropogenic practices that have disturbed or destroyed archaeological sites during the historic period.

Geologic formations along the LSJR and the Stanislaus, Tuolumne, and Merced Rivers downstream of the rim dams include eight Pleistocene or older sedimentary rock units that have a high paleontological potential and are mapped at the surface or beneath Holocene-age alluvium. As detailed below, these units are the Ione, Laguna, Mehrten, Modesto, Moreno, Riverbank, Turlock Lake, and Valley Springs Formations, each of which has yielded the fossilized remains of plants, invertebrates, or vertebrates.

Prehistoric Resources

A summary of prehistoric resources by county is provided in Table 12-2. Together, these counties have more than 2,600 recorded prehistoric sites and range from 2 to 15 percent surveyed for cultural resources. Although people were present in the northern San Joaquin Valley and Sierra Nevada foothills as early as 12,000 years ago (Rondeau et al. 2007:65; Rosenthal et al. 2007:151), the majority of prehistoric sites documented in this region are less than 500 years old (EA Engineering 1999:3.106–3.109). Prehistoric sites recorded in the region include villages, seasonal occupation areas, burials, bedrock mortars, and lithic scatters, among other site types.

Table 12-2. Documented Prehistoric Sites by County

County	Total Number of Recorded Sites	Number of Prehistoric Sites	Percentage of County Land Surveyed	Areas with High Density of Sites	Overall Amount of Significant Disturbance in the County
Calaveras	1,527	929	10–15	Stanislaus, N. Fork Stanislaus, and Mokelumne Rivers; creeks, ridge flats	Low
Mariposa	1,264	856	5	Merced River; along creeks; in Yosemite National Park	Low
Merced	341	316	2	Unknown	Low
San Joaquin	249	189	5	San Joaquin and Mokelumne Rivers	Low to moderate
Stanislaus	350	280	3	Stanislaus, Tuolumne, and San Joaquin Rivers; along smaller creeks	Low
Tuolumne	3,540	Unknown	10	Stanislaus and Tuolumne Rivers; along creeks, ridge flats	Low
Totals	7,271	>2,570			

Source: EA Engineering 1999: Table 3.7-2.

Table 12-3. Documented Historic Resources by County in the Northern San Joaquin Valley

County	Number of Historic Sites[a]	Number of Properties in the NRHP	Number of California Historical Landmarks	Number of Evaluated Sites in California Historical Resources Inventory	Number of California Points of Historical Interest
Calaveras	598	13	42	56	4
Mariposa	408	29	8	15	0
Merced	25	12	5	13	7
San Joaquin	60	31	23	28	8
Stanislaus	70	17	5	12	7
Tuolumne	Unknown	19	20	79	4
Totals	>1,161	121	103	203	30

Source: EA Engineering 1999: Tables 3.7-2 and 3.7-3.
NRHP = National Register of Historic Places
[a] Calculated by subtracting the number of prehistoric sites from the recorded sites total provided in Table 12-2.

The areas in the six counties with the highest density of documented prehistoric sites are along the rivers (Table 12-2). The natural channels and meanders of these rivers have changed during the historic period by agriculture, irrigation, and mining practices, eliminating much of the natural floodplains and terraces, creating large in-channel and off-channel pits, and resulting in relatively static channels with narrow floodways confined by dikes or levees and agricultural fields. Other activities, such as hydraulic mining practiced in the New Melones Lake Area, have also disturbed much of the river areas (USBR 2010:5–9). Historical dredge tailings remain visible, flanking the Merced River between Lake McSwain and the community of Hopeton, and locally along parts of the Tuolumne River between the community of La Grange and the city of Waterford, indicating past areas of substantial disturbance (Merced ID 2010a:2.5–2.6; TID and MID 2011a:5.8). Large-scale aggregate mining along the Lower Merced and Tuolumne Rivers began in the early 1900s, and gold mining continued on the Lower Tuolumne River near Waterford into the mid-1900s, which also disturbed large areas of the rivers (Merced ID 2008:7.1/3–7.1/4; TID and MID 2011a:5.8).

The prehistoric site data reflect the preference of indigenous Californians for occupation along major watercourses, as well as the location of cultural resource management projects during the last three to four decades. Although a high number of prehistoric archaeological sites have been recorded along the rivers, sites have been destroyed by agriculture and irrigation practices, mining activities, or development. Furthermore, although Table 12-2 indicates the overall amount of significant disturbance in the six counties is relatively low, many of the known sites along the rivers have been highly disturbed by these types of activities (EA Engineering 1999:3.106).

Historic Resources

A summary by county of historic-era resources listed in the NRHP and the California Historical Resources Inventory is provided in Table 12-3. Together, these six counties have more than 1,000 recorded historic sites, of which more than 200 have been evaluated for listing in the NRHP, California Register of Historical Resources (CRHR), or local registers. The counties also include a number of historic properties listed in the NRHP, as well as California Historical Landmarks and Points of Historical Interest.

The historic period in the northern San Joaquin Valley is characterized by agricultural settlement, while mining activities influenced the east side of the valley and the Sierra Nevada foothills. The availability of water, as well as soil and landform type, was an important factor in early agricultural settlement and the interrelated locations of settlements and towns (Caltrans 2006:16–17, 34–35; Caltrans 2007:31–35).

Many of the documented historic-era resources in the six counties shown in Table 12-3 represent early settlement along the rivers during the Gold Rush era. Historic-era resources recorded along the rivers include buildings, structures or features of farming and ranching homesteads and rural communities, cemeteries, ferry landings, bridges, boat ramps and anchors, irrigation ditches or canals, early trails and roadways, rock walls, and assorted historic features and debris. In the Sierra Nevada foothills, resources related to the establishment and growth of mining, most of which are located along the rivers and smaller waterways, are represented by the buildings or remnants of camps and towns, refuse deposits, ditches, earthen dams, flumes, prospect pits, rock walls, and remains of stamp mills and other mining structures. Recorded resources also include transportation features, such as abandoned railroad grades, bridges, and roadways that connected the mines, ferry crossings, and settlements in the foothills to the San Joaquin Valley.

The natural channels and meanders of the LSJR and the Lower Stanislaus, Tuolumne, and Merced Rivers have been extremely modified by anthropogenic processes during the historic period, particularly by agriculture, irrigation, and mining practices, as discussed above. Although a high number of historic period archaeological sites or built resources have been recorded along the rivers, many have been highly disturbed or destroyed. Due to these disruptive practices and considering the young age of the alluvial landforms, the potential for buried historic-era archaeological sites along the four rivers is considered low (Rosenthal and Meyer 2004:106–107, Table 18).

In addition to agriculture, irrigation practices, and aggregate mining, commercial and residential development continues to affect riverside cultural resources. For example, the riverside town of Burneyville, dating from the 1870s, has been absorbed by the expanding City of Riverbank on the Stanislaus River (Hoover et al. 2002:521). The City of Modesto, initially established in 1870 as a railroad town, prospered in the early 1900s following the establishment of the Modesto Irrigation District (MID) and modern irrigation practices, and has now absorbed lands along both sides of the Tuolumne River, an area sensitive for the presence of historic-era sites related to ranching, agriculture, and early transportation practices (ICF Jones & Stokes 2008:V/8.3–5). Similarly, the City of Livingston’s proposal to expand its sphere of influence within the agricultural lands along the southern side of the Merced River could affect historic-era resources (PMC 2008:1.0/5–6, Figure 2-1).

Paleontological Resources

The Holocene riverine floodplain deposits along the LSJR and the lower portions of the three eastside tributaries are surrounded mainly by a mixture of continental rocks and deposits that include younger Holocene and older Pleistocene alluvium, three Pleistocene formations (Modesto, Riverbank, and Turlock Lake), and the Pliocene Laguna Formation (Page 1986: Plate 2). There is a large area with Holocene-age sand dunes mapped on the stretch of the Merced River between the communities of Irwin and Cressey. A few small sand dune patches are also mapped on the Stanislaus River west of the city of Riverbank. The sand dunes vary in thickness, reaching up to approximately 140 ft (Page 1986:19). At the confluence of the three eastside tributaries with the LSJR are Holocene flood basin deposits, some of which may be Pleistocene Modesto Formation (Page 1986:18–19). The thickness of the flood basin deposits in the San Joaquin Valley is estimated to be as much as 100 ft. The geologic formations (e.g., Miocene and Pliocene-age Mehrten Formation deposits) in the area have a high paleontological potential and have produced fossils as described in Table 12-4.

As discussed previously, the natural channels and meanders of the LSJR and the Merced, Tuolumne, and Stanislaus Rivers have been extremely modified by anthropogenic processes, particularly agriculture, irrigation, and mining practices. The natural floodplains and terraces have been mostly eliminated and the rivers confined by dikes, levees, and agricultural fields to relatively static channels with narrow floodways. During the historic era, native soils and sediments along the waterways draining westward from the foothills were displaced or buried by hydraulic mining and dredging, two particularly destructive mining methods that have been followed by modern large-scale aggregate mining (USBR 2010:5–9; Merced ID 2008:7.1/3–7.1/4; Merced ID 2010a:2.5–2.6; TID and MID 2011a:5.8). Although a number of fossil localities have been recorded along the rivers in the northern San Joaquin Valley, these are typically identified at depths below surficial Holocene-age deposits, including those native sediments rearranged by the anthropogenic practices that have recontoured and continue to recontour the riverine landscapes.

Table 12-4. Summary of Formations with High Paleontological Potential along the LSJR and Three Eastside Tributaries

Formation	Characteristics	Documented Fossil Presence
Ione	This middle Eocene rock unit extends more than 200 miles along the western edge of the Sierra Nevada (Creely and Force 2007:10). The marine sandstone and kaolinitic clay deposits have produced few marine body fossils, but trace burrows are abundant in many places.	Plant fossils have been recovered from deposits in Calaveras County near Comanche Reservoir, and invertebrate fossils in Mariposa, Stanislaus and Tuolumne Counties (UCMP 2012). Near the alternatives, the Ione Formation contains fossils of an Eocene fossil index bivalve at the Planicosta Buttes just south of the bridge at Merced Falls (Arkley 1962:5).
Laguna	This Pliocene rock unit consists of moderately consolidated, interbedded, arkosic alluvial gravel, sand, and silt (Helley and Harwood 1985:17). The gravel beds are predominantly comprised of quartz and metamorphic rock fragments.	Land vertebrate fossils have been found in fine-grained deposits of the Laguna Formation, mainly along the Sierra Nevada foothills.
Mehrten	This rock unit is composed of a sequence of dark sandstone, conglomerate, and claystone beds of late Miocene and Pliocene age (Arkley 1962:6-7) that unconformably overlie the Valley Springs Formation and consist of fluvial material reworked from volcanic deposits. In the Modesto area, the Mehrten attains a maximum thickness of about 1,200 feet where it lies at a depth of about 1,100 feet (Page 1986:11).	Microfossils and fossilized plant specimens have been identified in the Mehrten in Tuolumne County. Vertebrate fossils, including horse, pronghorn, and peccary, have been found at Goodwin Dam in Calaveras County, near Columbia and Two Mile Bar in Tuolumne County, and at Oakdale and Turlock Lake State Recreation Area in Stanislaus County (UCMP 2012).
Modesto	This Pleistocene rock unit was deposited by rivers still existing today and forms alluvial terraces and fans of major rivers along the axis of the Central Valley, including the San Joaquin and Sacramento Rivers, and is widely distributed along the rivers in the Sacramento and San Joaquin Valleys (Helley and Harwood 1985:10). The upper and lower members are dated 9,000–73,000 years ago.	The type section for this unit is along the south bluff of the Tuolumne River south of Modesto. Vertebrate fossils have been recovered from sediments in Merced, San Joaquin and Stanislaus Counties, and from nearly every major community in the San Joaquin Valley, including Fresno, Lathrop, Lodi, Manteca, Merced, Modesto, Stockton, and Tracy (UCMP 2012).
Moreno	Late Cretaceous in age, the Moreno Formation is the most important fossil locality of Cretaceous-aged marine vertebrates in the western United States.	Fossilized bony fish and plesiosaur and mosasaur remains have been found in Merced County near Laguna Seca and Rattlesnake Creeks (UCMP 2012). Moreno Formation deposits in Merced and Stanislaus Counties have produced invertebrate fossils. Microfossils have been found in Merced and San Joaquin Counties. Fossilized plant remains have been identified near Del Puerto and Little Salado Creeks in Stanislaus County.

Formation	Characteristics	Documented Fossil Presence
Riverbank	Formed during the Pleistocene age, 2.6 million to 11,700 years ago, this formation forms arkosic alluvial terraces and fans consisting of weathered, reddish gravel, sand and silt with some mafic igneous rock fragments. In the San Joaquin Valley, the Riverbank is broken into informal upper and middle members (Helley and Harwood 1985:11).	Fossils have mainly been recovered from fine-grained deposits, typically at a depth of 12 feet or more below the surface. Vertebrate fossils have been identified at various locations in Merced, San Joaquin, and Stanislaus Counties.
Turlock Lake	The alluvial sediments of this Pleistocene rock unit originated from the Sierra Nevada, and the formation is more widespread in the San Joaquin Valley than the Sacramento Valley (Helley and Harwood 1985:11-12). The age of the lower and upper members is estimated to at least 730,000 years and 600,000 years ago, respectively.	A series of exposures in Turlock Lake State Recreation Area in Stanislaus County are the type site for this formation. The most well-known locality is the Fairmead Landfill near Chowchilla in Madera County that has produced more than 3,000 fossil specimens from 35 different species (Dundas et al. 1996).
Valley Springs	This formation is generally considered to be late Miocene age (Arkley 1962:5; Page 1986:10). It consists of a fluvial sequence of rhyolitic ash, sandy clay, and siliceous gravel, and in most areas lies unconformably over the Ione Formation.	Fossilized plant specimens have been found near the community of Burson in Calaveras County (UCMP 2012).

12.2.3 Extended Plan Area

In general, the rocks along the rivers or reservoirs in the extended plan area are pre-Tertiary metamorphic or igneous rocks with a low potential for paleontological resources. Additionally, Calaveras Formation limestone does not occur in the vicinity of the extended plan area reservoirs on the Stanislaus and Tuolumne Rivers so no cave-associated paleontological resources are expected at those locations. Reservoirs in the extended plan area were created in the location of former lakes or along the rivers (Carpenter and Kirn 1988); both of these site types have extensive historical or archaeological use. Consequently, historical and archaeological sites may be associated with them (Carpenter and Kirn 1988; Anderson and Moratto 1996). Some of the historical sites are related to dam construction or to the dams themselves (Carpenter and Kirn 1988). Most of these sites are inundated by their associated reservoirs (Carpenter and Kirn 1988). Tuolumne and Mariposa counties are in the heart of California's historic "Mother Lode," and contain many historically significant Gold Rush era towns, and both historic and prehistoric heritage sites (USFS n.d.).

12.2.4 Southern Delta Historic or Archaeological, and Paleontological Resources

The setting and summary of cultural and paleontological resources for the southern Delta are not presented in this section because the water quality of the southern Delta is expected to remain within historical conditions under SDWQ Alternatives 2 or 3 (refer to Section 12.4.2, *Methods and Approach [SDWQ Alternatives]* for details).

12.3 Regulatory Background

12.3.1 Federal

Relevant federal programs, policies, plans, or regulations related to cultural resources are described below.

National Historic Preservation Act of 1966

The National Historic Preservation Act of 1966 (NHPA) (54 United States Code [U.S.C.], § 300101 et seq.), as amended, is the primary federal law governing the preservation of cultural and historic resources in the United States. The NHPA establishes the federal government policy on historic preservation and the programs through which this policy is implemented. The NHPA requires federal agencies to take into account the effects of their undertakings on any historic property.

Archeological Resources Protection Act of 1979

The Archeological Resources Protection Act of 1979 (ARPA) (16 U.S.C., § 470aa) was enacted to protect archeological resources and site that are located on public lands and Indian lands. The ARPA governs the excavation and removal of archaeological resources and provides for enforcement to protect such sites.

American Indian Religious Freedom Act of 1978

The American Indian Religious Freedom Act (AIRFA) of 1978 (42 U.S.C., § 1996) established federal policy to protect and preserve rights involving traditional religions of Native Americans, including access to sacred sites.

Native American Graves Protection and Repatriation Act of 1990

For activities on federal lands, the Native American Graves Protection and Repatriation Act (NAGPRA) of 1990 (25 U.S.C., § 3001 et seq.) provides for the repatriation of Native American cultural items and establishes procedures for the inadvertent discovery of Native American cultural items on federal or tribal lands.

Federal Cave Resources Protection Act of 1988

The Federal Cave Resources Protection Act of 1988 (16 U.S.C., § 4301et seq.) provides for the protection and preservation of significant caves on federal lands. It requires inventory of significant caves on federal lands, implementation of management measures, and provides certain protections of cave resources. It provides for the issuance of permits for collection or removal of cave resources and identifies criminal and civil penalties for prohibited acts.

12.3.2 State

Relevant state programs, policies, plans, or regulations related to cultural resources are described below.

California Environmental Quality Act of 1972

As discussed below in the impact analysis, CEQA (Pub. Resources Code, § 21000, et seq.) requires an evaluation of a project's impacts on historical and archeological resources in California. Public Resources Code section 21083.2 specifically addresses unique archeological. Archeological resources that are not unique do not need to be considered. (Pub. Resources Code, § 21083.2, subds. (a), (h).) State CEQA Guidelines (Cal. Code Regs., tit. 14, § 15064.5), "Determining the Significance of Impacts to Archaeological and Historical Resources," provides further direction regarding cultural resources. Subsection (a) defines the term "historical resources." Subsection (b) explains when a project may be deemed to have a significant effect on historical resources and defines terms used in describing those situations. Subsection (c) describes CEQA's applicability to archaeological sites and provides a method for analyzing archeological sites that are historical resources and those that are not.

California Public Resources Code

The California Public Resources Code contains various provisions protecting historic, archeological, and paleontological sites. For example, Section 5024.1 establishes the CRHR, which is to be used by state and local agencies to identify the state's historical resources and to indicate what properties are to be protect, to the extent prudent and feasible, from substantial adverse change. Other provisions of the Public Resources Code protect resources on public lands. (See, e.g., Pub. Resources Code, §§ 5097–5097.7 [providing for protection of resources on state and public lands].)

12.3.3 Regional or Local

Relevant regional or local programs, policies, or regulations related to cultural resource are described below.

New Melones Resource Management Plan

The purpose of the New Melones Resource Management Plan (RMP) is to develop a framework for management guidance on recreational, natural, and cultural resource management. The RMP document reflects contemporary resource needs for the New Melones Lake Area, while ensuring the Eastside Division of the CVP continues to meet its authorized purposes of flood control, water supply, power, recreation, water quality, and fish and wildlife enhancement. The RMP serves as the basis for future resource management decision-making that, when implemented, may result in the desired future condition for the management area.

All documented or currently undocumented historic properties at New Melones would be protected and managed by the Resource Protection Plan administered by USBR at New Melones Lake Area (USBR 2010:1.5, 5.81). Projects undertaken by USBR follow the directives and guidelines found in a series of Policy and Directives and Standards in the USBR manual that establish policies for cultural resource identification, evaluation, and management. The policies include standard unanticipated discovery and treatment measures should any previously unknown cultural resources, including human remains, be discovered during continued operation of the dam. In addition, USBR park rangers currently patrol recreational facilities and check on the condition of cultural resources in the New Melones Lake Area (USBR 2010:5.73).

New Melones Lake Revised Cave Management Plan

The caves at New Melones are managed and protected in accordance with the directives of the *New Melones Lake Revised Cave Management Plan* administered by USBR (USBR 2007:3.5; USBR 2010:1.16). The plan was prepared in 1996 and updated the information presented in the Draft Cave Management Plan of 1978. The current plan includes guidance to minimize publicity and access to sensitive cave locations, to avoid constructing trails, and to install gates where necessary for conservation purposes.

Historic Properties Management Plans

All documented or currently undocumented cultural resources at New Don Pedro Reservoir or Lake McClure/Lake McSwain are being protected and managed under HPMPs. These plans were completed or are being prepared following the Historic Properties Study Plan as part of the FERC hydropower water quality certification for the Don Pedro Dam (FERC Project No. 2299) and the Merced River Hydroelectric Project (FERC Project No. 2179) (TID and MID 2011b and Merced ID 2012a: Exhibit E, 413–415). Requirements to protect cultural resources at New Don Pedro Reservoir and Lake McClure/Lake McSwain include site management measures, training for all operations and maintenance staff, and routine monitoring of known cultural resources. HPMPs also include standard unanticipated discovery and treatment measures should any previously unknown cultural resources, including human remains, be discovered during continued operation of the dams.

12.4 Impact Analysis

This section identifies the thresholds or significance criteria used to evaluate the potential impacts on cultural resources. It further describes the methods of analysis used to determine significance.

12.4.1 Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the State Water Board's Environmental Checklist in Appendix A of the State Water Board's CEQA regulations. (Cal. Code Regs, tit. 23, §§ 3720–3781.) The thresholds derived from the checklist have been modified, as appropriate, to meet the circumstances of the alternatives. (Cal. Code Regs., tit. 23, § 3777, subd. (a)(2).) Cultural resource impacts were determined to be potentially significant in the State Water Board's Environmental Checklist (see Appendix B, *State Water Board's Environmental Checklist*, in this SED) and therefore, are evaluated in this analysis as to whether the alternatives could result in the following.

- Cause a substantial adverse change in the significance of a historical resource or archaeological resource as defined in the State CEQA Guidelines Section 15064.5. (Cal. Code Regs., tit. 14, § 15064.5.)
- Disturb any human remains, including those interred outside of formal cemeteries.
- Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature.

Where appropriate, specific quantitative or qualitative criteria are described in Section 12.4.2, *Methods and Approach,* for evaluating these thresholds. However, State CEQA Guidelines Section 15064.5 provides that, in general, a resource not listed on state or local registers of historical resources shall be considered by the lead agency to be historically significant if the resource meets the criteria for listing on the CRHR. Section 15064.5 also provides standards for determining what constitutes a "substantial adverse change" that must be considered a significant impact on archaeological or historical resources. For example, a "substantial adverse change in the significance of an historical resource means physical demolition, destruction, relocation, or alteration of the resource or its immediate surroundings such that the significance of an historical resource would be materially impaired." (State CEQA Guidelines, Cal. Code Regs., tit. 14, § 15064.5, subd. (b)(1).)

Section 15064.5 of the State CEQA Guidelines pertains to the determination of the significance of impacts on archaeological and historical resources. Direct and indirect impacts may occur by any of the following means.

- Physically damaging, destroying, or altering all or part of the resource.
- Altering characteristics of the surrounding environment that contribute to the resource's significance.
- Neglecting the resource to the extent that it deteriorates or is destroyed.
- The accidental discovery of cultural resources during construction.

These could be facilitated through changes in reservoir water surface elevations and river flows that are expected to result from the implementation of each of the LSJR alternatives (discussed in more detail below).

12.4.2 Methods and Approach

LSJR Alternatives

This chapter evaluates the potential cultural resource impacts associated with the LSJR alternatives. Each LSJR alternative includes a February–June unimpaired flow[6] requirement (i.e., 20, 40, or 60 percent) and methods for adaptive implementation to reasonably protect fish and wildlife beneficial uses, as described in Chapter 3, *Alternatives Description*. In addition, a minimum base flow is required at Vernalis at all times during this period. The base flow may be adaptively implemented as described below and in Chapter 3. State Water Board approval is required before any method can be implemented, as described in Appendix K, *Revised Water Quality Control Plan*. All methods may be implemented individually or in combination with other methods, may be applied differently to each tributary, and could be in effect for varying lengths of time, so long as the flows are coordinated to achieve beneficial results in the LSJR related to the protection of fish and wildlife beneficial uses.

The Stanislaus, Tuolumne, and Merced Working Group (STM Working Group) will assist with implementation, monitoring, and assessment activities for the flow objectives and with developing biological goals to help evaluate the effectiveness of the flow requirements and adaptive implementation actions. Further details describing the methods, the STM Working Group, and the approval process are included in Chapter 3 and Appendix K. Without adaptive implementation, flow must be managed such that it tracks the daily unimpaired flow percentage based on a running average of no more than 7 days. The four methods of adaptive implementation are described briefly below.

1. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the specified annual February–June minimum unimpaired flow requirement may be increased or decreased to a percentage within the ranges listed below. For LSJR Alternative 2 (20 percent unimpaired flow), the percent of unimpaired flow may be increased to a maximum of 30 percent. For LSJR Alternative 3 (40 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 30 percent or increased to a maximum of 50 percent. For LSJR Alternative 4 (60 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 50 percent.
2. Based on best available scientific information indicating a flow pattern different from that which would occur by tracking the unimpaired flow percentage would better protect fish and wildlife beneficial uses, water may be released at varying rates during February–June. The total volume of water released under this adaptive method must be at least equal to the volume of water that would be released by tracking the unimpaired flow percentage from February–June.
3. Based on best available scientific information, release of a portion of the February–June unimpaired flow may be delayed until after June to prevent adverse effects on fisheries, including temperature that would otherwise result from implementation of the February–June flow requirements. The ability to delay release of flow until after June is only allowed when the

---

[6] *Unimpaired flow* represents the water production of a river basin, unaltered by upstream diversions, storage, or by export or import of water to or from other watersheds. It differs from natural flow because unimpaired flow is the flow that occurs at a specific location under the current configuration of channels, levees, floodplain, wetlands, deforestation and urbanization.

unimpaired flow requirement is greater than 30 percent. If the requirement is greater than 30 percent but less than 40 percent, the amount of flow that may be released after June is limited to the portion of the unimpaired flow requirement over 30 percent. For example, if the flow requirement is 35 percent, 5 percent may be released after June. If the requirement is 40 percent or greater, then 25 percent of the total volume of the flow requirement may be released after June. As an example, if the requirement is 50 percent, at least 37.5 percent unimpaired flow must be released in February–June and up to 12.5 percent unimpaired flow may be released after June. If after June the STM Working Group determines that conditions have changed such that water held for release after June should not be released by the fall of that year, the water may be held until the following year. See Chapter 3 and Appendix K for further details.

4. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the February–June Vernalis base flow requirement of 1,000 cubic feet per second (cfs) may be modified to a rate between 800 and 1,200 cfs.

The operational changes made using the adaptive implementation methods above may be approved if the best available scientific information indicates that the changes will be sufficient to support and maintain the natural production of viable native SJR Watershed fish populations migrating through the Delta and meet any biological goals. The changes may take place on either a short-term (e.g., monthly or annually) or longer-term basis. Adaptive implementation is intended to foster coordinated and adaptive management of flows based on best available scientific information in order to protect fish and wildlife beneficial uses. Adaptive implementation could also optimize flows to achieve the objective, while allowing for consideration of other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife.

Cultural resources for this analysis of the LSJR alternatives were identified through a review of the location, environmental setting, and available documentation, as described in Section 12.2, *Environmental Setting*, for the reservoirs and the rivers. No fieldwork was used to confirm the presence or absence of archaeological, architectural, or paleontological resources, and no evaluation of known resources was done to assess their significance. Unless determined previously, the significance evaluation of documented resources will be completed as part of the HPMPs under way for the FERC hydropower water quality certifications for the Don Pedro Project (FERC Project No. 2299) on the Tuolumne River and the Merced River Hydroelectric Project (FERC Project No. 2179), including Lake McClure, or for the RMP administered by USBR at New Melones Lake Area (USBR 2010:5.81; Merced ID 2011: Exhibit E, 334–335; TID and MID 2011b:2-3).

Potential direct and indirect impact mechanisms for disturbing, materially altering, or demolishing cultural resources, including buried human remains and paleontological resources, as a result of the LSJR alternatives were considered. Providing people access to known or currently unknown cultural resources is the primary direct mechanism to disturb, alter, or demolish cultural resources (e.g., vandalism, authorized collection of artifacts, use of off-highway vehicles). Additionally, cultural resources could be indirectly disturbed, altered, or demolished by activities that would substantially increase natural processes (e.g., weathering or erosion). Soil disturbance or grading is not considered a direct impact mechanism because soil disturbance or grading would not occur under the LSJR alternatives. The LSJR alternatives were evaluated by first determining the potential for known and unknown significant cultural resources to exist at the three reservoirs and along the rivers. The results of the State Water Board's Water Supply Effects (WSE) model were then used to qualitatively analyze the effects of altering reservoir elevations or modifying flows.

This chapter presents the quantitative results of the WSE modeling for the specified unimpaired flow requirement of each LSJR alternative (i.e., 20, 40, or 60 percent). This chapter also incorporates a qualitative discussion of adaptive implementation under each of the LSJR alternatives, including the potential environmental effects associated with adaptive implementation. To inform the qualitative discussion and account for the variability allowed by adaptive implementation, modeling was performed to predict conditions at 30 percent and 50 percent of unimpaired flow (as reported in Appendix F.1, *Hydrologic and Water Quality Modeling*). The modeling also allows some inflows to be retained in the reservoirs until after June, as could occur under method 3, to prevent adverse temperature effects. This variety of modeling scenarios provides information to support the analysis and evaluation of the effects of the alternatives and adaptive implementation. This chapter incorporates a qualitative discussion of the potential cultural resource impacts of adaptive implementation under each of the LSJR alternatives. For more information regarding the modeling methodology and quantitative flow and temperature modeling results, see Appendix F.1.

Reservoir Evaluation

The prevalence of cultural resources, within and adjacent to the reservoirs, determines the potential for direct and indirect impacts on cultural resources. There are documented significant cultural resources located at the reservoirs (see Section 12.2.1, *Reservoir Historic or Archaeological and Paleontological Resources*); however, the locations of many significant or potentially significant cultural resources remain unknown because survey of the reservoirs remains incomplete and there is a potential for buried resources. The LSJR alternatives could reduce reservoir elevations, which could potentially affect cultural resources by: (1) exposing known or currently unknown significant cultural resources now underwater, and (2) providing people access to these resources. Additionally, the LSJR alternatives could substantially increase natural processes (e.g., weathering or erosion) by inundating known or currently unknown significant cultural resources.

WSE model results were summarized in two ways to characterize the effect of the LSJR alternatives on both high and low reservoir elevations in order to assess changes in reservoir elevation that may: (1) increase inundation of cultural resources that are typically out of the water, or (2) increase exposure of cultural resources that are typically below the water surface. These two assessments also capture the change in the range of reservoir elevations. An increase in the range of elevations could result in more resources being within the zones that are repeatedly exposed or inundated.

For the first assessment, the highest elevations under LSJR Alternatives 2, 3, and 4 were identified at the 70, 80, and 90 percent cumulative distribution during June for each alternative, and the difference relative to baseline was calculated (the WSE model results for reservoir storage are end-of-month values). June was selected because during wet years, June is the month with the highest reservoir elevations. Reporting the results of the cumulative distribution accounts for the interannual variability over the 82-year modeled period. The change in high elevations is presented using the 70, 80, and 90 percent cumulative distribution because it is expected that at these elevation levels, cultural resources that typically remain dry would potentially be inundated. Table 12-5 summarizes the results of the 70, 80, and 90 percent cumulative distribution assessment for each reservoir.

Table 12-5. Reservoir Elevations (feet) and Expected Changes (feet) for June at the 70, 80, or 90 Percent Cumulative Distribution for New Melones, New Don Pedro, and Lake McClure

Cumulative Distribution	Baseline Elevations	LSJR Alternative 2 Minus Baseline	LSJR Alternative 3 Minus Baseline	LSJR Alternative 4 Minus Baseline
New Melones	Jun	Jun	Jun	Jun
70%	1,027	8	-6	-38
80%	1,039	5	-9	-33
90%	1,061	4	-11	-28
New Don Pedro				
70%	827	-5	-23	-40
80%	832	-3	-13	-35
90%	833	0	-3	-21
Lake McClure				
70%	861	-3	-23	-42
80%	867	0	-6	-30
90%	867	0	0	-9

Note: Negative numbers indicate a decrease in reservoir elevations; positive numbers indicate an increase in reservoir elevations. The absolute maximum value was not used because it only occurred a few years over the 82-year period, and therefore is not representative of typical conditions.

For the second assessment, the lowest elevations under LSJR Alternatives 2, 3, and 4 were identified at the 10, 20, and 30 percent cumulative distribution for June and September for each alternative, and the difference relative to baseline was calculated. June was selected because the reservoirs typically experience the heaviest use due to recreationists during that time of year, and the LSJR alternatives are most likely to affect reservoir elevations in June. September was selected because it represents the carryover storage at the end of the water year when reservoir levels are often at their lowest level. Reporting the results of the cumulative distribution accounts for the interannual variability over the 82-year modeled period. The change in elevation is presented using the 10, 20, and 30 percent cumulative distribution because it is expected that at these lowest elevation levels, there would be the potential to expose more cultural resources located in the reservoirs. Table 12-6 summarizes the results for each reservoir for the 10, 20, and 30 percent cumulative distribution.

Table 12-6. Reservoir Elevations (feet) and Expected Changes (feet) for June and September at the 10, 20, or 30 Percent Cumulative Distribution for New Melones, New Don Pedro, and Lake McClure

Cumulative Distribution	Baseline Elevations		LSJR Alternative 2 Minus Baseline		LSJR Alternative 3 Minus Baseline		LSJR Alternative 4 Minus Baseline	
New Melones	Jun	Sep	Jun	Sep	Jun	Sep	Jun	Sep
10%	870	837	46	57	47	68	44	72
20%	910	874	31	35	27	45	16	45
30%	941	913	27	25	11	17	2	19
New Don Pedro								
10%	748	706	-1	2	-14	3	-20	13
20%	767	727	1	2	-16	-1	-25	-1
30%	787	744	-3	-2	-26	-10	-33	-8
Lake McClure								
10%	692	636	56	73	37	72	17	69
20%	746	669	23	48	12	50	-2	48
30%	775	701	14	40	2	29	-9	41

Note: Negative numbers indicate a decrease in reservoir elevations; positive numbers indicate an increase in reservoir elevations. The absolute minimum value was not used because it only occurred 1 year over the 82-year period, and therefore is not representative of typical conditions.

River Evaluation

The prevalence of cultural resources within and adjacent to the three eastside tributaries and the LSJR (see Section 12.2.2, *River Historic or Archaeological and Paleontological Resources*) determines the potential for direct and indirect impacts on cultural resources in and adjacent to the rivers. The potential for currently unknown cultural resources to exist is low and many of the known cultural resources have likely been modified, altered, damaged, or destroyed. The expected changes (see below) in flow from the LSJR alternatives would not provide new or expanded access to known or unknown cultural resources. People currently using the rivers would continue to do so and would continue to experience the periodic fluctuations and changes in flow. Therefore, general trends for the LSJR alternatives were identified from the WSE model and used to analyze impacts on cultural resources along the rivers. These trends are summarized below.

- For LSJR Alternative 2, modeled monthly flows on the Stanislaus River were generally similar to baseline flows, although with some small shifting of flows from March to June. Flows for the Tuolumne and Merced Rivers and the LSJR were generally similar to or greater than baseline flows, depending on the month (Tables 5-16 and 5-17a, 5-17b, 5-17c, and 5-17d).
- For LSJR Alternatives 3 and 4, modeled monthly flows would generally increase relative to baseline flows on the Stanislaus, Tuolumne, and Merced Rivers and the LSJR (Table 5-16 and 5-17a, 5-17b, 5-17c, and 5-17d). In most cases, these rivers would experience substantial increases in median flows from February–June relative to baseline.
- For LSJR Alternatives 3 and 4, modeled results indicated occasional reductions in the highest flows caused by a reduced need for flood control releases when compared to baseline conditions. Flood control releases were most likely to occur when the reservoirs were filling

with storm flows or when the reservoirs had to be emptied in the fall in preparation for storms in winter and spring. Flood control releases occurred more often in wet years and were more common at New Don Pedro Reservoir and Lake McClure (i.e., the two smaller reservoirs). During wet years, reservoir releases were greater under LSJR Alternatives 3 and 4, so reservoir storage would reach the maximum allowed limit less often, and flood control releases would not be needed as much.

- The largest changes in flow associated with the LSJR alternatives occurred from February–June, but there were some smaller effects outside of this period. Changes from July–January were primarily related to changes in flood control releases, retention of unimpaired flow for later release in the fall as part of adaptive implementation described under the LSJR alternatives in Section 12.4.3, *Impacts and Mitigation Measures*, during wet conditions, and retention of water in the reservoirs to maintain carryover storage (by reducing diversions in dry years).

As described in Chapter 3, *Alternatives Description*, the percent of unimpaired flow, as specified by the LSJR alternatives, would not apply when such flows would cause flooding or other related public safety concerns.

Extended Plan Area

The analysis of the extended plan area generally identifies how the impacts may be similar to or different from the impacts in the plan area (i.e., downstream of the rim dams) depending on the similarity of the impact mechanism (e.g., changes in reservoir levels, reduced water diversions, and additional flow in the rivers) or location of potential impacts in the extended plan area. Where appropriate, the program of implementation is discussed to help contextualize the potential impacts in the extended plan area.

SDWQ Alternatives

As discussed in Chapter 5, *Surface Hydrology and Water Quality*, and Appendix B, *State Water Board's Environmental Checklist*, the baseline water quality in the southern Delta generally ranges from 0.2 deciSiemens per meter (dS/m)[7] and 1.2 dS/m during all months of the year. Under SDWQ Alternatives 2 or 3, salinity levels in the southern Delta are expected to remain within their historical range (i.e., 0.2 dS/m–1.2 dS/m) because the salinity in the southern Delta has a strong relationship with the salinity at Vernalis, and the program of implementation for SDWQ Alternatives 2 or 3 would still include requirements for USBR to maintain salinity at Vernalis in accordance with its water rights. Therefore, the chemical properties of the baseline water quality conditions in the southern Delta (identified in Chapter 5, *Surface Hydrology and Water Quality*) would not change, and would have no potential to cause a substantial adverse change in the significance of historical or archaeological resources, to disturb human remains, including those interred outside formal cemeteries, or to directly or indirectly destroy a unique paleontological resource, site or unique geologic feature. Therefore, impacts on historical resources, archaeological resources, human remains, or unique paleontological resources under the SDWQ alternatives are not further discussed

---

[7] In the 2006 Bay-Delta Plan, a salinity value—or electrical conductivity (EC) value—of 2.64 millimhos/centimeter (mmhos/cm) is used to represent the X2 location. X2 is the location of the 2 parts per thousand salinity contour (isohaline), 1 meter off the bottom of the estuary measured in kilometers upstream from the Golden Gate Bridge. Note, in this SED, EC is generally expressed in deciSiemens per meter (dS/m). The conversion is 1 mmhos/cm = 1 dS/cm.

in this chapter. To comply with specific water quality objectives or the program of implementation under SDWQ Alternatives 2 or 3, construction and operation of different facilities in the southern Delta could occur, which could involve impacts on cultural resources. These impacts are evaluated in Chapter 16, *Evaluation of Other Indirect and Additional Actions.*

12.4.3 Impacts and Mitigation Measures

Impact CUL-1: Cause a substantial adverse change in the significance of a historical or archaeological resource

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 *Water Quality Control Plan for the San Francisco/Sacramento-San Joaquin Delta Estuary* (2006 Bay-Delta Plan). See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

There is generally a high potential for currently known and unknown significant cultural resources to exist at the three reservoirs because some resources have already been documented at each of the reservoirs. As described in Section 12.2, *Environmental Setting*, two-thirds of the documented cultural resources at New Melones Reservoir are currently located in the permanent pool zone and/or the fluctuation pool zone. Few cultural resources have been documented below the average water level at New Don Pedro Reservoir. Documented archaeological sites and one built resource at Lake McClure are at or below the high water levels and currently experience inundation by water or exposure by receding water. Significant historical and archaeological resources (historic properties) are protected and managed under the HPMPs as part of the FERC hydropower water quality certifications for the Don Pedro Project (FERC Project No. 2299) on the Tuolumne River and the Merced River Hydroelectric Project (FERC Project No. 2179), including Lake McClure, and by the RMP administered by USBR at New Melones Reservoir.

There is a low potential for unknown significant cultural resources to exist on the three eastside tributaries and the LSJR because of prior disturbance by agriculture, irrigation practices, mining activities, or development within the riverine floodplains. Since the rivers have experienced extensive disturbances since the start of the historic period approximately 150 years ago, there is a low potential for unknown significant cultural resources to exist within the displaced or reworked soils or sediments in the confined river channels. Furthermore, although a high number of historic period archaeological sites or built resources have been recorded along the rivers, many have been highly disturbed or destroyed by these processes as the natural floodplains and terraces were modified and confined by levees or agricultural fields, or as early settlements or mining prospects were later displaced or buried by hydraulic mining and dredging, which continued into the mid-1900s in some places, such as the Lower Tuolumne River near Waterford, and then by modern large-scale aggregate mining (see Section 12.2.2, *River Historic or Archaeological and Paleontological Resources*).

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

Reservoirs

LSJR Alternative 2 would change reservoir elevations in New Melones Reservoir, New Don Pedro Reservoir, and Lake McClure. Table 12-5 and Table 12-6 summarize the expected changes. In general, under LSJR Alternative 2 there would be little change in the highest reservoir elevations in June (Table 12-5); there would be slight increases in New Melones Reservoir (less than 10 ft), and slight decreases in New Don Pedro Reservoir and Lake McClure (5 ft or less). Under LSJR Alternative 2, the lower reservoir elevations in September (Table 12-6) are expected to increase significantly at New Melones Reservoir (25–57 ft) and would be similar to baseline at New Don Pedro Reservoir. At Lake McClure, the very lowest reservoir elevations (10 percent cumulative distribution) would increase by 73 ft under LSJR Alternative 2 as a result of the LSJR alternative carryover storage requirements; moderately low elevations (30 percent cumulative distribution) would increase under LSJR Alternative 2 by 40 ft in September (Table 12-6).

Depending on the location at New Melones Reservoir, cultural resources could experience slight increases in inundation at high reservoir elevations under LSJR Alternative 2. However, while inundation might increase, higher water surface elevations would be expected to prevent human disturbance, and siltation could provide protection to existing cultural resources from human disturbance and other physical forces. Furthermore, under LSJR Alternative 2, the lowest elevations at the reservoirs are expected to be either similar to baseline or be above baseline elevations. The carryover storage requirement means that in some cases, cultural resources that occasionally were exposed during droughts under baseline conditions might no longer be exposed.

The existing archaeological and historic-era built environment resources currently experience, and would continue to experience, fluctuations in water levels at the reservoirs. Furthermore, the management plans for historic properties at the reservoirs would include standard unanticipated discovery and treatment measures should any previously unknown significant cultural resources be discovered during continued operation of the dams. Therefore, while cultural resources might experience variation in their physical environment due to changes in water level or siltation, these variations have an extremely low potential to cause a substantial adverse change in the characteristics that convey the historical significance of the resources. As such, under LSJR Alternative 2, impacts on historical or archaeological resources at the reservoirs would be less than significant.

Rivers

The potential for vandalism, unauthorized collection, and other anthropogenic disturbances is considered low along the LSJR and the three eastside tributaries because of the prior anthropogenic and natural disturbance of the rivers and adjacent areas. It is expected that each of the rivers would continue to experience episodic high flows during significant storm events as the flood capacities of the rivers are controlled and managed by USACE. LSJR Alternative 2 would not exceed flood control or management requirements. Furthermore, average and seasonal flows are expected to remain within the existing channels that have been previously disturbed by natural flows and anthropogenic activities. The potential for bank erosion on all four rivers under this alternative is expected to be similar to baseline conditions, including the occasional years with major flood events. Given the low potential for significant cultural resources to be located within and adjacent to the rivers, and because the expected change in flows has an extremely low potential to cause a substantial adverse change in the characteristics that convey the historical significance of any resources that may be present, impacts on historical or archaeological resources located within or adjacent to the rivers under LSJR Alternative 2 would be less than significant.

Adaptive Implementation

Based on best available scientific information indicating that a change in the percent of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation method 1 would allow an increase of up to 10 percent over the 20-percent February–June unimpaired flow requirement (to a maximum of 30 percent of unimpaired flow). A change to the percent of unimpaired flow would take place based on required evaluation of current scientific information and would need to be approved as described in Appendix K, *Revised Water Quality Control Plan*. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. However, an increase of up to 30 percent of unimpaired flow would potentially result in different effects as compared to 20-percent unimpaired flow, depending upon flow conditions and frequency of the adjustment.

Based on best available scientific information indicating that a change in the timing or rate of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation method 2 would allow changing the timing of the release of the volume of water within the February–June timeframe. While the total volume of water released February–June would be the same as LSJR Alternative 2 without adaptive implementation, the rate could vary from the actual (7-day running average) unimpaired flow rate. Method 2 would not authorize a reduction in flows required by other agencies or through other processes, which are incorporated in the modeling of baseline conditions. Method 3 would not be authorized under LSJR Alternative 2 since the unimpaired flow percentage would not exceed 30 percent.

Adaptive implementation method 4 would allow an adjustment of the Vernalis February–June flow requirement. WSE model results show that under LSJR Alternative 2 the 1,200-cfs February–June base flow requirement at Vernalis would require a flow augmentation in the three eastside tributaries and the LSJR only 2.7 percent of the time in the 82-year record analyzed. Similarly, flow augmentation would be required 0.7 percent of the time to meet a 1,000-cfs requirement and 0.5 percent of the time for an 800-cfs Vernalis base flow requirement. These results indicate that changes due to method 4 under this alternative would rarely alter the flows in the three eastside tributaries or the LSJR.

Impacts associated with adaptive implementation method 1 may be slightly different from those associated with methods 2 and 3. With method 1, if the specified percent of unimpaired flow were changed from 20 percent to 30 percent on a long-term basis, the conditions and impacts could become more similar to those described under LSJR Alternative 3 (e.g., 30 percent unimpaired flow). It is anticipated that over time the unimpaired flow requirement could increase or not change at all within a year or between years, depending on hydrology, and fish and wildlife conditions. If method 2 is implemented, the total annual volume of water associated with LSJR Alternative 2 (i.e., 20 percent of the February–June unimpaired flow) would not change. As a result, the total volume of water that would remain in the river would not change with adaptive implementation method 2. However, given that this method would not allow flows to go below what is required by existing requirements on the three eastside tributaries and the SJR, and given the prior anthropogenic and natural disturbance of the rivers and adjacent areas have resulted in a low potential for significant historical or archaeological resources to exist, impacts would be similar to those described above under LSJR Alternative 2. Implementing method 4 is expected to have little effect on conditions in the three eastside tributaries and the LSJR because it would rarely cause a change in flow and the volume of water involved would be relatively small. Consequently the impact determination of LSJR Alternative 2 with adaptive implementation for historical or archaeological resources would be the same as described above under LSJR Alternative 2 without adaptive implementation. Impacts would be less than significant.

LSJR Alternative 3 (Less than significant/Less than significant with adaptive implementation)

Reservoirs

LSJR Alternative 3 would change reservoir elevations in New Melones Reservoir, New Don Pedro Reservoir, and Lake McClure. Table 12-5 and Table 12-6 summarize the expected changes. In general, under LSJR Alternative 3, there would be slight decreases in the highest reservoir elevations, with the largest decrease (23 ft) occurring at the 70 percent cumulative distribution level at New Don Pedro Reservoir and Lake McClure (Table 12-5). Under LSJR Alternative 3, the lower reservoir elevations in September (Table 12-6) are expected to increase significantly at New Melones Reservoir (31–83 ft) and would be similar to baseline at New Don Pedro Reservoir. At Lake McClure, the very lowest reservoir elevations in September would increase under LSJR Alternative 3 (by 72 ft) as a result of carryover storage requirements that are part of LSJR Alternative 3, and the moderately low elevations (30 percent cumulative distribution) would increase by 29 ft. Similarly, at New Melones Reservoir, the very lowest reservoir elevations in September would increase under LSJR Alternative 3 (by 68 ft) as a result of carryover storage requirements that are part of LSJR Alternative 3, and the moderately low elevations (30 percent cumulative distribution) would increase by 17 ft. For instances in which LSJR Alternative 3 may reduce already low reservoir elevations, the reduction relative to baseline is greater in June than it is in September (Table 12-6). These reductions in elevation during a period of high recreational use (June) could expose cultural resources to more human-caused damage. However, actual elevations in June are significantly higher than in September. Exposure of some resources in June under LSJR Alternative 3 would not be consequential, given that the resources would ultimately be exposed by September under baseline conditions.

Under LSJR Alternative 3, resources high in the fluctuation pool zone may experience slightly less inundation. Furthermore, under LSJR Alternative 3, the lowest elevations at the reservoirs are expected to be either similar to baseline or be above baseline elevations. The carryover storage requirement for LSJR Alternative 3 means that in some cases, cultural resources that occasionally were exposed during droughts under baseline conditions might no longer be exposed. Cultural resources would continue to experience inundation and receding reservoir water levels.
As described under LSJR Alternative 2, any documented or currently unknown significant cultural resource would be managed by the various plans of the reservoirs (e.g., the New Melones Lake RMP and Resource Protection Plan, and the HPMPs for New Don Pedro and Lake McClure). Although cultural resources might experience variation in their physical environment due to changes in water level or siltation, these variations have an extremely low potential to cause a substantial adverse change in the characteristics that convey the historical significance of the resources. Therefore, under LSJR Alternative 3, impacts on historical or archaeological resources at the reservoirs would be less than significant.

Rivers

As discussed under LSJR Alternative 2, there is a low potential for unknown significant cultural resources to be located within and adjacent to the rivers due to past anthropogenic and natural modifications within river channels and adjacent to river channels. Under LSJR Alternative 3, average and seasonal flows are expected to remain within the existing channels, which have been previously disturbed by natural flows and anthropogenic activities. Furthermore, there is only a low potential for significant cultural resources to be located within or adjacent to the rivers, and the expected change in flows has an extremely low potential to cause a substantial adverse change in the characteristics that convey the historical significance of any resources that may be present. Therefore, impacts on historical or archaeological resources located within or adjacent to the rivers under LSJR Alternative 3 would be less than significant.

Adaptive Implementation

Under LSJR Alternative 3, impacts associated with adaptive implementation method 1 may be slightly different from those associated with adaptive implementation methods 2 and 3.

Implementing method 1 would allow an increase or decrease of up to 10 percent in the February–June, 40 percent unimpaired flow requirement (with a minimum of 30 percent and maximum of 50 percent) to optimize implementation measures to meet the narrative objective, while considering other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. Adaptive implementation must be approved using the process described in Appendix K, *Revised Water Quality Control Plan*. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. Adaptive implementation method 1 could affect the volume of water and level of flow in the LSJR and its tributaries. However, the frequency and duration of such a change is unknown. If the specified percent of unimpaired flow were changed from 40 percent to 30 percent, or 40 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternatives 2 or 4, respectively. It is anticipated that over time the unimpaired flow requirement could increase, decrease, or not change at all within a year or between years, depending on hydrology, and fish and wildlife conditions.

Under adaptive implementation methods 2 or 3, the overall volume of water from the February–June time period or after June would be the same as LSJR Alternative 3 without adaptive implementation, but the volume within each month could vary. Adaptive implementation method 3 is incorporated into the modeling; thus, the range of historical or archaeological effects is reflected in the results presented above under LSJR Alternative 3. Furthermore, given that these two methods would not allow flows to go below what is required by existing requirements on the three eastside tributaries and the SJR, and given that prior anthropogenic and natural disturbance of the rivers and adjacent areas have resulted in a low potential for significant historical or archaeological resources to exist, impacts would be similar to those described above under LSJR Alternative 3.

Implementing method 4 is expected to have little effect on conditions in the three eastside tributaries and the LSJR. WSE model results show that under LSJR Alternative 3 the 1,200-cfs February–June base flow requirement at Vernalis would require a flow augmentation in the three eastside tributaries and the LSJR only 1.2 percent of the time in the 82-year record analyzed. Similarly, flow augmentation would be required only 0.2 percent of the time to meet either a 1,000-cfs or 800-cfs Vernalis base flow requirement. These results indicate that adaptive implementation method 4 would rarely alter the flows in the three eastside tributaries or the LSJR under this alternative.

Consequently, the impact determination of LSJR Alternative 3 with adaptive implementation would be the same as described above under LSJR Alternative 3 without adaptive implementation, for historical or archaeological resources. Impacts would be less than significant.

LSJR Alternative 4 (Less than significant/Less than significant with adaptive implementation)

Reservoirs

LSJR Alternative 4 would change reservoir elevations in New Melones Reservoir, New Don Pedro Reservoir, and Lake McClure. Table 12-5 and Table 12-6 summarize the expected changes. In general, under LSJR Alternative 4, there would be decreases in the highest reservoir elevations, with all three reservoirs experiencing a roughly 40 foot decrease in carryover elevations at the 70 percent cumulative distribution level (Table 12-5). Under LSJR Alternative 4, the lower reservoir elevations (in September), are expected to increase significantly at New Melones Reservoir (19–72 ft) and at Lake McClure (41–69 ft) (Table 12-6). At New Don Pedro Reservoir, elevations in September would be similar to baseline with changes in elevation ranging from a decrease of 8 ft (30 percent cumulative distribution) to an increase of 13 ft (10 percent cumulative distribution) (Table 12-6). LSJR Alternative 4 is more likely to cause low elevations relative to baseline in June than in September (Table 12-6). These reductions in elevation during a period of high recreational use (June) could expose cultural resources to more human-related damage. However, actual elevations in June are significantly higher than in September. Exposure of some cultural resources in June under LSJR Alternative 4 would not be consequential, given that the resources would ultimately be exposed by September under baseline conditions.

Under LSJR Alternative 4, resources high in the fluctuation pool zone may experience less inundation. Furthermore, under LSJR Alternative 4, the lowest elevations at the reservoirs are expected to be either similar to baseline or be above baseline elevations. The carryover storage requirement for LSJR Alternative 4 means that in some cases, cultural resources that occasionally were exposed during droughts under baseline conditions might no longer be exposed. Cultural resources would continue to experience inundation and receding reservoir waters. As discussed under LSJR Alternative 2, cultural resources would be managed by the various plans of the reservoirs (e.g., the New Melones Lake RMP and Resource Protection Plan, and the HPMPs for New Don Pedro and Lake McClure). Although cultural resources might experience variation in their physical environment due to changes in water level or siltation, these variations have an extremely low potential to cause a substantial adverse change in the characteristics that convey the historical significance of the resources. Therefore, under LSJR Alternative 4, impacts on historical or archaeological resources at the reservoirs would be less than significant.

Rivers

There is a low potential for unknown significant cultural resources to be located within and adjacent to the rivers due to past anthropogenic and natural modifications within river channels and adjacent to river channels. As discussed under LSJR Alternative 2, any modification of flows has an extremely low potential to cause a substantial adverse change in the characteristics that convey the historical significance of documented or currently undocumented historical or archaeological resources located within or adjacent to the rivers. Therefore, impacts on historical or archaeological resources within or adjacent to the rivers under LSJR Alternative 4 would be less than significant.

Adaptive Implementation

Under LSJR Alternative 4, impacts associated with adaptive implementation method 1 may be slightly different from those associated with methods 2 and 3.

Implementing method 1 would allow a decrease of up to 10 percent in the annual February–June 60 percent unimpaired flow (to a minimum of 50 percent) to optimize implementation measures to meet the narrative objective, while considering other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. Adaptive implementation must be approved using the process described in Appendix K, *Revised Water Quality Control Plan*. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. If the specified percent unimpaired flow were changed from 60 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternative 3. It is anticipated that over time the unimpaired flow requirement could decrease or not change at all within a year or between years, depending on hydrology, and fish and wildlife conditions.

Under adaptive implementation methods 2 or 3, the overall volume of water from the February–June time frame or after June would be the same as under LSJR Alternative 4 without adaptive implementation, but the volume within each month could vary. Adaptive implementation method 3 is incorporated into the modeling; thus, the range of historical or archaeological effects is reflected in the results presented above under LSJR Alternative 4. Furthermore, given that these two methods would not allow flows to go below what is required by existing requirements on the three eastside tributaries and the SJR, and given the prior anthropogenic and natural disturbance of the rivers and adjacent areas have resulted in a low potential for significant historical or archaeological resources to exist, impacts would be similar to those described above under LSJR Alternative 4.

Implementing method 4 is expected to have little effect on conditions in the three eastside tributaries and the LSJR. WSE model results show that under LSJR Alternative 4 the 1,200-cfs February–June base flow requirement at Vernalis would require a flow augmentation in the three eastside tributaries and the LSJR only 0.7 percent of the time in the 82-year record analyzed. Similarly, flow augmentation would be required only 0.2 percent of the time to meet a 1,000-cfs requirement and is not affected at all for an 800-cfs requirement. These results indicate that adaptive implementation method 4 would rarely alter the flows in the three eastside tributaries or the LSJR under this alternative.

Consequently, the impact determination of LSJR Alternative 4 with adaptive implementation would be the same as described above under LSJR Alternative 4 without adaptive implementation, for historical or archaeological resources. Impacts would be less than significant.

Impact CUL-2: Disturb any human remains, including those interred outside formal cemeteries

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the*

No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1), for the No Project Alternative technical analysis.

LSJR Alternatives

As described in Section 12.2, *Environmental Setting*, human remains interred outside of formal cemeteries have been documented at relatively few archaeological sites at New Melones Reservoir and New Don Pedro Reservoir. No human remains have been documented to date at Lake McClure. Cemeteries have been documented at New Melones Reservoir; however, "cemetery" is not listed as a historic site type at New Don Pedro Reservoir or Lake McClure. Furthermore, no evidence of burials was found at a possible cemetery at Lake McClure. In compliance with procedures for the treatment of human remains discovered on state, private, or federal lands, documented human remains would have been left in place, reinterred under the maximum pool or elsewhere, or excavated, curated, and/or repatriated at each of the reservoirs if they had been discovered previously. In addition, documented or currently undocumented sites with human remains would be protected under federal and state laws and under the HPMPs for the New Don Pedro on the Tuolumne River and Lake McClure, and by the RMP administered by USBR at New Melones Reservoir. The potential for the presence of human remains in proximity to the reservoir fluctuation zones is considered low.

The potential for the presence of undocumented human remains within and adjacent to the LSJR and the three eastside tributaries is considered low due to prior disturbance of the riparian corridors by natural and historic-era anthropogenic processes. Any human remains discovered within and adjacent to the LSJR and the three eastside tributaries outside of formal cemeteries would also have been treated in accordance with state or federal regulations.

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

Reservoirs and Rivers

Since the potential for human remains to exist within the fluctuation zone of the reservoirs is low, the change in reservoir elevation described above in Impact CUL-1 would have a low potential to disturb documented or undocumented human remains. Considering the prior disturbance by agriculture, irrigation practices, mining activities, and development within the riverine floodplains, the change in flows under LSJR Alternative 2 would have an extremely low potential to disturb documented or undocumented human remains, including those interred outside formal cemeteries. The natural processes of localized soil erosion and siltation could also be beneficial by reducing the potential for access and unauthorized artifact collection or vandalism. Therefore, under LSJR Alternative 2, impacts on human remains, including those interred outside formal cemeteries, would be less than significant.

Adaptive Implementation

It is anticipated that adaptive implementation would not substantially change the less than significant determination for impacts on human remains. As discussed under Impact CUL-1, it is anticipated that over time the unimpaired flow requirement could increase or not change at all within a year or between years, depending on hydrology, and fish and wildlife conditions under adaptive implementation method 1. If method 2 is implemented, the total annual volume of water associated with LJSR Alternative 2 (i.e., 20 percent of the February–June unimpaired flow) would not change. As a result, the total volume of water that would remain in the river would not change with adaptive implementation method 2; therefore, impacts associated with total volume of water would not change. Given that this method would not allow flows to go below what is required by existing requirements on the three eastside tributaries and the SJR, impacts would be similar to those described under LSJR Alternative 2 without adaptive implementation. Implementing method 4 is expected to have little effect on conditions in the three eastside tributaries and the LSJR because it rarely would cause a change in flow and the volume of water involved would be relatively small. Consequently, the impact determination of LSJR Alternative 2 with adaptive implementation would be the same as described above under LSJR Alternative 2 without adaptive implementation, for human remains. Impacts would be less than significant.

LSJR Alternatives 3 and 4 (Less than significant/Less than significant with adaptive implementation)

For LSJR Alternatives 3 and 4, the impacts on human remains, including those interred outside formal cemeteries, would not differ from those described under LSJR Alternative 2, with and without adaptive implementation methods 1, 2, and 4. Under adaptive implementation method 3, the overall volume of water from the February–June time period or after June would be the same as LSJR Alternative 3 without adaptive implementation, but the volume within each month could vary. However, adaptive implementation method 3 is incorporated into the modeling; thus, the range of impacts on human remains is reflected in the results described above under LSJR Alternatives 3 and 4 under Impact CUL-1. In addition, given that these methods would not allow flows to go below what is required by existing requirements on the three eastside tributaries and the SJR, impacts would be similar to those described for LSJR Alternative 3 and 4. Therefore, impacts on human remains under LSJR Alternatives 3 and 4 with and without adaptive implementation would be less than significant.

Impact CUL-3: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis*.*

LSJR Alternatives

As described in Section 12.2, *Environmental Setting*, the rock units in proximity to the reservoirs have a low potential to contain paleontological resources. No paleontological resources have been documented at New Don Pedro Reservoir or Lake McClure. At New Melones Reservoir, fossils were recovered from more than 12 caves. More than 50 caves at New Melones Reservoir are inundated or subject to inundation. Three of the caves subject to inundation are considered significant paleontological resources. The documented caves are protected and managed under the Cave Management Plan administered by USBR at New Melones Reservoir.

As also described in Section 12.2, *Environmental Setting*, the potential for paleontological resources within and adjacent to the LSJR and the three eastside tributaries is considered low due to the depth of occurrence of rock units with high paleontological potential below reworked surficial sediments and Holocene-age floodplain and channel deposits. In other words, buried paleontological resources would be found at soil and rock depth too deep for the rivers to modify or change. The potential is also low due to disturbance or destruction of near-surface paleontological resources by historic-era anthropogenic practices or natural processes.

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

Reservoirs

As described above under Impact CUL-1, reservoir elevations currently experience, and would continue to experience, fluctuations in water levels at the reservoirs (Table 12-5 and 12-6). No paleontological resources have been documented at New Don Pedro Reservoir or Lake McClure. The low potential for rock units within proximity of these two reservoirs indicates that the change in elevation under LSJR Alternative 2 would have a low potential to affect any unknown paleontological resources. New Melones Reservoir may experience an increase in reservoir elevations. Many of the caves adjacent to the reservoir are currently above the spillway elevation, and of those that are below the spillway elevation, the increase in reservoir elevations could prevent human disturbance of the caves. The documented caves would continue to be protected and managed under the Cave Management Plan, which is administered by USBR at New Melones Reservoir. Therefore, under LSJR Alternative 2, impacts on paleontological resources or sites or unique geologic features associated with the reservoirs would be less than significant.

Rivers

The expected change in flows in the LSJR and the three eastside tributaries would have an extremely low potential to disturb paleontological resources. This is because these resources are typically identified at depths below the surficial sediments reworked by historic-era anthropogenic practices and the Holocene-age floodplain and channel deposits along the riparian corridors. In addition, it is likely that near-surface paleontological resources have been previously disturbed or destroyed by agriculture, irrigation practices, mining activities, or other development. Therefore, impacts on paleontological resources or sites or unique geologic features under LSJR Alternative 2 associated with the rivers would be less than significant.

Adaptive Implementation

It is anticipated that adaptive implementation would not substantially change the less than significant determination for impacts on paleontological or geologic features. As discussed under Impact CUL-1, it is anticipated that over time the unimpaired flow requirement could increase or not change at all within a year or between years, depending on hydrology, and fish and wildlife conditions, under method 1. If method 2 is implemented, the total annual volume of water associated with LJSR Alternative 2 (i.e., 20 percent of the February–June unimpaired flow) would not change. As a result, the total volume of water that would remain in the river would not change with adaptive implementation method 2. Given that this method would not allow flows to go below what is required by existing requirements on the three eastside tributaries and the SJR, impacts would be similar to those described under LSJR Alternative 2. Implementing method 4 is expected to have little effect on conditions in the three eastside tributaries and the LSJR because it rarely would cause a change in flow and the volume of water involved would be relatively small. Consequently the impact determination of LSJR Alternative 2 with adaptive implementation would be the same as described above under LSJR Alternative 2 without adaptive implementation, for paleontological or geologic features. Impacts would be less than significant.

LSJR Alternative 3 (Less than significant/Less than significant with adaptive implementation)

Reservoirs

Impacts for LSJR Alternative 3 would be the same as described above under LSJR Alternative 2 for New Don Pedro Reservoir and Lake McClure. At New Melones Reservoir, the highest reservoir elevations may decrease (Table 12-5) and the lowest reservoir elevations may increase (Table 12-6). This reduction in the range of elevations could reduce the potential to adversely affect the caves by natural processes such as erosion and weathering and/or could reduce access to the caves and the risk of vandalism or unauthorized collection of undocumented, newly eroded fossils. The documented caves would continue to be protected and managed under the Cave Management Plan, administered by USBR at New Melones Reservoir. Therefore, under LSJR Alternative 3, impacts on paleontological resources or sites or unique geologic features would be less than significant.

Rivers

Impacts for LSJR Alternative 3 would be the same as described above under LSJR Alternative 2 for the three eastside tributaries and the LSJR. Therefore, impacts on paleontological resources or sites or unique geologic features would be less than significant.

Adaptive Implementation

It is anticipated that adaptive implementation would not substantially change the less than significant determination for impacts on paleontological or geologic features. Adaptive implementation method 1 could affect the volume of water and level of flow in the LSJR and its tributaries. However, the frequency and duration of such a change is unknown. If the specified percent of unimpaired flow were changed from 40 percent to 30 percent or 40 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternatives 2 or 4, respectively. It is anticipated that over time the unimpaired flow requirement could increase, decrease, or not change at all within a year or between years, depending on hydrology, and fish and wildlife conditions.

Under adaptive implementation methods 2 or 3, the overall volume of water from the February–June time frame or after June would be the same as LSJR Alternative 3 without adaptive implementation, but the volume within each month could vary. However, given that these two methods would not allow flows to go below what is required by existing requirements on the three eastside tributaries and the SJR, impacts would be similar to those described above under LSJR Alternative 3. Implementing method 4 is expected to have little effect on conditions in the three eastside tributaries and WSE model results indicate that method 4 would rarely alter the flows in the three eastside tributaries or the LSJR under this alternative. Consequently, the impact determination of LSJR Alternative 3 with adaptive implementation would be the same as described above under LSJR Alternative 3 without adaptive implementation, for paleontological or geologic features. Impacts would be less than significant.

LSJR Alternative 4 (Less than significant/Less than significant with adaptive implementation)

Impacts for LSJR Alternative 4 would be the same as described above under LSJR Alternative 2 for New Don Pedro Reservoir and Lake McClure. Impacts would be the same as described above under LSJR Alternative 3 for New Melones Reservoir. Impacts would be the same as described above under LSJR Alternative 2 for the three eastside tributaries and the LSJR. Therefore, under LSJR Alternative 4 with and without adaptive implementation, impacts on paleontological resources or sites or unique geologic features would be less than significant.

12.4.4 Impacts and Mitigation Measures: Extended Plan Area

Cultural resources in the extended plan area could be affected by the bypassing of flow, as described in Chapter 5, *Surface Hydrology and Water Quality*. Bypassing flows could produce increased stream flows downstream of the reservoirs during the bypass period, or lower flows after the bypass period, and could produce lower reservoir levels. Effects on significant cultural resources could occur if existing significant cultural resource sites at these locations were exposed to increased erosion or other physical conditions resulting in deterioration. Additionally, sites exposed by lower reservoir levels could be vulnerable to discovery, disturbance, and artifact removal. However, both the river flow and reservoir level reductions would be similar to reductions under baseline conditions, although they could occur more frequency. Furthermore, because these reductions have occurred under baseline conditions, existing significant cultural resources have already been affected. Lastly, under the LSJR alternatives with or without adaptive implementation, erosion or exposure of existing significant cultural resources is not expected to be substantially different than under baseline conditions. Consequently, impacts on significant cultural resources under the LSJR alternatives with or without adaptive implementation would be less than significant in the extended plan area.

12.5 Cumulative Impacts

For the cumulative impact analysis, refer to Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources.*

Chapter 13
Service Providers

13.1 Introduction

This chapter describes the environmental setting for service providers and the regulatory background associated with service providers. This chapter also evaluates the environmental impacts on service providers that could result from the Lower San Joaquin River (LSJR) and southern Delta water quality (SDWQ) alternatives, and, if applicable, offers mitigation measures that would reduce or avoid any significant impacts.

This chapter describes the potential impacts of the LSJR and SDWQ alternatives associated with service providers within the area of potential effects, which includes: the plan area, as described in Chapter 1, *Introduction*; the Eastern San Joaquin, Modesto, Turlock, and Merced[1] Subbasins; and other areas outside the plan area with service providers that are affected by the alternatives. Service providers discussed in this chapter are public providers of water supply for municipal, industrial, and agricultural uses, and providers of wastewater treatment. Private wells that provide domestic water supply are also included in this chapter.

The extended plan area, also described in Chapter 1, *Introduction,* generally includes the area upstream of the rim dams.[2] The area of potential effects for this area would be service providers in this area relying on surface water diversions from the Stanislaus, Tuolumne, and Merced Rivers. Unless otherwise noted, all discussion in this chapter refers to the area of potential effects below the rim dams. Where appropriate, the extended plan area is specifically identified.

In Appendix B, *State Water Board's Environmental Checklist*, the State Water Resources Control Board (State Water Board) evaluated whether the plan amendments[3] would cause any adverse impact on resources in each of the listed environmental categories and provided a brief explanation for its determinations. It determined that impacts on public services (e.g., fire protection, police protection, schools, parks) and some impacts associated with utilities and service systems (e.g., stormwater drainage facilities, landfills) were either less than significant or had no impact. Impacts in the checklist that are identified as "Potentially Significant Impacts" under utilities and service systems or hydrology and water quality are discussed in detail in this chapter.

The State Water Board focuses the impact analysis in this chapter on specific issues associated with the LSJR and SDWQ alternatives that are related to potentially significant impacts identified in Appendix B (i.e., XVII b and IX a). The impacts listed below in Table 13-1 are specific to the LSJR and SDWQ alternatives; they are modified, as appropriate, from the impacts listed in Appendix B to be more relevant to effects that may occur in association with the alternatives. Particularly, they are

---

[1] As described in Chapter 9, *Groundwater Resources*, the Merced Subbasin was extended for the analysis to include a part of the Chowchilla Subbasin, creating the *Extended Merced Subbasin*.

[2] In this document, the term *rim dams* is used when referencing the three major dams and reservoirs on each of the eastside tributaries: New Melones Dam and Reservoir on the Stanislaus River; New Don Pedro Dam and Reservoir on the Tuolumne River; and New Exchequer Dam and Lake McClure on the Merced River.

[3] These plan amendments are the *project* as defined in State CEQA Guidelines, Section 15378.

modified to address effects associated with potential reductions in surface water supply to service providers. Accordingly this chapter evaluates whether the LSJR and SDWQ alternatives would: (1) require or result in the construction of new water supply facilities or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects, and (2) violate any water quality standards such that drinking water quality from (a) public water systems and (b) domestic wells would be affected.[4] Additionally, this chapter evaluates if the LSJR alternative would result in substantial changes to San Joaquin River (SJR) inflows to the Delta such that insufficient water supplies would be available to service providers relying on Central Valley Project (CVP)/State Water Project (SWP) exports. This is because changes to SJR inflow into the southern Delta resulting from the LSJR alternatives could change exports to service providers in the export service areas (i.e., CVP and SWP contractors) since some the inflow from the LSJR is exported at the CVP and SWP pumps to the export service areas. Section 13.4, *Impact Analysis*, describes the significance thresholds for determining whether a potential impact associated with service providers is significant.

A summary of the potential impacts of the LSJR and SDWQ alternatives on service providers is provided in Table 13-1. As described in Chapter 3, *Alternatives Description*, LSJR Alternatives 2, 3, and 4 each include four methods of adaptive implementation. This recirculated substitute environmental document (SED) provides an analysis with and without adaptive implementation because the frequency, duration, and extent to which each adaptive implementation method would be used, if at all, within a year or between years under each LSJR alternative is unknown. The analysis, therefore, discloses the full range of impacts that could occur under an LSJR alternative, from no adaptive implementation to full adaptive implementation. As such, Table 13-1 summarizes impact determinations with and without adaptive implementation.

Impacts related to the No Project Alternative (LSJR/SDWQ Alternative 1) are presented in Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* and the supporting technical analysis is presented in Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1).* More information and analysis regarding the environmental impacts associated with the construction and/or operation of water treatment facilities or water supply infrastructure or other actions that may be taken by service providers in response to implementation of the plan amendments are discussed in Chapter 16, *Evaluation of Other Indirect and Additional Actions*.

---

[4] As stated in Appendix B, *State Water Board's Environmental Checklist*, the LSJR Alternatives would change the volume of water in existing reservoirs and rivers and would not result in a violation of waste discharge requirements (WDRs). The SDWQ Alternatives 2 and 3 would articulate the water quality objective (i.e., standard) for salinity, from which requirements in WDRs would be derived; therefore, they would not violate WDRs. Thus, this chapter does not further discuss violations of WDRs.

Table 13-1. Summary of Service Provider Impact Determinations

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
Impact SP-1: Require or result in the construction of new water supply facilities or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note.[b]	Significant	NA
LSJR Alternative 2	Average surface water diversions on the Stanislaus, Tuolumne, and Merced Rivers would be reduced by 2 percent, 2 percent, and 6 percent, respectively, compared to baseline conditions. Further, there would not be a substantial depletion of groundwater supplies; therefore, it is not expected that service providers or public water suppliers would need to construct or operate new water supply or wastewater treatment facilities or expand existing facilities. However, if adaptive implementation method 1 were implemented on a long-term basis (an increase in the February–June percent of unimpaired flow from 20 percent up to 30 percent), it is expected that there would be a substantial reduction of surface water on the Merced and Tuolumne Rivers and a substantial depletion of groundwater supplies in the Extended Merced Subbasin. These reductions would potentially require service providers to construct new and expanded water supply or wastewater treatment facilities, the construction of which could result in significant environmental effects.	Less than significant	Significant and unavoidable[c]
LSJR Alternative 3	Surface water diversion reductions on the Stanislaus, Tuolumne, and Merced Rivers are expected to be approximately 12 percent, 14 percent and 16 percent, respectively. Further, as a result of the substantial reduction of surface water supply on the rivers, it is expected that there would be a substantial depletion of groundwater supplies in the Modesto, Turlock, and Extended Merced Subbasins. These reductions would potentially require service providers to construct new and expanded water supply or wastewater treatment facilities, the construction of which could result in significant environmental effects.	Significant and unavoidable	Significant and unavoidable

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
LSJR Alternative 4	Surface water diversion reductions on the Stanislaus, Tuolumne, and Merced Rivers are expected to be approximately 32 percent, 35 percent, and 32 percent, respectively. Further, as a result of the substantial reduction of surface water supply on the rivers, it is expected that there would be a substantial depletion of groundwater supplies in the Eastern San Joaquin, Modesto, Turlock, and Extended Merced Subbasins. These reductions would potentially require service providers to construct new and expanded water supply or wastewater treatment facilities, the construction of which could result in significant environmental effects.	Significant and unavoidable	Significant and unavoidable
SDWQ Alternative 2	The Cities of Stockton and Tracy, and Mountain House CSD, may need to construct new wastewater treatment facilities or expand existing facilities to comply with potential changes to NPDES effluent limitation implementing a 1.0 dS/m salinity objective, the construction of which could result in significant environmental effects.	Significant and unavoidable	NA
SDWQ Alternative 3	The construction of new wastewater treatment facilities is not expected in order to comply with changes to NPDES effluent limitations implementing a 1.4 dS/m objective for salinity. As such, construction would not occur and would not result in significant environmental effects.	Less than significant	NA

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
Impact SP-2a: Violate any water quality standards such that drinking water quality from public water systems would be affected			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note.[b]	Less than significant	NA
LSJR Alternative 2	Because service providers and irrigation districts relying primarily on surface water would not need to supplement their supply with groundwater under LSJR Alternative 2, there would likely be no degradation of groundwater quality. If an increase in the February–June percent of unimpaired flow from 20 percent up to 30 percent were implemented on a long-term basis, increased groundwater pumping and reductions in groundwater levels in the Extended Merced Subbasin could affect groundwater quality. However, a substantial increase in groundwater pumping would not necessarily result in violation of water quality standards for drinking water because recent data do not indicate increased water quality standard violations in public water systems despite greatly increased groundwater pumping, and if a drinking water quality problem is detected, action would be taken (as covered under Impact SP-1) to improve water quality. Therefore, impacts would be less than significant. During some months, salinity in the SJR at Vernalis and in the southern Delta channels may increase slightly, but on average, salinity is expected to be reduced; therefore, a substantial degradation of water quality affecting service providers diverting drinking water from the southern Delta would not occur, and impacts would be less than significant.	Less than significant	Less than significant
LSJR Alternatives 3 and 4	As a result of increased groundwater pumping, reductions in groundwater levels in the Modesto, Turlock, and Extended Merced Subbasins under LSJR Alternative 3, and also in the Eastern San Joaquin Subbasin under LSJR Alternative 4 with adaptive implementation method 1 could affect groundwater quality. However, a substantial increase in groundwater pumping would not necessarily result in an increase in violation of water quality standards for drinking water because recent data do not indicate increased water quality standard violations in public water systems despite greatly increased	Less than significant	Less than significant

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
	groundwater pumping, and if a drinking water quality problem is detected, action would be taken (as covered under Impact SP-1) to improve water quality. Salinity in the SJR at Vernalis and in the southern Delta channels is expected to be reduced; therefore, a substantial degradation of water quality affecting service providers diverting drinking water from the southern Delta would not occur. Therefore, impacts would be less than significant.		
SDWQ Alternatives 2 and 3	The USBR water rights permits will continue to include requirements to meet the current 0.7 EC April–August Vernalis salinity standard, as contained in the program of implementation. This would maintain the historical range of salinity in the southern Delta. Therefore, a substantial degradation of water quality affecting service providers diverting drinking water from the southern Delta would not occur.	Less than significant	NA
Impact SP-2b: Violate any water quality standards such that drinking water quality from domestic wells would be affected[c]			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note. [b]	Less than significant	NA
LSJR Alternative 2	Because service providers and irrigation districts relying primarily on surface water would not need to supplement their supply with groundwater under LSJR Alternative 2, there would likely be no degradation of groundwater quality. If an increase in the February–June percent of unimpaired flow from 20 percent up to 30 percent were implemented on a long-term basis, increased groundwater pumping and reductions in groundwater levels in the Extended Merced Subbasin could affect groundwater quality. Domestic well users are largely unregulated and are under no state requirements to monitor, test, and treat their water to meet the state and federal Safe Drinking Water Act. There is no required mechanism to prevent private domestic wells from using groundwater that may exceed MCLs. Therefore, impacts would be significant under LSJR Alternative 2, with adaptive implementation.	Less than significant	Significant and unavoidable

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
LSJR Alternatives 3 and 4	As a result of increased groundwater pumping, reductions in groundwater levels in the Modesto, Turlock, and Extended Merced Subbasins under LSJR Alternative 3, and also in the Eastern San Joaquin Subbasin under LSJR Alternative 4 with adaptive implementation method 1 could affect groundwater quality. Domestic well users are largely unregulated and are under no state requirements to monitor, test, and treat their water to meet the state and federal Safe Drinking Water Act. There is no required mechanism to prevent private domestic wells from using groundwater that may exceed MCLs. Therefore, impacts would be significant.	Significant and unavoidable	Significant and unavoidable
Impact SP-3: Result in substantial changes to SJR inflows to the Delta such that insufficient water supplies would be available to service providers relying on Central Valley Project (CVP)/State Water Project (SWP) exports			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note.[b]	Less than significant	NA
LSJR Alternative 2	Inflows would generally remain similar to baseline, which would result in an estimated average increase in exports of 18 TAF/y to the CVP and SWP export service areas. Therefore, insufficient water supplies to service providers relying on exports would not occur and would not require or result in the construction of new water supply facilities or wastewater treatment facilities or the expansion of existing facilities.	Less than significant	Less than significant
LSJR Alternative 3	Inflows would generally increase relative to baseline, which would result in an estimated average increase in exports of 76 TAF/y to the CVP and SWP export service areas. Therefore, insufficient water supplies to service providers relying on exports would not occur and would not require or result in the construction of new water supply facilities or wastewater treatment facilities or the expansion of existing facilities.	Less than significant	Less than significant

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
LSJR Alternative 4	Inflows would generally increase relative to baseline, which would result in an estimated average increase in exports of 194 TAF/y to the CVP and SWP export service areas. Therefore, insufficient water supplies to service providers relying on exports would not occur and would not require or result in the construction of new water supply facilities or wastewater treatment facilities or the expansion of existing facilities.	Less than significant	Less than significant

CVP = Central Valley Project
DDW = Division of Drinking Water
dS/m = deciSiemens per meter (1 dS/m = 1000 µS/cm)
MCLs = maximum contaminant levels
NA = not applicable
NPDES = National Pollution Discharge Elimination System
SWP = State Water Project
TAF/y = thousand acre-feet per year
USBR = U.S. Bureau of Reclamation

[a] Four adaptive implementation methods could occur under the LSJR alternatives, as described in Chapter 3, *Alternatives Description*, and summarized in Section 13.4.2, *Methods and Approach*, of this chapter.

[b] The No Project Alternative (LSJR/SDWQ Alternative 1) would result in implementation of flow objectives and salinity objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

[c] Salinity in the SJR at Vernalis and in the southern Delta is not relevant to groundwater and drinking water quality from domestic wells and, therefore, there would be no impact from the changes in salinity in these surface waters. This topic is not discussed further in Impact SP-2b.

13.2 Environmental Setting

This section characterizes the area of potential effects considered for the service providers impact analysis, which includes the plan area, the four groundwater subbasins as described in Chapter 9, *Groundwater Resources,* and those areas that receive water from the surface waters. This section provides information regarding the different service providers and the services provided by the water bodies in the area of potential effects. Numerous service providers rely on the water bodies in the area of potential effects for beneficial uses, such as irrigation and municipal and industrial supply. Services providers also use the water bodies as receiving waters in which to discharge treated wastewater effluent generated by residential, municipal, and industrial (i.e., domestic) uses in service districts in the area of potential effects.

13.2.1 Lower San Joaquin River and Tributaries

Service providers in the area of potential effects obtain their water supplies by either diverting surface water from the three eastside tributaries[5] or pumping groundwater from aquifers. These different sources of water and the service providers that rely on them are discussed below.

Surface Water and Service Providers

Five irrigation districts receive surface water from the Stanislaus, Tuolumne, and Merced Rivers and primarily supply agricultural uses with irrigation (Table 13-2). Descriptions and characteristics of the irrigation districts are provided in Chapter 2, *Water Resources* (Sections 2.3, 2.4, and 2.5). Some of the irrigation districts have contracts or agreements with other water users, such as water districts or conservation districts. The other water users provide water supply for both agricultural uses and municipal uses. These irrigation districts and the other water users are listed in Table 13-2.

Irrigation districts obtain the majority of their water supply from surface water diversions. The other water users primarily rely on groundwater or a combination of groundwater and surface water as their sources of water. Figure 13-1a identifies the location of the service providers that rely primarily or partially on surface water.

Groundwater and Service Providers

Groundwater is a vital resource in California. Typically, groundwater supplies approximately 30 percent of California's urban and agricultural uses. In dry years, groundwater use increases to approximately 40 percent statewide and 60 percent or more in some regions (DWR 2003). Drought conditions typically result in an increase of groundwater well activity and pumping to compensate for surface water supply shortages (DWR 2014). As a result of increased pumping in the recent drought, groundwater levels have decreased in many basins throughout the state since spring 2010. Basins with notable decreases in groundwater levels are in the Sacramento River, SJR, Tulare Lake, San Francisco Bay, Central Coast, and South Coast Hydrologic Regions (DWR 2014).

---

[5] In this document, the term *three eastside tributaries* refers to the Stanislaus, Tuolumne, and Merced Rivers.

Table 13-2. Primary Surface Water Diverters and Other Water Users

Tributary River	Primary Surface Water Diverters	Other Water Users
Stanislaus[a]	OID, SSJID[b]	SEWD,[c] CSJWCD,[d] Tracy, Manteca, Lathrop, Ripon, Escalon
Tuolumne	MID, TID[e]	Modesto, CCSF[f]
Merced	Merced ID[g]	LeGrand Athlone Water District,[h] El Nido Irrigation District,[h] Stevinson Water District, Eastside Water District,[I] Lake Don Pedro CSD[j]

OID = Oakdale Irrigation District
SSJID = South San Joaquin Irrigation District
SEWD = Stockton East Water District
CSJWCD = Central San Joaquin Water Conservation District
MID = Modesto Irrigation District
TID = Turlock Irrigation District
CCSF = City and County of San Francisco
Merced ID = Merced Irrigation District
CSD = Community Services District

[a] U.S. Bureau of Reclamation (USBR) is contracted to provide surface water to SEWD and CSJWCD.

[b] SSJID and OID jointly hold contract rights with USBR to divert 600 thousand acre-feet (TAF). The primary use of the surface water diversions in the SSJID and OID service areas is agriculture; however, there are some water districts that are contracted with SSJID to provide water to municipal users.

[c] SEWD provides water to CalWater Services Company and Stockton Municipal Utilities District. The County of San Joaquin receives less than 2,000 acre-feet per year (AF/y) from SEWD.

[d] Although CSJWCD receives surface water from USBR, its primary water source is groundwater (San Joaquin County Department of Public Works 2004.)

[e] TID and MID customers primarily use water for agricultural irrigation, although some treated surface water is delivered to the City of Modesto.

[f] CCSF has agreements with MID and TID to provide carryover storage in New Don Pedro Reservoir. CCSF does not divert water directly from New Don Pedro Reservoir but owns the right to store up to 740 TAF of water in the reservoir. The 740-TAF water right is senior to TID and MID water rights. The current CCSF demand for water is approximately 290 TAF.

[g] Merced ID is the primary water diverter on the Merced River. Merced ID uses the surface water from the Merced River primarily for agricultural irrigation.

[h] LeGrand Athlone Water District and El Nido Irrigation District are within the sphere of influence of Merced ID, and El Nido Irrigation District was incorporated into Merced ID service area prior to 2008 (AMEC 2008).

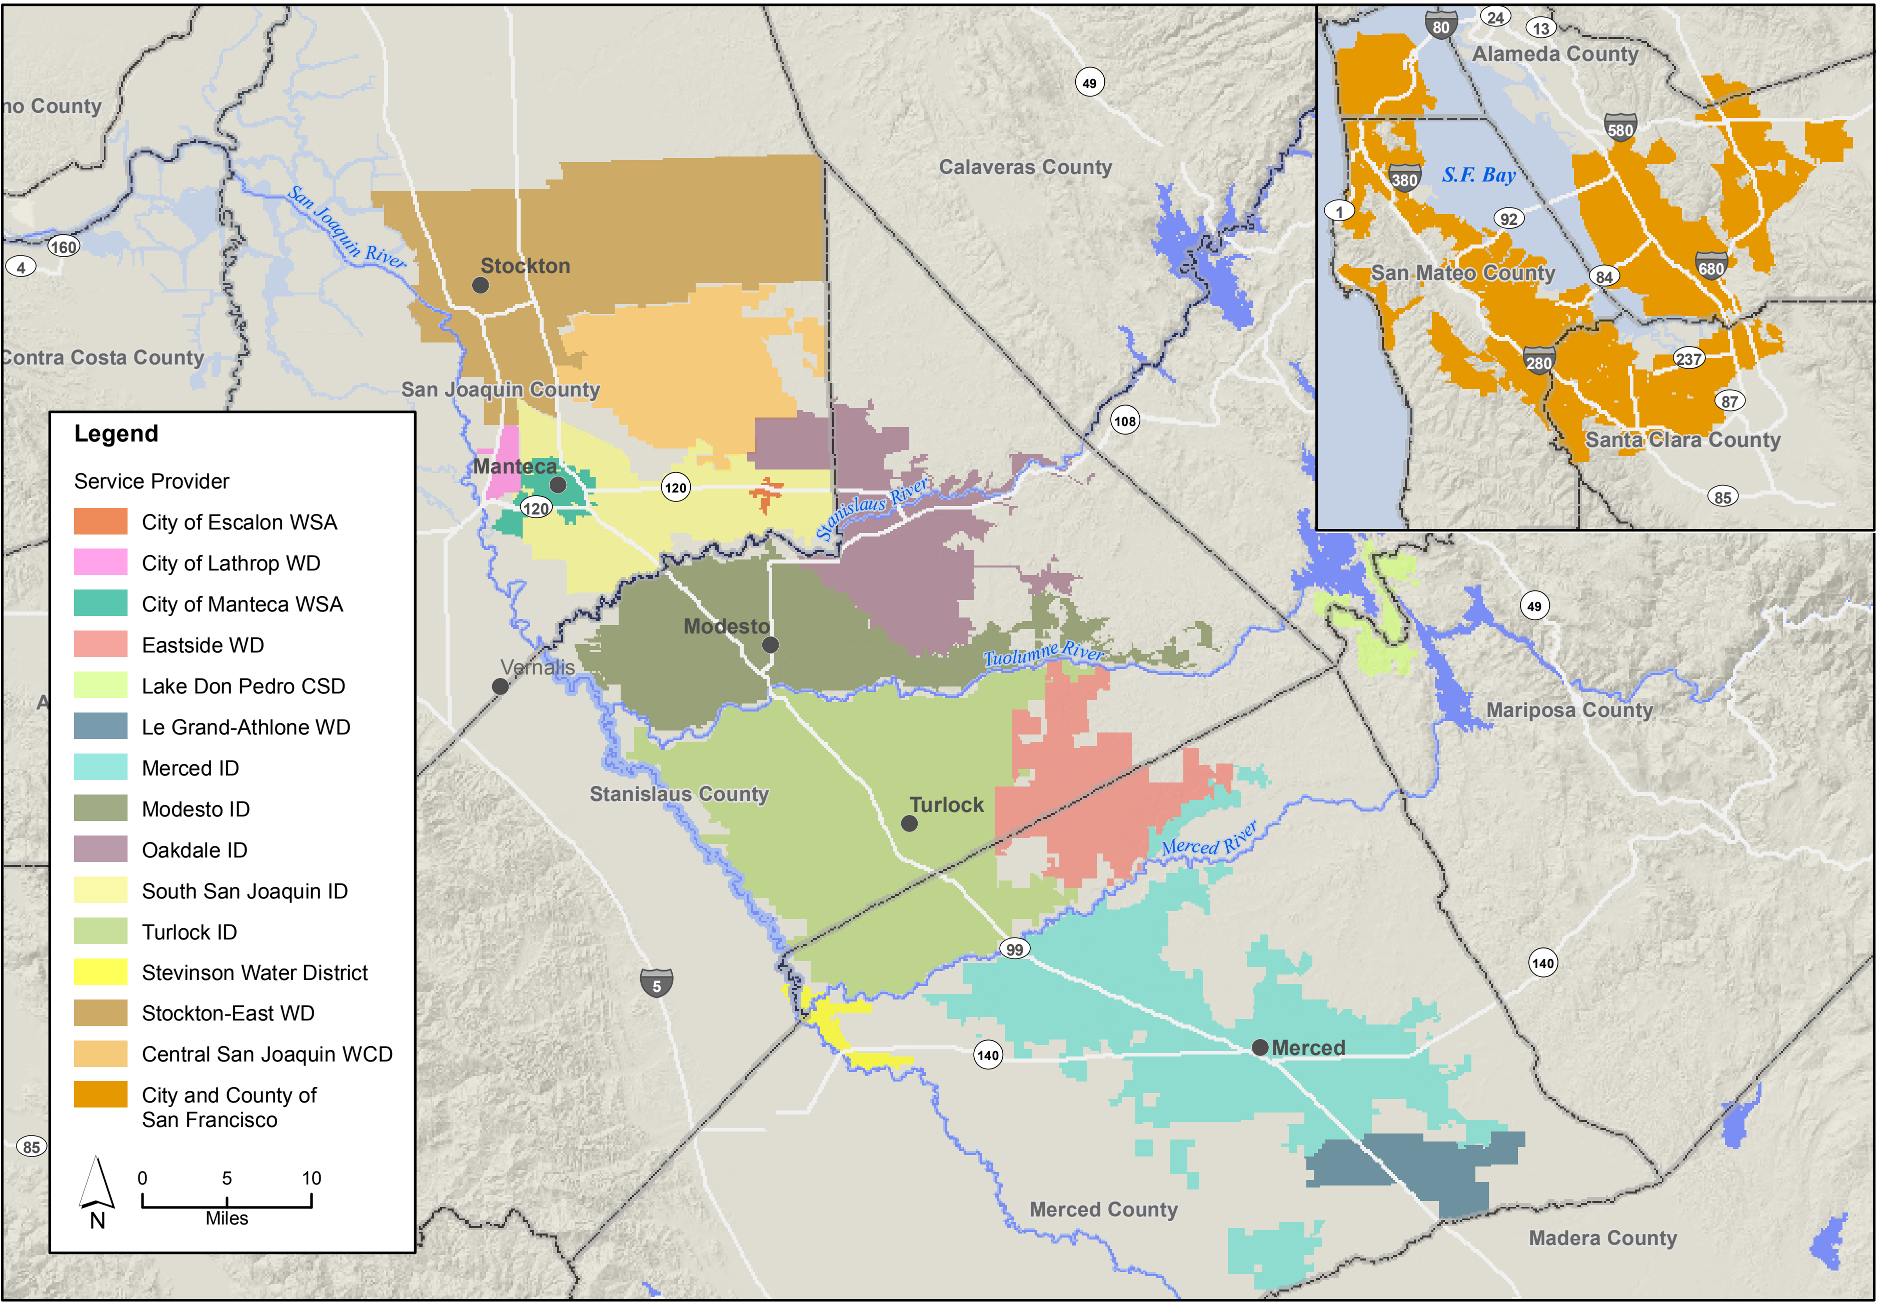
[i] Eastside Water District receives limited amounts of surface water from Merced ID only during wet years (TGBA 2008).

[j] Lake Don Pedro Community Services District can withdraw up to approximately 5,000 AF/y from Lake McClure (Merced ID 2013).

As described in Chapter 9, *Groundwater Resources*, Section 9.2.2, *Subbasin Groundwater Use*, there are four main groundwater subbasins in the area of potential effects—the Eastern San Joaquin, Modesto, Turlock, and Extended Merced. Approximately 1,248,000 people live in areas overlying these four subbasins (U.S. Census Bureau 2010), and of this population, approximately 1,115,000 people, or 89 percent, receive some portion of their water supply from a public water supplier (California Environmental Health Tracking Program 2016). The remaining 11 percent, equivalent to approximately 133,000 people in the four main groundwater subbasins, rely solely on domestic[6] (i.e., private) wells for their water supply (Johnson and Belitz 2015). However, given the

---

[6] For the purposes of this chapter, *municipal wells* refer to wells owned by public water suppliers, and domestic wells are private wells owned by individuals/households.



K:\Projects_2\SWRCB\00427_11_SJ_River\mapdoc\Fig_13_1a_Vicinity_20160329.mxd Date: 9/12/2016 Time: 11:54:46 AM 19393

incomplete records for private wells, it is difficult determine the actual number of people currently relying on private wells.

As shown in Table 13-3a (at the end of this chapter), 93 public water suppliers are identified within the four groundwater subbasins. Many of these water suppliers rely heavily or primarily on groundwater for municipal use. Table 13-3b identifies a subset of those public water suppliers listed in Table 13-3a. These are generally representative of the public water suppliers listed in Table 13-3a and well depth information could be obtained through the State Water Board's Division of Drinking Water (DDW) for this subset. Table 13-3b includes information regarding the size of the population served the water suppliers in 2014, the number of active wells owned by the suppliers in 2014, the percentage of groundwater supply reliance, the range of depths of the wells, and the range of depths to groundwater[7] at the wells. Figure 13-1b shows those service providers identified in Table 13-3b that rely solely on groundwater. Although information on private wells is limited, 66 domestic wells with well depth information were identified within the four groundwater subbasins based on information extract from the California Statewide Groundwater Elevation Monitoring (CASGEM) program (DWR 2015). The depth for these 66 wells ranges from 48 to 580 feet. Figure 13-2 shows the location of municipal and domestic wells relative to the groundwater subbasins and the irrigation districts in the area of potential effects.

Surface Water Quality

As discussed in Chapter 5, *Surface Hydrology and Water Quality*, the water quality of the Stanislaus, Tuolumne, and Merced Rivers is primarily dictated by reservoir operations and agricultural return flow. Electrical conductivity[8] (EC) generally increases as water moves downstream in all three rivers because of the relatively high EC in agricultural drainage and groundwater discharge to the river. Chloride, bromide, sulfate, and boron are specific ions that contribute to overall salinity and are constituents of concern. However, of these constituents of concern in the area of potential effects, only boron is included on California's statewide list of impaired waterbodies (the 303[d] lists). Table 5-4 shows the constituents identified in the Section 303(d)[9] list for impaired waters in the plan area and other areas. The Tuolumne River, for example, is identified on the 303(d) list for constituents associated with agricultural uses, such as pesticides (chlorpyrifos, diazinon, DDT), and temperature (State Water Board 2011). Salinity can affect multiple beneficial uses, including the yield of crops that are sensitive to these constituents. Additionally, high EC values in source water may limit the ability to utilize recycled water. The presence of bromide in municipal water sources is also a concern because bromide is the precursor to the formation of harmful byproducts of the water disinfection process. However there are no 303(d) listings for bromide.

---

[7] The depth to groundwater refers to depth to the top of the aquifer.

[8] In this document, EC is *electrical conductivity*, which is generally expressed in deciSiemens per meter (dS/m). Measurement of EC is a widely accepted indirect method to determine the salinity of water, which is the concentration of dissolved salts (often expressed in parts per thousand or parts per million). EC and salinity are therefore used interchangeably in this document.

[9] Clean Water Act section 303(d) requires states, territories, and authorized tribes to develop a ranked list of water quality limited segments of rivers that do not meet water quality standards.

CSD = Community Services District
SEWD = Stockton East Water District
WD = Water District
WSD = Water and Sanitary District

[a] Range of depths to groundwater at the locations of the active wells owned by the public water supplier.

[b] Range of difference between well depths and depths to groundwater.

[c] Gray-shaded cells indicate that the difference between the depth of a well owned by the supplier and depth to groundwater at that well is less than 100 feet, which indicates that the well is potentially at a higher risk of running dry in the future.

[d] SEWD does not supply water to individual customers. SEWD sells water wholesale to different agencies. The 50 people that the water district serves are the employees working in its water treatment plant.

[e] SEWD had been relying solely on surface water between 2010 and 2014. In 2015, for the second consecutive year, SEWD did not receive their contracted water supply allocation from USBR due to lack of available CVP supplies resulting from severe drought conditions (Association of California Water Agencies 2015; SEWD 2016). Accordingly, SEWD reactivated the district's two inactive wells, built a new well and converted two old irrigation wells into drinking water wells (Sahota pers. comm.). The number of active wells in 2015 was five.

[f] As described in Chapter 9, *Groundwater Resources*, the Extended Merced Subbasin includes a portion of the Chowchilla Subbasin.

[g] Depth to groundwater data available only for one of three groundwater wells.

[h] Although the City of Tracy is not located in the four subbasins, it is within the area of potential effects because it receives water from SSJID and can be affected by the LSJR alternatives. Therefore, it is included in this table.

Groundwater Quality

As discussed in Chapter 9, *Groundwater Resources*, groundwater quality varies substantially throughout the San Joaquin Valley Groundwater Basin. In general, groundwater throughout the SJR region is suitable for most urban and agricultural uses. Groundwater in shallower aquifers generally contains higher concentrations of anthropogenic contaminants, such as nitrates and pesticides, than in deeper aquifers (DWR 2013). In addition to agricultural and industrial sources, trace elements (such as arsenic, manganese, vanadium and uranium) that are naturally occurring in rocks and soils can come in contact with the water and present water quality problems.

The Priority Basin Project of the Groundwater Ambient Monitoring and Assessment Program (GAMA) (Section 13.3.2, *State [Regulatory Background])* provides a comprehensive assessment of the state's groundwater quality. Two study units of the Priority Basin Project include the four groundwater subbasins that are subject to the LSJR alternatives: the Northern San Joaquin Valley (NSJ) study unit that includes the Eastern San Joaquin Subbasin and the Central Eastside study unit, which includes the Modesto, Turlock, and Extended Merced Subbasins[10].

In the NSJ study unit, one or more inorganic constituents (i.e., trace elements and nutrients, such as nitrate and nitrite) were detected at high concentrations in approximately 13 percent of the primary aquifers and at moderate concentrations in approximately 29 percent. The rest of the primary aquifers (58 percent) had low or no detections of inorganic constituents. Common sources of nutrients include fertilizers used in farming, seepage from septic systems, and human and animal waste. In the NSJ study unit, nutrients were present at high and moderate concentrations in approximately 2 and 9 percent of the primary aquifers, respectively (USGS and State Water Board 2010a). One or more organic constituents (i.e. volatile organic compounds [VOCs] and pesticides) were detected at high concentrations in approximately 3 percent of the primary aquifers and at moderate concentrations in approximately 7 percent. The remaining primary aquifers (90 percent) had low or no detections of organic constituents (USGS and State Water Board 2010a). VOCs are present in many household, commercial, industrial, and agricultural products, and are characterized by their tendency to volatilize into the air. Pesticides (herbicides, insecticides, and fumigants) are applied to crops, gardens, lawns, around buildings, and along roads to help control weeds, insects, fungi, and other pests. In the NSJ study unit, fumigants were detected at high concentrations in approximately 3 percent of the primary aquifers, and at moderate concentrations in approximately 3 percent. Herbicides and insecticides were detected at low concentrations in the primary aquifer (USGS and State Water Board 2010a).

In the Central Eastside study unit, one or more inorganic constituents were detected at high concentrations in 18 percent of the primary aquifer and at moderate concentrations in 44 percent. The rest of the primary aquifers (38 percent) had low or no detections of inorganic constituents (USGS and State Water Board 2010b). Nitrate was detected at high concentrations in approximately 2 percent of the primary aquifers and at moderate concentrations in approximately 15 percent of the primary aquifer. Concentrations of nitrate were low in the rest of the primary aquifers (83 percent) in the Central Eastside study unit. One or more organic constituents were detected at high concentrations in 1 percent of the primary aquifer and at moderate concentrations in

---

[10] As described in Chapter 9, *Groundwater Resources*, the Merced Subbasin was extended for the analysis to include a part of the Chowchilla Subbasin.

14 percent. The rest of the primary aquifers (85 percent) had low or no detections of organic constituents (USGS and State Water Board 2010b). In the Central Eastside, the fumigant dibromochloropropane (DBCP)[11] was detected at high concentrations in approximately 1 percent of the primary aquifers, at moderate concentrations in approximately 8 percent of the primary aquifer, and at low or not detected in approximately 91 percent (USGS and State Water Board 2010b).

Salinity, measured as total dissolved solids (TDS) or EC, in the four subbasins is relatively low, while elevated salinity levels are common in San Joaquin Valley groundwater (DWR 2003a). Salinity is generally lower on the eastern side of the San Joaquin Valley Groundwater Basin than on the western side, and is generally higher in the shallow aquifer than the deep aquifer. The relatively low groundwater salinity on the eastern side can be attributed to the low salinity of Sierra Nevada runoff and application of surface water as a major irrigation source in the subbasins. However, there are some localized issues. For example, increased levels in groundwater salinity have been detected in the Stockton area due to a lateral saline front to the west (NSJCGBA 2004). In the Merced Groundwater Basin, high TDS concentrations are principally the result of the migration of a deep saline water body that originates in regionally deposited marine sedimentary rocks that underlie the San Joaquin Valley. Under natural pressure, the saline groundwater body is migrating upward. But pumping by deep wells in the western and southern parts of the Extended Merced Subbasin may be causing these saline brines to upwell and mix with fresh water aquifers more rapidly than under natural conditions (MAGPI 2008).

Quality of Groundwater as a Source of Drinking Water

It is estimated that 85 percent of California's community public water systems,[12] supplying more than 30 million residents, rely on groundwater for at least part of their drinking water supply (State Water Board 2013a). In addition, approximately 2 million Californians rely on groundwater from either private domestic wells or other groundwater-reliant systems not regulated by the state. Due to California's reliance on groundwater, and because many community water systems are entirely reliant on groundwater for their drinking water supply, contamination of this resource can have far-reaching consequences. Pursuant to the requirements of AB 2222 (Caballero, Chapter 670, Statutes of 2008), in 2013 State Water Board submitted a report to the legislature that identified: (1) communities in California that rely on contaminated groundwater as a primary source of drinking water, (2) the principal contaminants and other constituents of concern, and (3) potential solutions and funding sources to clean up or treat groundwater in community public water systems or provide alternative water supplies.

The report identifies that approximately one-fifth of California's groundwater-reliant community water systems, prior to any treatment, used a contaminated groundwater source between 2002 and 2010. During this period, of the 510 active wells (serving 148 community water systems) within the four subbasins, 134 active wells (serving 54 community water systems) had two or more MCL exceedances (State Water Board 2013a). It is important to note that these findings reflect raw, untreated groundwater quality and not necessarily the quality of the water that is eventually served to the public. Community water systems that rely on contaminated groundwater typically treat their well water before it is delivered and consumed. However, in some cases, when a community cannot

---

[11] Use of DBCP as a soil fumigant was discontinued in California in 1977.

[12] A *community public water system* (community water system) serves at least 15 service connections used by yearlong residents or regularly serves at least 25 yearlong residents. Community water systems are regulated by the state.

afford treatment or alternative sources of water are not available, contaminated water is served to the public until a solution is implemented. Over 98 percent of Californians on a public water supply are served safe drinking water (State Water Board 2013a).

The report also identifies 31 principal contaminants[13] in the community water systems that rely on a contaminated groundwater source. The 10 most frequently detected principal contaminants, summarized in Table 13-4, were found in over 90 percent of the contaminated groundwater wells prior to treatment. Twenty-one of the 31 principal contaminants detected in community water system wells are anthropogenic in origin. Some principal contaminants were more frequently detected within certain regions of the state, while other principal contaminants were found statewide. In general, naturally occurring contaminants are detected statewide, while anthropogenic contaminants tend to be detected in particular regions of the state. For example, arsenic (naturally occurring) is detected in a wide distribution of community water system wells across the state. In contrast, nitrate (anthropogenic) is predominantly detected above the MCL in areas of the state with current or historical agricultural activity, including the southern San Joaquin Valley, the Salinas Valley, and in the Southern California Inland Empire (State Water Board 2013a).

Table 13-4. Ten Most Frequently Detected Principal Contaminants Identified in State Water Board 2013a

Principal Contaminant	Number of Wells[a]	Type of Contaminant[b]
Arsenic	587	Naturally occurring
Nitrate	451	Anthropogenic nutrient
Gross alpha activity	333	Naturally occurring
Perchlorate	179	Industrial/Military use
Tetrachloroethylene (PCE)	168	Solvent
Trichloroethylene (TCE)	159	Solvent
Uranium	157	Naturally occurring
1,2-dibromo-3-chlropropane (DBCP)	118	Legacy pesticide
Fluoride	79	Naturally occurring
Carbon tetrachloride	52	Solvent

Source: State Water Board 2013a.

[a] This is the number of wells in which the contaminant was detected,

[b] Also can be naturally occurring, but typically at levels below the MCL

As shown in Table 13-4, nitrate is the second most frequently detected principal contaminant in groundwater, and at concentrations above its drinking water standard MCL of 45 milligrams per liter (mg/L), it is considered anthropogenic, making it the most frequently detected anthropogenic chemical above an MCL in drinking water sources. Agricultural fertilizers and animal wastes applied to cropland are major sources of nitrate in groundwater. Hence, nitrate is often used as an indicator of agricultural impact on groundwater quality. Nitrate is one of California's most prevalent groundwater contaminants, and can pose significant health risks at concentrations above the MCL (State Water Board 2013b). Harter et al. (2012) found that travel times of nitrate from source to wells range from a few years to decades in domestic wells, and from years to many decades and

---

[13] A *principal contaminant* is a chemical detected in a groundwater source sample above a primary MCL on two or more occasions during the most recent CDPH compliance cycle (2002–2010).

even centuries in deeper production wells. This means that elevated nitrate concentration in groundwater will remain high for a long time even if nitrate application is reduced today, and that reduction efforts are essential for any long-term improvement of drinking water sources.

Groundwater Quality and Over-Pumping

As discussed above, over pumping of groundwater has been depleting the groundwater resources in the San Joaquin Valley. One impact of over-drafting groundwater is degradation of groundwater quality. Prior to any development, natural recharge to, and discharge from, the groundwater system was in a dynamic steady state, and the groundwater table was stable. When a well is built and water is pumped from the aquifer, a cone of depression will be created at the well and the water table will be lowered. When pumping is stopped, subsequent recharge will allow the water level to rise, and the groundwater table is restored. If pumping continues, the groundwater level will decline and continue to do so until it stabilizes at a new, lower level. If pumping is persistently greater than recharge, the aquifer will eventually be dewatered. Lowering the groundwater table will alter the direction and rate of the groundwater flow and create a hydraulic gradient between the well and surrounding saturated zone. This can affect groundwater quality in the following ways.

1. Migration of surface contaminants to the well. Contaminants introduced at the land surface that infiltrate into the water table can flow towards the well. Contaminated shallow groundwater will also move downward within the aquifer and, eventually, into the zone of drinking water wells. Sources of chemicals introduced to ground water in this way include fertilizers, manure, and pesticides applied to agricultural lands; landfills; industrial-discharge lagoons; leaking gasoline storage tanks; cesspools and septic tanks; and domestically used chemicals. The slow movement of water from the surface through the unsaturated zone to deep aquifers means that it may be many years after a persistent chemical has entered the ground before it affects the quality of groundwater supplies (Morris et al. 2003; Harter et al. 2012). For example, while the San Joaquin Valley is not characterized by high concentrations of nitrates at the depth zone used for public supply, application of fertilizers and animal manure to agricultural land has caused downward movement of nitrates into the soil. As groundwater pumping continues and as irrigation water containing elevated concentrations of nitrate moves toward and through deeper parts of the aquifer, high concentrations of nitrates in the public water supply could be a concern in the future (Belitz et al. 2015).

2. Saline water intrusion. Under natural conditions the boundary between the freshwater and saltwater tends to be relatively stable, but pumping can cause saltwater to migrate inland and upward, resulting in saltwater contamination of the aquifer. Saltwater intrusion is an important consideration for aquifers adjacent to the coast or other saline bodies. The mobility of such saline waters depends upon the hydraulic gradients, permeability of the aquifer and the presence or absence of hydraulic barriers (Morris et al. 2003). Serious saline intrusion is confined to relatively few hydrogeological settings, but these are not necessarily coastal as paleo-saline waters may occur in inland aquifers at depth (Morris et al. 2003).

3. Mobilization of naturally-occurring trace elements such as uranium, arsenic, and radium. Pumping-induced mobilization of those elements has been studied around the world. Although the occurrence of trace elements (e.g., arsenic and uranium) is not anthropogenic, these elements can leach into groundwater and be mobilized by human activities (Smedley and Kinniburgh 2002; Barringer and Reilly 2013). For example, the downward infiltration of irrigation water with elevated bicarbonates caused movement of uranium in an area of the eastern San Joaquin Valley (Belitz et al. 2015).

The processes discussed above can be influenced by many factors, including location and depth of the well, the amount and frequency of groundwater pumping, number and proximity of nearby wells, aquifer characteristics (e.g., consolidated clays with low permeability or unconsolidated sands with high permeability), distance between the well(s) and the contaminant(s), contaminant characteristics (e.g., highly mobile in water or adhering primarily to soil), and land use near the well.

In general, water delivered to the end users from municipal drinking water wells does not exceed federal and state MCLs. This is because municipal wells are generally deep, and water quality tends to be better in deeper aquifers. Furthermore, water quality is managed such that if violation of drinking water standards is found at a public well, the well can be brought offline and corrective actions will be taken to ensure the water meet the MCL requirement again before it is delivered the consumers. For example, DBCP was detected over the MCL at two of the City of Atwater's wells. Granular Activated Carbon filtering systems were installed on these water sources to remove the contaminant prior to introduction of water into the city's water system (City of Atwater 2015). The City of Livingston, located in the Extended Merced Subbasin, recently improved filtration in order to reduce arsenic concentrations that were above the state MCL (Giwargis 2014).

In addition, water quality in community water systems is frequently monitored by the DDW and the service providers pursuant to various regulatory requirements stated in Section 13.3, *Regulatory Background*. As described in Section 13.3.1, *Federal [Regulatory Background]*, community water systems must provide annual drinking water quality reports, known as consumer confidence reports (CCRs), to their customers. Table 13-5 provides information from CCRs of selected municipalities in the groundwater subbasins during representative drought and non-drought years. These municipalities were selected because they are the major groundwater producers and together represent a wide range of total number of wells and locations in all four groundwater subbasins.

Private drinking water wells may have more significant water quality issues than municipal wells because they are often shallower than municipal wells and, therefore, are more susceptible to surface contaminants. However, the state does not regulate the water quality of private drinking water wells and does not require private drinking water well owners to test for water quality. As such, there is no comprehensive dataset on private drinking water quality, and there is a lack of water quality data for private drinking water wells within the area of potential effects.

Table 13-5. Primary Detected Contaminants in Exceedance of Maximum Contamination Level in Drinking Water for Selected Water Suppliers during Representative Non-Drought and Drought Years

		Non-Drought Year (2011)			Drought Year (2014)		
Public Water Supplier	Source of Water	Violation? (Y/N)	Primary Detected Contaminant	Corrective Action	Violation? (Y/N)	Primary Detected Contaminant	Corrective Action
Atwater	groundwater	N	NA	NA	N	NA	NA
Manteca	groundwater and surface water	Y	Arsenic in exceedance of the MCL (10 ppb) was detected in groundwater.[a]	Filters were installed to remove arsenic from wells where MCL was exceeded. Maximized water production from sources with low arsenic levels.	N	NA	NA

Source: City of Manteca 2012a and 2014; City of Merced 2011 and 2015; City of Modesto 2011 and 2014; City of Stockton 2011a and 2014; City of Turlock 2011 and 2014; City of Atwater 2011 and 2015; City of Riverbank 2011 and 2014; SEWD 2014.

SEWD = Stockton East Water District
MCL = maximum contaminant level
ppb = parts per billion
ppm = parts per million
NA = not applicable

[a] The U.S. Environmental Protection Agency reduced the MCL for arsenic from 50 ppb down to 10 ppb in 2001. This new MCL (10 ppb) became enforceable in January 2006. Water systems that are in violation of this MCL must include a health effects statement in their consumer confidence reports covering calendar year 2006 and beyond.

13.2.2 Extended Plan Area

There are 55 public water suppliers identified in the extended plan area (State Water Board 2016a; State Water Board 2016b; CEHTP 2016). Of these 55, 44 suppliers rely completely on groundwater and three have pre-1914 or riparian rights (State Water Board 2016a) and, as such, are not expected to be affected by water supply bypasses in the extended plan area. Twelve (identified in Table 13-6) of these 55 service providers have post-1914 water rights and rely on surface water diversions (State Water Board 2016a). The total annual water production by the 55 service providers in 2014 was 9.85 TAF, of which 7.61 TAF was produced by the 12 service providers listed in Table 13-6.

Table 13-6. Annual Water Use of Service Providers in the Extended Plan Area with Post-1914 Water Rights

Service Providers	Water Production in 2014 (TAF)
Calaveras County Water District (Copper Cove)	1.25
Calaveras County Water District (Ebbetts Pass)	1.50
City of Angels Camp	0.99

13.2.3 Southern Delta

Many factors influence southern Delta water quality, such as the amount and salinity concentration of SJR flow entering the southern Delta at Vernalis; daily tidal action; CVP and SWP pumping operations; agricultural return flows; municipal wastewater discharges; and other influences. Chapter 2, *Water Resources* (Section 2.7, *Southern Delta*) and Chapter 5, *Surface Hydrology and Water Quality* (Section 5.2.8, *Southern Delta*) also provide additional information regarding southern Delta hydrodynamics. The sections below summarize the information found in these two chapters and provide additional information that describes the southern Delta's water quality (salinity) objectives, the factors that affect its existing salinity, the wastewater treatment plants (WWTPs) that discharge into the southern Delta and their effluent limitations, and the water suppliers that use the southern Delta as a source for drinking water.

Water Quality Objectives

The 2006 *Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary* (2006 Bay-Delta Plan) identifies specific water quality objectives for EC, a primary indicator of salinity, for the southern Delta, for the protection of agricultural beneficial uses. The 2006 Bay-Delta Plan and the objectives are fully described in Section 13.3.2, *State [Regulatory Background]*, of this chapter. The numeric objectives for the southern Delta are as follows and are monitored at four compliance stations (SJR at Vernalis [C-10], SJR at Brandt Bridge [C-6], Old River near Middle River [C-8], and Old River at Tracy Boulevard Bridge [P-12]).

- 0.7 dS/m during the summer irrigation season (April–August).
- 1.0 dS/m during the winter season (September–March).

Water quality standards for drinking water are discussed below.

Existing Salinity

Salinity levels in the southern Delta are affected by complex hydrodynamics, including: inflow from the SJR at Vernalis; land use activities (e.g., agriculture) and discharges in the southern Delta; the seasons, tidal action, the placement of temporary barriers to reduce the effects of tidal action; the position of the Delta cross channel gates; and CVP and SWP exports.

The LSJR delivers water of relatively poor quality to the Delta, with agricultural drainage to the river being a major source of salts. Flow at Vernalis is typical of the inflow that the SJR contributes to the southern Delta. There is a strong relationship between the salinity concentrations at Vernalis and the salinity concentrations at Brandt Bridge and Old River at Middle River under most conditions (Appendix F.2, *Evaluation of Historical Flow and Salinity Measurements of the Lower San Joaquin River and Southern Delta)*. The salinity concentrations in the southern Delta typically increase slightly from agricultural drainage and treated effluent discharges to the southern Delta downstream of Vernalis.

Salinity also varies greatly in the southern Delta with the seasons and the tides. Winter salinity is mostly influenced by runoff from agricultural fields, while fall salinities tend to be influenced by seawater intrusion. The tides also influence the salinity by enhancing mixing. Generally, when temporary barriers are installed, tidal exchange is reduced. The temporary rock barriers (Old River Barrier near Delta-Mendota Canal, Middle River Barrier, and Grant Line Canal Barrier) are generally installed during the spring and removed in the fall (late September–November). Salinity in the southern Delta during lower flow periods can increase as a result of other sources (e.g., discharge of agricultural drainage, discharge of WWTPs).

An additional barrier, the Head of Old River Barrier (HORB), is occasionally installed during the spring to block passage of migrating fish into Old River. When installed, it reduces the normal diversion of SJR flow into Old River and the majority of the LSJR flows north to the Stockton Deep Water Ship Channel. However, some of the LSJR flow is drawn through Turner Cut and Middle River and Victoria Canal toward the CVP and SWP pumping facilities. The volume of water exported at the CVP and SWP can modify salinity concentrations in the southern Delta by affecting the partitioning of net flow through the various Delta channels.

Despite the variable hydrodynamics described above, the measured EC values throughout the southern Delta indicate the monthly patterns of EC are generally below the existing salinity objectives (i.e., 0.7 dS/m during the summer irrigation season [April–August] and 1.0 dS/m during the winter irrigation season [September–March]). The monthly increases in downstream salinity are greatest when the LSJR flow is low because dilution of agricultural drainage and municipal discharge will be less when the LSJR flow is low. Appendix F.2 describes the historical EC values at Vernalis and the interior compliance stations. There have been periodic exceedances in recent dry years at one or more of these southern Delta monitoring stations, but high salinity is not the general pattern. Based on the historical data, the salinity in the southern Delta is generally increased by a maximum of 0.2 dS/m above the Vernalis salinity, although the increment is sometimes higher in Old River at Tracy Boulevard. The existing salinity in the southern Delta generally ranges between 0.2 dS/m and 1.2 dS/m across all months of the year. Compliance with salinity objectives at Vernalis has been consistently achieved over the past 15 years. On average, salinity increases by 0.050 dS/m between Vernalis and Brandt Bridge (Chapter 5, *Surface Hydrology and Water Quality*, and Appendix F.2). The historical salinity increase between Vernalis and Old River at Tracy Boulevard is greater, averaging approximately 0.150 dS/m, with several monthly increases of more than 0.200 dS/m. Thus, when salinity at Vernalis is at the Vernalis EC objective, the salinity in the southern Delta is generally maintained between 0.7 dS/m and 1.2 dS/m (based on the historical monthly EC record).

Wastewater Dischargers

Existing WWTPs discharge treated wastewater effluent into the southern Delta and are considered point sources under the Clean Water Act (CWA). (33 U.S.C., § 1362, subd. (14).) Because treated wastewater effluent is a source of salt, these dischargers influence southern Delta salinity. There are six WWTPs that discharge into or are in the vicinity of the southern Delta, all of which are required to comply with effluent limitations established by National Pollution Discharge Elimination System (NPDES) permits (see Section 13.3.1, *Federal [Regulatory Background]*). These WWTPs, their receiving water bodies, and their total permitted discharge rates are listed in Table 13-7. Figure 2-12 shows the locations of WWTPs, compliance station locations, and nearby drinking water supply intakes.

Table 13-7. Wastewater Treatment Plants with Discharges in the Southern Delta

WWTP Facility	Current NPDES Permit Order Number	Receiving Water	Permitted Discharge (mgd)
Tracy [a]	R5-2012-0115	Old River (upstream of Doughty Cut)	16
Deuel	R5-2014-0014-01	Paradise Cut and Old River	0.62
Manteca [b]	R5-2015-0026	San Joaquin River	17.5
Stockton	R5-2014-0070	San Joaquin River	55
Mountain House CSD [c]	R5-2013-0004	Old River	5.4
Discovery Bay CSD	R5-2014-0073	Old River	2.1

WWTP = wastewater treatment plant
mgd = million gallons per day
NPDES = National Pollutant Discharge Elimination System
CSD = Community Services District

[a] In accordance with *City of Tracy v. State Water Board,* the existing southern Delta salinity objectives are not applied to Tracy and other municipal dischargers pending reconsideration of the southern Delta salinity objectives under Water Code §13241 and adoption of a proper program of implementation under Water Code §13242. Current capacity of Tracy's WWTP is 10.8 mgd, but there are plans to expand to 16.0 mgd within the permit term.

[b] Amended by Order R5-2015-0044. The Manteca Wastewater Quality Control Facility is currently designed for a discharge of 9.87 mgd but plans to expand to 17.5 mgd.

[c] The Mountain House CSD is currently designed for a discharge rate of 3 mgd but plans to expand to 5.4 mgd within the permit term.

Overall, the WWTPs have only a small effect on southern Delta salinity (Appendix C, *Technical Report on the Scientific Basis for Alternative San Joaquin River Flow and Southern Delta Salinity Objectives*, and Appendix F.2, *Evaluation of Historical Flow and Salinity Measurements of the Lower San Joaquin River and Southern Delta*). For example, Tracy's discharge has limited effects on the overall salinity in the southern Delta compared to other sources of salinity in the area (e.g., water from agricultural activities and groundwater accretions). The permitted maximum salinity loads from the Tracy, Deuel, and Mountain House Community Services District (CSD) entering at the Head of Old River indicates that the salt load from point sources in this part of the southern Delta is a small percentage of the salt load entering from upstream. The salinity from wastewater discharges is generally exported at the CVP Jones Pumping Plant and SWP Banks Pumping Plant.

These WWTPs have effluent limitations that are established through the NPDES permits and waste discharge requirements (WDRs) issued by the Central Valley Regional Water Quality Control Board (Central Valley Water Board) (see Section 13.3.1, *Federal [Regulatory Background]*). These effluent limitations are set by discharge permits for a wide variety of constituents including salt, and regulate the quality of the treated effluent discharged from the WWTPs. Except for Deuel,[14] the EC effluent limits for the WWTPs are currently based on facility performance to ensure salinity levels do not increase. Except for Deuel, at all of these WWTPs the existing NPDES requirements allow salinity of the discharge to be greater than the existing salinity objectives for the southern Delta as a result of litigation in *City of Tracy v. State Water Board*, under which the State Water Board was enjoined from applying the Delta salinity water quality objectives to the City of Tracy and other municipal discharger pending reconsideration and implementation of the objectives in accordance with Water Code Sections 13241 and 13242. Generally, the WWTPs of the southern Delta are in compliance with the current EC effluent limitations. The discharge permits also require the preparation of a salinity management plan (Harder pers. comm.; Martin pers. comm.). Table 13-8 identifies annual average EC of each WWTP for 2011–2014. Table 13-9 identifies the average April–August EC and the remainder of the year. Table 13-10 is a summary of southern Delta WWTPs' compliance with NPDES salinity requirements and salinity management plans.

Some service providers (i.e., WWTPs) are currently planning to modify existing facilities to reduce salinity loads. Of the six WWTPs discussed herein, two have made efforts or are working toward reducing salinity concentrations in their source water supplies, four are implementing pretreatment programs to reduce water softener use among water users, and three are either proposing to construct or are already operating a reverse osmosis (RO) treatment system. Table 13-11 summarizes the salinity reduction efforts of the various WWTPs.

---

[14] The EC effluent limits for Deuel are based on the 2006 Bay-Delta Plan water quality objectives for salinity, not on facility performance.

Table 13-11. Salinity Reduction Efforts of Southern Delta Wastewater Treatment Plant Dischargers

	Salinity Reduction Efforts		
WWTP Facility	Source Water	Pretreatment Program	WWTP Desalination
Tracy	Addition of freshwater from New Melones Reservoir to groundwater supplies Construction of an Aquifer Storage and Recovery (ASR) well pilot project; permanent ASR is anticipated based on pilot project	Reduction in water softeners	Currently proposing a desalination plant (RO treatment); released public initial study/mitigated negative declaration (IS/MND) for the Tracy Desalination and Green Energy Project in April 2012
Deuel	No plans for changes to groundwater supplies	No pretreatment program, and none required	Constructed an RO groundwater treatment system with brine concentrator in 2010
Manteca	No plans for changes to 50 percent surface water from SSJID and 50 percent groundwater	Reduction in water softeners	No plans for desalination at WWTP
Stockton	Implementing Delta Water Supply Project for conjunctive use planned for 2012	Reduction in water softeners and TDS from industries	No plans for desalination at WWTP, but proposes to replace alum with polymer, submit inflow and infiltration study to identify salinity sources and loads, and implement Capital Improvement Energy Plan to meet salinity limitations
Mountain House CSD	No plans for changes to surface water from Clifton Court Forebay	Reduction in water softeners	No plans for desalination at WWTP
Discovery Bay CSD	—	—	Evaluated feasibility of constructing RO treatment system in 2010 Wastewater Master Plan

Note: The past and current violations at Deuel are potentially attributed to a malfunction of the RO and brine conversion systems used by the facility to reduce the salinity of the groundwater supply.

WWTP = wastewater treatment plant
RO = reverse osmosis
SSJID = South San Joaquin Irrigation District
TDS = total dissolved solids
CSD = community service district

Each of the current dischargers to the southern Delta is described below, including characteristics of the WWTP, salinity requirements, recorded violations in 2011, and currently implemented salinity control measures.

City of Tracy

Tracy discharges tertiary treated wastewater into Old River, which is a side branch of the SJR and contributes water to Clifton Court Forebay, a drinking water source for Southern California. The current NPDES discharge permit (Order No. R5-2012-0115) covers the main domestic wastewater treatment facility and an industrial pretreatment facility, including pretreated wastewater from the Leprino Foods Company (Leprino), a local cheese manufacturer (Central Valley Water Board 2012). All wastewater is discharged from Discharge Point 001 to Old River, located 3.5 miles north of the WWTP upstream of Paradise Cut (Figure 2-12). The nearest compliance monitoring station is station P-12 (Old River at Tracy Boulevard Bridge), approximately 4 miles west (downstream) of the discharge point (Central Valley Water Board 2007a). The nearest drinking water intakes are the CVP and SWP, which are approximately 10 miles downstream of the discharge (Central Valley Water Board 2007a).

Tracy's treated wastewater effluent is high in salt partly due to the municipal water supply and from significant salt loading from Leprino. Although Leprino provides preliminary treatment of its wastewater to reduce the high organic loading typical of food processing waste, no specific pretreatment is provided to reduce the high salt loading.

Tracy does not currently have EC effluent limitations; however, it still monitors for EC, as required by its NPDES permit, and has initiated salinity reduction efforts. The average EC of Tracy's wastewater effluent has not changed substantially over the past few years, although it did experience a slight increase in 2014 (Tables 13-7 and 13-8). Tracy submitted a salinity reduction plan in 2008 that describes the approach to identify, evaluate, and implement measures to reduce salinity in the effluent discharge and meet the interim salinity goal. Tracy also submitted a salinity best practicable treatment or control evaluation and salinity pollution prevention plan (PPP) in compliance with NPDES permit requirements.

Salinity Reduction Efforts

Source Water Supplies

Historically, the largest source of salinity in Tracy's wastewater effluent was the groundwater used as a potable water supply for the community. Tracy has obtained surface water potable supplies to replace the use of groundwater. Groundwater usage was reduced from 7,176 acre-feet (AF) in 2004 to 1,327 AF in 2009. As a result, there has been a reduction of approximately 5,000 tons of salt per year (Bayley pers. comm.). Additionally, Tracy is contracted with SSJID to receive water from New Melones Reservoir, and this additional water contributes to the reduction of salinity in the effluent (Tracy Press 2011). Additionally, Tracy completed construction of an Aquifer Storage and Recovery (ASR) well pilot project in 2012. The Central Valley Water Board must approve pilot tests on injection of drinking water into the groundwater basin. The permanent ASR project is planned for 2013 upon completion of environmental review. Tracy successfully commenced a pilot project to store surplus surface water supplies in the Semitropic Water Storage District in Kern County (Marshall pers. comm. 2012a).

Salinity Pretreatment Program

Replacing some groundwater with surface water for source water supplies has reduced the need for salt-based, self-regenerating water softeners, which contribute additional salinity to wastewater. These water softeners contribute to salinity because as they reduce hardness ions (e.g., calcium and magnesium), they produce a byproduct of a concentrated solution of the hardness ions and chloride that is discharged to the WWTP. This discharge increases the salinity of the wastewater entering the WWTP and the overall salinity of the treated effluent discharged from the WWTP. According to Tracy, there has been an observable significant decrease in the salinity of the wastewater effluent due to a reduction in the use of water softeners (City of Tracy 2008).

Desalination at the WWTP

Tracy is upgrading the WWTP to improve treatment and expand capacity. The treatment system capacity will be expanded from 10.8 million gallons per day (mgd) to 16 mgd through a four-phase expansion. In order to increase discharge capacity, Tracy is planning to construct a second outfall, Discharge Point 002, approximately 800 feet downstream of Discharge Point 001. Tracy is currently proposing to build a desalination plant (Verma pers. comm.). Tracy released a public draft of the initial study/mitigated negative declaration (IS/MND) for the Tracy Desalination and Green Energy Project in December 2011 and final document in April 2012 (State Clearinghouse Number 2011122004).

Deuel Vocational Institution

The California Department of Corrections and Rehabilitation's (CDCR) current NPDES permit (Order No. R5-2014-0014) authorizes treated effluent discharges from the Deuel Vocational Institution. Deuel has general population housing of more than 3,700 inmates. Treated effluent is discharged into the Deuel Drain, which is tributary to Paradise Cut and Old River (Central Valley Water Board 2014a). The western end of Paradise Cut discharges to Old River.

Table 13-12 summarizes the WWTP NPDES permit enforcement orders showing violations of EC effluent limitations occurring during the existing NPDES permit term. Deuel has had 16 violations of its daily and monthly average EC effluent limitations since the existing NPDES permit was issued.[15] These violations are potentially attributed to a malfunction of the RO and Brine Concentrator systems used by the facility to reduce the salinity of the groundwater supply. The RO system has only operated for 16 months of the 48 months since it has been permitted to operate (i.e., it has operated 33percent of the time) (Central Valley Water Board 2015a).

Salinity Reduction Efforts

Source Water Supplies

Source water for Deuel comes from four on-site groundwater wells. The groundwater is treated prior to use via a RO system. Approximately 8,000 gallons per day of brine solution are removed and deposited to four evaporation ponds. Despite efforts to reduce salinity using this system, the facility continues to violate its effluent limitations; therefore, modifications to this facility are likely needed.

---

[15] ACLC R5-2014-0518 and ACLC 2014-0550 were issued in 2014 and cover violations that occurred March 1, 2011 through December 31, 2013, and January 1, 2014 through March 31, 2014, respectively. However, EC was not one of the constituent standards that was in violation (Central Valley Water Board 2014a).

Salinity Pretreatment Program

Deuel does not have a pretreatment program because the only source of wastewater is the prison, and it does not treat industrial wastewater.

Table 13-12. Recent Wastewater Treatment Plant National Pollution Discharge Elimination System Permit Enforcement Orders for the Deuel Vocational Institution

Enforcement Order for EC Violation	Dates of Noncompliance	Description
Cease and Desist (R5-2008-0165-01) as amended by Administrative Civil Liability Complaint (ACLC) (R5-2010-0010)	NA	Established new interim daily EC limit of 3.000 dS/m (3,000 µmhos/cm) effective until Dec 31, 2010
ACLC (R5-2009-0571)	April 30, 2009	1 violation of daily EC limit of 3.000 dS/m (3,000 µmhos/cm)
ACLC (R5-2010-0526)	Aug 31, 2009–Feb 28, 2010	1 violation of monthly EC limit of 0.700 dS/m (700 µmhos/cm); 3 violations of monthly EC limit of 0.700 dS/m (700 µmhos/cm)
ACLC (R5-2010-0549)	April 30, 2010–Aug 31, 2010	5 violations of monthly EC limit of 0.700 dS/m (700 µmhos/cm)
ACLC (R5-2011-0575)	Sept 30, 2010–Feb 28, 2011	6 violations of monthly EC limit of 1.000 dS/m (1,000 µmhos/cm)

NA = not applicable
EC = electrical conductivity (salinity)
dS/m = deciSiemens per meter
µmhos/cm = micromhos per centimeter. Conversion is 1 dS/m = 1000 µmhos/cm.

City of Manteca

Manteca's current NPDES permit (Order No. R5-2015-0026) regulates tertiary treated effluent discharges from Manteca and surrounding areas and a portion of Lathrop. Manteca discharges part of its treated effluent to irrigated fields. The remaining treated effluent is discharged to the SJR just upstream of the Mossdale EC monitoring station and SJR at Brandt Bridge (C-6) (Central Valley Water Board 2015b). The discharge is approximately 20 miles from the nearest drinking water intake (Central Valley Water Board 2009). Manteca receives municipal wastewater and wastewater from a produce washing and processing facility (Eckert Cold Storage). However, the food processing wastewater is only discharged to land and enters the facility through a separate collection system.

After the issuance of Manteca's former (2004) NPDES permit (Order No. R5-2004-0028), which included seasonal effluent limits for EC of 1.0 dS/m (September–March) and 0.7 dS/m (April–August), Manteca petitioned the State Water Board to amend the 0.7 dS/m effluent limit. On March 16, 2005, the State Water Board adopted Water Quality Order (WQO) 2005-005, which removed the 0.7 dS/m EC effluent limit. In October 2009, the Central Valley Water Board adopted Manteca's last NPDES permit (Order No. R5-2009-0095) that again included seasonal effluent limits for EC of 1.0 dS/m (September–March) and 0.7 dS/m (April–August)[16]. Since Manteca could not consistently comply with the 0.7 dS/m limitation, the Central Valley Water Board also adopted a time schedule order (No. R5-2009-0096), allowing Manteca until October 2014 to achieve compliance with the seasonal 0.7 dS/m effluent limitation. The time schedule order also required Manteca to update its salinity PPP, initially developed in 2005. Manteca submitted a revised PPP in April 2010. Under Order No. R5-2015-0026, effluent limitations based on the Delta salinity objectives were not imposed due to the *City of Tracy v. State Water Resources Control Board* litigation. Instead, a salinity effluent limitation based on current performance was imposed (calendar year annual average for EC is not to exceed 1.0 dS/m), as well as a continuing requirement to implement its PPP. The average EC of Manteca's wastewater effluent has not changed substantially over the past few years (Tables 13-7 and 13-8).

Salinity Reduction Efforts

Source Water Supplies

Manteca's groundwater supplies, and, consequently, their wastewater and treated effluent, have a high salt content. A portion of Manteca's water supply is pumped from groundwater wells with an EC level range of 0.3 dS/m to 0.6 dS/m. Starting in 2005, Manteca substituted a portion of its groundwater supply with surface water from the SSJID such that Manteca's water supplies are currently comprised of 50 percent surface water. Manteca is currently evaluating the possibility of installing salinity-removal technologies at some or all of its groundwater wells (City of Manteca 2010).

Salinity Pretreatment Program

A source of wastewater salinity is self-regenerating water softeners (City of Manteca 2010). In recent years, Manteca's water supply has reduced its water hardness by obtaining different source water (e.g., surface water), but the use of water softeners has not decreased significantly because most water softener systems were installed in homes prior to the water hardness reduction. In the 2010 PPP, Manteca proposed to launch an education campaign to encourage residents to switch from standard self-regenerating water softeners to high-efficiency water softeners or an exchange tank system.

Several Manteca commercial and industrial wastewater generators participate in the current wastewater pretreatment processes and have undertaken efforts to reduce salinity. For example, the wastewater from Eckert Cold Storage has been separated into two streams, one for the food-processing and one for all other wastewater, thus reducing salinity discharged into the SJR.

Desalination at the WWTP

Manteca has not proposed to modify its facilities for salt removal.

---

[16] Although the State Water Board removed the 0.7 dS/m EC limit in Manteca's 2004 NPDES permit, the Central Valley Water Board implemented the 0.7 dS/m EC limit again due to a subsequent State Water Board Order for the City of Tracy Wastewater Treatment Plant (WQO 2009-003).

City of Stockton

Stockton's current NPDES permit (Order No. R5-2014-0070) regulates tertiary treated effluent discharges from Stockton, the Port of Stockton, and surrounding urbanized San Joaquin County areas. The treated effluent is discharged to the SJR approximately 8 miles downstream from the SJR at Brandt Bridge compliance station (C-6) (Central Valley Water Board 2014b). There are no known drinking water intakes in the vicinity of the discharge (Central Valley Water Board 2014b). The average EC of Stockton's wastewater effluent has not changed substantially over the past few years (Tables 13-7 and 13-8). Stockton submitted a PPP to the Central Valley Water Board in 2005 and a draft salinity plan in June 2009. The average annual effluent is approximately 1.1 dS/m as stated in the 2011 salinity plan progress report based on effluent data collected from January to October 2010. These effluent data demonstrate compliance with the average annual salinity effluent limitation of 1.3 dS/m.

Salinity Reduction Efforts

Source Water Supplies

Stockton's existing water supply originates from groundwater wells, groundwater delivered by the California Water Service Company, and surface water delivered by SEWD from the Stanislaus and Calaveras Rivers. The average EC of the groundwater sources is approximately 0.5 dS/m (city wells) and approximately 0.4 dS/m (California Water Service wells), compared to 0.1 dS/m for surface water sources (City of Stockton 2009). The Delta Water Supply Project (DWSP) was completed in June 2012 and provides a new supplemental surface water supply from the SJR and includes a 30-mgd water treatment plant (City of Stockton 2011b).

Salinity Pretreatment Program

The extent of water softener use by Stockton residences is unknown (City of Stockton 2009). Stockton works with industrial dischargers within its service area to reduce TDS concentrations as part of its standard pretreatment program (City of Stockton 2009).

Desalination at the WWTP

Stockton is in the process of modifying the treatment plant to reduce salinity generated by alum (a chemical used to consolidate, and hence aid in the removal of, salt during the wastewater treatment process). It also will submit an inflow and infiltration study to the Central Valley Water Board as part of the capital improvement program to identify specific methods of reducing EC and TDS loads (City of Stockton 2011b).

Mountain House Community Services District

The Mountain House CSD's NPDES permit (Order No. R5-2013-0004) covers the discharge of tertiary treated effluent from the community of Mountain House in San Joaquin County into Old River (Central Valley Water Board 2013). The Jones Pumping Plant is located 4.5 miles west (downstream) of the discharge. The average EC of Mountain House CSD's wastewater effluent has not changed substantially over the past few years; however, it has slightly increased (Tables 13-7 and 13-8).

Salinity Reduction Efforts

Source Water Supplies

Mountain House CSD's source water is surface water from the Clifton Court Forebay, which has an EC of less than 0.3 dS/m (Central Valley Water Board 2007b).

Salinity Pretreatment Program

Mountain House CSD is required to implement a pretreatment program as specified in the current NDPES permit. Mountain House CSD continues to discourage the use of water softeners within its service area as part of its pretreatment program.

Desalination at the WWTP

Mountain House CSD currently neither operates a desalination system at the WWTP, nor does it plan to construct one.

Discovery Bay CSD

Discovery Bay CSD's NPDES permit (Order No. R5-2014-0073) regulates secondary treated discharges from the town of Discovery Bay to Old River (Central Valley Water Board 2014c). The Town of Discovery Bay owns the Discovery Bay WWTP, which serves approximately 16,000 people. Discovery Bay CSD's nearest compliance monitoring station is Clifton Court Forebay (2006 Bay-Delta Plan Station C-9). Bay-Delta Station C-9 is one of the four southern Delta salinity compliance stations and very little, if any, discharge from Discovery Bay CSD reaches the southern Delta (Marshall pers. comm. 2012b). However, because it is located within the southern Delta, it is included here as part of baseline conditions. The nearest drinking water intake is CCWD's Old River Intake for Los Vaqueros Reservoir. The average EC of Discovery Bay CSD's wastewater effluent has not changed substantially over the past few years; however, it has slightly decreased (Tables 13-7 and 13-8).

Salinity Reduction Efforts

Source Water Supplies

Discovery Bay CSD currently does not have any plans to change the source of its water supplies.

Salinity Pretreatment Program

Discovery Bay CSD currently does not have any plans to implement a salinity pretreatment program.

Desalination at the WWTP

According to the Discovery Bay Wastewater Treatment Master Plan (Discovery Bay CSD 2012), an RO treatment facility would be constructed to meet an effluent EC goal of 1.0 dS/m. However, because of the estimated high costs, high energy usage, and associated environmental impacts, the Discovery Bay CSD concluded in the master plan that RO treatment would only be constructed and used if mandated by the State (Discovery Bay CSD 2012).

Water Suppliers

Drinking water supply intakes are located in the southern Delta. These include the Jones and Banks pumping plants of the CVP and SWP, respectively, and the intakes for CCWD.

Central Valley Project and State Water Project

As described in Chapter 2, *Water Resources* (Section 2.6.2), and Chapter 5, *Surface Hydrology and Water Quality* (Sections 5.2.8 and 5.3.2), CVP and SWP export pumping is subject to 2006 Bay-Delta Plan objectives, which are implemented through the State Water Board's Water Right Decision 1641 (D-1641). Both the CVP and the SWP have maximum permitted pumping rates but are limited by water availability depending on precipitation, snowpack, and senior water rights holders' needs. Delta outflow requirements may also limit export pumping if the combined Delta inflow is not enough to satisfy both the in-Delta agricultural diversions and CVP and SWP pumping. The 1986 Coordinated Operations Agreement (COA) between the federal and state governments sets the rules by which the CVP and SWP jointly operate their water storage and conveyance facilities in order meet regulatory obligations, maximize their contractual water deliveries, including Delta export pumping, and not adversely affect each other's water rights or the rights of others.

Contra Costa Water District

The CCWD diverts water from the southern and central Delta for drinking water supplies to eastern and central Contra Costa County. As described in Chapter 2, *Water Resources*, CCWD has four surface water intakes: Mallard Slough Intake, Rock Slough Pumping Plant #1, Old River Intake near State Route (SR) 4, and the Victoria Canal Intake. Old River and Victoria Canal Intakes are located immediately north–northwest of the SDWA boundary (Figure 2-12). The Mallard Slough Intake and Rock Slough Intake are located further west and closer to the ocean. The Old River Intake is the largest intake operated and accounts for the majority of surface water diverted to CCWD (CCWD and USBR 2008.)

CCWD's rights to divert water from the Delta integrate CCWD's operations with the coordinated operations of the CVP and SWP. CCWD has a contract with USBR for the delivery of 195,000 acre-feet per year (AF/y) of CVP water for municipal and industrial uses and agricultural users in the CCWD service area. The water delivered under the contract may be diverted at the Rock Slough and Old River intakes at any time of the year. CCWD also has a water right for the Los Vaqueros Project that allows water to be diverted from Old River to Los Vaqueros Reservoir November–June during excess conditions in the Delta as defined in D-1629. CCWD also has a license and permit for diversions at Mallard Slough for up to 26,780 AF/y. Therefore, when CCWD operates within the terms of its CVP contract and water rights permits, it does so in conjunction with all other water supply interests (CCWD and USBR 2008).

CCWD's intakes are located in the western Delta where the effects of seawater intrusion are more pronounced. Generally, CCWD's intakes experience relatively fresh conditions in the late winter and early spring, and salinity increases in summer and fall as conditions become drier and regulatory standards governing Delta operations shift. This pattern can vary depending on hydrology (CCWD and USBR 2008). Use of the Mallard Slough Intake is generally restricted due to salinity concentrations because it experiences more tidal fluctuations as a result of its location. Water quality conditions have restricted diversions from Mallard Slough (an average of 3,100 AF/y) with no diversions available in dry years. When Mallard Slough supplies are used, CVP diversions at Rock Slough are reduced by an equivalent amount. The Victoria Canal Intake allows CCWD the flexibility to divert water with lower salinity and allows seasonal operations shifts between diversions. The seasonal variation in salinity between Old River/Rock Slough and Victoria Canal allows CCWD to divert predominantly in winter and spring from Old River. In the late summer, as salinity begins to rise, Victoria Canal salinity is generally lower than Old River salinity and remains lower until Delta outflow increases and Delta salinity improves (usually in December). Thus, CCWD typically diverts water in the summer and fall from Victoria Canal (CCWD and USBR 2008).

13.3 Regulatory Background

13.3.1 Federal

Relevant federal programs, policies, plans, or regulations related to service providers are described below.

Safe Drinking Water Act

The Safe Drinking Water Act (42 U.S.C., § 300f et seq.), originally passed by Congress in 1974 and amended in 1986 and 1996, was established to protect public health by regulating the nation's public drinking water supply. In addition to drinking water itself, the act requires the protection of its sources, such as rivers, lakes, reservoirs, springs, and groundwater wells. The act authorizes the U.S. Environmental Protection Agency (USEPA) to set national health-based standards for drinking water, such as MCLs, to protect against contaminants that may adversely affect public health. In California, as of July 1, 2014, the State Water Board's DDW implements the Safe Drinking Water Act. Included under the regulatory portion of the DDW program are: (1) issuance of permits for public water systems and their sources and treatment to ensure compliance with drinking water standards, (2) inspection of water systems, (3) tracking of monitoring requirements of water systems to determine compliance, and (4) enforcement actions.

The Safe Drinking Water Act mandates that all community water systems, regardless of water source (i.e., groundwater versus surface water) prepare and distribute an annual water quality report, or CCR. The CCR must summarize information on system source water, detected regulated contaminants in the drinking water, compliance to restore safe drinking water, and educational information, particularly regarding nitrate, arsenic, or lead in areas where these naturally occurring contaminants may be of concern. CCRs must be distributed to community water system customers by July 1 each year and the reports provide information on water quality for the preceding calendar year.

Clean Water Act

The federal CWA (33 U.S.C., § 1251 et seq.) places primary responsibility for developing water quality standards on the states. The CWA established the basic structure for regulating point and nonpoint discharges of pollutants into the waters of the United States and gave USEPA the authority to implement pollution control programs, such as setting wastewater standards for industry. The statute employs a variety of regulatory and non-regulatory tools to reduce pollutant discharges into waters of the United States, finance municipal wastewater treatment facilities, and manage polluted runoff.

Clean Water Act Section 402

Section 402 of the CWA regulates point-source discharges to surface waters through the NPDES program, which is administered by USEPA. In states with approved programs, like California, the State Water Board and the regional water boards have the primary responsibility to apply and enforce the requirements of the CWA as a substitute for direct regulation by USEPA (33 U.S.C. §§ 1342, subs. (b), (c); see related discussion of the Porter-Cologne Water Quality Control Act in Section 13.3.2, *State [Regulatory Background]*). The NPDES program provides for both general permits (those that cover a number of similar or related activities) and individual permits. Typically, NPDES permits are reissued every 5 years (see Table 13-7 for recent permit information of WWTPs within the area of potential effects). WWTPs are required to obtain NPDES permits that contain specific requirements limiting discharge pollutants for the discharge of treated wastewater. NPDES permits also require dischargers to monitor their wastewater to ensure treated effluent meets all permitted requirements. The Central Valley Water Board generally issues WWTP NPDES permits for wastewater discharges within the area of potential effects.

13.3.2 State

Relevant state programs, policies, plans, or regulations related to service providers are described below.

California Code of Regulations, Title 23

Title 23 of the California Code of Regulations contains the State Water Board's regulations. Section 106 identifies the policy of the state that the use of water for domestic purposes is the highest use, with irrigation being the next highest use. Section 106.3 identifies that every human being has the right to safe, clean, affordable, and accessible water adequate for human consumption, cooking, and sanitary purposes (also known as the "Human Right to Water"). Relevant state agencies, including the State Water Board, need to consider the human right to water when revising, adopting, or establishing policies and regulations relevant to domestic water use.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act (Porter-Cologne Act) (Wat. Code, § 13000 et seq.) establishes a comprehensive program for the protection of water quality. It addresses both point and non-point discharges to surface and ground waters. It provides for a statewide program for water quality control administered regionally, within a framework of statewide coordination and policy. (Wat. Code, § 13000.) The nine regional water boards have primary responsibility for permitting through waste discharge requirements, inspection and enforcement actions. (See Wat. Code, §§ 13260 et seq. and 13300 et seq.) The Porter-Cologne Act provides for the adoption of water quality control plans. (Wat. Code, §§ 13170, 13240 et seq.) The State Water Board and the regional water boards administer the CWA's NPDES permit program, with oversight from USEPA. (See Wat. Code, §§ 13370 et seq.) The State Water Board is updating the 2006 Bay-Delta Plan in accordance with the CWA and the Porter-Cologne Act.

Given the authority under the Porter-Cologne Act to protect water quality, the State Water Board can take various actions to respond to areas with water quality concerns. For example, in enforcement actions, it can order parties responsible for nitrate contamination to provide replacement water to impacted communities, as appropriate. Since 2014, the State Water Board has assisted regional water boards with negotiating replacement water orders, including bottled water and reverse-osmosis treatment, for nitrate-impacted drinking water.

San Francisco Bay/Sacramento–San Joaquin Delta Estuary Water Quality Control Plan

The 2006 Bay-Delta Plan was adopted by the State Water Board in December of 2006 following a review of the 1995 Bay-Delta Plan. The 2006 Bay-Delta Plan identifies beneficial uses of the Bay-Delta, water quality objectives (i.e., flow and salinity) for the reasonable protection of those beneficial uses, and a program of implementation for achieving the water quality objectives.

The numeric objectives for EC in the 2006 Bay-Delta Plan for the southern Delta are based on the protection of agricultural beneficial uses, which is 100 percent protection of salt-sensitive bean and alfalfa crops (Appendix E, *Salt Tolerance of Crops in the Southern Sacramento–San Joaquin Delta*). The numeric objectives are 0.7 dS/m during the summer irrigation season (April–August) and 1.0 dS/m during the winter season (September–March). Compliance with these objectives is currently monitored at four compliance locations: SJR at Vernalis (C-10), SJR at Brandt Bridge (C-6), Old River near Middle River (C-8), and Old River at Tracy Boulevard Bridge (P-12). The numeric objectives are not just applicable at the compliance monitoring locations, but they also apply to the receiving waters of WWTP discharge: “unless otherwise indicated, water quality objectives cited for a general area, such as for the southern Delta, are applicable for all locations in that general area, and compliance locations will be used to determine compliance with the cited objectives” (State Water Board 2006).

D-1641 contains the current water right requirements, applicable to the California Department of Water Resources’ (DWR’s) and the U.S. Bureau of Reclamation’s (USBR’s) operations of the SWP and CVP facilities, to implement the Bay-Delta water quality objectives. It requires that USBR release flows from New Melones Reservoir to maintain EC at Vernalis. The salinity objectives are the maximum 30-day running average (monthly average) of mean daily EC (0.700 dS/m April–August and 1.0 dS/m September–March for all water year types) (State Water Board 2006).

The existing objective for chloride concentration (related to salinity) is a year-round maximum mean daily chloride concentration of 250 mg/L measured at five Delta intake facilities, of which CCWD’s Pumping Plant No. 1 is one, for the reasonable protection of municipal beneficial uses. This is consistent with USEPA’s secondary MCL for chloride. Additionally, a maximum daily chloride concentration of 150 mg/L (measured either at Pumping Plant No. 1 or the SJR at the Antioch Water Works Intake) is included in the 2006 Bay-Delta Plan for the reasonable protection of industrial uses. A water quality goal for bromides (related to salinity) is set at 0.15 mg/L.

Sacramento River and San Joaquin River Basins Water Quality Control Plan

The Central Valley Water Board’s *Water Quality Control Plan for the Sacramento and San Joaquin River Basins* identifies the beneficial uses to be reasonably protected in the Sacramento and SJR Basin water bodies, water quality objectives, implementation programs, and surveillance and monitoring programs. It includes wasteload allocations for salt and boron discharges into the LSJR. The waste load allocations are the concentration limits set equal to the EC water quality objectives for the SJR at the Airport Way Bridge near Vernalis. The Central Valley Water Board implements the plan by issuing WDR or NPDES permits for wastewater discharges. Southern Delta dischargers have been issued NPDES permits for treated discharges and are listed in Table 13-7.

The plan incorporates, by reference, the State Water Board's DDW's (formerly part of the California Department of Public Health (DPH) numerical drinking water maximum contaminant levels (MCLs). The incorporation of the MCLs, which apply to treated drinking water systems regulated by the DDW, makes the MCLs also applicable to ambient receiving water with respect to the regulatory programs administered by the regional water boards.

The Central Valley Water Board also adopted, and the State Water Board approved, plan amendments to add policies for variances from surface water quality standards for point source dischargers, a variance program for salinity, and exception from implementation of water quality objectives for salinity.[17] The amendments are pending approval by USEPA before they become effective. Under the variance policy, the Central Valley Water Board would be allowed the authority to grant variances from meeting water quality-based effluent limitations for non-priority pollutants to dischargers subject to NPDES permits. Under the salinity variance program, domestic and municipal wastewater permittees subject to NPDES permits may apply to the Central Valley Water Board for a variance from meeting water quality-based effluent limitations for salinity constituents (i.e., EC, total dissolved solids, chloride, sulfate and sodium). The Central Valley Water Board may approve the permittee's salinity variance request for a period not exceeding ten years after finding, among other things, that the attainment of water-quality based effluent limitations for salinity is not feasible, the permittee has implemented or will implement feasible salinity reduction/elimination measures and permittee continues to participate in the Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS) effort, a stakeholder effort working to develop comprehensive salt and nitrate management plans. Under the salinity exception program, dischargers that are subject to WDRs that are not also NPDES permits and conditional waivers may obtain a limited-term exception to discharge requirements from the implementation of water quality objectives for salinity. SDWQ Alternatives 2 and 3 are subject to the variance policy, salinity variance program and salinity exception program adopted by the Central Valley Water Board under Resolution No. R5-2014-0074.

California Drinking Water Standards

The California drinking water standards are based on federal standards, which are listed in Title 22 of the California Code of Regulations and administered by the State Water Board's DDW. California MCLs, components of drinking water standards, are found in Title 22, Chapter 15, Division 4. Salinity can affect the taste, corrosivity, and other non-health-related characteristics of drinking water supplies. Drinking water has a recommended secondary MCL for specific conductance (i.e., salinity) of 0.900 dS/m. The upper secondary MCL is 1.600 dS/m and a short-term secondary MCL is 2.200 dS/m. No fixed consumer acceptance contaminant level has been established for conductance. Specific conductance concentrations lower than the recommended secondary MCL are desirable for a higher degree of consumer acceptance. The secondary MCL can be exceeded and is deemed acceptable to approach the upper MCL if it is neither reasonable nor feasible to provide more

---

[17] See *Central Valley Regional Water Quality Control Board Resolution No. R5-2014-0074* and *State Water Board Resolution No. 2015-010*.

suitable waters. In addition, concentrations ranging up to the short-term MCL are acceptable only for existing community water systems on a temporary basis.

California Safe Drinking Water Act

The California Health and Safety Code (Part 12, Chapter 4) defines public water systems as a system for the provision of water for human consumption through pipes or other constructed conveyance that has 15 or more service connections or regularly serves at least 25 individuals daily at least 60 days out of the year. A public water system includes the following.

- Any collection, treatment, storage, and distribution facilities under control of the operator of the system that are used primarily in connection with the system.
- Any collection or pretreatment storage facilities not under the control of the operator that are used primarily in connection with the system.
- Any water system that treats water on behalf of one or more public water systems for the purpose of rendering it safe for human consumption.

The Safe Drinking Water Act (at Health and Safety Code Section 116270 et seq.) includes the following summarized provisions regarding the controls to prevent contaminated water from getting to the end user of a public water system.

- Section 116287—DDW must place requirements on public water systems and water districts that are consistent with both the state and federal SDWA.
- Sections 116325 and 116350—DDW is responsible for ensuring that all public water systems are operated in compliance with the act and its regulations to protect public health.
- Section 116365—DDW must adopt primary drinking water standards for contaminants in drinking water that are not less stringent than the federal Safe Drinking Water Act.
- Section 116385—public water systems have to provide water analysis to DDW.
- Section 116395—DDW must assist local health officer in the evaluation of small public water systems for potential organic chemical contamination.
- Section 116400—if DDW determines a public water system is subject to potential contamination, it may require quarterly water analysis.
- Section 116425—DDW may exempt public water systems from any MCL or treatment requirements under certain compelling factors and other criteria, but only if it will not result in an unreasonable risk to health. Exemptions are granted for 12 months, but can be extended be up to 3 years if specific criteria are met.
- Section 116450—when primary drinking water standards are exceeded the public system operator has to notify DDW and users.
- Section 116470—public water systems are required to prepare and deliver consumer confidence reports; systems serving 10,000 service connections must disclose detections of contaminants and best available technologies to address the contamination.
- Section 116525 and 116540—operators of a public water system may not operate without a DDW permit. DDW may impose permit conditions, requirements for system improvements, and time schedule to ensure a reliable and adequate supply of water that is at all times pure, wholesome, potable, and does not endanger the health of consumers.

- Section 116550—public water systems may not change its source of supply or method of treatment without an amended permit.
- Section 116555—public water systems must comply with primary and secondary drinking water standards and provide pure, wholesome, healthful and potable water, among other requirements.
- Section 116655—DDW may issue compliance orders, which can include without limitation requiring treatment/purification, change in source water, or system repairs.

Detailed requirements for regular water quality monitoring are set forth in DDW's regulations at Cal. Code. Regs., tit. 22, Section 64400 et seq.

State Water Board Sources of Drinking Water Policy (Resolution No. 88-63)

The Sources of Drinking Water Policy (Resolution No. 88-63) established state policy that regional water boards must consider all surface water and groundwater, with certain exceptions, as suitable or potentially suitable for municipal or domestic supply. The policy defines the following three categories of waters potentially eligible for an exception from the designation and protection of a water source for municipal or domestic supply.

- Water bodies with high salinity (defined as TDS >3,000 mg/L), that either have naturally high contaminant levels that cannot reasonably be treated using either best management practices (BMPs) or best economically achievable treatment practices, or produce too low yield (<200 gallons per day).
- Waters designed or modified to treat wastewaters (domestic or industrial wastewater, process water, stormwater, mining discharges, or agricultural drainage), provided that such systems are monitored to ensure compliance with all relevant water quality objectives.
- Groundwater aquifers regulated as geothermal energy-producing sources or aquifers that have been exempted administratively by federal regulations for the purpose of underground injection of fluids associated with the production of hydrocarbon or geothermal energy.

Groundwater Ambient Monitoring and Assessment Program

GAMA is a comprehensive groundwater quality monitoring program based on interagency collaboration between the State Water Board, regional water boards, DWR, Department of Pesticide Regulations, U.S. Geological Survey, and Lawrence Livermore National Laboratory (LLNL), and cooperation with local water agencies and well owners. Developed by the State Water Board in 2000, GAMA was expanded by the passage of the Groundwater Quality Monitoring Act of 2001, and includes the following four projects to meet the statutory requirements of the act.

- The Priority Basin Project—currently assesses the water quality of shallow aquifers typically used for domestic supplies prioritizing areas with the greatest household densities relying on domestic wells.
- GeoTracker GAMA—a groundwater information system that provides water quality data from multiple sources on an interactive Google-based map.
- Domestic Well Project—samples private wells on a county level for well owners who volunteer when the project is active in their county. Results are used by GAMA to evaluate water quality of domestic wells.

- Special Studies Project—focuses on groundwater studies conducted by LLNL, which cover nitrate, wastewater and groundwater recharge.

Groundwater Quality Monitoring Act of 2001

The Groundwater Quality Monitoring Act of 2001 was established to improve statewide comprehensive groundwater monitoring and to provide the public with readily available information about groundwater quality in California. The Groundwater Quality Monitoring Act requires that the State Water Board integrate existing monitoring programs and, as necessary, establish new program elements in order to create a comprehensive groundwater monitoring program for assessing the quality of all priority groundwater basin in the state that account for over 90 percent of groundwater used in California.

The Sustainable Groundwater Management Act

It is California state policy (Water Code § 113) that "groundwater resources be managed sustainably for long-term reliability and multiple economic, social, and environmental benefits for current and future beneficial uses" and that sustainable groundwater management "is best achieved locally through the development, implementation, and updating of plans and programs based on the best available science."

The Sustainable Groundwater Management Act (SGMA) (Wat. Code, § 10720 et seq.) provides the framework to implement this policy by requiring that local agencies in high- and medium-priority basins (DWR 2014) form groundwater sustainability agencies (GSAs) by June 30, 2017 that will develop, and commence implementation of, groundwater sustainability plans (GSPs) by either 2020 or 2022[18] that will achieve sustainable groundwater management within 20 years. SGMA defines sustainable groundwater management as "the management and use of groundwater in a manner that can be maintained during the [50 year] planning and implementation horizon without causing undesirable results." SGMA's definition of undesirable results includes such effects as chronic lowering of groundwater levels, significant and unreasonable reductions in groundwater storage, degradations of water quality, and land subsidence that interferes with surface land uses. (Wat. Code, § 10721, subd. (x).)

SGMA recognizes regional differences and provides flexibility to local agencies to tailor plans that meet their needs, improves coordination between land use and groundwater planning, prioritizes basins with the greatest problems and protects water rights. The legislation provides two key management principles: It ensures that local and regional agencies have the resources they need to sustainably manage groundwater, including the necessary authority, better technical information, and financial resources; and, when local agencies cannot or will not manage their groundwater sustainably, the legislation provides for State Water Board intervention until local agencies develop and implement sustainable groundwater management plans.[19] SGMA is described in greater detail in Chapter 9, *Groundwater Resources.*

---

[18] SGMA requires critically overdrafted high and medium priority basins (as determined by DWR), to adopt GSPs by January 31, 2020. In the plan area this includes the Eastern San Joaquin, Merced and Chowchilla Subbasins. All other high and medium priority basins, such as the Modesto and Turlock Subbasins, must develop GSPs by January 31, 2022.

[19] The State Water Board can only intervene in a local area and develop an interim plan in limited circumstances: when no agency is willing to serve as a GSA (by 2017); when a GSA does not compete a GSP (by 2020); and when

13.3.3 Regional or Local

Relevant regional or local programs, policies, plans, or regulations related to service providers are described below. Although local policies, plans, or regulations are not binding on the state of California, below is a description of relevant ones.

Agricultural Water Management Plans

Several of the irrigation districts have prepared agricultural water management plans (AWMPs), in which they have identified methods for dealing with water supply shortages. Table 13-13 describes methods that are common throughout all of the irrigation district AWMPs for addressing surface water shortages.

Table 13-13. Irrigation District Methods for Addressing Surface Water Shortages

Irrigation District	Conjunctive Use	Reduction in Surface Water Allotments	Allowable Internal Transfers	Groundwater Used for Permanent Crops	Holds Carryover Surface Water for Crops	All Shortages Managed with Groundwater	Fair and Equitable Distribution	USBR Responsible for Shortages
SSJID	X	X	X	NA	NA	NA	X	X
OID	X	X	X	X	NA	NA	X	X

NA = not applicable

Urban Water Management Plans

The California Urban Water Management Planning Act requires urban water suppliers[20] to initiate planning strategies to ensure the appropriate level of reliability in their water service sufficient to meet the needs of the various categories of customers during normal, dry, and multiple dry water years. To do this, they must prepare an urban water management plan (UWMP) every 5 years. The intent of the UWMP is to present information about water supply, water usage, recycled water, and water use efficiency programs in a contracting water district's service area. The UWMP also serves as a resource for planners and policy makers over a 25-year planning time frame. Below is a brief summary of information contained in the UWMPs that are available for SSJID and MID and for entities that receive surface water from the irrigation districts.

---

both the GSP is inadequate or not implemented to achieve sustainability, and there is a condition of long-term overdraft or significant depletion of interconnected surface waters.

[20] *Urban water suppliers* are defined as suppliers that have 3,000 or more water connections or provide over 3,000 acre-feet of water annually.

South San Joaquin Irrigation District (SSJID)

SSJID is contracted to provide surface water to SEWD and the Cities of Tracy, Manteca, Lathrop, Ripon, and Escalon. In 2005, these cities, with the exception of Ripon, partnered with SSJID to construct a water treatment plant and pipeline to deliver treated water from the Woodward Reservoir to these participating cities as part of the South County Water Supply Project. The Cities of Manteca and Lathrop will receive 18,500 AF/y and 11,791 AF/y of treated potable water, respectively, once Phase II of the South County Water Supply Project is implemented (City of Lathrop 2009; City of Manteca 2012b).

SSJID's water comes from three sources: the Stanislaus River, groundwater pumping by SSJID and private land owners, and irrigation return flows from neighboring districts. The primary water supply is surface water diversions from the Stanislaus River. The majority of water users in the service area are agricultural, but the cities contracted with SSJID do serve municipal and urban users. SSJID projects it will have adequate supplies to meet water demands in normal years through 2030 (dependent upon the certainty of the available water supply, which is dependent upon each year's hydrology and regulatory uncertainty). SSJID would experience water shortages under single dry year conditions through 2030 that could not be compensated by conservation and only minimal shortages under multiple dry year conditions through 2030 that could likely be compensated by conservation (SSJID 2011).

Stockton East Water District (SEWD)

SEWD serves both urban and agricultural water users. SEWD's receives surface water from both the Stanislaus River (within the plan area) and Calaveras River (outside of the plan area). SEWD typically receives 75,000 AF/y from New Melones Reservoir on the Stanislaus River and under the OID/SSJID water transfer agreement, 8,000 to 30,000 AF/y[21]. SEWD typically receives approximately 56.5 percent of its water supply from New Hogan Reservoir on the Calaveras River. As such, based on total surface water supplies received in 2010 (118,216 AF): 51,540 AF (approximately 44 percent of the total) came from New Melones Reservoir for agricultural use; 26,900 AF (approximately 23 percent of the total) came from the OID/SSJID water transfer agreement; and the New Hogan Reservoir provided 39, 776 AF of water (approximately 34 percent of the total) for urban use (SEWD 2014). SEWD maintains two groundwater wells that are only pumped to supplement demand during dry years. Saline intrusion and contamination from agricultural chemicals limit the use of groundwater. The *Stockton East Water District Water Management Plan* (SEWD 2014) includes the existing and projected water demands associated with these water users. SEWD's Water Management Plan identifies that deficiencies in water supply would occur under normal, single dry, and multiple dry years and would be offset by additional groundwater pumping from urban retailers and the DWSP (SEWD 2014).

City of Tracy

Tracy obtains water from both surface and groundwater sources. The amount of water that Tracy uses from each source varies year to year based on contractual agreements, annual precipitation, and city policy (City of Tracy 2011a). Currently, Tracy's existing water supplies include 17,500 AF/y through

---

[21] This agreement is based on New Melones Reservoir storage and inflow as of April 1 of each year. This contract ended in 2009, with a potential 10-year renewal, pending studies. A one-year temporary water transfer agreement for the water year 2009–2010 allowed for a sale of up to 15,000 AF/y from both OID and SSJID.

the USBR CVP Interim Renewal Contract; 2,500 AF/y via USBR WSID Option; and 11,120 AF/y from the South County Water Supply Project (City of Tracy 2014). Tracy Hills, once built out, will receive 2,430 AF/y from Byron Bethany Irrigation District (City of Tracy 2014). The City of Tracy is planning to decrease groundwater use to 2,500 AF/y by 2015; however, up to 9,000 AF/y of groundwater is available to the City of Tracy to make up for shortfalls in the event of a severe drought or other water shortage (City of Tracy 2014). Tracy anticipates that it has sufficient water supply to meet the water demand through 2035 during normal years, single dry and multiple dry years.

City of Ripon

Ripon last prepared an UWMP in 2003 and updated it in 2011 to meet new state standards. Ripon has an agreement with SSJID to receive 2,000 AF/y, with a gradual increase to 6,000 AF/y by 2030 (SSJID 2011).

City of Modesto and Modesto Irrigation District (MID)

Modesto relies on a conjunctive water use strategy with two primary sources: groundwater and surface water from the Tuolumne River purchased from MID. During normal water years, MID delivers approximately 33,600 AF/y of treated surface water to the City of Modesto. This amount is projected to increase to approximately 67,000 AF/y by 2035. Groundwater use is expected to be reduced in the future with the introduction of additional surface water supplies from the Modesto Regional Water Treatment Plant (MRWTP), and this supply source will become Modesto's primary water supply, with groundwater supplementing the available surface water supplies to meet demand (City of Modesto and MID 2011). The Phase Two expansion of MRWTP will double the capacity of MID's water treatment plant, and an additional 33,602 AF/y of demand will be met with surface water supplies upon the completion of this expansion.

The surface water supplied by the MRWTP is provided through agreements with MID, and if it becomes necessary to reduce deliveries to its landowners, there would be proportional reductions to the City of Modesto. The City of Modesto and MID project that water demand will be met 100 percent of the time with the water supply in normal, single dry, and multiple dry years, through 2035. In general, projected demand is expected to be met through additional groundwater pumping (City of Modesto and MID 2011).

City and County of San Francisco (CCSF)

The CCSF regional water system obtains approximately 85 percent of its water from the Upper Tuolumne River Watershed, which is collected in Hetch Hetchy Reservoir. The remaining 15 percent of CCSF's water supply is obtained from surface water sources in the Alameda and San Francisco Peninsula Watersheds (SFPUC 2013). In 2015, CCSF provided approximately 196 mgd of surface water to approximately 1,800,897 wholesale and 847,370 retail customers, and an additional 2 mgd of groundwater and recycled water was also delivered to retail customers (SFPUC 2016). The amount of water available to CCSF varies from year-to-year depending on meteorological conditions, water rights, and statutory and contractual obligations (City and County of San Francisco 2008). Currently, groundwater use is generally limited to irrigation in Golden Gate Park and at the San Francisco Zoo (City and County of San Francisco 2008). However, ongoing groundwater storage projects including the Regional Groundwater Storage and Recovery Project (as part of the WSIP, discussed below) and the San Francisco Groundwater Supply Project, would increase water supply reliability and diversify CCSF's water supply (SFPUC 2015).

In normal water years water demand is met 100 percent of the time. At current delivery levels, CCSF expects to experience up to a 25 percent water supply shortage 15–20 percent of the time during multiple-year droughts. To enhance the ability of CCSF to meet service goals for water supply, as well as water delivery reliability, water quality, and seismic reliability, SFPUC is implementing the Water System Improvement Program (WSIP). The WSIP is, in part, a water supply program that will be implemented in phases to meet projected water purchases through 2030 in drought and normal water years. The WSIP establishes a mid-term planning milestone for 2018 at which point SFPUC would reevaluate water demand projections through 2030 in the context of information, analysis and available water resources in 2018. The WSIP includes the following water supply elements.

- Water supply delivery to regional water system customers through 2018 of 265 mgd average annual target delivery, which includes 184 mgd for wholesale customers and 81 mgd for retail customers;
- Water supply sources would include 265 mgd average annual from Tuolumne River, San Francisco Peninsula, and Alameda Creek Watersheds, and 20 mgd (divided evenly between retail and wholesale customers) of water conservation, recycled water and local groundwater developed within the SFPUC's service area; and
- Water supply projects to meet dry-year demands with no greater than 20 percent system-wide rationing in any one year, which would include restoring the capacity of Calaveras and Crystal Springs reservoirs; groundwater conjunctive use; and water transfers with MID and TID during dry years (average 2 mgd) (CCSF 2008).

Delta Regional Monitoring Program

Since 2012, the Delta Regional Monitoring Program (Delta RMP), initiated by the Central Valley Water Board, has had the main goal of tracking and documenting the effectiveness of beneficial use protection on restoration efforts through comprehensive monitoring of water quality constituents in the Delta. The Delta RMP is stakeholder-directed with a steering committee consisting of publicly-owned WWTPs, municipal stormwater dischargers, the Central Valley Water Board, the USEPA, California Natural Resources Agency, State and Federal Contractors Water Agency, and Interagency Ecological Program. The Delta RMP is still under development.

Order R5-2014-0122 considers the amendment of NPDES permits of several Sacramento–San Joaquin Delta-area dischargers in accordance with 40 CFR 122.62(a)(2), including the City of Stockton Regional Wastewater Control Facility; the City of Tracy WWTP; Mountain House CSD; Discovery Bay CSD; and Deuel Vocational Institution to allow for the participation in the Delta RMP in lieu of conducting their current individual monitoring efforts, when feasible and appropriate.

General Plans

City and county general plans can contain policies governing service providers, specifically with respect to water supply and wastewater. The goals and policies governing service providers within the area of potential effects are addressed in the applicable county general plans. Although local general plans are not binding on the state of California, relevant provisions of these county general plans are outlined below.

Stanislaus County

Goals and policies addressing water services and groundwater resources are presented in the *Stanislaus County General Plan Conservation and Open Space Element* (Stanislaus County 1995). These include: monitoring groundwater quality, preventing reduction of groundwater levels, and incorporating water conservation strategies into new development.

Merced County

Goals and policies addressing water services are presented in the *Public Facilities Element* and the *Water Element* of the *2030 Merced County General Plan* (Merced County 2013). The policies support the adequate provision of utilities to the residents of Merced County and ensure a reliable water supply sufficient to meet the existing and future needs of the county by implementing groundwater recharge projects, demonstrating sufficient water supply for new development, and investing in additional surface water storage opportunities.

San Joaquin County

Objectives and policies addressing water services and groundwater resources are presented in the *Resources Element* of San Joaquin County's general plan (San Joaquin County 1992). The objectives include obtaining sufficient supplemental water supplies to meet all municipal and agricultural needs; protecting groundwater resources from overdraft; and preventing water supply contamination. The policies discuss maintaining water quality and managing water resources such that conjunctive use and other groundwater and surface water management practices are undertaken.

Contra Costa County

Goals and policies addressing water services are presented in the *Contra Costa County General Plan Public Facilities/Service Element* section on water services (Contra Costa County 2005). These policies include assurance of meeting regulatory standards for water delivery, water storage, and emergency water supplies to residents. The general plan identifies goals of ensuring potable water availability in quantities sufficient to serve existing and future residents and ensuring that new development pays the costs related to the need for future increased water system capacity.

City of Tracy

The *Tracy General Plan Public Facilities and Services Element* contains policies stating that the approval of a new development is conditioned on the availability of sufficient wastewater collection and treatment capacity to service the proposed development. In addition, new development shall fully fund the cost of wastewater treatment and disposal facilities. Tracy's general plan contains objectives and policies generally stating that the City shall meet the demands of future development with adequate water supply and infrastructure. Policies also state that the City shall establish water demand reduction standards for new development (City of Tracy 2011c).

City of Stockton

The *2035 Stockton General Plan* contains policies that discuss the need for proper facility sizing to meet long-term needs, wastewater reuse, and protection of critical infrastructure. It also contains policies that reflect the City's need for facilities able to meet long-term demands (City of Stockton 2007).

City of Manteca

Goals and policies addressing water services and wastewater services are presented in the *City of Manteca's General Plan Public Facilities and Service Element* (City of Manteca 2003). Goals include maintaining existing target level of services for water delivery to residents and meeting the needs of existing and projected development. Policies to support the goals include principally relying on groundwater resources in the near term, developing new water sources as necessary to serve new development, ensuring water quality and preventing contamination, and developing and implementing water conservation measures.

City of Lathrop

Section D of the *Comprehensive General Plan for the City of Lathrop* provides guidance for the elimination of deficiencies in existing utility services and obstacles to the expansion of utility services to adequately serve existing and future development (City of Lathrop 2004). This guidance includes: developing and maintaining existing groundwater resources within city limits, participating in the South County Surface Water Supply Project, converting agricultural water entitlements, and obtaining rights to other water sources in the region.

City of Escalon

Goals and policies identified in the City of Escalon's general plan are meant to address the community need for public service and facilities (City of Escalon 2005). These goals and policies are meant to develop services and facilities, such as those for water supply, as the city grows and to plan for the future increase in demand for such services.

City of Ripon

Goals and policies identified in the *City of Ripon's General Plan Land Use and Growth Accommodations Element* are meant to address groundwater resources and water conservation as they relate to water supply (City of Ripon 2006). These include monitoring the existing groundwater conditions and supply, identifying and securing available sources of supplemental surface water for replacement or recharge of groundwater, and promoting water conservation.

13.4 Impact Analysis

This section identifies the thresholds or significance criteria used to evaluate the potential impacts on service providers. It further describes the methods of analysis used to determine significance. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant impacts accompany the impact discussion, if any significant impacts are identified.

13.4.1 Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based on the State Water Board's Environmental Checklist in Appendix A of the board's California Environmental Quality Act (CEQA) regulations. (Cal. Code Regs., tit. 23, §§ 3720–3781.) The thresholds derived from the checklist have been modified, as appropriate, to meet the circumstances of the alternatives. (Cal. Code Regs., tit. 23, § 3777, subd. (a)(2).) Impacts resulting from actions by service providers were identified as potentially significant in the State Water Board's Environmental Checklist (see Appendix B, *State Water Board's Environmental Checklist*) and, therefore, are discussed in this analysis as to whether the alternatives could result in the following.

- Require or result in the construction of new water supply facilities or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.
- Violate any water quality standards such that drinking water quality in (a) public water systems and (b) domestic wells would be affected.
- Result in substantial changes to SJR inflows to the Delta such that insufficient water supplies would be available to service providers relying on CVP/SWP exports.

Where appropriate, specific quantitative or qualitative criteria are described in Section 13.4.2, *Methods and Approach*, for evaluating these thresholds.

As described Appendix B, *State Water Board's Environmental Checklist,* the LSJR and SDWQ alternatives would result in either no impact or less-than-significant impacts on the following related to service providers and, therefore, are not discussed further within this chapter.

- Exceed wastewater treatment requirements of the applicable regional water quality control board.
- Have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed.
- Require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects.
- Result in a determination by the wastewater treatment provider, which serves or may serve the project, that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments.
- Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs.
- Comply with federal, state, and local statutes and regulations related to solid waste.

13.4.2 Methods and Approach

LSJR Alternatives

This chapter evaluates the potential service provider impacts associated with the LSJR alternatives. Each LSJR alternative includes a specific unimpaired flow[22] requirement (i.e., 20, 40 or 60 percent) from February–June and different methods for adaptive implementation to reasonably protect fish and wildlife beneficial uses, as described in Chapter 3, *Alternatives Description*. Impacts could occur through a change in either surface water supply or groundwater supply or a change in surface or groundwater water quality under the LSJR alternatives. The methods for evaluating these changes and the potential impacts are detailed in the following sections.

---

[22] *Unimpaired flow* represents the water production of a river basin, unaltered by upstream diversions, storage, or by export or import of water to or from other watersheds. It differs from natural flow because unimpaired flow is the flow that occurs at a specific location under the current configuration of channels, levees, floodplain, wetlands, deforestation and urbanization.

Surface Water Supply

Results from the Water Supply Effects (WSE) model were used to estimate the potential surface water diversion reductions on each of the three eastside tributaries (Impact SP-1). Table 13-14 shows the changes in the cumulative distribution of the diversions that are expected to occur as a result of the LSJR alternatives as simulated by the WSE model.

While substantially reducing existing surface water supplies of service providers can be considered an impact, the extent to which service providers are affected is a function of their ability to use existing alternative supplies (e.g., groundwater) or develop alternative water supplies. Therefore, surface water diversion reductions are then compared to service providers' reliance on surface water as characterized in Tables 13-3a and 13-3b. The reductions are considered within the general context of water supply agreements and contracts to qualitatively determine whether service providers may need new and expanded water supply treatment facilities or water supply infrastructure.

This chapter provides a programmatic-level analysis of the impacts on service providers and refers to Chapter 16, *Evaluation of Other Indirect and Additional Actions* (Section 16.2), with respect to environmental impacts caused by service provider actions associated with various potential responses to the alternative. Potential impacts that result from service provider actions associated with the LSJR alternatives depend upon the specific actions selected by the service providers responsible for implementing site-specific projects, most of which are public agencies subject to their own CEQA obligations. Service providers may choose any approach described in Chapter 16, or a combination of approaches, or they may identify another as-yet unknown approach to meet its own unique needs. Potential new water supply facilities or infrastructure are described in Chapter 16 and include but are not limited to substitution of surface water with groundwater, aquifer storage and recovery, and recycled water sources (Sections 16.2.2, 16.2.3, and 16.2.4, respectively).

Changes to SJR inflow into the southern Delta at Vernalis resulting from the LSJR alternatives could change exports to service providers in the export service areas (i.e., CVP and SWP contractors). This is because some of the inflow is exported at the CVP and SWP pumps to the export service areas. The methodology used to estimate exports is fully described in Chapter 5, *Surface Hydrology and Water Quality* and Appendix F.1, *Hydrologic and Water Quality Modeling* (Section F.1.7) and results are presented in Tables F.1.7-2 through F.1.7-5 and summarized in Table 5-21. These changes are used in this chapter to qualitatively discuss whether there would be sufficient water supplies to service providers relying on CVP/SWP exports (Impact SP-3). To estimate the possible effects on exports, analysis related to exports and outflow assumes the State Water Board will not change the export constraints to protect any increased flows downstream of Vernalis because the LSJR alternatives as described in Chapter 3, *Alternatives Description*, would not affect export regulations**.**

Table 13-14. Distribution of Annual Baseline Water Supply and Differences from Baseline (Changes in Diversions) in the Eastside Tributaries for the LSJR Alternatives for 1922–2003

TAF = thousand acre-feet

Groundwater Supply

Results from the WSE model, information from Tables 13-3a and 13-3b, and general information regarding municipal and potable wells were used to estimate the potential impact on groundwater supply for service providers (Impact SP-1). Specifically, the impact analysis draws from the following.

- Chapter 9, *Groundwater Resources*, assessment of Impact GW-1 (if reduction in surface water diversion would substantially deplete groundwater supplies or interfere with recharge).
- Public water suppliers' reliance on groundwater.
- Number of active groundwater wells operated by individual public water suppliers.
- Size of population served by the public water suppliers.
- Depths of selected wells shown in Table 13-3b and depths to groundwater at those wells.

In Chapter 9, it is determined that impacts on groundwater resources would be significant and unavoidable in the Extended Merced Subbasin under LSJR Alternative 2 with adaptive implementation; in the Modesto, Turlock, and Extended Merced Subbasins under LSJR Alternative 3; and in all four subbasins under LSJR Alternative 4. The public water suppliers located in the impacted subbasins (see Tables 13-3a and 13-3b) are more likely to be affected by a reduction in groundwater supply.

Municipal groundwater well depths in the four groundwater subbasins range from 110–1,216 feet (Table 13-3b), whereas domestic well depths range from 48–580 feet (State Water Board 2016b). In general, public wells are deeper than private wells because private entities generally do not have the resources to drill deep. Accordingly, private wells can run dry before public wells do during drought. The difference between well depth and depth to groundwater, as shown in Table 13-3b, is a rough indicator of the potential for a well to run dry in the future—the smaller the difference, the more likely that a particular well may go dry. This is a general indicator given that the depth to water in a well may be different from the depth to groundwater depending on the site-specific hydrogeologic characteristics of the aquifer and well depth. The depth to groundwater (Table 13-3b) refers to depth to the top of the aquifer; yet municipal drinking water wells can draw water from deeper confined aquifers, which can cause water level in a well to be different from the top of the aquifer. However, when the depth to groundwater approaches the well depth, there is more certainty that a well is close to running dry. A difference of 100 feet or less was selected to identify wells considered potentially at risk of running dry sooner relative to other wells (identified in the gray-shaded cells in Table 13-3b). If significant groundwater impacts are allowed to continue for multiple years, especially in combination with drought, these wells may be at greater risk of running dry.

As discussed for surface water supply, this chapter provides a programmatic-level analysis of the impacts on service providers and refers to Chapter 16, *Evaluation of Other Indirect and Additional Actions* (Sections 16.2 and 16.3), with respect to environmental impacts caused by service provider actions associated with various potential responses to the alternative. Potential new water supply facilities or infrastructure are described in Chapter 16 and include substitution of surface water with groundwater, aquifer storage and recovery, and recycled water sources (Sections 16.2.2, 16.2.3, and 16.2.4, respectively). With respect to CCSF, potential new water supply facilities or infrastructure may include in-Delta diversions and water supply desalination (Sections 16.2.5 and 16.2.6, respectively).

Surface Water Quality

The potential impacts of the LSJR alternatives on existing drinking water sources in the southern Delta are evaluated quantitatively using the expected change in inflow from the LSJR predicted by the WSE model and the simulated effects on salinity values in the southern Delta (Impact SP-2a). EC in the southern Delta is largely controlled by EC at Vernalis. Table 13-15 presents baseline EC at Vernalis. The effect of LSJR Alternatives 2, 3, and 4 on these EC values is presented in Tables 13-16, 13-17, and 13-18. These tables show effects of the LSJR alternatives over a range of year types with the wetter, high flow years being represented by the salinity values at the lower ranges of the cumulative distribution and the drier, low flow years being represented by the salinity values at the higher ranges of the cumulative distribution. Further information about Delta salinity and changes in salinity within the southern Delta is presented in detail in Chapter 5, *Surface Hydrology and Water Quality,* in Appendix F.1, *Hydrologic and Water Quality Modeling* (which presents salinity changes under each of the LSJR alternatives) and Appendix F.2, *Evaluation of Historical Flow and Salinity Measurements of the Lower San Joaquin River and Southern Delta* (which presents historic salinity data).

The magnitude of the effects of the alternatives at other locations within the southern Delta (e.g., Old River at Tracy Boulevard and SJR at Brandt Bridge) is expected to be slightly larger than the effects at Vernalis. This is because the Vernalis flow, which affects EC at Vernalis, also affects the change in EC between Vernalis and locations within the southern Delta. As a result, if an alternative is expected to cause a reduction in EC at Vernalis, it would be expected to cause a slightly greater reduction farther downstream. Similarly, if an alternative is expected to cause an increase in EC at Vernalis, it would be expected to cause a slightly greater increase farther downstream. This information is used to identify whether the salinity in the southern Delta would result in a substantial degradation to water quality such that municipal drinking water sources could be affected.

Groundwater Quality

The potential impact of the LSJR alternatives on groundwater quality in municipal drinking water wells in the Eastern San Joaquin, Modesto, Turlock, and Extended Merced Subbasins is evaluated qualitatively. The analysis is based, in part, on the discussion of potential indirect impacts on groundwater quality due to increased pumping and subsequent reduction of groundwater level as discussed in Section 13.2.1, *Lower San Joaquin River and Tributaries.* The analysis also considers MCL exceedance information for primary detected contaminants in groundwater wells of selected municipalities in the area of potential effects during a representative non-drought year and drought year (Table 13-5), when groundwater reliance increased. To determine whether drinking water sources could be significantly impacted, these variables are considered together within the context of the California Health and Safety Code provisions of the Safe Drinking Water Act to prevent contaminated water from getting to the end user of a public water system (Impacts SP-2a and SP-2b).

Adaptive Implementation

Each LSJR alternative includes a February–June unimpaired flow requirement (i.e., 20, 40, or 60 percent) and methods for adaptive implementation to reasonably protect fish and wildlife beneficial uses, as described in Chapter 3, *Alternatives Description*. In addition, a minimum base flow is required at Vernalis at all times during this period. The base flow may be adaptively implemented as described below and in Chapter 3. State Water Board approval is required before any method can be implemented, as described in Appendix K, *Revised Water Quality Control Plan*. All methods may be implemented individually or in combination with other methods, may be applied differently to each tributary, and could be in effect for varying lengths of time.

The Stanislaus, Tuolumne, and Merced Working Group (STM Working Group) will assist with implementation, monitoring, and assessment activities for the flow objectives and with developing biological goals to help evaluate the effectiveness of the flow requirements and adaptive implementation actions. The STM Working Group may recommend adjusting the flow requirements through adaptive implementation if scientific information supports such changes to reasonably protect fish and wildlife beneficial uses. Scientific research may also be conducted within the adaptive range to improve scientific understanding of measures needed to protect fish and wildlife and reduce scientific uncertainty through monitoring and evaluation. Further details describing the methods, the STM Working Group, and the approval process are included in Chapter 3 and Appendix K.

Without adaptive implementation, flow must be managed such that it tracks the daily unimpaired flow percentage based on a running average of 7 days. The four methods of adaptive implementation are described briefly below.

1. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the specified annual February–June minimum unimpaired flow requirement may be increased or decreased to a percentage within the ranges listed below. For LSJR Alternative 2 (20 percent unimpaired flow), the percent of unimpaired flow may be increased to a maximum of 30 percent. For LSJR Alternative 3 (40 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 30 percent or increased to a maximum of 50 percent. For LSJR Alternative 4 (60 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 50 percent.
2. Based on best available scientific information indicating a flow pattern different from that which would occur by tracking the unimpaired flow percentage would better protect fish and wildlife beneficial uses, water may be released at varying rates during February–June. The total volume of water released under this adaptive method must be at least equal to the volume of water that would be released by tracking the unimpaired flow percentage from February–June.
3. Based on best available scientific information, release of a portion of the February–June unimpaired flow may be delayed until after June to prevent adverse effects to fisheries, including temperature, which would otherwise result from implementation of the February–June flow requirements. The ability to delay release of flow until after June is only allowed when the unimpaired flow requirement is greater than 30 percent. If the requirement is greater than 30 percent but less than 40 percent, the amount of flow that may be released after June is limited to the portion of the unimpaired flow requirement over 30 percent. For example, if the flow requirement is 35 percent, 5 percent may be released after June. If the requirement is 40 percent or greater, then 25 percent of the total volume of the flow requirement may be released after June. As an example, if the requirement is 50 percent, at least 37.5 percent unimpaired flow must be released in February–June and up to 12.5 percent unimpaired flow may be released after June. If after June the STM Working Group determines that conditions have changed such that water held for release after June should not be released by the fall of that year, the water may be held until the following year. See Chapter 3 and Appendix K for further details.

4. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the February–June Vernalis base flow requirement of 1,000 cubic feet per second (cfs) may be modified to a rate between 800 and 1,200 cfs.

The operational changes made using the adaptive implementation methods above may be approved if the best available scientific information indicates that the changes will be sufficient to support and maintain the natural production of viable native SJR Watershed fish populations migrating through the Delta and meet any biological goals. The changes may take place on either a short-term (e.g., monthly or annually) or longer-term basis. Adaptive implementation is intended to foster coordinated and adaptive management of flows based on best available scientific information in order to protect fish and wildlife beneficial uses. Adaptive implementation could also optimize flows to achieve the objective, while allowing for consideration of other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. While the measures and processes used to decide upon adaptive implementation actions must achieve the narrative objective for the reasonable protection of fish and wildlife beneficial uses, adaptive implementation could result in flows that would benefit or reduce impacts on other beneficial uses that rely on water.

The quantitative results included in the figures, tables, and text of this chapter present WSE modeling of the specified unimpaired flow requirement for each LSJR alternative (i.e., 20, 40, or 60 percent). However, the modeling does allow some inflows to be retained in the reservoirs after June, as could occur under adaptive implementation method 3, to prevent adverse temperature effects and this is included in the results presented in this chapter. If the percent of unimpaired flow is not specified in this chapter, these are the percentages of unimpaired flow evaluated in the impact analysis. However, as part of adaptive implementation method 1, the required percent of unimpaired flow could change by up to 10 percent if the STM Working Group agrees to adjust it. The highest possible percent of unimpaired flow associated with an LSJR alternative is also evaluated in the impact analysis if long-term implementation of method 1 has the potential to affect a determination of significance. For example, if the determination for LSJR Alternative 2 at 20 percent unimpaired flow is less than significant, but the determination for LSJR Alternative 3 at 40 percent unimpaired flow is significant, then LSJR Alternative 2 is also evaluated at the 30 percent unimpaired flow. This use of modeling provides information to support the analysis and evaluation of the effects of the alternatives and adaptive implementation. For more information regarding the modeling methodology and quantitative flow and temperature modeling results, see Appendix F.1, *Hydrologic and Water Quality Modeling*.

Extended Plan Area

The analysis of the extended plan area generally identifies how the impacts may be similar to or different from the impacts in the plan area (i.e., downstream of the rim dams) depending on the similarity of the impact mechanism (e.g., changes in reservoir levels, reduced water diversions, and additional flow in the rivers) or location of potential impacts in the extended plan area. Where appropriate, the program of implementation is discussed to help contextualize the potential impacts in the extended plan area.

SDWQ Alternatives

The potential impacts of the SDWQ alternatives on existing drinking water sources in the southern Delta are evaluated qualitatively. The general range of historical salinity levels in the southern Delta are presented in Chapter 5, *Surface Hydrology and Water Quality* (Tables 5-15a-d), Appendix F.2, *Evaluation of Historical Flow and Salinity Measurements of the Lower San Joaquin River and Southern Delta*, and Section 13.2.3, *Southern Delta*.

The SDWQ alternatives would amend the southern Delta salinity objectives identified in the 2006 Bay-Delta Plan. The 2006 Bay-Delta Plan established salinity objectives to protect agricultural beneficial uses in the southern Delta. Under the CWA, the Central Valley Water Board is required to impose permit effluent limitations to achieve water quality objectives in the Bay-Delta Plan for point-source dischargers where there is a reasonable potential for the discharge to cause or contribute to an excursion above a water quality objective. (40 C.F.R., § 122.44, subd. (d).) The average annual effluent EC data, existing regulatory effluent limitations, and evaluation of enforcement orders are used to qualitatively discuss whether service providers could meet the objectives of the SDWQ alternatives. For this assessment, it is assumed that under baseline conditions, WWTP effluent limitations would be based on the current limitations. With the exception of Deuel, these are less stringent than the southern Delta salinity objectives specified in the 2006 Bay-Delta Plan. If the salinity objectives are changed according to SDWQ Alternatives 2 and 3, WWTP effluent limitations for salinity would have be modified and set equal to the new objectives. The potential impacts of the SDWQ alternatives on WWTPs are evaluated qualitatively (Impact SP-1).

The Central Valley Water Board has determined the discharge from Discovery Bay CSD does not have reasonable potential to cause or contribute to an exceedance of the 2006 Bay-Delta Plan water quality objectives in Old River or the southern Delta (Marshall pers. comm. 2012a). This is because of the large dilution in Old River and the good quality of water in Old River coming down from the Sacramento River (Marshall pers. comm. 2012a). Thus, Discovery Bay CSD can comply with the water quality objectives and does not need effluent limits based on the 2006 Bay-Delta Plan water quality objectives (Marshall pers. comm. 2012a). Since SDWQ Alternatives 2 and 3 are higher than the existing salinity water quality objectives, Discovery Bay CSD would likely continue to not have a reasonable potential to cause or contribute to exceedance of the proposed salinity water quality objectives such that effluent limitations would not be required. Therefore, Discovery Bay CSD is not included in the analysis in Section 13.4.3, *Impacts and Mitigation Measures*.

This chapter provides a programmatic-level analysis of the impacts on service providers and refers to Chapter 16, *Evaluation of Other Indirect and Additional Actions* (Section 16.4), with respect to environmental impacts caused by service provider actions associated with various methods of compliance. Service providers may choose any method of compliance described in Chapter 16, or a combination of methods, or they may identify another as-yet unknown method of compliance to comply with requirements from the revised objectives. Potential new water supply facilities or infrastructure are described in Chapter 16 and include the following: new source water supplies including new and expanded infrastructure to support such supplies; salinity pretreatment programs; desalination, including new and expanded salinity removal facilities at existing WWTPs; and the real-time management of agricultural return flow, including the use of detention ponds (Sections 16.4.2, 16.4.3, 16.4.4, respectively).[23]

---

[23] The City of Tracy finalized and adopted the *Initial Study/Mitigated Negative Declaration for the Tracy Desalinization and Green Energy Project* in April of 2012 (City of Tracy 2011b, 2012). Impact determinations from this document are incorporated herein. This document identified available and feasible mitigation necessary to reduce potentially significant environmental effects on aesthetics, agriculture, air quality, biological resources,

As noted in Chapter 9, *Groundwater Resources*, and discussed in Appendix B, *State Water Board's Environmental Checklist,* the SDWQ alternatives would not result in a change in the minimal groundwater pumping that currently takes place in the southern Delta; therefore, with regard to groundwater supply, and associated effects on drinking water supply, the SDWQ alternatives are not addressed in this chapter.

13.4.3 Impacts and Mitigation Measures

Impact SP-1: Require or result in the construction of new water supply facilities or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternative 2 (Less than significant/Significant and unavoidable with adaptive implementation)

Surface Water Supply

Results of the WSE model indicate that service providers diverting surface water from the Stanislaus, Tuolumne, and Merced Rivers would generally be able to divert similar surface water amounts at similar times under LSJR Alternative 2 when compared to baseline (Table 5-19). For LSJR Alternative 2, the average percent reduction in water supply on the Stanislaus, Tuolumne, and Merced Rivers was estimated to be 2 percent, 2 percent, and 6 percent, respectively (Table 13-14). Service providers relying on surface water diversions are expected to receive similar surface water supplies relative to baseline conditions. Because it is expected these service providers would have sufficient sources of surface water, it is not expected they would need to construct new or expanded water treatment facilities or water supply infrastructure.

Groundwater Supply

As described in Chapter 9, *Groundwater Resources*, the slight reduction in recharge compared to baseline, due to small changes to average surface water diversions under LSJR Alternative 2, would not likely result in a substantial reduction in groundwater levels. As such, those service providers (Tables 13-3a and 13-3b) and private users that rely primarily on groundwater would have sufficient sources for municipal and domestic uses under LSJR Alternative 2 and, therefore, it is not

---

cultural resources, geology and soils, hydrology and water quality, hazards and hazardous materials, and land use and planning. With the implementation of mitigation measures, impacts on these resources were determined by the City to be reduced to a less-than-significant level.

expected they would need to construct new or expand existing water treatment facilities or water supply infrastructure. Impacts would be less than significant.

Adaptive Implementation

Based on best available scientific information indicating that a change in the percent of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation method 1 would allow an increase of up to 10 percent over the 20-percent February–June unimpaired flow requirement (to a maximum of 30 percent of unimpaired flow). A change to the percent of unimpaired flow would take place based on required evaluation of current scientific information and would need to be approved as described in Appendix K, *Revised Water Quality Control Plan.* Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. However, an increase of up to 30 percent of unimpaired flow would potentially result in different effects as compared to 20-percent unimpaired flow, depending upon flow conditions and frequency of the adjustment. While the total volume of water released February–June would be the same as LSJR Alternative 2 without adaptive implementation, the rate could vary from the actual (7-day running average) unimpaired flow rate.

Based on best available scientific information indicating that a change in the timing or rate of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation method 2 would allow changing the timing of the release of the volume of water within the February–June time frame. While the total volume of water released February–June would be the same as LSJR Alternative 2 without adaptive implementation, the rate could vary from the actual (7-day running average) unimpaired flow rate. Method 2 would not authorize a reduction in flows required by other agencies or through other processes, which are incorporated in the modeling of baseline conditions. Method 3 would not be authorized under LSJR Alternative 2 since the unimpaired flow percentage would not exceed 30 percent.

Adaptive implementation method 4 would allow an adjustment of the Vernalis February–June flow requirement. WSE model results show that under LSJR Alternative 2 the 1,200-cfs February–June base flow requirement at Vernalis would require a flow augmentation in the three eastside tributaries and LSJR only 2.7 percent of the time in the 82-year record analyzed. Similarly, flow augmentation would be required 0.7 percent of the time to meet a 1,000 cfs requirement and 0.5 percent of the time for an 800 cfs Vernalis base flow requirement. These results indicate that changes due to method 4 under this alternative would rarely alter the flows in the three eastside tributaries or the LSJR.

Surface Water Supply

At 30 percent unimpaired flow under LSJR Alternative 2 with adaptive implementation method 1, the average percent reduction in water supply on the Stanislaus, Tuolumne, and Merced Rivers was estimated to be 5 percent, 7 percent, and 10 percent, respectively. Thus, surface water supply reductions would be greater at the 30 percent unimpaired flow level compared to 20 percent unimpaired flow. Reductions would be greatest for service providers receiving Merced River diversions (i.e., Merced ID), but would also be substantial for Tuolumne River service providers (i.e., TID, MID, and CCSF).

The extent to which service providers' surface water supplies would actually be reduced is a function of the mechanisms by which they receive the water (e.g., water rights or contracts), existing policies, regulations, and the type of water use they supply. Some water supply contracts have provisions that dictate when and how much surface water other water users receive from irrigation districts. For example, contracts could require the irrigation district to supply the full contracted amount of surface water to the other water user at all times, including during drought or water restricted periods. Some irrigation districts have policies in place that may require curtailment of water supplies during periods of surface water reduction (Table 13-13). Although California recognizes water for domestic purposes as the most important use of water and irrigation as the next most important use (Cal. Code Regs., tit. 23, § 106), this does not necessarily mean that the water supply for domestic uses cannot be modified. Furthermore, if other water districts that supply domestic uses are receiving water through contracts with irrigation districts, then these uses would not necessarily be protected. For example, if MID experiences water shortages, its deliveries to service providers serving urban uses (e.g., City of Modesto) could be cut back proportionally, as described in MID's various plans and policy documents.

The extent to which service providers that primarily rely on surface water are affected by a reduction in surface water diversions is a function of their ability to develop alternative water supplies or rely on their current existing alternative supplies (e.g., groundwater). Service providers that rely heavily or primarily on surface water diversions to supply water to their service areas could experience significant reductions in water supply, depending on the various factors described above (i.e., mechanism by which they receive the water, existing policies, regulations, and the type of water use they supply). Thus, the extent of the effect under LSJR Alternative 2 with adaptive implementation method 1 would be great when compared to baseline. MID, TID, and Merced ID currently rely on surface water diversions from the Tuolumne and Merced Rivers as their primary water supply. The City of Modesto currently relies on surface water diversions to meet nearly 40 percent of its water demand (Table 13-3b). If surface water diversions were reduced on the Tuolumne and Merced Rivers, (depending on the mechanism by which they receive the water, existing policies, regulations, and the type of water use they supply) these service providers would likely be greatly affected. The LSJR Alternative 2 program of implementation states that the State Water Board will take actions as necessary to ensure implementation of flow objectives does not impact supplies of water for minimum health and safety needs, particularly during drought periods. Actions may include assistance with funding and development of water conservation efforts and regional water supply reliability projects and regulating public drinking water systems and water rights. These actions would be aimed at those service providers supplying water to municipal users and may offset water supply reduction impacts on providers. However, it is expected service providers may need to construct or expand new water treatment facilities or water supply infrastructure to try to accommodate reductions in surface water supplies. Additionally, as a result of reduced water supply, LSJR Alternative 2 with adaptive implementation method 1 may necessitate WWTPs and related infrastructure to be modified to allow or augment water recycling or meet pretreatment or NPDES permit requirements.

As discussed in Appendix L, *City and County of San Francisco Analyses*, some portion of the increased release flows from New Don Pedro Reservoir on the Tuolumne River could be shared by CCSF (especially during a prolonged drought), thus potentially reducing water supply. This would depend on a number of factors, including the assignment of responsibility to CCSF or the irrigation districts to meet the flow requirements through a proceeding amending water rights or through FERC relicensing, the interpretation of the Fourth Agreement, whether CCSF pays the irrigation districts to release water to meet the flow requirement, and any future agreement between the irrigation districts and CCSF. If a prolonged drought occurred, and CCSF was required to share in the release of flows, thus potentially reducing water supply, it may need to construct new and expanded water treatment supply infrastructure for in-Delta diversion and desalination to accommodate reductions in surface water supplies, as identified in Chapter 16, *Evaluation of Other Indirect and Additional Actions,* Sections 16.2.5 and 16.2.6, respectively.

Identifying the exact nature of the new and expanded facilities potentially needed by those irrigation districts and other water suppliers to replace potentially reduced surface water supplies is speculative (as discussed in Chapter 16, *Evaluation of Other Indirect and Additional Actions*). However, it is reasonably foreseeable that new and expanded facilities could include the following.

- New and expanded infrastructure, if needed, to convey water obtained through water transfers or sales from other entities or watershed.[24]
- New and expanded groundwater well(s) and distribution infrastructure (e.g., underground pipes) and infrastructure to treat groundwater, if needed.
- New and expanded conjunctive groundwater use program(s), which could use available capacity in unlined canals and agricultural fields that are not in production to recharge groundwater basins during high flow events.
- New and expanded facilities at existing WWTPs and distribution infrastructure (e.g., underground pipes) to increase the supply of recycled water as a possible source of water.
- New surface water reservoir and distribution infrastructure.

Depending on the location and particular construction and operational requirements, construction of the new and modified facilities described above could result in physical environmental impacts on resources such as those listed below (Chapter 16, Section 16.2.1, Section 16.2.2 and Table 16-7; Section 16.2.3 and Table 16-9; Section 16.2.4 and Table 16-10; and Section 16.2.7 and Table 16-11b).

- Air quality and greenhouse gases, as a result of emissions generated by construction equipment and construction trips.
- Biological resources, as a result of potential dust, noise, or possible removal of special-status species and habitat.
- Cultural resources, as a result of excavation, grading, and other soil-disturbing activities, if construction takes place in an area moderately or highly sensitive for cultural resources.
- Geology, as a result of potential erosion or construction on unstable soils.
- Water quality, as a result of runoff associated with dust control or other construction activities, or as a result of potential construction material spills, such as of lubricants or fuel.
- Hazards, as a result of handling, use, and disposal of hazardous materials during construction.
- Mineral resources, as a result of potentially inhibiting access to known mineral resources.

---

[24] One of the options that the service providers have to compensate for the reduction of surface water and groundwater availability due to the LSJR alternatives is water purchase or transfer from other entities. As discussed in Chapter 16, *Evaluation of Other Indirect and Additional Actions*, Section 16.2.1, it is not expected that additional infrastructure would be needed. If new and expanded infrastructure is needed, the physical environmental impacts of the construction would be similar to those discussed in Chapter 16, Section 16.2.2 and Table 16-7; Section 16.2.3 and Table 16-9; and Section 16.2.4 and Table 16-10).

- Noise, as a result of the use of construction equipment within proximity to potential sensitive receptors (e.g., residences).
- Traffic, as a result of the use of construction equipment and commuting of construction workers.

Depending on the location and particular construction and operational requirements, operation of new and modified facilities could result in physical environmental impacts on resources such as those listed below (Chapter 16, Section 16.2.1, Section 16.2.2, and Table 16-7; Section 16.2.3 and Table 16-9; Section 16.2.4 and Table 16-10; and Section 16.2.7 and Table 16-11b).

- Aesthetics, as a result of operational lighting or blocking of views if views are designated and present and sensitive receptors are present.
- Air quality and greenhouse gases, as a result of increased energy demand.
- Biological resources, as a result of potential water quality impacts related to treating new water source(s).
- Water quality, as a result of the need to treat new water source(s).
- Hazards, as a result of handling materials (e.g., chlorine) potentially needed to treat new water source(s).
- Mineral resources, as a result of potentially inhibiting access to known mineral resources.
- Noise, as a result of new equipment operating within proximity to potential sensitive receptors (e.g., residences).

Should service providers need to construct new and expanded water treatment facilities or water supply infrastructure as a result of implementation of method 1 under LSJR Alternative 2, the activities involved therein are anticipated to either be discretionary actions and/or meet the definition of a project for CEQA. (State CEQA Guidelines, §§ 15377–15378.) If the activities are not discretionary actions and/or do not meet the definition of a project under CEQA (e.g., private well construction or modification), then it is presumed there would be very limited environmental impacts such that they would not rise to the level of causing potentially significant environmental impacts necessitating environmental documentation (e.g., mitigated negative declaration, environmental impact report). The decision-making body of the lead agency (e.g., public water supplier or local agency) would approve discretionary action(s) associated with any new or modified facilities or infrastructure. The approval of new or modified facilities would require the preparation and approval of a CEQA document identifying project-specific details and specific resource analyses of potentially significant impacts. The CEQA document would disclose any project-specific, potentially significant environmental impacts resulting from new or modified facilities. As part of this process, the decision-making body would be responsible (not the State Water Board) for imposing mitigation measures or BMPs if project-specific environmental impacts deemed potentially significant.

Although the exact scope and scale of environmental impacts cannot be determined because identifying the exact nature of the new and expanded facilities is speculative, Table 16-38 in Chapter 16 lists possible mitigation measures that would likely reduce potentially significant impacts on environmental resources as a result of construction and operation of new or modified facilities or infrastructure. For example, potentially significant environmental impacts due to construction may be mitigated through design, timing, and construction BMPs. Infrastructure could be designed to have minimal impact on the surrounding environment (e.g., pipelines could be buried under existing roads). Construction-timing mitigation measures may include scheduling such that work in surface waters, if needed, takes place after aquatic species have migrated out of the area. BMPs for construction activities could include the use of erosion prevention practices near surface waters, for example.

An SED must identify feasible mitigation measures for each significant environmental impact identified in the SED. (Cal. Code Regs., tit. 23, § 3777, subd. (b)(3).) CEQA does not grant agencies new, discretionary powers independent of the powers granted to the agencies by other laws. (Pub. Resources Code, § 21004; Cal. Code Regs., tit. 14, § 15040.) Accordingly, a mitigation measure may be legally infeasible if the lead agency does not have the authority to require or implement it. (Pub. Resources Code, § 21004; Cal. Code Regs., tit. 14, § 15040.) Since the State Water Board would not be responsible for or have discretionary authority to approve the construction of any new or modified facilities or infrastructure, it is not feasible for the State Water Board to impose the possible mitigation measures listed in Table 16-38. Moreover, the State Water Boards lacks authority to impose mitigation measures related to impacts on certain resources (e.g., air, noise or traffic). Agencies responsible for approving the project-specific new or modified facilities can and should impose the applicable mitigation measures in Table 16-38. The storage capacities for the reservoirs are fixed. Accordingly, there is no possibility of increasing the total water supply to provide more water for surface water diversions as mitigation under LSJR Alternative 2. More water released to the rivers would leave less water for surface water diversions. Therefore, there is no feasible mitigation the State Water Board can implement to reduce environmental impacts resulting from the need for new or modified facilities or infrastructure. Impacts would be significant and unavoidable.

Groundwater Supply

MID, TID and Merced ID may need to supplement their surface water supplies with groundwater to meet their needs, under adaptive implementation method 1, as described above and in Chapter 9, *Groundwater Resources*. Impacts on groundwater would increase relative to the 20 percent unimpaired flow level in the Extended Merced Subbasin depending on the use by Merced ID. As described in Chapter 9, LSJR Alternative 2 adaptive implementation method 1 would result in a substantial depletion of groundwater supplies in the Extended Merced Subbasin if implemented on a long-term basis. Were that to occur, service providers and private users relying heavily or primarily on groundwater sources for municipal and domestic use could experience significant reductions in water supply over the long term. The magnitude or severity of the effect would depend on additional factors such as the size of the population being served and the number of active municipal wells in their service area, and the range of differences between well depths and depths to groundwater (Table 13-3b), and other factors (e.g., physical condition of wells). For example, Le Grand CSD serves a population of 1,700 with three active wells (Table 13-3b), and the range of difference between well depths and depths to groundwater for those three wells is 91–536 feet. In light of these three factors, the demand for municipal and domestic water supply in the service area of Le Grand CSD with implementation of LSJR Alternative 2 with adaptive implementation method 1 could likely be met in the short term. But the district's wells are aging, and two have experienced age-related failures recently (Chauhan pers. comm.). If groundwater reductions were to continue for multiple years, especially in combination with drought conditions, these wells may be at risk of running dry.

Similar to the above discussion related to surface water supply, over the long term, service providers in the Extended Merced Subbasin may need to construct new and expanded water treatment facilities or water supply infrastructure (e.g., additional wells) to meet demands. Additionally, as a result of reduced water supply, implementation of LSJR Alternative 2 with adaptive implementation method 1 may necessitate WWTPs and related infrastructure to be modified to allow or augment water recycling or meet pretreatment or NPDES permit requirements. Therefore, impacts would be significant. Drinking water sourced from domestic wells would be affected similarly, and it is assumed that those affected would need to find an alternative drinking water supply such as bottled water or drill additional groundwater wells, and impacts would be significant.

Similar to the reductions in surface water supply, the reduction in groundwater supply to service providers in the Extended Merced Subbasin identified in Table 13-3a would likely require these entities to construct new and expanded water treatment facilities or water supply infrastructure (e.g., additional wells) to replace groundwater supplies. Identifying the exact nature of the new and expanded facilities needed to replace potentially reduced surface water diversions and groundwater supplies is speculative (as discussed in Chapter 16, *Evaluation of Other Indirect and Additional Actions*). However, it is reasonably foreseeable that the facilities could include the following.

- New and expanded infrastructure, if needed, to convey water obtained through water transfers or sales from other entities.
- New and expanded groundwater well(s) and distribution infrastructure (e.g., underground pipes) and infrastructure to treat groundwater, if needed.
- New and expanded conjunctive groundwater use program(s), which could use available capacity in unlined canals and agricultural fields that are not in production to recharge groundwater basins during high flow events.
- New and expanded facilities at existing WWTPs and distribution infrastructure (e.g., underground pipes) to increase the supply of recycled water as a possible source of water.

Similar to the above discussion related to surface water supply, identifying the exact nature of the new and expanded facilities potentially needed to replace potentially reduced groundwater supplies is speculative (as discussed in Chapter 16). Depending on the location and particular construction and operational requirements, construction of the new or modified facilities, as described above, could result in significant physical environmental impacts on resources (Chapter 16 Section 16.2.1; Section 16.2.2 and Table 16-7; Section 16.2.3 and Table 16-9; and Section 16.2.4 and Table 16-10). Although the exact scope and scale of environmental impacts cannot be determined because identifying the exact nature of the new and expanded facilities is speculative, Table 16-38 in Chapter 16 lists possible mitigation measures that would likely reduce potentially significant impacts on environmental resources as a result of construction and operation of new or modified facilities or infrastructure. Because the State Water Board would not be responsible for or have discretionary authority to approve the construction of any new or modified facilities or infrastructure, it is not feasible for the State Water Board to implement the possible mitigation measures listed in Table 16-38. Moreover, the State Water Board lacks authority to impose mitigation measures related to impacts such as air and noise. Agencies responsible for approving the project-specific new or modified facilities can and should impose the mitigation measures. The storage capacities for the reservoirs are fixed. Accordingly, there is no possibility of increasing the total water supply to provide more water for surface water diversions as mitigation under LSJR Alternative 2 with adaptive implementation method 1. More water released to the Merced River would leave less water for surface water diversions. Therefore, there is no feasible mitigation the State Water Board can implement to reduce environmental impacts on service providers and domestic groundwater users resulting from the need for new or modified facilities or infrastructure. Impacts would be significant and unavoidable.

LSJR Alternative 3 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

Surface Water Supply

As a result of LSJR Alternative 3, WSE model results predict surface water diversions would be generally reduced when compared to baseline conditions on the Stanislaus, Tuolumne, and Merced Rivers (Table 5-19). The average percent reduction in water supply on the Stanislaus, Tuolumne, and Merced Rivers was estimated to be 12 percent, 14 percent, and 16 percent, respectively, for LSJR Alternative 3 (Table 13-14). The impacts of LSJR Alternative 3 would be similar to those described above for LSJR Alternative 2 with adaptive implementation method 1; however, more irrigation districts and other water suppliers would likely be impacted as surface water supplies would be significantly reduced on the Stanislaus, Tuolumne, and Merced Rivers. Those irrigation districts and other water suppliers on the Tuolumne and Merced Rivers would be affected as described above for LSJR Alternative 2 with adaptive implementation method 1 (i.e., MID, TID, and Merced ID, City of Modesto and CCSF[25]). Additionally, it is expected that SSJID, OID, the City of Tracy, and SEWD may also be affected under LSJR Alternative 3, given the predicted reductions in surface water supplies and because they rely heavily or primarily on surface water to meet demand.

The reductions in surface water supply to service providers would likely require these entities to construct new and expanded water treatment facilities or water supply infrastructure to replace reduced surface water supplies. Identifying the exact nature of the new and expanded facilities needed to replace potentially reduced surface water diversions is speculative (as discussed in Chapter 16, *Evaluation of Other Indirect and Additional Actions*). Because the surface water diversions on the Stanislaus, Tuolumne, and Merced Rivers would be reduced, potentially requiring the construction of new and expanded water treatment facilities or water supply infrastructure, impacts would be significant.

Similar to the discussion of surface water supply impacts under LSJR Alternative 2 with adaptive implementation method 1, identifying the exact nature of the new and expanded facilities potentially needed by service providers and domestic groundwater users to replace potentially reduced groundwater supplies is speculative (as discussed in Chapter 16). Depending on location and particular construction and operational requirements, construction of the new or modified facilities, as described above, could result in significant physical environmental impacts on environmental resources (Chapter 16, Section 16.2.2 and Table 16-7; Section 16.2.3 and Table 16-9; and Section 16.2.4 and Table 16-10). Although the exact scope and scale of environmental impacts cannot be determined because identifying the exact nature of the new and expanded facilities is speculative, Table 16-38 in Chapter 16 lists possible mitigation measures that would likely reduce potentially significant impacts on environmental resources as a result of construction and operation

---

[25] With respect to CCSF and similar to the discussion under LSJR Alternative 2, with adaptive implementation method 1, and as discussed in Appendix L, *City and County of San Francisco Analyses*, a potential reduction in water supply during a prolonged drought would depend on a number of factors, including the assignment of responsibility to CCSF or the irrigation districts to meet the flow requirements through a proceeding amending water rights or through FERC relicensing, the interpretation of the Fourth Agreement, whether CCSF pays the irrigation districts to release water to meet the flow requirement, and any future agreement between the irrigation districts and CCSF. If a prolonged drought occurred, and CCSF was required to share in the release of flows, thus potentially reducing water supply, it may need to construct new and expanded water treatment supply infrastructure to accommodate reductions in surface water supplies.

of new or modified facilities or infrastructure. Because the State Water Board would not be responsible for or have discretionary authority to approve the construction of any new or modified facilities or infrastructure, it is not feasible for the State Water Board to impose the possible mitigation measures listed in Table 16-38. Moreover, the State Water Board lacks authority to impose mitigation measures related to impacts such as air and noise. Agencies responsible for approving the project-specific new or modified facilities can and should impose the applicable mitigation measures in Table 16-38. The storage capacities for the reservoirs are fixed. Accordingly, there is no possibility of increasing the total water supply to provide more water for surface water diversions as mitigation under LSJR Alternative 3. More water released to the river would leave less water for surface water diversions. Therefore, there is no feasible mitigation the State Water Board can implement to reduce environmental impacts resulting from the need for new or modified facilities or infrastructure. Impacts would be significant and unavoidable.

Groundwater Supply

The average annual groundwater balance is expected to be substantially reduced in the Modesto, Turlock, and Extended Merced Subbasins under LSJR Alternative 3, which would eventually produce a measureable decrease in groundwater elevations (Chapter 9, *Groundwater Resources*). This effect would be more severe in dry years and in areas farther from the LSJR, the valley low point toward which groundwater moves. These substantial reductions in groundwater supplies would, in turn, impact service providers (Tables 13-3a and 13-3b) and private groundwater users in these subbasins who are relying heavily or primarily on groundwater sources for municipal and domestic uses. These entities would likely experience significant reductions in their groundwater supply, particularly over the long term and in dry years. As discussed under LSJR Alternative 2 with adaptive implementation method 1, the magnitude or severity of the effect would depend on additional factors, such as the size of the population being served, the number of active municipal wells in their service area, the range of differences between well depths and depths to groundwater (Table 13-3b), and other factors (e.g., physical condition of wells). Service providers at particular risk include those that have a higher potential for a well to run dry in the future. For example, Hickman, Hilmar CWD, Hughson, and Keys CSD in the Turlock Subbasin; Le Grand CSD and the City of Merced in the Extended Merced Subbasin; and the City of Modesto in the Modesto Subbasin (Table 13-3b). This is because these service providers have relatively few active wells relative to the size of the population served and/or the range of difference between well depths and depths to groundwater is less than 100 feet (Table 13-3b). Private groundwater users are also at risk because domestic wells are typically more shallow and older than public municipal wells. Impacts would be significant and unavoidable.

Adaptive Implementation

As discussed under LSJR Alternative 2, adaptive implementation methods 2 and 4 are not expected to result in impacts on surface water diversions or groundwater supplies. Adaptive implementation method 3 would result in a shift in the volume of February–June water available to other parts of the year and would be unlikely to affect surface water diversions or groundwater supplies because the total amount of water available for diversion would be unaffected. Adaptive implementation method 1 would allow an increase or decrease of up to 10 percent in the February–June, 40 percent minimum unimpaired flow requirement (with a minimum of 30 percent and maximum of 50 percent) to optimize implementation measures to meet the narrative objective, while considering other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. Adaptive implementation must be approved using the process described in Appendix K, *Revised Water Quality Control Plan*. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. If the specified percent of unimpaired flow were changed from 40 percent to 30 percent or 40 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternative 2 with adaptive implementation method 1 or LSJR Alternative 4 with adaptive implementation method 1, respectively. Reducing the unimpaired flow percentage from 40 percent to 30 percent would reduce impacts on several service providers, and effects may be limited to MID, TID, CCSF, and Merced ID, and those service providers (Tables 13-3a and 13-3b) and private groundwater users that rely solely on the Extended Merced Subbasin for water supply. However, increasing the unimpaired flow percentage from 40 percent to 50 percent would increase the magnitude and severity of the impacts on those service providers at 40 percent unimpaired flow because there would be less surface water available at 50 percent unimpaired flow. In addition, the Eastern San Joaquin Basin could be affected. As such, impacts would be significant. As discussed under LSJR Alternative 2 with adaptive implementation method 1, there is no feasible State Water Board mitigation to reduce these impacts, and impacts would be significant and unavoidable. Agencies responsible for approving the project-specific new or modified facilities can and should impose the applicable mitigation measures in Table 16-38.

LSJR Alternative 4 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

Surface Water Supply

As a result of LSJR Alternative 4, WSE model results predict surface water diversions would be greatly reduced when compared to baseline conditions on all three eastside tributaries. The average percent reduction in water supply on the Stanislaus, Tuolumne, and Merced Rivers was estimated to be 32 percent, 35 percent, and 32 percent, respectively, for LSJR Alternative 4 (Table 13-14). As discussed above under LSJR Alternative 3, the extent to which service providers' surface water supplies could be reduced is a function of the mechanism by which they receive the water (e.g., water rights, contracts), existing policies and regulations, and the type of water use they supply. The extent to which service providers are affected by a reduction in surface water diversions is a function of their abilities to use existing alternative supplies (e.g., groundwater) or develop alternative water supplies. Service providers that currently use surface water as a significant source of water supply could experience reductions in surface water supplies (e.g., irrigation districts, Tracy, SEWD, Modesto, CCSF[26]) similar to impacts described above for LSJR Alternative 3 with and without adaptive implementation. LSJR Alternative 4 program of implementation describes actions to assure that implementation does not impact supplies of water for minimum health and safety

---

[26] With respect to CCSF, and similar to the discussion under LSJR Alternative 2 with adaptive implementation method 1, and as discussed in Appendix L, *City and County of San Francisco Analyses*, a potential reduction in water supply during a prolonged drought would depend on a number of factors, including the assignment of responsibility to CCSF or the irrigation districts to meet the flow requirements through a proceeding amending water rights or through FERC relicensing, the interpretation of the Fourth Agreement, whether CCSF pays the irrigation districts to release water to meet the flow requirement, and any future agreement between the irrigation districts and CCSF. If a prolonged drought occurred, and CCSF was required to share in the release of flows, thus potentially reducing water supply, it may need to construct new and expanded water treatment supply infrastructure to accommodate reductions in surface water supplies.

needs, and these actions may offset water supply reduction impacts on service providers for municipal uses. However, impacts would be significant.

The reductions in surface water supply to service providers would likely require these providers to construct new and expanded water treatment facilities or water supply infrastructure to replace reduced surface water supplies. Additionally, as a result of reduced water supply, LSJR Alternative 4 may necessitate WWTPs and related infrastructure to be modified to allow or augment water recycling or meet pretreatment or NPDES permit requirements. Identifying the exact nature of the new and expanded facilities needed to replace potentially reduced surface water diversions is speculative (as discussed in Chapter 16, *Evaluation of Other Indirect and Additional Actions*). Because the surface water diversions on the Stanislaus, Tuolumne, and Merced Rivers would be reduced, potentially requiring the construction of new and expanded water treatment facilities or water supply infrastructure, impacts would be significant.

Similar to the discussion of surface water supply impacts under LSJR Alternative 2, with adaptive implementation method 1, identifying the exact nature of the new and expanded facilities potentially needed by public and private water suppliers to replace potentially reduced municipal groundwater supplies is speculative (as discussed in Chapter 16). Depending on the location and the particular construction and operational requirements, construction of the new or modified facilities, as described above, could result in significant physical environmental impacts on environmental resources (Chapter 16, Section 16.2.2 and Table 16-7; Section 16.2.3 and Table 16-9; and Section 16.2.4 and Table 16-10). Although the exact scope and scale of environmental impacts cannot be determined because identifying the exact nature of the new and expanded facilities is speculative, Table 16-38 in Chapter 16 lists possible mitigation measures that would likely reduce potentially significant impacts on environmental resources as a result of construction and operation of new or modified facilities or infrastructure. Because the State Water Board would not be responsible for or have discretionary authority to approve the construction of any new or modified facilities or infrastructure, it is not feasible for the State Water Board to impose the possible mitigation measures listed in Table 16-38. Moreover, the State Water Boards lacks authority to impose mitigation measures related to impacts such as air and noise. Agencies responsible for approving the project-specific new or modified facilities can and should impose the applicable mitigation measures in Table 16-38. The current storage capacities for the reservoirs are fixed. Accordingly, there is no possibility of increasing the total water supply to provide more water for surface water diversions as a means of mitigation under LSJR Alternative 4 with adaptive implementation. More water released to the river would leave less water for surface water diversions. Therefore, there is no feasible mitigation the State Water Board can implement to reduce environmental impacts resulting from the need for new or modified facilities or infrastructure. Therefore, impacts under LSJR Alternative 4, with adaptive implementation, would be significant and unavoidable.

Groundwater Supply

The average annual groundwater balance is expected to be substantially reduced under LSJR Alternative 4, with or without adaptive implementation, in the Eastern San Joaquin, Modesto, Turlock, and Extended Merced Subbasins (Chapter 9, *Groundwater Resources*). This would eventually produce a measureable decrease in groundwater elevations. This affect would be more severe in dry years and in areas farther from the SJR, the valley low point toward which groundwater moves. These substantial reductions in groundwater supplies would in turn impact service providers (Tables 13-3a and 13-3b) and private groundwater users in these subbasins that are relying heavily or primarily on groundwater sources for municipal and domestic needs. These entities would likely experience significant reductions in groundwater supply, particularly over the long term and in dry years. As discussed under LSJR Alternative 2, with adaptive implementation method 1, the magnitude or severity of the effect would depend on additional factors such as the size of the population being served, the number of active municipal wells in their service area, the range of differences between well depths and depths to groundwater (Table 13-3b), and other factors (e.g., physical condition of wells). Service providers and private groundwater users at particular risk include those that have a higher potential for a well to run dry in the future, including those identified under LSJR Alternative 3, with adaptive implementation. In addition, service providers in the Eastern San Joaquin Subbasin that may be more likely to be affected include Escalon and Lathrop (Table 13-3b). This is because these service providers have relatively few active wells relative to the size of the population served and/or the range of difference between well depths and depths to groundwater is less than 100 feet (Table 13-3b). Impacts would be significant and unavoidable.

SDWQ Alternative 2 (Significant and unavoidable)

The historical range of salinity in the southern Delta would be maintained under SDWQ Alternative 2 (Section 13.2.3, *Southern Delta*, and Impact SP-2a). Therefore, it is not anticipated that service providers supplying drinking water from the southern Delta would need to construct or modify water treatment facilities or water supply infrastructure because of increased salinity.

Under SDWQ Alternative 2, the Vernalis and southern Delta salinity objectives would be changed to a year-round value of 1.0 dS/m. However, EC at Vernalis would be maintained at or below 0.7 dS/m April–August and 1.0 dS/m September–March through requirements in USBR's water rights permits as provided for in the program of implementation. This would provide some assimilative capacity downstream of Vernalis and protect beneficial agricultural uses. Of the six WWTPs discussed herein, two have made efforts or are working toward reducing salinity concentrations in their source water supplies, four are implementing pretreatment programs to reduce water softener use among water users, and three are either proposing to construct or are already operating a RO treatment system. Table 13-11 summarizes the salinity reduction efforts of the various WWTPs. These activities would be expected to reduce the salinity in the treated effluent discharged into the southern Delta by the service providers. Fixing existing RO systems or upgrading existing facilities would be expected to reduce salts more, when compared to other efforts such as educational programs or salt pretreatment programs. However, the total effect of these various projects to the southern Delta water quality depends on many variables, such as the type of activity, salt content of the source water, and operating efficiency of the activity.

The average annual EC values for WWTPs in the past few years were generally very close to or just over 1.0 dS/m. Table 13-19 identifies the average EC for each WWTP and their potential ability to comply with a potential 1.0 dS/m effluent limitation based on the violations documented to date and annual average EC data.

Manteca would be expected to comply with a 1.0 dS/m effluent limitation because their average annual EC values are currently near or below 1.0 dS/m, and they have not had any violations in the past. Because it is anticipated that this WWTP would not exceed wastewater treatment requirements, it is not likely to need additional facilities. Impacts would be less than significant.

Table 13-19. Southern Delta Wastewater Treatment Plant 2011-2014 Annual Average EC Effluent Data and Potential to Comply with an Effluent Limitation set to the SDWQ Alternative 2 EC Objective (dS/m [µmhos/cm])

WWTP Facility	2011 Annual Average EC Effluent	2012 Annual Average EC Effluent	2013Annual Average EC Effluent	2014 Annual Average EC Effluent	2015 Annual Average EC Effluent	Potential to Comply with an Effluent Limitation Set to the SDWQ Alternative 2 (1 dS/m) Objective? (Y/N)
Tracy	1.2 [1,171]	1.2 [1,229]	1.2 [1,250]	1.3 [1,342]	1.2 [1,246]	N

Sources: See Table 13-8 for sources and additional information.

EC = electrical conductivity (salinity)

WWTP = Wastewater treatment plant

dS/m = deciSiemens per meter. Conversion is 1 dS/m = 1000 µmhos/cm. Numbers presented in dS/m were rounded.

µmhos/cm =micromhos per centimeter

CIWQS = California Integrated Water Quality System

CSD = Community Services District

[a] No data on CIWQS, so the comparison to potential effluent limitations is based on recent ACLC R5-2011-0575, which reported an average monthly EC value of 2,260 µmhos/cm on January 31, 2011 and 2,570 µmhos/cm on February 28, 2011.

Deuel currently has an NPDES permit with an EC standard based on the 2006 Bay-Delta plan EC objective. It has previously violated the permit standards. The past and current violations are potentially attributed to a malfunction of the RO and brine concentrator systems used by the facility to reduce the salinity of the groundwater supply. SDWQ Alternative 2 would not change the permit standards for Deuel and thus would not increase the number of existing violations, increase the salinity of the discharge at Deuel, or change the existing RO and brine concentrator facilities. Therefore, Deuel could potentially continue to have exceedances of the permit requirements and continue to violate their permit under SDWQ Alternative 2. Therefore, a change in baseline conditions is not expected with respect to Deuel. Impacts would be less than significant.

Mountain House CSD, Stockton, and Tracy currently have annual EC averages equal to or greater than 1.0 dS/m; therefore, they could have some exceedances of the wastewater treatment requirements if an effluent limitation is set at 1.0 dS/m. However, these exceedances would only potentially result in an exceedance of the salinity objective (i.e., 1.0 dS/m) for the southern Delta for half of the year (between the months of September and March), when salinity at Vernalis may be as high as 1.0 dS/m, which would provide no assimilative capacity. Mountain House CSD, Stockton, and Tracy may exceed an effluent limitation set at the water quality objective proposed under SDWQ Alternative 2 and this could require modifications to their wastewater treatment plants. For Tracy, these modifications could exceed those expected under their Desalinization and Green Energy Project. The Mountain House CSD and the Cities of Stockton and Tracy may apply for a variance under the Central Valley Water Board's Variance Policy discussed above once it is approved by USEPA. Under the policy, Mountain House CSD and Stockton and Tracy could be granted a variance from meeting the water quality-based effluent limitations for salinity constituents for a period of up to ten years. If the variance is not authorized, or if it is and after the expiration of the variance, Mountain House CSD and Stockton and Tracy still cannot meet the effluent limitations for salinity based on SDWQ 2, it is reasonably foreseeable that modifications to their facilities could occur. It is anticipated modifications could include the following (Chapter 16, *Evaluation of Other Indirect and Additional Actions*, Section 16.4.1, 16.4.2 and 16.4.3).

- New and expanded infrastructure to support new source water supplies, which could include canals, underground pipelines, and obtaining water transfers from one location to another to supply the new source water.
- New and expanded salinity pretreatment programs relying on industrial facility pretreatment or residential program(s), which could include modifications to existing industrial facilities such that waste is treated prior to discharge in the sewer system or a residential program educating people to remove water softeners.
- New and expanded salinity removal facilities at existing WWTPs (e.g., RO), which could include modifications to existing wastewater treatment plants such that salinity is removed from the treated effluent prior to discharge.

Depending on the type of facility, location, and particular operational requirements, construction of the facilities described above could result in physical environmental impacts on resources such as those listed below (Chapter 16, Section 16.4.1 and Table 16-25; Section 16.4.2 and Table 16-28; and Section 16.4.3 and Table 16-30).

- Air quality and greenhouse gases, as a result of construction equipment emissions and construction trips.

- Biological resources, as a result of dust, noise, or possible removal of sensitive biological species if present.
- Cultural resources, as a result of excavation, grading, and other soil disturbing activities, if construction takes place in a moderately or highly sensitive area for cultural resources.
- Geologic resources, as a result of erosion or constructing in unstable soils.
- Hazards, as a result of handling hazardous material during construction such as lubricants or diesel.
- Water quality, as a result of potentially generating runoff associated with dust control or other construction activities.
- Noise, as a result of the use of construction equipment if sensitive receptors (e.g., residences) are located within close proximity of the WWTP.
- Traffic, as a result of the use of construction equipment and commuting construction workers.

Depending on the type of facility, location, and particular operational requirements, operation of new or modified facilities could result in physical environmental impacts on resources such as those listed below (Chapter 16, Section 16.4.1 and Table 16-25; Section 16.4.2 and Table 16-28; and Section 16.4.3 and Table 16-30).

- Aesthetics, as a result of operational lighting.
- Air quality and greenhouse gases, as a result of operational emissions associated with salt removal techniques.
- Hazardous materials, as a result of an increase in hazardous materials on site associated with salt removal techniques.
- Noise, as a result of new equipment operating within proximity to sensitive receptors (e.g., residences).
- Traffic, as a result of an increase in employees to operate the new equipment or equipment modifications.

Therefore, since WWTPs may not be able to meet a new NPDES effluent limitation based on SDWQ Alternative 2, the construction and operation of new or modified wastewater treatment facilities or infrastructure is expected and impacts would be significant.

New or modified wastewater treatment facilities or infrastructure would be under the jurisdiction of the service providers performing the action or the jurisdiction of the local agency in which the new or modified facility or infrastructure is proposed. The activities described above (e.g., new and expanded facilities at WWTPs) are anticipated to either be discretionary actions and/or meet the definition of a project for CEQA. (State CEQA Guidelines, §§ 15377–15378.) If they are not discretionary actions and/or do not meet the definition of a project under CEQA, then it is presumed there would be very limited environmental impacts such that they would not rise to the level of causing potentially significant environmental impacts necessitating environmental documentation (e.g., mitigated negative declaration, environmental impact report). As part of this process, the decision-making body (e.g., board of the service provider or municipality) would impose mitigation measures or BMPs if project-specific environmental impacts were deemed potentially significant. Although the exact scope and scale, and extent of potentially significant environmental impacts cannot be determined, Table 16-38 in Chapter 16 identifies mitigation measures that would likely reduce potentially significant impacts on environmental resources as a result of construction and operation of new or modified facilities or infrastructure. For example, potentially significant environmental impacts due to construction may be mitigated through design, timing, and construction BMPs. Facilities could be designed to have minimal impact on the surrounding environment (e.g., pipelines could be buried under existing roads). Construction-timing mitigation measures may include scheduling such that work in surface waters, if needed, would take place after aquatic species have migrated out of the area. BMPs for construction activities could include the use of straw bales to prevent erosion near surface waters.

The State Water Board does not have the authority to approve the construction of any of the new or modified facilities or infrastructure. Accordingly, it is not feasible for the State Water Board to impose mitigation measures related to the construction of new and modified facilities to reduce potentially significant environmental impacts. Moreover, the State Water Board lacks authority to impose mitigation measures related to impacts on certain resources (e.g., air, noise, or traffic). Lead agencies can and should impose the mitigation measures in Table 16-38 when approving construction of these facilities. Until and unless that occurs, impacts would remain significant and unavoidable.

With respect to the operation of any new or modified facility or infrastructure, the Central Valley Water Board issues NPDES permits for the WWTPs that impose discharge requirements to implement requirements of the Clean Water Act and applicable water quality control plans. None of the mitigation measures in Table 16-38 for the operation of any new or modified facility or infrastructure is a measure the Central Valley Water Board has authority to impose in NPDES permits. Lead agencies can and should impose the mitigation measures in Table 16-38 when approving the operation of these facilities. Until and unless that occurs, impacts would remain significant and unavoidable.

SDWQ Alternative 3 (Less than significant)

The historical range of salinity in the southern Delta would be maintained under SDWQ Alternative 3 (Section 13.2.3, *Southern Delta*, and Impact SP-2a). Therefore, it is not anticipated that service providers supplying drinking water from the southern Delta would need to construct or modify water treatment facilities or water supply infrastructure because of increases in salinity.

Table 13-20 identifies the average EC for each WWTP and each one's potential ability to comply with SDWQ Alternative 3 without new or modified facilities, based on past violation information and 2011–2014 EC data.

All of the service providers would be expected to be able to comply with SDWQ Alternative 3 without new or modified facilities based on annual average EC data and previous EC violations. Deuel currently has EC averages that are below the SDWQ Alternative 3 objectives, but has had past EC violations. As discussed above under SDWQ Alternative 2, the past violations are potentially attributed to a malfunction of the RO and brine concentrator systems used by the facility to reduce the salinity of the groundwater supply. Because no additional service providers are expected to require modifications or new facilities, impacts would be less than significant.

Table 13-20. Current Southern Delta Wastewater Treatment Plant 2011–2014 Annual Average EC Effluent Data and Potential to Comply with an Effluent Limitation set to the SDWQ Alternative 3 EC Objective (dS/m [µmhos/cm])

CSD = Community Services District

[a] No data on CIWQS, so the comparison to potential effluent limitations is based on recent ACLC R5-2011-0575, which reported an average monthly EC value of 2,260 µmhos/cm on January 31, 2011 and 2,570 µmhos/cm on February 28, 2011.

Impact SP-2a: Violate any water quality standards such that drinking water quality from public water systems would be affected

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

Groundwater Subbasins

There would likely be no degradation of groundwater quality under LSJR Alternative 2 because substantial additional pumping is not expected and, thus, the direction of groundwater flow would not change such that any localized groundwater contamination that exists in the subbasins would be affected (as described in Chapter 9, *Groundwater Resources*). Accordingly, LSJR Alternative 2 would have a less-than-significant impact on the quality of water for public water systems.

Southern Delta

Salinity is a concern for service providers (e.g., CCWD) diverting drinking water from the southern Delta. Because drinking water effects associated with salinity are considered to be related to taste and not harmful to human health, secondary drinking water MCLs are established for EC as summarized in Section 13.2.3, *Southern Delta*. As discussed in Chapter 5, *Surface Hydrology and Water Quality*, the WSE model predicts that average inflows from the LSJR would generally increase (Tables 5-16 and 5-17d), which is expected to lead to a slight decrease in average salinity in the southern Delta (Table 13-16). At Vernalis, any increases in EC would generally be very small and occur during July and December–March. Relatively large decreases in EC are predicted to occur during May and June. Overall, under LSJR Alternative 2, salinity in the southern Delta is not expected to differ much from baseline salinity and would decrease on average. In addition, generally a large portion of drinking water originates from the Sacramento River due to the locations of some drinking water intakes in the Delta (e.g., western Delta); as such, changes in SJR flow are unlikely to modify flows on the Sacramento River such that exceedances in drinking water standards would result. Therefore, LSJR Alternative 2 is not expected to substantially degrade water quality, specifically with respect to salinity, and service providers diverting water for domestic purposes would not be affected by the quality of water in the southern Delta under this alternative. Impacts would be less than significant.

Higher Delta inflow from the LSJR helps improve other water quality constituents besides salinity. For example, higher inflow (and outflow) helps to limit seawater intrusion, which brings salinity and bromide into the Delta, and it helps dilute water quality components that are generated within the Delta, such as organic carbon. Organic carbon also enters the Delta in the tributary water. Rainfall runoff events would continue to bring organic carbon from the tributaries into the Delta under the LSJR Alternative 2 in a manner similar to baseline conditions. However, releases from large reservoirs tend to have relatively low organic carbon, so higher releases from New Melones Reservoir, New Don Pedro Reservoir, and Lake McClure would not cause an increase in organic carbon. Releases from the eastside reservoirs and inflow to the southern Delta would generally be similar to baseline conditions (although slightly higher on average) under LSJR Alternative 2; therefore, the effect of the alternative on water quality constituents besides salinity would also be less than significant.

Adaptive Implementation

Groundwater

As discussed under Impact SP-1, LSJR Alternative 2 with adaptive implementation could result in substantial groundwater depletions from increased pumping within the Extended Merced Subbasin. This could affect the direction of groundwater flow, and localized groundwater contamination could move in undesirable directions as explained in Section 13.2.1, *Lower San Joaquin River and Tributaries*, potentially affecting groundwater as a source of drinking water. The change in groundwater flow is dependent on the location of pumping, the amount of groundwater pumped and the frequency at which pumping occurs, and hydrogeological characteristics of the aquifer (e.g., consolidated clays with low permeability or unconsolidated sands with high permeability). As discussed previously, the impact of groundwater pumping on groundwater quality also depends on a number of different variables, including location and depth of the well, the amount and frequency of groundwater pumping, number and proximity of nearby wells, hydrogeological characteristics of the aquifer, distance between the well(s) and the contaminant(s), contaminant characteristics (e.g., highly mobile in water or adhering primarily to soil), and land use near the well. In addition, it is not possible to predict how the affected parties would respond to the reduction of surface water due to the LSJR alternatives. They may deepen existing wells or build new wells. If they build new wells, it is impossible to determine the number of new wells and their location. Thus, while groundwater pumping can affect groundwater flow and quality, for all of the foregoing reasons, it is speculative to specifically determine what that change in groundwater flow, and its impact on groundwater quality, would be from increased groundwater pumping.

If LSJR Alternative 2, with adaptive implementation, is implemented frequently and long term, it is expected that service providers relying on surface water supplies may need to find alternative supplies (e.g., groundwater), especially those service providers relying on the Merced and Tuolumne Rivers for surface water supplies (i.e., MID, TID and Merced ID, City of Modesto [Table 13-2]). Furthermore, those service providers (Tables 13-3a and 13-3b) relying on the Extended Merced Subbasin for groundwater supply to meet their water needs potentially could be affected by changes in groundwater quality from the migration of contaminants. However, a substantial increase in groundwater pumping would not necessarily result in the use of drinking water that violates water quality standards for several reasons, as described below.

1. During the recent drought, the amount of groundwater pumped for drinking purposes and the service providers' reliance on groundwater greatly increased, and yet there was not a greater number of MCL violations as compared to a wet year based on the CCRs prepared by the service providers (Table 13-5).
2. While drinking water quality standard exceedances have been detected at the wellhead in different locations in the area of potential effects, these exceedances reflect raw, untreated groundwater quality. Service providers are required take actions to ensure that the water is in compliance with relevant drinking water standards before it is served to the public. Such actions

include monitoring groundwater quality regularly, and if any exceedances are detected, bringing the well offline until the problem is rectified (see Section 13.3.2, *State [Regulatory Background]*). Treatment options include blending, large-scale treatment systems, wellhead treatment systems, or Point-of-Use (POU)/Point-of-Entry (POE) systems used in homes or residences. These types of treatment options are currently used by service providers if and when a water quality concern is identified. Potential environmental impacts resulting from these types of new and expanded facilities are addressed under Impact SP-1.

3. While increased groundwater pumping may expedite the migration of contaminants introduced at the land surface, such as nitrate from fertilizer application on crop lands, into the water table and flow towards the well, the effect would be localized (i.e., at the well; see Section 13.2.1, *Lower San Joaquin River and Tributaries*). Hence, it would be unlikely that such contamination would spread to other parts of the aquifer.

Therefore, under LSJR Alternative 2, with adaptive implementation, it is not expected that the quality of groundwater used in public water systems would be affected such that violations of water quality standards would occur. Accordingly, impacts would be less than significant.

While mitigation is not required for less-than-significant impacts, local agencies can and should nevertheless exercise their authorities under SGMA to prevent and/or mitigate any degradation of groundwater quality from the migration of contaminants. As explained in Section 9.3.2 of Chapter 9, *Groundwater Resources*, under SGMA,[27] local agencies in high- and medium-priority basins are required to form groundwater sustainability agencies by June 30, 2017, that will develop and implement GSPs that achieve sustainable groundwater management within 20 years. Sustainable groundwater management includes not causing chronic lowering of groundwater levels and significant and unreasonable degradation of water quality, including the migration of contaminant plumes that impair water supplies. GSPs must be adopted by January 31, 2020, for the Extended Merced Subbasin (as well as the Eastern San Joaquin and Chowchilla Subbasins). GSPs for the Modesto and Turlock Subbasins must be adopted by January 31, 2022). Upon GSP adoption, SGMA grants the local GSA specific authorities to manage and protect its groundwater basin including, but not limited to, the ability to require reporting of groundwater withdrawals and to control groundwater extractions by regulating, limiting, or suspending extractions from wells. If a local agency is unwilling or unable to manage its groundwater resources to prevent undesirable results as defined under the SGMA, which include chronic lowering of groundwater levels or migration of contamination, then SGMA empowers the state to provide interim management until local agencies are able to assume management. Thus, under SGMA, local agencies can and should manage groundwater subbasins both in terms of over-pumping and groundwater quality degradation from migrating contaminants.

Southern Delta

LSJR Alternative 2, with adaptive implementation method 1, would result in overall higher flows into the southern Delta. Higher Delta inflow from the LSJR helps improve water quality constituents, including salinity. For example, higher inflow (and outflow) helps to limit seawater intrusion, which brings salinity and bromide into the Delta, and it helps dilute water quality components that are generated within the Delta, such as organic carbon. Adaptive implementation method 2 would not

---

[27] The State Water Board is required to consider the policies of SGMA when revising or adopting policies, regulations, or criteria. (Wat. Code, § 10720.9.)

authorize a reduction in flows required by other agencies or through other processes, which are incorporated in the modeling of baseline conditions. Adaptive implementation method 3 would not be authorized under LSJR Alternative 2 since the unimpaired flow percentage would not exceed 30 percent. Adaptive implementation method 4 would allow an adjustment of the Vernalis February–June minimum flow requirement. WSE model results indicate that changes due to method 4 under this alternative would rarely alter the flows in the three eastside tributaries or the LSJR. As such, releases from the eastside reservoirs and inflow to the southern Delta would generally be higher on average under LSJR Alternative 2, with adaptive implementation methods 1, 2, and 4; therefore, the effect of the alternative on surface water quality constituents including salinity is expected to be less than significant.

LSJR Alternatives 3 and 4 (Less than significant/Less than significant with adaptive implementation)

Groundwater Subbasins

Reductions in groundwater levels in the Modesto, Turlock, and Extended Merced Subbasins and also the Eastern San Joaquin Subbasin under LSJR Alternatives 3 and 4with or without adaptive implementation, could occur as a result of increased pumping. This could affect the direction of groundwater flow, and localized groundwater contamination could move in undesirable directions as explained in Section 13.2.1, *Lower San Joaquin River and Tributaries*, potentially affecting groundwater as a source of drinking water. As discussed previously, the impact of groundwater pumping on groundwater quality depends on a number of different variables, including location and depth of the well, the amount and frequency of groundwater pumping, number and proximity of nearby wells, hydrogeological characteristics of the aquifer (e.g., consolidated clays with low permeability or unconsolidated sands with high permeability), distance between the well(s) and the contaminant(s), contaminant characteristics (e.g., highly mobile in water or adhering primarily to soil), and land use near the well. In addition, it is not possible to predict how the affected parties would respond to the reduction of surface water due to the LSJR alternatives. The affected parties may deepen existing wells or build new wells. If they build new wells, it is impossible to determine the number of wells and their location. Thus while groundwater pumping can affect groundwater flow and quality, for all of the foregoing reasons, it is speculative to specifically determine what that change in groundwater flow and its impact on groundwater quality would be from to increased groundwater pumping.

If LSJR Alternatives 3 or 4, with or without adaptive implementation, is implemented, it is expected that service providers relying on surface water supplies may need to find alternative supplies (e.g., groundwater). Furthermore, those service providers relying on the Modesto, Turlock, and Extended Merced Subbasins for groundwater supply under LSJR Alternatives 3 and 4 (in addition the Eastern San Joaquin Subbasin under LSJR Alternative 4) to meet their water needs (Table 13-3a), potentially could be affected by changes in groundwater quality from the migration of contaminants. The potential reduction in groundwater quality under Alternatives 3 and 4, with or without adaptive implementation, could degrade drinking water quality for those service providers relying entirely, or in large part, on groundwater for municipal supply (see Tables 13-3a and 3-3b). However, as described for LSJR Alternative 2, a substantial increase in groundwater pumping would not necessarily result in the use of drinking water that violates water quality standards for several reasons as described below.

1. During the recent drought, the amount of groundwater pumped for drinking purpose and the service providers' reliance on groundwater greatly increased and yet there was not a greater number of MCL violations as compared to a wet year based on the CCRs prepared by the service providers (Table 13-5).
2. While drinking water quality standard exceedances have been detected at the wellhead in different locations in the area of potential effects, these exceedances reflect raw, untreated groundwater quality. Service providers are required take actions to ensure that the water is in compliance with relevant drinking water standards before it is served to the public. Such actions include monitoring groundwater quality regularly, and if any exceedances are detected, bringing the well offline until the problem is rectified (see Section 13.3.2*, State [Regulatory Background]*. Treatment options include blending, large-scale treatment systems, wellhead treatment systems, or POU/POE systems used in homes or residences. These types of treatment options are currently used by service providers if and when a water quality concern is identified. Potential environmental impacts resulting from these types of new and expanded facilities are addressed under Impact SP-1.
3. While increased groundwater pumping may expedite the migration of contaminants introduced at the land surface, such as nitrate from fertilizer application on crop lands, into the water table and flow towards the well, the effect would be localized, i.e., at the well (see Section 13.2.1, *Lower San Joaquin River and Tributaries*). Hence, it would be unlikely that such contamination would spread to other parts of the aquifer.

Therefore, under LSJR Alternatives 3 and 4, with or without adaptive implementation, it is not expected that the quality of groundwater used for public water systems would be affected such that violations of water quality standards would occur. Accordingly, impacts would be less than significant.

While mitigation measures are not required for less-than-significant impacts, local agencies can and should nevertheless exercise their authorities under SGMA to prevent and/or mitigate any degradation of groundwater quality from the migration of contaminants. As explained in Section 9.3.2 of Chapter 9, *Groundwater Resources*, under SGMA, local agencies in high- and medium-priority basins are required to form groundwater sustainability agencies by June 30, 2017, that will develop and implement GSPs that achieve sustainable groundwater management within 20 years. Sustainable groundwater management includes not causing chronic lowering of groundwater levels and significant and unreasonable degradation of water quality, including the migration of contaminant plumes that impair water supplies. GSPs must be adopted by January 31, 2020, for Eastern San Joaquin, Merced and Chowchilla Subbasins. GSPs for Modesto and Turlock Subbasins must be adopted by January 31, 2022. Upon GSP adoption, SGMA grants the local GSA specific authorities to manage and protect its groundwater basin including, but not limited to, the ability to require reporting of groundwater withdrawals and to control groundwater extractions by regulating, limiting, or suspending extractions from wells. If a local agency is unwilling or unable to manage its groundwater resources to prevent undesirable results as defined under the SGMA, which include but are not limited to chronic lowering of groundwater levels or migration of contamination, then SGMA empowers the state to provide interim management until local agencies are able to assume management. Thus, under SGMA, local agencies can and should manage their groundwater subbasins both in terms of over-pumping and groundwater quality degradation from migrating contaminants.

Southern Delta

Inflows from the LSJR to the southern Delta are expected to generally increase February–June and have relatively small changes the rest of the year. Additional water into the southern Delta under LSJR Alternative 3 or LSJR Alternative 4, is not expected to substantially degrade the existing water quality of the southern Delta. Some months may experience small increases in salinity, but these increases would be the most noticeable during periods of high flow when Vernalis EC is relative low and would not cause drinking water problems (primarily within the minimum to 40th percentile of the cumulative distribution for December, January, July, and August [Tables 13-16 and 13-17]). In general, southern Delta salinity would be expected to decrease with LSJR Alternatives 3 and 4, particularly during March through June for both alternatives, as well as during February for LSJR Alternative 4 (Tables 13-16 and 13-17).

Similar to LSJR Alternative 2, LSJR Alternatives 3 and 4 with adaptive implementation methods 1 and 2 would result in overall higher flows into the southern Delta. Higher Delta inflow from the LSJR helps improve other water quality constituents, including salinity. For example, higher inflow (and outflow) helps to limit seawater intrusion, which brings salinity and bromide into the Delta, and it helps dilute water quality components that are generated within the Delta, such as organic carbon. In addition, adaptive implementation method 3 would not authorize a reduction in flows required by other agencies or through other processes, which are incorporated in the modeling of baseline conditions. Adaptive implementation method 4 would allow an adjustment of the Vernalis February–June minimum flow requirement. WSE model results indicate that changes due to adaptive implementation method 4 under LSJR Alternatives 3 and 4 would rarely alter the flows in the three eastside tributaries or the LSJR. As such, releases from the eastside reservoirs and inflow to the southern Delta would generally be higher on average under LSJR Alternatives 3 and 4, with adaptive implementation methods 1, 2, 3, and 4, when compared to baseline.

Additional inflow would provide additional assimilative capacity to receiving waters for constituents (e.g., salinity) and in general reduce the salinity and other water quality constituents in the southern Delta (Chapter 5, *Surface Hydrology and Water Quality*, Tables 5-29a–c). Therefore, LSJR Alternatives 3 and 4 with or without adaptive implementation are not expected to substantially degrade water quality, and service providers diverting water for municipal purposes from the southern Delta would not be impacted by the quality of water in the southern Delta. Impacts would be less than significant.

SDWQ Alternative 2 (Less than significant)

Salinity is a concern for service providers diverting drinking water from the southern Delta. Because drinking water effects associated with salinity are considered to be related to taste and not harmful to human health, secondary drinking water MCLs are established for EC as summarized in Section 13.3.2. As identified in Section 13.2.3, *Southern Delta*, baseline salinity in the southern Delta is between 0.2 dS/m and 1.2 dS/m during all months of the year, and the salinity at Vernalis has a strong relationship with the salinity of the southern Delta. Under SDWQ 2, the program of implementation would maintain EC at Vernalis at or below 0.7 dS/m April-August and 1.0 dS/m September-March, similar to current conditions, through actions undertaken by USBR in accordance with its water rights. Thus, it is expected the southern Delta would experience salinity levels similar to or better than (see Chapter 5, *Surface Hydrology and Water Quality*, which shows EC exceedances declining under the alternatives) baseline conditions (i.e., 0.2 dS/m–1.2 dS/m). Salinity in the southern Delta would remain below the upper limit for the secondary drinking water MCL (1.6

dS/m) and would still occasionally be above the recommended lower limit for the secondary drinking water MCL (0.9 dS/m). Therefore, SDWQ Alternative 2 is not expected to degrade water quality, and service providers diverting water for domestic purposes would not be impacted by the quality of water in the southern Delta under this alternative. Impacts would be less than significant.

SDWQ Alternative 3 (Less than significant)

Impacts would generally be the same as those discussed under SDWQ Alternative 2. Under SDWQ 3, the program of implementation would maintain EC at Vernalis at or below 0.7 dS/m April–August and 1.0 dS/m September–March, similar to current conditions, through actions undertaken by USBR in accordance with its water rights. This would maintain the historical range of salinity in the southern Delta (i.e., 0.2 dS/m–1.2 dS/m). Salinity in the southern Delta would remain below the upper limit for the secondary drinking water MCL (1.6 dS/m) and would still occasionally be above the recommended lower limit for the secondary drinking water MCL (0.9 dS/m). Salinity levels would not exceed the short term MCL (2.2 dS/m). Therefore, SDWQ Alternative 3 is not expected to degrade water quality and violate standards, and service providers diverting water for domestic purposes would not be impacted by the quality of water in the southern Delta under this alternative. Impacts would be less than significant.

Impact SP-2b: Violate any water quality standards such that drinking water quality from domestic wells would be affected

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternative 2 (Less than significant/ Significant and unavoidable with adaptive implementation)

Groundwater Subbasins

As discussed in SP-2a, there would likely be no degradation of groundwater quality under LSJR Alternative 2 because substantial additional pumping is not expected to occur in the subbasins (as described in Chapter 9, *Groundwater Resources*). Accordingly, LSJR Alternative 2 would have a less-than-significant impact on the quality of water in domestic wells.

Southern Delta

LSJR Alternative 2, would result in overall higher flows into the southern Delta. Higher Delta inflow from the LSJR helps improve water quality constituents, including salinity. Therefore, the effect of the alternative on surface water quality constituents, including salinity, is expected to be less than significant.

Adaptive Implementation

Groundwater

As discussed under Impact SP-1, LSJR Alternative 2 with adaptive implementation could result in substantial groundwater depletions from increased pumping within the Extended Merced Subbasin. This could affect the direction of groundwater flow, and localized groundwater contamination could move in undesirable directions as explained in Section 13.2.1, *Lower San Joaquin River and Tributaries*, potentially affecting groundwater as a source for drinking water. The change in groundwater flow is dependent on the location of pumping, the amount of groundwater pumped and the frequency at which pumping occurs, and hydrogeological characteristics of the aquifer (e.g., consolidated clays with low permeability or unconsolidated sands with high permeability). As discussed previously, the impact of groundwater pumping on groundwater quality also depends on a number of different variables including, but not limited to, location and depth of the well, the amount and frequency of groundwater pumping, number and proximity of nearby wells, hydrogeological characteristics of the aquifer, distance between the well(s) and the contaminant(s), contaminant characteristics (e.g., highly mobile in water or adhering primarily to soil), and land use near the well. In addition, it is not possible to predict how the affected parties would respond to the reduction of surface water due to the LSJR alternatives. They may deepen existing wells or build new wells. If they build new wells, it is impossible to determine the number of new wells and their location. Thus while groundwater pumping can affect groundwater flow and quality, for all of the foregoing reasons, it is speculative to specifically determine what that change in groundwater flow and its impact on groundwater quality would be from the increased groundwater pumping.

If LSJR Alternative 2, with adaptive implementation, is implemented frequently and long term, it is expected that service providers relying on surface water supplies may need to find alternative supplies (e.g., groundwater), especially those service providers relying on the Merced and Tuolumne Rivers for surface water supplies (i.e., MID, TID and Merced ID, City of Modesto [Table 13-2]). Furthermore, those service providers relying on the Extended Merced Subbasin for groundwater supply to meet their water needs (Tables 13-3a and 13 3b) potentially could be affected by changes in groundwater quality from the migration of contaminants.

In contrast to drinking water served by public water systems, a substantial increase in groundwater pumping may result in the use of drinking water by private domestic wells that does not meet water quality standards due to the potential for changes to groundwater quality from the migration of contaminants in the Extended Merced Subbasin. While it is true that pumping greatly increased during the drought and yet there was not a greater number of MCL violations as compared to a wet year as reported by service providers, there is a lack of information to support that this was also the case for private domestic wells. Importantly, private domestic well users are largely unregulated and are under no state requirements to monitor, test, and treat their water to meet the state and federal Safe Drinking Water Act. Therefore, there is no required mechanism to prevent private domestic wells from using groundwater that may exceed MCLs.

Therefore, under LSJR Alternative 2 with adaptive implementation there is a potential for the quality of groundwater used in private domestic wells to be affected such that violations of water quality standards would occur. Accordingly, impacts would be significant.

The State Water Board does not have authority to require implementation of mitigation that could reduce this impact to a less-than-significant level, because it does not regulate private domestic wells. It can and does assist in identifying water quality threats through the GAMA Program, which is the State Water Board's comprehensive groundwater quality monitoring program for California, and GeoTracker GAMA, which provides water quality data in California via the internet. Using the data collected in GAMA since year 2000, DDW also provides an online, map-based, tool called "Is My Property Near a Nitrate-Impacted Water Well?" for the domestic owners to evaluate the risk of their well to nitrate contamination. The map-based tool displays well locations of recent nitrate contamination above the MCL within a 2,000 feet radius of an address that the user provides. The tool can be accessed at http://www.waterboards.ca.gov/water_issues/programs/nitrate_project/nitrate_tool/.

Possible mitigation measures owners and operators of private domestic wells should undertake to avoid or reduce potential drinking water impacts at private domestic wells include the following.

- Having a licensed contractor construct wells in accordance with well construction standards.
- Choosing a location for a well to make sure it is free of potential sources of contamination.
- Testing well water at certified drinking water laboratories to ensure its quality.
- If necessary, installing a water treatment system tailored to the overall water chemistry and constituents that need to be removed. Example systems include activated alumina filters, activated charcoal filters, air stripping, anion exchange, and ultraviolet radiation.
- If necessary, drilling a new well that taps into a cleaner aquifer or finding an alternative water source.
- Properly destroying unused and abandoned wells to prevent contamination.

In addition, local agencies can and should exercise their police powers and groundwater management authority under SGMA, described above, to address groundwater contamination so as to prevent and/or mitigate drinking water impacts on private domestic wells. Specifically, under SGMA, local agencies in high- and medium-priority basins are to form GSAs by June 30, 2017, which will develop and implement GSPs that achieve sustainable groundwater management within 20 years. Sustainable groundwater management is defined as "the management and use of groundwater in a manner that can be maintained during the [50 year] planning and implementation horizon without causing undesirable results." (Wat. Code, § 10721, subd. (v).) "Undesirable results" includes "significant and unreasonable degraded water quality, including the migration of contaminant plums that impair water supplies." (Wat. Code, § 10721, subd. (x)(4).) GSPs must be developed for critically overdrafted high- and medium-priority basins by January 31, 2020 (DWR 2016). In the area of potential effects, this deadline applies to the Eastern San Joaquin, Merced, and Chowchilla Subbasins. All other high- or medium-priority basins must adopt GSPs by January 31, 2022. In the study area, this includes Modesto and Turlock Subbasins.

Each GSP must also include measureable objectives as well as milestones in increments of 5 years, to achieve the sustainability goal in the basin within 20 years of the implementation of the plan. (Wat. Code, § 10727.2.)

If local agencies are unwilling or unable to manage their groundwater resources, SGMA authorizes the State Water Board to step in to protect a groundwater basin in limited circumstances: (1) if no agency has opted by the June 30, 2017 to serve as a GSA for a basin, (2) when a GSA does not complete a GSP by the relevant deadline (2020 or 2022), or (3) when the GSP is inadequate or the GSP is not being implemented in a manner that is likely to achieve the plan's sustainability goal(s), and the basin is either in a condition of long-term overdraft or, after January 31, 2025, the State

Water Board determines that the basin is in a condition where groundwater extractions result in significant depletions of interconnected surface waters.

Thus, at this time, local agencies are vested with the mandatory duty to achieve sustainable groundwater management, which includes preventing significant and unreasonable degradation to water quality. These agencies, therefore, can and should exercise their full authorities to address degradation of groundwater quality, both under SGMA and their police powers. Doing so would prevent and/or mitigate private domestic well drinking water supply impacts. Due to inherent uncertainty in the degree to which this mitigation and those listed above may be implemented by local agencies and owners and operators of private domestic wells, drinking water impacts on private domestic wells would remain significant and unavoidable.

Southern Delta

As discussed in Impact SP-2a, LSJR Alternative 2, with adaptive implementation (including method 1), would result in overall higher flows into the southern Delta. Higher Delta inflow from the LSJR helps improve water quality constituents, including salinity. Therefore, the effect of the alternative on surface water quality constituents including salinity is expected to be less than significant.

LSJR Alternatives 3 and 4 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

Groundwater Subbasins

Reductions in groundwater levels in the Modesto, Turlock, and Extended Merced Subbasins and also the Eastern San Joaquin Subbasin under LSJR Alternatives 3 and 4 with or without adaptive implementation could occur as a result of increased pumping. This could affect the direction of groundwater flow, and localized groundwater contamination could move in undesirable directions as explained in Section 13.2.1, *Lower San Joaquin River and Tributaries*, potentially affecting groundwater as a source for drinking water. The change in groundwater flow is dependent on the location of pumping, the amount of groundwater pumped and the frequency at which pumping occurs, and hydrogeological characteristics of the aquifer (e.g., consolidated clays with low permeability or unconsolidated sands with high permeability). As discussed previously, the impact of groundwater pumping on groundwater quality also depends on a number of different variables, including location and depth of the well, the amount and frequency of groundwater pumping, number and proximity of nearby wells, hydrogeological characteristics of the aquifer, distance between the well(s) and the contaminant(s), contaminant characteristics (e.g., highly mobile in water or adhering primarily to soil), and land use near the well. In addition, it is not possible to predict how the affected parties would respond to the reduction of surface water due to the LSJR alternatives. They may deepen existing wells or build new wells. If they build new wells, it is impossible to determine the number of new wells and their location. Thus while groundwater pumping can affect groundwater flow and quality, for all of the foregoing reasons, it is speculative to specifically determine what that change in groundwater flow and its impact on groundwater quality would be from the increased groundwater pumping.

In contrast to drinking water served by public water systems, a substantial increase in groundwater pumping may result in the use of drinking water by private domestic wells that does not meet water quality standards due to the potential for changes in groundwater quality from the migration of contaminants in the Modesto, Turlock and Extended Merced Subbasins and also the Eastern San Joaquin Subbasin under LSJR Alternatives 3 and 4 with or without adaptive implementation. While it is true that pumping greatly increased during the drought and yet there was not a greater number of MCL violations as compared to a wet year as reported by service providers, there is a lack of information to support that this was also the case for private domestic wells. Importantly, private domestic well users are largely unregulated and are under no state requirements to monitor, test, and treat their water to meet the state and federal Safe Drinking Water Act. Therefore, there is no required mechanism to prevent private domestic wells from using groundwater that may exceed MCLs.

Therefore, under LSJR Alternatives 3 and 4, with or without adaptive implementation, there is a potential for the quality of groundwater used in private domestic wells to be affected such that violations of water quality standards would occur. Accordingly, impacts would be significant.

The State Water Board does not have authority to impose mitigation that could reduce this impact to a less-than-significant level, because it does not regulate private domestic wells. It can and does assist in identifying water quality threats through the GAMA Program and GeoTracker GAMA. Using the data collected in GAMA since year 2000, DDW also provides the online, map-based, tool called “Is My Property Near a Nitrate-Impacted Water Well?” for the domestic owners to evaluate the risk of their well to nitrate contamination, described previously under Impact SP-2b, LSJR Alternative 2.

Possible mitigation measures owners and operators of private domestic wells should undertake to avoid or reduce potential drinking water impacts at private domestic wells include the following.

- Having a licensed contractor construct wells in accordance with well construction standards.
- Choosing a location for a well to make sure it is free of potential sources of contamination.
- Testing well water at certified drinking water laboratories to ensure its quality.
- If necessary, installing a water treatment system tailored to the overall water chemistry and constituents that need to be removed. Example systems include activated alumina filters, activated charcoal filters, air stripping, anion exchange, and ultraviolet radiation.
- If necessary, drilling a new well that taps into a cleaner aquifer or finding an alternative water source.
- Properly destroying unused and abandoned wells to prevent contamination.

In addition, local agencies can and should exercise their police powers and groundwater management authority under SGMA, described above, to address groundwater contamination so as to prevent and/or mitigate drinking water impacts on private domestic wells. Specifically, under SGMA, local agencies in high- and medium-priority basins are to form GSAs by June 30, 2017, which will develop and implement GSPs that achieve sustainable groundwater management within 20 years. Sustainable groundwater management is defined as “the management and use of groundwater in a manner that can be maintained during the [50 year] planning and implementation horizon without causing undesirable results.” (Wat. Code, § 10721, subd. (v).) “Undesirable results” includes “significant and unreasonable degraded water quality, including the migration of contaminant plums that impair water supplies.” (Wat. Code, § 10721, subd. (x)(4).) GSPs must be developed for critically overdrafted high- and medium-priority basins by January 31, 2020 (DWR 2016). This deadline applies to the Eastern San Joaquin, Merced, and Chowchilla Subbasins. All other high- or medium-priority basins must adopt GSPs by January 31, 2022. This includes Modesto and Turlock Subbasins.

Each GSP must also include measureable objectives as well as milestones in increments of 5 years, to achieve the sustainability goal in the basin within 20 years of the implementation of the plan. (Wat. Code, § 10727.2.)

If local agencies are unwilling or unable to manage their groundwater resources, SGMA authorizes the State Water Board to step in to protect a groundwater basin in limited circumstances: (1) if no agency has opted by the June 30, 2017 to serve as a GSA for a basin, (2) when a GSA does not complete a GSP by the relevant deadline (2020 or 2022), or (3) when the GSP is inadequate or the GSP is not being implemented in a manner that is likely to achieve the plan's sustainability goal(s), and the basin is either in a condition of long-term overdraft or, after January 31, 2025, the State Water Board determines that the basin is in a condition where groundwater extractions result in significant depletions of interconnected surface waters.

Thus, at this time, local agencies are vested with the mandatory duty to achieve sustainable groundwater management, which includes preventing significant and unreasonable degradation to water quality. These agencies, therefore, can and should exercise their full authorities to address degradation of groundwater quality, both under SGMA and their police powers. Doing so would prevent and/or mitigate private domestic well drinking water supply impacts. Due to inherent uncertainty in the degree to which this mitigation and those listed above may be implemented by local agencies and owners and operators of private domestic wells, drinking water impacts on private domestic wells under LSJR Alternatives 3 and 4 would remain significant and unavoidable.

Impact SP-3: Result in substantial changes to SJR inflows to the Delta such that insufficient water supplies would be available to service providers relying on CVP/SWP exports

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

There would be no reduction in annual average CVP/SWP exports under LSJR Alternative 2 (Section 13.4.2, *Methods and Approach*, and detailed in Chapter 5, *Surface Hydrology and Water Quality*). Modeling results of LSJR Alternative 2 indicate a slight increase in average inflow into the southern Delta from the LSJR. This slight increase in Delta inflow results in an estimated average increase in exports of 18 thousand acre-feet per year (TAF/y). This increase is minimal compared to the historic average annual export of 5,185 TAF/y. As such, under LSJR Alternative 2, the change in exports would be 0 percent of historic average annual exports. Because this change would not reduce the average volume of exported water, it is not expected that service providers relying on exports would experience insufficient water supplies. LSJR Alternative 2, with adaptive implementation method 1, would allow an increase of up to 10 percent over the 20 percent February–June unimpaired flow requirement and, thus, would not reduce the average inflow into the southern Delta from the LSJR. Accordingly, this would not result in a reduction in available water supplies to service providers relying on CVP/SWP exports. As part of LSJR Alternative 2, with adaptive implementation method 2, timing of the release of water within the February–June period would change. By shifting the release time, the shifted release would be affected by different Delta regulations, but the associated change in exports would be relatively small compared to total exports, and the average would not decrease relative to baseline, as a result of overall higher SJR inflow to the Delta. Adaptive implementation method 3 would not be authorized under LSJR Alternative 2 since the unimpaired flow percentage would not exceed 30 percent. LSJR Alternative 2, with adaptive implementation method 4, would allow an adjustment of the Vernalis February–June flow requirement. However, as described under Impact SP-1, changes due to adaptive implementation method 4 under this alternative would rarely alter the flow in the LSJR and, thus, average inflow to the southern Delta would not be changed such that export would be reduced. Impacts would be less than significant.

LSJR Alternative 3 (Less than significant/Less than significant with adaptive implementation)

There would be no reduction in annual average CVP/SWP exports under LSJR Alternative 3 (Section 13.4.2, *Methods and Approach*, and detailed in Chapter 5, *Surface Hydrology and Water Quality*). Modeling results of LSJR Alternative 3 indicate a slight increase in average inflow into the southern Delta from the LSJR. This slight increase in Delta inflow would result in an estimated average increase in exports of 76 TAF/y. This small increase is approximately 1 percent of the historic average annual export of 5,185 TAF/y. Because this change would not reduce the average volume of exported water, it is not expected that service providers relying on exports would experience insufficient water supplies. LSJR Alternative 3, with adaptive implementation method 1, would allow an increase or decrease of up to 10 percent in the February–June. Effects with a 10 percent decrease would be similar to those described for LSJR Alternative 2, with adaptive implementation method 1. As such, service providers would not be impacted. Adaptive implementation methods 2, 3 and 4 are not expected to result in substantial changes to CVP/SWP exports such that service providers relying on these exports are significantly impacted. LSJR Alternative 3, with adaptive implementation methods 2 or 3, could result in a change to the timing of the release of water within the February–June period. By shifting the release time, the shifted release would be affected by different Delta regulations, but the associated change in exports would be relatively small compared to total exports, and the average volume of exported water would not decrease relative to baseline. Changes in CVP/SWP exports and associated effects on service providers receiving those exports under LSJR Alternative 3 with adaptive implementation method 4 would be similar to LSJR Alternative 2 with adaptive implementation method 4 and as such, service providers would not be significantly impacted. Impacts would be less than significant.

LSJR Alternative 4 (Less than significant/Less than significant with adaptive implementation)

There would be no reduction in annual average CVP/SWP exports under LSJR Alternative 4 (Section 13.4.2, *Methods and Approach*, and detailed in Chapter 5, *Surface Hydrology and Water Quality*). Modeling results of LSJR Alternative 4 indicate an average increase in inflow into the southern Delta from the LSJR. This increase in Delta inflow results in an estimated average increase in exports of 194 TAF/y. This small increase is approximately 4 percent of the historic average annual export of 5,185 TAF/y. Because this change would not reduce the average volume of exported water, it is not expected that service providers relying on exports would experience insufficient water supplies. LSJR Alternative 4, with adaptive implementation method 1, would allow for a decrease of unimpaired flow to a minimum of 50 percent and would result in an increase in exports; therefore, service providers relying on these exports would not be affected. As part of LSJR Alternative 4 with adaptive implementation methods 2 or 3, timing of the release of water within the February–June period would change. By shifting the release time, the shifted release would be affected by different Delta regulations, but the associated change in exports would be relatively small compared to total exports, and the average volume of exported water would not decrease relative to baseline. Changes in CVP/SWP exports and associated effects on service providers receiving those exports with LSJR Alternative 4 with adaptive implementation method 4 would be similar to LSJR Alternative 2 with adaptive implementation method 4. Impacts would be less than significant.

13.4.4 Impacts and Mitigation Measures: Extended Plan Area

Bypass flows, as described in Chapter 5, *Surface Hydrology and Water Quality*, could be required much more frequently and be larger than under baseline conditions, resulting in potentially less surface water to the 12 service providers identified in the extended plan area in Table 13-6. As such, a small fraction of the water supply effect in the plan area to those service providers relying wholly or in part on surface water to meet water supply needs could be shifted to junior water rights holders in the extended plan area. To the extent that this water supply effect is shifted from agriculture uses downstream in the plan area to consumptive domestic and municipal uses upstream in the extended plan area, the effects on service providers would increase slightly in the extended plan area from that described for the plan area. The service providers identified in Table 13-6 have the potential to have their water supply affected to the extent that their water rights are junior to the senior downstream water right holders.

Under LSJR Alternative 2 without adaptive implementation water supply of downstream senior rights holders would generally be similar to baseline. Therefore, the impacts of LSJR Alternative 2 without adaptive implementation on service providers in the extended plan area would be less than significant.

Similar to the plan area, the extent to which service providers that primarily rely on surface water are affected by a reduction in surface water diversions is a function of their ability to develop alternative water supplies, including water purchases from senior water right holders, or rely on their current existing alternative supplies (e.g., groundwater) under LSJR Alternative 2 with adaptive implementation and LSJR Alternatives 3 and 4 with or without adaptive implementation. The program of implementation states that the State Water Board will take actions as necessary to ensure implementation of flow objectives does not impact supplies of drinking water for minimum health and safety needs, particularly during drought periods. Actions may include assistance with funding and development of water conservation efforts and regional water supply reliability projects and regulating public drinking water systems and water rights. These actions would be aimed at those service providers supplying water to municipal users and may offset water supply reduction impacts on providers. However, similar to those service providers in the plan area, it is expected that service providers in the extended plan area may need to construct or expand new water treatment facilities or water supply infrastructure to try to accommodate reductions in surface water supplies.

Some of these service providers would be able to implement groundwater pumping to replace some of the bypassed surface water. However, groundwater basins with sufficient quantity to replace the volume required are limited. Some individuals who rely on these service providers may put in their own groundwater wells to supplement that water. Similar to the plan area, significant environmental impacts could occur during construction or operation of new and expanded water facilities and lead agencies can and should implement mitigation measures (listed in Table 16-38). CEQA does not grant agencies new, discretionary powers independent of the powers granted to the agencies by other laws. (Pub. Resources Code, § 21004; Cal. Code Regs., tit. 14, § 15040.) Accordingly, a mitigation measure may be legally infeasible if the lead agency does not have the discretionary authority to impose or implement it. (Pub. Resources Code, § 21004; Cal. Code Regs., tit. 14, § 15040.) Since the State Water Board would not be responsible for or have discretionary authority to approve the construction of any new or modified facilities or infrastructure, it is not feasible for the State Water Board to impose possible mitigation measures listed in Table 16-38. Moreover, the State Water Boards lacks authority to impose mitigation measures related to impacts such as traffic and noise. Agencies responsible for approving the project-specific new or modified facilities can and should impose the applicable mitigation measures in Table 16-38. Therefore, there is no feasible mitigation the State Water Board can impose to reduce environmental impacts resulting from the need for new or modified facilities or infrastructure. Impacts would be significant and unavoidable. Consequently, under LSJR Alternative 2, with adaptive implementation, and LSJR Alternatives 3 and 4, with or without adaptive implementation, the impacts would be significant and unavoidable for Impact SP-1 in the extended plan area.

The groundwater source area[28] underlying the extended plan area is primarily fractured bedrocks. There is only one DWR Bulletin 118-designated groundwater basin, the Yosemite Valley Basin in Yosemite National Park in Mariposa County, in the extended plan area; the rest of the area is primarily fractured bedrocks. These fracture systems produce relatively small, localized, and isolated groundwater areas. If surface water available to the service providers in the extended plan area is reduced due to implementation of the LSJR alternatives, there could be more groundwater pumping over time in the extended plan area. However, the impact of such an increase in pumping on groundwater quality would be minimal for the following reasons.

- The increase in pumping would be small based on the relatively small amount of total municipal use that occurs in the extended plan area (Section 13.2.2, *Extended Plan Area*).
- The groundwater in the fractured rocks are localized and isolated; hence, the influence of increased pumping on the migration of any contaminants would be minimal.

Thus, impacts on groundwater quality (Impacts SP-2a and SP-2b) would be less than significant in the extended plan area. As discussed in Chapter 5, *Surface Hydrology and Water Quality*, changes on flow upstream of the major rim dams in the Stanislaus, Tuolumne, and Merced Rivers would be small and would not change flows downstream of the rim dams. SJR inflows to the Delta would not be affected even if the extended plan area is taken into consideration. Therefore, impact of the LSJR alternatives with or without adaptive implementation to the service providers relying on CVP/SWP exports (Impact SP-3) would be less than significant.

---

[28] Although alluvial aquifers are most common in California, other groundwater development occurs in fractured crystalline rocks, fractured volcanics, and limestones. These nonalluvial areas that provide groundwater are referred to as *groundwater source areas*, while the alluvial aquifers are called *groundwater basins* in DWR Bulletin 118 (DWR 2003a). It is generally referring to areas of fractured bedrock in foothill and mountainous terrain.

13.5 Cumulative Impacts

For the cumulative impact analysis, refer to Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources.*

Note: Gray-shaded rows indicate those public water suppliers shown in Table 13-3b.

CSD = Community Services District
CWD = County Water District
ID = Irrigation District
MID = Modesto Irrigation District
PWS = Public Water System
PUD = Public Utilities District
SEWD = Stockton East Water District
WD = Water District

[a] Although the City of Tracy is not located in the Eastern San Joaquin, Modesto, Turlock, or Extended Merced Subbasin, it is within the area of potential effects because it receives water from SSJID and can be affected by the LSJR alternatives. Therefore, it is included in this table.

[b] The City of Modesto, Central Turlock has no groundwater wells, but purchases groundwater from Turlock.

Chapter 14
Energy and Greenhouse Gases

14.1 Introduction

This chapter describes the environmental setting and overall regulatory framework for energy and greenhouse gases (GHGs). It also evaluates environmental impacts on energy and climate change that could result from the Lower San Joaquin River (LSJR) alternatives and, if applicable, offers mitigation measures that would reduce significant impacts.

The area of potential effects evaluated in this chapter includes the plan area, described in Chapter 1, *Introduction,* and the Central Valley Project (CVP) and State Water Project (SWP) export service areas. However, once emitted from their sources, GHGs become free to move within the atmosphere and can travel far away from their sources during their lifetimes. In addition, climate change is a global issue and GHGs are global pollutants, unlike criteria air pollutants (such as ozone precursors), which are primarily pollutants of regional and local concern. No single emitter of GHGs is large enough to trigger climate change on its own. Hence, the discussion of GHGs and climate change in this chapter extends outside of the plan area to evaluate the impacts on *climate change* of GHG emissions generated within the plan area.

The extended plan area, also described in Chapter 1, generally includes the area upstream of the rim dams. [1] It also includes the reservoirs on the upper reaches of the Stanislaus, Tuolumne, and Merced Rivers. Unless otherwise noted, all discussion in this chapter refers to the plan area. Where appropriate, the extended plan area is specifically identified.

The LSJR alternatives propose specified unimpaired flow[2] (i.e., 20, 40 or 60 percent) requirements on the three eastside tributaries[3] in February–June. Such requirements could affect reservoir operations, surface water diversions, and the associated timing and amount of hydropower generated by dams on the three eastside tributaries. This chapter evaluates the effects on hydropower production, electric grid reliability, and the resulting increase in energy consumption in the plan area that would result from the LSJR alternatives. This chapter also evaluates the effects of the LSJR alternatives on climate change and GHG emissions.

In Appendix B, *State Water Board's Environmental Checklist*, the State Water Board determined whether the plan amendments[4] would result in any adverse impact on resources in each environmental category in the checklist and provided a brief explanation for its determination. Impacts that are listed as "Potentially Significant Impacts" are discussed in detail in this chapter.

---

[1] In this document, the term *rim dams* is used when referencing the three major dams and reservoirs on each of the eastside tributaries: New Melones Dam and Reservoir on the Stanislaus River; New Don Pedro Dam and Reservoir on the Tuolumne River; and New Exchequer Dam and Lake McClure on the Merced River.

[2] *Unimpaired flow* represents the water production of a river basin, unaltered by upstream diversions, storage, or by export or import of water to or from other watersheds. It differs from natural flow because unimpaired flow is the flow that occurs at a specific location under the current configuration of channels, levees, floodplain, wetlands, deforestation and urbanization.

[3] In this document, the term *three eastside tributaries* refers to the Stanislaus, Tuolumne, and Merced Rivers.

[4] These plan amendments are the *project* as defined in State CEQA Guidelines, Section 15378.

Appendix B, Section VII, identified the alternatives as having potentially significant impacts relating to GHG emissions, because they might: (1) generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment; and (2) conflict with an applicable plan, policy, or regulation adopted for the purpose of reducing the emissions of GHGs. In order to analyze these potential impacts, GHG impacts were generally evaluated on exceedance of regulatory thresholds that could negatively impact the environment and long-term management implications affecting climate change.

As stated in Appendix B, Section VII, the general historical range of salinity in the southern Delta would remain unchanged under the SDWQ alternatives and, thus, would not result in GHG emissions or conflict with an applicable plan, policy or regulation adopted for the purpose of reducing GHG emissions. Therefore, the SDWQ alternatives are not further analyzed in this chapter, except as they relate to the effect of climate change on the alternatives. SDWQ Alternative 2 could result in service providers having to construct and operate new or expanded wastewater treatment or water supply facilities, which would involve changes in energy consumption and GHG emissions, and is evaluated in Chapter 13, *Service Providers*, and Chapter 16, *Evaluation of Other Indirect and Additional Actions.*

The State Water Board determined that additional types of potentially significant adverse impacts that are not listed in the checklist in Appendix B should be evaluated. Accordingly, this chapter also evaluates the LSJR alternatives' impacts on energy resources that either may potentially (1) adversely affect the reliability of California's electric grid, or (2) result in inefficient, wasteful, and unnecessary energy consumption. The detailed discussion regarding the hydropower production on the LSJR's three eastside tributaries, the electric grid reliability, and the surface water diversions is presented in Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*, Chapter 5, *Surface Hydrology and Water Quality*, and Appendix F.1, *Hydrologic and Water Quality Modeling.*

A summary of the potential impacts of the LSJR alternatives on energy and GHG emissions is provided in Table 14-1. As described in Chapter 3, *Alternatives Description*, LSJR Alternatives 2, 3, and 4 each include four methods of adaptive implementation. Table 14-1 also considers the effect of climate change on the LSJR and SDWQ alternatives. This recirculated substitute environmental document (SED) provides an analysis with and without adaptive implementation because the frequency, duration, and extent to which each adaptive implementation method would be used, if at all, within a year or between years under each LSJR alternative, is unknown. The analysis, therefore, discloses the full range of impacts that could occur under an LSJR alternative, from no adaptive implementation to full adaptive implementation. As such, Table 14-1 summarizes impact determinations with and without adaptive implementation.

Impacts related to the No Project Alternative (LSJR/SDWQ Alternative 1) are presented in Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* and the supporting technical analysis is presented in Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1).* Impacts related to methods of compliance are discussed in Chapter 16, *Evaluation of Other Indirect and Additional Actions*.

Table 14-1. Summary of Energy and Greenhouse Gases Impact Determinations

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
Impact EG-1: Adversely affect the reliability of California's electric grid			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note. [b]	Less than significant	NA
LSJR Alternatives 2 and 3	Transmission line loadings would not exceed the limits under contingency outage conditions because hydropower generation and reservoir elevation would not be substantially modified. Therefore, adverse effects on the reliability of California's electric grid would not occur.	Less than significant	Less than significant
LSJR Alternative 4	Transmission line loadings would not exceed the limits under contingency outage conditions after re-dispatch of generator facilities to correct a minor violation between Borden and Gregg substations and Gregg and Storey substations. Re-dispatches are regular occurrences in the California energy grid, and they provide a solution to redistribute power. Therefore, adverse effects on the reliability of California's electric grid would not occur.	Less than significant	Less than significant
Impact EG-2: Result in inefficient, wasteful, and unnecessary energy consumption			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note. [b]	Less than significant	NA
LSJR Alternatives 2, 3, and 4	Additional groundwater pumping would not result in inefficient, wasteful, and unnecessary consumption of energy to the extent groundwater pumping is used to meet water supply irrigation demand in accordance with state law. Additional energy generation at other facilities to compensate for a potential loss of hydropower would not be considered inefficient, wasteful, and unnecessary as it is energy that would be generated to maintain the energy supply level that is currently supplied by hydropower. Therefore, there would be no inefficient, wasteful, or unnecessary energy consumption.	Less than significant	Less than significant

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
Impact EG-3: Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note. [b]	Significant	NA
LSJR Alternative 2	Emissions would not exceed 10,000 MT CO_2e threshold, even if adaptive implementation method 1 were implemented on a long-term basis (an increase in the February–June percent of unimpaired flow from 20% up to 30%). Therefore, GHG emissions would not have a significant impact on the environment.	Less than significant	Less than significant
LSJR Alternatives 3 and 4	Emissions exceed 10,000 MT CO_2e threshold with and without adaptive implementation. Therefore, GHG emissions would have a significant impact on the environment.	Significant and unavoidable	Significant and unavoidable
Impact EG-4: Conflict with an applicable plan, policy, or regulation adopted for the purposes of reducing GHG emissions			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note. [b]	Significant	NA
LSJR Alternative 2	Since GHG emissions would not exceed the 10,000 MT CO_2e threshold, even if adaptive implementation method 1 were implemented on a long-term basis, there would be no conflict with applicable plans, policies or regulations adopted for the purpose of reducing GHGs.	Less than significant	Less than significant
LSJR Alternatives 3 and 4	Since GHG emissions would exceed the 10,000 MT CO_2e threshold, with and without adaptive implementation, it is expected there would be a conflict with applicable plans, policies or regulations adopted for the purpose of reducing GHGs.	Significant and unavoidable	Significant and unavoidable
Impact EG-5: Effect of climate change on the LSJR and SDWQ alternatives			
No Project Alternative (LSJR/SDWQ Alternative 1)	See note. [b]	Less than significant	NA

Alternative	Summary of Impact(s)	Impact Determination without Adaptive Implementation	Impact Determination with Adaptive Implementation[a]
LSJR Alternatives 2, 3, and 4	Climate change would not significantly affect the LSJR alternatives because adaptive implementation would allow agencies to respond to changing circumstances with respect to flow and water quality that might arise due to climate change. Furthermore, the required review and update of WQCPs, accounted for in the program of implementation, continually accounts for changing conditions related to water quality and water planning such as climate change.	Less than significant	Less than significant
SDWQ Alternatives 2 and 3	Climate change would not significantly affect the SDWQ alternatives because the required review and update of WQCPs, accounted for in the program of implementation, continually accounts for changing conditions related to water quality and water planning, such as climate change.	Less than significant	NA

MT = metric ton
CO_2e = carbon dioxide equivalent
WQCP = water quality control plan

[a] Four adaptive implementation methods could occur under the LSJR alternatives, as described in Chapter 3, *Alternatives Description*, and summarized in Section 14.4.2, *Methods and Approach,* of this chapter.

[b] The No Project Alternative (LSJR/SDWQ Alternative 1) would result in implementation of flow objectives and salinity objectives established in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

14.2 Environmental Setting

14.2.1 Lower San Joaquin River and Eastside Tributaries Hydropower Production

There are numerous hydropower generation plants on the three eastside tributaries. The major power plants are those associated with the New Melones Reservoir (New Melones Dam) on the Stanislaus River, New Don Pedro Reservoir (New Don Pedro Dam) on the Tuolumne River, and Lake McClure (New Exchequer Dam) on the Merced River. The total hydropower generation capacity of the three eastside tributaries combined is about 803 megawatts (MW), and the three facilities considered here represent 87 percent of the total capacity of the three eastside tributaries (Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*). Table 14-2a lists the hydropower facilities in the plan area and extended plan area. Table 14-2b shows the characteristics of the three major hydropower plants on the tributaries—New Melones, New Don Pedro, and New Exchequer. The head for each of the major hydropower plants is the difference between the maximum elevation and tail-water elevation and the corresponding maximum capacity of the power plants.

Table 14-2a. List of Hydropower Facilities

River Basin	Hydroelectric Power Plant Name	Nameplate Capacity (MW)	% of Power Capacity in Basin	Location Relative to Rim Dams
Stanislaus	Woodward	2.85	0.4	Off-stream
	Frankenheimer	5.04	0.6	Off-stream
	Tulloch	17.10	2.2	Inline
	Angels	1.40	0.2	Upstream

Table 14-2b. Elevation and Maximum Capacity at Major Hydropower Plants on Eastside Tributaries

Power Plant	Maximum Elevation (feet)	Tail-water Elevation (feet)	Headwater (feet)	Maximum Capacity (MW)
New Melones	1,088	503	585	300
New Don Pedro	830	310	520	203
New Exchequer	867	400	467	95

Source: Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*.
MW = megawatts

The existing hydropower production was estimated for the various power plants on the three eastside tributaries. Actual hydropower generation in any given period is variable and depends on the amount of surface water captured and stored in the reservoir during wet and dry years; Table 14-3 summarizes the average annual hydropower generation on each of the three eastside tributaries to provide an overall sense of hydropower generation.

Table 14-3. Annual Baseline Hydropower Generation on LSJR Eastside Tributaries

LSJR Tributary	Average Annual Hydropower Generation (GWh)
Stanislaus River	586
Tuolumne River	656
Merced River	408
Project-Wide Total	1,650

GWh = gigawatt hours

14.2.2 Transmission System in Central California

This section provides a brief overview of the transmission systems and the balancing authorities for the areas in which the New Melones, New Don Pedro, and New Exchequer hydropower plants are located. According to the North American Electric Reliability Corporation (NERC), a balancing authority is defined as the responsible entity that integrates resource plans ahead of time, maintains load-interchange-generation balance and supports interconnection frequency in real time. The balancing authorities are listed in Table 14-4 and discussed in the sections below. This information provides context for the capacity reduction calculation and power flow analysis discussed below in Section 14.4.2, *Methods and Approach*.

Table 14-4. Balancing Authority of Major Hydropower Plants on LSJR Eastside Tributaries

Power Plant	Balancing Authority
New Melones	Balancing Authority of Northern California (BANC)
New Don Pedro	Turlock Irrigation District (TID—68%) and Sacramento Municipal Utility District (SMUD)—32%
New Exchequer	California Independent System Operator (CAISO)

Source: Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*.

Note: Don Pedro hydropower plant is jointly owned by TID and Modesto Irrigation District (MID). BANC performs the balancing authority function for MID's portion of the plant, while TID is the balancing authority for its portion. SMUD is a member of BANC.

California Independent System Operator

The New Exchequer hydropower plant lies in the Greater Fresno local capacity areas. These are areas that are transmission-constrained and require a certain minimum amount of local generation for meeting the local load requirements. California Independent System Operator (CAISO) operates the high-voltage, long-distance power lines that make up 80 percent of California's wholesale power grid. It is responsible for system reliability in the local capacity areas and other areas throughout California by scheduling available transmission capacity. The California Public Utilities Commission (CPUC) adopted the Resource Adequacy (RA) program in 2004 with the twin objectives of (1) providing sufficient resources to CAISO to ensure the safe and reliable operation of the grid in real time, and (2) providing appropriate incentives for the siting and construction of new resources needed for reliability in the future (CPUC 2011). Each year CAISO performs the Local Capacity Technical (LCT) Study to identify local capacity requirements (LCRs) within its territory. The results of this study are provided to CPUC for consideration in its RA program. These results are also be used by CAISO for identifying the minimum quantity of local capacity necessary to meet the NERC reliability criteria used in the LCT Study (CAISO 2010). Table 14-5 shows the historical local capacity requirements, peak load, and total dependable local area generation for the Greater Fresno area. The table also shows the local capacity area as a percentage of the total dependable local generation. For example, in 2011, the LCR in Greater Fresno was 2,448 MW, while the peak load stood at 3,306 MW; the LCR was 74 percent of the peak load. At the same time, the total dependable generation stood at 2,919 MW, which meant that the LCR was 84 percent of the total dependable generation. In other words, in 2011, Greater Fresno had sufficient local resources available to meet its local capacity requirements. As previously mentioned, these are minimum generation requirements imposed on transmission-constrained regions within the state.

Table 14-5. Local Capacity Requirements versus Peak Load and Local Area Generation for Greater Fresno Area

Year	Local Capacity (MW)	Peak Load (MW)	Local Capacity as % of Peak Load	Dependable Local Generation (MW)	Local Capacity Area as % of Dependable Local Generation
2006	2,837	3,117	91	2,651	107
2007	2,219	3,154	70	2,912	76
2008	2,382	3,260	73	2,991	80
2009	2,680	3,381	79	2,829	95
2010	2,640	3,377	78	2,941	90
2011	2,448	3,306	74	2,919	84

Source: Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*.
MW = megawatts

In the CAISO board of governors-approved 2010/2011 transmission plan, CAISO identified a number of transmission upgrades that are needed in the Greater Fresno area to maintain system reliability between 2011 and 2020. Pacific Gas & Electric Company (PG&E) proposed a number of projects to maintain system reliability in the area (CAISO 2011).

Balancing Authority of Northern California/Sacramento Municipal Utility District

The Balancing Authority of Northern California (BANC) is a joint powers authority comprised of the Sacramento Municipal Utility District (SMUD), MID, Roseville Electric, Redding Electric Utility and Trinity Public Utility District. The third largest balancing authority in California, BANC, assumed balancing authorities from SMUD in in 2011.

SMUD, established in 1946, is the nation's sixth largest community-owned electric utility in terms of customers served (approximately 590,000) and covers a 900-square-mile area that includes Sacramento County and a small portion of Placer County. While the New Melones power plant physically resides in the CAISO balancing authority area, Sierra Nevada Region (SNR), Sacramento SMUD, and CAISO operate New Melones as a pseudo-tie generation export from CAISO into the SMUD balancing authority area (Western Area Power Administration 2010). The pseudo-tie generation export arrangement implies that New Melones is electrically and operationally included as part of the SMUD balancing authority area. For purposes of Qualifying Capacity, SNR has designated the New Melones power plant as part of the CVP resource in the SMUD balancing authority area.

As part of the biennial resource adequacy and resource plan assessments for publically owned utilities, the California Energy Commission (CEC) published its biennial report in November 2009 detailing the need and availability of generation resources to meet the future load and planning reserve margin requirements within the territory of publically owned utilities (CEC 2009a). The report indicates that SMUD will be able to meet its resource adequacy requirements in the near term; however, in 2018, SMUD's generation resources may not be sufficient to meet its load and planning reserve margin obligations. The expected deficiency in 2018 is estimated to be 347 MW, but the CEC does not expect this to be an issue due to the lead time available to resolve the expected deficiency.

SMUD also carries out an annual 10-year transmission planning process to ensure that NERC and Western Electricity Coordinating Council (WECC) Reliability Standards are met each year of the 10-year planning horizon. Major projects that have been proposed in the 2010 transmission plan for the 2016–2020 time period are expected to improve the reliability of SMUD's electric system as well as increase its load-serving capability.

Turlock Irrigation District

The Turlock Irrigation District (TID) operates as a balancing authority located between Sacramento and Fresno in California's Central Valley (California Transmission Planning Group). Westley 230 kilovolt (kV) and Oakdale 115 kV lines provide import access for TID. The TID balancing authority incorporates all 662 square miles of TID's electric service territory as well as a 115 kV loop with three 115 kV substations owned by the Merced Irrigation District (Merced ID). The Merced ID facilities are interconnected to TID's August and Tuolumne 115 kV substations and are located just south of TID's service territory and north of the city of Merced. TID is the majority owner and operating partner of the New Don Pedro power plant with 68.46 percent ownership, and MID has a 31.54 percent ownership. BANC performs the balancing authority function for MID's portion of the plant.

14.2.3 Climate Change

The phenomenon known as the *greenhouse effect* keeps Earth's atmosphere near the surface warm enough for successful habitation by humans and other forms of life. GHGs present in the earth's lower atmosphere play a critical role in maintaining Earth's temperature as they trap some of the long-wave infrared radiation emitted from Earth's surface that otherwise would have escaped to space.

The accelerated increase of fossil fuel combustion and deforestation since the Industrial Revolution of the nineteenth century has exponentially increased concentrations of GHGs in the atmosphere. Increases in the atmospheric concentrations of GHGs in excess of natural ambient concentrations increase the natural greenhouse effect.

This increased greenhouse effect has contributed to global warming, which is the gradual increase of Earth's average surface temperature over a long term. Specifically, increases in GHGs lead to increased absorption of long-wave infrared radiation by the earth's atmosphere and further warm the lower atmosphere, thereby increasing evaporation rates and temperatures near the surface. Warming of Earth's lower atmosphere induces large-scale changes in ocean circulation patterns, precipitation patterns, global ice cover, biological distributions, and other changes to Earth's systems that are collectively referred to as *climate change*.

The Intergovernmental Panel on Climate Change (IPCC) has been established by the World Meteorological Organization and United Nations Environment Programme to assess scientific, technical, and socioeconomic information relevant to the understanding of climate change, its potential impacts, and options for adaptation and mitigation. The IPCC estimates that the average global temperature rise between the years 2000 and 2100 could range from 1.1°C, with no increase in GHG emissions above year 2000 levels, to 6.4°C, with substantial increase in GHG emissions (IPCC 2007). Large increases in global temperatures could have massive deleterious impacts on the natural and human environments.

Principal Greenhouse Gases

GHGs are gases that trap heat in the atmosphere. GHGs are both naturally occurring and artificial. Examples of GHGs that are produced both by natural and anthropogenic (human-made) processes are carbon dioxide (CO_2), methane (CH_4), and nitrous oxide (N_2O). Examples of GHGs created and emitted primarily through human activities are hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6). The primary GHGs generated by the LSJR alternatives—CO_2, CH_4, and N_2O—are discussed below.

The IPCC estimates that CO_2 accounts for more than 75 percent of all anthropogenic GHG emissions. Three quarters of anthropogenic CO_2 emissions are the result of fossil fuel burning, and approximately one quarter result from land use change (IPCC 2007). CH_4 is the second largest contributor of anthropogenic GHG emissions and is the result of growing rice, raising cattle, combustion, and mining coal. N_2O, while not as abundant as CO_2 or CH_4, is a powerful GHG. Sources of N_2O include agricultural processes, nylon production, fuel-fired power plants, nitric acid production, and vehicle emissions.

In order to simplify reporting and analysis, methods have been set forth to describe emissions of GHGs in terms of a single gas. The most commonly accepted method to compare GHG emissions is the global warming potential (GWP) defined in the IPCC reference documents (IPCC 1996, 2001). The IPCC defines the GWP of various GHGs on a normalized scale that recasts all GHG emissions in terms of carbon dioxide equivalent (CO_2e). Hence, GWP is a measure of a gas's heat-absorbing capacity and lifespan relative to a reference gas, CO_2 (CO_2 has a GWP of 1, by definition).

Table 14-6 lists the global warming potential of CO_2, CH_4, and N_2O; their lifetimes; and abundances in the atmosphere in parts per million (ppm) and parts per trillion (ppt).

Table 14-6. Lifetime and Global Warming Potentials

GHG	Global Warming Potential (100 years)	Lifetime (years)	Current Atmospheric Abundance (ppm)
CO_2	1	50–200	399
CH_4	28	12.4	1,893
N_2O	265	121	326

Sources: IPCC 2013; Carbon Dioxide Information Analysis Center 2014; CO2Now.org 2015.
GHG = greenhouse gas
ppm = parts per million

Greenhouse Gas Emissions Inventories

A GHG inventory is a quantification of GHG emissions and sinks within a selected physical and/or economic boundary over a specified time. GHG inventories can be performed on a large scale (i.e., for global and national entities) or on a small scale (i.e., for a particular building or person). GHG sinks typically refer to removals of GHGs from the atmosphere as a result of carbon sequestration. Carbon sequestration is the process by which plants absorb and store atmospheric CO_2.

Table 14-7 outlines the most recent global, national, and statewide GHG inventories to help contextualize the magnitude of potential alternative-related emissions. Figures 14-1, 14-2, and 14-3 show global, national, and state GHG emissions by source/sector, respectively.

Table 14-7. Global, National, and State Greenhouse Gas Emissions Inventories

Emissions Inventory	Total GHG Emissions and Sinks in CO_2e (metric tons)
2010 IPCC Global GHG Emissions Inventory	52,000,000,000
2013 USEPA National GHG Emissions Inventory	6,673,000,000
2013 ARB State GHG Emissions Inventory	459,280,000

Sources: IPCC 2014; USEPA 2015a; ARB 2015.
IPCC = Intergovernmental Panel on Climate Change
GHG = greenhouse gas
USEPA = U.S. Environmental Protection Agency
ARB = California Air Resources Board

GHG Emissions in the Plan Area and Extended Plan Area

There is no regional GHG inventory for the plan area or extended plan area. There are some local inventories for individual jurisdictions, but there is currently no assessment of GHG emissions for the Central Valley region or Mountain region as a whole. However, primary sources of GHG emissions in the plan area include those described above under the statewide emissions by source, such as: on-road transportation from vehicle travel, residential and nonresidential building energy use, and agricultural activity including off-road equipment fuel combustion, fugitive emissions from livestock production (enteric fermentation and manure management), and fertilizer application. Primary sources of GHG emissions in the extended plan area are similar to those described above under the statewide emissions by sources and in the plan area; however, there is expected to be less agricultural activity related emissions given the relatively limited amount of agriculture in the extended plan area when compared to the plan area and the rest of the state.

Climate Change Effects on State Climate Trends

Climate change is a complex phenomenon that has the potential to alter local climatic patterns and meteorology. Although modeling indicates that climate change will result in such things as sea level rise and changes in regional climate and rainfall, a high degree of scientific uncertainty still exists with regard to characterizing future climate characteristics and predicting how various ecological and social systems will react to any changes in the existing climate at the local level. Regardless of this uncertainty, it is widely understood that some form of climate change is expected to occur in the future.

Several recent studies have attempted to characterize future climatic scenarios for California. While specific estimates and statistics on the severity of changes vary, sources agree that the San Joaquin Valley and the Delta will witness warmer temperatures, increased heat waves, and changes in rainfall patterns. In addition, reduced snow pack and stream flow in the Sierra Nevada could lead to changes in water supply into the Delta region. Specifically, the CEC estimates that average annual temperatures in the state will increase by approximately 1°C–3°C between 2010 and mid-century, according the model for the Sacramento region. Climatic models also predict that between 2035 and 2064, the number of heat wave days for the Sacramento region will increase by more than 100 days,

Statewide GHG Emissions by Source

relative to the previous 30-year period between 2005 and 2034. Annual precipitation may experience a declining trend, but remain highly variable, suggesting that the Sacramento Valley will be vulnerable to increased drought. Warmer temperatures will lead to increased precipitation in the form of rain, both of which will contribute to decreased snowpack in the Sierra Nevada. Such effects will translate into earlier snowmelt and increased potential for flooding as a result of insufficient reservoir capacity to retain earlier snowmelt. (IPCC 2007; California Natural Resources Agency 2009; CEC 2009b; USBR 2016).

Sea level rise during the next 50 years is expected to increase dramatically over historical rates. The CEC predicts that by 2050, sea level rise, relative to the 2000 measurements, will range from 30 to 45 centimeters. Coastal sea level rise could result in saltwater intrusion to the Delta and associated biological impacts in the San Joaquin Valley. Changes in soil moisture and increased risk of wildfires also may dominate future climatic conditions in the area. (IPCC 2007; California Natural Resources Agency 2009; CEC 2009b).

The changes in temperature, precipitation and sea level may have substantial effects on other resources areas. The primary effects of climate change anticipated in California are listed below (California Natural Resources Agency 2009).

- Increased average temperatures (air, water, and soil).
- Reduced or slightly increased annual precipitation amounts.
- Change from snowfall (and spring snowmelt) to rainfall.
- Decreased Sierra snowpack (earlier runoff, reduced maximum storage).
- Increased evapotranspiration.
- Increased frequency and intensity of Pacific storms (flood events).
- Increased severity of droughts.
- Increased frequency and severity of extreme heat events.
- Increased frequency and severity of wildfire events.
- Sea level rise (with increased salt water intrusion in the Delta).
- Changes in species distribution and ranges.
- Decreased number of species.
- Increased number of vector-borne diseases and pests (including impacts on agriculture).
- Altered timing of animal and plant lifecycles (phenology).
- Disruption of biotic interactions (e.g., predator-prey relationships amongst species and increased invasive species abundance).
- Changes in physiological performance, including reproductive success and survival of plants and animals.
- Increase in invasive species.
- Altered migration patterns of fishes, aquatic-breeding amphibians, birds, and mammals.
- Changes in food (forage) base.
- Changes in habitat, vegetation structure, and plant and animal communities.

DWR (2010a) analyzed the flows of the four rivers in the SJR Watershed (Stanislaus, Tuolumne, Merced, and San Joaquin). This report documented that the combined unimpaired runoff from April–July has declined by approximately 7 percent relative to the total water year runoff over the past 100 years. Therefore, while total runoff in these watersheds has decreased, April–July runoff has decreased at a greater rate (DWR 2010a). USBR has also evaluated flows under climate change scenarios within the Sacramento-San Joaquin River Basin concluding that the basin will experience a shift in runoff to more during late fall and winter and less during the spring as a result of more precipitation, higher temperatures during the winter, and less snowpack (USBR 2016). As a result, reservoirs in the basin, including New Melones, New Don Pedro, and Lake McClure, are likely to fill earlier and release excess runoff, thereby potentially limiting overall storage capability and reducing water supply (USBR 2014, 2016). These changes have implications for water quality, water supply, flooding, aquatic ecosystems, energy generation, and recreation throughout the region (USBR 2014, 2016).

Guidance documents have been drafted and published to discuss strategies to protect resources from climate change in California (e.g., the *State of California Sea-Level Rise Interim Guidance Document*, Coastal and Ocean Working Group of the California Climate Action Team 2010). Many federal, state, and local agencies are incorporating adaptive strategies into their planning processes and planning documents to account for the potential changes in water resources and the effect on water supply reliability and other factors (see Sections 14.3.2, *State [Regulatory Background]*, and 14.3.3, *Regional or Local [Regulatory Background]*, regarding state and local planning documents related to climate change).

14.3 Regulatory Background

The legal framework addressing climate change regulatory background is complex and evolving. This section identifies key legislation, executive orders, as well as plans and policies relevant to the environmental assessment of GHG emissions.

14.3.1 Federal

Relevant federal programs, policies, plans, or regulations related to GHG emissions are described below.

Mandatory Greenhouse Gas Reporting Rule

On September 22, 2009, the U.S. Environmental Protection Agency (USEPA) released its final Greenhouse Gas Reporting Rule (Reporting Rule). The Reporting Rule is a response to the fiscal year (FY) 2008 Consolidated Appropriations Act (H.R. 2764; Public Law 110-161), which required USEPA to develop "… mandatory reporting of GHGs above appropriate thresholds in all sectors of the economy…." The Reporting Rule would apply to most entities that emit 25,000 metric tons (MT) of CO_2e or more per year. Starting in 2010, facility owners are required to submit an annual GHG emissions report with detailed calculations of facility GHG emissions. The Reporting Rule also would mandate recordkeeping and administrative requirements in order for USEPA to verify annual GHG emissions reports. All electrical distribution utilities (EDU) except Investor-Owned Utilities (IOUs) must comply with the Reporting Rule. This includes SMUD and TID, which are within the plan area.

Omnibus Public Land Management Act

The Omnibus Public Land Management Act, also known as the SECURE Water Act, was passed by Congress in 2009. This act establishes that Congress finds that adequate and safe supplies of water are fundamental to the health, economy, security, and ecology of the United States although global climate change poses a significant challenge to the protection of these resources. The act authorized USBR to continually evaluate and report on the risks and impacts from a changing climate and to identify appropriate adaptation and mitigation strategies using the best available science in conjunction with stakeholders. USBR has released several reports under the SECURE Water Act, the first of which was released in 2011. The reports address the requirements of the act including: each effect of, and risk resulting from, global climate change with respect to the quantity of water resources located in each major USBR river basin; impact of global climate change with respect to the operations of the secretary in each major river basin; each mitigation and adaptation strategy considered and implemented; each coordination activity conducted by the U.S. Geological Survey, National Oceanic and Atmospheric Administration, U.S. Department of Agriculture, or other resource agency (USBR 2011).

Since USBR maintains and operates reservoirs in the SJR Basin (e.g., New Melones Reservoir) these reports include information regarding the basin and effects of climate change. They also contain a wide variety of recommendations for responding to resource changes under climate changes (USBR 2016). These include the following potential adaptation strategies to address vulnerability: agricultural water use and municipal and industrial water use efficiency, ocean desalination; precipitation enhancement; conjunctive management; improvements of CVP/SWP operations; improvement of tributary and Delta environmental inflows; enhance groundwater recharge; increase San Joaquin Valley surface storage; improve regulatory flexibility and adaptation; improve river temperature management; and improve salinity and nutrient management (USBR 2016).

14.3.2 State

Relevant state laws, programs, policies, plans, or regulations related to GHG emissions are described below.

Executive Order S-3-05

Signed by Governor Arnold Schwarzenegger on June 1, 2005, Executive Order S-3-05 asserts that California is vulnerable to the effects of climate change. To combat this concern, Executive Order S-3-05 established the following GHG emissions reduction targets for state agencies.

- By 2010, reduce GHG emissions to 2000 levels.
- By 2020, reduce GHG emissions to 1990 levels.
- By 2050, reduce GHG emissions to 80 percent below 1990 levels.

Executive Order S-13-08

Executive Order S-13-08, signed by Governor Schwarzenegger in November 2008, requires the California Natural Resources Agency to develop a state Climate Adaptation Strategy in coordination with local, regional, state and federal public and private entities. The National Academy of Sciences must convene an independent panel to complete the first California Sea Level Rise Assessment Report, which will advise how California should plan for future sea level rise. The order directs the state's Business, Transportation and Housing Agency to assess the vulnerability of state transportation systems to sea level rise and directs the Governor's Office of Planning and Research (OPR) to provide state land-use planning guidance related to sea level rise and other climate change impacts.

Executive Order B-30-15

Signed by Governor Jerry Brown on April 29, 2015, Executive Order B-30-15 establishes a California GHG reduction target of 40 percent below 1990 levels by 2030.

Assembly Bill 32, California Global Warming Solutions Act of 2006

In September 2006, the California State Legislature adopted Assembly Bill 32, the California Global Warming Solutions Act of 2006 (AB 32). AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the California Air Resources Board (ARB) is required to take the following actions.

- Adopt early action measures to reduce GHGs.
- Establish a statewide GHG emissions cap for 2020 based on 1990 emissions.
- Adopt mandatory report rules for significant GHG sources.
- Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions.
- Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs.

California Climate Adaptation Strategy 2009 and 2013 Update

In 2009, California adopted a statewide Climate Adaptation Strategy (CAS). The CAS summarizes climate change impacts and recommends adaptation strategies for seven sectors: public health, biodiversity and habitat, oceans and coastal resources, water, agriculture, forestry, and transportation and energy (California Natural Resources Agency 2009). The California Natural Resources Agency is engaged in updating the CAS to augment strategies in light of advances in climate science.

California Renewables Portfolio Standard (California Senate Bill 1078 and 107)

Established in 2002 under Senate Bill (SB) 1078, and amendments thereto, the California Renewables Portfolio Standard (RPS) requires investor-owned utilities, electric service providers, and community choice aggregators to increase procurement from eligible renewable energy resources to 33 percent of total procurement by 2020. The California Public Utilities “Commission and the California Energy Commission jointly implement the RPS program. SB 107 (2006) accelerated the RPS by requiring electric corporations to increase procurement from eligible renewable energy resources by at least 1 percent of their retail sales annually, until they reach 20 percent by 2010.

California Air Resources Board Climate Change Scoping Plan

The California Global Warming Solutions Act of 2006 (AB 32) required ARB to prepare and adopt a plan that identified measures that would achieve reductions in GHG emissions in the State. In 2008, the ARB first considered the Climate Change Scoping Plan and in 2014 approved the first update to the plan (Scoping Plan). In particular, the Scoping Plan contains six strategies or measures for the water sector to implement that are expected to reduce GHG emissions due to the fact that water use requires significant amounts of energy. The six strategies for the water sector to implement include Water Use Efficiency (Measure W-1), Water Recycling (Measure W-2), Water System Energy Efficiency (Measure W-3), Reuse Urban Runoff (Measure W-4), Increase Renewable Energy Production from Water (Measure W-5), and a Public Goods Charge (Measure W-6). Efficient water conveyance, treatment and use can result in reductions in GHG emissions for those activities. The implementation of Measures W-1 through W-5 is expected to result in a total reduction of 4.8 MMT of CO_2e by 2020. The 2014 update to the Scoping Plan provides a status update of each of the measures but did not change the measures. The State Water Board is a sponsor of climate mitigation measures in the Scoping Plan (State Water Board 2011).

CEQA Statutes and Guidelines

SB 97 of 2007 requires that the Governor's OPR prepare guidelines for adoption by the California Resources Agency (now California Natural Resources Agency) regarding mitigation of GHG emissions or the effects of GHG emissions as required by the California Environmental Quality Act (CEQA). The amendments became effective in 2010.

State CEQA Guidelines Section 15064.4 specifically address how to determine the significance of impacts from GHG emissions. Section 15064.4 calls for a good-faith effort to describe, calculate, or estimate GHG emissions resulting from a project. Section 15064.4 further states that an agency should include certain factors when assessing the significance of GHG emission impacts on the environment, including the extent to which the project would increase or reduce GHG emissions, exceed an applicable threshold of significance, and comply with regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of GHG emissions. The revisions also state that a project may be found to have a less-than-significant impact if it complies with an adopted plan consistent with State CEQA Guidelines Section 15183.5 that includes specific measures to sufficiently reduce GHG emissions. (State CEQA Guidelines, § 15064.4, subd. (b)(3.) However, the revised guidelines do not require or recommend a specific analysis methodology or provide quantitative criteria for determining the significance of GHG emissions.

In order to assure that wise and efficient use of energy is considered in project decisions, CEQA requires that environmental impact reports (EIRs) include a discussion of the potential energy impacts of proposed projects, including identifying mitigation measures proposed to reduce inefficient, wasteful, and unnecessary consumption of energy. Appendix F of the State CEQA Guidelines also includes guidelines for evaluating potential energy impacts.

California Water Plan Update 2009 and 2013

The California Water Plan (CWP) is the long-term strategic plan for guiding the management and development of water resources in the state. Since its first publication in 1957, California Department of Water Resources (DWR) has prepared eight water plan updates (known as the Bulletin 160 series). The California Water Code requires that the CWP be updated every 5 years.

CWP Update 2009 incorporated climate change in water plan scenarios to evaluate impacts on California's water resources and to identify and recommend statewide and regional adaptation strategies (DWR 2010b). The State Water Board staff was actively engaged in preparation and review of sections of the CWP Plan Update 2009 (State Water Board 2011).

The CWP Update 2013 includes regionally appropriate and statewide water management and planning adaptation and mitigation strategies, resource management strategies, and decision support for climate change scenarios (California Natural Resources Agency and DWR 2013).

Progress on Incorporating Climate Change into Management of California's Water Resources (Technical Memorandum Report)

In response to Executive Order S-3-05 (described above), DWR developed this report, which describes progress made incorporating climate change into existing water resources planning and management tools and methodologies for California. This report focuses on assessment methodologies and preliminary study results and is primarily focused on the potential effects of climate change on the Central Valley and associated water resource systems (DWR 2010a).

Water Boards' Water Quality Control Plans and Strategic Plan

The State Water Board and Regional Water Quality Control Boards regularly review water quality control plans (WQCP). This planning process provides an opportunity to consider information related to water quality, such as developing information about climate change. The 2006 *Water Quality Control Plan for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary* (2006 Bay-Delta Plan) identifies climate change as an emerging issue to be addressed in the WQCP planning process. The *2008–2012 State Water Board Strategic Plan* also calls for consideration of climate change in several areas, including the planning process for WQCPs. Under climate change scenarios, it is likely that increased flow variability and shifts in timing of high flows would occur.

Water Conservation Bill of 2009 (SBX7-7)

In 2009, the Legislature enacted a water reform package that included requirements for urban water suppliers and agricultural water suppliers. The Urban Water Management Planning Act requires urban water suppliers to prepare urban water management plans, which must be updated every 5 years. The Agricultural Water Management Planning Act requires agricultural water suppliers to adopt agricultural management plans that describe the quality and quantity of water resources of the supplier, including an analysis of the effect of climate change on future water supplies. Agricultural water suppliers were required to prepare the agricultural water management plans (AWMPs) by December 2012, and update those plans by December 2015 and every 5 years thereafter.

14.3.3 Regional or Local

Relevant regional or local programs, policies, or regulations related to GHG emissions are described below. Although local policies, plans, and regulations are not binding on the State of California, below is a description of relevant ones.

San Joaquin Valley Air Pollution Control District

In December 2009, the San Joaquin Valley Air Pollution Control District (SJVAPCD) formally adopted the region's first GHG thresholds for determining significant climate change impacts in the SJVAPCD. The guidance is intended to streamline CEQA review by pre-quantifying emissions reductions that would be achieved through the implementation of Best Performance Standards (BPS). Projects are considered to have a less-than-significant cumulative impact on climate change if any of the following conditions are met.

1. Comply with an approved GHG reduction plan.
2. Achieve a score of at least 29[5] using any combination of approved operational BPS.
3. Reduce operational GHG emissions by at least 29 percent over business-as-usual (BAU) conditions (demonstrated quantitatively).

SJVAPCD guidance recommends quantification of GHG emissions for all projects in which an EIR is required, regardless of whether BPS achieve a score of 29 (SJVAPCD 2009a). While the thresholds adopted by the SJVAPCD were developed for internal use for projects in which the SJVAPCD is the lead agency, these thresholds also serve as the basis for guidance issued by the SJVAPCD for other agencies that are establishing their own processes for determining significance related to climate change (SJVAPCD 2009b).

Agricultural Water Management Plans

All irrigation districts within the plan area have adopted AWMPs and provided these to DWR as required by SBX7-7 (described in Section 14.3.2, *State [Regulatory Background]*). These plans all have sections that discuss the expected effects of climate change on agriculture within their districts and on the water supply used within the districts. Table 14-8 summarizes those effects and their associated action plans and recommendations as stated in the AWMPs.

Urban Water Management Plans

The municipal water providers within the plan area that receive surface water from the irrigation districts have all prepared urban water management plans (UWMPs) for their respective service areas as required by the California Urban Water Management Plan Act (described in Section 14.3.2, *State [Regulatory Background]*). These municipal water providers, described in Chapter 13, *Service Providers*, are: Stockton East Water District (SEWD); City and County of San Francisco (CCSF); City of Modesto and MID; Contra Costa Water District (Contra Costa WD); City of Manteca (City of Manteca); City of Stockton (Stockton); and City of Tracy (Tracy). Some of the providers' UWMPs have sections that discuss the expected effects of climate change on water demand within their service areas and on the water supply used within their service areas. Table 14-9 summarizes the climate-change related information presented in the UWMPs.

---

[5] A score of 29 represents a 29 percent reduction in GHG emissions relative to unmitigated conditions (1 point = 1 percent). This goal is consistent with the reduction targets established by AB 32.

Table 14-8. Agricultural Water Management Plans and Climate Change

Water Supplier	Evaluated Climate Change? (Yes/No)	Potential Effects on Agricultural Water Demand	Potential Effects on Agricultural Water Supply	Potential Effects on Water Quality	Planning Recommendations or Actions
South San Joaquin Irrigation District (SSJID)	Yes	• Increased crop water demands due to increased temperatures and other climate change factors. • Increased irrigation requirements to meet increased evapotranspiration demands.	• Reduced total inflows to New Melones Reservoir would increase the probability that total inflows would be less than 600 TAF/y, which would result in supplies less than 300 TAF more often than predicted, based on historical data. • There would be no effect on SSJID's annual water supply allotment due to the shift in runoff to winter because SSJID's annual available supply under the 1988 Agreement (described in Chapter 2, *Water Resources*, Section 2.6.2, *Water Diversion and Use*) is based on total annual inflows to New Melones Reservoir.	• Increased erosion and turbidity would not likely significantly affect the water quality of the Stanislaus River. • Increased water temperatures could result in an increase in aquatic plants within SSJID's distribution system, which could pose challenges to filtering canal water for microirrigation. • There are no known contaminants that could be concentrated to levels that would affect agricultural irrigation if spring runoff decreases, particularly due to dilution in reservoirs upstream of SSJID.	• Implement climate change mitigation strategies identified in the California Water Plan 2009 and 2013 Updates (DWR 2010b and 2013); The California Natural Resources Agency and DWR 2013) and in the California Climate Adaptation Strategy (California Natural Resources Agency 2009), as needed.[a]

Water Supplier	Evaluated Climate Change? (Yes/No)	Potential Effects on Agricultural Water Demand	Potential Effects on Agricultural Water Supply	Potential Effects on Water Quality	Planning Recommendations or Actions
Oakdale Irrigation District (OID)	Yes	• Increased irrigation requirements to meet increased evapotranspiration demands due to increased temperatures. • Increased crop water demands due to increased temperatures and other factors related to climate change. • Changes in the timing of crop planting, development, and harvest due to increased temperatures and other factors related to climate change could result in changes to the timing of irrigation demands during the year.	• The shift in runoff to the winter period could potentially affect surface water supply if sufficient storage is not available to retain winter runoff. Because OID's annual entitlement is based on total annual inflows to New Melones Reservoir, the timing of runoff would not affect OID's annual allotment. • Entitlements less than 300 TAF could occur more often than predicted (based on analysis of historical data) because future reduced total inflows to New Melones Reservoir would increase the probability that total inflows would be less than 600 TAF in any given year.	• Increased erosion and turbidity would not likely significantly affect the water quality of the Stanislaus River. • Increased water temperatures could result in increased algae and other water plant growth, which would pose challenges to filtering OID canal water for microirrigation. • There are no known contaminants that could be concentrated to levels that would affect agricultural irrigation if spring runoff decreases, particularly due to dilution in reservoirs upstream of OID.	• Implement climate change mitigation strategies identified in the California Water Plan 2009 and 2013 Updates (DWR 2010b and 2013); California Natural Resources Agency and DWR 2013) and in the California Climate Adaptation Strategy (California Natural Resources Agency 2009), as needed.[a]

Water Supplier	Evaluated Climate Change? (Yes/No)	Potential Effects on Agricultural Water Demand	Potential Effects on Agricultural Water Supply	Potential Effects on Water Quality	Planning Recommendations or Actions
Turlock Irrigation District (TID)	Yes	• Increased crop evapotranspiration due to increased temperatures. • Increased crop water demands due to increased temperatures.	• The shift in runoff to the winter period and projected reduction in total runoff could potentially affect water supply in the future if sufficient storage is not available to retain winter runoff and provide additional carryover storage from wet to dry years.	• Increased erosion and turbidity would not likely significantly affect the water quality of the Tuolumne River.	• Implement climate change mitigation strategies identified in the California Water Plan 2009 and 2013 Updates (DWR 2010b and 2013); California Natural Resources Agency and DWR 2013)and in the California Climate Adaptation Strategy (California Natural Resources Agency 2009), as needed.[a]
Modesto Irrigation District (MID)	Yes	• Faster plant development, shorter growing seasons, increased evapotranspiration, and potential heat stress for some crops due to increased temperatures. • Increased crop water demands, particularly for fruit crops, due to increased air temperatures. • Increase in water demand. • Impacts on agriculture due to climate change are anticipated to be significant.	• Reduced average annual snowpack due to a rise in the snowline and thinner snowpack in low- and medium-elevation zones. • Changes in the timing, intensity, location, amount, and variability of precipitation, including a shift in snowmelt runoff to earlier in the year, and increased precipitation falling as rain instead of as snow. • Increase in evaporation will require additional water supply.	Not addressed	• Adaptive management of water. • Water conservation. • Improve operational control within MID.

Water Supplier	Evaluated Climate Change? (Yes/No)	Potential Effects on Agricultural Water Demand	Potential Effects on Agricultural Water Supply	Potential Effects on Water Quality	Planning Recommendations or Actions
Merced Irrigation District (Merced ID)	Yes	• Faster plant development, shorter growing seasons, changes to reference evapotranspiration, and potential heat stress for some crops due to increased temperatures. • Fruit crops may require additional water as climate warms to maintain yield and quality. • Increased agricultural water demands due to increased temperatures and evapotranspiration rates. Increased fallow land and retired land acreage.	• Exacerbated groundwater overdraft due to increased demands on groundwater as a result of decreased surface flows. • Additional water storage would be required to ensure water supply reliability due to early spring runoff and a reduction in mean flow.	• Degraded surface and groundwater quality due to lower flows, groundwater overdraft, meadow reduction, and increased drought frequency and severity, and storm events.	• Implement resource management strategies for water management approaches in the region identified in the California Water Plan 2009 and 2013 Updates (DWR 2010b and 2013); California Natural Resources Agency and DWR 2013). • Augmenting crop water requirements by pumping groundwater, improving irrigation efficiency, and shifting to high-value and salt-tolerant crops in response to climate change

Water Supplier	Evaluated Climate Change? (Yes/No)	Potential Effects on Agricultural Water Demand	Potential Effects on Agricultural Water Supply	Potential Effects on Water Quality	Planning Recommendations or Actions
Stockton East Water District (SEWD)	Yes	Not addressed	• Water supply originating from the Stanislaus River could be affected by climate change because a significant portion of that surface water is derived from snow melt. Any decrease in snow melt resulting from climate change would have a significant impact on New Melones Dam storage. • A reduction in rainfall would affect water supply	Not addressed	• Although not specific to water shortages due to climate change, in response to water shortages, SEWD would implement an agricultural water shortage plan for dry year or drought conditions, which includes voluntary reductions in use the first dry year and second subsequent dry year, and potential mandatory reductions in the third subsequent dry year.

Sources: SSJID 2012; OID 2012; TID 2012; MID 2012; Merced ID 2013; SEWD 2014.

TAF/y = thousand acre-feet per year

[a] Many of the climate change mitigation strategies that are applicable to irrigation districts are currently being implemented in some form to meet local and regional water management objectives.

Table 14-9. Urban Water Management Plans and Climate Change

Water Supplier	Evaluated Climate Change? (Yes/No)	Potential Effects on Water Supply	Planning Recommendations or Actions
City of Stockton	Yes	• Water supply originating from the Stanislaus River could be affected by climate change because a significant portion of that surface water is derived from snow melt. Any decrease in snow melt resulting from climate change would have a significant impact on New Melones Dam storage. • A reduction in rainfall would affect water supply.	Although not specific to water shortages due to climate change, in response to a water shortage emergency, the City of Stockton would implement their five-stage rationing plan, which includes both voluntary (10 percent reduction) and mandatory (up to 20 percent in past years) reductions.
City and County of San Francisco	Yes	• A rise in temperature of 1.5°C between 2000 and 2025 would result in less or no snowpack between 6,000 and 6,500 feet (ft) and faster melting of the snowpack above 6,500 ft. • Approximately 7 percent of the runoff currently draining into Hetch Hetchy Reservoir would shift from spring/ summer to fall/winter in the Hetch Hetchy basin by 2025. This percentage is within the current interannual variation in runoff and is within the range accounted for during normal runoff forecasting and existing reservoir management practices.	Prepare climate change modeling and evaluation to inform risk-based decisions for the future and prepare a work plan for the SFPUC climate change assessment of Hetch Hetchy and local watersheds.
Contra Costa Water District	No	NA	NA
City of Manteca	No	NA	NA

Water Supplier	Evaluated Climate Change? (Yes/No)	Potential Effects on Water Supply	Planning Recommendations or Actions
City of Modesto and Modesto Irrigation District	Yes	• Reduced snowpack may shift spring runoff to earlier in the year.	• Implement a water conservation program (Section 11-1.14 of Title XI of the Modesto Municipal Code), including the completing the residential metering program to help reduce water demands and to conserve energy as a result of decreased treatment, conveyance, and pumping requirements. • The City of Modesto's compliance with SBx7-7 and its interim and final per capita water use targets will ensure continued water and energy conservation. • The City of Modesto's increased use of surface water supplies from MID's Modesto Regional Water Treatment Plant Phase Two will help to further diversify Modesto's water supplies and enhance water supply reliability to adapt to the changing hydrologic conditions associated with climate change.
City of Tracy	Yes	• Reduced snowpack may shift spring runoff to earlier in the year.	• For conservative planning/projection purposes, the City of Tracy has reduced the predicted available water supply to 75 percent of the city's Central Valley Project annual entitlement in a normal water year, and 65 percent in a single dry year.

NA = not applicable

14.4 Impact Analysis

This section identifies the thresholds or significance criteria used to evaluate the potential impacts on energy resources, GHG emissions and climate change. It further describes the methods of analysis used to determine significance. Measures to mitigate (i.e., avoid, minimize, rectify, reduce, eliminate, or compensate for) significant impacts accompany the impact discussion, if any significant impacts are identified.

14.4.1 Thresholds of Significance

The thresholds for determining the significance of impacts for this analysis are based, in part, on the State Water Board's Environmental Checklist in Appendix A of the Board's CEQA regulations (Cal. Code Regs., tit. 23, §§ 3720–3781) and Appendix F of the State CEQA Guidelines. The thresholds derived from the checklist have been modified, as appropriate, to meet the circumstances of the alternatives. (Cal. Code Regs., tit. 23, § 3777, subd. (a)(2).) GHG impacts were determined to be potentially significant in the State Water Board's Environmental Checklist (see Appendix B, *State Water Board's Environmental Checklist*) and, therefore, are discussed in this analysis. In addition, this chapter evaluates impacts on energy resources, as recommended by Appendix F of the State CEQA Guidelines, and climate change, as recommended by Appendix G of the State CEQA Guidelines. Although Appendix G calls for a determination of the significance of GHG emissions (as opposed to climate change), *climate change* in this document refers to an assessment of GHG emissions per the guidelines and is used interchangeably in this analysis.

Energy Resources

Energy impacts would be significant if the LSJR alternatives result in any of the following.

- Adversely affect the reliability of California's electric grid.
- Result in inefficient, wasteful, and unnecessary energy consumption.

According to CEQA Appendix F, the goal of conserving energy implies the wise and efficient use of energy. In order to assure that energy implications are considered in project decisions, CEQA requires a discussion of the potential energy impacts of proposed projects and the impacts of avoiding or reducing inefficient, wasteful, and unnecessary consumption of energy.

GHG Emissions/Climate Change

Climate change impacts would be significant if the LSJR alternatives result in any of the following.

- Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment.
- Conflict with an applicable plan, policy, or regulation adopted for the purposes of reducing GHG emissions.

Potential changes in electricity generation and distribution could occur; however, local air pollution control districts have not adopted GHG thresholds directly relevant to the alternatives to evaluate climate change impacts.[6] As there is no acceptable GHG reduction plan from which to evaluate project significance consistent with State CEQA Guidelines Sections 15183.5 and 16064.4(b)(3), and local air district thresholds are not directly applicable to the alternatives, a threshold of 10,000 MT of CO_2e per year is used for evaluating the GHG emission impact of the project under CEQA. The threshold of 10,000 MT of CO_2e per year was adopted by the South Coast Air Quality Management District (SCAQMD) and the Bay Area Air Quality Management District (BAAQMD) for industrial projects that would capture 90 percent of all GHG emissions from stationary sources in each air basin. Because the alternatives would affect facilities in several air pollution control districts, the GHG threshold, although conservative, would be appropriate measure to evaluate climate change impacts.

State CEQA Guidelines Section 15126.2(a) states that the CEQA analysis should analyze any significant impact the project might cause by bringing development and people into the area affected and should analyze any potentially significant impacts of locating a project in areas susceptible to hazardous conditions. The California Supreme Court has held that this provision is valid to the extent it calls for evaluating a project's potentially significant exacerbating effects on existing environmental hazards and that CEQA's provisions are best read to focus almost entirely on how the project affects the environment, not how the environment affects the project (*California Building Industry Association v. Bay Area Air Quality Management District* [2015] 62 Cal.4th 367). The alternatives do not involve environmental hazards. Nevertheless, the analysis presented below also evaluates how the LSJR and SDWQ alternatives may be affected by climate change.

14.4.2 Methods and Approach

LSJR Alternatives

This chapter evaluates the potential energy and GHG impacts associated with the LSJR alternatives. Each LSJR alternative includes a February–June unimpaired flow requirement (i.e., 20, 40, or 60 percent) and methods for adaptive implementation to reasonably protect fish and wildlife beneficial uses, as described in Chapter 3, *Alternatives Description*. In addition, a minimum base flow is required at Vernalis during this period. The base flow may be adaptively implemented as described below and in Chapter 3. State Water Board approval is required before any method can be implemented, as described in Appendix K, *Revised Water Quality Control Plan*. All methods may be implemented individually or in combination with other methods, may be applied differently to each tributary, and could be in effect for varying lengths of time, so long as the flows are coordinated to achieve beneficial results in the LSJR related to the protection of fish and wildlife beneficial uses.

The Stanislaus, Tuolumne, and Merced Working Group (STM Working Group) will assist with implementation, monitoring, and assessment activities for the flow objectives and with developing biological goals to help evaluate the effectiveness of the flow requirements and adaptive implementation actions. The STM Working Group may recommend adjusting the flow requirements through adaptive implementation if scientific information supports such changes to reasonably protect fish and wildlife beneficial uses. Scientific research may also be conducted within the adaptive range to improve scientific understanding of measures needed to protect fish and wildlife and reduce scientific uncertainty through monitoring and evaluation. Further details describing the

---

[6] While the SJVPACD has established thresholds of significance for climate change impacts, there are no BPS that are directly applicable to the alternatives and the SJVAPCD's 29 percent reduction in GHG emissions is not directly applicable to the alternatives, as the alternatives would not have any direct control over GHG generating activities.

methods, the STM Working Group, and the approval process are included in Chapter 3 and Appendix K.

Without adaptive implementation, flow must be managed such that it tracks the daily unimpaired flow percentage based on a running average of 7 days. The four methods of adaptive implementation are described briefly below.

1. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the specified annual February–June minimum unimpaired flow requirement may be increased or decreased to a percentage within the ranges listed below. For LSJR Alternative 2 (20 percent unimpaired flow), the percent of unimpaired flow may be increased to a maximum of 30 percent. For LSJR Alternative 3 (40 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 30 percent or increased to a maximum of 50 percent. For LSJR Alternative 4 (60 percent unimpaired flow), the percent of unimpaired flow may be decreased to a minimum of 50 percent.
2. Based on best available scientific information indicating a flow pattern different from what would occur by tracking the unimpaired flow percentage would better protect fish and wildlife beneficial uses, water may be released at varying rates during February–June. The total volume of water released under this adaptive method must be at least equal to the volume of water that would be released by tracking the unimpaired flow percentage from February–June.
3. Based on best available scientific information, release of a portion of the February–June unimpaired flow may be delayed until after June to prevent adverse effects to fisheries, including temperature, which would otherwise result from implementation of the February–June flow requirements. The ability to delay release of flow until after June is only allowed when the unimpaired flow requirement is greater than 30 percent. If the requirement is greater than 30 percent but less than 40 percent, the amount of flow that may be released after June is limited to the portion of the unimpaired flow requirement over 30 percent. For example, if the flow requirement is 35 percent, 5 percent may be released after June. If the requirement is 40 percent or greater, then 25 percent of the total volume of the flow requirement may be released after June. As an example, if the requirement is 50 percent, at least 37.5 percent unimpaired flow must be released in February–June and up to 12.5 percent unimpaired flow may be released after June. If after June the STM Working Group determines that conditions have changed such that water held for release after June should not be released by the fall of that year, the water may be held until the following year. See Chapter 3 and Appendix K for further details.
4. Based on best available scientific information indicating that more flow is needed or less flow is adequate to reasonably protect fish and wildlife beneficial uses, the February–June Vernalis base flow requirement of 1,000 cfs may be modified to a rate between 800 and 1,200 cfs.

The operational changes made using the adaptive implementation methods above may be approved if the best available scientific information indicates that the changes will be sufficient to support and maintain the natural production of viable native SJR Watershed fish populations migrating through the Delta and meet any biological goals. The changes may take place on either a short-term (e.g., monthly or annually) or longer-term basis. Adaptive implementation is intended to foster coordinated and adaptive management of flows based on best available scientific information in order to protect fish and wildlife beneficial uses. Adaptive implementation could also optimize flows to achieve the objective, while allowing for consideration of other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. While the measures and processes used to decide upon adaptive implementation actions must achieve the narrative objective for the reasonable protection of fish and wildlife beneficial uses, adaptive implementation could result in flows that would benefit or reduce impacts on other beneficial uses that rely on water. For example, terrestrial riparian species could benefit by receiving additional flows during key germination times in the late spring.

The quantitative results included in the figures, tables, and text of this chapter present Water Supply Effects (WSE) modeling of the specified unimpaired flow requirement for each LSJR alternative (i.e., 20, 40, or 60 percent). The modeling does allow some inflows to be retained in the reservoirs after June, as could occur under adaptive implementation method 3, to prevent adverse temperature effects and this is included in the results presented in this chapter. This use of modeling provides information to support the analysis and evaluation of the effects of the alternatives and adaptive implementation. For more information regarding the modeling methodology and quantitative flow and temperature modeling results, see Appendix F.1, *Hydrologic and Water Quality Modeling*.

However, as part of adaptive implementation, method 1 would allow the required percent of unimpaired flow to change by up to 10 percent if the STM Working Group agrees to adjust it. The highest possible percent of unimpaired flow associated with an LSJR alternative is also evaluated in the impact analysis if long-term implementation of method 1 has the potential to affect a significance determination. For example, if the determination for LSJR Alternative 2 at 20 percent unimpaired flow is less than significant, but the determination for LSJR Alternative 3 at 40 percent unimpaired flow is significant, then LSJR Alternative 2 is also evaluated at the 30 percent unimpaired flow.

Reduction in Hydropower Production

This section summarizes the method to estimate the potential reduction in hydropower generated by power plants on the three eastside tributaries as a result of the LSJR alternatives. Detailed information related to this methodology is in Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*. The method relies on the WSE model to estimate the effects of the LSJR alternatives on reservoir releases and storage (elevations head) and allowable diversions to off-stream generation facilities, and then calculate the associated change in monthly and annual amounts of energy produced in comparison to the baseline model run. Specific details of the LSJR alternatives are provided in Chapter 3, *Alternatives Description*, and are the basis for how the alternatives are modeled in this analysis.

Hydropower facilities on the three eastside tributaries were grouped into four categories (in-stream, rim dam, off-stream, and upstream), based on where they are located relative to the three eastside tributary dams and whether they are in-stream facilities or off-stream facilities.

Detailed discussions on calculating hydropower from each of the categories are provided in Appendix J. Table 14-10 contains a summary of the average annual hydropower generation change on each of the three eastside tributaries due to LSJR Alternatives 2, 3, and 4. These changes are also represented as a percent of baseline generation. Generally, as the percent unimpaired flow increases, the amount of power generated annually is reduced. Overall, hydropower generation is expected to increase with LSJR Alternative 2, remain about the same with LSJR Alternative 3, and decrease with LSJR Alternative 4 relative to baseline.

Table 14-10. Change in Average Annual Hydropower Generation from Baseline

Alternative		Stanislaus River (GWh)/(%)	Tuolumne River (GWh)/(%)	Merced River (GWh)/(%)	Plan-wide Total (GWh)/(%)
	Baseline Conditions Power Generation	586 (100)	656 (100)	408 (100)	1,650 (100)
	Change of Hydropower Generation (Alternative minus Baseline)				
LSJR Alternative 2	20% Unimpaired Flow	18 (3)[a]	2 (0)	8 (2)	29 (2)
	Adaptive Implementation Method 1: 30% Unimpaired Flow	11 (2)	0 (0)	4 (1)	15 (1)
LSJR Alternative 3		4 (1)	-6 (-1)	-3 (-1)	-4 (0)
LSJR Alternative 4		-23 (-4)	-41 (-6)	-23 (-6)	-87 (-5)

Source: Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*.
GWh = gigawatt hours
[a] Modeled results indicate that LSJR Alternative 2 would result in an increase in hydropower production.

The monthly pattern of the average change (over 82 years of simulation) in hydropower generation from the plan area when compared to the baseline condition is presented in Figure 14-4. This shows a general increase in energy production in the months of February–June as more flow would be released from the reservoirs to meet the unimpaired flow objectives. For LSJR Alternatives 3 and 4, a decrease in hydropower generation during the summer months of July–September is due to less water being released from the major reservoirs as a result of reduced diversions downstream, as well as lower reservoir elevations. During November–January, a decrease in hydropower generation associated with LSJR Alternatives 3 and 4 is related to lower reservoir elevations and a reduced need for flood control releases. These effects are more pronounced as the percentage of unimpaired flow requirement of the LSJR alternatives increases.

	OCT	NOV	DEC	JAN	FEB	MAR	APR	MAY	JUN	JUL	AUG	SEP
Alternative 2	3	1	1	1	2	0	-1	12	10	-2	1	2

Figure 14-4. Change in Average Monthly Hydropower Generation across 82 Years of Simulation Associated with the LSJR Flow Alternatives Compared to Baseline

Power Flow Assessment

The LSJR alternatives could reduce the hydropower generation in the summer months of July–September because less water would be stored during those months in the reservoirs as a result of being released earlier in the year (e.g., February–June), thereby reducing the amount of water available for hydropower generation. Since California's electric grid is most stressed during the summer months of June–August, with peak demand typically occurring in the month of July, a reduction in hydropower capacity during this time has the potential of stressing the grid even further.

The results of a steady-state power flow assessment of the California grid are used to determine if reduction in hydropower capacities at New Melones, New Don Pedro, and New Exchequer power plants would adversely impact the grid reliability as defined by NERC (see Appendix J, *Hydropower and Electric Grid Analysis of LSJR Flow Alternatives*, for discussion of NERC reliability). The reduction in hydropower capacity at the three power plants was calculated using the WSE model for the month of July during the 82-year period (water years 1922–2003) for LSJR Alternatives 2, 3, and 4. July was chosen because it is a peak energy-use month and, therefore, has some of the largest hydropower capacity effects. Detailed discussions on the capacity reduction calculation are presented in Appendix J. LSJR Alternative 2 would lead to no power capacity reduction from the baseline condition and, therefore, is not considered further in this analysis. The power flow assessment was conducted for LSJR Alternatives 3 and 4, assuming a reduction in capacity of 5 percent and 8 percent, respectively (slightly greater impacts than what was estimated with the WSE model, as described in Appendix J).

Detailed discussions of the power assessment are presented in Appendix J. In summary, the study examined the operation of the electric grid under peak summer demand conditions, using the following steps.

- Develop a baseline case and separate change cases for LSJR Alternatives 3 and 4. All cases are developed for both normal and contingency conditions. Under normal conditions, all transmission and generator facilities are assumed to be in service. Contingency conditions refer to the unplanned outage of power system equipment.
- Select analysis contingency conditions for transmission and generator facilities.
- Select the analysis areas based on the transmission line/transformer loadings and substation voltages.
- Model the transmission line/transformer loadings and substation voltages for baseline and LSJR Alternatives 3 and 4 under both normal and contingency conditions.
- Determine the impact of LSJR Alternatives 3 and 4 on the reliability of California's electric grid by comparing the analysis results to baseline.

If the comparison showed that transmission line/transformer loadings or substation voltages are within violation limits in baseline, but outside the limits in LSJR Alternatives 3 and 4, the alternatives could be considered to have an adverse impact on the reliability of California's electric grid.

Generally, a well operated transmission system should have line flows that are within the ratings of the transmission lines and substation voltages that are close to the nominal voltages. Typically, transmission lines have normal and emergency ratings. The analysis uses the normal and long-term emergency ratings (LTE) for the normal and contingency analyses, respectively.

Voltage limits were established relative to the nominal voltages. Under normal conditions, system operators regulate nodal voltages within ±5 percent of their nominal values. Under contingency conditions, this limit is relaxed to ±10 percent of the nominal value. These limits are typically set by the transmission owning utilities and the grid operator. When voltages or line loadings deviate from these limits it is referred to as a reliability violation. The limits used in the study for transmission line/transformer loading were the normal and LTE ratings. Under the normal conditions, transmission line/transformer flows should remain within the normal ratings. Under contingency conditions, transmission line/transformer flows should remain within the LTE ratings. Under normal conditions, substation voltages should remain within ±5 percent limit of the voltages of their nominal values. Under contingency conditions, the substation voltages should remain within ±10 percent limit of the nominal values.

The results of the power flow analysis for LSJR Alternatives 3 and 4 are presented in detail in Appendix J and are summarized below. These results are used to determine significant impacts on California's power grid.

- Under normal operating conditions, neither LSJR Alternatives 3 nor 4 triggered any transmission line or transformer to violate the normal and LTE ratings.
- Under contingency conditions, no line/transformer limit violation was found for LSJR Alternative 3. However, under LSJR Alternative 4, the 230 kV line between Borden and Gregg substations showed a minor violation under the outage of the 230 kV line between Gregg and Storey substations. A re-dispatch of the three Helms generator units (Helms Unit 1, 2, and 3) reduced the minor violation. The new loading of the analysis element after this re-dispatch was 99.81 percent.

- No line/transformer limit violations were found that could be exclusively attributed to LSJR Alternatives 3 or 4 under generator contingencies.
- No voltage violations were found that could be exclusively attributed to the reduced hydropower capacity in LSJR Alternatives 3 or 4.

Increase in Energy Consumption

As described in Chapter 5, *Surface Hydrology and Water Quality*, the LSJR alternatives are expected to change annual water supply from the Stanislaus, Tuolumne, and Merced Rivers. To satisfy the existing water demand for the purpose of identifying energy and climate change impacts, it is assumed that the reduced water supply would be partially compensated by pumping groundwater by the end users. Increases in groundwater pumping associated with LSJR Alternatives 2, 3, and 4 were estimated as described in Chapter 9, *Groundwater Resources*. It was assumed that in times of shortage of surface water supply, the irrigation districts could increase groundwater pumping up to their maximum capacity based on 2009 (baseline) infrastructure. The assumption of partial replacement creates a realistic scenario for energy impacts. Table 14-11 summarizes the increase in average annual groundwater pumping estimated for each of the three eastside tributaries for LSJR Alternatives 2, 3, and 4.

To estimate energy impacts, it is assumed that the compensated pumping would be electric, and the electricity consumption for groundwater pumping is calculated using the rate of 478 kilowatt hours (kWh) per acre-feet (AF). The rate is based on a conservative assumption that the groundwater is at a uniform 189-foot depth (Burt 2011). Table 14-12 summarizes the increased annual electricity consumption for groundwater pumping, while Table 14-13 summarizes annual energy consumption in the service area of the LSJR and three eastside tributaries. It is anticipated that most deep wells are and would be powered by electric pumps, while a smaller portion will be powered by diesel generators. It is currently unknown what proportion of ground water pumping at deep wells would use electric- or diesel-powered pumps because it is unknown exactly which existing wells would pump more under the LSJR alternatives. Electric pumps are more efficient than diesel pumps and produce fewer emissions per unit of power. It is anticipated that, given the same horsepower rating, an electric pump would generate less than 3 percent of the GHG emissions than a diesel pump would (Leib 2012).Therefore, it was assumed groundwater wells would be powered by electric pumps.

Table 14-11. Increase in Estimated Average Annual Groundwater Pumping by the Irrigation Districts Relative to Baseline (TAF/y)

Alternative		Stanislaus River	Tuolumne River	Merced River	Total
	Baseline Groundwater Pumping	91	103	69	262

GHG Emissions

The majority of the GHGs generated under the LSJR alternatives would result from the increase in power generation and energy consumption, which are described below.

Power Generation to Offset the Reduced Hydropower Production

LSJR alternatives 3 and 4, overall, would cause a reduction in annual hydropower production (although the change associated with LSJR Alternative 3 would be minimal). Table 14-10 summarized the reduction of average annual hydropower produced by each of the three eastside tributaries for LSJR Alternatives 2, 3, and 4 in comparison to the baseline hydropower production. To maintain the power supply for the end users, the lost hydropower would need to be compensated by ramping up other generation facilities by the following providers: PG&E, MID, TID, and Merced ID. The analysis of climate change impacts includes an analysis of GHG emissions associated with other generation facilities to offset the lost hydropower generation associated with the alternatives. The direct GHG emissions generated from the electricity produced by the other offsetting facilities are calculated using the CO_2 emission factor published in the 2008 TID Annual Emissions Report[7] (CCAR 2009) and the CH_4 and N_2O emission factors published by USEPA (2015b). Table 14-14 lists the emission factors for CO_2, CH_4, and N_2O used to estimate GHG emissions associated with offset power generation. These emission factors are multiplied by the change in electricity generation indicated in Table 14-10 and Table 14-11 to determine the change in GHG emissions associated with the project.

Table 14-14. Greenhouse Gas Emission Factors (lb/MWh)

Area	CO_2	CH_4	N_2O
Turlock Irrigation District Service Areas	790.00[a]	0.03112[b]	0.00567[b]
California Region[c]	650.31	0.03112	0.00567

Sources: [a] CCAR 2009; [b] No CH_4 or N_2O emission factors were reported by CCAR 2009. The emission factors published by USEPA are used (USEPA 2015b); [c] USEPA 2015b.

lb/MWh = pounds per megawatt hour
CO_2 = carbon dioxide
CH_4 = methane
N_2O = nitrous oxide

Energy Consumption from Potential Increase in Groundwater Pumping

As shown in Table 14-11, some of the LSJR alternatives would result in an increase in groundwater pumping to satisfy the existing water demand, which could cause an increase in electricity consumption for pumping. Because it is unknown what specific energy providers supply affected end users, the GHG emissions generated from the electricity consumption for the groundwater pumping were calculated by multiplying the GHG factors published by USEPA (2015b) for the California region to represent an average or composite rate of emissions (Table 14-15) by the change in electricity generation indicated in Table 14-10 and Table 14-11.

---

[7] The California Climate Action Registry (CCAR) does not have published emission factors for MID or Merced ID. While PG&E represents a larger service area than Turlock ID, the emission factor associated with Turlock ID was used in the emissions calculations, as it is larger than the PG&E emission factor and represent a worst-case estimate of the maximum amount of emissions that could be anticipated to result from the project.

The decrease in water available for cropland irrigation could result in a decrease in the acreage of cropland that would be farmed if groundwater pumping did not occur. It is anticipated that some croplands would be removed from active agricultural production; however, this would have the potential to reduce GHG emissions as these lands would no longer require the use of fertilizers, which are a major source of GHG emissions. In addition, fallowed agricultural lands would not require the use of agricultural machinery, which would also reduce emissions of GHGs. Fallow lands would be expected to retain crop stubble cover and would ultimately experience vegetative regrowth, which could result in a net carbon sequestration.

Table 14-15. Estimated Annual Greenhouse Gas Emissions (MT CO_2e/year)

Alternative		GHGs from Power Generation (to compensate for loss of hydropower)	GHGs from Energy Consumption (to compensate for increased groundwater pumping)	Total GHG Emissions
Baseline Conditions		0	0	0
LSJR Alternative 2	20% Unimpaired Flow	-10,342[a]	3,267	-7,075
	Adaptive Implementation Method 1: 30% Unimpaired Flow	-5,280	5,609	330
LSJR Alternative 3		1,541	15,408	16,948
LSJR Alternative 4		31,285	31,698	62,984

MT CO_2e/year = metric ton carbon dioxide equivalent per year

[a] Modeled results indicate that LSJR Alternative 2 would result in an increase in hydropower production.

However, changes to land use as a result of a decrease in water available for cropland irrigation are considered speculative. The population growth rate, the available water supply, the timing, and alternatives to replace the cropland are uncertain. Consequently, the GHG emission reduction resulting from land use changes were not included in the analysis.

Energy Consumption from Potential Change in Exports

As discussed in Chapter 5, *Surface Hydrology and Water Quality*, and Appendix F.1, *Hydrologic and Water Quality Modeling*, the expected inflow from the LSJR could modify the CVP and SWP exports such that exports are expected to either remain the same or increase. The analysis related to exports and outflow assumes the State Water Board does not change export constraints to protect any increased flows downstream of Vernalis. The State Water Board is currently in the process of reviewing the export restrictions included in the 2006 Bay-Delta Plan as part of its periodic review of the plan. Through that process, the State Water Board will determine what changes, if any, should be made to the export restrictions. The State Water Board will then determine what actions are needed to implement changes to the flow and export objectives. As indicated in the program of implementation, the State Water Board plans to take action to protect the additional flows in future proceedings. As such the potential increase in exports is likely overstated in this analysis but is evaluated to provide a worst case analysis of the potential impacts related to additional exports.

Modeling results presented in Chapter 5 (Table 5-21) and Appendix F.1 (Table F.1.7-2b) indicate annual average exports would increase by 1 percent for LSJR Alternative 3 and 4 percent for LSJR Alternative 4 relative to historic conditions. It is appropriate to use the annual average when considering GHG emissions because GHG emissions are calculated and reported on an annual basis per standard inventorying procedures (e.g., IPCC, USEP). The extent to which a net increase in GHG emissions would occur cannot be quantified. This is because it is currently unknown how increased exports[8] would specifically affect other GHG emission producing activities in the CVP and SWP export service areas (e.g., groundwater pumping) or other energy-intensive water supply activities, such as drinking water treatment or transport. Because the change in groundwater pumping due to increased water exportation cannot be estimated, the net change in GHG emissions associated with water exports (i.e., emissions associated with exports and other activities that could be influenced by changes in exports) cannot be fully quantified. Therefore, impacts associated with a change in exports are discussed qualitatively for each of the LSJR alternatives.

Extended Plan Area

The analysis of the extended plan area generally identifies how the impacts may be similar to or different from the impacts in the plan area (i.e., downstream of the rim dams) depending on the similarity of the impact mechanism (e.g., changes in reservoir levels, reduced water diversions, and additional flow in the rivers) or location of potential impacts in the extended plan area. Where appropriate, the program of implementation is discussed to help contextualize the potential impacts in the extended plan area.

SDWQ Alternatives

As stated in Appendix B, *State Board's Environmental Checklist*, Section VII, the general historical range of salinity in the southern Delta would remain unchanged under the SDWQ alternatives (see also Chapter 5, *Surface Hydrology and Water Quality*) and, thus, would not result in GHG emissions or conflict with an applicable plan, policy or regulation adopted for the purpose of reducing GHG emissions. For the same reason, there would be no impacts related to the reliability of the electric grid or inefficient, wasteful and unnecessary energy consumption. Therefore, the SDWQ alternatives are not further analyzed in this chapter, except as they relate to the effect of climate change on the alternatives (EG-5). SDWQ Alternative 2 could result in service providers having to construct and operate new or expanded wastewater treatment or water supply facilities, which would involve changes in energy consumption and GHG emissions, and is evaluated in Chapter 13, *Service Providers*, and Chapter 16, *Evaluation of Other Indirect and Additional Actions*.

14.4.3 Impacts and Mitigation Measures

Energy Resources

This section evaluates the impact of LSJR alternatives on energy sources. The LSJR alternatives would affect energy by potentially reducing the power production at hydropower facilities along the three eastside tributaries.

---

[8] Changes in water exports could influence GHG emissions as increases or decreases in exported water could lead to changes in GHG-generating activities (e.g., groundwater pumping, water transport, water treatment) that would accommodate the changes in water export.

Impact EG-1: Adversely affect the reliability of California's electric grid

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

Based on the analysis approach described in Section 14.4.2, *Methods and Approach*, LSJR Alternative 2 would lead to no power capacity reduction for the three hydropower plants. For LSJR Alternatives 3 and 4, grid reliability was assessed by assuming a 5 percent and 8 percent reduction in July hydropower capacity, respectively, at the three plants.

The LSJR alternative substation voltages and line/transformer loadings were modeled and then compared with those of the baseline. If the comparison showed that substation voltages or transmission line/transformer loadings are within limits (defined in Section 14.4.2) under baseline, but outside the limits in the LSJR alternatives, the alternatives could be considered to have an adverse impact on the reliability of California's electric grid.

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

Based on the analysis approach described in Section 14.4.2, *Methods and Approach*, LSJR Alternative 2, with or without adaptive implementation, would lead to no power capacity reduction from baseline. Therefore, this alternative is not expected to affect the reliability of California's electric grid. The impact would be less than significant.

LSJR Alternative 3 (Less than significant/Less than significant with adaptive implementation)

As described above, by comparing the results of LSJR Alternative 3 to baseline, LSJR Alternative 3, with or without adaptive implementation, would not result in any violations of line/transformer limits and substation voltage limits under normal and contingency conditions. Therefore, this alternative is not expected to affect the reliability of California's electric grid. The impact would be less than significant.

LSJR Alternative 4 (Less than significant/Less than significant with adaptive implementation)

As described above, LSJR Alternative 4, specifically the high unimpaired flow requirement of 60 percent of unimpaired flow, could adversely impact the reliability of California's electric grid because of minor violations between Borden and Gregg substations and Gregg and Storey substations. However, the results indicate that a simple re-dispatch of generator facilities would correct the minor violation. This violation of transmission line limit under the contingency outage condition can be easily eliminated through a re-dispatch of the three Helms generator units (Helms Units 1, 2, and 3). The new loading of the analysis element after this re-dispatch was

99.81 percent of the LTE rating. Therefore, there would be no violation after the re-dispatch. Re-dispatches are regular occurrences in the California energy grid and they provide a solution to re-distribute power based on the re-dispatch. Under the various adaptive implementation methods, it is anticipated the re-dispatch would not be needed or would be less given the unimpaired flow requirement is less (i.e., 50 percent unimpaired flow). Therefore, impacts would be less than significant.

Impact EG-2: Result in inefficient, wasteful, and unnecessary energy consumption

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project* Alternative (LSJR Alternative 1 and SDWQ Alternative 1), for the No Project Alternative technical analysis.

LSJR Alternatives

LSJR Alternatives 2, 3, and 4 (Less than significant/Less than significant with adaptive implementation)

Although LSJR Alternatives 2, 3, and 4, with or without adaptive implementation, could result in additional energy consumption by potentially increasing groundwater pumping as shown in Table 14-12, they would not result in inefficient, wasteful, and unnecessary consumption of energy. This is because any additional groundwater pumping would be used to meet the water supply irrigation demand.

Even under the conservative estimates used to project energy consumption associated with a potential increase in groundwater pumping, the LSJR alternatives would only increase the consumption by 0.08 percent (11 GWh), 0.38 percent (52 GWh), and 0.78 percent (107 GWh) under the LSJR Alternatives 2, 3, and 4, respectively, compared to the total annual electricity consumption in San Joaquin, Stanislaus, and Merced Counties (Table 14-13).

In addition to increased energy consumption associated with increased groundwater pumping, the LSJR alternatives could result in additional energy generation at other facilities to compensate for the loss of hydropower predicted by the model results, as shown in Table 14-10. However, by itself, this increased electricity generation is not considered inefficient, wasteful, and unnecessary, as it is energy that would be generated to maintain the energy supply level that is currently supplied by hydropower. LSJR Alternatives 2 and 3 are not expected to cause an overall reduction in hydropower generation. LSJR Alternative 4 would only reduce hydropower generation by 5 percent (87 GWh) compared to baseline. Modeled results indicate that LSJR Alternative 2 would result in an increase in hydropower production by 2 percent (29 GWh), and that LSJR Alternative 3 would result in minimal (4 GWh) change in hydropower production compared to baseline.

Therefore, none of the alternatives, with or without adaptive implementation, result in an inefficient, wasteful, or unnecessary consumption of energy, and none are anticipated to have a significant impact on the energy resources or supplies of the plan area. The impact would be less than significant.

GHG Emissions/Climate Change

This section evaluates the impact of LSJR alternatives on generation of GHG emissions and climate change. The LSJR alternatives would affect GHG emissions by potentially reducing the power production at hydropower facilities along the three eastside tributaries and by potentially reducing surface water supply. The State Water Board is committed to the adoption and implementation of effective actions to mitigate GHG emissions and adaptation of our policies and programs to the environmental conditions resulting from climate change. The State Water Board is a member of the Cal/EPA Climate Action Team, the Water Working Group of Climate Adaptation Strategies Team, and the 20x2020 Agency Team (State Water Board 2011).

Impact EG-3: Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

Table 14-15 summarizes the annual GHG emissions generated from (1) the increased power generation at other generation facilities to balance the loss of hydropower production, and (2) the increased energy consumption for groundwater pumping to compensate for the reduction of surface water supply. The total GHG emissions generated by LSJR Alternatives 2, 3, and 4 are compared against the significance threshold of 10,000 MT CO_2e per year to determine the LSJR alternatives' impacts on climate change.

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

As shown in Table 14-15, GHG emissions (7,075 MT CO_2e/year) are expected to be reduced under LSJR Alternative 2. This is because the increase in hydropower production is anticipated to result in a decrease in power production from other power generation facilities, which reduces GHG emissions. This decrease in emissions outweighs the increase in GHG emissions from the increased energy consumption for groundwater pumping. Furthermore, as identified in Table F.1.7-2b, the average annual exports are not expected to change from baseline under LSJR Alternative 2. Therefore, impacts would be less than significant.

Adaptive Implementation

Based on best available scientific information indicating that a change in the percent of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation method 1 would allow an increase of up to 10 percent over the 20-percent February–June unimpaired flow requirement (to a maximum of 30 percent of unimpaired flow). A change to the percent of unimpaired flow would take place based on required evaluation of current scientific information and would need to be approved as described in Appendix K, *Revised Water Quality Control Plan.*

Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. However, an increase of up to 30 percent of unimpaired flow would potentially result in different effects as compared to 20-percent unimpaired flow, depending upon flow conditions and frequency of the adjustment. If the adjustment occurs frequently or for extended durations, impacts under LSJR Alternative 2 could become more like the impacts under LSJR Alternative 3. At the 30 percent unimpaired flow level, average annual total hydropower generation would be similar to baseline (i.e., slightly less than at the 20 percent unimpaired flow level, Table 14-10) but groundwater pumping would increase by an average total of 40 thousand acre-feet per year (TAF/y) relative to baseline (17 TAF/y more than LSJR Alternative 2, Table 14-11). The net effect is an increase in the average annual GHG emissions of 330 MT CO_2e/year (Table 14-15), which is less than the GHG threshold of 10,000 MT CO_2e/year. Consequently, LSJR Alternative 2, with the incorporation of adaptive implementation method 1, would not substantially impact GHG emissions.

Based on best available scientific information indicating that a change in the timing or rate of unimpaired flow is needed to reasonably protect fish and wildlife, adaptive implementation method 2 would allow changing the timing of the release of the volume of water within the February–June time frame. While the total volume of water released February–June would be the same as LSJR Alternative 2 without adaptive implementation, the rate could vary from the actual (7-day running average) unimpaired flow rate. Method 2 would not authorize a reduction in flows required by other agencies or through other processes, which are incorporated in the modeling of baseline conditions. A change in the timing of the flow releases would not affect diversions or groundwater pumping, and on average it would have little effect on hydropower generation. Therefore, method 2 would not substantially affect GHG emissions. Method 3 would not be authorized under LSJR Alternative 2 since the unimpaired flow percentage would not exceed 30 percent. Adaptive implementation method 4 would allow an adjustment of the Vernalis February–June flow requirement. WSE model results indicate changes due to method 4 under this alternative would rarely alter the flows in the three eastside tributaries or the LSJR, and thus would not affect GHG emissions.

Consequently the impact determination would be the same as described above for LSJR Alternative 2 and would not substantially increase GHG emissions. Impacts would be less than significant.

LSJR Alternative 3 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

As shown in Table 14-15, GHG emissions (16,948 MT CO_2e/year) would exceed the GHG threshold of 10,000 MT CO_2e/year and impacts would be significant. Most of this increase (15,408 MT CO2e/year) would come from the predicted increase in groundwater pumping.

As discussed in Section 14.4.2, *Methods and Approach*, the annual average of water exports is expected to increase approximately 1 percent under LSJR Alternative 3 relative to historic export levels. While it is anticipated that this slight increase in water exports would result in a slight increase in the electricity consumption and associated GHG emissions, it is also expected that other water supply activities that may currently generate GHG emissions would be reduced as a result of the slight increase in exports. For example, an increase in water exports would be expected to lead to decreases in groundwater pumping, although the amount by which groundwater pumping would decrease cannot be quantified. In addition, other more energy-intensive means of water transport associated with water supply may decrease if water purveyors use slightly more exported water, depending on economic conditions, because it is less energy intensive. For example, if energy resources currently used to treat a local water supply rise such that treatment and distribution of the local supply is less cost effective than relying on imported water and the treatment is more energy intensive than relying on exported water, then using exported water could reduce cost and reduce energy use. Therefore, it is anticipated the modeled increase in exports would not contribute to a significant increase in GHG emissions.

A substitute environmental document (SED) must identify feasible mitigation measures for each significant environmental impact identified in it. (Cal. Code Regs., tit. 23, § 3777, subd. (b)(3).) A review of GHG mitigation measure guidance documents was conducted to determine if additional actions could be taken to reduce GHGs. These documents include: California Air Resources Board *Climate Change Scoping Plan* (ARB 2008), which was incorporated into the State Water Board's GHG guidance (State Water Board 2009); DWR Draft *Climate Action Plan* (DWR 2012), the Office of the Attorney General (OAG) list of proposed project-level GHG Mitigation Measures (OAG 2010); the California Air Pollution Control Officers Association (CAPCOA) *Quantifying Greenhouse Gas Mitigation Measures* report (CAPCOA 2010); and a number of reports from the USEPA, including the *Water Conservation Plan Guidelines* document (USEPA 1998), the *Control and Mitigation of Drinking Water Losses in Distribution Systems* report (USEPA 2010), the *Energy Management Guidebook for Wastewater and Water Utilities* (USEPA 2008), and the *Energy Efficiency in Water and Wastewater Facilities* report (USEPA 2013). In addition, Federal Energy Regulatory Commission (FERC) pre-application documents were reviewed. Example measures from these documents are listed below.

- Increase water system energy efficiency to reduce energy consumption related to irrigation deliveries (State Water Board 2009).
- Increase water use efficiency to reduce water demand related to agricultural uses (State Water Board 2009).
- Create water-efficient landscapes (e.g., by reducing lawn sizes; planting vegetation with minimal water needs, such as California native species; choosing vegetation appropriate for the climate of the project site; and choosing complementary plants with similar water needs or the ability to provide each other with shade and/or water) (OAG 2010; CAPCOA 2010).
- Reduce turf in landscapes and lawns (CAPCOA 2010).
- Install water-efficient irrigation systems and devices, such as soil moisture-based irrigation controls (OAG 2010).
- Devise a comprehensive water conservation strategy appropriate for the project and location. The strategy may include many of the specific items listed above, plus other innovative measures that are appropriate to the specific project (OAG 2010).
- Implement integrated resource management on both the supply-side (such as source-water protection strategies to conserve water resources and avoid costly new supplies) and the demand-side (such as comprehensive end-use audits) (USEPA 1998).
- Provide education about water conservation, such as through an "informative" water bill (OAG 2010; USEPA 1998).
- Increase energy efficiency of pumps and turbines throughout the SWP system through design, construction, and refurbishment methods (OP-2 Energy Efficiency Improvements) (DWR 2012).

- Improve efficiency of water system operations, such as by installing Supervisory Control and Data Acquisition (SCADA) software, which can increase the efficiency of process monitoring and operating control (USEPA 2013).
- Increase the proportion of energy used to run the SWP with energy supplies from renewable sources (OP 3 Renewable Energy Procurement Plan) (DWR 2012).
- Implement environmental restoration activities that have the potential to improve sequestration of carbon by natural processes (OP-6 Carbon Sequestration Actions) (DWR 2012).
- Use reclaimed water instead of new potable water supplies (CAPCOA 2010)
- Use graywater for non-potable uses instead of new potable water supplies (CAPCOA 2010)
- Use locally-sourced water supplies or water from less energy-intensive sources instead of imported water or other sources of water that have high energy intensities (CAPCOA 2010).
- Implement water pricing, such as metered rates, non-promotional rates, block rates, time-of-day pricing, water surcharges, and seasonal rates (USEPA 1998).
- Increase efficiency of existing hydropower facilities and operations (Merced ID 2008; TID and MID 2011).

Improving irrigation efficiency can be a mitigation measure because the surface water diversions primarily support agriculture in the plan area. Local water suppliers, regional groundwater management agencies, and irrigation districts could require modifications to existing agricultural practices to increase irrigation efficiency. To some extent, irrigation efficiencies have already resulted from the implementation of SBX7-7 requirements (see Section 11.3.1, *State [Regulatory Background]*) and as discussed by climate change mitigation strategies listed in Table 14-8 (e.g., California Water Plan 2009 and 2013 Updates [DWR 2010b]). Improving irrigation efficiency measures will reduce the overall amount of irrigation water needed because the water applied to the crops would have fewer losses to deep percolation and surface runoff. Furthermore, increasing irrigation efficiency may reduce the amount of supplemental groundwater pumping required to replace reduced surface water diversions. Increasing irrigation efficiency reduces the amount of water required for application without reducing the amount available for consumptive use. Increasing the irrigation efficiency could be done using the following methods.

- Increase the use of irrigation management services to better determine how much water is needed by crop and when to apply it.
- Convert current inefficient irrigation systems (e.g., surface irrigation) to more efficient ones (e.g., use of micro irrigation).
- Increase the capability of irrigation water suppliers to provide delivery flexibility, such as the use of irrigation district regulating reservoirs to allow flexible delivery durations, scheduling, and flow rates.

Any quantification of the effects of applying irrigation efficiency measures would be speculative; however, even with well-implemented irrigation efficiency measures, GHG emissions are not expected to be reduced to less-than-significant levels.

Many of the measures identified in the guidance documents are project-level measures appropriate for project-specific development. Individual projects will be subject to the appropriate level of environmental review at the time they are proposed, and mitigation would have to be identified to avoid or reduce significant effects, prior to any project-level action. Some potential actions, however, may not require discretionary approvals, and may not be subject to project-level CEQA review. For example, there is little to no project-level CEQA review of the potential increase in the use of percolating groundwater in areas that do not have a regulatory framework for groundwater management. Nevertheless, local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified above. It is infeasible for the State Water Board to impose mitigation measures at this time because it is undertaking a programmatic analysis of the potential GHG impacts and does not now have specific facts associated with an individual project to legally and technically apply the above mitigation measures in an adjudicative proceeding. The State Water Board will consider and impose these measures where legally supportable as part of individualized water right proceedings to implement the flow objectives.

In addition, while the State Water Board may impose water conservation or efficiency requirements through the adoption of regulations, the amount of time, high cost, and commitment of staff resources associated with such rule-making proceedings also renders adopting the mitigation measures now infeasible. Adopting regulations right now would require considerable staff time to research, formulate and develop, require extensive stakeholder outreach, and require numerous public meetings before the regulations would take effect. The State Water Board currently has limited resources to pursue adoption of such regulations as most of its budget for the water right program is supported by fees imposed on water right permit and license holders, and is used for program activities related to the diversion and use of water subject to the permit and license system. Only a small amount of funding is available for other regulatory activities and it is speculative to anticipate that additional funding will be made available. Therefore, at this time the imposition of the above mitigation measures is infeasible and impacts under LSJR Alternative 3 would remain significant and unavoidable.

Adaptive Implementation

As discussed under LSJR Alternative 2, adaptive implementation methods 2 and 4 are not expected to result in impacts on GHG emissions. Adaptive implementation method 3 would result in a shift in the volume of February–June water available to other parts of the year and is included in the modeling results presented above for LSJR Alternative 3. Because a change in the timing of the flow releases would not affect diversions or groundwater pumping, and on average it would have little effect on hydropower generation, method 3 would not substantially affect GHG emissions.

Adaptive implementation method 1 would allow an increase or decrease of up to 10 percent in the February–June, 40-percent unimpaired flow requirement (with a minimum of 30 percent and maximum of 50 percent) to optimize implementation measures to meet the narrative objective, while considering other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. Adaptive implementation must be approved using the process described in Appendix K. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. If the specified percent of unimpaired flow were changed from 40 percent to 30 percent or 40 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternatives 2 (less than significant) or 4 (significant and unavoidable), respectively. Because GHG emission impacts under LSJR Alternatives 3 and 4 are considered to be significant and adaptive implementation methods 1, 2, 3, and 4 would not alter this determination, LSJR Alternative 3 with adaptive implementation would cause significant GHG emissions.

The SED must identify feasible mitigation measures for each significant environmental impact identified in. (Cal. Code Regs., tit. 23, § 3777, subd. (b)(3).) As discussed above, guidance documents for possible GHG mitigation measures and possible methods to improve irrigation efficiency were reviewed and identified. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified above. For the reasons stated above, at this time, it is infeasible for the State Water Board to impose the above mitigation measures. Therefore, impacts under LSJR Alternative 3 with adaptive implementation would remain significant and unavoidable.

LSJR Alternative 4 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

As shown in Table 14-15, GHG emissions (62,984 MT CO_2e/year) would exceed the GHG threshold of 10,000 MT CO_2e/year and impacts would be significant. The increases associated with compensation for loss of hydropower and compensation for the predicted increased groundwater pumping are similar in magnitude (i.e., 31,285 and 31,698 MT CO_2e/year, respectively). As discussed in Section 14.4.2, *Methods and Approach*, the annual average of water exports is expected to increase approximately 4 percent under LSJR Alternative 4 relative to historic export levels. While it is anticipated that this slight increase in water exports would result in a slight increase in electricity consumption and associated GHG emissions, it is also expected that other water supply activities that may currently generate GHG emissions would be reduced as a result of the slight increase in exports as discussed under LSJR Alternative 3. Therefore, it is anticipated the modeled increase in exports would not contribute to a significant increase in GHG emissions.

The SED must identify feasible mitigation measures for each significant environmental impact identified in in. (Cal. Code Regs., tit. 23, § 3777, subd. (b)(3).) As discussed above, guidance documents (under LSJR Alternative 3) for possible GHG mitigation measures and possible methods to result in better irrigation efficiency were reviewed and identified. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified above. For the reasons stated above under LSJR Alternative 3, at this time, it is infeasible for the State Water Board to impose the above mitigation measures. Therefore, impacts under LSJR Alternative 4 would remain significant and unavoidable.

Adaptive Implementation

As discussed under LSJR Alternatives 2 and 3, adaptive implementation methods 2, 3, and 4 are not expected to result in changes to impacts on GHG emissions. Adaptive implementation method 1 would allow a decrease of up to 10 percent in the February–June, 60-percent unimpaired flow requirement (with a minimum of 50 percent) to optimize implementation measures to meet the narrative objective, while considering other beneficial uses, provided that these other considerations do not reduce intended benefits to fish and wildlife. Adaptive implementation must be approved using the process described in Appendix K. Accordingly, the frequency and duration of any use of this adaptive implementation method cannot be determined at this time. If the specified percent of unimpaired flow were changed from 60 percent to 50 percent on a long-term basis, the conditions and impacts could become more similar to LSJR Alternative 3 (i.e., less severe for GHG emissions, but still significant). Similar to the impact determination of LSJR Alternative 3 and 4, impacts would be significant. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified above. For the reasons stated above in LSJR Alternative 3, at this time, it is infeasible for the State Water Board to impose the above mitigation measures. Therefore, impacts under LSJR Alternative 4 with adaptive implementation would remain significant and unavoidable.

Impact EG-4: Conflict with an applicable plan, policy, or regulation adopted for the purposes of reducing GHG emissions

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

Clean Air Act (CAA) requirements for GHGs are the GHG emissions standards for vehicles and do not apply to projects that do not generate GHG emissions from vehicles. GHG emissions from the largest stationary sources (such as electricity utilities, refineries, etc.) are typically covered by CAA Prevention of Significant Deterioration (PSD) and Title V Operating Permit Programs. This requires permitting for facilities in excess of 100,000 MT CO_2e/year. The electric utilities that could be affected by the LSJR alternatives as a result of reduced hydropower or increased groundwater pumping would be subject to these permitting requirements regardless of LSJR alternatives, and the LSJR alternatives would not alter or modify these permit requirements. Therefore, the LSJR alternatives would not conflict with the requirements or CAA.

A GHG threshold of 10,000 MT CO_2e per year has been adopted by SCAQMD and BAAQMD and was used for this analysis. In using this threshold for the analysis, the following considerations were made: consistency with a GHG reduction plan,[9] the predicted emissions reductions from statewide regulatory measures and resulting emissions inventories, and the efficacies of GHG mitigation measures. It addresses a broad range of combustion sources and thus provides for a greater amount of GHG reductions to be analyzed and mitigated through the CEQA process. (BAAQMD 2010) Therefore, the LSJR alternatives would conflict with the state goals listed in AB 32 or in any preceding state policies and plans adopted to reduce GHG emissions if the GHG emissions generated by the alternatives are greater than the GHG threshold of 10,000 MT CO_2e per year.

---

[9] There is no acceptable GHG reduction plan from which to evaluate project significance consistent with State CEQA Guidelines Sections 15183.5 and 16064.4(b)(3).

LSJR Alternative 2 (Less than significant/Less than significant with adaptive implementation)

As discussed for Impact EG-3, LSJR Alternative 2 is expected to reduce GHG emissions. Therefore, the alternative is not expected to conflict or be inconsistent with the state goals listed in AB 32 or in any preceding state policies and plans adopted to reduce GHG emissions. This impact would be less than significant.

Adaptive Implementation

As discussed for Impact EG-3, incorporation of adaptive implementation could potentially increase GHG emissions, but emissions would still be well below 10,000 MT of CO_2e per year. Therefore, impacts would be less than significant.

LSJR Alternative 3 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

As discussed for Impact EG-3, LSJR Alternative 3 would generate GHG emissions in excess of 10,000 MT of CO_2e per year, which is considered to be inconsistent with the state goals listed in AB 32 or in any preceding state policies and plans adopted to reduce GHG emissions. This impact would be significant. Implementation of the measures discussed in Impact EG-3 would reduce GHG emissions, but cannot be quantified. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified in Impact EG-3 for LSJR Alternative 3. For the reasons stated in Impact EG-3 for LSJR Alternative 3, at this time, it is infeasible for the State Water Board to impose those mitigation measures. Consequently, this impact would remain significant and unavoidable.

Adaptive Implementation

As discussed for Impact EG-3, incorporation of adaptive implementation could increase GHG emissions if adaptive implementation method 1 results in a long-term increase in the unimpaired flow requirement. Therefore, impacts would be significant. Similar to LSJR Alternative 3, implementation of the measures discussed in Impact EG-3 would reduce GHG emissions but cannot be quantified. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified in Impact EG-3 for LSJR Alternative 3. For the reasons stated above in Impact EG-3 for LSJR Alternative 3, at this time, it is infeasible for the State Water Board to impose those mitigation measures. Consequently, this impact would remain significant and unavoidable.

LSJR Alternative 4 (Significant and unavoidable/Significant and unavoidable with adaptive implementation)

As discussed for Impact EG-3, LSJR Alternative 4 would generate GHG emissions in excess of 10,000 MT of CO_2e per year, which is considered to be inconsistent with the state goals listed in AB 32 or in any preceding state policies and plans adopted to reduce GHG emissions. This impact would be significant. Implementation of the measures discussed for Impact EG-3 would reduce GHG emissions, but cannot be fully quantified. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified in Impact EG-3 for LSJR Alternative 3. For the reasons stated Impact EG-3 for LSJR Alternative 3, at this time, it is infeasible for the State Water Board to impose those mitigation measures. Consequently, this impact would remain significant and unavoidable.

Adaptive Implementation

As discussed for Impact EG-3, incorporation of adaptive implementation could increase GHG emissions if adaptive implementation method 1 results in a long-term increase in the unimpaired flow requirement. Therefore, impacts would also be significant. Similar to LSJR Alternative 4, implementation of the measures discussed in Impact EG-3 would reduce GHG emissions but cannot be quantified. Local water districts and suppliers, regional groundwater agencies, irrigation districts, and local agencies and governments can and should, either voluntarily or as required by CEQA when approving discretionary projects that are undertaken in response to the LSJR alternatives, adopt the relevant mitigation measures identified in Impact EG-3 for LSJR Alternative 3. For the reasons stated Impact EG-3 for LSJR Alternative 3, at this time, it is infeasible for the State Water Board to impose those mitigation measures. Consequently, this impact would remain significant and unavoidable.

Impact EG-5: Effect of climate change on the LSJR and SDWQ alternatives

No Project Alternative (LSJR/SDWQ Alternative 1)

The No Project Alternative would result in implementation of flow objectives identified in the 2006 Bay-Delta Plan. See Chapter 15, *No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative impact discussion and Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1),* for the No Project Alternative technical analysis.

LSJR Alternatives

As discussed in Section 14.2.3, *Climate Change*, and Section 14.3, *Regulatory Background,* scientific studies and sources agree that the San Joaquin Valley and the Delta will experience changes to the historical hydrology as a result of climate change. It is expected that climate change will result in higher temperatures, increased heat waves, changes in rainfall patterns, and sea level rise (DWR 2010a, 2010b; USBR 2014, 2016). In addition, reduced snow pack and stream flow in the Sierra Nevada is expected to lead to changes in water supply into the Delta region (DWR 2010a, 2010b; USBR 2014, 2016). Depending on the climate change scenarios evaluated in the scientific studies, it has been predicted that climate change will affect snow pack, runoff, water supply reliability, water quality and quantity, aquatic ecosystems, evapotranspiration, and hydropower. Specifically, from scenarios compiled for the IPCC's Fourth Assessment Report, four climate change scenarios were selected for DWR's climate change studies. The four climate change scenarios consist of two GHG emissions scenarios, A2 and B1, each represented by two different global climate models, the Geophysical Fluid Dynamic Lab (GFDL) model and the Parallel Climate Model (PCM) model, respectively. The A2 emissions scenario assumes high population growth, regional based economic growth, and slow technological changes that results in significantly higher GHG emissions. The B1 scenario represents low population growth, global based economic growth, and sustainable development that results in the lowest increase of GHG emission of the IPCC scenarios. Both models project future warming; however, the GFDL model indicates a greater warming trend than the PCM model.

Hydrology impacts associated with the different climate change scenarios are summarized below. These summaries are based on of the CWP 2013 Update, Chapter 3: *California Water Today, Regional Reports for San Joaquin River Hydrologic Region and Sacramento-San Joaquin Delta*, and Chapter 22: *Ecosystem Restoration* (The California Natural Resources Agency and DWR 2013). The summaries are also consistent with information contained in the *Sacramento and San Joaquin Basins Climate Impact Assessment* (USBR 2014, 2016).

- **Reduced water supply and reliability.** Climate change is anticipated to bring heavier and warmer storms in the winter that result in less snowfall at lower elevations, reduce the total snowpack, and shift the timing of associated runoff, which in turn affects water storage capability in reservoirs and reduces water supply availability and reliability to water users. Much of the state's water infrastructure was designed to capture the slow spring snowmelt and deliver it during the drier summer and fall months. However, as average temperatures continue to increase, the snowpack will melt earlier, resulting in increased winter runoff and reduced spring snowmelt. Intense rainfall events and rapid snowmelt will make water more difficult to capture in reservoirs or retain for groundwater recharge and, therefore, reduce the region's water supply.
- **Increased water demand.** Climate change is expected to increase the water demand for both agricultural and urban use as a result of rising temperatures, increased evapotranspiration, reduced chill-hours in winter, and increased frequency and intensity of droughts. Higher temperatures are likely to extend growing seasons and also increase evapotranspiration, thereby increasing the amount of water that is needed for the irrigation of certain crops, urban landscaping, and environmental needs.
- **Degraded water quality.** Climate change is expected to degrade water quality as a result of rising temperatures and changed precipitation patterns. Higher water temperatures result in reduced dissolved oxygen levels in the water, which can have an adverse effect on water quality. Where river and lake levels fall due to increased evapotranspiration and changed precipitation and runoff patterns, pollutant concentrations in water will increase. Increased frequency and intensity of rainfall result in more direct runoff and flooding, which will produce more pollution and sedimentation in river and lakes. Sea level rise increases sea water intrusion into the Delta, which will further increase salinity in Delta and degrade drinking and agricultural water quality and alter ecosystem conditions in the region.
- **Altered aquatic ecosystems.** Climate change is anticipated to affect aquatic life due to rising temperatures, changes in river flow, and the continued rise in sea level. Higher water temperatures result in reduced dissolved oxygen levels, which can have an adverse effect on aquatic life. In many low- and middle-elevation streams in the region today, summer temperatures often approach the upper tolerance limits for salmon and trout; higher air and water temperatures will exacerbate this problem. Increases in water temperature and reductions in cold water in upstream reservoirs to be released in in spring and summer will also exacerbate this problem and hurt spawning and recruitment success of native fishes. For example, summer water temperatures in the major SJR tributaries upstream from the major reservoirs currently cause stress for coldwater species, such as steelhead/rainbow trout, and also for hardhead and Kern brook lamprey. By 2030, average summer air temperatures are expected to rise as much as 8°F, and water temperatures in the major SJR tributaries and their

reservoirs are expected to measurably increase. Significant increases in water temperatures could significantly impact rainbow trout and land-locked Kokanee that reside in and above the reservoirs. Surface water temperatures are also expected to rise in the reservoirs, but most of the species in the reservoirs are warmwater species that would not be affected by the expected water temperature increases or potential associated decreases in DO concentrations. Juveniles and smolts may become exposed to further reductions in the availability of coldwater habitat below dams and increasing abundance of nonnative warmwater species that prey on salmonids (Katz et al. 2013)

Inflow from the major SJR tributaries is expected to increase during winter months and decrease during spring and early summer months because of reduced snowpack associated with climate change. The changes in seasonal inflows are likely to affect Central Valley fall-run Chinook salmon, Central Valley spring-run Chinook salmon, Sacramento River winter-run Chinook salmon, Central Valley steelhead, green sturgeon, Sacramento splittail, longfin smelt, and delta smelt. Spawning migrations and other lifecycle processes of these species are adapted to high spring flows in the major SJR tributaries and into the Delta, and reductions in these flows would have significant impacts on several life stages.

Continued rise in sea level and upstream encroachment of salt water will affect aquatic habitat. Average sea levels are expected to rise about 1 foot by 2030, which would cause increased salinities in the Delta. Delta smelt and longfin smelt spawn in the fresher water portions of the Delta, and delta smelt remain in areas with low salinities throughout their lifecycle. Increased salinity would be stressful to delta smelt and longfin smelt, particularly during their egg and larval stages. The brackish and fresh aquatic habitats of the Sacramento–San Joaquin Estuary, which are critical to many at-risk species, will be forced to shift upstream and inland.

- **Declined hydropower generation.** The energy sector is also vulnerable to potential impacts of climate change. This vulnerability has been evaluated by a modeling study simulating hydropower generation under regional climate warming in the Sierra Nevada. This study indicates the most substantial decrease of the mean annual hydropower generation will be in the northern Sierra Nevada watersheds as a result of declining runoff. The study also projects that with rising temperatures there will be steady declines in hydropower generation in the southern watersheds.

As discussed in Section 14.3.2, *State [Regulatory Background]*, CWP is the long-term strategic plan for guiding the management and development of water resources in the state. The CWP Update 2009 incorporated climate change in water plan scenarios to evaluate impacts on California's water resources and to identify and recommend statewide and regional adaptation strategies. The current Update 2013 builds on the contents of the Update 2009 and includes regionally appropriate and statewide water management and planning adaptation and mitigation strategies, resource management strategies, and decision support for climate change scenarios. Many of the resource management strategies provide benefits for adapting to climate change in addition to meeting water management objectives. As discussed in Section 14.3.3, *Regional or Local [Regulatory Background]*, the AWMPs prepared by irrigation districts, summarized in Table 14-8, have sections that discuss the expected effects of climate change on water supply, demand, and quality within their irrigation districts and recommend implementation of climate change mitigation strategies identified in the CWP 2009 and 2013 Updates. The UWMPs, summarized in Table 14-9, have sections that discuss the expected effects of climate change on water supply and demand within their service areas and identify planning recommendation or actions to mitigate the effects of climate change. The various strategies aim to reduce water demand include the following.

- **Reduce water demand**: agricultural/urban water use efficiency.
- **Improve operational efficiency**: regional/local conveyance; system reoperation.
- **Increase water supply**: conjunctive management and groundwater; precipitation enhancement; regional/local surface storage.
- **Improve water quality**: pollution prevention; salt and salinity management.
- **Practice resource stewardship**: ecosystem restoration; land use planning and management; recharge area protection; watershed management.

LSJR Alternatives 2, 3, and 4 and SDWQ Alternatives 2 and 3 (Less than significant)

The LSJR alternatives, with or without adaptive implementation, would be subject to climate change impacts discussed above resulting from past, present, and future GHG emissions regardless of the success of local, state, national, or international efforts in reducing future GHG emissions due to the existing concentrations of GHG emissions in the atmosphere and the inevitable additional emissions before GHG reductions plans provide reductions. As mentioned earlier, potential climate change impacts in California and the San Joaquin Valley might include sea level rise, saltwater intrusion, reduced snowpack and water supplies, and increased water demand.

Less snowpack and earlier runoff potentially means that there will be a reduced water supply later in the year because reservoir capacity is limited and water may be released earlier than usual. The problem of low water supply would likely be compounded by higher air temperatures, which would likely result in an increase in the amount of water needed to grow crops. The LSJR alternatives have the potential to exacerbate the water supply condition under climate change because they generally would reduce water supplies (particularly LSJR Alternatives 3 and 4).

Less snowpack and earlier runoff means that runoff from December–March may increase, whereas runoff from April–July may decrease (California Natural Resources Agency and DWR 2013; USBR 2014, 2016) relative to baseline conditions. In general, the earlier runoff would likely result in greater flood control releases from December–March. The increase in February–March flood control releases that may be expected with climate change may be reduced by implementation of the LSJR alternatives. This is because the LSJR alternatives would require increased reservoir releases, which would thereby increase the available storage space in reservoirs.

In the absence of the LSJR alternatives, increased flood control releases would make the flow downstream of the reservoirs closer to the magnitude of the unimpaired flow under climate change. During a large runoff event, flood control releases in the absence of the LSJR alternatives might equal or exceed what would be required by one of the LSJR alternatives. As a result, climate change may help attain February–March flows required by the LSJR alternatives.

The SDWQ alternatives and the program of implementation would maintain the existing Vernalis EC. As such, water would continue to be required to be released from New Melones Reservoir. Similar to the conditions described above with the LSJR alternatives, less snow pack and earlier runoff means that there may be less water later in the season, and it may be more difficult to release water from New Melones Reservoir under climate change conditions.

The LSJR alternatives are based on a percent of unimpaired flow. If the unimpaired flow is less under climate change conditions, then the amount of water required by the LSJR alternatives would also be less. In addition, the adaptive implementation methods of the LSJR alternatives would provide the State Water Board and the Stanislaus, Tuolumne, and Merced Working Group the ability to respond to changing circumstances with respect to flow and water quality that may arise due to climate change (e.g., more rain and less snow pack) as it relates to protecting beneficial uses such as fish and wildlife on the three eastside tributaries and agricultural uses in the southern Delta. Finally, the State Water Board is required to prepare WQCPs and regularly review the plans to update water quality standards, as they are currently doing evaluating the LSJR and SDWQ alternatives. Consistent with this requirement, the program of implementation for the LSJR and SDWQ alternatives includes updates to the 2006 Bay-Delta Plan as information becomes available upon implementation of the objectives, including through monitoring and special studies. As a result, the planning process continually accounts for changing conditions related to water quality and water planning, such as climate change. Because the State Water Board is preparing for the effects of climate change on its programs and adaptive implementation would account for circumstances that arise from climate change, this impact would be less than significant.

14.4.4 Impacts and Mitigation Measures: Extended Plan Area

Bypassing flows, as described in as described in Chapter 5, *Surface Hydrology and Water Quality* could potentially impact energy (hydropower electrical production) resources in upstream reservoirs in the extended plan area on the Stanislaus and Tuolumne Rivers because these two rivers have major reservoirs that are used to produce hydropower. These potential impacts could occur if reservoirs experienced substantial reductions in reservoir volume, especially during drought conditions under LSJR Alternative 3 and LSJR Alternative 4 with or without adaptive implementation. Hydropower production is related to both water discharge volume and reservoir head (elevation difference between the reservoir surface and the hydropower outlet). Lower reservoir volumes would reduce head and could reduce discharge to some extent. However, under baseline conditions these reservoirs undergo substantial annual elevation and volume reduction as hydropower is produced and water is released for instream flow requirements (USGS Reservoir Gage Data). Consequently the hydropower production effects associated with the reservoir volume reduction under LSJR Alternatives 2 and 3 (in most years) would be similar to baseline conditions, even with adaptive implementation. These volume reductions, however, would occur more frequently and be more severe during drought conditions, particularly under LSJR Alternatives 3 and LSJR Alternative 4 with or without adaptive implementation and, to a lesser extent, LSJR Alternative 2 with adaptive implementation. Consequently there could be significant hydropower production reductions at reservoirs under these LSJR alternatives in the extended plan area.

Additional GHG production would occur in the extended plan area if service providers and individuals had to increase groundwater pumping to replace junior water bypassed to achieve the required flows in the Stanislaus, Tuolumne, and Merced Rivers, and the LSJR. However, in these circumstances the volume of bypassed junior water would reduce the amount that downstream users would need to pump from groundwater. Therefore, the amount of additional GHG production related to upstream groundwater pumping impacts in the extended plan area would be offset by equivalent reductions in the downstream plan area. GHG production could also be affected by potentially reducing hydropower production at reservoirs in the extended plan area if hydropower is replaced by non-renewable energy sources, which produce greater amounts of GHGs. As noted above, there is the potential there could be adverse hydropower production impacts at reservoirs under LSJR Alternative 2 with adaptive implementation and LSJR Alternatives 3 and 4 with or without adaptive implementation in the extended plan area. Consequently, there could be related adverse GHG production impacts in the extended plan area.

The increased frequency of lower reservoir levels resulting from the LSJR alternatives and the associated physical changes in hydropower and GHGs, however, would be limited by the program of implementation under each of the LSJR alternatives. The program of implementation requires minimum reservoir carryover storage targets or other requirements to help ensure that providing flows to meet the flow objectives will not have adverse temperature or other impacts on fish and wildlife or, if feasible, on other beneficial uses (e.g., hydropower). Other requirements, for example, include, but are not limited to, limits on required bypass flows for reservoirs that store water only for non-consumptive use so that some water can be temporarily stored upstream. The program of implementation also states that the State Water Board will take actions as necessary to ensure that implementation of the flow objectives does not impact supplies of water for minimum health and safety needs, particularly during drought periods. Accordingly, when the State Water Board implements the flow objectives in a water right proceeding, it will consider impacts on fish, wildlife, and other beneficial uses, such as hydropower, and health and safety needs, along with water right priority. Until the State Water Board assigns responsibility to meet the flow objectives in the Bay-Delta Plan, it is speculative to identify the exact extent, scope and frequency of reduced diversions, reduced reservoir levels and their effects on hydropower and GHG emissions, in the extended plan area. When implementing the flow objectives, the State Water Board would identify project-specific impacts and avoid or mitigate significant impacts of lower reservoir levels on hydropower and GHGs in accordance with CEQA.

At the time of preparation of this programmatic analysis, it is unclear to what extent any significant impacts could be fully mitigated to hydropower and GHG. Thus, the potential exists for significant impacts. Therefore, this analysis conservatively concludes that impacts associated with lower reservoir levels under LSJR Alternatives 2 with adaptive implementation and LSJR Alternatives 3 and 4 with or without adaptive implementation are significant. The following mitigation measure is proposed: When considering carryover storage and other requirements to implement the flow water quality objectives in a water right proceeding, the State Water Board shall ensure that reservoir levels upstream of the rim dams do not cause significant hydropower and GHG impacts, unless doing so would be inconsistent with applicable laws. The impact is considered significant even with mitigation, because the mitigation may not fully mitigate the impact in all situations.

14.5 Cumulative Impacts

Chapter 15
No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)

15.1 Introduction

The California Environmental Quality Act (CEQA) Guidelines require that the potential impacts of not approving a proposed project be evaluated under a No Project Alternative. "The purpose of describing and analyzing a no project alternative is to allow decision makers to compare the impacts of approving the proposed project with the impacts of not approving the proposed project." (Cal. Code Regs., tit. 14, § 15126.6(e)(1).) When the project is the revision of an existing regulatory plan, such as the 2006 *Water Quality Control Plan for the San Francisco Bay/Sacramento–San Joaquin Delta Estuary* (2006 Bay-Delta Plan), the No Project Alternative will be the continuation of the existing plan as currently implemented into the future. (Cal. Code Regs., tit. 14, § 15126.6(e)(3)(A).) In general, the existing plan and the projects initiated under the existing plan would continue until the new plan amendments[1] are approved. The No Project Alternative analysis must discuss the existing conditions "as well as what would be reasonably expected to occur in the foreseeable future if the project were not approved, based on current plans and consistent with available infrastructure and community services." (Cal. Code Regs., tit. 14, § 15126.6(e)(2).)

For the purposes of this analysis, the No Project Alternative is the continuation of the State Water Resources Control Board's (State Water Board) 2006 Bay-Delta Plan, as implemented through the State Water Board's Water Right Decision 1641 (D-1641), including implementation of the San Joaquin River (SJR) at Vernalis flow objectives (also referred to as the SJR flow objectives) and the southern Delta salinity (EC[2]) objectives (including the salinity objective on the SJR at Vernalis). Lower San Joaquin River (LSJR) Alternative 1 and Southern Delta Water Quality (SDWQ) Alternative 1 are referred to as the No Project Alternative in this recirculated substitute environmental document (SED).

This chapter describes the No Project Alternative and the environmental impacts of the alternative compared to impacts under the proposed plan amendments. The No Project Alternative is not baseline for determining whether the impacts of the proposed plan amendments are significant. Baseline is described in Chapter 4, *Introduction to Analysis*, and in the environmental setting section of each resource chapter. The environmental impacts of the other alternatives are described in Chapters 5–14. The cumulative impacts of the No Project Alternative are described in this chapter and the cumulative impacts of the other project alternatives are analyzed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*. The impacts for all project alternatives, including the No Project Alternative, are summarized in Chapter 18, *Summary*

---

[1] These plan amendments are the *project* as defined in State CEQA Guidelines, Section 15378.

[2] In this document, EC is *electrical conductivity*, which is generally expressed in deciSiemens per meter (dS/m). Measurement of EC is a widely accepted indirect method to determine the salinity of water, which is the concentration of dissolved salts (often expressed in parts per thousand or parts per million). EC and salinity are therefore used interchangeably in this document.

of Impacts and Comparison of Alternatives. The No Project Alternative focuses on effects related to implementation of Vernalis flow and southern Delta salinity objectives because these objectives are the ones proposed to be amended. The environmental impacts of the No Project Alternative were evaluated by comparing the State Water Board's Water Supply Effects (WSE) modeling results for the No Project Alternative to baseline and the other alternatives (summarized in Table 15-1).

Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)*, describes the assumptions used in the WSE modeling of the baseline and No Project Alternative and modeling results. This chapter uses the data and results presented in Appendix D to analyze and summarize the expected impacts associated with the No Project Alternative. Select Appendix D figures and tables are duplicated in this chapter.

The WSE model is discussed in further detail in Appendix F.1, *Hydrologic and Water Quality Modeling*.

15.2 Description of the No Project Alternative

The No Project Alternative assumes continued implementation of, and full compliance with, the 2006 Bay-Delta Plan, as implemented through D-1641. The No Project Alternative focuses on efforts related to the implementation of Vernalis flow and southern Delta salinity objectives because these objectives are the ones proposed to be amended. The Vernalis flow objectives were first established in the 1995 Bay-Delta Plan to protect fish and wildlife beneficial uses. These objectives include the minimum monthly flow rates for fish and wildlife beneficial uses during specific times of the year, as presented in Table 3 of the 2006 Bay-Delta Plan and implemented through D-1641. In D-1641, the State Water Board assigned compliance with these minimum flows on the SJR at Vernalis to the U.S. Bureau of Reclamation (USBR). When the State Water Board subsequently amended the Bay-Delta Plan in 2006, it approved an interim flow regime through the Vernalis Adaptive Management Program (VAMP) experiment, as proposed in the San Joaquin River Agreement (SJRA), in lieu of meeting the April–May pulse flow objective (as presented in Table 3 of the 2006 Bay-Delta Plan).

No Project Alternative conditions differ from the baseline because the Vernalis flow objectives in Table 3 of the 2006 Bay-Delta Plan have not been fully implemented and are not part of the baseline because of implementation of the SJRA and VAMP. The VAMP flows, which are generally lower than the Table 3 flows in the 2006 Bay-Delta Plan, are thus included in the baseline. During VAMP, a portion of the flows needed to comply with VAMP came from the three eastside tributaries[3]even though the 2006 Bay-Delta Plan and D-1641 do not contain numeric or narrative flow requirements specific to these rivers. However, the No Project Alternative does not include VAMP flows because that experimental flow regime concluded in 2011. The No Project Alternative and the baseline both include the 2009 National Marine Fisheries Service (NMFS) Biological Opinion (BO) flow requirements on the Stanislaus River, Federal Energy Regulatory Commission (FERC) requirements on the Tuolumne and Merced Rivers, and the Davis-Grunsky requirements on the Merced River.

The No Project Alternative assumes that the flows would continue to be the responsibility of USBR and that the objectives would be met with additional releases from New Melones Reservoir on the Stanislaus River. There are other possible ways that compliance with the objectives could be achieved, but it is speculative to identify which other measures, or combination of measures, would be used. For example, the flow objective could be achieved by a combination of releases from New

---

[3] In this document, the term *three eastside tributaries* refers to the Stanislaus, Tuolumne, and Merced Rivers.

Melones Reservoir and other actions (e.g., water purchases and transfers among different water users and other upstream SJR actions [such as SJR Restoration Program[4] flows]). However, these other actions are difficult to predict or quantify. The analytical approach used here evaluates increased releases from New Melones Reservoir to meet the objectives, because such releases could be the primary method by which the Vernalis flow objectives and southern Delta salinity objectives would be achieved. Focusing the evaluation on New Melones Reservoir releases affords an evaluation of maximum potential water supply impacts compared to assuming that increases in Vernalis flow would be distributed among the tributaries.

The No Project Alternative also assumes the continuation of the southern Delta salinity objectives for agricultural beneficial uses, as identified in Table 2 of the 2006 Bay-Delta Plan, and full compliance with these objectives as implemented through D-1641. Under D-1641, compliance with the numeric salinity objectives on the SJR at Vernalis (station C-10) is the obligation of USBR. Compliance with the numeric salinity objectives at the three interior southern Delta compliance stations—SJR at Brandt Bridge (station C-6), Old River near Middle River (station C-8), and Old River at Tracy Road Bridge (station P-12)—are the combined obligation of USBR and the California Department of Water Resources (DWR).

15.3 Model Results

WSE model results for the No Project Alternative are compared to the baseline for the three eastside tributaries in Appendix D *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1).* This chapter summarizes model results focused on flow, as presented in Appendix D. Figures 15-1a through 15-1c compare the annual baseline flows to the annual No Project Alternative flows for the Stanislaus, Tuolumne, and Merced Rivers, respectively. Table 15-1 compares the monthly cumulative distributions of baseline flow and differences from baseline for the No Project Alternative for the three eastside tributaries and the SJR. Figures 15-2 through 15-5 are exceedance plots for the three eastside tributaries and the SJR, which present the No Project Alternative, the baseline, and the LSJR alternative WSE model results for (a) February–June flow volumes, (b) end-of-September storage (i.e., carryover), (c) diversions, and (d) February–June flow as a percentage of the unimpaired flow[5]. The exceedance plots present the results for the LSJR alternatives to evaluate No Project Alternative impacts if the hydrologic effects of the No Project Alternative are within the range of hydrologic effects evaluated for the LSJR alternatives in Chapters 5–14.

15.3.1 Stanislaus River

The No Project Alternative would greatly affect flow, storage, and water supply diversions on the Stanislaus River. WSE model simulations for all LSJR alternatives and baseline assume Vernalis salinity objectives are met by increased New Melones Reservoir releases if necessary. As described in Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)*, the No Project Alternative would result in additional New Melones Reservoir releases to meet

---

[4] Implementation of the settlement and the Friant Dam release flows required by the San Joaquin River Restoration Program are expected to increase the existing SJR flows at Stevinson in the near future.

[5] *Unimpaired flow* represents the water production of a river basin, unaltered by upstream diversions, storage, or by export or import of water to or from other watersheds. It differs from natural flow because unimpaired flow is the flow that occurs at a specific location under the current configuration of channels, levees, floodplain, wetlands, deforestation and urbanization.

D-1641 Vernalis flow objectives and D-1641 salinity objectives for south Delta compliance locations downstream of Vernalis. As such, under the No Project Alternative, Stanislaus River February–June flow volumes are generally higher than they were under baseline (Table 15-1, Figure 15-1, and Figure 15-2a). The additional releases required under the No Project Alternative would reduce end-of-September storage (i.e., carryover) in New Melones Reservoir and the volume of water available for diversions along the Stanislaus River. The WSE model results show that New Melones Reservoir carryover storage under the No Project Alternative is lower than it is under baseline in almost all years (1922–2003) (Figure 15-2b). Additionally, the model shows that No Project Alternative diversions from the Stanislaus River are less than baseline diversions in approximately 50 percent of the years; No Project Alternative diversions are substantially reduced during approximately 15 percent of the years (Figure 15-2c).

No Project Alternative flow and storage volumes were also compared to the LSJR alternatives on the Stanislaus River (Figures 15-2a through 15-2d). Under the No Project Alternative, Stanislaus River February–June flow volumes are generally greater than LSJR Alternative 2 flow volumes, except in approximately 35 percent of the wetter years. No Project Alternative flow volumes are less than the LSJR Alternative 3 flow volumes in approximately 65 percent of years, and except under very dry conditions, the No Project Alternative flow volumes are generally much less than the LSJR Alternative 4 flow volumes (Figure 15-2a). New Melones Reservoir carryover storage is similar to or less than storage under LSJR Alternatives 2 and 3 in all years; storage is less than LSJR Alternative 4 storage in approximately half of the years (Figure 15-2b). Lastly, diversions are generally similar to or less than they are under LSJR Alternative 2, especially during drought years; however, the diversions under the No Project Alternative are usually much greater compared to LSJR Alternatives 3 and 4, except again in the driest years when diversions are close to zero (Figure 15-2c).

15.3.2 Tuolumne, Merced, and Lower San Joaquin Rivers

The No Project Alternative would affect the Tuolumne and Merced Rivers differently than it would affect the Stanislaus River. Under baseline, some of the Vernalis flow requirements would come from the Tuolumne and Merced Rivers as part of VAMP (Table D-3). Under the No Project Alternative, the VAMP flows would no longer be in effect; releases to satisfy Vernalis flow requirements would come entirely from the USBR through releases at New Melones Reservoir on the Stanislaus River (Table D-3).

As discussed in Appendix D, *Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)*, Tuolumne River February–June flows (Figures 15-3a and 15-3d), reservoir storage (Figure 15-3b), and diversions (Figure 15-3c) are similar under baseline and the No Project Alternative. The VAMP flows, which are included in the baseline, come primarily from the Stanislaus and Merced Rivers; therefore, replacing VAMP with the full implementation of D-1641, as called for under the No Project Alternative, has minimal effect on the Tuolumne River.

Under the No Project Alternative, February–June flows on the Merced River are lower than they are under baseline in more than 50 percent of years (Figure 15-4a); reduced flows occur during the VAMP months of April and May (Table 15-1). The lower flows under the No Project Alternative would increase the carryover storage in Lake McClure (Figure 15-4b), which is located on the Merced River..

Lastly, driven by the increases in flow on the Stanislaus River, total SJR February–June flows at Vernalis are slightly higher under the No Project Alternative than they are under baseline

(Table 15-1 and Figure 15-5a). In most years, total February–June flows experienced similar increases under LSJR Alternative 2 and the No Project Alternative. However, during the driest years, total February–June flows are slightly lower under LSJR Alterative 2 than they are under the No Project Alternative (Figure 15-5a). In addition, during July and August flows sometimes increase slightly under the No Project Alternative relative to baseline (Table 15-1).

15.4 Impacts of the No Project Alternative

The impacts of the No Project Alternative vary among the southern Delta and the three eastside tributaries and reservoirs. These impacts, including cumulative impacts, are summarized in Sections 15.4.1 through 15.4.4. Table 15-2 summarizes the impact determinations for the No Project Alternative.

As described above, the No Project Alternative is the continuation of the current 2006 Bay-Delta Plan as currently implemented into the future. No discretionary approvals would be required to continue operations under the current plan. Since no new project would be approved or carried out in association with the No Project Alternative, potential mitigation is not included in the discussion of impacts below.

15.4.1 Southern Delta

As described above in Section 15.2, *Description of the No Project Alternative*, and Appendix D*, Evaluation of the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)*, the WSE model includes the flows necessary to meet the Vernalis salinity objectives and the downstream salinity objectives. Because the Vernalis objective would continue to be maintained, water quality at Vernalis and in the southern Delta would not change from baseline. As explained below in Table 15-2, however, it is unlikely that service providers would be able to meet the current 2006 Bay-Delta Plan salinity objectives at all times and that to avoid exceedances of the objectives or permit requirements, they may construct new wastewater treatment facilities or other facilities, or expand such facilities, which could cause significant environmental effects.

15.4.2 Stanislaus River and New Melones Reservoir

The No Project Alternative February–June flows would be greater than baseline and LSJR Alternative 2 in approximately 65 percent of the years on the Stanislaus River. Furthermore, the No Project Alternative flows would be higher than LSJR Alternative 3 in the driest 35 percent of the years and higher than LSJR Alternative 4 in the driest 10 percent of the years (Figure 15-2a). As discussed in Chapters 5–14, the impacts on many flow-dependent resources (e.g., aquatic resources and terrestrial biological resources) associated with the No Project Alternative would generally be similar to those impacts associated with LSJR Alternative 3. However, New Melones Reservoir carryover storage levels would be lower under the No Project Alternative than they would be under baseline. The lower carryover under the No Project Alternative would increase the salmon and steelhead populations' exposure to stressful summer and fall water temperatures in the Stanislaus River relative to baseline.

Surface water diversions would also be lower under the No Project Alternative than under baseline or LSJR Alternative 2 conditions in approximately 50 to 65 percent of the years; diversions would be substantially reduced in approximately 15 percent of the years (Figure 15-2c). In all but the driest 10 percent of the years, more diversions could occur under the No Project Alternative than under LSJR Alternatives 3 and 4 (Figure 15-2c). Overall, the reductions to surface water diversions associated with the No Project Alternative would fall between the impacts associated with LSJR Alternatives 2 and 3.

Reductions in surface water supply deliveries under the No Project Alternative would result in resource impacts similar to those identified for LSJR Alternative 3 in Chapter 11, *Agricultural Resources,* and Chapter 9, *Groundwater Resources*. New Melones Reservoir elevation and carryover storage would be significantly lower under the No Project Alternative than under the baseline or LSJR Alternatives 2 or 3. Additionally, during years with low storage (i.e., storage less than median), New Melones Reservoir storage would be much lower under the No Project Alternative than it would be under LSJR Alternative 4 (Figure 15-2b). No Project Alternative conditions would result in much greater impacts on certain resources (e.g., recreation, cultural resources, and energy) than the conditions described for LSJR Alternatives 2, 3, or 4 in Chapters 5–14.

Impacts on aquatic resources resulting from the No Project Alternative on the Stanislaus River and at New Melones Reservoir were determined to be significant (Table 15-2). Although some of the impacts could be reduced or eliminated by allowing lower flows than those required in the 2006 Bay-Delta Plan the State Water Board is required to comply with adopted or approved water quality control plans (Water Code, § 13247). As such, the State Water Board cannot authorize lower flows than those required by the 2006 Bay-Delta Plan without amending the 2006 Bay-Delta Plan which would be inconsistent with the concept and definition of the No Project Alternative (i.e., continuation of the 2006 Bay-Delta Plan).

15.4.3 Tuolumne River and New Don Pedro Reservoir

The No Project Alternative February–June flows on the Tuolumne River would generally be the same as under baseline (Figure 15-3). Given the minimal difference between the No Project Alternative and baseline, flow impacts on the Tuolumne River would generally not occur. Furthermore, surface water diversions from the Tuolumne River and carryover storage in the New Don Pedro Reservoir (on the Tuolumne River) would be similar to baseline. Therefore, surface water diversion impacts and reservoir storage impacts under the No Project Alternative would not be substantially different from impacts under baseline (Figure 15-3). There would be no impact.

15.4.4 Merced River and Lake McClure

Under the No Project Alternative, carryover storage in Lake McClure on the Merced River would be greater than under baseline because of the reduction in flows otherwise released for VAMP under baseline (Figure 15-4b). Under the No Project Alternative, February–June flows on the Merced River would be less than baseline in more than 50 percent of years (Figure 15-4a), with all the reductions occurring during April and May (Table 15-1), as a result of no VAMP implementation..

Under LSJR Alternatives 2, 3, and 4, the Merced River flows would generally be increasingly higher than they would be under baseline. Therefore, impacts on resources requiring or relying on flows in the Merced River (e.g., aquatic resources) under the No Project Alternative would generally be more severe than those of the LSJR Alternatives 2, 3, and 4, as described in Chapters 5–14. Surface water diversions would be similar to baseline on the Merced River; therefore, surface water diversion impacts would not change substantially from baseline (Figure 15-4c).

In Table 15-2, impacts resulting from the No Project Alternative on the Merced River are determined to be significant

15.4.5 The Extended Plan Area

The State Water Board implemented the No Project Alternative through Decision 1641, and the responsibility for implementation does not extend to the extended plan area. Thus, there are no impacts in that area resulting from the No Project Alternative.

15.5 Cumulative Impacts of the No Project Alternative

Cumulative impacts are defined in the State CEQA Guidelines as "two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts." (Cal. Code Regs., tit. 14, § 15355.) A cumulative impact from several projects is "the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonable foreseeable probable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time." (Cal. Code Regs., tit. 14, § 15355, subd. (b).)

Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*, includes Table 17-1, a list of past, present, and reasonably foreseeable future projects considered for the cumulative analysis of the impacts of all the alternatives. Present and reasonably foreseeable future projects are projects that are currently under construction, approved for construction, have submitted a request for approval or review by an agency, or are in the final stages of formal planning. These projects were identified by reviewing available information and are summarized in Chapter 17. All past, present, and reasonably foreseeable future projects listed in Chapter 17 are considered, as appropriate, for the No Project Alternative cumulative analysis.

15.5.1 Summary of Potential Cumulative Impacts on Resource Areas

This section summarizes the potential cumulatively considerable effects of the No Project Alternative and potentially significant cumulative impacts. The cumulative impact determinations for the No Project Alternative are based on the changes to the environment described by region in Section 15.4 (more detailed descriptions of the environmental settings for various resources can be found in Chapters 5-14). Impacts resulting from the No Project Alternative, which are described in Table 15-2, are considered in combination with impacts resulting from projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*, Table 17-1, to determine if, in light of the other projects, the impacts of the No Project Alternative are cumulatively considerable or result in a significant cumulative effect. As discussed in Section 15.4, the No Project Alternative would have no impact on Tuolumne River resources or resources affected by New Don Pedro Reservoir operations. Because the No Project Alternative would have no impact on resources within the Tuolumne River Watershed, it would have no cumulative impact in that watershed. The relevant projects listed in Table 17-1 and the No Project Alternative could cause cumulative impacts primarily through changes to flows in the tributaries or in the LSJR, changes in groundwater pumping, or through changes to the operation of the primary rim reservoirs in the plan area.

15.5.1.1 Hydrology and Water Quality

The No Project Alternative, based on the 2006 Bay-Delta Plan, would generally increase flows on the Stanislaus River, have no change on the Tuolumne River, and reduce flows on the Merced River. Because the Vernalis objective would continue to be maintained, water quality at Vernalis and in the southern Delta would not change from baseline and in fact may improve due to increased flows from New Melones. Reduced flow on the Merced River would have a significant impact under the No Project Alternative (see Impact WQ-3 in Table 15-2). The No Project Alternative may result in a cumulatively considerable incremental contribution to a cumulative effect or in a potentially significant cumulative effect on hydrology and water quality in combination with other projects described in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*, that divert water from, or potentially add to or otherwise concentrate pollution in, the Merced River. The cumulative impact on hydrology and water quality is potentially significant.

15.5.1.2 Flooding, Sediment and Erosion

Under the No Project Alternative, flows would be lower than channel capacities on the three tributaries and LSJR as described in Chapter 6, *Flooding, Sediment, and Erosion*. Flows under the No Project Alternative would also not change reservoir flood storage capacity or violate U.S. Army Corps of Engineers flood reservation for the reservoirs in the plan area. Therefore the No Project Alternative would not result in a cumulatively considerable incremental contribution to cumulative impacts and there is no significant cumulative impact related to flooding, sediment, and erosion.

15.5.1.3 Aquatic Resources

The changes to the environment potentially caused by the No Project Alternative (see Table 15-2)—especially changes in flows to the three tributaries, changes in reservoir operations and storage levels, and changes to habitat within the plan area—are potentially similar to the impacts that may be caused by projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*, that affect hydrology and reservoir operations in the watershed. Therefore the No Project Alternative may result in a cumulatively considerable incremental contribution to a cumulative impact or in potentially significant cumulative impact on aquatic resources in combination with other projects. The cumulative impact on aquatic resources is potentially significant.

15.5.1.4 Terrestrial Biological Resources

The changes to the environment potentially caused by the No Project Alternative (see Table 15-2), especially a reduction in flow on the Merced River and changes to riparian habitat within the plan area, are potentially similar to the impacts that may be caused by several of the projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*. Therefore the No Project Alternative could result in cumulatively considerable incremental effects and may result in significant cumulative impacts on terrestrial biological resources.

15.5.1.5 Groundwater Resources

Surface water diversions on the Stanislaus River would be reduced by approximately 9 percent under the No Project Alternative (see Table 15-2). This reduction could lead to an increase in groundwater pumping and in subsidence, which is potentially similar to the impacts that may be caused by several of the projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*. Although the impacts of the No Project Alternative to groundwater are not found to be significant, the No Project Alternative could result in a cumulatively considerable incremental effect on groundwater resources.

15.5.1.6 Recreational Resources and Aesthetics

The No Project Alternative could potentially result in reduced access to boat ramps and potentially degrade the visual quality or character of New Melones Reservoir. The potential reduction in the level of New Melones Reservoir caused by the No Project Alternative (see Table 15-2), is potentially similar to the impacts that may be caused by several of the projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*. Therefore the No Project Alternative could result in cumulatively considerable incremental effects in connection with the effects of other projects and potentially significant cumulative impacts on recreational resources and aesthetics.

15.5.1.7 Agricultural Resources

The No Project Alternative could result in conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural uses as a result of the reductions in surface water diversions on the Stanislaus River (see Table 15-2). A reduction in diversions on the Stanislaus River may also be caused by projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*. Therefore the No Project Alternative could result in cumulatively considerable incremental effects or in potentially significant cumulative impacts on agricultural resources.

15.5.1.8 Cultural Resources

The end-of-September storage at New Melones Reservoir, under the No Project Alternative, is anticipated to be greatly reduced in over half the years when compared to baseline. This would potentially expose cultural resources and raise the potential for adverse impacts (see Table 15-2). A reduction in storage at New Melones Reservoir may also be caused by several of the projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*. For example, compliance with BOs and salinity control related projects could add to a reduction in storage. Therefore the No Project Alternative could result in cumulatively considerable incremental effects or in a significant cumulative effect in combination with other projects on cultural resources.

15.5.1.9 Service Providers

Based on current effluent discharge concentrations and past exceedances, it is unlikely that existing service providers would be able to meet the current 2006 Bay-Delta Plan salinity objective of 0.7 dS/m from April to August as would be implemented under the No Project Alternative. Additionally, it is unlikely that the Cities of Tracy and Stockton meet the current 2006 Bay-Delta Plan salinity objective of 1.0 dS/m from September–March (see Table 15-2.) There are projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*, that potentially change flow paths and salinity in locations that could affect service providers' ability to comply with the southern Delta salinity objectives in the 2006 Bay-Delta Plan.

Therefore the No Project Alternative could result in cumulatively considerable and incremental effects or potentially significant cumulative impacts on service providers.

15.5.1.10 Energy and Greenhouse Gases

The reduction in diversions on the Stanislaus River could cause a shift to more groundwater pumping and a potential shift from hydropower to non-hydropower energy production. Changes in operations and storage levels at New Melones reservoir could result in reliability impacts on electrical production at the New Melones hydroelectric plant. See Table 15-2 for further details. Similar impacts involving a reduction in flows on the Stanislaus River or impacts on storage levels in New Melones Reservoir may be caused by several of the projects listed in Chapter 17, *Cumulative Impacts, Growth-Inducing Effects, and Irreversible Commitment of Resources*. For example, compliance with BOs and salinity control related projects could add to a reduction in storage. Therefore the No Project Alternative could result in cumulatively considerable incremental effects or in potentially significant cumulative impacts on energy and greenhouse gases.

15.5.2 Additional Resource Areas Considered for Cumulative Impacts under the No Project Alternative

Resource areas were initially evaluated using Appendix B, *State Water Board's Environmental Checklist*. Resource areas that were determined to need further analysis (i.e., impacts are listed as "Potentially Significant Impacts") are evaluated in the resource chapters (Chapters 5–14). However, some resource areas determined to have "Less-than-Significant Impacts" and thus are were only evaluated in Appendix B. These resource areas are discussed below to assess if their incremental impacts are cumulatively considerable when added to the potential impacts of the projects listed in Table 17-1. If an impact does not result in part from the No Project Alternative, it is not discussed.

15.5.2.1 Air Quality

Air quality impacts are discussed in Appendix B, *State Water Board's Environmental Checklist,* Section III, *Air Quality*. In summary, changes in operations at New Melones Reservoir could result in decreased hydropower generation. This loss in hydropower generation may necessitate increased production from other power facilities to offset the loss. Implementation of the No Project Alternative may also result in additional groundwater pumping to replace Stanislaus River diversions. This groundwater pumping is anticipated to be within irrigation service areas and could require additional electrical use. Electric pumps are assumed as the No Project Alternative would be implemented over the long term since they are cheaper and more efficient than diesel pumps over a long term. Reduction in surface diversions from the Stanislaus River could also result in removal of croplands from agricultural production. As discussed in Appendix B, Section III(c), the net effect of would not increase fugitive dust emissions. Implementation of air quality plans would not be affected. There would be no impacts on air quality related to SDWQ from implementation of the No Project Alternative.

The analysis in Appendix B, Section III, does not reveal potential for the No Project Alternative to have an cumulatively considerable incremental effect on air resources. There is no significant cumulative impact.

15.5.2.2 Geology and Soils

Impacts on geology and soils are initially discussed in Appendix B, , *State Water Board's Environmental Checklist,* Section VI, *Geology and Soils*. Detailed analysis of subsidence is included in Chapter 9, *Groundwater*, and erosion is analyzed in Chapter 6, *Flooding, Sediment, and Erosion*. Erosion impacts related to reduced irrigation of irrigated lands are not cumulatively considerable and are less than significant. As discussed in Chapter 11, *Agricultural Resources*, while some agricultural land could be taken out of irrigated agricultural use as a result of the LSJR alternatives (particularly LSJR Alternatives 3 and 4), many of these lands could remain in agricultural use, even if they are not irrigated. Further, they must remain in uses that are compatible with applicable local land use plans, policies or regulations. In addition, the implementation of agricultural practices to address dust control, weed abatement, and revegetation would result in an insubstantial amount of soil erosion or loss of topsoil. None of the other impact areas included in Section VI have impacts caused by any of the project alternatives, including the No Project Alternative. Any other potential cumulative impacts related to subsidence and erosion caused by the No Project Alternative are discussed in Section 15.5.1 under the two topics Flooding, Sediment and Erosion and Groundwater Resources. There would be no impacts on geology and soils specifically related to the SDWQ from implementation of the No Project Alternative.

Other than as discussed in Section 15.5.1 there are no cumulatively considerable impacts on geology and soils caused by the No Project Alternative.

15.5.2.3 Land Use and Planning

Impacts involving land use and planning are initially discussed in Appendix B, *State Water Board's Environmental Checklist,* Section X, *Land Use and Planning*. Two areas within Section X included potentially significant impacts and are analyzed in Chapter 8, *Terrestrial Biological Resources,* and Chapter 11, *Agricultural Resources*. Discussion of cumulative impacts on land use and planning for the No Project Alternative are covered under these two topics in Section 15.5.1. Other areas related to land use and planning do not result in significant cumulative effects.

15.5.2.4 Utilities and Service Systems

Impacts on utilities and service systems are initially discussed in Appendix B, *State Water Board's Environmental Checklist*, Section XVII, *Utilities and Service Systems*. Analysis of the potential for construction of new or expanded water, wastewater or drainage facilities, or any impact on water supplies is covered by Chapter 5, *Surface Hydrology and Water Quality*; Chapter 9, *Groundwater Resources*; and Chapter 13, *Service Providers*. Any cumulative impacts related to utilities and service systems caused by the No Project Alternative are discussed in Section 15.5.1 under the three topics of Chapters 5, 9, and 13. There would be no other impacts on utilities and service systems related to SDWQ from implementation of the No Project Alternative. No further areas related to utilities and service systems require discussion.

Table 15-2. Summary of Impact Determinations for the No Project Alternative (LSJR Alternative 1 and SDWQ Alternative 1)

Impact Statement	Impact Determination	Discussion
Hydrology and Water Quality		
Impact WQ-1: Violate water quality standards by increasing the number of months with EC above the water quality objectives for salinity at Vernalis or southern Delta compliance stations	Less than significant	The No Project Alternative is the continuation of the existing 2006 Bay-Delta Plan, which includes implementation measures to achieve water quality objectives (e.g., the Vernalis and southern Delta EC objectives). Under baseline, the southern Delta EC objectives are not always be attained. Evaluation of monthly flows (Table 15-1) shows that, although a few of the median No Project Alternative flows are less than baseline, Vernalis flows are generally higher under the No Project Alternative, especially during years with low flow (which would be more likely to have EC violations). Because higher flows generally reduce EC, the No Project Alternative would not be expected to cause an increase in the amount of time the water quality objectives for salinity are exceeded at Vernalis or southern Delta compliance stations.-Therefore, increased exceedance of EC objectives at the Vernalis or southern Delta compliance stations would be unlikely to occur under the No Project Alternative. The impact is less than significant.
Impact WQ-2: Substantially degrade water quality by increasing Vernalis or southern Delta salinity (EC) such that agricultural beneficial uses are impaired	Less than significant	For the reasons described in the Impact WQ-1 discussion, the No Project Alternative would be unlikely to cause an increase in EC such that beneficial agricultural uses would be impaired.
Impact WQ-3: Substantially degrade water quality by increasing pollutant concentrations caused by reduced river flows	Significant	Under the No Project Alternative, flows would not be substantially reduced on the Stanislaus, Tuolumne, or LSJR such that contaminant concentrations would increase (Table 15-1). However, on the Merced River, flows under the No Project Alternative would be substantially reduced during April and May compared to baseline, which could result in a significant increase in contaminant concentrations above baseline.
Flooding, Sediment, and Erosion		
Impact FLO-1: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner that would result in substantial erosion or siltation on- or off-site	Less than significant	Under the No Project Alternative, flows would be lower than channel capacities on the Stanislaus, Tuolumne, and Merced Rivers, as described under LSJR Alternative 4 in Chapter 6, *Flooding, Sediment, and Erosion*. Sediment transport, bank erosion, or meander-bend migration issues and contributions to levee instability would not increase. It is expected that very occasional gravel transport and bank erosion would occur in the upper gravel-bedded reaches of the Stanislaus, Tuolumne, and Merced Rivers. The amount of bank erosion would be limited by flood action levels and existing bank armoring. Impacts would be less than significant.

Impact Statement	Impact Determination	Discussion
Impact FLO-2: Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner that would result in flooding on- or off-site	Less than significant	Flows would be much lower than channel capacities on the Stanislaus, Tuolumne, and Merced Rivers, as described under LSJR Alternative 4 in Chapter 6, *Flooding, Sediment, and Erosion*. Therefore, significant flooding impacts would not occur outside of floodways. The No Project Alternative would not change reservoir flood storage capacity and would not violate the U.S. Army Corps of Engineers flood reservation; thus, there would be no changes in flood control releases during major flood events. Impacts would be less than significant.
Aquatic Resources		
Impact AQUA-1: Changes in spawning success and habitat availability for warmwater species resulting from changes in reservoir water levels	Significant	Under the No Project Alternative, month-to-month fluctuations in reservoir elevations at New Don Pedro Reservoir would remain similar to the baseline elevations during April-September (the primary spawning, incubation, and early rearing months). Therefore, the availability of warmwater reservoir species habitat and their spawning success would not change at the New Don Pedro Reservoir. However, month-to-month fluctuations at New Melones Reservoir and Lake McClure would increase under the No Project Alternative during April-September, as compared to baseline. Monthly fluctuations greater than or equal to 15 feet (ft) would increase by more than 10% during April-August at New Melones Reservoir and during April at Lake McClure. Therefore, warmwater reservoir species habitat would be significantly altered under the No Project Alternative, which would affect the spawning success of these species.
Impact AQUA-2: Changes in availability of coldwater species reservoir habitat resulting from changes in reservoir storage	Significant	Under the No Project Alternative, End-of-September storage at New Don Pedro and Lake McClure would remain similar to, or be greater than, the storage under baseline elevations. End-of-September storage is not expected to be significantly reduced when compared to baseline. Therefore, the availability of coldwater reservoir species habitat and their spawning success are not expected to change at these reservoirs. However, on average, end-of-September storage at New Melones Reservoir would be reduced by 27%. Therefore, coldwater reservoir species habitat would be significantly altered under the No Project Alternative, which would affect the spawning success of these species.
Impact AQUA-3: Changes in quantity/quality of physical habitat for spawning and rearing resulting from changes in flow	Less than significant	Under the No Project Alternative, flows on the Stanislaus River would increase, while flows on the Tuolumne River would be similar to baseline flows and thus would not reduce the quantity and quality of spawning and rearing habitat. Under the No Project Alternative, the Merced River would experience a relatively large percentage reduction in flows in April and May compared to baseline (Tables D-6). However, predicted changes in flow within this range correspond to only minor increases or decreases in weighted usable area (WUA) and no changes in floodplain inundation area. Therefore, they are not likely to substantially affect the amount of physical habitat for Chinook salmon juvenile rearing and steelhead fry rearing.

Impact Statement	Impact Determination	Discussion
Impact AQUA-4: Changes in exposure of fish to suboptimal water temperatures resulting from changes in reservoir storage and releases	Significant	Under the No Project Alternative, temperatures would not increase on the Tuolumne River because flows and end-of-September storage would be similar to baseline. However, reductions in April and May flows on the Merced River (Table 15-1) would very likely increase temperatures in the river in more than half the years (mostly below normal and dry years), which would increase the frequency of stressful temperatures for Chinook salmon and steelhead rearing and smolt life stages. On the Stanislaus River, higher summer and fall release temperatures associated with reduced storage in New Melones Reservoir are also expected to increase the frequency of stressful water temperatures for Chinook salmon and steelhead adult migration, Chinook salmon spawning and incubation, and steelhead rearing life stages, especially in dry years (Figure 15-2b). Flows and water temperatures in the LSJR would remain largely unchanged relative to baseline (Table 15-1 and Figure 15-5a), which would result in little or no change in exposure of migrating adults and juveniles to stressful water temperatures.
Impact AQUA-5: Changes in exposure to pollutants resulting from changes in flow	Significant	Under the No Project Alternative, the exposure to pollutants resulting from changes in flow would not increase on the Stanislaus or Tuolumne Rivers because flows in these rivers would generally be similar to, or greater than, baseline flows. However, on the Merced River, reductions in April and May flows under the No Project Alternative, especially during dry periods, would very likely increase pollutant exposure to fish compared to the baseline.
Impact AQUA-6: Changes in exposure to suspended sediment and turbidity resulting from changes in flow	Less than significant	As described for LSJR Alternative 4 in Chapter 7, *Aquatic Biological Resources*, and Chapter 6, *Flooding, Sediment and Erosion*, changes in the frequency, duration, and magnitude of increased suspended sediment and turbidity levels would be minor and within the range of historical levels experienced by native fishes and other aquatic species on the three eastside tributaries and the LSJR. Because the No Project Alternative flows during wet years would be less than those described in LSJR Alternative 4 on the Stanislaus River, impacts would be less than those described above. Similar but fewer impacts than those described above would occur on the Tuolumne and Merced Rivers because flows under the No Project Alternative would be similar to or less than baseline flows on these rivers. Therefore, the change in flows would not mobilize more suspended sediment.
Impact AQUA-7: Changes in redd dewatering resulting from flow fluctuations	Less than significant	Under the No Project Alternative, changes in the frequency and magnitude of flow fluctuations resulting in redd dewatering would not occur on the Stanislaus, Tuolumne, and Merced Rivers compared to baseline. Therefore, redd dewatering impacts on Chinook salmon and steelhead populations in the Stanislaus, Tuolumne, and Merced Rivers would be less than significant.
Impact AQUA-8: Changes in spawning and rearing habitat quality resulting from changes in peak flows	Less than significant	Under the No Project Alternative, substantial changes in the frequency and magnitude of peak flows would not occur compared to LSJR Alternatives 2, 3, and 4 (because the February–June flows at the zero to 10% exceedance level are between those for LSJR Alternatives 2 and 4 [Figure 15-2a]). Therefore, changes in peak flows would not deleteriously affect the frequency and magnitude of gravel mobilization events in the Stanislaus, Tuolumne, and Merced Rivers, and long-term changes in geomorphic conditions significantly affecting spawning and rearing habitat quality would not occur.

Impact Statement	Impact Determination	Discussion
Impact AQUA-9: Changes in food availability resulting from changes in flow and floodplain inundation	Less than significant	Under the No Project Alternative, no substantial changes in frequency and magnitude of floodplain inundation and associated food web conditions would occur on the Stanislaus, Tuolumne, and Merced Rivers and the LSJR (because there would be no substantial decreases in the highest flows [Table 15-1]). Therefore, no significant impacts on food availability would occur.
Impact AQUA-10: Changes in predation risk resulting from changes in flow and water temperature	Significant	Under the No Project Alternative, predation risk would be unlikely to change on the Tuolumne River because flow, storage, and water temperature would be similar to baseline. However, reductions in flow and associated higher temperatures on the Merced River in April and May would very likely increase predation risk for Chinook salmon and steelhead during rearing and smolt life stages. On the Stanislaus River, higher summer and fall release temperatures associated with reduced storage in New Melones Reservoir would also increase predation risk for juvenile steelhead, especially in dry years (Figure 15-2b). Flows and water temperatures on the LSJR would remain largely unchanged relative to baseline (Table 15-1 and Figure 15-5a), which would result in little or no change in predation risk.
Impact AQUA-11: Changes in disease risk resulting from changes in water temperature	Significant	Under the No Project Alternative, higher summer and fall release temperatures on the Stanislaus River associated with reduced storage in New Melones Reservoir would increase disease risk for Chinook salmon and steelhead adult migration, Chinook salmon spawning and incubation, and steelhead-rearing life stages, especially in dry years (Figure 15-2b). On the Tuolumne River, disease risk would be unlikely to change under the No Project Alternative because flow, storage, and water temperature would be very similar to baseline. However, reductions in flow and associated higher temperatures on the Merced River in April and May would very likely increase disease risk for Chinook salmon and steelhead-rearing and smolt life stages. Flows and water temperatures on the LSJR would remain largely unchanged relative to baseline (Table 15-1 and Figure 15-5a), which would result in little or no change in disease risk.
Impact AQUA-12: Changes in southern Delta and estuarine habitat resulting from changes in SJR inflows and export effects	Less than significant	Under the No Project Alternative, Delta operations would continue to be governed by current restrictions on export pumping rates, inflow/export ratios, and Old Middle River flows to protect listed fish species from direct and indirect impacts of southern Delta operations. Furthermore, during the primary months of concern for fish using the Delta (December–June), changes in exports would be relatively small and less than the changes under LSJR Alternatives 3 and 4, while average monthly Delta outflow would either be similar to or slightly greater than baseline outflow. Therefore, no significant changes in southern Delta and estuarine habitat would occur under the No Project Alternative.

Impact Statement	Impact Determination	Discussion
Terrestrial Biological Resources		
Impact BIO-1: Have a substantial adverse effect on any riparian habitat or other sensitive natural terrestrial communities identified in local or regional plans, policies, or regulations or by California Department of Fish and Wildlife (CDFW) or United States Fish and Wildlife Service (USFWS)	Significant	Fluctuations in reservoir elevations would not be substantially different than those that currently occur. Therefore, the No Project Alternative would not have adverse effects on riparian or other sensitive natural terrestrial communities around the reservoirs. Under the No Project Alternative, flow on the Stanislaus and Tuolumne Rivers and LSJR would not substantially alter riparian habitat or other sensitive natural terrestrial communities because flows on these rivers would be similar to, or greater than, baseline. However, the reduced flow on the Merced River under the No Project Alternative compared to the baseline (Table 15-1) would very likely result in a substantial alteration of riparian habitat or other sensitive natural terrestrial communities on this river, especially during moderate to dry years in the spring growing season (April and May).
Impact BIO-2: Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrologic interruption, or other means	Significant	See Impact BIO-1 discussion.
Impact BIO-3: Facilitate a substantial increase in distribution and abundance of invasive plants or nonnative wildlife that would have a substantial adverse effect on native terrestrial species	Less than significant	As described in Chapter 8, *Terrestrial Biological Resources*, invasive plants and animals already exist throughout the watersheds of the Stanislaus, Tuolumne, and Merced Rivers and the LSJR. Although the No Project Alternative could alter vegetation patterns at specific locations, there is no information available to suggest that increased flows on the Stanislaus River or decreased flows on the Merced River would substantially increase the distribution or abundance of invasive plant or nonnative wildlife in a manner that would substantially native terrestrial species
Impact BIO-4: Have a substantial adverse effect, either directly or through habitat modifications, on any terrestrial animal species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by CDFW or USFWS	Significant	Impacts on special-status animal species dependent on riparian habitat and impacts on riparian habitat would be similar to those in the ImpactBIO-1 discussion. Under the No Project Alternative, flows on the Stanislaus and Tuolumne Rivers and LSJR would be similar to or greater than baseline. Therefore, the special-status animal species on these rivers would not be substantially affected. However, the reduced flow on the Merced River under the No Project Alternative compared to the baseline (Table 15-1) could result in substantial effects on special-status species reliant on riparian habitat on this river. Therefore, it is expected that special-status animal species on the Merced River would be adversely affected.

Impact Statement	Impact Determination	Discussion
Impact BIO-5: Conflict with the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, or state habitat conservation plan or conflict with any local policies or ordinances protecting biological resources	Significant	Under the No Project Alternative, flow on the Stanislaus and Tuolumne Rivers and LSJR would not substantially affect riparian habitat or special-status species. Therefore, the No Project Alternative would not conflict with habitat conservation plans or natural community conservation plans for these rivers. However, the reduced flow on the Merced River under the No Project Alternative compared to baseline could reduce habitat value, which could result in conflicts with habitat conservation plans or natural community plans, which are discussed in Chapter 8, *Terrestrial Biological Resources*.
Groundwater Resources		
Impact GW-1: Substantially deplete groundwater supplies or interfere substantially with groundwater recharge	Less than significant	Groundwater pumping would increase under reduced surface water diversions (i.e., reduced surface water availability); therefore, impacts on groundwater would increase as the percent of reduction in surface water diversions increases. Surface water diversions on the Tuolumne and Merced Rivers would be similar under the No Project Alternative and baseline. Because there would be no change in surface water availability, the groundwater subbasins (Modesto, Turlock, and Extended Merced) served by these rivers would not be affected by the No Project Alternative. However, surface water diversions on the Stanislaus River would be reduced by approximately 9% under the No Project Alternative. As such, the Eastern San Joaquin Subbasin, which is served by the Stanislaus River, would be affected by the reduced surface water diversions. However, as discussed in Chapter 9, *Groundwater Resources*, diversions would be reduced under LSJR Alternative 3 approximately on average by 12%, but the groundwater impacts associated with LSJR Alternative 3 would be less than significant. Because surface water diversions reductions under No Project Alternative (9%) would be less than surface water diversion reductions under LSJR Alternative 3 (12%), the groundwater affects associated with the No Project Alternative would also be less than significant.
Impact GW-2: Cause subsidence as a result of groundwater depletion	Less than significant	As described above for Impact GW-1, the effect of the No Project Alternative on groundwater supplies is expected to be less than significant. As a result, subsidence resulting from the No Project Alternative is also expected to be less than significant.
Recreational Resources and Aesthetics		
Impact REC-1: Substantially physically deteriorate existing recreational facilities on the rivers or at reservoirs	Significant	During the primary recreation months of May–September, the No Project Alternative could slightly shift recreational activities on the Stanislaus River between May and August. Activities suited to higher flows would be slightly shifted to different months and activities suited to lower flows on the Merced River during May would be slightly shifted to other times. (Table 15-1). These shifts would be unlikely to cause significant recreational impacts. Under the No Project Alternative, reservoir elevations at New Don Pedro and Lake McClure would remain similar to baseline. Therefore, substantial physical deterioration at existing recreational facilities at these reservoirs would not occur. However, end-of-September reservoir elevations at New Melones

Impact Statement	Impact Determination	Discussion
		would be greatly reduced compared to baseline, especially during the years with lowest storage (Figure 15-2b). At New Melones Reservoir, boat launches are inoperable when the reservoir elevation is below 850 ft; under the No Project Alternative, the surface of New Melones Reservoir would be below 850 ft approximately 30% of the time in September, which is when recreationists use the reservoir. Therefore, it is anticipated that the No Project Alternative would interfere with the operation of boat ramps which could potentially result in a substantial physically deterioration of facilities at New Melones Reservoir, and thus reduce the use of existing recreation facilities.
Impact REC-2: Substantially degrade the existing visual character or quality of the reservoirs	Significant	Under the No Project Alternative, reservoir elevations at New Don Pedro and Lake McClure would remain relatively constant and would not be substantially reduced compared to baseline. Therefore, substantial degradation of the visual character and quality of area surrounding these reservoirs would not occur. However, summer elevations at New Melones Reservoir would be reduced compared to baseline, especially during years with lowest storage. At the 30%cumulative distribution level, the May–September seasonal average No Project Alternative elevation would be reduced by more than 50 ft, well above the 10-foot level identified in Chapter 10, *Recreational Resources and Aesthetics,* as the criterion for significance. This reduction would substantially degrade the existing visual character or quality of the New Melones Reservoir.
Agricultural Resources		
Impact AG-1: Potentially convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural use	Significant	Under the No Project Alternative, in areas that receive surface water from the Tuolumne and Merced Rivers, a conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural uses would not be expected because surface water diversions on the Tuolumne and Merced Rivers would not be significantly reduced. Therefore, it is anticipated that a substantial reduction in crop acreage would not occur in these watersheds, and a conversation of these types of farmland to nonagricultural uses would not occur. The No Project Alternative would result in conversion of Prime Farmland, Unique Farmland, or Farmland of Statewide Importance to nonagricultural uses as a result of the reductions in surface water diversions on the Stanislaus River. The average reduction in surface water diversions of 9% would be slightly greater than the reduction that would occur under LSJR Alternative 2 with adaptive implementation (average reduction of 5% with implementation of adaptive implementation method 1 [i.e., 30%unimpaired flow]) and slightly less than the reduction described for LSJR Alternative 3 (average reduction of 12% at 40% unimpaired flow requirement). As described in Chapter 11, *Agricultural Resources*, LSJR Alternative 3 would result in significant impacts on agricultural resources of the irrigation districts that receive water from the Stanislaus River. Although reductions in surface water supply under the No Project Alternative would be slightly less than those expected under LSJR Alternative 3, significant impacts could occur.

Impact Statement	Impact Determination	Discussion
Impact AG-2: Involve other changes in the existing environment which, due to their location or nature, could result in a conversion of farmland to nonagricultural use	Less than significant	Flows on the Stanislaus River would be increased, which may result in seepage; however, given the small amount of acreage for crops that could be affected, impacts would be less than significant. Similar to conditions under the LSJR alternatives, given the cost of feed input compared to other dairy inputs and the availability of the feed input, the value of dairy production in the LSJR area of potential effects, and the potential use of equitable distributions from local water suppliers, it is unlikely that dairies, as an agricultural use, would be converted to nonagricultural uses. Impacts would be less than significant.
Impact AG-3: Conflict with existing zoning for agricultural use or a Williamson Act contract	Less than significant	The No Project Alternative would not conflict with existing zoning for agricultural use or Williamson Act contracts because the No Project Alternative would not change zoning. Lands that are under Williamson Act contracts must be maintained in the compatible uses specified in those contracts until non-renewed, canceled, or otherwise withdrawn from contract. Lands that experience a reduction in surface water supply could be dry farmed, rotated, or fallowed, all of which are agricultural activities that are consistent with agricultural zoning and Williamson Act contracts.
Impact AG-4: Conflict with any applicable land use plan, policy, or regulation related to agriculture of an agency with jurisdiction over a project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect	Less than significant	The No Project Alternative would not conflict with applicable land use plans, policies, or regulations because while some agricultural land could be taken out of irrigated agricultural use as a result of the No Project Alternative, many of these lands could actually remain in agricultural use, even if they are not irrigated. Furthermore, local agencies have accommodated the conversion and preservation or protection of agricultural lands through various means, including agricultural mitigation programs, agricultural preservation easements, or general plan policies that protect and preserve agricultural land (described in Chapter 11, *Agricultural Resources)*.
Cultural Resources		
Impact CUL-1: Cause a substantial, adverse change in the significance of a historical or archaeological resource	Significant	As discussed in Chapter 12, *Cultural Resources*, changes in river flows are not expected to alter the low potential for significant cultural resources to exist along rivers due to previous natural and anthropogenic disturbances. Given the low potential, impacts would be less than significant on the three eastside tributaries and the LSJR. Reservoir elevations at New Don Pedro and Lake McClure would remain relatively constant when compared to baseline. Therefore, substantial adverse changes in the significance of historical or archeological resources are not expected at these reservoirs. However, the end-of-September storage at New Melones Reservoir is anticipated to be greatly reduced in over half the years when compared to baseline; this would most likely regularly expose cultural resources, which could result in a substantial adverse change to the significance of existing cultural resources if they were disturbed by people or disturbed by another physical method (e.g., light, exposure).

Impact Statement	Impact Determination	Discussion
Impact CUL-2: Disturb any human remains, including those interred outside formal cemeteries	Less than significant	As discussed in Chapter 12, *Cultural Resources*, the potential for human remains to exist within the fluctuation zone of the reservoirs is low. As a result, the changes in New Melones Reservoir elevations under the No Project Alternative would be unlikely to result in the disturbance of human remains. In addition, considering the prior disturbance by agriculture, irrigation practices, mining activities, and development within the riverine floodplains, the change in flows under the No Project Alternative would have an extremely low potential to disturb documented or currently undocumented human remains, including those interred outside formal cemeteries.
Impact CUL-3: Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature	Significant	As described in Chapter 12, *Cultural Resources*, the potential for paleontological resources within and adjacent to the LSJR and the Stanislaus, Tuolumne, and Merced Rivers is considered low due to the depth of occurrence of rock units with high paleontological potential below reworked surficial sediments and Holocene-age floodplain and channel deposits. Buried paleontological resources would be found at soil and rock depth too deep for the rivers to modify or change. Reservoir elevations at New Don Pedro and Lake McClure would remain relatively constant or generally greater, not significantly reduced, when compared to baseline. Therefore, disturbance of unique paleontological resources is not expected at these reservoirs. However, the-end-of September storage at New Melones is anticipated to be greatly reduced in more than half the years compared to baseline, and this could lead to the disturbance of paleontological resources, such as caves.
Service Providers		
Impact SP-1: Require or result in the construction of new water supply facilities or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects	Significant	Under existing conditions, existing wastewater treatment plant dischargers (i.e., Cities of Tracy, Stockton, and Manteca, and Mountain House CSD) are required to comply with National Pollution Discharge Elimination System (NPDES) permit requirements and waste discharge requirements, as described in Section 13.2.3, *Southern Delta,* of Chapter 13, *Service Providers*. However, the southern Delta salinity water quality objectives do not currently apply to the City of Tracy and other municipal dischargers. If the southern Delta salinity objectives are not applied to the municipal dischargers, then the No Project Alternative would not result in a change to the NPDES permit or other discharger requirements; the No Project Alternative would not result in the need to expand existing facilities or infrastructure and would not result in significant environmental effects. However, it is reasonable to expect that the litigation in *City of Tracy v. California State Water Resources Control Board* (discussed in Section 13.2.3) will be resolved in the foreseeable future in a manner that will allow for the application of the Delta salinity objectives to municipal wastewater dischargers. The increase in flow expected under the No Project Alternative would reduce the salinity in the southern Delta at the interior compliance stations and help achieve compliance at these stations. However, based on current effluent discharge concentrations and past violations, it is unlikely that service providers would be able to meet the current 2006 Bay-Delta Plan salinity objective of 0.7 dS/m from April to August. Additionally, it is unlikely that the Cities of Tracy and Stockton would meet the current 2006 Bay-Delta Plan salinity objective of 1.0 dS/m from September–March. Therefore, these service providers, to avoid

Impact Statement	Impact Determination	Discussion
		exceedances of the objectives or permit requirements during some parts of the year may construct new wastewater treatment facilities, or expand existing facilities or infrastructure; construction or operation of the facilities could cause significant environmental effects.
Impact SP-2a: Violate any water quality standards or waste discharge requirements such that drinking water for public wells would be affected	Less than significant	The No Project Alternative could affect drinking water quality in one of two ways. First, the No Project Alternative could cause a reduction in the quality of surface water; however, the No Project Alternative is unlikely to reduce surface drinking water quality because flows at Vernalis would be higher than baseline at the lower flow levels (Table 15-1). In addition, a higher flow at Vernalis is generally associated with better water quality. The reduction in flow and associated potential for increased contaminants along the Lower Merced River is unlikely to cause a substantial reduction in drinking water quality because the baseline Merced River water quality is high enough that degradation would not cause violation of drinking water standards. Second, the No Project Alternative could affect drinking water by causing a reduction in quality of groundwater that is used for drinking water. Reduced groundwater quality could occur if aquifer drawdown causes low-quality water to move toward wells. However, a reduction in the quality of groundwater drinking supply is not expected because the effect of the No Project Alternative on groundwater supplies is expected to be less than significant (as shown in Impact GW-1 under the No Project Alternative).
Impact SP-2b: Violate any water quality standards or waste discharge requirements such that drinking water for domestic wells would be affected	Less than significant	See above.
Impact SP-3: Result in substantial changes to SJR inflows to the Delta such that insufficient water supplies would be available to service providers relying on Central Valley Project (CVP)/State Water Project (SWP) exports	Less than significant	Because average annual inflows to the Delta at Vernalis would increase slightly relative to baseline as a result of the No Project Alternative, exports may also increase. Average annual exports could increase slightly, by 26 TAF/year. Consequently, service providers relying on CVP/SWP exports are unlikely to be negatively affected by the No Project Alternative.
Energy Resources and Greenhouse Gases		
Impact EG-1: Adversely affect the reliability of California's electric grid	Less than significant	Under the No Project Alternative, a moderate reduction in the capacity of the New Melones hydroelectric plant in July and August during dry years could result in minor reliability violations. However, the New Melones hydroelectric plant is located in a Sacramento Municipal Utility District (SMUD) region; SMUD's 2013 Ten-year Transmission Assessment Plan indicates that there are adequate generating resources in the SMUD region to meet load demands and planning reserve margin obligations until 2018. This means that it is likely that minor violations could

Impact Statement	Impact Determination	Discussion
		be alleviated by re-dispatching electrical power from other generating resources available either in a local region or neighboring regions. Therefore, the No Project Alternative would not adversely affect the reliability of California's electric grid, and the impact of New Melones' reduced capacity would be less than significant.
Impact EG-2: Result in inefficient, wasteful, and unnecessary energy consumption	Less than significant	The No Project Alternative could result in additional energy consumption by groundwater pumping. However, because groundwater pumping may be necessary to maintain the water supply irrigation demand, the No Project Alternative would not result in inefficient, wasteful, and unnecessary consumption of energy. Furthermore, it is anticipated that if new groundwater wells were to be installed, they would be energy efficient. The No Project Alternative could result in additional energy generation at other facilities to compensate for a potential loss of hydropower. However, this increased electricity generation is not considered inefficient, wasteful, and unnecessary, as it is energy that would be generated to maintain the energy supply level that is currently supplied by hydropower.
Impact EG-3: Generate greenhouse gas (GHG) emissions, either directly or indirectly, that have a significant impact on the environment	Significant	The No Project Alternative could result in an increase in groundwater pumping and a potential shift from hydropower to non-hydropower energy production as a result of the expected reduction in surface water diversions and changes to flow on the Stanislaus River. These changes would be expected to generate GHG emissions greater than the threshold of 10,000 metric tons (MT) of GHGs, as described for LSJR Alternative 3 and 4 in Chapter 14, *Energy and Greenhouse Gases*.
Impact EG-4: Conflict with an applicable plan, policy, or Impact regulation adopted for the purposes of reducing the GHG emissions	Significant	Since the No Project Alternative would exceed the 10,000 MT GHG threshold, it would conflict with existing applicable plans, policies or regulations adopted for the purposes of reducing GHG emissions, such as Assembly Bill 32, the California Global Warming Solutions Act.
Impact EG-5: Effect of global climate change on the LSJR and SDWQ alternatives	Less than significant	The State Water Board is required to prepare Water Quality Control Plans (WQCPs). The WQCPs are regularly reviewed to update water quality standards. As a result, the planning process continually accounts for changing conditions related to water quality and water planning, such as climate change. Therefore, the effect of global climate change under the No Project Alternative would be less than significant.

Chapter 16
Evaluation of Other Indirect and Additional Actions

16.1 Introduction

This chapter covers a broad range of topics related to the Lower San Joaquin River (LSJR) Alternatives 2, 3, and 4 and the South Delta Water Quality (SDWQ) Alternatives 2 and 3. It programmatically evaluates other indirect actions and additional actions associated with LSJR Alternatives 2, 3, and 4. The actions include those that the regulated community could take to reduce potential reservoir or water supply effects associated with implementing LSJR Alternatives 2, 3, and 4 with or without adaptive implementation or that would inform the body of scientific information under LSJR Alternatives 2, 3, and 4 with adaptive implementation (i.e., non-flow measures). This chapter also identifies and evaluates the reasonably foreseeable methods of compliance that the regulated community could take to comply with the SDWQ Alternatives 2 and 3 to meet the requirements of Public Resources Code Section 21159 and Section 3777 of the State Water Resources Control Board's (State Water Board's) regulations. It augments the analyses in the preceding chapters relating to the reasonably foreseeable methods of compliance, such as reducing surface water diversions and releasing or bypassing flows at reservoirs in order to comply with the LSJR Alternatives 2, 3, and 4 with or without adaptive implementation. This chapter identifies potentially significant adverse environmental impacts associated with all of these actions and the mitigation measures that would minimize or avoid significant impacts. For the reasonably foreseeable methods of compliance and the other actions, this analysis takes into account a reasonable range of environmental, economic, and technical factors. (Pub. Res. Code, § 21159, subd. (c).)

A project-level analysis is not required for other indirect actions, additional actions, or the reasonably foreseeable methods of compliance. (See, e.g., Id., subd. (d).). Future project-specific actions the State Water Board would take to impose responsibility for implementing the objectives, such as conditioning of water rights through a water rights proceeding or water quality certification under Section 401 of the Clean Water Act through the Federal Energy Regulatory Commission licensing process, would be further analyzed at the time of those actions, undergoing a separate California Environmental Quality Act (CEQA) and economic review. The State Water Board does not under the Porter-Cologne Water Quality Control Act specify the actual means by which other entities choose to comply with the revised water quality objectives. (See, e.g., Cal. Wat. Code, § 13360, subd. (a).) The actual environmental effects will depend on the decisions made by the regulated entities. Any potential environmental impacts depend upon the action, and mitigation selected by or required of the entities implementing site-specific projects. CEQA may require a project-level analysis when actions are undertaken or approved.

This evaluation assumes that all responsible entities will conduct, as appropriate, site-specific environmental analyses to evaluate potentially adverse, project-level environmental impacts, alternatives, and mitigation measures. This evaluation also assumes that responsible entities will design, evaluate, and implement studies, pilot projects, management practices, and controls in compliance with all applicable laws, regulations, ordinances, and formally adopted municipal and/or agency codes, standards, and practices. The specific actions that could be undertaken by an entity to comply with the revised water quality objectives will depend on a number of factors, including feasibility, cost, flexibility, time to implement, location, and likelihood of success.

This chapter is also intended to meet California Water Code (Water Code) Section 13141 requirements. Prior to the implementation of an agricultural water quality control program, the State Water Board must provide an estimate of the total cost of the program together with an identification of potential sources of financing. The SDWQ alternatives are not specifically intended to regulate agriculture; however, this chapter evaluates the associated costs and sources of financing in Sections 16.4.4, *Agricultural Return Flow Salinity Control,* 16.4.5*, South Delta Temporary Barriers,* and 16.4.6, *Low Lift Pumping Stations*.

16.1.1 Chapter Scope and Organization

The chapter is organized primarily by other indirect actions and additional actions that could occur under the LSJR alternatives and the methods of compliance that could occur under the SDWQ alternatives.

Section 16.2, *Lower San Joaquin River Alternatives – Other Indirect Actions*, describes actions that could be undertaken in response to indirect effects of the alternatives (e.g., surface water supply reduction). This chapter presents a suite of reasonably foreseeable actions affected entities may undertake to address possible surface water supply reductions anticipated under LSJR Alternatives 2, 3, and 4 with or without adaptive implementation and analyzes the indirect environmental impacts associated with those actions. While not any one option alone would provide replacement of surface water that may be needed under LSJR Alternatives 2, 3, and 4, with or without adaptive implementation a combination could reduce water supply effects (i.e., less surface water supply to meet various demands). The different types of other indirect actions that could be taken in response to each of the alternatives are unknown; therefore, specific combinations of actions cannot be predictably matched with each alternative. While entities could take one or more of these actions, the combination of actions that entities would take under each alternative is speculative and unknowable. The cost and potential environmental effects of these actions are programmatically evaluated in this chapter using reference projects, standard assumptions regarding the type and potential location of these actions, and impact mechanisms likely to occur as a result of taking these actions. The other indirect actions evaluated in Section 16.2 include:

- Transfer/Sale of Surface Water
- Substitution of Surface Water with Groundwater
- Aquifer Storage and Recovery
- Recycled Water Sources for Water Supply
- In-Delta Diversions
- Water Supply Desalinization
- New Surface Water Supplies

Section 16.3, *Lower San Joaquin Alternatives – Non-Flow Measures*, describes measures that would inform the body of scientific information potentially used to make adaptive implementation decisions under LSJR Alternatives 2, 3, and 4 with adaptive implementation (i.e., non-flow actions). Not any one measure alone could fully inform the body of scientific information, and as such, a combination could occur. Specific combinations of measures cannot be predictably aligned with each alternative because entities could take one or more of these non-flow measures, the combination of measures that entities would take under each alternative is speculative and unknowable. The cost and potential environmental effects of non-flow measures are programmatically evaluated using reference projects, standard assumptions regarding the type and potential location of these measures, and impact mechanisms likely to occur under these measures. The non-flow measures are grouped into habitat restoration, fish passage, and other actions as follows:

- Habitat Restoration
    - Floodplain and Riparian Habitat Restoration
    - Reduce Vegetation-Disturbing Activities in Floodplains and Floodways
    - Gravel Augmentation
    - Enhance In-Channel Complexity
    - Improve Temperature Conditions
- Fish Passage Improvements
    - Fish Screens (screen unscreened diversions in tributaries and LSJR)
    - Physical Barrier in the Southern Delta
    - Removal or Modification to Human-Made Barriers to Fish Migration
- Other
    - Predatory Fish Control
    - Invasive Aquatic Vegetation Control

Section 16.4, *Southern Delta Water Quality Alternatives – Reasonably Foreseeable Methods of Compliance,* describes reasonably foreseeable methods of compliance measures that could be undertaken by the regulated community to comply with the SDWQ alternatives. The cost and potential environmental effects of these methods of compliance are programmatically evaluated using reference projects, standard assumptions regarding the type and potential location of these measures, and impact mechanisms likely to occur under these measures. The methods of compliance in Section 16.4 include:

- New Source Water Supplies
- Salinity Pretreatment Programs
- Desalination
- Agricultural Return Flow Salinity Control
- Southern Delta Temporary Barriers
- Low Lift Pumping Stations

Section 16.5, *Sources of Funding*, provides a brief summary of the federal and state sources of funding for those actions that could occur under the LSJR or SDWQ alternatives.

Section 16.6, *Potential Mitigation Measures*, summarizes potential mitigation measures that could be applied by other lead agencies and responsible entities to reduce potentially significant impacts identified in the environmental evaluations of Sections 16.2, 16.3, and 16.4. These potential mitigation measures were developed based on a review of similar projects. The scope, scale, and location of a particular project would dictate the need for, and the type of, mitigation. While the particular circumstances and location of a project may result in significant and unavoidable impacts post mitigation, lead agencies and entities may be able to fully mitigate impacts to a less-than-significant level (using one or more of the potential mitigation measures identified in Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions,* and Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*). In addition, as required by CEQA (State CEQA Guidelines § 15126.2) lead agencies and entities would describe a reasonable range of alternatives based on project-specific conditions and project-specific objectives, and one of the alternatives may, in and of itself reduce significant environmental impacts. The effectiveness of mitigation is contingent upon several other factors, such as those listed below.

- The ability of lead agencies and entities to implement the mitigation.
- The other responsible agencies involved in the project.
- The thresholds lead agencies use to evaluate the impact.
- Site-specific conditions.

Section 16.6 identifies potential and appropriate mitigation measures for each action by resource. Lead agencies or other entities may fully mitigate impacts to a less-than-significant level (using one or more of the potential mitigation measures identified in this section in Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions,* and Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*). However, depending on project specifics, implementing mitigation measures may not be fully able to reduce significant impacts, and such impacts may remain significant and unavoidable after mitigation. Therefore, until such time that potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Section 16.7, *Cumulative Impacts*, provides a broad cumulative impact discussion for all actions identified in this chapter.

16.2 Lower San Joaquin River Alternatives—Other Indirect Actions

This section describes the actions that affected entities may take to develop alternative water supply sources needed to replace surface water that may no longer be available due to implementation of an LSJR alternative and its associated environmental effects. The actions evaluated include:

- Transfer/Sale of Surface Water
- Substitution of Surface Water with Groundwater
- Aquifer Storage and Recovery

- Recycled Water Sources for Water Supply
- In-Delta Diversions
- Water Supply Desalinization
- New Surface Water Supplies

16.2.1 Transfer/Sale of Surface Water

Reductions in surface water diversions are expected as a result of approving an LSJR alternative and the respective program of implementation. One reasonably foreseeable method to augment a water source is to obtain a surface water supply from another party. General costs and potential environmental impacts associated with obtaining surface water supplies are evaluated below along with a more specific discussion of the costs and potential environmental impacts associated with the City and County of San Francisco (CCSF) developing other alternative water supplies.

Cost Evaluation

General

This analysis focuses on the costs to a water purveyor (e.g., irrigation or water supply district) to obtain alternative surface water supplies. For this potential action, it was assumed that a water purveyor would have either purchased water through contracts, transfers, or implementation of Water Code Section 1485.[1] The duration and cost for purchasing water are subject to many factors, but a useful indicator of water prices is the Environmental Water Account (EWA) Spot Price. A summary of EWA contract sales is listed in Table 16-1, *Environmental Water Account Contract Sales 2002–2004*.

---

[1] Section 1485 of the Water Code provides that any municipality, governmental agency, or political subdivision that produces disposal water meeting the requirements of the appropriate regional board, and that disposes that water in the San Joaquin River, may file an application to appropriate the same amount of water out of the San Joaquin River or the Sacramento-San Joaquin Delta, downstream.

Table 16-1. Environmental Water Account Contract Sales 2002–2004

Year	Buyer	Seller	Type	Quantity (AF)	Price ($/AF)	2010 Nominal Price ($/AF)
2004	Westlands WD	Widren WD	CVP	2,990	$1,500	$1,741

CVP = Central Valley Project.
SWP = State Water Project.
AF = acre-feet.

A water transfer is a change in the way water was originally allocated. A water transfer may change the place of use, the point(s) of diversion, or the purpose of use. A water transfer cannot increase the amount of water a diverter is permitted to use, nor can it change the season when water is diverted. Water transfers can be temporary (i.e., short-term or temporary transfers of 1 year or less), long-term (more than 1 year), or permanent. Water Code Section 1735 and California Code of Regulations Section 811 et seq. allow a water right permittee, licensee, or adjudicated water right holder to file a petition for a long-term transfer of water involving the change in the point of diversion or place or purpose of use with the State Water Board. A summary of long-term transfers is listed in Table 16-2, *Long Term Transfers 1997–2005*.

Table 16-2. Long-Term Transfers 1997–2005

Year	Buyer	Seller	Water Source	Length	Quantity (AF/y)	Price ($/AF)	2010 Nominal Price
2003	City of Lodi	Woodridge ID	NOD	40 years	6,000	$200	$238
2003	Cities of Tracy, Lathrop, Manteca, and Escalon	South San Joaquin ID	SOD	30 years	43,090	$191	$228

2000	Northridge WD	Placer County Water Agency	NOD	15 years	12,000	$435	$565
1997	Metropolitan WD	Arvin Edison WSD	SOD	25 years	50,000	$165	$233
						Average	$310

Source: USBR 2006a.
WD = Water District.
ID = Irrigation District.
WSD = Water Storage District.
AF/y = acre-feet per year.
AF = acre-feet.

Based on the nominal prices shown in Tables 16-1, *Environmental Water Account Contract Sales 2002–2004,* and 16-2, *Long Term Transfers 1997–2005*, a reasonable cost of $1,716 per acre-foot is assumed for an EWA contract sale or $310 per acre-foot for a long-term transfer. These cost estimates are based solely on the projected cost of surface water and do not include capital costs (e.g., conveyance of water from source to point of use), administrative, engineering, or legal costs related to securing the water supply.

CCSF Cost Evaluation

Reductions in surface water diversions could potentially affect CCSF by reducing some portion of their current water supply obtained from the Tuolumne River during a 6-year drought as described in Appendix L, *City and County of San Francisco Analyses*. Under certain LSJR alternatives (i.e., higher unimpaired flow[2] LSJR Alternatives 3 and 4), the San Francisco Public Utilities Commission (SFPUC) may need to obtain water through a water transfer as described in Appendix L. The cost of this water transfer to CCSF depends ultimately on the amount of water needed, purchase price per AF of water, and the duration of the transfer. Details are presented in Appendix L. Annual costs could range between $14 million and $208 million depending on the LSJR alternative (Table L.5-1).

---

[2] *Unimpaired flow* represents the water production of a river basin, unaltered by upstream diversions, storage, or by export or import of water to or from other watersheds. It differs from natural flow because unimpaired flow is the flow that occurs at a specific location under the current configuration of channels, levees, floodplain, wetlands, deforestation and urbanization.

Environmental Evaluation

Summary of Potential Action

A surface water transfer would involve transferring a volume of water from one party to another based upon an agreed upon price and subject to the applicable Water Code and California Code of Regulations requirements where the point of diversion or place or purpose of use of water is proposed to be changed. Only water that is available under applicable operational restrictions, or water rights, can be transferred. Water Code provisions require that surface water transfers must occur (1) without injuring any other legal user of water; (2) without unreasonably affecting fish, wildlife, or other instream beneficial uses; and (3) without unreasonably affecting the overall economy or environment of the county from which the water is being transferred, in the case of transfers using a state or local agency's conveyance facility. Temporary changes of point of diversion, place of use, or purpose of use involving surface water transfers based on post-1914 appropriative[3] water rights must obtain approval from the State Water Board consistent with Water Code Section 1725 et seq. These changes approved under Water Code Section 1725 are exempt from CEQA. Long-term or permanent water transfers would require an analysis of environmental impacts by the agency(ies) selling and transferring water. The State Water Board would be a responsible agency and would review and act on any environmental document. Transfers that require the use of State, regional, or a local public agency's conveyance facilities require the owner of the conveyance facilities (e.g., DWR, USBR) to determine that the transfers will not harm any other legal user of water, will not unreasonably affect fish and wildlife, and will not unreasonably affect the overall economy of the county from which the water is transferred. Both DWR and USBR provide guidance on the requirements and approvals needed to transfer water using their facilities, which generally includes the need for CEQA and/or NEPA documentation and ESA consultation to address fish and wildlife resources.

There are three common types of water transfers: groundwater substitution, cropland idling, and reservoir storage releases (DWR and State Water Board 2015). For water transfers based on groundwater substitution, a water user with surface water diversion rights would forgo diverting surface water and would pump groundwater for the period of the transfer, and in so doing, make the forgone surface water diversions available to a user downstream. Cropland idling water transfers would make water available by reducing the consumptive use of surface water applied for irrigation. This would result in the idling of land that would have been planted during the transfer period in the absence of the transfer. With water transfers involving reservoir storage releases, surface water would be made available for transfer by reservoir storage release when reservoir operations release water in excess of what would be released annually under normal operations, and the water must be released at a time when it can be captured and/or diverted downstream.

Of the three common types of water transfers, those associated with cropland idling or groundwater substitution would be more likely to occur under the LSJR alternatives with or without adaptive implementation within the watersheds of the Stanislaus, Tuolumne, and Merced Rivers. This is because, as the available surface water supplies become more limited, a higher value is placed on the supply. For these two types of transfers, reservoir releases would generally be unchanged. Water transfers involving reservoir storage releases in excess of what would normally be released annually

---

[3] Appropriative rights to surface water are rights to use water that is surplus, or unappropriated, to the needs of riparian owners and prior appropriators and prescriptors.

is less likely to occur especially under the LSJR alternatives because most of the water rights associated with existing reservoirs would be fully used and the reservoir releases would occur regardless of the water transfer (i.e., release of excess water would not be a response to the LSJR alternatives). The number and location of surface water transfers that entities would undertake in response to surface water reductions as a result of approving the LSJR alternatives is speculative and unknowable. Individual agencies or entities would decide whether a water transfer would be suitable for their particular circumstances. The water transfer would have the same maximum diversion and the same season of diversion, but would result in a change to the end use of the water (i.e., the terms and conditions of the right).

Water transfers or sales of stored water by agencies or entities can occur in a manner that either contributes to achieving streamflow requirements or potentially exceeds such requirements. For example, in 2013, OID and SSJID released 80 TAF into the Stanislaus River below Goodwin that exceeded the RPA base flow and pulse flow requirements, causing flows to increase by approximately 2,000 cubic feet per second (cfs) over and above the NMFS RPA New Melones dry year type requirement (NOAA Fisheries 2013). This flow release in late April, described as "water rights water," contributed to the pulse flow requirements at Vernalis under D-1641 that would not otherwise have occurred from any other source. Even though USBR, as the operator of the CVP and New Melones, bears responsibility for meeting the objectives, in times of scarcity the stored water in New Melones and elsewhere in the Stanislaus system is claimed by OID and SSJID as senior and contract entitlements, or appropriative water rights. Thus, in the years 2014, 2015, and 2016, USBR filed Temporary Urgency Change Petitions (TUCPs) for modifications of Vernalis flow requirements due to inability to meet the normal requirements. In 2016, OID and SSJID made another water sale of 75 TAF that contributed to streamflow at Vernalis (State Water Board 2016). The sale of transfer water releases to downstream users may meet multiple benefits including contributing to instream flow requirements in transit.

The Water Supply Improvement Program (WSIP) Program Environmental Impact Report (PEIR) evaluated a water transfer between SFPUC and Modesto Irrigation District (MID) and Turlock Irrigation District (TID) for 25 million gallons per day (mgd) during drought years. The final WSIP PEIR reduced the water transfer to 2 mgd during droughts (SFPUC 2008; BAWSCA 2016). While neither 25 mgd nor 2 mgd may be enough to potentially compensate for the potential need under the LSJR alternatives described in Appendix L, *City and County of San Francisco Analyses*, Section L4, *Water Bank Account Modeling*, this information provides context for the potential to transfer water, the types of impacts associated with the transfer of water, and potentially mitigation measures needed to reduce potentially significant impacts. Further, this is an example of a potentially large consumptive use in the extended plan area that could potentially be satisfied though a water transfer. As such, information and potential mitigation measures from the WSIP PEIR is incorporated below, where appropriate, into the discussion of potential environmental effects associated with a water transfer.

Since the program of implementation would result in conditioning water rights and Clean Water Act Section 401 water quality certification conditions to meet the LSJR alternatives, it is not expected that additional intakes or other construction activities would occur for water transfers because the overall volume of water in the watersheds available for surface water diversions would be reduced, and such transfers would likely use existing infrastructure. Because new infrastructure would likely not be constructed, there would be no construction-related environmental effects resulting from such transfers. If new infrastructure was required, potential environmental effects associated with construction would be similar to those impacts discussed for recycled water sources (Section 16.2.4, *Recycled Water Sources for Water Supply*) and new source water supplies (Section 16.4.1, *New Source Water Supplies*), for example. Groundwater wells could potentially be constructed as part of groundwater substitution transfers, and if this were to occur, potential environmental effects associated with construction and operation would be similar to those impacts discussed for substitution of surface water with groundwater (Section 16.2.2, *Substitution of Surface Water with Groundwater*). SFPUC identified various activities that could be undertaken by the selling party of the water transfer (i.e., MID/TID) in the WSIP PEIR, as summarized in Attachment 1 of Appendix H, *Supporting Materials for Chapter 16*. These various activities generally involve the construction or operation of different facilities and these measures are similar to mitigation summarized in Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions,* for impacts discussed in Section 16.2.2, Section 16.2.4, or Section 16.4.1.

Potential Environmental Effects

The type of potential environmental effects, as well as the magnitude and severity of such effects, associated with surface water transfers would be dependent upon the type of surface water transfer(s), the volume of water transferred, the location and duration of the transfer, and use(s) that the water is being transferred to and from. The type, magnitude, and severity of environmental effects would depend on the transferring entity's ability to absorb a reduction in surface water, depending on the use, for a period of time, and the receiving entities particular demand and the duration of the water transfer needed to satisfy the demand.

The WSE modeling results capture conditions under which a sale or transfer of water could occur because the modeling describes the needed amount of water to meet the LSJR alternatives, the potential reduction in surface water supply, and change in reservoir and river conditions under each LSJR alternative. The potential reduction in surface water supply and changes in reservoir and river conditions would occur regardless of if a water transfer is implemented in response to the LSJR alternatives. However, impacts disclosed in other parts of this document could be relevant to a potential water transfer and would capture the types of effects that could occur, depending on the type, location, and duration of the water transfer and the entities involved. For example, if a transfer is made from an irrigation district to a municipality in order to compensate for a surface water supply shortage imposed by the LSJR alternatives, the potential agricultural effects on the irrigation district would fall within those presented in Chapter 11, *Agricultural Resources*, because the analysis in Chapter 11 assigns all reductions in diversions to agriculture. However, if a municipality receives water from an irrigation district, then the municipality may not have a water supply shortage, as discussed in Chapter 13, *Service Providers,* and the effects potentially would be less than those disclosed in Chapter 13. The evaluation of potential environmental effects resulting from new surface water transfers, in response to the LSJR alternatives is general, references information from other parts of this document as needed, and provides examples of the types of effects that may result from water transfers depending on the type and duration of the transfer because the specifics of each transfer cannot be predicted or known at this time.

SFPUC evaluated a water transfer in the WSIP PEIR. The evaluation determined that impacts would be less than significant on the following resources on the Upper Tuolumne River: streamflow and reservoir water levels, geomorphology, surface water quality, surface water supplies, groundwater, fisheries, biological resources, recreational and visual resources, and energy resources. However, mitigation measures, are required to reduce impacts to a less-than-significant level for terrestrial biological resources and are further discussed below (SFPUC 2008, 2012; ESA+Orion Joint Venture 2012).

Agricultural Resources

Surface water transfers based on cropland idling could affect agricultural uses. If cropland is idled, rotationally fallowed, or deficit irrigated (i.e., reduction in irrigation water applied) regardless of the duration, it would still be considered farmland. However, as discussed in Chapter 11, *Agricultural Resources*, lands designated as Prime Farmland, Unique Farmland, Farmland of Statewide Importance, require irrigation water to meet the designation. If irrigation water was reduced due to a longer-term transfer to non-agricultural use, conditions may result similar to those described in Chapter 11, in the plan area. As a result, agricultural impacts associated with cropland idling would be similar to those described in Chapter 11 (Impact AG-1, LSJR Alternative 2 with adaptive implementation, and LSJR Alternatives 3 and 4 with or without adaptive implementation) and would be significant. Mitigation measures are proposed in Chapter 11, but impacts would be significant and unavoidable.

Air Quality

Surface water transfers based on groundwater substitution could affect air quality by potentially increasing emissions from an increase in groundwater pumping. Power needed for increased groundwater pumping would come from facilities that currently generate power, such as other renewable generating sources or non-renewable sources. The generation of additional power could result in increased criteria pollutant[4] emissions at other power facilities. However, these power facilities are already built and permitted to emit a maximum amount of criteria pollutants. These facilities are required to offset additional power generation by using pollution credit under existing regulations. Therefore, if additional emissions are generated as a result of an increase in groundwater pumping, these emissions would be generated by facilities that are permitted to do so. The permit requirements would ensure that there would be no net increase in pollutant emissions, and would be consistent with the air quality plans because there would be no net increase due to the facility's permit requirements. Impacts would be less than significant.

Surface water transfers based on cropland idling could affect agricultural uses and could affect air quality. Cropland idling would result in reduced irrigation to existing agricultural lands and could result in less water spread over more acreage (such as increased agricultural irrigation efficiencies) or less water applied to the same crops with a potential reduction in yield. If a reduction in irrigation water resulted in a reduction of agricultural acres actively farmed, or a reduction in the intensity of acreage farmed, air quality would potentially benefit (i.e., reduced smoke, fugitive dust, and equipment exhaust emissions) because there would be a reduction in controlled field burning, soil tilling, crop harvesting, and herbicide/pesticide application. In addition, some lands where irrigation is reduced or removed would still retain crop stubble cover, experience vegetative regrowth, or both. This plant matter would serve to reduce the potential for fugitive dust emissions. In the event that some croplands became and remained unvegetated, fugitive dust emissions could increase from wind-blown dust in those areas. However, in those same areas active agricultural activities and

---

[4] The federal and state governments have established ambient air quality standards (AAQSs) for the following criteria pollutants: ozone, carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), particulate matter (both particulate matter smaller than 10 microns or less in diameter [PM10] and particulate matter smaller than 2.5 microns or less in diameter [PM2.5]), and lead.

associated emissions that usually occur on a permanent basis, such as crop burning, soil tillage, crop harvesting, and pesticide and herbicide application would be reduced or eliminated. Therefore it is anticipated that the limited amount of fugitive dust emissions associated with unvegetated areas would be significantly less than the potential long-term emissions associated with active agricultural activities. Consequently, impacts would be less than significant.

Biological Resources

In general surface water transfers for groundwater substitution or cropland idling may have small effects on instream flow, but effects on biological resources are unlikely. Reservoir releases for water supply would likely not go beyond what was simulated by the WSE model and disclosed in Chapter 7, *Aquatic Biological Resources* and Chapter 8*, Terrestrial Biological Resources*. The WSE model releases water needed to satisfy water rights. There would be no releases for diversions beyond what would meet full water rights. Releases would only be greater than what is needed for water rights and instream flow requirements when flood-control releases are needed, which are also included in the model. In addition, in acting on petitions related for water transfers involving the change of point of diversion, place of use or purpose of use, the State Water Board would have to find no unreasonable effects on fish and wildlife or other instream beneficial uses to approve the transfer. Therefore, impacts would be expected to be less than significant in the plan area. However, as discussed in the WSIP PEIR, impacts on terrestrial biological resources in the Upper Tuolumne River, and consequently in the extended plan area, as a result of a water transfer would be potentially significant and could be mitigated to a level of less than significant (SFPUC 2008, 2012; ESA+Orion Joint Venture 2012). These mitigation measures include the following and Attachment 1 of Appendix H, *Supporting Materials for Chapter 16* provides descriptions of the mitigation measures for biological resources associated with the water transfer described in the WSIP PEIR.

- Measure 5.3.6-4a Avoidance of Flow Changes by Reducing Demand for Don Pedro Reservoir Water
- Measure 5.3.6-4b Fishery Habitat Enhancement
- Measure 5.3.7-2 Controlled Releases to Recharge Groundwater in Streamside Meadows and Other Alluvial Deposits
- Measure 5.3.7-6 Lower Tuolumne River Riparian Habitat Enhancement

Under the LSJR alternatives as described in Appendix L, *City and County of San Francisco Analyses*, there could be a need for a larger water transfer or a longer duration than the one described by the WSIP PEIR. If this were to occur, it is anticipated that the mitigation incorporated into the WSIP PEIR for biological resources would be required and SFPUC can and should implement them. It is possible that additional mitigation to protect biological resources may be necessary, but it is infeasible to identify them until project-specific details like the amount of water and the transfer period are known. Until such time that the potential mitigation measures identified in the WSIP PEIR are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Surface water transfers based on cropland idling could affect special-status terrestrial species that use the fields for forage, cover, nesting and breeding and the magnitude and severity of the effect would depend on the duration of the transfer and location and extent of cropland. Similar to what is discussed in Chapter 8, *Terrestrial Biological Resources*, while agricultural lands usually provide greater habitat function when compared to urban or industrial land use types, it is expected that potential idling of active agriculture on some lands would not result in a significant adverse effect on special-status and sensitive species. A reduction of active agricultural management, soil tilling, crop harvesting, and herbicide and pesticide application would potentially benefit special-status species by reducing disturbance to potentially suitable habitat and by reducing overall population and habitat fragmentation. Special-status species within the plan area or extended plan area, such as California tiger salamander (*Ambystoma californiense*), San Joaquin kit fox (*Vulpes macrotis mutica*), Swainson's hawk (*Buteo swainsoni*), and various other California native wildlife populations declined as a result of the conversion of California's annual grasslands to agricultural lands (CDFG 2000; Estep 1989; Loredo et al. 1996; Wheeler 2003; CDFW n.d.). Idle lands could prove valuable in providing habitat connectivity and reducing fragmentation for special-status and sensitive species, depending on the location and the amount left idled. The special-status terrestrial wildlife habitat value for idled fields or pasture lands is typically higher than that of active agricultural fields due to the lack of seasonal anthropogenic disturbances and a reduction of the overall vegetative uniformity (USFWS 2009; USFWS 2010; CDFW 2014; Woodbridge 1991). As such, idling with the resultant halting of mechanized agriculture, pesticide and rodenticide application, and anthropogenic disturbance is unlikely to result in a substantial adverse effect on sensitive or special-status species. Furthermore, crops are regularly idled or fallowed for different periods of time throughout the Central Valley, based on weather conditions, crop conditions, crop pricing, water availability, and other variables that factor into farming profitability and decision making. Finally, when agricultural lands are being idled for surface water transfers, landowners are encouraged to cultivate or retain non-irrigated cover crops or natural vegetation for the purpose of providing habitat to waterfowl and other wildlife. (Water Code, § 1018.) Accordingly, cropland idling water transfers would not likely substantially affect special-status terrestrial wildlife and would likely be less than significant.

Hydrology, Water Quality, Geology and Soils

Surface water transfers implemented through cropland idling would be unlikely to substantially affect surface hydrology and surface water quality or result in substantial flooding, sediment, or erosion. While water quality may depend on the timing of the transfer (e.g., lower flows in fall may reduce water quality), surface water transfers typically must be within the same season. As such, the transfer would not be expected to result in a violation of a water quality standard or a degradation of water quality in a river. Water transfers would follow flood control rules and regulations governing releases from reservoirs and as such would not be expected to result in flooding or levee failure as a result of releases during different times of the year from reservoirs because as a result of following flood control rules and regulations channel capacities would not be exceeded. The potential mobilization of sediment and the potential for stream channel alteration and erosion would be considered low given the flows would be within the historic variation. Impacts would be less than significant.

Cropland idling could result in a reduction of acres designated as Prime, Unique, and Farmland of Statewide Importance, but not beyond what is identified in Chapter 11, *Agricultural Resources*. Less-intensive uses such as dryland farming, deficit-irrigation (i.e., reduction in irrigation), and grazing, could take place on lands that are no longer regularly irrigated. In addition, implementation of water conservation measures could allow less water to service more acres. For example, some crops (e.g., alfalfa and pasture) are able to survive under deficit irrigation where only a portion of the crop water demands are met (Putnam et al. 2015a, 2015b). While there could be a decline in yield for these types of crops or a reduction in the full use of pasture, if the full water requirements were continually restricted, they could still potentially remain in agricultural use (Putnam et al. 2015a, 2015b). Finally, even some fallowed lands would be expected to retain crop stubble cover, ultimately experience vegetative regrowth, or both. This root material and regrowth would stabilize soils and serve to reduce the potential for erosion. Currently, there is active agriculture in all three watersheds of the Stanislaus, Tuolumne, and Merced Rivers and along the LSJR. While the level of connectivity of any specific active agricultural acreage to local drainages (i.e., the ability of loose soil to be delivered to a stream) is unknown, soil disturbance associated with active agriculture practices and irrigation practices currently results in disturbance of topsoil and leads to soil erosion, primarily in the plan area. Active agricultural production, such as soil disturbance resulting from soil tillage, the harvesting of crops, and other activities, is a source of erosion and sedimentation associated (Grismer et al. 2006; O'Geen 2006; Singer 2003). Furthermore, even when soil is not being disturbed, agriculture practices often result in bare soil during the rainy season, which is more susceptible to erosion than soil with vegetation. In contrast, if lands are subject to less intensive use due to a reduction in surface water irrigation (e.g., dryland farming, deficit irrigation, or grazing), there would be no change or potentially less sedimentation and erosion. If active agriculture is reduced, there may be an initial period of increased sedimentation or erosion; however, ultimately, it is expected that the reduced tillage and other activities would result in less sedimentation and erosion. As such, reducing existing levels of soil disturbance associated with active agricultural practices and irrigation could reduce erosion and the loss of topsoil. Thus, the potential for soil erosion and sediment delivery to streams would be reduced overall. Consequently, impacts would be less than significant.

Groundwater

Surface water transfers implemented through groundwater substitution could result in a lowering of groundwater levels if groundwater is pumped in substitution for transferred water and could contribute to impacts on groundwater levels or groundwater quality, as described in Chapter 9, *Groundwater Resources*. Chapter 9 assumes that reductions in surface water supply would be replaced with groundwater pumping up to a maximum amount. Based on this analysis, significant impacts would occur on four primary subbasins (Eastern San Joaquin, Turlock, Modesto, and the Extended Merced[5]). Impacts under a water transfer would be based on where pumping currently occurs if it is transferred from one basin to another. As such, a water transfer may not affect total pumping but could affect total recharge. Alternatively, water transfers could affect in-lieu groundwater recharge activities. Under in-lieu recharge programs, water users increase their surface water deliveries in order to temporarily decrease the amount of groundwater they pump from the aquifer. Decreased pumping allows natural recharge to accumulate in the underground aquifer for use during dry years. If water that otherwise would have been used to facilitate in-lieu recharge were to be transferred, then groundwater would still be pumped, which could result in a lowering of groundwater levels. In which case, impacts would be similar to those described in Chapter 9 and would be significant. Mitigation measures are proposed in Chapter 9. While these measures are feasible, they would require action by other entities. As such, until such time that the potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

---

[5] The *Extended Merced Basin* is used to reference the Merced Basin and a portion of the Chowchilla Basin, as defined in Chapter 9, *Groundwater Resources*.

Recreation and Aesthetics

Surface water transfers implemented through cropland idling or groundwater substitution is unlikely to affect recreational resources at reservoirs or in or adjacent to rivers because reservoir releases for water supply would occur regardless of the water transfer. Furthermore, while impacts on recreational resources may result from the timing of the transfer (e.g., more recreational uses during the summer), surface water transfers typically must be within the same season and, as such, would limit impacts to that particular season. In general, water transfers would not affect reservoir storage, total diversions, or river flows at the downstream ends of the rivers and, as such, would have limited effects on recreation and aesthetics. However, water transfers could result in a change in the point of diversion, which could affect river flows between the old and new points of diversion, particularly in the extended plan area. For example, recreational and aesthetic resources in the Upper Tuolumne River could be affected as a result of lower river flows beyond what was previously identified in the WSIP PEIR. This could occur because of the potential large consumptive use upstream (e.g., CCSF) and the potential point of diversion at which it may leave the system (Upper Tuolumne). Although the water transfer would be limited to the capacity of existing infrastructure and existing agreements, depending on the magnitude and severity of the change in river levels, impacts could be significant. These types of conditions are less likely to occur on the Stanislaus River given the relatively small consumptive uses upstream of New Melones Reservoir; however, conditions would also depend on the size of the transfer. The State Water Board has authority when considering transfer petitions, to ensure that reservoir levels in the upper watersheds do not cause significant recreation and aesthetic impacts, unless doing so would be inconsistent with applicable laws. Even with this type of mitigation, the impact is considered significant, because the mitigation may not fully mitigate the impact in all situations.

Greenhouse Gases and Energy

Surface water transfers implemented through groundwater substitution could result in groundwater pumping up to existing capacities, which could produce GHGs in exceedance of applicable thresholds, as described in Chapter 14, *Energy and Greenhouse Gases*. The incremental increase in GHG production could be small because in the absence of the transfer, the recipients of the water transfer could potentially pump groundwater to meet their needs, and the water transfer may prevent this pumping. However, the amount of GHGs produced would depend on the details of the transfer, including the amount of water transferred and what would occur in the absence of the transfer (e.g., groundwater pumping by the recipient or alternative action that may not produce GHGs, such as water conservation). If water is transferred such that it results in a change in the point of diversion in the extended plan area, it is possible that there could be a reduction in the amount of water passed through the major hydropower reservoirs. This would likely either be a small volume or could pass through alternative hydropower facilities (e.g., CCSF water could pass through Kirkwood and Moccasin powerhouses), thus minimizing the potential effect to hydropower. Depending on the actions of the parties in the absence of a transfer and the amount of water transferred, the impacts associated with GHGs would be similar to what is described in Chapter 14, and GHG emissions would be significant. Mitigation measures are proposed in Chapter 14; however, the measures are deemed infeasible; as such, impacts would remain significant and unavoidable.

Other Resources

In addition to the resources discussed above, a water transfer implemented through cropland idling and groundwater substitution would be unlikely to substantially affect the following resources:

noise, traffic, cultural resources (significant historical, archeological, or paleontological resources, or human remains), hazards and hazardous materials, population and housing, public services, land use, mineral resources, and utilities and service systems; therefore, there would either be no impact or a less-than-significant impact on these resources. A water transfer would not result in activities that generate noise or traffic. Noise or traffic on local roads could overall decrease if crops are idled temporarily or long term. Surface water transfers would not result in activities that could disturb cultural resources or human remains because ground-disturbing activities would not occur and reservoirs would be operated within their existing capacities and historical elevation variation (similar to what is described in Chapter 12*, Cultural Resources*). An increase in the use, transport, or disposal of hazardous materials would not occur because reservoir operations do not handle, transport, or use hazardous materials and use of hazardous materials (e.g., pesticides/herbicides) would not increase (and may actually decline) as a result of cropland idling because there would either be fewer crops in acreage or less overall production due to potentially less water. Conflicts with public airports or private airstrips or airport management plans would not occur because water transfers would not use these services. Depending on the parties associated with the transfer of water, utilities and service systems may benefit because they may receive water needed to meet demand. A water transfer is not expected to result in an increase in population or growth or the development of housing, or the need for housing, because the water would be used to meet existing demand in a particular service area for a particular duration of time. A water transfer is not expected to physically divide an established community because construction is not expected. The demand for public services (police, fire, parks, other facilities) is expected to remain unchanged because the water being transferred would meet existing demand and, as such, demand and use for public services is not expected to increase. A water transfer would likely be used to meet existing demand for an existing land use, and as such it would likely not result in a conflict with land use and would support an existing use. A water transfer would either use the existing river channel, or off river channels below the reservoir to transfer the water, as such, it would not result in a loss of a mineral resource of value to the region and the residents of the state or of local importance. The mineral resources adjacent to an existing river channel would continue to exist and could be accessed depending on the demand and needs of the area. A water transfer would not affect utilities or service systems such as storm water drains, solid waste disposal, and wastewater treatment capacity or exceed wastewater treatment standards because a water transfer would not require the use of these types of facilities or services.

16.2.2 Substitution of Surface Water with Groundwater

Reductions in surface water diversions are expected as a result of approving the LSJR alternatives and the respective program of implementation. A reasonably foreseeable method to augment a surface water supply is to obtain more water from groundwater resources. This could be achieved by additional pumping from existing wells or the development of new groundwater wells. The costs and potential environmental impacts associated with obtaining more water from groundwater resources are evaluated below.

Cost Evaluation

Groundwater well characteristics are varied throughout the plan area and extended plan area. Major variables in developing groundwater resources include: soil type, intended use, distance to distribution system, design flow, depth to standing water, and pumping plant efficiency (Burt 2011). These variables then determine specific groundwater well characteristics, such as what type of well to construct, what type of pump is needed, and what level of water treatment is needed. Table 16-3, *Typical Well Pump Test Data in the San Joaquin Groundwater Basin*, is a description of typical groundwater well characteristics in the plan area.

Table 16-3. Typical Well Pump Test Data in the San Joaquin Groundwater Basin

Parameter	Value
Average Input Power	56 kW
Average Weighted Power per Acre-foot Pumped	478 kWh per acre-foot
Average Weighted Total Dynamic Head	260 feet
Average Weighted Flow Rate	1,099 gallons per minute
Average Weighted Depth from Surface to Standing Water Level	189 feet
Average Weighted Motor Horsepower	116 horsepower
Average Weighted Overall Pumping Plant Efficiency	57%

Source: Table is reproduced from data presented by Burt 2011.

Note: All weighted values are weighted by input power (kW).

kW = kilowatt.

kWh = kilowatt hour.

Groundwater well operations and maintenance costs are highly variable and depend on pump efficiency, depth of the water, cost of electricity, volumetric flow, cost of maintenance, proximity to water distribution system, and staff needed to maintain equipment and facilities. The ideal scenario is one with very efficient pumps (above 70 percent efficiency), that require little maintenance, and that pump from relatively shallow wells.

One of the dominant cost categories in the operations and maintenance budget for groundwater wells is the cost for electricity. Energy costs are published annually by the California Public Utilities Commission (CPUC). Historical electric rates are shown in Table 16-4, *Pacific Gas & Electric Average Bundled Rates by Class 2007–2011*.

Table 16-4. Pacific Gas & Electric Average Bundled Rates by Class 2007–2011

	Cents per kWh					
Rate Payer Class	2007	2008	2009	2010	2011	Average
Agricultural	12.4	13.2	14.2	14.2	14.6	13.7
Small/Medium Commercial	15.1	14.7	16.4	16.9	16.8	16.0
Large Commercial and Industrial	11.5	10.7	12.4	12.6	12.6	12.0

Source: CPUC 2011.

Note: Table is a summary of data presented by the California Public Utilities Commission. Data omitted was for non-pertinent ratepayer classes (e.g., residential) and data from 2000 to 2006.

kWh = kilowatt hour.

To estimate average electricity costs, average weighted power per AF pumped from Table 16-3, *Typical Well Pump Test Data in the San Joaquin Groundwater Basin*, is multiplied by the average cost per kilowatt hour (kWh) shown in Table 16-4, *Pacific Gas & Electric Average Bundled Rates by Class 2007–2011.*[6] Based on information presented in these tables, it is reasonably estimated that groundwater pumping electrical costs in the plan area are between $57.36 and $76.48 per AF. This estimate is for a groundwater well with the characteristics in Table 16-3, *Typical Well Pump Test Data in the San Joaquin Groundwater Basin*. However, pumps that are more efficient or pump from shallower wells would have a lower electrical cost per AF. Conversely, less efficient pumps and deeper wells would have a higher electrical cost per AF.

Energy costs could represent 50–75 percent of a water utility's budget (Flex Your Power 2012). Using the upper end electricity cost calculated above ($76.48 per AF), the total operations and maintenance cost of a groundwater project could be estimated between $101.97 and $152.96 per AF annually.

As part of the California Water Plan Update 1994, the California Department of Water Resources (DWR) analyzed agricultural groundwater production costs. This analysis described the average costs at specific locations within a region, including capital, operations, maintenance, and replacement costs. These costs are presented in Table 16-5, *Typical Agricultural Groundwater Production Costs by Hydrologic Region*, in 1992 dollars and calculated 2010 dollars (DWR 1994).

Table 16-5. Typical Agricultural Groundwater Production Costs by Hydrologic Region

Groundwater Basin	1992 Groundwater Costs ($/AF)	2010 Groundwater Costs ($/AF)
San Joaquin	$30–$40	$48–$64
Tulare Lake	$40–$80	$64–$127
Sacramento River	$30–$60	$48–$95

Source: DWR 1994.

Note: From DWR Bulletin 160-93 Table 7-10, California Water Plan Update Oct 1994; costs normalized by State Water Board staff.

AF = acre-feet.

Agricultural and municipal groundwater production costs are not the same. Costs to municipal water users would likely be higher due to treatment, permitting, overhead, and labor costs not normally realized by agricultural users. Table 16-6, *Example New Groundwater Well Projects Funded by the California Department of Water Resources Integrated Regional Water Management Implementation Grant Program, Phase 1*, presents a summary of representative groundwater projects funded by the Proposition 84 Integrated Regional Water Management Implementation Grant Program, Phase 1 (IRWM). These projects generally construct a new groundwater well or wells, and the associated facilities to connect the well(s) to a municipal water distribution system. Cost estimates also include soft costs, such as the cost of planning, design, permitting, and administration. These projects were awarded funding in 2011, but costs are represented in 2009 dollars (DWR 2011a).

---

[6] As described in Appendix G, *Agricultural Economic Effects of the Lower San Joaquin River Flow Alternatives: Methodology and Modeling Results,* average groundwater pumping costs vary. An average energy price of $0.189/kWh, is used in the Statewide Agricultural Production (SWAP) model (CH2MHill 2012). Many irrigation districts have hydropower projects and receive discounted power.

Table 16-6. Example New Groundwater Well Projects Funded by the California Department of Water Resources Integrated Regional Water Management Implementation Grant Program, Phase 1

Applicant	Project	Project Cost	Operations & Maintenance Budget ($/year)	Production (AF/y)	20-Year Amortized Cost ($/AF/y)
City of Sacramento	E.A. Fairbairn Groundwater Well Project[a]	$1,578,454	$240,000	2,250	$142
Sacramento Suburban Water District	Coyle Avenue and Roseview Park Pump Stations and Treatment Systems Project[b]	$5,735,537	$68,000	5,750	$62

Source: DWR 2011a.

Note: All projects generally construct new groundwater wells and associated pumps and facilities to pump groundwater.

AF/y = acre-feet per year.

[a] As part of the E.A. Fairbairn Groundwater Well Project, the City of Sacramento proposes to construct one well, which would operate 65 percent of the time in an average water year and produce 1,462 AF/y. In dry years the well would operate 100 percent of the time, producing 2,250 AF/y, and in wet years, well operation would be reduced to 15 percent of the time, producing 337 AF/y (DWR 2011a).

[b] Sacramento Suburban Water District's project proposes to construct two wells (one 2,250 AF/y and one 3,500 AF/y well).

Within the plan area and extended plan area, there are many water suppliers that rely on groundwater to meet water demands. The City of Merced relies completely on groundwater to meet municipal water demands. The City of Merced operates 22 active groundwater wells, 340 miles of distribution pipelines, 4 major water storage tanks, and supplies 7 billion gallons of water to its customers annually. The City of Merced's 2010–2011 budget for water services and infrastructure was $41,621,784 (City of Merced 2010). Based on the entire operating budget and total groundwater production, this equates to $1,937.50 per AF.

The City of Merced's groundwater pumping costs represent the high end of costs for this potential action because these costs include water treatment, maintenance of a substantial transmission system, funding a significant capital improvement plan, and 29 staff to plan, manage, operate, and maintain the entire water infrastructure for a city of more than 80,000 people (City of Merced 2010). Smaller water systems, such as those operated by smaller water suppliers and agricultural users, are likely to incur less cost per AF produced.

In areas above the rim dams[7] most groundwater originates from cracks or fractures in hard rocks, such as granite, greenstone, and basalt (County of Mariposa 2014). For those attempting to create new wells the location of fractures and the quantity and quality of groundwater within the fractures underlying any particular parcel is unknown (County of Mariposa 2014). Typical groundwater wells

---

[7] In this document, the term *rim dams* is used when referencing the three major dams and reservoirs on each of the eastside tributaries: New Melones Dam and Reservoir on the Stanislaus River; New Don Pedro Dam and Reservoir on the Tuolumne River; and New Exchequer Dam and Lake McClure on the Merced River.

in the upper watersheds of the Sierra Nevada are drilled to depths of between 150 and 600 feet (ft), include a solid casing or a seal from the land surface to a depth of between 50 and 200 ft, and are either open or have a perforated casing below that depth (Fram and Belitz 2014). Half of all hard rock wells yield 10 gallons per minute (GPM) or less, which is only enough for individual domestic supplies, but if conditions are good they can produce hundreds of GPM (DWR 2011b).

In response to the 2013–2015 drought many additional wells were drilled within the areas above the rim dams of the eastside tributaries. New private well costs were reported ranging from $10,000 to $20,000 (Petersen 2014, James 2015). In 2014 the Lake Don Pedro Community Services District (CSD) proposed construction of a new 72 GPM groundwater well as part of the Yosemite-Mariposa Integrated Regional Water Management Plan. Lake Don Pedro CSD estimated that the well would cost $125,000 to construct and an additional $4,000 annually for maintenance (Lake Don Pedro CSD 2014). In 2015, as the drought worsened, Lake Don Pedro CSD planned construction of three more 100 GPM wells at about $400,000 each, not including potential water treatment costs up to $150,000 per well (Sierra Sun Times 2015). In addition, the Lake Don Pedro CSD reported on June 7, 2016 that another new well had been completed with a total cost of $475,000, mostly funded by grants from DWR and State Water Board (Lake Don Pedro CSD 2016). In Tuolumne County the Twain Harte CSD constructed a 50 GPM well to improve water supply reliability. The well was fully funded by a State Water Board emergency drought grant and the final project cost was $250,000 (Twain Harte CSD 2015).

Environmental Evaluation

Summary of Potential Action

While it is unknown exactly how surface water users could respond to a reduction in their surface water supply as a result of a program of implementation which could limit their water rights, it is reasonable to assume that some amount of groundwater would replace surface water use. Currently, irrigation districts pump groundwater during dry years to supplement surface water diversions. Additionally, some municipalities in the watersheds primarily rely on groundwater and augment their supplies with surface water.

It is possible that some irrigators/irrigation districts and some municipalities may need to construct and operate new groundwater wells. New agricultural or municipal groundwater wells and associated distribution systems could be constructed and operated by existing irrigation districts (e.g., South San Joaquin Irrigation District, Oakdale Irrigation District, Modesto Irrigation District, Turlock Irrigation District, Merced Irrigation District), water districts (e.g., Stockton East Water District, City of Merced, City of Modesto, Stevinson Water District), or individual agricultural users. Both irrigation districts and water districts provide water to agricultural users for irrigation and municipal users for domestic, municipal, and industrial purposes. It is not possible to estimate the location, timing of construction, details of operation, and number of groundwater wells and associated distribution system that may be constructed in the future. However, it is reasonable to assume that new agricultural groundwater wells would be constructed close to the location of use (e.g., agricultural fields). It is likely these would be operated using electricity from the grid, though some of them could use fossil fuel powered generators. It is assumed new municipal groundwater wells would be located within urban or suburban areas to be located near the existing municipal distribution system. They would be operated using electricity and would be required to follow existing drinking water treatment standards. Some new municipal wells may need well head treatment to comply with state and federal drinking water standards. This type of treatment typically would occur at the wellhead site.

Potential Environmental Effects

Construction of either agricultural groundwater wells for primarily agricultural purposes or municipal groundwater wells for domestic, industrial, and commercial purposes may result in minor, temporary, and localized effects typically associated with construction activities, including dust and air quality effects and ground disturbance. Wells would most likely be placed in areas that are already disturbed through agricultural practices or urban development, so the potential natural and cultural resources (significant historical, archeological, or paleontological resources) effects could be minimal.

It is reasonable to assume that any new wells would be professionally installed by municipal water purveyors or agricultural users using best management practices (BMPs) typically used in drilling new wells, minimizing potential cross-connection of aquifers and related potential effects associated with water quality and hazardous materials. Wells are commonly constructed and operated in both rural and urban areas, are a common land use, and are part of the landscape. Well construction may result in minor increases of electricity and fossil fuel use; however, these increases would largely be offset by a reduction in surface water diversions and the associated pumping costs.

Table 16-7, *Potential Environmental Effects of Substituting Surface Water with Groundwater*, summarizes the potential environmental effects associated with new groundwater supplies. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of new groundwater supplies and is referenced in Table 16-7 where appropriate.

Table 16-7. Potential Environmental Effects of Substituting Surface Water with Groundwater

Potential Environmental Effects of Substituting Surface Water with Groundwater	
Resource	Discussion
Aesthetics	• Construction and operation of new agricultural wells would not be expected to significantly affect the visual character or quality of agricultural areas in the plan area or extended plan area because groundwater wells currently exist in agricultural areas and are part of the visual character of agricultural areas. Wells are generally low to the ground and are typically not located in areas where there are sensitive receptors (e.g., recreationists), which would be affected by changes in views or visual character and quality. Agricultural wells are not expected to have operational lights that would generate substantial light or glare. Impacts would be less than significant. • Construction and operation of new municipal groundwater wells would not be expected to significantly affect the visual character or quality of municipal areas in the plan area or extended plan area because groundwater wells are generally low to the ground, may be contained within a small structure to protect above-ground piping infrastructure, and would likely be fenced for security, which could prevent direct views. Operation of new municipal groundwater wells may have operational and safety lights. Impacts would depend on the location of sensitive receptors to potential lighting; however, lights would be expected to follow lighting guidelines and lighting plans of local jurisdictions approving the construction and operation of the wells. Table 16-38 identifies potential mitigation measures lead agencies (e.g., municipal water purveyors) can and should implement to reduce potentially significant environmental effects associated with lighting. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the potential location of possible sensitive receptors and the ability of reducing light and glare.
Agriculture and Forestry Resources	• Construction of new agricultural groundwater wells would result in ground disturbance of agricultural land in and immediately around the well site, and accordingly could result in the temporary impact on Prime or Unique Farmland, or Farmland of Statewide Importance. However, because agricultural groundwater wells would be installed to support the continued use of the land for agriculture, it is likely that the land immediately surrounding the new agricultural well would be returned to agricultural use once the well was constructed. Impacts would be less than significant. • Operation of new agricultural groundwater wells would occur on agricultural land (potentially including Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) and would be used to support the continued agricultural use of the land by supplying irrigation water. The groundwater wells would be expected occupy less than one quarter of an acre per well, and therefore, they would not substantially reduce the area available for crop production. Impacts would be less than significant. • Limited forestry resources occur in the plan area. Although extensive forestry resources occur in the extended plan area (e.g., Stanislaus National Forest), it is expected that construction and operation of new agricultural groundwater wells would occur on land zoned for agriculture and not on land zoned for forest land or timberland.

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	Therefore, construction and operation of new agricultural wells would not be expected to result in conflicts with existing zoning for, or cause rezoning of, forest land or timberland, or result in the loss of forest land or conversion of forest land to non-forest use. Impacts would be less than significant. • Construction and operation of new municipal groundwater wells would not be expected to be located on lands used for agriculture, but rather would be located close to the urban and suburban uses they supply and within proximity to existing water supply infrastructure. If new municipal groundwater wells were located on agricultural land (including Prime Farmland, Unique Farmland, or Farmland of Statewide Importance), they would be located on relatively small areas of land, which would represent only a very small fraction of the existing agricultural land. Impacts would be less than significant. • Construction and operation of new municipal groundwater wells would likely not occur on lands zoned for forest or timberlands because the wells would necessarily be located within proximity to urban and suburban areas and existing water supply infrastructure. Accordingly, the construction and operation of new municipal groundwater wells would not be expected to result in the loss of forest land or conversion of forest land to non-forest use. Impacts would be less than significant.
Air Quality	• The plan area is located in the San Joaquin Valley Air Basin (SJVAB) and partially located in the Mountain Counties Air Basin (MCAB). The extended plan area is also partially located in the SJVAB, MCAB, and the Great Basin Valleys Air Basin (GBVAB). New agricultural or municipal groundwater wells could be located in any or all of these air basins, which generally cover San Joaquin, Stanislaus, Merced, Mariposa, Tuolumne, Calaveras, Alpine, and Madera Counties, because the water supplied by the wells would support agricultural and municipal uses in these areas. The plan area and extended plan area occur within the jurisdictions of the San Joaquin Valley Air Pollution Control District (SJVAPCD), Calaveras County Air Pollution Control District (CCAPCD), the Great Basin Unified Air Pollution Control District (GBUAPCD), Mariposa County Air Pollution Control District (MCAPCD), and Tuolumne County Air Pollution Control District (TCAPCD). SJVAPCD's published guidelines, *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002) do not require the quantification of construction emissions. Rather, the guidelines require implementation of effective and comprehensive feasible control measures to reduce PM10[8] emissions (SJVAPCD 2002). SJVAPCD considers PM10 emissions to be the greatest pollutant of concern when assessing construction-related air quality impacts and has determined that compliance with its Regulation VIII, including implementation of all feasible control measures specified in its *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), constitutes sufficient mitigation to reduce construction-related PM10 emissions to less-than-significant levels and minimize adverse air quality effects. All construction projects must abide by Regulation VIII. This would include the implementation of a Dust Control Plan (Siong pers. comm.). Further consultation with SJVAPCD staff indicates that though explicit thresholds for construction-related emissions of ozone precursors are not enumerated in the *Guide for Assessing and Mitigating Air Quality Impacts*, SJVAPCD considers a significant impact to occur when construction

---

[8] PM10 standard includes particulate matter with a diameter of 10 micrometers (microns) or less.

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	or operational emissions of reactive organic gases (ROG) or nitrogen oxides (NO_X) exceed 10 tons per year or if PM10 or PM2.5[9] emissions exceed 15 tons per year (Siong pers. comm.). For project components within the boundaries of the CCAPCD, a significant impact would occur if project emissions are greater than 150 pounds per day for ROG, NO_X, or PM10 or less, in either the construction or operational periods. No thresholds for other criteria pollutants, their precursors, or GHGs have been established by the CCAPCD. The GBUAPCD does not have adopted quantitative thresholds of significance for criteria pollutants for proposed projects for the purposes of CEQA, although thresholds from neighboring air districts (e.g., CCAPCD, TCAPCD, SJVAPCD) may be used to evaluate impacts within the GBUAPCD. For construction impacts, the GBUAPCD requires that project proponents adopt comprehensive mitigation measures to mitigate fugitive dust impacts. For emissions associated with the operation of stationary sources, the GBUAPCD considers stationary emissions to be less than significant if they are exempt from Rule 202 pursuant to Rule 209-A(B)(2). Rule 209-A identifies emission limits of 250 pounds per day for ROG, NO_X, sulfur oxides (SO_X), and particulate matter.[10] For project components within the boundaries of the MCAPCD, a significant impact would occur if project operational emissions are greater than 100 tons per year for ROG, NO_X, CO, SO_X, PM10, and PM2.5.[11] For project components within the boundaries of the TCAPCD, a significant impact would occur if project emissions are greater than 100 tons per year or 1,000 pounds per day for ROG, NO_X, CO, SO_X, and PM10. • Construction of new agricultural or municipal groundwater wells would likely result in emissions associated with construction equipment and construction vehicles, as well as fugitive dust emissions from ground disturbance. The quantity, duration, and the intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be “diluted” relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since construction of groundwater wells does not require lengthy construction activities, the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the applicable air pollution control districts’ (APCDs)’ regulations and established thresholds. Lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that

---

[9] PM2.5 standard includes particulate matter with a diameter of 2.5 micrometers (microns) or less.

[10] For existing stationary sources that have net emissions of 250 pounds or more per day of particulate matter measured as total suspended particulate, a net increase in emissions of 80 or more pounds per day of PM10 due to modifications requires the use of best available control technology.

[11] No construction-period thresholds have been established by MCAPCD.

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	impacts could be mitigated to less than significant once mitigation measures were implemented given the relatively short term of construction and the limited use of equipment. • New municipal groundwater wells would likely use electric power to operate the pumps because of their expected locations in urban and suburban areas and the expected location in close proximity to existing water supply infrastructure. The need for additional energy to operate additional agricultural well pumps could result in increased criteria pollutant emissions at other power facilities. However, the power facilities that would compensate for the additional power are already built and permitted to emit a maximum amount of criteria pollutants. These facilities are required to offset additional power generation by the use of pollution credit. Therefore, if additional emissions are generated, they would be generated by facilities that are permitted to do so. Impacts would be less than significant. • They may use fossil-fuel powered back-up generators during intermittent emergency situations and their cumulative operation could result in exceedances of the thresholds for SJVAPCD, CCAPCD, GBUAPCD, MCAPCD, and TCAPCD. The potential increase in criteria pollutant emissions could be potentially offset by reductions in surface water diversions that often require the use of electric or fuel pumps to lift water into canals. Operations for new groundwater wells would include facility inspection and maintenance activities and are expected to require similar or less inspection and maintenance than existing municipal groundwater wells. It is expected that new groundwater wells would generally require very little maintenance once construction is completed and only as-needed. Emissions generated during operations would be minimal and would comply with applicable emissions thresholds for SJVAPCD, CCAPCD, GBUAPCD, MCAPCD, and TCAPCD. Impacts would be less than significant. • Operation of new agricultural wells is expected to use electric power to operate the pumps because it is a more economical source of power when compared to fossil fuel power generation; however, if fossil fuel powered generators are used to run the groundwater well pumps, there would be air quality pollutant emissions associated with burning fossil fuels (e.g., PM10) and their cumulative operation could result in exceedances of the thresholds for SJVAPCD, CCAPCD, GBUAPCD, MCAPCD, and TCAPCD. For electric wells, the need for additional energy to operate additional agricultural well pumps could result in increased criteria pollutant emissions at other power facilities. However, the power facilities that would compensate for the additional power are already built and permitted to emit a maximum amount of criteria pollutants. These facilities are required to offset additional power generation by the use of pollution credit. Therefore, if additional emissions are generated, they would be generated by facilities that are permitted to do so. Impacts would be less than significant. • The various APCDs have determined some common types of facilities that have been known to produce odors in the region. These facilities include wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants. Construction and operation of new agricultural and municipal wells would not involve the type of facility identified by, for example, SJVAPCD, as a known odor source (SJVAPCD 2002). Consequently, it is expected new agricultural

Potential Environmental Effects of Substituting Surface Water with Groundwater	
Resource	Discussion
	and municipal wells would not create objectionable odors affecting a substantial number of people. Impacts would not occur. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction and operation of new agricultural and municipal groundwater wells would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction and operation of new agricultural and municipal groundwater wells would not result in growth because new groundwater wells would be constructed and operated to replace a water source that was reduced (e.g., surface water) rather than to increase capacity to serve new water supply users. The construction and operation of new agricultural and municipal groundwater wells would not result in population or employment growth that would result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Accordingly, this impact is less than significant.
Biological Resources	• It is expected that construction and operation of new agricultural groundwater wells would be in agricultural lands or adjacent to agricultural lands in the plan area and extended plan area. Agricultural lands generally have a low potential for special-status plant species, animal species, and habitat because they are actively managed, modified, and disturbed regularly for agricultural activities. Agricultural groundwater wells have a relatively small footprint (e.g., less than 1/4 of an acre) so the wells could be located to avoid special-status plant species, animal species, or habitat if needed. Therefore, there is a low potential for construction and operation of new agricultural groundwater wells to result in a conflict with local policies or ordinances protecting biological resources, or adopted habitat conservation plans or natural community conservation plans. Table 16-38 lists potential mitigation measures that lead agencies (e.g., irrigation districts) can and should implement in the unlikely circumstance that special-status biological resources and habitat are present within a proposed groundwater well site. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the relatively small footprint of disturbance and relatively short term duration of construction. • It is expected that construction and operation of new municipal groundwater wells in the plan area and extended plan area would be in urban and suburban areas close to existing municipal water supply systems (e.g., wells, distribution pipelines and infrastructure, and water supply treatment facilities). These areas are expected to have a low potential for special-status biological resources and habitat (including federally protected wetlands) to occur because these areas are typically developed with impervious surfaces that generally do not support the required habitat. However, any vegetated areas disturbed during construction would be revegetated, as necessary, to avoid

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	impacts on biological resources. Further, because municipal groundwater wells would have a relatively small footprint (e.g., between 1/4 and 1 acre), it is expected the wells could be located to avoid sensitive biological resources and habitats, if needed. Therefore, there is a low potential for construction and operation of new municipal groundwater wells to conflict with local policies or ordinances protecting biological resources, or adopted habitat conservation plans or natural community conservation plans. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipal water purveyors) can and should implement, in the unlikely circumstance special-status biological resources and habitat are present, to reduce potentially significant environmental effects on special-status biological resources and habitat. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the relatively small footprint of disturbance and the potential ability to avoid sensitive biological resources.
Cultural Resources	• Construction of agricultural and municipal groundwater wells would result in ground-disturbing activities. Ground-disturbing activities have the potential to affect significant unknown cultural resources (significant historical, archeological, or paleontological resources) if they exist at the groundwater well site. • Construction and operation of new agricultural groundwater wells in the plan area and extended plan area would likely be located in existing agricultural lands or adjacent to active agricultural lands. Active agricultural lands are regularly disturbed and are considered permanently disturbed after a period of time. Therefore, construction of agricultural groundwater wells would have a low potential to have existing unknown significant cultural resources. Operation of agricultural groundwater wells has a very low potential to affect cultural resources because the wells would only be pumping groundwater. Impacts would be less than significant. • Construction and operation of new municipal groundwater wells in the plan area and extended plan area would likely exist in urban and suburban areas adjacent or within close proximity to existing water supply infrastructure. While it is unknown if cultural resources exist, urban and suburban areas are likely previously disturbed, reducing the potential for significant unknown cultural resources to exist. Impacts would be less than significant. • Operation of municipal groundwater wells has a very low potential to affect cultural resources because the wells would only be pumping groundwater to the potable water distribution systems. Impacts would be less than significant. • As described above, it is expected the new groundwater well sites would be previously disturbed. The depth of sediment disturbance generally would be minimal (e.g., less than 5 ft), with the exception of the exact location of each well, which could disturb sediment up to the depth of the well (e.g., 35–400 ft). Therefore, it is highly unlikely that human remains, typically buried at depths of 6 ft, would be disturbed during construction. If human remains are uncovered during construction, compliance with the State Health and Safety Code would be required. As specified by Section 7050.5 of the Health and Safety Code, and described in Table 16-38, no further disturbance would occur until the county coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code Section 5097.98. If the coroner recognizes the remains to be Native American, he or she would contact the Native

Potential Environmental Effects of Substituting Surface Water with Groundwater	
Resource	Discussion
	American Heritage Commission (NAHC), which would appoint the Most Likely Descendent. Additionally, if the human remains are determined to be Native American, a plan would be developed regarding the treatment of human remains and associated burial objects, and the plan shall be implemented under the direction of the Most Likely Descendent. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because of the relatively small footprint of disturbance and the low potential for human remains to exist.
Geology and Soils	• It is assumed that placement of any new groundwater wells would be done such that the following would be avoided: areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. Any new facilities would be constructed using the latest geotechnical information for the site-specific conditions. Operation of agricultural or municipal groundwater wells would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. Further, changing the volume of groundwater pumped would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Construction of agricultural or municipal groundwater wells would result in limited ground-disturbing activities that could cause soil erosion or loss of topsoil; however, ground-disturbing activities would be limited in duration and geography. Ground-disturbing activities on 1 acre or greater would require preparation and implementation of a Storm Water Pollution Prevention Plan (SWPPP), as required by the Central Valley Regional Water Quality Control Board (Central Valley Water Board). The SWPPP would require soil and erosion control mechanisms. Table 16-38 includes potential mitigation measures that lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement to reduce potentially significant impacts on geologic resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the need to comply with existing storm water pollution and control regulations and the relatively small area of disturbance. • The construction and operation of new agricultural or municipal groundwater wells would not involve constructing or operating septic tanks and, therefore, septic tanks would not be affected by soils incapable of supporting the use of them or other alternative wastewater disposal systems. Impacts would not occur.
Greenhouse Gas Emissions	• Construction of new agricultural and municipal groundwater wells would result in increased GHG emissions because heavy equipment would be used. Similarly, operation of new agricultural and municipal groundwater wells would result in increased use of electricity and fossil fuels for pumping groundwater and for the routine transport of chemicals for those wells requiring a disinfection system (i.e., municipal wells), and, therefore, operations would result in an increase in GHG emissions. The potential increase in GHG emissions could be potentially offset by reductions in surface water diversions that often require the use of electric or fuel pumps to lift water into canals. MCAPCD has established a threshold of significance for carbon dioxide (CO_2) and methane (CH_4) at 500 tons per year. These thresholds of significance are for the operational phase only, as no construction-period thresholds have

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	been established. Although the *Tuolumne County Regional Blueprint Greenhouse Gas Study* (Tuolumne County 2012) identified a project-level greenhouse gas (GHG) emissions threshold of 4.6 metric ton carbon dioxide equivalent (MT CO_2e) per service population (the sum of the number of jobs and the number of residents provided by a project), the threshold is not applicable to the LSJR alternatives because they are not typical of a land use project with associated jobs and residents. Although the SJVAPCD has not established construction-related GHG thresholds, they have identified a level of GHG emissions per year (230 MT CO_2e) below which project-specific increases in GHG emissions would be considered equivalent to zero for CEQA purposes. This amount, known as a zero equivalency level (ZEL), can be used to evaluate construction emissions when they are amortized over a project's anticipated operational lifespan. A project using a 30-year operational lifespan would be considered significant if total construction emissions would exceed 6,900 MT CO_2e (230 MT CO_2e/year* 30 years = 6,900 MT CO_2e), while a project using a 50-year operational lifespan would be considered significant if total construction emissions would exceed 11,500 MT CO_2e (230 MT CO_2e/year * 50 years = 11,500 MT CO_2e). If wellhead treatment was required and depending on the type of treatment and what the water is being treated for, additional energy may be required beyond just pumping requirements. It is possible that substituting surface water with groundwater could result in a potentially significant GHG impact beyond the SJVAPCD ZEL, although the extent to which is unknown. For air districts in which there is no adopted GHG threshold (e.g., CCAPCD), the ZEL for SJVAPCD could be applied. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipal water purveyors) can and should implement to reduce potentially significant impacts related to construction and operation activities and GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted Assembly Bill 32, the California Global Warming Solutions Act of 2006 (AB 32). AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the California Air Resources Board (ARB) is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs • AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions

Potential Environmental Effects of Substituting Surface Water with Groundwater	
Resource	Discussion
	associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Construction activities associated with installing agricultural or municipal groundwater wells would be short term in nature and may involve limited transport, storage, use, and disposal of small quantities of hazardous materials such as fuel and lubricating grease for motorized heavy equipment. Some examples of typical hazardous materials handling are fueling and servicing construction equipment on the site, and transporting fuels, lubricating fluids, solvents, and bonding adhesives. These types of materials are not acutely hazardous, and storage, handling, and disposal of these materials are regulated by local, county, and state laws. Further, the quantities of these materials used during construction would be limited (e.g., less than 100 gallons) because of the short construction timeline. If a hazardous material spill occurred, it could be contained. Table 16-38 lists potential mitigation measures that lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement to reduce potentially significant impacts related to construction activities and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the relatively amount of materials to be used, handled or transported and the short duration of use over the course of construction. • The location of where new agricultural and municipal groundwater wells would be sited is not yet known; however, construction could be located within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. As such, if a school existed within close proximity to construction of new agricultural and municipal groundwater wells, those mitigation measures identified table 16-38 applied to project-specific construction needs would reduce potentially significant impacts during construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962. These sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the Department of Toxic Substances Control (DTSC) for Alpine, Calaveras, Tuolumne, or Mariposa Counties (CalEPA 2016). There were a total of 19 sites identified for Madera, Merced, San Joaquin, and Stanislaus Counties. In addition to these sites identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received cease and desist

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	orders (CDOs) or clean up abatement orders (CAOs), and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 520 leaking underground storage tanks designated as open in these counties (CalEPA 2016). There are approximately 60 facilities in these counties that have received CDOs/CAOs not identified as non-hazardous wastes, domestic wastewater, or domestic sewage (CalEPA 2016). The active and open leaking underground storage tank cases and the CDO/CAO facilities are located throughout these counties. Although it is not yet known where the new agricultural and municipal groundwater wells would be constructed, it is reasonable to assume that groundwater and soil would be tested prior to drilling, given the groundwater would ultimately be used. Thus if soil or groundwater contamination was present the well site would be relocated or modified (i.e., potential wellhead treatment). It is also reasonable to assume these Cortese List sites would not be selected as project sites given that drilling and excavation would be required for well installation and that groundwater could potentially be contaminated. However, if a new agricultural or municipal groundwater well were constructed and operated on a Cortese Site there would be potential for release of existing soil contaminants into soil or groundwater and surface water depending on the type of contaminant and its location, and to other proximal land areas due to ground disturbance during construction, and to water use during operation, of the wells. Were this to occur, impacts would be significant. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. Operation of new agricultural wells would likely not use hazardous materials because agricultural well water does not need to be treated or meet drinking water quality standards. Impacts would not occur. • Operation of new municipal groundwater wells could use a disinfection system, which could require the routine transport, use, storage, and disposal of hazardous materials, such as chlorine gas, sodium hypochlorite, or ammonia. Depending on the location of the new municipal groundwater wells, these materials could be used within 1/4 mile of a school because municipal groundwater wells would likely be within urban and suburban areas to serve existing water users. These materials are commonly used by water purveyors to disinfect groundwater prior to release in the distribution system and comply with safe drinking water standards. Chlorine gas is a non-flammable, non-explosive, and non-combustible gas. However, chlorine gas can form explosive compounds with other chemicals such as ammonia. Chlorine gas exposure can cause severe skin, eye, and lung tissue burns (ATSDR 2016). Sodium hypochlorite (solution of 12.5 percent) is a non-flammable, non-explosive, and non-combustible liquid that can cause skin and eye irritation or burns (HASA MSDS 2011). It is unlikely to be inhaled and is not typically anticipated to be ingested; however, vapor may cause irritation to the upper respiratory tract if inhaled (HASA MSDS 2011). It is not listed by the Occupational Safety and Health Administration (OSHA) as a carcinogen (HASA MSDS 2011). Ammonia (solution of 29 percent) is a non-combustible, non-explosive, and non-flammable liquid (MSDS 2011).

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	However, ammonia vapors are released if the chemical is heated (MSDS 2011). Primary potential routes of entry to humans are dermal (skin) contact and respiratory (breathing). Ammonia vapors are known to be a strong irritant to the eyes, skin, and respiratory tract (MSDS 2011). Generally, municipal wells that use these types of chemicals (i.e., sodium hypochlorite and ammonia) have double containment systems and are located in a spill containment area as required by local fire departments for the management and handling of these types of chemicals. Chlorine gas would be used and stored in accordance with applicable local, county, and state regulations and laws. Further, they would likely be in a locked building, and the water purveyors would be expected to conduct regularly scheduled inspection and maintenance of disinfection systems as they currently do on other municipal wells. Because of these precautionary design features, it is highly unlikely a spill of the sodium hypochlorite or ammonia would occur. However, in the unlikely event of a spill, the primary hazard to humans would be direct contact with skin and respiratory irritation as it currently is with the existing disinfection system. Operation of a new municipal groundwater well could also require onsite treatment and removal of water pollutants (e.g., arsenic), which could also require transportation and potentially disposal of hazardous waste. Disposal of any hazardous waste would be in accordance with applicable federal, state, and local laws and regulations at approved facilities. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipal water purveyors) can and should implement to reduce potentially significant impacts related to operational activities and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The U.S. Department of Transportation (USDOT), the Federal Highway Administration, and the Federal Railroad Administration are the three entities that regulate the transport of hazardous materials at the federal level. The Hazardous Materials Transportation Act governs the transportation of hazardous materials. The regulations under this act are promulgated by the USDOT and enforced by the U.S. Environmental Protection Agency (USEPA). Therefore, all hazardous material deliveries would be tracked, and vehicles would be required to use roadways approved for the transportation of hazardous materials. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipal water purveyors) can and should implement to reduce potentially significant impacts related to operational activities and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • As specified in California Code of Regulations, title 19, division 2, chapter 4.5 (California Accidental Release Prevention [CalARP] Program Detailed Analysis), all businesses that handle specific quantities of hazardous materials are required to prepare a California Accidental Release Prevention Program Risk Management Plan (CalARP RMP). The CalARP RMP is the state equivalent of the federal RMP. CalARP RMPs include the preparation of an offsite consequence analysis of worst-case release of the stored chemicals and the preparation of emergency response plans, including coordination with local emergency response agencies. CalARP RMPs are required to be updated at least every 5 years and when there are significant changes to the stored chemicals. Additionally, water

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	purveyors using these types of chemicals for their disinfection systems would be subject to the Hazardous Materials Release Response Plans and Inventory Act (also known as the Business Plan Act), which requires an entity or business using hazardous materials to prepare a business plan describing the facility, inventory, emergency response plans, and training programs. These plans must be submitted to the local Certified Unified Program Agency (CUPA) (e.g., San Joaquin County, Stanislaus County, Merced County, or local fire departments). Water purveyors must also comply with the CalARP Program and prepare an RMP, if required. The RMP is a detailed analysis of the potential accident factors and mitigation measures that can be implemented to reduce accident potential. The RMP may include items such as safety information, hazard review, operating procedures, emergency response plan, training requirements, and compliance audits. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipal water purveyors) can and should implement to reduce potentially significant impacts related to operational activities and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • It is unlikely that a well for potable water purposes would be drilled on a hazardous materials site. Prior to drilling the well, the lead agency (e.g., municipal water purveyors) would need to conduct subsurface studies to determine the site suitability and test the soil and groundwater for contamination. Impacts would be less than significant. • Construction and operation of new agricultural or municipal groundwater wells would not be a hazard or cause safety concerns to public or public use airports or private airstrips due to the low profile of the wells. As such, construction and operation of new agricultural or municipal groundwater wells would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Construction and operation of new agricultural or municipal groundwater wells would not physically interfere with an adopted emergency response plan or emergency evacuation plan because they would not be located within roadways. Impacts would not occur. • Construction and operation of new agricultural or municipal groundwater wells would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur.
Hydrology and Water Quality	• Construction of agricultural or municipal groundwater wells could result in temporary changes to storm water drainage, the existing drainage pattern of the site, erosion, or runoff associated with typical construction activities, such as grading or preparation of land. Operation of new agricultural or municipal groundwater wells would likely not create or contribute runoff water that would increase the capacity of existing or planned storm water drainage systems, modify existing drainage patterns, increase erosion, or increase runoff because the wells would likely not result in substantial increases in impervious surfaces (e.g., concrete pads), which are typically associated with modification of drainages, erosion, and runoff. As discussed in the Geology and Soils section of this table, water purveyors would be required to prepare and implement a SWPPP for disturbed areas of over 1 acre. In addition, as discussed in this table for Hazards and Hazardous Materials, construction of new agricultural

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	and municipal groundwater wells may involve the limited transport, storage, use, and disposal of hazardous materials, which, if spilled, could have adverse effects on water quality depending on the location and magnitude of the spill. However, storage, handling, and disposal of these materials is regulated by local, county, and state laws, and the quantities of these materials used during construction would be small (e.g., less than 100 gallons) and construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained and, as such, violations of water quality standards are not expected to occur. Table 16-38 lists potential mitigation measures that lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the relatively small area of disturbance and the short duration of construction. • The location of all new agricultural and municipal groundwater wells are as yet unknown. However, if the wells were located within a 100-year flood hazard area, the wells and any structure protecting the wells would have a low potential to impede or redirect flood flows given that these structures would be relatively low profile. Further, construction and operation of new agricultural and municipal wells would not affect housing and therefore would not place housing within a 100-year flood hazard area. Construction of agricultural and municipal wells would not result in flooding or otherwise cause flooding. Impacts would not occur. • New agricultural and municipal wells would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to flood hazard locations. As such, construction and operation of new wells would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Well construction is regulated by DWR (DWR 2012). The legislature authorized the establishment of well standards (DWR Bulletins 74–81 and 74–90) and regulations pertaining to the construction, alteration, and destruction of wells. Water Code Section 13750.5 requires that those responsible for the construction, alteration, or destruction of water wells, cathodic protection wells, groundwater monitoring wells, or geothermal heat exchange wells possess a C-57 Water Well Contractor's License. This license is issued by the Contractors State License Board. Water Code Section 13751 requires that anyone who constructs, alters, or destroys a water well, cathodic protection well, groundwater monitoring well, or geothermal heat exchange well must file with DWR a report of completion within 60 days of the completion of the work. Further, most counties and some cities have adopted ordinances to protect groundwater quality (e.g., where groundwater wells would likely be drilled in San Joaquin, Stanislaus, and Merced Counties). These ordinances require permits to be issued before a well can be drilled or modified. Thus, adequate well drilling procedures are established to avoid cross connections between aquifers. Avoiding aquifer cross connection ensures the wells and the aquifers are appropriately protected and do not result in groundwater contamination. Impacts would be less than significant.

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	• Construction new agricultural and municipal groundwater wells would not result in a substantial depletion of groundwater supply because construction activities would not use substantial amounts of water. Impacts would not occur. • Construction of a single well only requires the water used by the drilling equipment and the water to test the well and pump prior to operation (DWR 2012). Impacts would be less than significant. • The State Water Board's Division of Drinking Water (DDW) regulates drinking water supplies in the state of California, including municipal groundwater wells. Drinking water related statutes are from the Education Code, Food and Agricultural Code, Government Code, Health and Safety Code, Public Resources Code, and Water Code. Regulations are from Title 17 and Title 22 of the California Code of Regulations. The DDW permits all water purveyors in the state with water supply permits. Therefore, municipal wells are not expected to result in a reduction or change in water quality, and would not violate water quality standards. Impacts would be less than significant. • Groundwater wells are not typically located on the side of steep slopes. New agricultural or municipal groundwater wells would likely be located in flat areas. Therefore, the locations would not support mudflows, which typically need steep slopes and large amounts of precipitation to occur. Additionally, the wells would not be adjacent to the ocean and would not be affected by tsunamis. Impacts would be less than significant. • Increases in localized groundwater pumping could occur if municipal or agricultural providers pump groundwater instead of performing some other indirect action (e.g., developing recycled water sources or reducing demand). However, increases in localized groundwater pumping could result in similar impacts on groundwater and geologic resources to those broadly discussed by groundwater subbasin in Chapter 9, *Groundwater Resources*. Table 16-38 lists potential mitigation measures that lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Operation of new agricultural and municipal groundwater wells would not need the construction of additional storm water drains because the amount of impervious surfaces that could generate storm water runoff is anticipated to be very small. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction of new agricultural and municipal groundwater wells is not expected to occur in close proximity to a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of new agricultural or municipal groundwater wells could result in a substantial degradation of water quality.

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
Land Use and Planning	• Construction and operation of new agricultural or municipal groundwater wells would not physically divide an established community because wells and well fields are generally relatively small in scale (e.g., less than 1 acre) and would likely be located in existing available and open land (e.g., existing agricultural lands or land not being used for homes). Impacts would be less than significant. • Agricultural and municipal infrastructure, such as groundwater wells, are typically allowed in different land use designations (e.g., public facilities, residential, industrial) and different zoning designations. If the groundwater wells were inconsistent with applicable land use plans, policies, or regulations, an amendment or variant from the local jurisdiction approving the discretionary action associated with the groundwater wells would be required prior to approval and construction of the well. If no discretionary actions occur as a result of the construction or operation of new groundwater wells, then it is assumed those wells would not result in a conflict with local land use plans, policies, or regulations. Impacts would be less than significant. • Potential conflicts with applicable habitat conservation plans or natural community conservation plans, or other plans, policies and regulations protecting biological species and resources are evaluated in the Biological Resources section of this table.
Mineral Resources	• Construction and operation of new agricultural or municipal groundwater wells would have a very low potential to result in the removal or inability to access state or locally designated mineral resource areas in the plan area and extended plan area. This is because the groundwater well sites would be relatively small, and they are expected to be located either within or in close proximity to agricultural lands or within urban and suburban areas. If the groundwater wells are located within a state or locally designated mineral resource area, the drilling and operation of a groundwater well would not permanently remove access to a mineral resource as there would be other locations around the groundwater well that could provide access to the mineral resource.
Noise	• Construction of agricultural groundwater wells could generate temporary noise. There is low probability that sensitive receptors (e.g., residential homes, hospitals, schools) would be located within close proximity to experience the temporary noise generated by the drilling of a groundwater well because these wells would be constructed either within agricultural lands or immediately adjacent to the lands. Construction of these wells would not result in ground-borne vibrations because vibrations are typically associated with pile driving or heavy industrial processes, and construction of groundwater wells do not require these types of activities. Impacts would be less than significant. • Construction of municipal groundwater wells could generate temporary noise. It is likely new municipal wells would be drilled in areas with suitable land use designations and zoning for infrastructure (e.g., agriculture or public facilities). However, the location of any new well would be speculative and sensitive receptors to noise (e.g., residential homes, hospitals) maybe located within proximity. As such, construction activities could temporarily expose people to noise levels in excess of standards established the local general plan, noise ordinance, or applicable standards of other agencies. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipal water purveyors) can and should implement to reduce potentially significant impacts related to noise during construction. Until such time that these potential mitigation measures are implemented, the impacts would

Potential Environmental Effects of Substituting Surface Water with Groundwater	
Resource	Discussion
	remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the location of potential sensitive receptors because of the relatively short duration of construction. • The operation of agricultural or municipal groundwater wells may generate temporary noise when the groundwater well is pumping. However, the wells do not pump continuously. It is anticipated there would be low probability that sensitive receptors (e.g., residential homes, hospitals, schools) would be located within close proximity to experience the temporary operating noise generated. Municipal groundwater wells are often enclosed in some type of small low-profile structure or enclosed by a fence that would reduce the temporary operating noise of the well. However, the location of any new agricultural or municipal well would be speculative and it may be located near receptors sensitive to noise (e.g., residential homes, hospitals, schools, parks). Table 16-38 lists potential mitigation measures that lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement to reduce potentially significant impacts related to noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented during operation depending on the potential location of possible sensitive receptors. • The construction and operation of new agricultural or municipal groundwater wells would not bring people within close proximity to an airport or expose people to airport noise. Impacts would not occur.
Population and Housing	• The construction and operation of new agricultural or municipal groundwater wells would not involve the construction of new homes or businesses, extension of roads, or other actions that may induce substantial property growth in an area. Construction and operation of new agricultural or municipal groundwater wells would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people to the plan area and extended plan area. Finally, new groundwater wells would be constructed and operated to replace a water source that was reduced (e.g., surface water) rather than increasing capacity to serve new water supply users. Impacts would be less than significant. • The construction and operation of new agricultural or municipal groundwater wells would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the wells would be located in relatively small, isolated areas. New groundwater wells are likely be located on existing vacant land (e.g., within or in close proximity to agricultural lands or within or adjacent to existing drinking water supply infrastructure). Impacts would be less than significant.

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, the construction and operation of new agricultural or municipal groundwater wells would not involve an increase in population or housing in the plan area and extended plan area. In addition, new agricultural or municipal groundwater well projects would not include proposals for new housing or increase demands for school services or facilities. Impacts would not occur.
Recreation	• Recreational facilities are not typically located in agricultural fields, and the construction and operation of an agricultural groundwater well would not result in impacts on recreational facilities. In addition, construction and operation of new agricultural wells would not lead to the construction or expansion of recreational facilities in the plan area and extended plan area, which might have an adverse physical effect on the environment. Impacts would not occur. • New municipal groundwater wells would likely be located within close proximity to existing municipal wells or existing municipal distribution systems so that potable water can be distributed. If recreational facilities were located within very close proximity to the construction location, construction of municipal wells may affect the recreational facilities (e.g., construction noise, dust). However, it is expected that construction would be limited in duration (e.g., less than 3 months) and space because municipal wells typically have small dimensions. Construction and operation of new municipal groundwater wells would not increase the use of existing parks or recreational facilities in the plan area and extended plan area, and would not result in the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Construction of new agricultural or municipal groundwater wells could result in additional trips associated with construction workers. Agricultural groundwater wells would likely be located within or adjacent to agricultural lands and generally these areas do not experience traffic congestion. New municipal groundwater wells may be located in urban and suburban areas within the plan area and extended plan area that could already experience some traffic congestion. However, the temporary increased traffic during construction would have a low potential of exceeding level of service standards on roadways because of the relatively few trips anticipated and the relatively short construction time. Table 16-38 lists potential mitigation measures that lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement to reduce potentially significant transportation and traffic impacts related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented during construction given the temporary nature of construction and the low potential for exceeding level of service standards. • Construction and operation of new agricultural or municipal groundwater wells would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.

Potential Environmental Effects of Substituting Surface Water with Groundwater

Resource	Discussion
	• Operation of new agricultural groundwater wells would not generate additional trips beyond those required to maintain and farm the active agricultural lands. Municipal groundwater wells may generate maintenance trips, but it is likely they would not be a substantial addition to the trips already being incurred by the road system by water purveyors who maintain existing wells. Impacts would be less than significant.
Utilities and Service Systems	• Construction and operation of new agricultural or municipal groundwater wells in the plan area and extended plan area would not affect the ability to meet the wastewater treatment requirements of the Central Valley Water Board because the wells would not involve the discharge of recycled water from a wastewater treatment plant (WWTP). Additionally, because a well does not generate wastewater, it would not affect the treatment capacity of an existing WWTP. Impacts would not occur. • Construction and operation of new agricultural or municipal groundwater wells could involve the construction of water treatment facilities in the form of wellhead treatment at municipal wells. Environmental effects associated with onsite treatment facilities are discussed in this table for all resources (i.e., Aesthetics through Transportation and Traffic). Table 16-38 lists potential mitigation measures that lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement to reduce potentially significant construction or operation impacts on all environmental resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Construction and operation of new agricultural or municipal groundwater wells would not need the construction of additional storm water drains because the amount of impervious surfaces that could generate storm water runoff is anticipated to be very small. Impacts would be less than significant. • Construction and operation of new agricultural or municipal groundwater wells would not need new entitlements for water supply. Impacts would not occur. • The construction and operation of new agricultural or municipal groundwater wells in the plan area and extended plan area is not expected to generate substantial volumes of solid waste and would be required comply with all state requirements regulating solid waste. Impacts would be less than significant.

16.2.3 Aquifer Storage and Recovery

Reductions in surface water diversions are expected as a result of approving an LSJR alternative and the program of implementation. A reasonably foreseeable method to augment a water supply system is to store water in an aquifer for later use. Aquifer storage and recovery is the process of storing surface water in a groundwater basin so it is available later for extraction and beneficial use. This process augments groundwater basins by allowing storage of any excess available surface water so it can be used later when it would otherwise be unavailable. Typical storage components are gravity recharge basins or injection wells that move water under pressure from the surface to an underground aquifer. Typical water extraction components are wells that pump groundwater from the aquifer and send the water to an existing treatment plant or directly into a distribution system for beneficial use. Aquifer storage and recovery may also be a source of water for underground storage and surface water diverted under a specific basis of right. The costs and potential environmental impacts associated with obtaining more water from aquifer storage and recovery are evaluated below.

Cost Evaluation

Table 16-8, *Groundwater Recharge Projects Funded by the California Department of Water Resources Integrated Regional Water Management Implementation Grant Program, Phase 1*, identifies recently funded groundwater recharge projects. These projects are from the IRWM. The costs identified in Table 16-8 include planning, design, permitting, land acquisition/rights of way, construction, and administrative costs in 2009 dollars for the Consolidated Irrigation District's South and Highland Basin Project (DWR n.d.).

Table 16-8. Groundwater Recharge Projects Funded by the California Department of Water Resources Integrated Regional Water Management Implementation Grant Program, Phase 1

Applicant	Project	Project Cost	Operations & Maintenance Budget ($/year)	Production (AF/y)	20-Year Amortized Cost ($/AF/y)
Joshua Basin Water District	Joshua Basin Water District Recharge Basin and Pipeline	$8,028,000	$75,000	2,000	$238
Consolidated Irrigation District	South and Highland Basin Project	$4,627,000	$164,500	2,500	$158

Sources: Mojave Water Agency 2010; DWR n.d.

AF/y = acre-feet per year.

Environmental Evaluation

Summary of Potential Action

A standard aquifer storage and recovery approach could utilize existing irrigation canals and existing agricultural fields (primarily during the off-irrigation season of October–March, when the canals and fields have capacity) to release an unspecified volume of water such that it would percolate through the unlined canals and soil in the fields to recharge the groundwater. It is expected there would be no construction associated with this type of aquifer storage approach because existing canals and agricultural fields are suitable for allowing water to percolate into the ground and existing groundwater wells would be suitable for extraction. Excess surface water would be used to recharge the aquifer in certain months or water year types. It is anticipated that this type of standard aquifer storage and recovery approach could be instituted by agreements between irrigation districts and their members who privately own agricultural land or irrigation districts, members who own agricultural land, and local governments, local water purveyors, or groundwater management districts. Depending on the water users, their agreements, the surface water that is diverted, a particular users' right to store water would influence their ability to do so.

Another aquifer storage and recovery approach also could be established using active groundwater recharge with storage components, such as wells that move water under pressure from the surface to an underground aquifer, and extraction components, such as wells that pump groundwater from the aquifer and send the water to an existing treatment plant or directly into a distribution system for beneficial use. Assuming active groundwater recharge is used, the activities and infrastructure associated with an aquifer storage and recovery program would be similar to the activities described in Section 16.2.2, *Substitution of Surface Water with Groundwater*. Although aquifer storage projects sometimes include infiltration basins specifically designed and constructed to facilitate rapid infiltration to underground storage, constructing infiltration basins would likely remove agricultural land from production. Therefore, this is not anticipated to occur and the environmental effects of constructing infiltration basins are not analyzed.

Summary of Potential Environmental Effects

Development of a more standard aquifer storage and recovery program would reduce changes in groundwater levels and new facilities required to recover the stored water are not anticipated. Potential environmental effects associated with the development of a standard aquifer storage and recovery approach in the plan area and extended plan area are described in Table 16-9, *Potential Environmental Effects of Aquifer Storage and Recovery*. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, at the end of this chapter, lists potential mitigation measures associated with the development of this action and is referenced in Table 16-9 below where appropriate.

Development of an active groundwater recharge approach would result in impacts similar to those identified in Section 16.2.2, *Substitution of Surface Water with Groundwater*, and Table 16-7, *Potential Environmental Effects of Substituting Surface Water with Groundwater*. This is because active groundwater recharge could require the construction and operation of groundwater wells and distribution pipeline, resulting in similar environmental effects as those described in Table 16-7 for the construction and operation of municipal groundwater wells. Impacts associated with developing wells to facilitate aquifer storage and recovery are identified in Table 16-7 and are not incorporated into Table 16-9, *Potential Environmental Effects of Aquifer Storage and Recovery*.

Table 16-9. Potential Environmental Effects of Aquifer Storage and Recovery

Potential Environmental Effects of Aquifer Storage and Recovery	
Resource	Discussion
Aesthetics	• Aquifer storage would not necessarily involve physical alteration of existing agricultural lands or canals in the plan area and extended plan area. Aquifer storage could change the volume of water in canals and on agricultural lands during the winter season. This would not represent a substantial degradation to the visual character or quality of agricultural lands because viewers are frequently subjected to change under active agricultural practices. Aquifer storage and recovery is not anticipated to involve lights or glare. Impacts would not occur.
Agriculture and Forestry Resources	• Aquifer storage would involve adding water to canals or flooding agricultural lands (potentially including Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) in the plan area in the winter months. There are limited agricultural resources in the extended plan area and no designated Prime Farmland, Unique Farmland, or Farmland of Statewide Importance. The agricultural lands are already used for agricultural purposes. Using agricultural lands for groundwater recharge during the winter would not modify its agricultural purpose during the irrigation season (generally April–September). Additionally, the groundwater recharge would support agricultural use because stored water could be pumped from the aquifer to irrigate agricultural fields. Impacts would be less than significant. • Aquifer storage would likely occur on agricultural lands and not on land zoned for forest land or timberland, because those lands wouldn't be particularly suited to support aquifer storage and recovery. Therefore, aquifer storage would not be expected to result in conflicts with existing zoning for, or cause rezoning of, forest land or timberland, or result in the loss of forest land or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Aquifer storage and recovery is not expected to affect air quality because aquifer storage would not include activities (e.g., construction activities) that generate air quality emissions. Changing the timing and/or volume of water in existing canals and agricultural fields would not have the potential to generate air quality emissions. While there may be some energy required as part of lift pumps and stations, the additional energy would not be beyond what is currently experienced when operating the canals. Impacts would be less than significant. • The various APCDs have determined some common types of facilities that have been known to produce odors in the region. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants. Construction and operation of an aquifer storage and recovery project would not involve the type of facility identified by, for example, SJVAPCD, as a known odor source (SJVAPCD 2002). Consequently, it is expected aquifer storage and recovery would not create objectionable odors affecting a substantial number of people. Impacts would not occur. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean aquifer storage and recovery would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions

Potential Environmental Effects of Aquifer Storage and Recovery

Resource	Discussion
	budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. Aquifer storage and recovery would not result in growth because it would be operated to replace a water source that was reduced (e.g., surface water) rather than to increase capacity to serve new water supply users. Aquifer storage and recovery would not result in population or employment growth that would result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Accordingly, this impact is less than significant.
Biological Resources	• Aquifer storage would likely occur during wet years when there is extra water and during the winter when fish spawning is generally not occurring. Therefore, aquifer storage is not anticipated to affect special-status fish species or their habitat or the migration of such species. Aquifer storage is not anticipated to conflict with local policies or ordinances in the plan area and extended plan area protecting special-status fish species, adopted habitat conservation plans, or natural community conservation plans. Impacts would be less than significant.
	• An aquifer storage and recovery project is expected to flood agricultural lands in the plan area and extended plan area that might not otherwise be flooded during certain times of year (e.g., nonagricultural seasons, such as winter). Additionally, it could use existing canals that have additional capacity during the irrigation season, typically April–September. Agricultural lands generally have a low potential for special-status plant species, animal species, and habitat (including federally protected wetlands) because they are actively managed and are modified and disturbed regularly by agricultural activities. Further, flooding agricultural fields during the nonagricultural seasons may provide habitat to bird species migrating during this time period. Therefore, aquifer storage is not anticipated to conflict with local policies or ordinances protecting biological resources or conflict with an adopted habitat conservation plan or natural community conservation plan. Impacts would be less than significant.
Cultural Resources	• Aquifer storage and recovery would require no construction or ground disturbance. Aquifer storage and recovery would use existing canals and fields to allow surface water to percolate into the ground and recharge existing groundwater basins. This recharge method is expected to change the volume of water in existing irrigation canals and fields. There is a low potential for cultural resources (significant historical, archeological, or paleontological resources) to exist in these locations due to excessive and regular disturbance of land in the agricultural fields and due to the primary use of the canals to convey irrigation water. Impacts would be less than significant. • Since aquifer storage and recovery would have no ground-disturbing activities, it would not result in disturbance of unknown or known human remains. Impacts would not occur.

Potential Environmental Effects of Aquifer Storage and Recovery	
Resource	Discussion
Geology and Soils	• Changing the volume of water in a canal or on agricultural land in the plan area and extended plan area would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, unstable geologic units, expansive soils, or landslides. Additionally, changing the volume of water in a canal or on agricultural land would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur. • To allow surface water to percolate into the aquifer, the additional water must be kept in the canals and agricultural fields. Surface water flows that could result in soil erosion would not be released into the canals or agricultural fields, and the water released would be of an appropriate volume and timing to allow for groundwater recharge. Therefore, water erosion and runoff is unlikely to occur. Impacts would not occur. • Aquifer storage and recovery would not involve constructing or operating septic tanks. Further, aquifer storage and recovery projects would be planned away from existing septic tanks so that they would not be affected by soils incapable of supporting their use or other alternative wastewater disposal systems. Impacts would not occur.
Greenhouse Gas Emissions	• It is not expected that aquifer storage and recovery would generate GHG emissions because it would not involve physical changes (i.e., construction) and is not expected to result in activities that would generate GHGs. While there may be some energy required as part of lift pumps and stations, the additional energy would not be beyond what is currently required when operating the canals. Impacts would be less than significant.
Hazards and Hazardous Materials	• Aquifer storage and recovery would not involve transporting, using, or disposing of hazardous materials nor would it emit hazardous emissions because water and changing the volume of water in different areas is not considered hazardous. In addition, aquifer storage would not result in the reasonably foreseeable upset or accident conditions associated with hazardous materials. Impacts would not occur. • Aquifer storage and recovery has no potential to affect public or public use airports or private airstrips, or airport safety because it would not result in building structures near airports. Accordingly, aquifer storage and recovery would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Because hazardous materials, substances or waste would not be handled for implementation of aquifer storage and recovery, there would be no related impact on schools within one-quarter mile of where aquifer storage and recovery would occur. Impacts would not occur. • An aquifer storage and recovery project is expected to flood agricultural lands in the plan area and extended plan area. As such, given the location these projects would not occur on a hazardous materials site list compiled under Government Code Section 65962 (i.e., Cortese Site List). Impacts would not occur. • Aquifer storage and recovery would not involve building structures, construction of housing or an increase in population Therefore, there would be no wildland fire threat to people or structures from aquifer storage and recovery implementation.

Potential Environmental Effects of Aquifer Storage and Recovery

Resource	Discussion
	• Canals and agricultural fields are located in areas that typically do not have emergency response plans or emergency evacuation plans. Therefore, aquifer storage and recovery would not impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. Impacts would not occur.
Hydrology and Water Quality	• While aquifer storage could result in a change in drainage such that inundation of agricultural lands may occur more frequently, aquifer storage would likely not generate more runoff relative to existing conditions. Therefore this action would not result in the capacity of existing or planned storm water drainage systems being exceeded. Holding water for infiltration is designed such that agricultural lands hold the water so it can percolate into the groundwater basin. Water flow in canals and water volume in agricultural fields would be controlled to prevent runoff. Water quality standards would be maintained because any discharge would have to comply with the Central Valley Water Board's water quality requirements. Impacts would be less than significant. • Aquifer storage and recovery would not involve the construction or operation of new structures. Existing infrastructure would be used to release surface water during wet years into agricultural lands and canals. Surface water would be used to inundate agricultural lands otherwise unused and allowed to percolate without flooding other areas. Therefore, aquifer storage is not expected to result in flooding or result in a flood risk to people or structures. Impacts would be less than significant. • Aquifer storage and recover would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to flood hazard locations. As such, aquifer storage and recovery would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Because aquifer storage and recovery would not involve the construction or operation of new structures, flood flows would not be impeded or redirected even if this action were to take place within a 100-year flood hazard area. In addition, aquifer storage and recovery would not affect housing and therefore would not place housing within a 100-year flood hazard area. Impacts would not occur. • Aquifer storage is intended to augment the water supply, and would result in an increase in groundwater recharge, which would be beneficial. Aquifer storage and recovery is not expected to result in increased groundwater pumping beyond the volume of water stored as a result of recharge. Impacts would be less than significant. • Aquifer storage would be located in areas of flat relief because active agricultural lands and canals are typically not located on the side of steep slopes. The locations would not be expected to support mudflows, which typically need very steep slopes and large amounts of precipitation to occur. Also, these areas would not be adjacent to the ocean or affected by tsunamis. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Aquifer storage and recovery is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which aquifer storage and recovery could result in a substantial degradation of water quality.

Potential Environmental Effects of Aquifer Storage and Recovery

Resource	Discussion
Land Use and Planning	• Aquifer storage and recovery is not expected to physically divide an established community because the canals and agricultural lands already exist. It is anticipated that aquifer storage and recovery would support agricultural land use and zoning designations as it would not remove agricultural land from production. If aquifer storage and recovery was inconsistent with local land use plans, policies, or regulations, and required a discretionary action by a local government agency, it would require an amendment or variant from the local jurisdiction prior to operation. Impacts would be less than significant. • Potential conflicts with applicable habitat conservation plans and natural community conservation plans, or other plans, policies and regulations protecting biological species and resources are evaluated in the Biological Resources section of this table.
Mineral Resources	• Aquifer storage would not result in the removal or inability to access state or locally designated mineral resource areas because aquifer storage would be located within existing canals and agricultural use areas. If existing canals and agricultural uses are located in a mineral resource area, the periodic flooding of agricultural lands would not permanently remove access to a mineral resource as there would be other locations and times of year that could provide access to the mineral resource. Impacts would be less than significant.
Noise	• Aquifer storage would require releasing surface water into existing canals to flood agricultural lands during the winter. This activity would not generate temporary or permanent noise or ground-borne vibrations. This activity would not bring people within close proximity to an airport or expose people to airport noise. Impacts would not occur.
Population and Housing	• Aquifer storage and recovery would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property growth in an area. Further, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people to the plan area and extended plan area. Finally, it would be operated to replace a water source that was reduced (e.g., surface water) rather than increasing capacity to serve new water supply users. Impacts would not occur. • Aquifer storage and recovery would not displace substantial numbers of people or existing housing or necessitate construction of replacement housing elsewhere because the change in volume of water (and timing of water release) would occur in existing canals and agricultural lands and not where people currently reside. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As population increases, the need for additional or new public services and public service facilities generally increases. Aquifer storage and recovery would not involve an increase in population or housing in the plan area and extended plan area. In addition, aquifer storage and recovery would not include proposals for new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.

Potential Environmental Effects of Aquifer Storage and Recovery

Resource	Discussion
Recreation	• Recreational facilities are not typically located in agricultural fields. Aquifer storage under agricultural lands in the plan area and extended plan area would not result in impacts on recreational facilities. In addition, aquifer storage and recovery would not lead to the construction or expansion of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Aquifer storage and recovery would not require construction so the actions would not generate construction trips. Aquifer storage and recovery would also not require substantial number of operation and maintenance trips beyond those that may be currently conducted because existing canals and agricultural lands would be used. Impacts would be less than significant. • Aquifer storage and recovery would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Aquifer storage and recovery would not involve the need for utilities or service systems because it would not require the construction or operation of wastewater or water supply facilities. It would not result in the generation of solid waste and would not require a new water supply. Impacts would not occur.

16.2.4 Recycled Water Sources for Water Supply

Reductions in surface water diversions are expected as a result of approving an LSJR alternative and the respective program of implementation. To overcome potentially reduced water supplies, recycled water may be used by surface water users. Recycled water is wastewater treated to an acceptable water quality standard at a WWTP and then distributed for use. Typically, recycled water costs less than potable water because it does not need to be treated to the same water quality standards. For example, a farmer can purchase recycled water at a discount to irrigate alfalfa for a dairy instead of purchasing potable water or pumping groundwater. Thus less potable water would be used for irrigation and could be available for other beneficial uses (e.g., municipal uses). The costs and potential environmental impacts associated with obtaining water from recycled water sources are evaluated below.

Cost Evaluation

The complexity and cost of a recycled water project depends on many factors, such as the level of treatment at the WWTP, the desired water quality for the second beneficial use, the volume of recycled water needed, and the distance from where recycled water is treated to where recycled water is used. Some categories of recycled water projects are listed in detail below.

Landscape Irrigation

Recycled water could be used to offset potable water used to irrigate parks, commercial campus landscapes, ornamental ponds, golf courses, recreational sports fields, botanical gardens, and other spaces where humans will not have direct contact with recycled water. To construct a landscape irrigation project, a wastewater treatment agency would likely need to determine potential recycled water users, determine the required water quality to meet recycled water demand, determine the volume of recycled water needed, secure agreements with potential recycled water users, make improvements to increase treatment at the WWTP, and construct a recycled water distribution system (with pumps). Landscape irrigation recycled water projects typically cost between $400 and $2,100 per AF, including capital, operations, and maintenance (WRF 2011).

Agricultural Irrigation

Similar to landscape irrigation, recycled water could be used to offset potable water used to grow crops. Due to permitting requirements, most recycled water used for agricultural irrigation is for nonhuman consumptive crops (e.g., alfalfa grown for livestock). Recycled water used for human consumptive crops is required to be treated to a higher water quality than recycled water used on nonhuman consumptive crops. The process to construct an agricultural irrigation recycled water project is similar to a landscape irrigation recycled water project and typical costs assume similar project components.

Direct Potable Reuse

Recycled water could be used to replace potable water for domestic use. Technology is available to treat WWTP effluent to drinking water standards. Direct potable reuse is practiced in areas where water supply is extremely scarce, such as Singapore, Namibia, and remote communities in the American West (WRF 2011). Major concerns for direct potable reuse are: public perception, balancing water chemistry, engineered storage buffers, blending with other water sources, and multiple barriers to ensure public safety (WRF 2011). Direct potable reuse projects typically cost $700–$1,200/AF, including capital, operations, and maintenance (WRF 2011).

Process Water

Recycled water could be used by the commercial, institutional, or industrial (CII) sector as process water. Some processes, such as water used in cooling towers at power plants, could use recycled water to offset their need for potable water. Water quality is a concern for CII users because the recycled water is likely used in systems designed for use with potable water, or highly treated potable water. Use of water of less quality may damage CII process equipment, reducing the economic feasibility of using recycled water. Constructing a process water recycled water project is the same as explained above under *Landscape Irrigation*, but more treatment is likely needed at the WWTP. Process water recycling projects typically cost the same as direct potable reuse projects due to the need for higher water quality.

Environmental Evaluation

Summary of Potential Action

The location, timing of construction, and details of the modifications to existing WWTPs and respective distribution systems to support the development of recycled water sources, are unknown at this time. It is assumed these modifications may be carried out by the municipalities and wastewater treatment service providers in the plan area that would have their surface water sources reduced. Municipalities and wastewater treatment service providers include, but are not limited to: City of Merced, City of Manteca, City of Modesto, City of Tracy, Lake Don Pedro CSD, and City of Stockton. Whether the WWTPs are modified or not depends on a number of variables, such as market availability for recycled water use, future agreements reached between wastewater treatment service providers and potential end users water districts (if they are the end users), and funding availability.

For purposes of this discussion, it is assumed construction and operation would occur within the footprint of an existing WWTP or within very close proximity to one because wastewater recycling needs to be integrated into the existing wastewater treatment. It is also assumed WWTPs are located within close proximity to receiving waters (e.g., creeks or rivers) because WWTPs typically discharge treated effluent into receiving waters. Finally, it is assumed WWTPs are located in more urbanized areas adjacent to industrial and urban uses because (1) they must be located in an area to serve their existing municipal customers, and (2) they are typically considered public facilities that are generally located on lands designated and zoned for public facilities and industrial uses. The distribution system for recycled wastewater distribution would likely be constructed and operated within existing rights of way of roads and would be located below ground surface adjacent to existing utility lines at depths of 3–8 ft. The new lines would likely be in municipal service district areas and generally within urban areas.

Modifications required for existing WWTPs cannot be known at this time because they would depend on the type of wastewater treatment currently conducted at a WWTP, the availability of resources (e.g., funding and space), and the management of the WWTP by the local wastewater treatment special district or municipality. However, for the purposes of this discussion, it is assumed the operation of a modified WWTP to produce recycled water would be similar to the existing normal operation of a WWTP and would not result in a substantial increase in the volume of treated effluent discharged because the effluent would be distributed to recycled water users. Furthermore, it is anticipated that the operation of the recycled water facilities within the WWTP would be conducted by the existing employees at the WWTP.

Potential Environmental Effects

Construction of any recycled water facilities would likely result in temporary, and localized effects typically associated with similar activities including air quality effects and ground disturbance. Increased use of recycled water (e.g., landscape irrigation) may result in some runoff into local waterways; however, the quality of recycled water for such uses is highly regulated and approaches potable quality. In addition, increased use of recycled water will result in an equivalent decrease in discharge of lower quality treated effluent, thereby resulting in no negative impacts related to water quality of local waterways.

Recycled water treatment facilities are typically relatively energy intensive; however, the overall increased electrical demand would be small compared to the existing electrical demand of the service area. Therefore, it is unlikely to require the construction of major new power generation or transmission facilities. The operation of recycled water facilities may require a slight increase in chemical transport and storage, but as the treatment facilities would likely be constructed within or adjacent to existing WWTPs, the increase would be negligible compared to existing chemical use and transport at these locations.

It is likely that recycled water facilities would be constructed in areas that are already disturbed by urban development, and most facilities would be located within existing facility footprints and rights-of-way. In addition, any new recycled water projects would undergo CEQA review and other required regulatory compliance at the time they are proposed.

Table 16-10, *Potential Environmental Effects of Developing Recycled Water Sources*, summarizes the potential environmental effects associated with developing recycled water sources. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this action and is referenced in Table 16-10 where appropriate.

Table 16-10. Potential Environmental Effects of Developing Recycled Water Sources

Potential Environmental Effects of Developing Recycled Water Sources	
Resource	Discussion
Aesthetics	• Construction and operation of recycled water facilities would not be expected to significantly affect the visual character or quality of areas because they would be located within the existing footprint of WWTPs or within close proximity and would be similar in size and scale as the existing WWTP facilities. Construction of the recycled water distribution system would include installing pipeline generally along the rights-of-way of existing roads. Construction of the distribution system could result in temporary impacts on the visual character or quality of chosen sites and surroundings due to ground disturbance. Ground-disturbing construction activities would have the potential to disturb or remove mature vegetation (i.e., landscaping) and create dust clouds, which could affect views. Impacts would depend on the location of sensitive receptors relative to these construction sites. At this time, however, no specific projects have been proposed, and future distribution system alignments are unknown. Construction and operation of recycled water facilities may have operational and safety lights. Impacts would depend on the location of sensitive receptors to potential lighting. However, lights would be expected to follow lighting guidelines and lighting plans of local jurisdictions approving the construction and operation of the recycled water facilities. In addition, the recycled water facilities would likely be located adjacent to wastewater treatment facilities and infrastructure that may already have operational and safety lighting. Table 16-38 identifies potential mitigation measures lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant environmental effects associated with lighting and removal of mature landscaping vegetation. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the potential location of possible sensitive receptors and the ability to reduce light and glare.
Agriculture and Forestry Resources	• Recycled water treatment facilities would not be expected to be constructed on agricultural land (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) but rather within the footprint of an existing WWTP or within very close proximity to one. Construction of a recycled water distribution system would include installing pipeline generally along the rights-of-way of existing roads, and therefore it is unlikely that agricultural land would be affected. However, if any portions of distribution pipelines were installed on agricultural land, agricultural use of that land would be temporarily precluded during construction. Construction on agricultural land would be avoided to the extent feasible and could potentially occur outside of the agricultural production season, depending on the crop and location. Construction in agricultural fields may also require removal of crops, depending on the crop and time of year. Table 16-38, identifies potential mitigation measures lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant environmental effects on agricultural resources. At this time, no specific projects have been proposed, and the actual future distribution system alignments are unknown. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of potential disturbance of agricultural lands during construction. It is also expected that recycled water would

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	partially replace surface water diversions for agricultural irrigation, which could potentially offset impacts on agricultural land affected by the recycled water facilities. • Limited forestry resources occur in the plan area. Although extensive forestry resources occur in the extended plan area (e.g., Stanislaus National Forest), because recycled water treatment facilities would be expected to be sited within the footprint of an existing WWTP or within close proximity to one, construction and operation of the facilities would likely not conflict with existing zoning for, or cause rezoning of, forest land or timberland, or result in the loss of those zoned lands. Impacts would be less than significant.
Air Quality	• The plan area is located in the SJVAB and partially located in the MCAB. The extended plan area is also partially located in the SJVAB, MCAB and the GBVAB. The recycled water sources could be located in any or all of these air basins, which generally cover San Joaquin, Stanislaus, Merced, Mariposa, Tuolumne, Calaveras, Alpine, and Madera Counties, because the water supplied by the wells could support agricultural or municipal uses in these areas. The plan area and extended plan area occur within the jurisdictions of the SJVAPCD, CCAPCD, the GBUAPCD, MCAPCD, and TCAPCD. Recycled water facilities would likely be located in the SJVAB, which generally covers San Joaquin, Stanislaus, Merced, and Madera Counties. SJVAPCD's published guidelines, *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002) do not require the quantification of construction emissions. Rather, the guidelines require implementation of effective, comprehensive, and feasible control measures to reduce PM10 emissions (SJVAPCD 2002). SJVAPCD considers PM10 emissions to be the greatest pollutant of concern when assessing construction-related air quality impacts and has determined that compliance with its Regulation VIII, including implementation of all feasible control measures specified in its *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), constitutes sufficient mitigation to reduce construction-related PM10 emissions to less-than-significant levels and minimize adverse air quality effects. All construction projects must abide by Regulation VIII. Since the publication of the district's guidance manual, the district has revised some of the rules comprising Regulation VIII. Guidance from district staff indicates that implementation of a Dust Control Plan would satisfy all of the requirements of SJVAPCD Regulation VIII (Siong pers. comm.). Further consultation with SJVAPCD staff indicates that, though explicit thresholds for construction-related emissions of ozone precursors are not enumerated in the *Guide for Assessing and Mitigating Air Quality Impacts*, SJVAPCD considers it a significant impact when construction or operational emissions of ROG or NO_X exceed 10 tons per year or if PM10 or PM2.5 emissions exceed 15 tons per year (Siong pers. comm.). For projects within CCAPCD jurisdiction a significant impact would occur if project emissions are greater than 150 pounds per day for ROG, NO_X, or PM10 in either the construction or operational periods. No thresholds for other criteria pollutants or their precursors have been established by the CCAPCD. The GBUAPCD does not have adopted quantitative thresholds of significance for criteria pollutants for proposed projects for the purposes of CEQA, although thresholds from neighboring air districts (e.g., CCAPCD, TCAPCD, SJVAPCD) may be used to evaluate impacts within the GBUAPCD. For construction impacts, the GBUAPCD requires that project proponents adopt comprehensive mitigation measures to mitigate fugitive dust impacts. For emissions associated with the operation of stationary sources, the GBUAPCD considers stationary emissions to be less than significant if they are exempt from Rule 202 pursuant to Rule 209-A(B)(2). Rule 209-A identifies emission limits of 250 pounds per day for ROG, NO_X, SO_X, and particulate matter. For projects within MCAPCD jurisdiction a significant impact would occur if project operational emissions are greater than 100 tons per year for ROG, NO_X, CO, SO_X,

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	PM10, and PM2.5 (County of Mariposa 2006). For projects within TCAPCD jurisdiction a significant impact would occur if project emissions are greater than 100 tons per year or 1,000 pounds per day for ROG, NO_X, CO, and PM10. • Construction of recycled water treatment facilities and distribution pipelines would likely result in emissions associated with construction equipment and construction worker vehicle trips, as well as fugitive dust emissions from ground disturbance. The quantity, duration, and the intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Depending on the level of activities and amount of infrastructure built, construction of recycled water facilities could exceed air quality thresholds established by the applicable APCDs and project proponents would be required to implement measures to help reduce or minimize construction-related emissions. Lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on air quality associated with construction emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the regulatory requirement to implement all required feasible measures to reduce emissions during construction and the potential for the duration and frequency of activities during construction to reduce overall emissions (e.g., diluting emissions over time). • Prior to constructing a project dealing with a stationary source of emissions (such as a WWTP), project proponents must obtain permits from their respective air districts to ensure the permitted facility will not cause a new violation, or contribute to an existing violation, of national ambient air quality standard. For example, an Authority to Construct (ATC) would be required from SJVAPCD if a facility were constructed within the SJVAB. The project would be subject to the requirements of SJVAPD Rule 2201. As stated under Sections 1.1 and 1.2 of Rule 2201[12]: *The purpose of this rule is to provide for the following:* *1.1 The review of new and modified Stationary Sources of air pollution and to provide mechanisms including emission trade-offs by which Authorities to Construct such sources may be granted, without interfering with the attainment or maintenance of Ambient Air Quality Standards;*

---

[12] Sources whose primary function is permitted by the SJVAPCD through Rules 2010 and 2201 are not subject to SJVAPCD Rule 9510 (Indirect Source Review). Projects subject to Rule 9510 are required to quantify and reduce indirect (i.e., mobile source emissions), area-source (e.g., space heating, landscaping, and maintenance), and construction exhaust emissions.

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	1.2 No net increase in emissions above specified thresholds from new and modified Stationary Sources of all nonattainment pollutants and their precursors. Rule 2201 applies to new stationary sources and all modifications to existing stationary sources that are subject to permit requirements and after construction may emit one or more affected pollutant.[13] The requirements of this rule go in effect on the date the application is determined to be complete by the SJVAPD's Air Pollution Control Officer. • Operation of recycled water treatment facilities would likely use electricity because of their expected locations in urban and suburban areas in close proximity to existing wastewater treatment infrastructure. They may use nonelectric backup generators for intermittent emergency circumstances. Operations could include facility inspection and maintenance activities. The need for additional energy could result in increased criteria pollutant emissions at power generation facilities. However, the power facilities that would compensate for the additional demand are already built and permitted by the applicable local air district to emit a maximum amount of criteria pollutants. As part of the permitting process, these facilities are required to offset additional power generation by the use of emission reduction credits as required by applicable local air district New Source Review programs. Therefore, if additional emissions are generated, they would be generated by regulated facilities. Lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects associated with operational emissions and air quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The various APCDs have identified common types of facilities that are known to produce odors in the region. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants. Construction and operation of recycled water facilities would not involve the type of facility identified by, for example, SJVAPCD, as a known odor source (SJVAPCD 2002). The recycled water facilities would be located at the wastewater treatment facility but would not produce additional odors beyond what currently may be produced. This is because the recycled water process typically uses the existing volume of wastewater that is already treated in accordance with Clean Water Act permit requirements. The recycled water process further treats the wastewater to meet recycled water quality standards. Therefore, the additional processing of the treated wastewater does not produce any additional odors because the odors are typically generated

---

[13] Affected pollutants are those pollutants for which an Ambient Air Quality Standard has been established by the USEPA or by the ARB, and the precursors to such pollutants and those pollutants regulated by the USEPA under the federal Clean Air Act or by the ARB under the Health and Safety Code including, but not limited to, VOC, NOx, SOx, PM2.5, PM10, CO, and those pollutants which the USEPA, after due process, or the ARB or the Air Pollution Control Officer, after public hearing, determine may have a significant adverse effect on the environment, the public health, or the public welfare.

Potential Environmental Effects of Developing Recycled Water Sources	
Resource	Discussion
	during pre-treatment, primary treatment, and biosolids removal. Consequently, it is expected that recycled water facilities would not create objectionable odors affecting a substantial number of people. Impacts would be less than significant. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction and operation of recycled water treatment facilities would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. Construction and operation of recycled water treatment facilities would not result in growth because the facilities would be constructed and operated to replace a water source that was reduced (i.e., surface water) rather than to increase capacity to serve new users. Construction and operation of recycled water treatment facilities would not result in population or employment growth that would result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Accordingly, this impact is less than significant.
Biological Resources	• Construction and operation of recycled water treatment facilities in the plan area and extended plan area is expected to be in urban and suburban areas within the footprint of existing WWTPs. These areas are expected to have a very low potential for special-status plant species, animal species, and habitat (including federally protected wetlands), and are unlikely to support special-status biological resources because they are typically industrial facilities with buildings and primarily impervious surfaces. Construction of the recycled water distribution system would include installing pipeline generally along the rights-of-way of existing roads, and potentially in agricultural fields and other areas (e.g., parks, commercial campus landscapes, golf courses). With the exception of agricultural fields, these other areas are expected to have a very low potential for special-status plant species, animal species, and habitat, because they are typically located in developed, urban areas. Some agricultural fields can provide suitable foraging habitat for special-status raptor species such as Swainson's hawk and white-tailed kite; however, given the temporary nature of construction activities associated with installing recycled water distribution pipelines and that activities typically could be scheduled to avoid active periods of these types of species, there is a low potential for effects. Further, there is also a low potential for special-status plant species, animal species, and habitat to be affected, it is not expected that construction and operation would conflict with local policies protecting biological resources or conflict with provisions of an adopted habitat conservation plan or natural community conservation plan. Depending on the actual location and the season of construction, Table 16-38 lists potential mitigation measures lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant environmental effects of construction and operations on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that construction

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	impacts could be mitigated to less than significant once mitigation measures were implemented, given the need to comply with regulatory seasonal restrictions. • It is expected that operation of recycled water facilities would not result in an increased volume of treated wastewater effluent discharged or change the quality of the treated wastewater effluent discharged, because it would be distributed to the end user for use on landscaping, potable use, or agricultural fields. As such, it is not expected to adversely affect special-status fish species. It is expected that recycled water production would meet all appropriate treated wastewater effluent limitations and standards and would not affect special-status fish species or the migration of such species. Impacts would be less than significant. • Use of recycled water by consumers (e.g., golf courses or industrial processes) could result in runoff entering receiving water and potentially affecting aquatic resources. However, consumers are required to have management plans to control runoff and reduce receiving water inflow. Specifically the applicable regional water quality control board is required by California Code of Regulations, title 22, division 4, to issue a Master Water Recycling Permit that includes specific requirements for the use of recycled water (SDRWQCB 2009). Further, the quality of recycled water for such uses is highly regulated by the regional water quality control boards and the California Department of Public Health by regulations or laws such as the Health and Safety Code (Division 104, Part 12, Chapter 4, Article 7, § 116551) and approaches potable water quality (CDPH 2011). Impacts would be less than significant.
Cultural Resources	• Construction and operation of recycled water treatment facilities would likely occur in urban and suburban areas adjacent or within close proximity to existing wastewater treatment facilities and infrastructure. While it is unknown if cultural resources (significant historical, archeological, or paleontological resources) exist in these locations, these areas likely would have been previously disturbed during the construction of the existing wastewater treatment facilities, reducing the potential for significant unknown cultural resources to exist. Operation of recycled water facilities would have a very low potential to affect cultural resources because operation would consist of recycled water treatment within previously constructed facilities. Impacts would be less than significant. • Construction and operation of the recycled water distribution system would include installing pipeline generally along the rights-of-way of existing roads. Construction of the distribution system has the potential to encounter significant unknown buried cultural resources because it cannot be predicted with certainty whether significant unknown buried cultural remains are currently present or absent. No specific projects have been proposed at this time, and the actual future distribution system alignments are unknown. However, given that most of the construction would occur within highly developed public rights-of-way where much of the sediments have been previously disturbed, the potential to encounter significant buried cultural resources is greatly reduced. In addition, due to the shallow depth of disturbance cultural resources have likely been previously disturbed. Therefore, there is a very low potential for unknown cultural resources to be located in these areas. Lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on cultural resources associated with construction of recycled water treatment and distribution facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable,

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the depth of disturbance and the low potential for resources to exist. • As described above, it is expected the wastewater treatment sites and public-rights-of ways would be previously disturbed. Therefore, it is highly unlikely that human remains, typically buried at depths of 6 ft, would be encountered or disturbed during construction. However, if human remains are uncovered during construction, compliance with the State Health and Safety Code would be required. As specified by Section 7050.5 of the Health and Safety Code, and described in Table 16-38, no further disturbance would occur until the county coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code Section 5097.98. If such a discovery occurs, excavation or construction would halt in the area of the discovery, the area would be protected, and consultation and treatment would occur as prescribed by law. If the coroner recognizes the remains to be Native American, he or she would contact the NAHC, who shall appoint the Most Likely Descendent. Additionally, if the human remains are determined to be Native American, a plan would be developed regarding the treatment of human remains and associated burial objects, and the plan shall be implemented under the direction of the Most Likely Descendent. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.
Geology and Soils	• The locations of any new recycled water facilities could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, recycled water facilities would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. Any new facilities would be constructed using the latest geotechnical information for the site-specific conditions. Finally, recycled water facilities would not bring people to the risk of earthquakes or geologic hazards, meaning the operation of the recycled water facilities would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts related to geology and soils associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the temporary disturbance of soils during construction and the need to follow existing building code requirements. • The construction and operation of recycled water facilities would not involve constructing or operating septic tanks. Therefore, septic tanks would not be affected by soils incapable of supporting the use of them or other alternative wastewater disposal systems. Impacts would not occur.

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	• Construction of recycled water treatment facilities and distribution systems would result in limited ground-disturbing activities that could cause soil erosion or loss of topsoil; however, ground-disturbing activities would be limited in duration and geography. Furthermore, ground-disturbing activities of 1 acre or greater would require preparation and implementation of a SWPPP, as required by the Central Valley Water Board. The SWPPP would require soil and erosion control mechanisms. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts related to soil erosion and storm water runoff and erosion associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given that construction would be temporary and the need to comply with existing storm water pollution and control regulations. • Increases in groundwater pumping are not expected to occur under the construction of recycled water treatment facilities or the distribution system. Operation of recycled water facilities may result in replenishment of groundwater resources or a reduction of the groundwater pumping because the recycled water would be used as an alternative source of water. Impacts would be less than significant.
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-7, because construction and operation of recycled water treatment facilities and distribution systems would result in increased use of electricity and fuels, and therefore there would be an increase in GHG emissions. Depending on the level of construction activities, construction-related GHG emissions could exceed the SJVAPCD ZEL and result in a potentially significant impact. For air districts in which there is no adopted GHG threshold (e.g., CCAPCD), the ZEL for SJVAPCD could be applied. The recycled water treatment and distribution process is an energy-intensive process (e.g., brackish water reverse osmosis energy use will vary depending upon the salinity and temperature of the source water; the higher the salinity or the colder the water temperature, the more energy it takes to remove the salt to meet water quality standards [Kennedy/Jenks Consultants 2013]). However, the overall increased electrical load due to operation of a recycled water treatment facility would be extremely small compared to the existing local electrical demand and it is unlikely to require the construction of new major power generation or transmission facilities. However, these increased electricity-related GHG emissions could potentially exceed the applicable SJVAPCD ZEL threshold and result in a significant impact. For air districts in which there is no adopted GHG threshold (e.g., CCAPCD), the ZEL for SJVAPCD could be applied. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts due to GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs.

Potential Environmental Effects of Developing Recycled Water Sources	
Resource	Discussion
	○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Construction of recycled water treatment facilities and the distribution systems would be short term and may involve the transport, storage, use, and disposal of hazardous materials such as fuel and lubricating grease for motorized heavy equipment. Some examples of typical hazardous materials handling are fueling and servicing construction equipment onsite and transporting fuels, lubricating fluids, solvents, and bonding adhesives. These types of materials are not acutely hazardous, and storage, handling, and disposal of these materials are regulated by local, county, and state laws. Furthermore, due to the limited construction period, the quantities of these materials used during construction is also anticipated to be small (e.g., less than 100 gallons). If a spill occurred, it could be readily and easily contained. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary. • The location of where recycled water treatment facilities and distribution systems would be constructed is not yet known; however, these facilities could be constructed within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation activities. As such, if a school existed within close proximity to construction of recycled water treatment facilities and distribution systems, those mitigation measures identified table 16-38 applied to project-specific construction needs would reduce potentially significant impacts during construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g.,

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction.
	• Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962, these sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the DTSC for Alpine, Calaveras, Tuolumne, or Mariposa Counties (CalEPA 2016). There were a total of 19 sites identified for Madera, Merced, San Joaquin, and Stanislaus Counties. None of these sites are identified as a WWTPs. In addition to these sites identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 520 leaking underground storage tanks designated as open in these counties (CalEPA 2016). There are approximately 60 facilities in these counties that have received CDOs/CAOs not identified as non-hazardous wastes, domestic wastewater, or domestic sewage (CalEPA 2016). There are approximately 13 facilities identified as WWTPs in these counties as having non-hazardous active CDOs/CAOs (CalEPA 2016). The active and open leaking underground storage tank cases and the CDO/CAO facilities are located throughout these counties and although some of them are identified as non-hazardous, they are identified on a Cortese List. Construction and operation of recycled water treatment facilities would likely occur in urban and suburban areas adjacent or within close proximity to existing wastewater treatment facilities and infrastructure. It is not yet known precisely where recycled water treatment facilities would be constructed, and which WWTPs may choose to construct recycled water treatment facilities. If a recycled water treatment facility were constructed on a Cortese Site because construction of these facilities would likely entail some ground disturbing activities, there would be potential for release of existing soil or groundwater contaminants depending on the known or unknown existing or historical contamination at the site. Were this to occur, impacts could be significant. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed.
	• Construction and operation of recycled water treatment facilities would likely occur within close proximity to existing wastewater treatment facilities and infrastructure and therefore would not physically interfere with an adopted emergency response plans or emergency evacuation plans because construction and operation activities would not prohibit the mobility of people to escape potential emergencies. Standard practices and protocols with respect to emergencies that are currently implemented by wastewater treatment facilities would apply and recycled water treatment

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	facilities would be incorporated into the standard practices and protocols. Furthermore, construction and operation of these facilities would not involve an increase in population that would necessitate reconsideration of how to evacuate people in an emergency. Impacts would not occur. • Operation of recycled water treatment facilities could use chemicals during the wastewater treatment process, which could require the routine transport, use, storage, and disposal of hazardous materials, such as chlorine gas, sulfur dioxide, and aqueous ammonia. These materials are commonly used by WWTPs during their treatment process to comply with effluent discharge standards set by the Central Valley Water Board. These chemicals are considered corrosive and represent inhalation, ingestion, and contact hazards. WWTPs are required to have hazardous materials inventory (HMI) statements and a consolidated contingency plan, as well as a federal RMP and a CalARP RMP, to properly manage and control these hazardous materials per federal RMP regulations (40 CFR Part 68) and the federal OSHA's Process Safety Management regulations (29 CFR Part 1910.119). The RMPs include the preparation of an offsite consequence analysis of worst-case release of the stored chemicals, and preparation of emergency response plans, including coordination with local emergency response agencies. The RMPs are required to be updated at least every 5 years and when there are significant changes to the quantities of stored chemicals. In addition, the Hazardous Materials Release Response Plans and Inventory Act (also known as the Business Plan Act) requires a business using hazardous materials to prepare a Business Plan describing the facility, inventory, emergency response plans, and training programs. The local CUPA (e.g., San Joaquin County, Stanislaus County, or Merced County, or local fire departments) and USEPA have authority over the management of hazardous materials at WWTPs. WWTPs would likely be within urban and suburban service areas, potentially storing these hazardous materials within 1/4 mile of a school. Per existing regulations, the CalARP RMP would be updated accordingly to reflect the additional volume of chemicals that might be transported, used, or disposed of as a result of including recycled water facilities. Added transport, use, or disposal of chemicals would also require implementation of a revised CalARP RMP. As part of revising the CalARP RMP, the wastewater treatment facilities would evaluate if current containment systems would be adequate for the additional truck deliveries and make any necessary modifications. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during operation. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the need to comply with state and federal regulations in order to operate the recycled water facility. • Recycled water is not considered a hazardous waste (e.g., material that is corrosive, flammable, reactive). There are many regulations controlling the release, use, and management of recycled water to protect public health and the environment. For example, purple pipe systems are required for new recycled water distribution systems so that the systems are appropriately connected to the end use (e.g., landscaping), and minimize potential cross connection with potable water systems. Therefore, people would not be exposed to hazards or hazardous materials as a result of the use of recycled water. Impacts would be less than significant.

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	• Construction and operation of recycled water treatment facilities and the distribution system would not be a hazard or cause safety concerns to public or public use airports or private airstrips because recycled water facilities would be constructed and operated within the existing footprint of wastewater treatment facilities or within close proximity and distribution systems would be underground. As such, construction and operation of recycled water treatment facilities and the distribution system would not result in a safety hazard for people residing or working in or near the project area. Impacts would be less than significant. • Construction and operation of recycled water treatment facilities and distribution systems would not physically interfere with an adopted emergency response plan or emergency evacuation plan since they would be located within existing facilities and the existing rights-of-way of roads. During construction of the distribution systems, road shoulders or lanes may be closed, but typical traffic control methods would be employed to direct and control traffic and minimize traffic impacts. Impacts would be less than significant. • Construction and operation of recycled water treatment facilities and distribution systems would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur.
Hydrology and Water Quality	• Construction of recycled water treatment facilities and distribution systems could result in temporary changes to existing drainage patterns, erosion, or runoff associated with typical construction activities, such as grading or preparation of land. As discussed earlier in this table (Geology and Soils), soil disturbance of over 1 acre would require wastewater treatment special districts or municipalities to prepare and implement a SWPPP. Water quality measures such as monitoring turbidity during construction to ensure compliance with the applicable water quality objectives (e.g., Water Quality Control Plan for the Sacramento River and SJR Basins) and construction BMPs would be implemented as either mitigation measures under CEQA or permit requirements and conditions to ensure water quality standards are not exceeded. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary. • Because construction and operation of recycled water facilities would not substantially alter the existing drainage pattern of the site, or substantially increase the rate or amount of surface runoff, new recycled water facilities would not result in flooding or otherwise cause flooding on- or off-site, or exceed the capacity of existing or planned storm water drainage systems. Impacts would be less than significant. • It is likely that the recycled water facilities would be located in a flood hazard area because wastewater treatment facilities are typically located adjacent to rivers and streams so they can discharge treated effluent into receiving waters. However, because the recycled waste facilities would be located within the existing WWTP footprint, the addition of the recycled water facilities would not substantially add to the existing structures such that flood flows in a 100-year flood hazard area

Potential Environmental Effects of Developing Recycled Water Sources	
Resource	Discussion
	would be impeded or redirected. Further, the recycled water facilities would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to flood hazard locations or place housing within a 100-year flood hazard area. As such, construction and operation of recycled water facilities would not expose people to significant loss, injury, or death related to flooding. Impacts would be less than significant. • Operation of recycled water treatment facilities would have to comply with all regulations pertaining to water quality standards and regulations to prevent degradation of water quality in receiving waters. It is not anticipated that the recycled water facility would discharge recycled water into receiving waters because the water would be distributed to users in the service area. The users of recycled water (e.g., golf courses) would have to prepare plans and undergo inspections by the municipality operating the WWTP and prepare management plans to limit and control runoff into receiving waters. Impacts would be less than significant. • Construction of recycled water treatment facilities and distribution systems would not result in a substantial depletion of groundwater or interfere with groundwater recharge because construction would generally take place within existing facility footprints and would not need substantial volumes of water. Operation of recycled water facilities could increase actual groundwater recharge if it is used to augment groundwater basins. Users of recycled water (e.g., golf courses) may reduce their use of groundwater because they would have an alternative source of water by using the recycled water. Impacts would be less than significant. • Construction and operation of recycled water treatment facilities and the distribution systems would be located in areas of flat relief because these types of facilities are typically not located on the side of steep slopes. The locations would not support mudflows, which typically need very steep slopes and large amounts of precipitation to occur. Further, these areas would not be adjacent to the ocean and would not be affected by tsunamis. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction recycled water treatment facilities is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of recycled water treatment facilities could result in a substantial degradation of water quality.
Land Use and Planning	• Construction and operation of recycled water facilities would not physically divide an established community because the facilities would likely be located in the existing footprint of the wastewater facility. Construction of the recycled water distribution system would include installing pipeline generally along the rights-of-way of existing roads, and potentially in agricultural fields and other areas (e.g., parks, commercial campus landscapes, golf courses). Construction activities would be temporary and pipelines would be below grade and therefore would not create an obstruction or barrier that would divide an established community. Impacts would be less than significant. • Construction and operation of recycled water facilities would take place within the footprint of an existing WWTP or within close proximity and would not conflict with land use designations or zoning because WWTPs are typically located in areas that are for public facilities or industrial uses. If the recycled water facilities or distribution systems were

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	inconsistent with applicable land use plans, policies, and regulations, an amendment or variant from the local jurisdiction approving the discretionary action associated with the recycled water facilities would be required by the project proponent prior to project approval and construction. If no discretionary action were to occur as a result of the construction or operation of the recycled water facilities or distribution systems, it is assumed it would not result in a conflict with local land use plans, policies, and regulations. Impacts would be less than significant. • Potential conflicts with applicable habitat conservation plans and natural community conservation plans are evaluated in the Biological Resources section of this table.
Mineral Resources	• Construction and operation of recycled water facilities would have a very low potential to result in the removal or inability to access state or locally designated mineral resource areas. This is because recycled water facility sites would be within the footprint of existing WWTPs. If the recycled water facilities or distribution systems are located within a state or local designated mineral resource area, construction and operation of the recycled water facilities would not permanently remove access to a mineral resource as there would be other locations around the facilities that could provide access to the mineral resource. Impacts would be less than significant.
Noise	• Construction of recycled water facilities could temporarily generate noise or ground-borne vibrations if pile driving is used. It is likely that recycled water facilities would be constructed in areas with suitable land use designations and zoning for infrastructure (e.g., public facilities or industrial) or within the footprint of existing facilities. It would be unlikely to have sensitive receptors (e.g., residential homes, hospitals, schools) to noise within close proximity to construction activities. If sensitive receptors were adjacent to construction activities and experienced construction noise, construction would be temporary and would be required to follow existing local noise ordinances limiting the timing of construction (e.g., generally Mondays– Fridays, 7am–6pm). Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts related to noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the location of potential sensitive receptors and the duration of the particular noise generating activities. • Wastewater treatment facilities do not generally run continuously because there are peak hours during the day (e.g., early in the morning and the evening) when wastewater is primarily generated. The operation of recycled water facilities would run accordingly and would likely not add substantial noise to existing WWTP operations. Additionally, the existing WWTPs already generate intermittent noise (e.g., from alarm bells, pumps, and generators). It is anticipated there would be a very low probability that sensitive receptors (e.g., residential homes, hospitals, schools) would be located within close proximity to experience the operating noise generated because it is anticipated that the WWTPs would be located in areas with similar land uses (e.g., other public facilities or industrial facilities). Finally, most of the wastewater treatment facilities are enclosed within buildings that reduce the operating noise. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts related to noise. Until such time that these potential mitigation measures are implemented, the impacts

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented depending on the potential location of possible sensitive receptors and given the need to have equipment located within buildings. • Construction of the distribution system would likely exceed noise standards established in local general plans or noise ordinances. This construction would generally occur within road rights-of-way. However, it is not known where distribution lines would be located; they could be located in residential neighborhoods or within immediate proximity to other sensitive receptors (e.g., hospitals, schools, parks). Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts related to noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Once operational, the distribution system would be underground and would transport recycled water to end users. Because new pumping stations would be needed as part of the new recycled water distribution system, operation of these pumping stations could introduce a new noise source, but would generally be enclosed or fenced as to protect it and prevent the public from accessing it. These enclosures would serve to reduce noise and any noise generated would be intermittent throughout the day. As such, the operation of the distribution system is not expected to exceed standards established by a local general plan or noise ordinance. Impacts would be less than significant. • The construction and operation of recycled water facilities would not bring people within close proximity to an airport or expose people to airport noise.
Population and Housing	• The construction and operation of recycled water treatment facilities and distribution systems would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Furthermore, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people to the plan area and extended plan area. Finally, the facilities would be constructed and operated to replace a water source that was reduced (i.e., surface water) rather than increasing capacity to serve new users. Impacts would not occur. • The construction and operation of recycled water treatment facilities and distribution systems would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the facilities would be expected to be located within the footprint of existing WWTPs, and the distribution system would be located in the rights-of-way of existing roads. No homes or people would be displaced. Impacts would not occur.

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, the construction and operation of recycled water treatment facilities and distribution systems in the plan area and extended plan area would not involve an increase in population or housing. In addition, these actions would not include proposals for new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.
Recreation	• Construction of recycled water facilities in the plan area and extended plan area would likely occur within the footprint or immediately adjacent to existing wastewater treatment facilities. These facilities are typically located adjacent to receiving waters and in industrial or urban areas to provide wastewater service to the urban, suburban, and industrial users. It is unlikely that recreational facilities would be located in areas near where wastewater treatment facilities currently exist. However, if recreational facilities were located within very close proximity, construction of water recycling facilities may affect them. Construction of the recycled water distribution system would include installing pipeline below grade generally along the rights-of-way of existing roads, and potentially in agricultural fields and other areas (e.g., parks, commercial campus landscapes, golf courses). If installation of pipelines is done in parks or golf courses, use of these areas may be disrupted during construction. However, it is unlikely that there would be significant effects on recreational facilities due to construction of the recycled water treatment facilities and distribution systems because construction would be temporary and limited. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant indirect impacts on recreational resources related to construction activities (noise, air quality, etc.). Impacts would be less than significant. • Construction and operation of recycled water treatment facilities and distribution systems would not require the construction or expansion of recreational facilities. Therefore, potential environmental impacts associated with such construction or expansion would not occur.
Transportation and Traffic	• Construction of recycled water treatment facilities and distribution systems could result in some additional trips associated with construction workers. Wastewater treatment facilities may be located in urban and suburban areas that could already experience some congestion. Similarly, distribution pipelines could be installed in urban and suburban areas for landscape irrigation (e.g., parks, golf courses) where additional trips associated with construction workers may increase existing traffic. The temporary increased traffic during construction could exceed local or regional road trip thresholds. However, the number of construction trips that might be needed is unknown. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant transportation and traffic impacts related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.

Potential Environmental Effects of Developing Recycled Water Sources

Resource	Discussion
	• Operation of recycled water treatment facilities and distribution systems would not generate additional trips beyond those required for existing WWTP maintenance. It is unlikely that operation of the new water recycling facilities would result in a substantial increase in the number of WWTP employees, the amount of traffic generated on a daily basis is not expected to increase. Impacts would be less than significant. • Construction and operation of recycled water treatment facilities and distribution systems would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Construction and operation of recycled water treatment facilities and distribution systems would not be expected to affect the ability to meet the wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of recycled water from a WWTP. The purpose of developing recycled water is to use it as a replacement for other water sources (e.g., potable water, irrigation water), not to dilute WWTP effluent. Additionally, recycled water facilities would not increase the actual volume of wastewater generated in the service area or affect the WWTPs capacity. Impacts would be less than significant. • Construction and operation of recycled water treatment facilities and distribution systems involves construction at wastewater treatment facilities and other areas where the distribution pipelines would be installed. Environmental effects are discussed earlier in this table (Aesthetics through Transportation and Traffic sections). Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant construction or operation impacts related to all environmental resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Operation of recycled water facilities would not need the construction of additional storm water drains because the facilities would likely be built within the footprint of existing WWTPs, which currently have impervious surfaces that generate runoff. It is expected that existing storm water infrastructure would be used. Construction and operation of the distribution system would not require the construction of additional storm water drains because the pipeline would be located underground. Impacts would be less than significant. • Construction and operation of recycled water facilities would not be expected to require a new water supply or increased water supply because these facilities would be treating existing wastewater. Impacts would be less than significant. • Construction and operation of recycled water treatment facilities and distribution systems is not expected to result in a substantial increase in solid waste. WWTPs generate solid waste in the form of biosolids and other byproducts of the treatment stream. While recycled water facilities may also have solid waste, it is anticipated that biosolids would be minimal since they are removed during the wastewater treatment process. Generally, this type of solid waste is not considered hazardous, and the disposal of it follows all regulations and guidelines of solid waste at normal landfills. Impacts would be less than significant.

16.2.5 In-Delta Diversions

Reductions in surface water diversions are possible as a result of approving an LSJR alternative and the respective program of implementation. These reductions in surface water could potentially affect SFPUC by reducing some portion of its current water supply obtained from the Tuolumne River during a 6-year drought, as described in Appendix L, *City and County of San Francisco Analyses*. Under certain LSJR alternatives (i.e., higher unimpaired flow LSJR Alternatives 3 and 4), SFPUC may need multiple new water supplies to augment its current drought supply. As described in SFPUC documents, specifically the Water Supply Options (WSO) report (SFPUC 2007), SFPUC has several options for augmenting or increasing its water supply including diverting water from the Sacramento–San Joaquin Delta (Delta). The SFPUC WSO report was developed in support of the SFPUC WSIP prepared by SFPUC to increase reliability of the regional water system that provides water to San Francisco and neighboring communities (SFPUC 2008). In the 2008 WSIP Programmatic Environmental Impact Report (PEIR), SFPUC concluded that the in-Delta diversion option was infeasible, in part, because it would not achieve consistent year-round diversions due to uncertainties regarding the availability of water supplies and pumping capacities (SFPUC 2008). Nonetheless, a discussion of this possible water supply option has been included in light of the changing circumstances since 2008 (e.g., Pelagic Organism Decline, climate change, California WaterFix, and the State Water Board's *Final Report on the Development of Flow Criteria for the Sacramento Delta Flow Criteria* [State Water Board 2010]).

This section uses information regarding a delta diversion project as was analyzed in the WSO report to evaluate costs and potentially significant environmental impacts. The project as described in the WSO report has a design capacity of 28,000 acre-feet per year (AF/y) and would require relatively little new infrastructure. This design capacity would replace a portion of the supplies potentially reduced by the higher range of the LSJR alternatives (i.e., LSJR Alternative 4) and would likely be needed in addition to other supplies under certain LSJR alternatives given the amount of water potentially needed by SFPUC (see Appendix L, *City and County of San Francisco Analyses*). A delta diversion project would potentially allow SFPUC to use any of the rivers that flow into the Delta as a water supply source, instead of the Tuolumne River. Under this type of project, it is anticipated water would be purchased from any user upstream from the Delta or from a State Water Project (SWP) or Central Valley Project (CVP) contractor south of the Delta. A new connection to either the California Aqueduct or the Delta-Mendota Canal would be constructed to accommodate the transfer. Water would be pumped by the Projects (the SWP and CVP) from the Delta and would be treated and introduced to the system at Tesla Portal. Infrastructure requirements would include diversion from aqueduct, treatment facilities, and modification of Tesla Portal.

Cost Evaluation

SFPUC estimated a delta diversion project with a design capacity of 28,000 AF/y to cost about $306.1 million for capital cost, $7.8 million for annual operation and maintenance costs, and $357.1 million for lifecycle costs (SFPUC 2007). For a project of 28,000 AF/y, this results in approximately $255 per AF over the 50-year lifecycle. The cost per AF of additional water from a delta diversion for a larger project could be less than $255 per AF because of the economies of scale (i.e., the larger infrastructure projects are, the less they cost per unit per year). These costs do not include the cost of purchasing the water from willing sellers to supply the diversion project. Purchase costs would vary depending on market conditions, entities selling the water, and water-year conditions (i.e., drought), but could range from about $50 to $600 per AF, which could result in costs of $1.4–$16.8 million per year (PPIC 2011, Maven's Notebook 2015).

Environmental Evaluation

Summary of Potential Action

The precise location, size, timing of construction, and details of a delta diversion project cannot be known at this time. It is assumed that the project would be carried out by SFPUC; however, other service providers in the region may partake in a joint effort which may increase overall efficiency and reduce costs per unit water diverted. The size of the project may need to be larger than what was examined in the WSO report which is summarized below.

Water diverted from the Tuolumne River is unfiltered and delivered directly to customers after disinfection at the Tesla Portal near Tracy. Any water diverted from the Delta would need to be fully treated before it is blended with Hetch Hetchy water. The project, as outlined in the WSO report (SFPUC 2007), would include a new Delta intake and pumping plant, a new pipeline, a new Delta water treatment plant, and a new blending facility at Tesla Portal.

The intake facilities would draw from the California Aqueduct or the Delta-Mendota Canal. The intake would require a right-of-way purchase and permits to penetrate the aqueduct levee. The pumping capacity would be about 100 million gallons per day (mgd) operating against a head of 180 ft. The pumping plant would be large enough to house five 1,400 brake horsepower (bhp) vertical turbine pump units. Water would be conveyed from the pumping plant to the treatment facilities via a new 60-inch diameter welded steel pipe about 4 miles long. This new pipeline would run parallel to the existing San Joaquin Pipeline and would be within the Hetch Hetchy right-of-way. The new pipeline would be routed through agricultural land but would need to cross Interstate 580. SFPUC's report describes the new Delta water treatment plant as having a 100 mgd capacity and requiring about an 18-acre footprint. The site would be located within SFPUC property boundary just north of the Tesla Portal. A blending facility would be located at Tesla Portal to blend the newly treated water with the disinfected Hetch Hetchy water before being delivered through the existing system.

Potential Environmental Effects

Construction of any diversion and treatment facilities would likely result in temporary, and localized effects typically associated with similar activities including air quality effects and ground disturbance.

Effects associated with exporting water from the Delta are being debated and analyzed by U.S. Bureau of Reclamation (USBR), DWR, and various fisheries agencies as part of the California WaterFix process. If water was purchased from a south of Delta contractor there would be no increase in Delta exports. If water was purchased from a contractor upstream of the Delta, there may be an increase in Delta exports, which could affect Delta fish. This effect would likely be very small due to the size (39 cfs to SFPUC versus 10,000 cfs of combined exports) and would be minimized by operating under current fisheries agencies and State Water Board regulations and requirements.

Potable water treatment and pumping facilities are typically relatively energy intensive; however, the overall increased electrical load would be extremely small compared to the existing electrical load from the large Delta export pumps. Therefore, it is unlikely to require the construction of major new power generation or transmission facilities. The operation of Delta diversion facilities may require a slight increase in chemical transport and storage; however, because the facilities would likely be constructed within or adjacent to existing treatment facilities, the increase would be negligible compared to existing chemical use and transport at these locations.

The Delta diversion facilities would be constructed in areas that are already disturbed by urban development, and most facilities would be located within existing facility footprints and rights-of-way. In addition, because such facilities are publicly owned and subject to CEQA and other environmental regulations, depending on site-specific conditions, any new water treatment projects would undergo the appropriate level of CEQA and other required regulatory compliance at the time they are proposed.

As part of the WSO report, SFPUC prepared a preliminary analysis of environmental effects of a conceptual Delta diversion facility (SFPUC 2007). The analysis identified environmental commitments and/or potential mitigation measures to be implemented by SFPUC to reduce potentially significant impacts for the following resources: aesthetics, agriculture, air quality, biological resources, cultural resources, geology and soils, GHG emissions, hazards and hazardous materials, hydrology and water quality, land use and planning, noise, transportation and traffic, and utilities and service systems. Attachment 2 of Appendix H, *Supporting Materials for Chapter 16*, contains the analysis of the conceptual plan and is incorporated into this evaluation. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, lists potential mitigation measures that SFPUC can and should implement to reduce potentially significant environmental effects on the environmental resources identified in Attachment 2 of Appendix H, *Supporting Materials for Chapter 16*. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, similar to construction impacts disclosed in Section 16.2.4, *Recycled Water Sources for Water Supply*, it is likely impacts related to the construction of facilities could be mitigated to less than significant once mitigation measures were implemented. This is because of the temporary nature of construction, the relative short duration of construction, and that construction would generally occur within existing facility footprints or the public right-of-way. However, the generation of GHGs during construction and operation over the lifetime of the project may not be lessened with mitigation measures and as such, may result in exceedances of existing air quality management basin thresholds resulting in GHG impacts and utilities and service system impacts that cannot be mitigated to less than significant levels.

16.2.6 Water Supply Desalination

Reductions in surface water diversions are expected as a result of approving an LSJR alternative and the program of implementation. These reductions in surface water could potentially affect SFPUC by reducing some portion of their current water supply obtained from the Tuolumne River during a 6-year drought as described in Appendix L, *City and County of San Francisco Analyses*. Under certain LSJR alternatives (i.e., higher unimpaired flow LSJR Alternatives 3 and 4), SFPUC may need multiple new water supplies to augment their current drought supply. One option is desalination of ocean or brackish water. The WSO report addressed potential challenges or issues associated with constructing and operating a year-round desalination facility (capacity of 28,000 AF/y) near the existing Oceanside Water Pollution Control Plant in San Francisco (SFPUC 2007). In the WSIP PEIR (SFPUC 2008), the Oceanside site, along with two other alternative locations, were identified as potential sites for desalination in drought years as part of the Bay Area Regional Desalination

Program (BARDP). SFPUC included the BARDP in the WSIP PEIR analysis as part of a "variant" of the WSIP. The BARDP would involve a partnership among five regional water agencies—SFPUC, Contra Costa Water District (CCWD), East Bay Municipal Utility District (EBMUD), Santa Clara Valley Water District (SCVWD), and Zone 7 Water Agency (Zone 7). In addition to the WSIP PEIR analysis of the BARDP, feasibility studies evaluating various sites, a site-specific pilot study and other site-specific analyses have been completed for the BARDP since 2003. Following the Institution Feasibility Analysis, the participating water agencies concluded that the Oceanside site and the Bay Bridge site in Oakland were not feasible (CCWD et al 2016). Presently, water supply desalination is being considered for all hydrologic year types under the BARDP at Mallard Slough in the Delta, with an estimated production of 20,900 AF/y (CCWD 2014).

This section presents information regarding a desalination project (maximum capacity of 28,000 AF/y) provided in the Bay Area Regional Desalination Project Site Specific Analyses Final Report (CCWD 2014), the Final Draft Bay Area Regional Desalination Project Greenhouse Gas Analysis (Kennedy/Jenks Consultants 2013), and the WSIP PEIR (SFPUC 2008), as well as information for the Poseidon Desalination Facility in Carlsbad (capacity of 56,000 AF/y). The cost and environmental evaluation for the BARDP presented in the following sections are based on information from site-specific pilot studies and feasibility studies, and assumes the BARDP desalination plant and intake to be located at the existing Mallard Slough intake/pump station site.

A desalinization project would provide a reliable water supply regardless of the water year type or other surface water supplies used by SFPUC. A desalinization project would likely need to be larger than analyzed in the WSO report, or the BARDP feasibility studies, for LSJR Alternatives 3 and 4. Therefore, costs and environmental impacts associated with the larger Poseidon Desalination Facility in Carlsbad are also provided below.

Cost Evaluation

The State Water Board analyzed the potential water needed in the service area of SFPUC during a 6-year drought sequence (Appendix L, *City and County of San Francisco Analyses*). The analysis determined SFPUC may need to replace between 13,800 AF/y and 207,810 AF/y during a 6-year drought sequence. The conveyance and storage options being considered for the BARDP would involve the use of CCWD's Mallard Slough, Transfer, Old River, and Middle River pumping plants and CCWD's Old River, Transfer, and Los Vaqueros pipelines, as well as storage in Los Vaqueros Reservoir. CCWD developed a cost estimate for the BARDP use of the Mallard Slough Pump Station, conveyance to Los Vaqueros storage, storage in Los Vaqueros, and delivery from storage to the Mokelumne Aqueduct. Those cost estimates are provided in Table 16-11a, *Cost Estimates for BARDP Use of Existing Water Conveyance and Storage Facilities*.

Table 16-11a. Cost Estimates for BARDP Use of Existing Water Conveyance and Storage Facilities

BARDP Component	Estimated Cost ($/AF/y)
Use of Mallard Slough Pump Station and associated water rights	$86–$121
Conveyance to Los Vaqueros Reservoir	<$1
Storage in Los Vaqueros Reservoir	$70–$105
Delivery from Los Vaqueros Reservoir[a]	$16

Source: CCWD 2014.

BARDP = Bay Area Regional Desalination Project.

AF/y = acre-feet per year.

[a] Cost does not include the East Bay Municipal Utility District's costs for wheeling water through their system for final delivery to other BARDP participating water agencies.

In 2010, a cost estimate was prepared as part of a pilot study at the Mallard Slough Pump Station. It was estimated that the capital cost for a facility that would use 28,000 AF/y of brackish or ocean water to produce approximately 22,175 AF/y of treated water, including the intake and pipeline for conveyance to the existing conveyance system, would be $168 million, or approximately $8.50 per gallon per day. This includes contingencies and planning, permitting, engineering, and administrative costs. The annual operating cost was estimated at approximately $10.5 million (MWH 2010).

Current desalination projects under development in California have estimated costs between $1,000 and $3,000 per AF (WaterReuse 2012, SDCWA 2015). Poseidon Resources is currently developing the Carlsbad Desalination Project, and will own and operate the facility after construction is completed. However, the County of San Diego has the option to purchase the plant in 30 years. A purchase agreement for water from the plant is in place and water is expected to cost between $1,849 and $2,064 per AF in 2012 dollars (SDCWA 2015). Based on total costs per AF of other desalination facilities in California (WaterReuse 2012, SDCWA 2015) it is estimated that the total cost for water produced would be between $1,000 and $2,200 per AF.

Environmental Evaluation

Summary of Potential Action

The BARDP would entail diverting water from the Delta through an existing intake at the CCWD Mallard Slough Pump Station (available capacity up to 40 mgd subject to existing water rights, terms and conditions) through existing pipelines to a proposed desalination plant for treatment. The desalination plant and connections to the existing water conveyance network in the region are the only new infrastructure anticipated for the project. The desalination plant is expected to draw a constant 21 mgd of water. Treated water from the new BARDP desalination plant would be conveyed via CCWD's Multi-Purpose Pipeline for delivery to CCWD customers or the Mokelumne Aqueduct for delivery to EBMUD's water treatment plants and subsequent delivery to the participating water agencies, or both (Kennedy/Jenks Consultants 2013). Based on pilot project results, it is assumed that the brine stream from the new desalination plant would be a constant 20 percent of the diverted 21 mgd, or approximately 5 mgd (CCWD 2014). Two potential existing WWTPs have been identified to dispose of the brine originating from the desalination treatment process: Central Contra Costa Sanitary District (CCCSD) and Delta Diablo Sanitation District (DDSD). It is estimated that given the current the dry weather discharge capacities of CCCSD and DDSD, CCCSD would have the capacity to accept the brine through 2030 (CCWD 2014).

BARDP desalinated water production would exceed participating water agencies' demands in non-drought years, but would fall short of the higher combined demands in drought years. Excess BARDP water production would be stored in Los Vaqueros Reservoir in non-drought years through an exchange with CCWD, and the stored BARDP water would be released from the reservoir in drought years. The minimum BARDP demand would be approximately 14 mgd in all years. EBMUD, SCVWD, and CCWD BARDP water demand would occur less frequently and is based on hydrologic year type as well as other factors, but estimated demand could be as high as approximately 46 mgd in some drought years. In drought years, the demand of all five water agencies could not be met with only BARDP production. However, unused production stored via exchange in Los Vaqueros Reservoir during non-drought years (maximum 4.6 mgd) could augment deliveries in drought years. CCWD estimated over an 82-year CalSim II modeling period that the combined demand of SFPUC, EBMUD, SCVWD, CCWD, and Zone 7 is 1,754 thousand AF (TAF) and the maximum BARDP production would be 1,714 TAF. Accordingly, approximately 98 percent of the combined demand could be met. This is considered an upper limit that assumes all excess BARDP production could be stored in Los Vaqueros Reservoir (CCWD 2014).

Potential Environmental Effects

As part of the WSIP PEIR, SFPUC prepared a conceptual-level, generalized impact analysis of the BARDP, which, at the time of the analysis, was based on limited, preliminary information regarding project design and operation, and site location. Because of this limited project-specific information, it was generally determined that most of the potential impacts associated with construction and operation of a desalination plant and associated facilities would be potentially significant for the following resources: land use and visual quality; geology, soils, and seismicity; air quality; cultural resources; GHG emissions; hazards; noise and vibration; traffic, transportation, and circulation; public services and utilities; recreational resources; and agricultural resources (SFPUC 2008). However, for these resources it was presumed that potentially significant impacts could be avoided or reduced to a less-than-significant level through site selection, project design, and implementation of "environmentally-sensitive" construction and operation techniques or through implementation of mitigation measures (SFPUC 2008). With respect to mineral resources and population and housing that were not evaluated by the WSIP PEIR, it's anticipated that impacts would not occur under construction and operations. This is because the desalination facilities would not result in a loss of mineral resources. In addition, the facilities would not be built to accommodate an increase in population in the service area and would not include housing or other amenities that might result in an increase in population. Construction and operation of the BARDP would require substantial nonrenewable energy resources and although some of the impacts could potentially be mitigated through project design with application of energy-saving technologies, impacts were considered significant and unavoidable to be conservative (SFPUC 2008). It was determined in the WSIP PEIR impact analysis that operation of the BARDP would result in potentially significant and unavoidable impacts on hydrology and water quality, biological resources, and energy resources. Although potential water quality impacts due to brine and associated impacts on biological resources (specifically, aquatic resources including special-status species) for the BARDP could potentially be mitigated through design/operation, mitigation measures, and regulatory compliance, the impact was considered significant and unavoidable, to be conservative (SFPUC 2008). Attachment 3 of

Appendix H, *Supporting Materials for Chapter 16,* contains a summary of the impacts, mitigation measures, and SFPUC construction measures applicable to the BARDP. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, as noted by the WSIP PEIR, significant impacts associated with the following resources could likely be reduced to less than significant with the implementation of mitigation measures: land use and visual quality; geology, soils, and seismicity; air quality; cultural resources; GHG emissions; hazards; noise and vibration; traffic, transportation, and circulation; public services and utilities; recreational resources; and agricultural resources.

BARDP feasibility studies done for a desalination facility at the Mallard Slough intake analyzed potential water quality impacts of operating the desalination facility and brine disposal, as well as the potential impacts on sensitive fish populations due to operating the facility (CCWD 2014). In addition, the study estimated GHG emissions associated with operation of the desalination facility and water conveyance to participating water agencies (Kennedy/Jenks Consultants 2013). Based on water quality modeling, it was determined that changes in ambient water quality associated with BARDP operations and brine disposal at CCWD or DDWD were too small to be accurately measured in the field, and that during most conditions, operations would not have a significant impact on water quality or beneficial uses (i.e., municipal water supply, wildlife, agriculture). Further, during critically dry water years, BARDP operations would need to be coordinated with CVP, SWP, and the City of Antioch[14] operations to avoid impacts (CCWD 2014). Construction of the BARDP would produce one-time estimated GHG emissions associated with the use of construction equipment and vehicles. As estimated by the GHG analysis performed for the BARDP, facility operations would produce approximately 9,200 MT CO_2e emissions (Kennedy/Jenks Consultants 2013). Potential GHG reduction measures/projects identified in the 2013 GHG analysis for the project included: green building design, pump energy optimization program, commercial/residential rebates (solar hot water heater program), invest in large-scale renewable energy, local solar photovoltaic projects, fleet fuel reduction, GHG offset purchases, and wetlands restoration (Kennedy/Jenks Consultants 2013).

A facility that is larger than the BARDP (e.g., 56,000 AF/y) would have similar types of construction and operation impacts. The types of construction activities associated with a large desalination facility with a capacity of 56,000 AF/y would be similar to those required for a smaller facility like the BARDP and would likely result in temporary, and localized effects typically associated with similar activities including air quality effects and ground disturbance. Long-term operational impacts associated with a large desalination facility with a capacity of 56,000 AF/y would be similar in nature to those described in the feasibility studies as well as in the WSIP PEIR for the BARDP, and are primarily related to marine life entrainment, brine outfall, and impact on open space and recreation areas. Desalination facilities are typically relatively energy intensive. The increased electrical demand as a result of a larger design capacity (i.e., increase from 28,000 to 50,000 AF/y) could result in increases in GHG emissions and air quality impacts under operating conditions. The operation of desalination facilities may require a slight increase in chemical transport and storage, but as the facilities would likely be constructed within or adjacent to existing treatment facilities, the increase would be negligible compared to existing chemical use and transport at these locations.

---

[14] The City of Antioch has an intake in close proximity to the proposed BARDP facilities.

While there are many geographic differences between the San Francisco Bay–Delta and Carlsbad, similar environmental impacts were identified for the project-level analysis of the Carlsbad facility (City of Carlsbad 2015). Cumulative regional impact on air quality for the production of ozone and PM10 were determined to be significant and unavoidable. The following resources were identified as less than significant after mitigation for the Carlsbad facility: cultural resources, hazards and hazardous materials, hydrology and water quality, land use and planning, and traffic and circulation.

16.2.7 New Surface Water Supplies

Reductions in surface water diversions are expected as a result of implementing an LSJR alternative. As such, some water suppliers may explore the feasibility of constructing and operating on- or off-stream reservoirs to obtain new surface water supplies. However, new reservoirs present unique technological challenges that require extensive engineering, biological, and environmental studies to evaluate the feasibility of constructing, operating, and maintaining them. Amongst many considerations, the feasibility of constructing and operating a surface water reservoir depends on the implementation of an LSJR alternative and whether water is available in the Stanislaus, Tuolumne, and Merced River Watersheds for such use.

It is likely that the implementation of the LSJR alternatives would reduce surface water availability on the Stanislaus, Tuolumne, and Merced Rivers. With more water devoted to instream flow requirements, existing surface water reservoirs on these rivers would receive less water relative to current conditions. As such, any new surface water reservoir would be in competition with older reservoirs that likely have senior water rights. If the new reservoir could not capture enough storage, or generate enough hydropower, to outweigh the costs of construction and operation, it may be deemed infeasible. Furthermore, some parts of the Upper Stanislaus, Tuolumne, and Merced Rivers Watersheds are fully appropriated, meaning all available water has been claimed. Specifically, 8 percent of the Upper Stanislaus River Watershed, 3 percent of the Upper Tuolumne River Watershed, and 14 percent of the Upper Merced River Watershed are fully appropriated. This would constrain potential locations for a new surface water reservoir and potentially limit the volume of water that could be stored. In addition, planning and constructing new surface water reservoirs would likely not occur within a reasonable timeframe to augment or provide new water supplies in the foreseeable future. For example, Tuolumne Utilities District (TUD) is considering a backup reservoir for one of its current water delivery flumes in its service area on the Stanislaus River and has estimated it could be built and filled within the next 10 years (The Union Democrat 2016). In addition, the Temperance Flat Reservoir on the Upper SJR has been contemplated, discussed, and evaluated for over 15 years (Friant Waterline 2014). These projects typically have incredibly long-lead times because multiple pre-project studies for engineering, environmental, and economic analyses would be required before any construction could begin. These studies would need to show that a proposed on- or off-stream reservoir in the eastside LSJR tributary watersheds could be constructed and operated with an estimated average annual water supply yield and associated benefits to justify the cost. Given the above, the likelihood of constructing and operating a new surface water reservoir is low. However, general costs associated with constructing and operating new reservoirs are still evaluated below, as well as environmental resources for which there could be a significant and unavoidable impacts. The environmental analysis does not include the construction of new reservoirs within Yosemite National Park because it is not reasonably foreseeable.

Cost Evaluation

The costs associated with constructing and operating a reservoir depend on numerous factors including, but not limited to: its potential location, the size of the reservoir, the type of demand to be served, the infrastructure needed to convey stored water to end users, and the regulatory and political climate.

Within the state, several reservoirs are in the planning stage, including the Temperance Flat Reservoir, which would be located in Fresno and Madera Counties between Friant Dam and Kerckhoff Dam, on the Upper SJR (SJVWIA 2016). The total estimated investment cost for the Temperance Flat Reservoir is $2.5–$2.8 billion (USBR 2014a, SJVWIA 2016). The project would include a dam at river mile (RM) 274 on the Upper SJR, diversion and outlet works, a low-level intake structure, valve house, powerhouse, transmission facilities, and access roads (USBR 2014a). Total annual costs once the dam and reservoir are operational would be approximately $116–$121 million. This cost would include operation and maintenance for the reservoir facilities, hydropower mitigations, and net additional CVP and SWP power costs (USBR 2014a). The estimated annual cost does not include water conveyance costs beyond the net power requirement for delivering the new water supply (USBR 2014a).

The California Water Commission (CWC) has been accepting concept papers for other potential new reservoirs or reservoir expansions across California in preparation for funding projects with Proposition 1. Three of these projects were proposed by TUD to serve Tuolumne County and would be located on tributaries to the Stanislaus River above New Melones. Given that the details of the projects are not yet known, it is speculative to analyze them prior to the project proponent's funding, approval, and design; however, they are provided here as comparison points to the Temperance Flat Reservoir. The three projects are the expansion of the Herring Creek Reservoir, Sierra Pines Reservoir, and Upper Strawberry Reservoir, with expected costs of $150 million, $40 million, and $120 million, respectively (TUD 2016a, TUD 2016b, TUD 2016c). However, none of these proposals included justification of additional water supply to meet demand, rather they cited water supply reliability in the event of an unanticipated need. The expansion of the Herring Creek Reservoir would include construction of a 130-foot high dam to store 11,000 AF on Herring Creek, a tributary to the South Fork of the Stanislaus River, because the current reservoir is silted and abandoned (TUD 2016a). The Sierra Pines Reservoir proposal would construct and operate an 850 AF reservoir and recreational area at the existing confluence of the Pacific Gas and Electric Company (PG&E) Tuolumne Main Canal and the TUD Section 4 Ditch. It would not add to the existing water supply of TUD, but rather would be used in the event that there is a critical distribution outage. This proposal is undergoing feasibility studies, but the water source to fill this reservoir would come from an existing contract with PG&E for diversions out of the Tuolumne Main Canal (TUD 2016b). The Upper Strawberry Reservoir proposal would include constructing a 120-foot high dam to store 6,000 AF just above Pinecrest Lake (TUD 2016c).

Environmental Evaluation

Summary of Potential Action

It is unknown exactly how surface water users would respond to a reduction in their surface water supply as a result of the program of implementation and the potential of developing surface water storage is low because of the limits on available water supplies. Further, it is not possible to estimate the construction parameters of potential reservoirs here because their construction will depend on too many factors unknown at this time. However, the Temperance Flat Reservoir can be used as an example for describing the construction and operation of a potential reservoir, given that Temperance Flat would be located on the Upper SJR Watershed. Using the Temperance Flat Reservoir as an example does not mean it would be constructed or operated. It is simply used to provide context for the type of significant environmental impacts that could occur if new surface water reservoirs were constructed and operated. Any project-specific conditions for this reservoir or other surface water reservoirs that may be constructed and operated would need to be considered, analyzed, and mitigated. For example, Temperance Flat is a significantly larger reservoir than the three reservoirs described in the concept papers by TUD. As such, smaller reservoirs would likely result in smaller construction and operation footprints and thus have reduced or fewer impacts when compared to larger projects, such as Temperance Flat. In addition, reservoirs constructed in different locations than Temperance Flat with a different physical environment would have different impacts and mitigation measures to accommodate those physical environmental conditions.

The Temperance Flat reservoir and dam, if constructed, would be built in the upstream portion of Millerton Lake on the SJR. The reservoir would provide approximately 1,260 TAF of additional storage capacity and increased water supply reliability. In addition, it would improve system operational flexibility for agricultural, urban, and environmental purposes in the CVP's Friant Division, as well as in other San Joaquin Valley areas and other regions of California (USBR 2014b).

Currently, a preferred alternative for the Temperance Flat reservoir project has not been chosen, and five alternatives, including a no action alternative, have been analyzed in the Draft Environmental Impact Report (DEIR) for the project. All action alternatives adjust Friant Dam operations for delivery of new water supplies via the SJR to Mendota Pool. The action alternatives also propose modifying the timing and quantity of water diverted to Madera and Friant-Kern canals, which would increase water supply reliability to Friant Division contractors and provide opportunities for groundwater banking. Further, the action alternatives would improve conjunctive management in the Friant Division of the CVP by increasing incidental groundwater storage and/or recharge. The action alternatives primarily differ in terms of carryover storage for Millerton Lake and Temperance Flat Reservoir, beneficiaries and routing of new water supply, and type of intake. (USBR 2014b).

Potential Environmental Effects

If the construction and operation of a new dam and the Temperance Flat Reservoir proceeds, it would result in temporary and permanent environmental impacts. Significant and unavoidable construction- and operations-related impacts were identified for the following resources in the DEIR: air quality and GHG emissions; fisheries and aquatic ecosystems; botanical and wetlands resources; wildlife; cultural resources; paleontological resources; geology and soils; land use, planning and agricultural resources; transportation; noise; energy; recreation; and visual resources (USBR 2014b). Impacts that were mitigable to a less-than-significant level were identified for the following resources: air quality, botanical and wetlands resources, wildlife, paleontological resources, surface water quality, geology and soils, transportation, recreation, public health and hazardous materials, and utilities and service systems (USBR 2014b).

Table 16-11b, *Potential Environmental Effects of New Surface Water Supplies*, summarizes the potential environmental effects of the Temperance Flat Reservoir as well as the potential impacts of construction and operation of a large reservoir on the Stanislaus, Tuolumne, or Merced Rivers upstream of the rim dams. As noted above, it is not reasonably foreseeable that new reservoirs would be constructed within Yosemite National Park; therefore, such reservoirs are not analyzed. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this action and is referenced in Table 16-11b, where appropriate.

Table 16-11b. Potential Environmental Effects of New Surface Water Supplies

Potential Environmental Effects of New Surface Water Supplies	
Resource	Discussion
Aesthetics	• Construction of new surface water supplies (dams and associated storage reservoir) would be expected to significantly affect the visual character or quality of areas because construction would be a multi-year process with major excavation for the dam footprint, excavation of major aggregate source areas at or near the site, creation of multiple access roads to the new dam and associated structures for personnel and equipment access, clearing and grading for equipment staging areas, clearing and grading for onsite, temporary construction buildings, nighttime lighting for construction, safety and security, and cutting of all trees that would be in the reservoir inundation zone. Once the dam was completed, reservoir filling for dam stability testing would convert the natural river canyon scenery to a placid lake. Construction and operation of new surface water storage facilities may have operational, security and safety lights. Impacts would depend on the location of sensitive receptors to potential lighting; however, lights would be expected to follow lighting guidelines and lighting plans of local jurisdictions approving the construction and operation of the new surface water storage facilities. Table 16-38 identifies potential mitigation measures lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant environmental effects associated with lighting. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • If new surface water reservoirs were constructed and operated in the portions of rivers designated as National Wild and Scenic River (83 miles of the Tuolumne River: 47 miles wild, 23 miles scenic, 13 miles recreational) or studied as potentially eligible (Stanislaus River) then the impacts would be significant and unavoidable. The impacts would be significant and unavoidable because of the substantial change to the visual character and quality of the surrounding area from natural river canyon scenery to a placid lake and there is no mitigation available that would reduce these aesthetic impacts to less than significant.
Agriculture and Forestry Resources	• Construction and operation of new surface water storage facilities would not be expected to take place on lands used for agriculture (including Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) because there is limited agricultural land adjacent to the river systems where new reservoirs might be built. Impacts would be less than significant. • Construction and operation of new surface water facilities could affect forestry resources, either private forest lands or federal National Forest System lands (e.g., Stanislaus National Forest) because most of the potential reservoir sites partially overlap forest vegetation zones. As such, there would be a conflict with existing zoning for forest land and potentially timberland, and potentially a loss or conversion of forest land to non-forest use. Table 16-38 identifies potential mitigation measures lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant environmental effects on forestry resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. If forest land or timberland is permanently removed from production due to construction and operation of new surface water facilities, then it is likely impacts would not be fully mitigated and would be significant and unavoidable.

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
Air Quality	• It is expected that a new surface water reservoir would be located upstream of the existing rim dams, and potentially in the MCAB, and the GBVAB. New surface water storage facilities and associated recreation facilities could be located in these air basins. This could occur within the jurisdictions of CCAPCD, the GBUAPCD, MCAPCD, and TCAPCD. For projects within CCAPCD jurisdiction a significant impact would occur if project emissions are greater than 150 pounds per day for ROG, NO_X, or PM10 in either the construction or operational periods. No thresholds for other criteria pollutants or their precursors have been established by the CCAPCD. The GBUAPCD does not have adopted quantitative thresholds of significance for criteria pollutants for proposed projects for the purposes of CEQA, although thresholds from neighboring air districts (e.g., CCAPCD, TCAPCD, SJVAPCD) may be used to evaluate impacts within the GBUAPCD. For construction impacts, the GBUAPCD requires that project proponents adopt comprehensive mitigation measures to mitigate fugitive dust impacts. For emissions associated with the operation of stationary sources, the GBUAPCD considers stationary emissions to be less than significant if they are exempt from Rule 202 pursuant to Rule 209-A(B)(2). Rule 209-A identifies emission limits of 250 pounds per day for ROG, NO_X, SO_X, and particulate matter. For projects within MCAPCD jurisdiction a significant impact would occur if project operational emissions are greater than 100 tons per year for ROG, NO_X, CO, SO_X, PM10, and PM2.5 (County of Mariposa 2006). For projects within TCAPCD jurisdiction a significant impact would occur if project emissions are greater than 100 tons per year or 1,000 pounds per day for ROG, NO_X, CO, and PM10. If SJVAPCD requirements are used their published guidelines, *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), do not require the quantification of construction emissions. Rather, the guidelines require implementation of effective and comprehensive feasible control measures to reduce PM10 emissions (SJVAPCD 2002). SJVAPCD considers PM10 emissions to be the greatest pollutant of concern when assessing construction-related air quality impacts and has determined that compliance with its Regulation VIII, including implementation of all feasible control measures specified in its *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), constitutes sufficient mitigation to reduce construction-related PM10 emissions to less-than-significant levels and minimize adverse air quality effects. All construction projects must abide by Regulation VIII. Further consultation with SJVAPCD staff indicates that, though explicit thresholds for construction-related emissions of ozone precursors are not enumerated in the *Guide for Assessing and Mitigating Air Quality Impacts*, SJVAPCD considers it a significant impact when construction or operational emissions of ROG or NO_X exceed 10 tons per year or if PM10 or PM2.5 emissions exceed 15 tons per year (Siong pers. comm.). • Construction of new surface water storage and recreation facilities would result in emissions associated with: general construction equipment, concrete batch plants, heavy-duty off-road equipment, materials transport in haul trucks, worker commute to the site, and increases in recreational visitors to the area. The amount of criteria air pollutant emissions would be less if amortized over the total life of the project (i.e., total daily or yearly emissions would be averaged over a longer time interval). Fugitive dust emissions would occur from exposed soils during the construction period. Depending on the level of activities and amount of infrastructure built, construction of new surface water storage facilities could exceed air quality thresholds established by applicable APCDs and would be required to implement measures to help reduce or minimize construction-related emissions. Lead agencies (e.g., state or federal agencies, utility districts) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
	on air quality from construction-related emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Operation of new surface water storage facilities would result in minimal air quality related emissions because one of the primary activities would be hydroelectric generation. Associated recreational facilities would generate air quality related emissions from vehicle trips, motorized boating or Jet Ski use, and electricity use. However, local electricity use would likely be from the dam hydroelectric facility itself, so there would be no emissions from other region-wide electrical generation. Emissions from vehicle trips, motorized boating or Jet Ski use could result in exceedances of applicable APCDs within the plan area or extended plan area, and could result in a potentially significant impact. Lead agencies (e.g., state or federal agencies, utility districts) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on air quality associated with operational emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • The various APCDs have determined some common types of facilities that have been known to produce odors in the region. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants. Construction and operation of new surface water storage facilities would not involve the type of facility identified by, for example, SJVAPCD, as a known odor source (SJVAPCD 2002). Consequently, it is expected that new surface water storage facilities would not create objectionable odors affecting a substantial number of people. Impacts would be less than significant. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction and operation of new surface water storage facilities would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. Construction and operation of new surface water storage facilities would not result in growth because the facilities would not involve the construction of new homes in the area, the extension of roads, or other infrastructure that may induce substantial property or population growth in an area, and because the storage facilities would be constructed and operated to replace a water source that was reduced (i.e., surface water) rather than to increase capacity to serve new users. Construction and operation of new surface water storage facilities would not result in population or employment growth that would result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Accordingly, this impact is less than significant.

Potential Environmental Effects of New Surface Water Supplies	
Resource	Discussion
Biological Resources	• It is expected that construction and operation of new surface water facilities would be in natural landscapes that could include chaparral, oak woodland, conifer forest and perhaps alpine, depending on location. These areas are expected to have a high potential for special-status plant species, animal species, and habitat (including federally protected wetlands). Additionally, these habitats would be completely replaced by aquatic lake habitats. There is minimal potential to fully mitigate these impacts. In addition, operation of new surface water facilities would result in a change in the flow regime and potentially alter temperature downstream, which could result in impacts to aquatic species. There is also potential that construction or operation of new surface water storage facilities would result in a conflict with an existing local policy or an adopted habitat conservation plan or natural community conservation plan. Reservoir construction within the boundaries of the Stanislaus or Sierra National Forests or the Bureau of Land Management lands could conflict with their existing management direction. Table 16-38 lists potential mitigation measures lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant environmental effects of construction and operations on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even after mitigation, however, impacts would still likely remain significant and unavoidable due to the large scale replacement of habitat with an aquatic lake habitat.
Cultural Resources	• Construction of new surface water storage facilities would likely take place in relatively natural settings, however, these areas have an extensive history of use by Native American tribes and Euro-Americans during and subsequent to the Gold Rush era. Consequently, extensive archaeological and historical resources would likely be disrupted by construction, filling and operation of new surface water storage facilities. Construction may result in ground-disturbing activities which have the potential to disturb or destroy buried, unknown, significant cultural resources (significant historical, archeological, or paleontological resources). Lead agencies (e.g., state or federal agencies, utility districts) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on cultural resources associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even after mitigation, however, impacts would still likely remain significant and unavoidable due to the potential large scale disturbance of the area. • Operation of reservoir facilities has the potential to affect cultural resources during reservoir drawdown which could expose cultural resource sites to discovery and disruption by the general public. Lead agencies (e.g., state or federal agencies, utility districts) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on cultural resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even after mitigation, however, impacts would still likely remain significant and unavoidable due to the potential large scale disturbance of the area. • As described above, it is expected that new surface water storage sites would not have been previously disturbed. Therefore, there is potential that human remains, typically buried at depths of 6 ft, would be disturbed during construction. If, in the highly unlikely event human remains are uncovered during construction, compliance with the State Health and

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
	Safety Code would be required. As specified by Section 7050.5 of the Health and Safety Code, and described in Table 16-38, no further disturbance would occur until the county coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code Section 5097.98. If such a discovery occurs, excavation or construction would halt in the area of the discovery, the area would be protected, and consultation and treatment would occur as prescribed by law. If the coroner recognizes the remains to be Native American, he or she would contact the NAHC, who would appoint the Most Likely Descendent. Additionally, if the human remains are determined to be Native American, a plan would be developed regarding the treatment of human remains and associated burial objects, and the plan would be implemented under the direction of the Most Likely Descendent. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even after mitigation, however, impacts would still likely remain significant and unavoidable due to the potential large scale disturbance of potential areas.
Geology and Soils	• The locations of new surface water storage facilities could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, the counties in the extended plan area do not contain known Alquist-Priolo faults and are in a zone of low seismic shaking. The new surface water supply facilities could result in an impact on or be affected by expansive soils, or landslides. Landslides could occur on cut slopes created for dam building or from the reservoir side slopes when filled with water. New structures would be required to follow all appropriate building codes and dam design criteria and would be designed to withstand seismic-related activities as identified by the building codes and dam design criteria. Dam design criteria include those from the DWR Division of Safety of Dams (DSOD), federal Dam Safety and Security Act of 2002 (Public Law 107-310), as well as geological engineering, geotechnical engineering, and engineering design standards. New surface water storage facilities would not substantially increase the number of people exposed to the risk of earthquakes since the areas are not in areas with Alquist-Priolo faults or strong seismic shaking. If there was an increase in reservoir side slope instability, people drawn to the reservoir for recreational opportunities would be exposed to that geologic hazard. However, geological engineering and geotechnical engineering studies for new surface water storage facilities would address these potential instabilities. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts related to geology and soils associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the need to follow the building code and other state and federal building and dam design requirements. • The construction and operation of new surface water storage and related facilities would potentially involve constructing or operating septic tanks for construction crews or for post-construction recreation facilities. Therefore, septic tanks could be affected by soils incapable of supporting the use of them or other alternative wastewater disposal systems. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts related to septic tanks associated with construction and operations. Until such time

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
	that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction and the relatively small scale of the recreation facilities. • Construction of new surface water storage facilities would result in substantial ground-disturbing activities that could cause soil erosion or loss of topsoil that would occur with a construction period of multiple years. Ground-disturbing activities of 1 acre or greater would require preparation and implementation of a SWPPP, as required by the Regional Water Quality Control Board. The SWPPP would require soil and erosion control mechanisms for all stages of construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts on soil erosion and storm water runoff associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary, albeit multi-year, nature of construction.
Greenhouse Gas Emissions	• Generation of GHG emissions associated with new surface water storage facilities and associated recreation facilities would result from: general construction equipment, concrete batch plants, heavy-duty off-road equipment, materials transport in haul trucks, worker commute to the site, increases in recreational visitors to the area, and loss of CO_2 sequestration from vegetation that dies within the reservoir inundation zone. The total amount of GHG emissions would be less if amortized over the total life of the project. The following APCDs do not have applicable GHG thresholds: CCAPCD, MCAPCD, TCAPCD. For air districts in which there is no adopted GHG threshold, the ZEL for SJVAPCD could be applied. As such, it is anticipated that increased GHG emissions could exceed the applicable SJVAPCD ZEL threshold and result in a potentially significant impact. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts of construction and operations from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
	AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Construction of new surface water storage facilities would occur over several years and would involve the limited transport, storage, use, and disposal of hazardous materials such as fuel and lubricating grease for motorized heavy equipment. Some examples of typical hazardous materials handling are fueling and servicing construction equipment on the site, and transporting fuels, lubricating fluids, solvents, and bonding adhesives. Operation of hydroelectric generation facilities at the dam would involve various oils and greases for lubrication. These types of materials are not acutely hazardous, and storage, handling, and disposal of these materials are regulated by local, county, and state laws. While the quantities of these materials used during construction would not be small, the amount used at any one time would be small (e.g., less than 100 gallons). Therefore, if a spill occurred, it could be readily and easily contained. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary, albeit multi-year, nature of construction. • The precise location of where new surface water storage facilities would be constructed is not yet known; however, these facilities could be constructed within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation activities. As such, if a school existed within close proximity to construction of new surface water storage facilities, those mitigation measures identified table 16-38 applied to project-specific construction needs would reduce potentially significant impacts during construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction.

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
	• Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962, these sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the DTSC for Alpine, Calaveras, or Tuolumne Counties (i.e., counties where the Stanislaus or Tuolumne Rivers are located) (CalEPA 2016). In addition to these sites identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 62 active open leaking underground storage tanks in these counties (CalEPA 2016). There are approximately 7 facilities in these counties identified as having active CDOs/CAOs (CalEPA 2016). The active and open leaking underground storage tank cases and the CDO/CAO facilities are located throughout these counties. Although it is not yet known precisely where in the extended plan area new surface water storage facilities would be constructed, if they were constructed on a Cortese Site, there would be potential for release and spread of existing soil or groundwater contaminants because construction of new surface water storage facilities would entail substantial excavation. Were release and spread of existing soil contaminants to occur, impacts could be significant. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • Operation of new surface water storage facilities would not involve the use of hazardous materials and impacts would not occur. • Construction and operation of new surface water storage facilities would not be a hazard or cause safety concerns to public or public use airports or private airstrips because the facilities would be constructed and operated within, or immediately adjacent to, the river banks and channels and would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, construction and operation of new surface water storage would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Construction and operation of new surface water storage facilities would not physically interfere with an adopted emergency response plan or emergency evacuation plan. Reservoirs could potentially restrict the mobility of people to escape potential emergencies in the vicinity of the reservoir (e.g., wild fires, forest fires). Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts associated with restricted travel routes during construction or reservoir operations. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction and the fact that there are relatively few road systems in these areas that could potentially be blocked by new reservoirs.

Potential Environmental Effects of New Surface Water Supplies	
Resource	Discussion
	• Construction and operation of new surface water storage facilities would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Because construction would involve substantial clearing of work sites and construction laydown areas, onsite workers would have access to substantial shelter-in-place areas from wildfires during that time. These cleared areas would also be useable by local residents evacuating wildfires in the areas. Impacts would not occur.
Hydrology and Water Quality	• Construction of new surface water storage facilities and associated recreation facilities could result in temporary and permanent changes to drainages, erosion, or runoff associated with typical construction activities, such as grading or preparation of land as well as major excavation and blasting for dam foundation preparation. As discussed earlier in this table (Geology and Soils section), for soil disturbance of over 1 acre, wastewater treatment special districts or municipalities would be required to prepare and implement a SWPPP. In addition, as discussed in this table for Hazards and Hazardous Materials, construction of new surface water storage facilities may involve the limited transport, storage, use, and disposal of hazardous materials, which, if spilled, could have adverse effects on water quality depending on the location and magnitude of the spill. However, storage, handling, and disposal of these materials is regulated by local, county, and state laws, and the quantities of these materials used during construction would be small (e.g., less than 100 gallons) and construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained and, as such, violations of water quality standards are not expected to occur. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts of construction on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary, albeit multi-year, nature of construction. • It is likely that the new surface water storage facilities would be located in a flood hazard area because the dam and reservoir would be within an existing river channel. However, the flood hazard area would be relatively narrow as the dam and reservoir would likely be built in a relatively deep canyon to maximize storage. Once constructed the reservoir area would prevent flooding within the reservoir zone and also provide storage to minimize major floods downstream of the dam. Additionally, construction and operation of the new surface water storage facilities would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to or place housing within flood hazard locations (including 100-year flood hazard areas). Construction and operation of new surface water storage facilities would not expose people to significant loss, injury, or death related to flooding. Impacts would be less than significant. • Construction of new surface water storage facilities would not substantially alter the existing drainage pattern of the site or area, or substantially increase the rate or amount of surface runoff such that the new surface water storage facilities would result in flooding or otherwise cause flooding, or create or contribute runoff water. New structures would be required to follow all appropriate building codes, dam design criteria, and engineering design standards, which would address drainage of the site. Impacts would be less than significant. • Operation of new surface water storage facilities and associated recreation facilities would not likely contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems. However, because there

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
	would potentially be an increase in impervious surfaces associated with new recreational facilities (e.g., restrooms), stormwater runoff could increase. Table 16-38, under “Geology and Soils” lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts of recreational facility operation related to storm water runoff and drainage. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction of new surface water storage facilities and associated recreation facilities would not increase the volume of treated effluent discharged into receiving waters. This is because effluent would be treated via septic systems or contained in closed vault toilet systems. Therefore, it is expected that hydrology would not be affected. However, since these facilities may use septic systems, Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts of reservoir construction and operations and recreational facility operation related to septic systems. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Increases in groundwater pumping are not expected to occur under the construction and operation of new surface water storage facilities because such facilities would only pump groundwater to locally dewater wet areas during construction. Because construction of new surface water storage facilities would not result in a substantial increase in impervious surfaces and therefore would not interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or lowering of the local groundwater table. Impacts would be less than significant. • Construction and operation of new surface water storage facilities would primarily be located in areas of relatively steep relief because they would be within deep river canyons. Therefore, these locations would support mudflows, which typically need very steep slopes and large amounts of precipitation to occur. Additionally, reservoir filling would potentially increase landslides and mudflows from the steep reservoir side slopes as they were saturated by reservoir water. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts of reservoir construction and operations and recreational facility operation related to landscape instability. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • New surface water storage reservoirs are not expected to experience sufficient seismic ground shaking to generate in-reservoir seiches that could inundate recreational sites. However, large fast landslides into the reservoir could generate splash waves that would affect recreational sites along the reservoir. The potential for these large, fast landslides would depend on the local slope steepness, geologic materials, and thickness of surficial deposits. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts of reservoir creation on large fast landslides. Until such time that these potential mitigation

Potential Environmental Effects of New Surface Water Supplies	
Resource	Discussion
	measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • There are no other ways in which construction or operation of new surface water storage reservoirs could result in a substantial degradation of water quality.
Land Use and Planning	• Construction and operation of new surface water storage facilities would not physically divide an established community because there are few communities in the vicinity of potential construction sites. Impacts would not occur. • Construction and operation of new surface water storage facilities would likely take place within areas designated as rural residential, open space or timber production zone (if on private lands) or on areas managed for forestry and wildlife (if on National Forest System lands or Bureau of Land Management administered lands). These lands are unlikely to be designated for dam and reservoir development and would require changes in zoning (for county or private lands) and changes in land use management designation (for National Forest System lands or Bureau of Land Management administered lands). • If the new surface water storage facilities were inconsistent with applicable land use plans, policies, or regulations, an amendment or variant from the local jurisdiction or National Forest or Bureau of Land Management approving the discretionary action associated with these facilities would be required to be obtained by the project proponent prior to project approval and construction. If no discretionary action occurred as a result of the construction or operation of the new surface water storage facilities, it is assumed they would not result in a conflict with local land use plans, policies, or regulations. Impacts would be less than significant. • Potential conflicts with habitat conservation plans, natural community conservation plans, Stanislaus or Sierra National Forest Plans or Bureau of Land Management plans or other plans, policies and regulations protecting biological species and resources are evaluated in the Biological Resources section of this table.
Mineral Resources	• Construction and operation of new surface water storage facilities would have a potential to result in the removal or inability to access state or locally designated mineral resource areas. This is because the new surface water storage facilities would inundate a large area along an existing river which could potentially include such designated mineral resource areas. If the new surface water storage facilities construction or inundation zone are located within a state or locally designated mineral resource area, construction and operation of these facilities would permanently remove access to these mineral resources. Before constructing new surface water facilities, sites would be assessed for suitability and property ownership as part of design and engineering feasibility studies. Sites would be assessed to determine if they are located on a state or locally designated mineral resource area, and mineral resource areas would be avoided to the extent feasible so that impacts on mineral resources can be avoided or minimized. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts associated with mineral resources during construction or reservoir operations. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, other than aggregate resources, there is limited potential to mitigate the loss of access to these mineral resources and impacts would be significant and unavoidable if they occurred.

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
Noise	• Construction of new surface water storage facilities could generate temporary noise or ground-borne vibrations if blasting is used. It is likely that the new surface water storage facilities would be constructed in areas relatively removed from towns or population centers with sensitive receptors (e.g., homes, hospitals, schools). Additionally, since this would be a major, multi-year construction effort public access to the area would be restricted, thereby limiting the potential for public exposure to construction noise. If sensitive receptors were adjacent to construction activities and experienced construction noise, the impacts would likely be temporary and would be required to follow existing local noise ordinances limiting the timing of construction (e.g., generally Mondays–Fridays, 7am–6pm). However, given the large scale of constructing a new surface water reservoir and the unique types of construction required, it is likely that activities may need to occur for extended periods of time in 24-hour intervals. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant noise impacts related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • New surface water storage facilities would generate minimal noise during operation. The noise would be from release of water from the dam, from hydroelectric components within the dam, or alarm bells. This noise would only occur within the immediate vicinity of the reservoir dam. It is anticipated there would be a very low probability that sensitive receptors (e.g., homes, hospitals, schools) would be located within close proximity to experience the operating noise generated because it is anticipated that the facilities would be not be located near an existing town or population center. People exposed to the noise would be those visiting or recreating in the immediate vicinity and noise associated with the facility would be an expected part of that experience. Impacts would be less than significant. • The construction and operation of new surface water storage facilities would not bring people within close proximity to an airport or expose people to airport noise. Impacts would not occur.
Population and Housing	• The construction and operation of new surface water storage facilities would not involve the construction of new homes in the area. However, some operational personnel would be necessary for dam and hydroelectric operation and development of recreation facilities on the reservoir are likely. Depending on the distance to local small towns, onsite housing might be required for operational personnel. Recreation could involve camping, hiking, swimming, non-motorized or motorized boating, jet skis, hunting and angling. Depending on the size of the reservoir there is potential that new local small businesses (such as marinas, house boats, tent camp grounds, camp grounds with recreational vehicle utility hook ups, grocery and general purpose stores) could be located onsite or nearby. These recreational and business amenities would be expected to draw seasonal recreational users. The construction and operation of new surface water storage facilities would not involve the construction of new homes, the extension of roads, or other infrastructure that may induce substantial property or population growth in an area. Accordingly, impacts would be less than significant. • The construction and operation of new surface water storage facilities would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the facilities would be located in relatively remote areas. Impacts would not occur.

Potential Environmental Effects of New Surface Water Supplies	
Resource	Discussion
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. The operation of new surface water storage facilities and associated recreation facilities would involve an increase in people in the area, primarily for seasonal recreational purposes. The increased recreational use in an area would require additional local fire protection, wild land fire protection (e.g., CALFIRE), police protection, electrical service, and water service. Electrical service would likely be provided by dam hydroelectric power and the local water supply would likely come from the new reservoir. The need for new schools is not considered likely given that any population growth, if it occurs, is expected to be small. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts on public services related to operations and recreational use. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Recreation	• If new surface water reservoirs were constructed and overlapped the portions of rivers designated as National Wild and Scenic River (83 miles of the Tuolumne River: 47 miles wild, 23 miles scenic, 13 miles recreational) or studied as potentially eligible (Stanislaus River) then the impacts would be significant and unavoidable. The impacts are considered significant and unavoidable because of the elimination of these designated recreational resources and there is no mitigation available that would reduce these recreation impacts to less than significant. • Construction of new surface water storage facilities would likely involve the development of reservoir-associated recreation facilities. Recreation could involve camping, hiking, swimming, non-motorized or motorized boating, jet skis, hunting, and angling. Depending on the size of the reservoir there is potential that new local small businesses (such as marinas, house boats, tent camp grounds, camp grounds with recreational vehicle utility hook ups, grocery and general purpose stores) could be located on site or nearby. These recreational and business amenities would be expected to draw recreational users and some permanent residents to the area. These new recreation opportunities would be a benefit to recreational use in the vicinity of the new surface water storage facilities. Potential impacts on other resources as a result of constructing new recreational facilities are addressed by resource in this table. • Construction and operation of new surface water storage facilities could increase the use of existing parks or recreational facilities in the local region as recreationists unfamiliar with the area explore the area. However, it is not anticipated that additional new recreational facilities would be constructed beyond those described for Population and Housing in this table (e.g., marinas, house boats, tent camp grounds). Impacts would not occur.

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
Transportation and Traffic	• Construction of new surface water storage facilities would result in substantial additional trips associated with pre-construction surveys (e.g., geotechnical, environmental), construction workers, and equipment delivery over a multi-year period. New surface water storage facilities likely would be located in rural, low population areas with a limited and narrow lane road network with limited baseline congestion. The increased traffic over this multi-year period would exceed local or regional road trip thresholds. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts on transportation and traffic related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction. • Operation of new surface water storage facilities and new recreational use of reservoir facilities would generate additional vehicle trips by workers and recreationists. The number of trips by dam workers would be small. However, recreation and recreation-associated traffic would likely be substantial at times (such as summer holiday weekends) potentially exceeding local or regional trip thresholds. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts on transportation and traffic associated with operations. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Construction of new surface water storage facilities would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Construction and operation of new surface water storage facilities would not be expected to exceed wastewater treatment requirements of the Central Valley Water Board because water releases from a new dam would be expected to meet water quality objectives in the receiving water. The additional storage could also provide flexibility to meet water quality objectives in the rim dams if there was additional control of inflowing water. Dam operational facilities and recreation sites would not be expected to require a new WWTP in the vicinity. Wastewater would be addressed via properly designed septic systems and/or closed vault toilet systems. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts from septic systems associated with construction and operations. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The construction and operation of new surface water storage facilities would require the construction of additional storm water drains for them or for the associated recreational facilities. However, surface water drainage design from these locations would be required to ensure that new septic system leach fields function properly. Table 16-38 lists potential mitigation measures that lead agencies (e.g., state or federal agencies, utility districts) can and should implement to reduce potentially significant impacts from septic systems associated with construction and operations (identified in the table under Utilities and Service Systems), and from storm water drains (identified in the table under Hydrology and Water

Potential Environmental Effects of New Surface Water Supplies

Resource	Discussion
	Quality). Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of new surface water storage facilities could generate solid waste from construction debris, from operational facilities and from recreation sites at the reservoir. Most of this type of solid waste is not considered hazardous. Disposal of hazardous and non-hazardous materials would follow all regulations and guidelines of solid waste in Class I (hazardous waste)/II landfills (non-hazardous waste landfills). Impacts would be less than significant.

16.3 Lower San Joaquin River Alternatives – Non-Flow Measures

This section describes non-flow measures that affected entities may undertake in the plan area between the rim dams on the Stanislaus, Tuolumne, and Merced Rivers or on the LSJR and in the southern Delta. Non-flow measures would not be implemented above the rim dams in the extended plan area. These non-flow measures would inform the body of scientific literature and understanding regarding special-status fish species and the stressors and mechanisms that have contributed to their decline on the three tributaries and in the southern Delta. The information provided by these measures could potentially be used to inform adaptive implementation decisions under each of the LSJR alternatives. The non-flow measures evaluated in this section include the following.

- Floodplain and Riparian Habitat Restoration
- Reduce Vegetation-Disturbing Activities in Floodplains and Floodways
- Gravel Augmentation
- Enhance In-Channel Complexity
- Improve Temperature Conditions
- Fish Passage Improvements—Fish Screens (screen unscreened diversions in tributaries and LSJR)
- Fish Passage Improvements—Physical Barriers in the Southern Delta
- Fish Passage Improvements—Removal or Modification to Human-Made Barriers to Fish Migration
- Predatory Fish Control
- Invasive Aquatic Vegetation Control (i.e., plant control)

While these actions may inform adaptive implementation, the State Water Board would not be undertaking these actions since these non-flow measures are beyond its regulatory authority to undertake; rather, it is the entities affected by the LSJR alternatives, or resource agencies with the authority to do so, who could choose to undertake one or more of these actions to inform adaptive implementation. The environmental impacts of these potential actions are evaluated below.

16.3.1 Floodplain and Riparian Habitat Restoration

Floodplain and riparian habitat restoration is recognized as a key component of comprehensive ecosystem restoration and species recovery efforts in the Central Valley. These types of projects are typically focused on the lowland mainstem and tributary reaches of Central Valley rivers, such as the Stanislaus, Tuolumne, and Merced Rivers, where channels, bars, and floodplains are formed and maintained through the processes of sediment transport, deposition, and channel migration. In addition to flow modification to promote natural physical and ecological processes that form and sustain riparian and floodplain habitat (Opperman 2012), a number of non-flow actions, typically acting in concert with flow, have been identified as integral components of floodplain and riparian habitat restoration. It is broadly recognized that historical and contemporary impacts on floodplain and riparian habitat associated with flow regulation, channelization, levee building, and human land use have greatly diminished the capacity of Central Valley rivers to support the ecologic functions necessary to restore native fish and wildlife populations (CALFED 2000a, USFWS 2001), and that active, physical modification of existing and historical river corridors is also required to substantially improve these functions (McBain and Trush 2000).

Typical non-flow measures to restore floodplain and riparian habitats include the following:

- Creation or expansion of natural or engineered floodways or flood bypasses.
- Modifications of river and floodplain geometry (e.g., floodplain lowering) to increase floodplain inundation.
- Active planting or allowing natural establishment of riparian vegetation on restored floodplain surfaces or converted agricultural land.
- Hydrologic reconnection of historical floodplains to active river channels through levee breaches and/or setbacks.
- Removal of riprap or other bank protection (e.g., dredger tailings) restricting active channel migration and floodplain creation.

Cost Evaluation

Floodplain and riparian habitat restoration can be achieved through the different approaches described above. While site-specific conditions influence the cost of the approach, in general, removal of riprap or other bank protection and active plantings are generally lower cost approaches when compared to creating or expanding natural or engineered floodways, modifications of river and floodplain geometry, or hydrologic reconnection of historical floodplains through levee breaches and/or setbacks. This is generally because removal of riprap and active plantings may require fewer feasibility and design studies, fewer permits, and fewer responsible agencies may be involved and require limited adaptive management and mitigation monitoring plans to evaluate the effectiveness of the projects. In addition, removal of riprap and active plantings are less likely to require the purchase of property, which can be a substantial cost associated with floodplain and riparian habitat restoration. For example, the LSJR Floodplain Protection and Restoration Project acquired a total of 223.54 acres of wildlife habitat adjacent to the SJR and eastside tributaries for preservation and future enhancement of riparian and wetland habitats for a cost of $1.1 million (CALFED ERP 2016). The Basso Bridge Ecological Reserve and Merced River Ranch Land Acquisitions on the Merced River were purchased for approximately $830,000 of riparian habitat in 1997 to protect spawning riffles and enhance riparian species (CALFED ERP 2016). At the time of purchase, it was simply to secure the land and active restoration was not planned (CALFED ERP 2016). Levee breaches depending on the size, scale, and location of the projects, can be very costly. For example, the Cosumnes River Floodplain Restoration Project, where the U.S. Army Corps of Engineers breached and abandoned 5.5 miles of levees to allow the river to flow into the floodplain as a result of the 1997 floods, resulted in a cost of $1.55 million (Swenson et al. n.d.).

Environmental Evaluation

The primary sources of information for the following general description of floodplain and riparian restoration projects and associated environmental impacts were DWR (2013a), National Marine

Fisheries Service (NMFS) (2013), U.S. Fish and Wildlife Service (USFWS) (2013), and McBain and Trush (2000). Additional references are cited below.

Summary of Potential Action

Planning and design activities for floodplain and riparian restoration projects may include topographic surveys, flood frequency analysis, hydraulic modeling, geomorphic investigations, and sediment modeling of alternative design scenarios. Integration of ecological criteria to define specific hydrologic, hydraulic, and topographic attributes of functional floodplain and riparian habitat may also be used to guide restoration design and optimize benefits for target restoration species (Williams et al. 2009, Matella and Merenlender 2014).

The magnitude of construction impacts on vegetation, soils, streambed substrates, and water quality depends on the extent and duration of disturbance to existing habitat and species, and the extent of temporary and permanent habitat loss. Construction activities for floodplain and riparian restoration projects may include demolition and/or relocation of roads, utilities, and other existing structures; clearing and grubbing of staging and work areas; removal and/or placement of rock or biotechnical slope protection (depending on hydraulic considerations); grading of river–floodplain connections and floodplain surfaces; stockpiling of equipment and materials; and installation of irrigation systems and restoration plantings. Typical construction equipment includes graders, excavators, loaders, cranes, and barges. Common environmental commitments or BMPs to avoid, minimize, or offset potential environmental effects may include seasonal work windows; preconstruction biological surveys; biological monitoring during construction; invasive species prevention; construction noise and light reduction measures; traffic control; SWPPP; spill prevention, control, and countermeasure plan; turbidity compliance monitoring; and soil hazard testing and disposal.

Operation and maintenance of floodplain and riparian restoration sites may include vegetation maintenance (irrigation, weeding, and monitoring), control of burrowing rodents, road reconditioning, visual inspections, and slope repair. To address uncertainties in the ecological processes governing floodplain and riparian habitat formation and maintenance at selected sites, progress toward achieving the objectives or optimizing the benefits of these projects is typically monitored and guided through an adaptive management process.

Potential Environmental Effects

Depending on the size and scale of floodplain or riparian restoration, these types of projects may fit within a categorical exemption under CEQA. CEQA allows categorical exemptions for classes of projects which have been determined not to have a significant effect on the environment. (Pub. Res. Code, § 21084.) Specifically, small habitat restoration projects, on sites that do not exceed 5 acres, are exempt from CEQA review under a Class 33 categorical exemption provided that:

- There would be no significant adverse effect on endangered, rare, or threatened species or their habitat.
- There are no hazardous materials or toxic waste at or around the project site that may be disturbed or removed.
- The project would not result in impacts that are significant when viewed in connection with effects of past projects, the effects of current projects, and the effects of probable future projects.

Small habitat restoration projects include stream or river bank revegetation to improve habitat for amphibians or native fish.

If a floodplain or riparian habitat restoration project does not meet the Class 33 exemption requirements, then the project would require CEQA review. Construction of floodplain and riparian habitat restoration projects may result in temporary and localized effects typically associated with construction activities, including a change in water quality, air quality effects, and ground and channel disturbance. Floodplain and riparian restoration would likely occur below the dams which are accessible to Chinook salmon and steelhead on the LSJR, and Stanislaus, Tuolumne, and Merced Rivers where there is currently a lack of floodplain and riparian habitats. The restoration areas would vary by river, depending on the channel geometry and if fish are currently using the areas. River channels would be graded and riparian vegetation planted in areas that could support special-status fish species such as Chinook salmon and steelhead. Aquatic and terrestrial biological resources would be the most affected during construction activities to restore floodplain and riparian habitat.

It is reasonable to assume that restoration of floodplain and riparian habitat would be professionally installed by contractors familiar with such projects. Depending on the magnitude of the projects, construction could last anywhere from several weeks to several months. If the project is large enough, it may extend over two construction seasons but last no more than a total of 12 months, to comply with June–October in-water work restrictions. It is expected construction activities would occur during the dry season (typically June–October) when anadromous fish would not be spawning and in compliance with endangered species requirements. BMPs for controlling sediment and contaminant release into waterbodies would be used to minimize potential effects associated with water quality and hazardous materials per regulations under the Clean Water Act and any permitting requirements and conditions from the Central Valley Water Board or the U.S. Army Corps of Engineers. Floodplain restoration sites would result in changes to hydraulics, channel substrate, and stream habitats. Riparian restoration would increase habitat for special-status wildlife and fish species. The changes to hydraulics, channel substrate, stream habitats, and increases in habitat conditions are expected to achieve the purpose of restoring the habitat and benefit aquatic and terrestrial biological resources.

Table 16-12, *Potential Environmental Effects of Floodplain and Riparian Habitat Restoration*, summarizes the potential environmental effects associated with floodplain and riparian habitat restoration. Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this non-flow measure and is referenced in Table 16-12 where appropriate.

Table 16-12. Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration	
Resource	Discussion
Aesthetics	• Construction and operation of floodplain and riparian restoration projects could affect scenic vistas, but only temporarily during construction and they would not permanently alter scenic vistas. Construction may be observable for a temporary period of time when heavy equipment is used to grade banks, move sediment, and plant vegetation around the project site. However, it is anticipated that the location of these projects would not be within close proximity to sensitive viewers (e.g., recreationists or residents) given the remote location of the projects within rivers. If sensitive viewers are located within close proximity, the temporary nature of construction and the fact that views would not be permanently changed would be such that significant impacts would not occur. Operation may be noticeable at first during the time it takes for natural processes such as establishment of riparian vegetation and river channel dynamics to occur. After that, the river channel may be more aesthetically pleasing due to the enhanced vegetation and restoration of natural river morphology. Lighting is not expected to be used during floodplain and riparian restoration projects. Construction is expected to occur during daylight hours given the location of the projects. Impacts would be less than significant.
Agriculture and Forestry Resources	• Construction and operation of floodplain and riparian restoration projects could be located on lands used for agriculture if the expansion of floodplain habitat included setback levees and breaches. Land use below the dams on the rivers is predominantly zoned as general agriculture and limited agriculture. Allowed uses for general agriculture typically include compatible public, quasi-public, and special uses and natural open space areas. Limited agriculture also allows for compatible public, quasi-public, a special uses such as parks and natural open spaces. Floodplain expansion and riparian vegetation planting or natural establishment may occur on agricultural land (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) if located close to the river channel. In some instances, if agricultural land is allowed for special uses and natural open spaces, floodplain expansion and riparian vegetation restoration could fall into these categories and there would be no conflict with existing zoning for agriculture use or a Williamson Act contract. If agricultural land is not allowed for special uses and natural open space, then floodplain expansion and riparian vegetation may permanently convert Prime Farmland, Farmland of Statewide Importance and Unique Farmland to nonagricultural uses (i.e., restored floodplain and riparian habitat). The extent of the impact would depend on the total acres permanently removed from agricultural use and whether they were in Williamson Act contracts. Agricultural mitigation programs and agricultural preservation statutes are designed to compensate for the premature and unnecessary conversion of agricultural land to urban uses, discourage discontiguous urban development patterns, and promote the conservation, preservation, and continued existence of open space lands. For this reason, traditional agricultural mitigation programs, such as agricultural conservation easements, may be inapplicable to habitat projects, which retain land in open space use even if it is not agricultural. As a result, agencies have taken different approaches in addressing conversion of agricultural lands for ecosystem improvements, based, in part, on their missions. Table 16-39 identifies mitigation strategies that may be applicable that lead agencies can and should implement, which have been identified for prior habitat

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration	
Resource	Discussion
	projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Forest land is limited or does not occur below the dams on the rivers; therefore there would be no conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Construction of floodplain and riparian restoration projects would likely result in emissions associated with construction equipment and construction worker vehicle trips. The quantity, duration, and the intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. Floodplain and riparian restoration could take several weeks to several months, depending on the magnitude of the project. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since construction of groundwater wells does not require lengthy construction activities, the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the SJVAPCD regulations and established thresholds. Lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction of floodplain and riparian restoration projects would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction of floodplain and riparian restoration projects would not result in growth because these projects are habitat restoration projects for the benefit of special-status fish species. Accordingly, these projects would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • Operation of floodplain and riparian restoration projects would likely result in scheduled maintenance or monitoring vehicular trips. Emissions from the vehicles would not prevent compliance with regulations or exceed thresholds established by SJVAPCD, conflict with or obstruct implementation of the applicable air quality plan or violate any air quality standard or contribute substantially to an existing or projected air quality violation, or result

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration	
Resource	Discussion
	in a net increase of any criteria pollutant for which the project region is nonattainment under applicable federal or state ambient air quality standards, given the limited number of vehicles over a longer timeframe. Impacts would be less than significant. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). Floodplain and riparian restoration projects would not create objectionable odors affecting a substantial number of people. Impacts would not occur.
Biological Resources	• Construction of floodplain and riparian restoration projects could release sediment and possibly hazardous materials (e.g., oil or gas from construction equipment) into waterbodies, affecting water quality. Release of sediment can bury macroinvertebrates which are prey for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat. Operation of floodplain and riparian restoration projects would change aquatic habitat by changing river width, river habitat types (riffles, pools, runs), and hydraulics. While construction may have some temporary adverse effects, overall restoration would have beneficial long-term effects for sensitive aquatic and terrestrial species (e.g., Chinook salmon, steelhead, California red-legged frog, western yellow-billed cuckoo). Water quality measures such as monitoring turbidity during construction to ensure compliance with the objectives of the Water Quality Control Plan for the Sacramento River and SJR Basins (Basin Plan) and construction BMPs would be implemented as either mitigation measures under CEQA or permit requirements and conditions. Furthermore, a mitigation, monitoring, and management plan (MMP) would be enforced after restoration is completed. These measures are part of permitting requirements and conditions by resource agencies including USFWS, California Department of Fish and Wildlife (CDFW), Central Valley Water Board, and U.S. Army Corps of Engineers. The floodplain and riparian restored areas would need maintenance to control invasive plant species, and monitoring to determine survival of planted riparian vegetation and to ensure the floodplain is functioning as designed and benefiting fish and wildlife species once construction is complete. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction of floodplain and riparian restoration projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction of floodplain and riparian restoration projects would not interfere with the movement of native residential or migratory fish species and associated migratory corridors, or impede the use of nursery sites because any work done in the water would occur during June to October when fish are not spawning or migrating. In addition, overall it is expected that there would be a beneficial effect on special-status fish species following restoration. Impacts would not occur.

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
	• The surrounding habitat on river banks may include riparian vegetation and/or wetlands. Riparian vegetation may have to be removed to facilitate heavy equipment movement and wetlands may also be disturbed during construction activities. This would result in a significant impact on riparian habitat and wetlands. Under operations, wetlands would not be affected and riparian vegetation would be enhanced. Removal and/or disturbance of riparian and wetlands habitats would be compensated for at a ratio appropriate for the disturbance per standard permit requirements or conditions from the U.S. Army Corps of Engineers and the Central Valley Water Board, or the floodplain and riparian restoration would be self-mitigating if it included wetland habitat. This would reduce and minimize impacts on fish and wildlife species and their habitats. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction of floodplain and riparian restoration projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of floodplain and riparian restoration projects would be located in river reaches that support special-status fish species such as Chinook salmon and steelhead. These areas are expected to have high potential for special-status plant species, animal species, and habitat, and support biological resources. Floodplain and riparian restoration projects would occur during the least sensitive periods of special-status species life stages, (i.e., during the dry season between June and October), as this would reduce and minimize impacts on aquatic species and would be required through either the CEQA process or through permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce potentially significant environmental effects of construction and operations on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • While construction may result in temporary localized adverse effects on special-status species, plants, and habitat, construction activities are highly unlikely to result in population level adverse effects for any species. Floodplain and riparian restoration are discussed under the SJR Wildlife Refuge CCP and the San Joaquin County Multi-Species Habitat Conservation and Open Space Plan (SJMSCP) as a means to enhance fish habitat on the rivers. In addition, conflicts with local policies as a result of construction are not considered significant because of the temporary and localized nature of the effects. As such, this impact would be less than significant.

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
Cultural Resources	• Construction and operation of floodplain and riparian restoration projects would be within existing river banks and channels or immediately adjacent. It is unknown if cultural resources (significant historical, archeological, or paleontological resources) exist in these locations, and river banks that contain cultural resources could be excavated for floodplain restoration during construction. Typically the river channels have had high levels of disturbance because of hydraulic conditions; and as such, there is a low potential for significant cultural resources to exist within the rivers. Similarly, there would be a low potential for the discovery of human remains due to the regular disturbance. However, if levees were breached during construction, there could be cultural resources or human remains within the potential levee. Operation of floodplain and riparian restoration areas would have a very low potential to affect cultural resources because operation would be along the river bank and channels. Where construction within areas that may contain cultural resources cannot be avoided, an assessment would be conducted of the potential for damage to cultural resources prior to construction. The assessment may require hiring a qualified cultural resources specialist to determine the presence of significant cultural resources or human remains. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant effects on cultural resources associated with construction of floodplain and riparian restoration projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.
Geology and Soils	• Floodplain and riparian restoration could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, floodplain and riparian restoration would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, or landslides. Impacts would not occur. • Project sites would be evaluated before construction begins for the potential of soil erosion in the design of the restoration project. Floodplain and riparian restoration projects should not result in substantial erosion or sedimentation that would not support the objectives of the restoration under operating conditions. However, given construction would likely take place along rivers and in riparian areas where erosion can take place depending on the soil characteristics, geology, and area of disturbance, lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant erosion or sediment effects associated with construction or operation of floodplain and riparian restoration projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Floodplain and riparian restoration would not bring people to the risk of earthquakes or geologic hazards, meaning the operation of the restored areas would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur.

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
Greenhouse Gas Emissions	• Construction of floodplain and riparian restoration would result in increased GHG emissions from use of heavy equipment. While construction activities would be limited from several weeks to several months, it is likely that restoration activities could result in a potentially significant GHG impact. Although the SJVAPCD has not established construction-related GHG thresholds, they have identified a level of GHG emissions per year (230 MT CO$_2$e) below which project-specific increases in GHG emissions would be considered equivalent to zero for CEQA purposes. This amount, known as a ZEL, can be used to evaluate construction emissions when they are amortized over the project's anticipated operational lifespan. For example, a project using a 30-year operational lifespan would be considered significant if total construction emissions would exceed 6,900 MT CO$_2$e (230 MT CO$_2$e/year* 30 years = 6,900 MT CO$_2$e), while a project using a 50-year operational lifespan would be considered significant if total construction emissions would exceed 11,500 MT CO$_2$e (230 MT CO$_2$e/year * 50 years = 11,500 MT CO$_2$e). Depending on the level of construction activities and the potential operational lifespan of the project, construction-related GHG emissions could exceed these values and result in a potentially significant impact. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • During operation, some vehicles may be needed for monitoring or maintenance of restored areas. However, the trips would be limited, of very short duration, and over a long period of time (e.g., one trip every year). As such, they would likely result in extremely small quantities of GHG emissions. However, GHG emissions may still exceed SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
	inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Construction and operation of floodplain and riparian restoration would not be a hazard or provide a safety concern to public or public use airports or private airstrips because restoration would be constructed and operated within, or immediately adjacent to, the river banks and channels and would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, construction and operation of floodplain and riparian restoration would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Construction and operation of floodplain and riparian restoration would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road and within, or immediately adjacent to, the river banks and channels. Impacts would not occur. • Construction and operation of floodplain and riparian restoration projects would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • Construction of floodplain and riparian restoration projects could involve the temporary use of small amounts of hazardous materials, such as gasoline or diesel, to power construction equipment. Excavation would be necessary and utility lines could be within proximity to the project site. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due to hazards and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The precise location of where floodplain and riparian restoration projects would be constructed is not yet known; however, these projects could be constructed within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation activities. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
	hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962. These sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the DTSC for Calaveras, Tuolumne, or Mariposa Counties (CalEPA 2016). There were a total of 17 sites identified for Merced, San Joaquin, and Stanislaus Counties. In addition to these sites identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 500 leaking underground storage tanks designated as open in these counties (CalEPA 2016). There are approximately 55 facilities in these counties that have received CDOs/CAOs not identified as non-hazardous wastes, domestic wastewater or domestic sewage (CalEPA 2016). The active and open leaking underground storage tank cases and the CDO/CAO facilities are located throughout these counties. Although it is not yet known precisely where floodplain and riparian restoration would be constructed, if restoration were done on a Cortese Site, because construction activities would likely entail some ground disturbance (e.g., grading), there would be potential for release of existing soil contaminants. Were this to occur, impacts could be significant. Table 16-39 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • Construction of floodplain and riparian restoration sites would require excavation. Utilities may be underneath the sites or adjacent to a site and may need to be relocated or avoided. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potential hazards associated with excavation around utilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.
Hydrology and Water Quality	• Construction of floodplain and riparian restoration projects may temporarily change water quality due to grading the river banks and channels. Excavating the river bank and driving heavy equipment in and near the river channel could result in a temporary increase in turbidity. Due to the limited nature of construction and construction activities limited to the dry season, it is not expected that water quality standards for the protection of fish and wildlife would be exceeded because construction timing (i.e., June–October) would avoid the most sensitive life stages of special-status fish species. Additionally, turbidity would be monitored to maintain compliance with Basin Plan water quality objectives. Construction of floodplain and riparian restoration projects would not alter the capacity of existing or planned storm water drainage systems, and would not provide substantial additional sources

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
	of polluted runoff. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of floodplain and riparian restoration projects would not substantially deplete groundwater supplies or interfere substantially with groundwater recharge because these projects would not require groundwater during construction or operation, and would not result in an increase in impervious surfaces. Impacts would not occur. • Operation of floodplain and riparian restoration projects could alter the existing drainage pattern of the site or area, but is not expected to cause substantial erosion, siltation, substantial runoff, or result in flooding on- or offsite. Floodplain restoration is typically used as a mechanism to decrease flooding. Floodplains allow water to spread across a wider area and relieve constricted channels of flow. Constriction of flow typically results in erosion or siltation. Additionally, site design would assess existing hydrology and channel geomorphology to ensure the restoration of floodplain or riparian habitat meets project objectives and provides benefits to intended targeted species. An MMP, which is part of the permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers, would be implemented to ensure no erosion is occurring, floodplain design is successful, and newly planted riparian vegetation is surviving. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of floodplain and riparian restoration projects would not place housing within a 100-year flood hazard area because implementation of these restoration project would not entail the construction of housing. Impacts would not occur. • Construction and operation of floodplain and riparian restoration projects would not substantially increase the number of people exposed to the risk of flooding because these projects would not draw people to flood hazard locations. As such, construction and operation of floodplain and riparian restoration projects would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Construction and operation of floodplain and riparian restoration projects would not entail the construction of structures in a 100-year flood hazard area that would impede or redirect flows. Impacts would not occur. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Floodplain and riparian restoration is not expected to occur near a lake or reservoir. Impacts would not occur.

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
	• There are no other ways in which construction or operation of floodplain and riparian restoration areas could result in a substantial degradation of water quality.
Land Use and Planning	• Construction and operation of floodplain and riparian restoration projects would not physically divide an established community because they would be located within existing river banks and channels, or immediately adjacent to them, and communities are not established in these areas. Impacts would not occur. • Construction and operation of floodplain and riparian restoration sites would occur in existing river banks and channels, or immediately adjacent to them, and would not conflict with land use designations or zoning. Frequently these areas are designated natural resource or open space areas by land use plans. Restoration would be consistent with those designations because it would enhance existing habitat for fish and wildlife species. Impacts would not occur. • The following habitat conservation plans cover parts of the Stanislaus, Tuolumne, and Merced Rivers: SJR Wildlife Refuge CCP and the SJMSCP. These plans protect special-status species within the San Joaquin, Stanislaus, Tuolumne, and Merced Rivers. As described in the Biological Resources section of this table, there would be some temporary construction impacts on adjacent riparian and/or wetland areas, but lead agencies would mitigate these temporary impacts through measures identified in Table 16-39. As such, no conflicts are expected with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations. Impacts would not occur.
Mineral Resources	• There are known aggregate mines along all three eastside tributaries[15] (Clinkenbeard 1999, Clinkenbeard 2012a and 2012b, Higgins and Dupras 1993, Rapp et al. 1977, Smith and Clinkenbeard 2012). Although these may not all be active at present, it is assumed some exist on each river even if their exact location with respect to active channel proximity is unknown. Construction and operation of floodplain and riparian restoration could have the potential to result in the removal or inability to access state or locally designated mineral resource areas, depending on the location of the restoration area and the location of the active mining site. However, there are several reasons why there is a low potential for this to occur. Before constructing floodplain and riparian restoration areas, sites would be assessed for suitability and property ownership as part of design and engineering feasibility studies. Restoration sites would be assessed to determine if they are located on a state or locally designated mineral resource area. It is likely these areas would be avoided for restoration because these areas do not have the characteristics needed for successful floodplain and riparian habitat restoration projects (i.e., suitable substrate and lack of aggregate). Further, it is unlikely that a gravel operator/owner would allow floodplain and riparian restoration on a designated mineral resource area that is being actively mined. In addition, aggregate mine operators are required to reclaim mined areas once the mining is complete and there may be opportunities to enter into cooperative agreements for floodplain and riparian habitat restoration projects once active mining is complete. Therefore, there is a low

---

[15] In this document, the term *three eastside tributaries* refers to the Stanislaus, Tuolumne, and Merced Rivers.

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
	potential that the construction and operation of floodplain and riparian restoration would remove or prevent access to state or locally designated mineral resource areas. As such, impacts would be less than significant.
Noise	• Construction of the floodplain and riparian restoration sites would create noise related to the use of heavy construction equipment. The sites would be located within, or immediately adjacent to, river banks and channels on the San Joaquin, Stanislaus, Tuolumne, and Merced Rivers where people generally do not live. It is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies due to the remote location of these projects from populous areas. Excessive ground-borne vibration or ground-borne noise levels are also not expected due to the location of the projects and the standard type of construction equipment that would be used. Temporary elevated noise in excess of standards established in local general plans, noise ordinance, or applicable standards, may occur during the day (as construction is not expected to occur at night) and for short periods of time. However, given the limited exposure of potential sensitive receptors to this potential temporary increase and low likelihood of potential sensitive receptors to exist because of the remoteness of the project sites, it is expected impacts would be less than significant. Operation of the floodplain and riparian restoration sites would not create noise. There may be some maintenance activities requiring construction equipment and vehicular trips for monitoring, but they would not create a permanent increase in ambient noise and would be temporary in duration and infrequent. This impact would be less than significant. • Construction and operation of floodplain and riparian restoration sites would not generate excessive noise that would result in people's exposure to excessive noise levels near airports. Impacts would not occur.
Population and Housing	• The construction and operation of floodplain and riparian restoration sites would not involve construction of new homes or businesses, extension of roads, or other actions that may induce substantial property or population growth in an area. Furthermore, restoration sites would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • The construction and operation of floodplain and riparian restoration sites would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere. Restoration sites would be located within, or immediately adjacent to, river banks and channels. No homes or people would be displaced. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, construction and operation of floodplain and riparian restoration sites would not involve an increase in population or housing. In addition, these actions would not include proposals for new housing or increase demands for school services or facilities. Impacts would not occur.

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
Recreation	• Construction of floodplain and riparian restoration sites would occur within, or immediately adjacent to, river banks and channels on the San Joaquin, Stanislaus, Tuolumne, and Merced Rivers. It is possible that recreational facilities would be located in areas where floodplain and riparian restoration sites would occur. If recreational facilities were located within very close proximity, construction of floodplain and riparian restoration sites may affect them; however, it is unlikely that there would be significant effects on recreational facilities because construction would be temporary and limited (e.g., several weeks to several months). Construction and operation of floodplain and riparian restoration sites would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would be less than significant.
Transportation and Traffic	• Construction of floodplain and riparian restoration sites could result in some additional vehicle trips associated with construction workers. The temporary increased traffic during construction would likely not exceed local or regional road trip thresholds, because generally a small number of construction workers are required. Generally these types of projects require approximately 45 additional trips per day for construction workers and approximately 50 trips per day for borrow material transport (CVFPB 2013). Additionally, the duration of construction would be short (e.g., several weeks to several months). Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant transportation and traffic impacts related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Operation of floodplain and riparian restoration sites would not generate additional trips beyond those required to maintain the sites. If maintenance activities are needed, they would be temporary in nature, infrequent and operation of the sites would not increase traffic. Impacts would not occur. • Construction of floodplain and riparian restoration sites would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.

Potential Environmental Effects of Floodplain and Riparian Habitat Restoration

Resource	Discussion
Utilities and Service Systems	• Construction and operation of floodplain and riparian restoration sites would not affect the ability to meet wastewater treatment and discharge requirements of the Central Valley Water Board because site restoration would not involve wastewater. Impacts would not occur. • Construction and operation of floodplain and riparian restoration sites would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. As such, impacts would not occur. • Construction and operation of floodplain and riparian restoration sites would not need the construction of additional storm water drains because the restoration would be built within, or immediately adjacent to, river channels and would not generate storm water and would not need storm water infrastructure. Impacts would not occur. • Construction and operation of floodplain and riparian restoration sites would not generate an increase in solid waste because modifications would be limited to the river bank and channel and would not generate large quantities of solid waste. Impacts would not occur. • Construction and operation of floodplain and riparian restoration sites would not require a water supply because modifications to the river bank and channel do not require a water supply. Impacts would not occur.

16.3.2 Reduce Vegetation-Disturbing Activities in Floodplains and Floodways

This action may be included as part of discretionary or non-discretionary permit conditions, guidelines, or policies governing existing levee and floodway maintenance activities as well as implementation of floodplain, floodway, or riparian management and restoration plans in areas adjacent or within the Stanislaus, Tuolumne, and Merced River channels. Participating entities may include NMFS, CDFW, USFWS, Central Valley Water Board, Central Valley Flood Protection Board, U.S. Army Corps of Engineers, local landowners, county governments, local agricultural commissions, and other land management agencies in the watersheds of the LSJR, Stanislaus, Tuolumne, and Merced Rivers. Where such actions do not conflict with existing federal, state, or local flood risk reduction policies, regulations, or ordinances, reducing vegetation-disturbing activities would apply to grazing, mowing, cutting, spraying, disking, and other activities to promote preservation and restoration of riparian vegetation in floodplains or floodways.

Cost Evaluation

Removal of floodway vegetation is typically considered a maintenance cost by the responsible flood control agencies. Reduction in floodway vegetation removal could be accomplished as a collaborative effort between the flood control and environmental agencies. The flood control agency maintenance costs would be reduced by allowing vegetation to stay in the floodway. If environmental agencies incentivized retaining vegetation, then flood control agencies could receive a credit for increasing habitat.

Environmental Evaluation

Measures to reduce vegetation-disturbing activities in floodplains and floodways include but are not limited to the following:

- Develop grazing strategies that protect and improve streamside vegetation and minimize bank disturbance.
- Conduct outreach to inform landowners of state and federal laws and regulations that protect riparian, wetland, and Endangered Species Act (state and federal) protected vegetation.
- Review and potentially modify existing floodplain, floodway, and riparian vegetation management plans, or develop new ones using the best available science, to balance the needs of the ecosystem, public safety, and other considerations.
- Compile data, conduct studies, and review literature to determine the influence that large trees and other vegetation types have on levee and floodway safety, and use this information to make science-based floodplain and floodway management decisions.

Potential Environmental Effects

The measures listed above that would reduce vegetation-disturbing activities have a relatively limited ability to result in significant physical impacts on the environment. These measures would generally not require substantial construction activities, and would not result in potential construction-related environmental impacts.

CEQA allows categorical exemptions for classes of projects which have been determined not to have a significant effect on the environment. (Pub. Res. Code, § 21084.) Specifically, information collection is exempt from CEQA review under a Class 6 categorical exemption. The Class 6 exemption consists of basic data collection, research, experimental management, and resource evaluation activities which do not result in a serious or major disturbance to an environmental resource. These may be strictly for information gathering purposes or as part of a study leading to an action which a public agency has not yet approved, adopted or funded. (Pub. Res. Code, § 21084.) In addition, a Class 7 categorical exemption consists of actions taken by regulatory agencies to assume the maintenance, restoration, or enhancement of natural resources where the regulatory process involves procedures for protection of the environment. (Pub. Res. Code, § 21084.) Examples include, but are not limited to, wildlife preservation activities by CDFW. Since the measures to reduce vegetation-disturbing activities in floodplains and floodways generally do not require construction activities, some of the measures may be categorically exempt from CEQA including: conducting outreach to land owners, compiling data, and reviewing literature for reducing vegetation-disturbing activities.

Reviewing and modifying management plans could physically affect the environment if the modifications are implemented. If modification to these plans resulted in more floodplain restoration projects and riparian habitat restoration projects, then impacts would be similar to those disclosed in Section 16.3.1, *Floodplain and Riparian Habitat Restoration*, and in Table 16-12, *Potential Environmental Effects of Floodplain and Riparian Habitat Restoration*. Developing strategies to protect and improve streamside vegetation could result in actions such as fencing off certain areas to prevent or reduce grazing or other more intensive ground-disturbing agricultural activities or reducing streamside application of herbicides and pesticides. These types of physical actions taken to reduce vegetation disturbance would be considered minor, and are not expected to result in significant environmental impacts on resources, including special-status species, given the limited geographic scope and scale when compared to areas that would not be affected by the actions.

Reducing vegetation-disturbing activities in floodplains and floodways may result in long-term beneficial effects on water quality, hydrology, and channel geometry because vegetation stabilizes slopes and retains sediment resulting in clearer water, creates more complex habitat for fish by changing water velocity, and can narrow or widen the river channel. The reduction of vegetation-disturbance activities would likely occur below the major rim dams on the LSJR, and the Stanislaus, Tuolumne, and Merced Rivers where there is a lack of riparian habitat or there is active vegetation disturbance. A change in vegetation could result in changes to hydraulics, channel substrate, and stream habitats. Controlling erosion and allowing riparian vegetation to become re-established by fencing off streams from cattle, would improve water quality and habitat for special-status wildlife and fish species. These changes are expected to benefit aquatic and terrestrial biological resources.

Table 16-13, *Potential Environmental Effects of Reducing Vegetation-Disturbing Activities in Floodplains and Floodways*, summarizes the potential environmental effects associated with reducing vegetation-disturbing activities in floodplains and floodways. Those impacts associated with floodplain or habitat restoration are identified in Table 16-12, *Potential Environmental Effects of Floodplain and Riparian Habitat Restoration,* and are not incorporated into Table 16-13.

Table 16-13. Potential Environmental Effects of Reducing Vegetation-Disturbing Activities in Floodplains and Floodways

Potential Environmental Effects of Reducing Vegetation-Disturbing Activities in Floodplains and Floodways	
Resource	Discussion
Aesthetics	• Studies or activities implemented to reduce vegetation-disturbing activities would not affect or change scenic vistas. No lighting would be used during the activities, all would be done during daylight hours. Impacts would not occur.
Agriculture and Forestry Resources	• Reduction of vegetation-disturbing activities could be located on lands used for agriculture or forestry, depending on how far reducing vegetation-disturbing activities extend from the Stanislaus, Tuolumne, and Merced Rivers and the extent of implementation of the vegetation-disturbing reduction activities. While these measures may decrease the level of agricultural activities or grazing occurring adjacent to a river, they are not expected to result in a conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use. Furthermore, it would be expected that modifications to management plans and strategies would assess conflicts with existing zoning for agriculture use or a Williamson Act contract, or conflict with existing zoning of forest land in order to balance the needs of the ecosystem and the needs of public safety and other land use considerations. Impacts would not occur.
Air Quality	• Air quality would not be affected by reducing vegetation-disturbing activities because no heavy construction equipment would be used. Emissions from the vehicles used for implementation and monitoring of the measures identified to reduce vegetation-disturbing activities would not prevent compliance with regulations or exceed thresholds established by SJVAPCD, conflict with or obstruct implementation of the applicable air quality plan or violate any air quality standard or contribute substantially to an existing or projected air quality violation, result in a net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standards, or create objectionable odors. Impacts would not occur.
Biological Resources	• Reduction of vegetation-disturbing activities would not: (1) have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations; (2) adversely affect riparian habitat or federally protected wetlands; (3) interfere with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites; or (4) conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance. This is mainly because reduction of vegetation-disturbing activities would not require substantial construction activities, the use of heavy construction equipment, or removal of habitat. These reduction of vegetation-disturbing activities are expected to have a beneficial effect on fish and wildlife species habitat. Additionally these activity-reduction measures would not conflict with the provisions of the SJR Wildlife Refuge CCP and the SJMSCP, which covers the San Joaquin, Stanislaus, Tuolumne, and Merced Rivers. Impacts would not occur.
Cultural Resources	• Reduction of vegetation-disturbing activities would not cause a substantial adverse change in the significance of cultural resources (significant historical, archaeological, or paleontological resources), directly or indirectly destroy a unique paleontological resource or site or unique geologic feature, or disturb any human remains because substantial ground-disturbing activities are not expected as a result of implementing the reduction measures. Impacts would not occur.

Potential Environmental Effects of Reducing Vegetation-Disturbing Activities in Floodplains and Floodways

Resource	Discussion
Geology and Soils	• Reduction of vegetation-disturbing activities would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. The activities would not increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Reducing vegetation-disturbing activities would actually prevent erosion and sediment release because less activities would occur adjacent to the river channels. Impacts would not occur.
Greenhouse Gas Emissions	• Reduction of vegetation-disturbing activities would not result in increased GHG emission because no heavy construction equipment would be used. Activities may require vehicle trips to perform any studies required, but these would be trips of very short duration over a long period of time and would have less-than-significant impacts from GHG emissions, as potential GHG emissions could be reduced as vegetation- disturbing activities are reduced. Impacts would be less than significant.
Hazards and Hazardous Materials	• Reduction of vegetation-disturbing activities does not require the use or transportation of hazardous materials. Therefore, reduction of vegetation-disturbing activities would not be expected to create a significant hazard to the public or the environment through release of these types of substances, or result in a hazard to schools if these activities occur within one-quarter mile of a school or schools. Impacts would not occur. • Reduction of vegetation-disturbing activities would not be a hazard or provide a safety concern to public or public use airports or private airstrips because they would not result in the construction of tall structures and would be located either within, or immediately adjacent to, the Stanislaus, Merced and Tuolumne Rivers banks and channels. As such, reduction of vegetation-disturbing activities would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Reduction of vegetation-disturbing activities would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road and within, or immediately adjacent to, the river banks and channels. Impacts would not occur. • Reduction of vegetation-disturbing activities would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • Reduction of vegetation-disturbing activities would not entail substantial ground disturbing activities (e.g., grading, excavation) and would actually result in fewer ground disturbing activities. As such, if reduction of vegetation-disturbing activities occurred on a Cortese Site (i.e., hazardous waste site list compiled pursuant to Government Code, § 65962), there would be no significant hazard to the public or environment as a result. Impacts would not occur.

Potential Environmental Effects of Reducing Vegetation-Disturbing Activities in Floodplains and Floodways	
Resource	Discussion
Hydrology and Water Quality	• Reduction of vegetation-disturbing activities could affect water quality if activities included in-water work. However, in-water work would be short term and only one or two persons would be in the river channel, and therefore water quality standards would not be violate. Impacts would not occur. • Reduction of vegetation-disturbing activities would not substantially deplete groundwater supplies or interfere substantially with groundwater recharge because these activities would not require groundwater and would not result in an increase in impervious surfaces. Impacts would not occur. • Reduction of vegetation-disturbing activities may alter the existing drainage pattern of the site or area or alter the course of a stream or river, depending on the action taken (i.e., fencing off cattle from a stream), but this would not result in substantial erosion or siltation on- or offsite or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or offsite or alter the capacity of existing or planned storm water drainage systems. Reduction of vegetation-disturbing activities would be beneficial in stopping erosion and flooding because it would allow further establishment of riparian communities and vegetation. Impacts would not occur. • Reduction of vegetation-disturbing activities would not substantially increase the number of people exposed to the risk of flooding because these projects would not draw people to flood hazard locations. As such, these activities would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Reduction of vegetation-disturbing activities would not involve the construction of housing, therefore this activity would not place housing within a 100-year flood hazard area. Impacts would not occur. • Reduction of vegetation-disturbing activities would not involve the construction of structures. Therefore, this activity would not place structures which would impede or redirect flood flows within a 100-year flood hazard area. Impacts would not occur. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Reduction of vegetation-disturbing activities is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which reduction of vegetation-disturbing activities could result in a substantial degradation of water quality.
Land Use and Planning	• There would be no impact on land use and planning due to reduction of vegetation-disturbing activities. Implementation of the reduction measures would not conflict with any applicable land use plan, policy, or regulation including general plan, specific plan, local coastal program, or zoning ordinance adopted for the purpose of avoiding or mitigating an environmental effect. Reduction of vegetation-disturbing activities that take place within existing river banks and channels would be consistent with land use designations or zoning because frequently these areas are designated natural resource or open space areas by land use plans, and the reduction measures would enhance existing habitat for fish and wildlife species. Measures to reduce vegetation-disturbing activities would also not conflict with any applicable habitat conservation plan or natural community conservation plan which covers the San Joaquin, Stanislaus, Tuolumne, and Merced Rivers such as the SJR Wildlife Refuge CCP and the SJMSCP. Impacts would not occur.

Potential Environmental Effects of Reducing Vegetation-Disturbing Activities in Floodplains and Floodways

Resource	Discussion
Mineral Resources	• Reduction of vegetation-disturbing activities would not result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state or loss of a locally important mineral resource recovery site delineated on a local general plan, specific plan, or other land use plan because there would be no substantial construction activities. Impacts would not occur.
Noise	• Reduction of vegetation-disturbing activities would not result in exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or generate excessive ground-borne vibration or ground-borne noise levels because there would be no substantial construction activities and because the proximity to sensitive receptors (e.g., residences) is expected to be limited. Impacts would not occur.
Population and Housing	• Population and housing would not be affected by reduction of vegetation-disturbing activities because activities would not induce population growth, displace people or existing housing, or necessitate the construction of replacement of new housing. Impacts would not occur.
Public Services	• Reduction of vegetation-disturbing activities would not result in the need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services because they would not result in population growth or the need for these services. Impacts would not occur.
Recreation	• Reduction of vegetation-disturbing activities would not affect recreational facilities because these activity-reduction measures would not remove vegetation or result in substantial construction that could affect the use of existing recreational facilities. Reduction of vegetation-disturbing activities would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Reduction of vegetation-disturbing activities would not result in a significant increase in traffic because it would not require large numbers of people or vehicles to conduct studies or implement the reduction measures. Impacts would not occur. • Reduction of vegetation-disturbing activities would not result in an increase demand for air traffic or the need for airports because these activities would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Reduction of vegetation-disturbing activities would not involve the discharge of wastewater, construction of additional storm water drains, generate an increase in solid waste, nor require a water supply. Additionally, these activities would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur.

16.3.3 Gravel Augmentation

Gravel augmentation is the artificial addition of spawning-sized gravel to streams to increase the quantity and quality of spawning and incubation habitat where the natural processes of gravel recruitment have been disrupted by dams, regulated flows, gravel mining, and other instream activities (e.g., bank stabilization). In the Central Valley, gravel augmentation projects are generally focused on gravel-bed reaches of streams below mainstem dams where historical degradation of spawning habitat has been identified as a major limiting factor for salmon and steelhead populations (USFWS 2001 or AFRP 2002, 2003, 2004; see Bunte 2004).

The general approaches to spawning gravel augmentation include the following.

- Gravel injection, a passive approach in which relatively large amounts of spawning-sized gravel are dumped in channel areas where high flows can transport the gravel to downstream spawning areas.
- Spawning bed enhancement, an active approach in which spawning-sized gravel is either added directly to known spawning areas (e.g., riffles), and/or modified through mechanical grading, ripping, or cleansing (i.e., reducing fine sediment) to create or restore the streambed and hydraulic characteristics of functional spawning habitat.
- Hydraulic structure placement, an active approach which may be used in conjunction with spawning bed enhancement, entails placement of large woody debris, boulder clusters, weirs, or other structures to create localized hydraulic conditions conducive to gravel deposition and retention.

Different methods can be used to place and distribute spawning gravel depending on site constraints. Heavy construction equipment is typically used but various kinds of conveyor belts, slurries, high pressure pipes, helicopters, and cable lines also may be used depending on the project.

Cost Evaluation

Gravel augmentation can be achieved through the three approaches identified above. While site specific conditions influence the cost of the approach, generally gravel injection is the lower cost approach, while hydraulic structure installation is the higher cost approach. This section provides discussion of the general costs associated with the three approaches, and then summarizes actual costs associated with gravel augmentation projects in the Central Valley (Table 16-14, *Central Valley Project Improvement Act Spawning & Rearing Habitat Restoration Projects*).

The costs associated with gravel injection are primarily related to fuel costs for gravel delivery. These costs are estimated at $15–$20 per ton plus $0.16–$0.20 per mile to transport. Gravel injection is typically used where flows are high enough to mobilize the material such as downstream of a reservoir or on locations with easy access to the river for placement of the gravel (Cramer Fish Sciences 2010).

Spawning bed enhancement is more expensive than gravel injection because it typically requires engineering design. The cost of spawning bed enhancement is estimated at $25–$33 per ton ($19–$25 per cubic yard) (Bunte 2004). This cost does not include engineering design. The design involves choosing the appropriate location and gravel mix as the variability of gravel sizes is crucial for successful augmentation. For example, if the gravel is too large, female salmonids may be unable to mobilize enough substrate to build a high-quality redd or they may build shallow redds, resulting in higher risk of scour. If the gravel is too small, egg or alevin survival may be low if temperature and oxygen levels are compromised as a result of reduced redd permeability (Zeug et al 2014).

Hydraulic structure installation is generally the most expensive of the approaches because it requires engineering analysis and in-stream work with heavy equipment which results in necessary permits from different agencies that can take 6–18 months to obtain. Project costs for this approach can range from $1,500 to $100,000 depending on the complexity of the project, project length, and materials (Cramer Fish Sciences 2010).

The costs provided above do not include maintenance and monitoring which depend on the approach selected. A project's budget typically includes basic monitoring costs that would enable implementation of adaptive management appropriate for the size, scale, and site-specific conditions and needs. Adaptive management helps refine the actions needed to meet certain restoration objectives based on data obtained from monitoring (Cramer Fish Sciences 2010).

Table 16-14. Central Valley Project Improvement Act[a] Spawning & Rearing Habitat Restoration Projects

Project	Description	Construction/ Implementation[b]	Monitoring + Adaptive Mgt.[c]
Sacramento River Project	Annual placement of 10,000 tons of gravel for spawning and rearing habitat restoration – between Clear Creek & Keswick Dam	$795,000	$120,000
American River Project	Annual placement of 7,000 tons of gravel at Nimbus Basin on the American River	$745,000	$6,000 + $100,000
Stanislaus River Project	Annual placement of 3,000 tons of gravel at the Two Mile Bar or Upper Honolulu Bar along the Stanislaus River	$670,000	$15,000
Program Management & Support (for 3 projects over 2 fiscal years)		$450,000

[a] The Central Valley Project Improvement Act of 1992 (CVPIA) is a collaboration of agencies that includes the Department of the Interior, Bureau of Reclamation, USFWS in collaboration with state and local governments, tribes and stakeholders.

[b] Costs provided are the requested funding for Fiscal Year 2015 and 2016. Costs represent the amount being cost-shared between the state and federal agencies in CVPIA.

[c] The adaptive management cost is intended to build a model and assemble information to create model parameters to identify restoration actions and monitoring priorities for the American River Project.

Environmental Evaluation

The primary sources of information for the following general description of gravel augmentation projects and associated environmental impacts were Bunte (2004), DWR (2004), NMFS (2013), and USFWS (2013). Additional references are cited below.

Summary of Potential Action

Pre-project assessment, planning, and design activities for gravel augmentation projects may include geomorphic surveys, topographic/bathymetric surveys, sediment sampling, hydrologic analyses, and hydraulic and sediment transport modeling. Integrated approaches utilizing quantitative hydraulic, sediment transport, and habitat modeling tools have been developed to facilitate the design process and improve success of spawning habitat rehabilitation projects (Pasternack et al. 2004; Wheaton et al. 2004a, 2004b).

The magnitude of construction impacts on vegetation, soils, streambed substrates, and water quality during construction activities depends on site selection and gravel placement methods (e.g., passive or active). Potential construction activities include clearing of vegetation to construct temporary roads, access, and staging areas; placement of temporary gravel berms or other structures to provide construction access and isolate work areas from the river; permanent placement of gravel, boulders and other flow or sediment control structures; and grading, ripping, and recontouring of newly deposited or existing gravel. Typical construction equipment includes graders, excavators, and loaders. Common environmental commitments or BMPs to avoid, minimize, or offset potential environmental effects may include seasonal work windows, preconstruction biological surveys; biological monitoring during construction; construction noise; traffic control; SWPPP; spill prevention, control, and countermeasure plan; and turbidity compliance monitoring.

Operation and maintenance of gravel augmentation projects may include periodic replenishment of gravel as needed. Post-project monitoring activities typically include monitoring and evaluation of key geomorphic, hydraulic, and biological parameters in an adaptive management framework.

Potential Environmental Effects

Construction of gravel augmentation projects may result in temporary and localized effects typically associated with construction activities, including a change in water quality, air quality effects, and ground and channel disturbance. Gravel placement would be located in areas that support spawning for special-status fish species such as Chinook salmon and steelhead. These areas are below the dams on the Stanislaus, Tuolumne, and Merced Rivers where most spawning occurs and gravel is lacking.

It is reasonable to assume that new gravel placement would be professionally installed by contractors familiar with such projects. Depending on the magnitude of the projects, construction could last from 1 to 12 weeks (i.e., up to 3 months) depending on the nature of the project and amount of gravel to be augmented (e.g., Feather River Gravel Supplementation Project duration is 3 months). Construction activities would occur during the dry season (typically June–October) when anadromous fish would not be spawning. BMPs for controlling sediment and contaminant release into waterbodies would be used to minimize impacts on water quality. Gravel augmentation sites would result in changes to hydraulics, channel substrate, and stream habitat types such as pools, runs, and riffles. However, all of these changes are expected to benefit aquatic biological resources.

Table 16-15, *Potential Environmental Effects of Gravel Augmentation*, summarizes the potential environmental effects associated with gravel augmentation. Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this non-flow measure and is referenced in Table 16-15 where appropriate.

Table 16-15. Potential Environmental Effects of Gravel Augmentation

Potential Environmental Effects of Gravel Augmentation	
Resource	Discussion
Aesthetics	• Construction and operation of gravel augmentation projects would not be expected to significantly affect scenic vistas because they would be located within or immediately adjacent to existing river channels. Construction and operation of the augmented areas would not have a substantial adverse effect on a scenic vista. Construction may be observable for a temporary period of time when heavy equipment is used to transfer gravel in and around the project site. However, it is anticipated that the location of these projects would not be within close proximity to sensitive viewers (e.g., recreationists or residents) given the potential remote location of the projects within rivers. If sensitive viewers are located within close proximity, the temporary nature of construction and the fact that views would not be permanently changed would be such that significant impacts would not occur. Operation may be noticeable at first during the time it takes for natural processes such as establishment of vegetation and gravel movement to occur. After that, the river channel may be more aesthetically pleasing due to the enhanced gravel habitat and movement of the channel. Lighting is not expected to be used during gravel augmentation activities because the construction would occur during the day given the need to work within or immediately adjacent to the channels. This impact would be less than significant.
Agriculture and Forestry Resources	• Construction and operation of gravel augmentation projects would not be expected to be located on lands used for agriculture or forestry because they would be located within or immediately adjacent to existing river channels. There would be no conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use, conflict with existing zoning for agriculture use or a Williamson Act contract, conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Construction of gravel augmentation projects would likely result in emissions associated with construction equipment and construction worker vehicle trips. The quantity, duration, and the intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since construction of gravel augmentation projects does not require lengthy construction activities, the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the SJVAPCD regulations and established thresholds. Lead agencies (e.g., irrigation districts or municipal water purveyors) can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction of gravel augmentation projects would be

Potential Environmental Effects of Gravel Augmentation

Resource	Discussion
	inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction of gravel augmentation projects would not result in population or employment growth because these projects are habitat restoration projects for the benefit of special-status fish species. Therefore, construction of gravel augmentation projects would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • Operation of gravel augmentation projects would likely result in scheduled maintenance or monitoring vehicle trips. Given the limited number of vehicles and monitoring trips, over a longer timeframe, emissions from the vehicles would not be expected to prevent compliance with regulations or exceed thresholds established by SJVAPCD, conflict or obstruct implementation of the applicable air quality plan, violate any air quality standard, contribute substantially to an existing or projected air quality violation, or result in a net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standards. Impacts would be less than significant. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). Gravel augmentation projects would not create objectionable odors affecting a substantial number of people. Impacts would not occur.
Biological Resources	• Construction of gravel augmentation projects would release sediment and possibly hazardous materials (e.g., oil or gas from construction equipment) into waterbodies, affecting water quality. Release of sediment can bury macroinvertebrates which are prey for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat. Operation of gravel augmentation projects would change aquatic habitat by changing river width, stream habitat types (riffles, pools, runs), and hydraulics. While construction may have some temporary significant impacts, gravel augmentation would have beneficial long-term effects on Chinook salmon and steelhead spawning habitat. Water quality measures such as monitoring turbidity during construction to ensure compliance with Basin Plan water quality objectives and construction BMPs would be implemented as either mitigation measures under CEQA or permit requirements and conditions. Furthermore, an MMP would be enforced after restoration is completed, which is part of permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. After construction is complete, the gravel augmented areas would need to be monitored to determine if the quantity and location of gravel was correct and to ensure the augmented areas are functioning as designed and benefiting Chinook salmon and steelhead. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction

Potential Environmental Effects of Gravel Augmentation

Resource	Discussion
	of gravel augmentation projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction of gravel augmentation projects would not interfere with the movement of native residential or migratory fish species and associated migratory corridors, or impede the use of nursery sites because any work done in the water would occur during June to October when fish are not spawning or migrating. Impacts would not occur. • The surrounding habitat on river banks may include riparian vegetation and/or wetlands. Riparian vegetation may have to be removed to facilitate heavy equipment operation. Wetlands may also be disturbed during construction activities. This would result in a temporary significant impact on riparian habitat and wetlands. Under operations, riparian habitat and wetlands would not be affected. Removal and/or disturbance of riparian and wetlands habitats would be compensated for at a ratio appropriate for the disturbance per standard permit requirements or conditions from U.S. Army Corps of Engineers, Central Valley Water Board, and other responsible agencies. This would reduce and minimize impacts on fish and wildlife species and their habitats. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction of gravel augmentation projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of gravel augmentation projects would be located in river reaches that support special-status fish species such as Chinook salmon and steelhead. These reaches are expected to have high potential for special-status plant species, animal species, and habitat, and support biological resources. Gravel augmentation projects would occur during the least sensitive periods of special-status species life stages (i.e., during the dry season, June–October), as required through either the CEQA process or through permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce potentially significant environmental effects of construction and operations on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • While construction may result in temporary localized adverse effects on special-status species, plants, and habitat, construction activities are highly unlikely to result in population level adverse effects for any species. As such, these activities are not expected to conflict with habitat conservation plans such as the SJR Wildlife Refuge CCP or the SJMSCP, which are meant to provide protection at the population level. In addition, conflicts with local policies as a result of construction are considered less than significant because of the temporary and localized nature. Finally, because gravel augmentation is expected to produce beneficial results for special-status fish and other wildlife species, ultimately gravel augmentation would not conflict with local policies protecting biological resources or with provisions of an

Potential Environmental Effects of Gravel Augmentation	
Resource	Discussion
	adopted habitat conservation plan or natural community conservation plan (e.g., SJR Wildlife Refuge CCP, SJMSCP). This would be a less-than-significant impact.
Cultural Resources	• Construction and operation of gravel augmentation projects would be within or immediately adjacent to existing river channels. While it is unknown if cultural resources (significant historical, archaeological, or paleontological resources) or human remains exist in these locations, these areas would not be excavated and ground disturbance would not occur, which are two of the primary mechanisms for affecting cultural resources or human remains. Gravel would be placed on the existing substrate in the river channel. Operation of gravel augmentation would have a very low potential to affect cultural resources because the gravel would be in the river and would be augmented periodically. Typically the river channels have had high levels of disturbance because of hydraulic conditions; and as such, there is a low potential for significant cultural resources or human remains to existing within the rivers. This would be a less-than-significant impact.
Geology and Soils	• The locations of gravel augmentation could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, gravel augmentation would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. Gravel augmentation would not bring people to the risk of earthquakes or geologic hazards, meaning the operation of the augmented areas would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur. • Project sites would be evaluated before construction begins for the potential of soil erosion in the design of the augmentation project. Construction would likely take place within stream channels and adjacent to rivers and in riparian areas. Erosion could take place depending on the site-specific soil characteristics, geology, area of disturbance by construction equipment, and construction equipment used. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant erosion or sediment effects associated with construction or operation of gravel augmentation projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.

Potential Environmental Effects of Gravel Augmentation

Resource	Discussion
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-12, augmentation of gravel would result in increased GHG emissions because heavy construction equipment would be used. While construction activities would be relatively limited and short term in duration, it is likely that gravel augmentation activities could result in a potentially significant GHG impact beyond the SJVAPCD ZEL. Depending on the level of construction activities and the potential operational lifespan of the project, construction-related GHG emissions could exceed SJVAPCD's ZEL and result in a potentially significant impact. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • During operation, heavy equipment may be needed to replenish gravel sites, but these would be limited activities of very short duration and would likely result in small quantities of GHG emissions. In addition, vehicles may be needed for monitoring or maintenance of restored areas. However, the trips would be limited, of very short duration, and over a long period of time (e.g., one trip every year). As such, they would likely result in small quantities of GHG emissions. However, GHG emissions may still exceed SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Potential Environmental Effects of Gravel Augmentation	
Resource	Discussion
Hazards and Hazardous Materials	• Construction and operation of gravel augmentation would not be a hazard or provide a safety concern to public or public use airports or private airstrips because augmentation would be constructed and operated within or immediately adjacent to river channels, and would not result in the construction of tall structures. As such, construction and operation of gravel augmentation would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Construction and operation of gravel augmentation would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road and within or adjacent to river channels. Impacts would not occur. • Construction and operation of gravel augmentation projects would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • Construction of gravel augmentation projects could involve the temporary use of small amounts of hazardous materials, such as fuel to power construction equipment. There is a low potential for a hazardous materials spill associated with construction equipment to affect the environment given the short duration of construction and the generally limited number of construction equipment that would be used. However, given the projects would be within or immediately adjacent to existing river channels, Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due to hazards and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The precise location of where gravel augmentation would occur is not yet known; however, these projects could be constructed within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • The precise location of where gravel augmentation would occur is not yet known; however, gravel augmentation would not entail substantial ground disturbing activities (e.g., grading, excavation). As such, if gravel augmentation occurred on a Cortese Site (i.e., hazardous waste site list compiled pursuant to Government Code, § 65962), there would be no significant hazard to the public or environment as a result because if soil or groundwater contamination occurred it would not be released. Impacts would not occur.

Potential Environmental Effects of Gravel Augmentation	
Resource	Discussion
Hydrology and Water Quality	• Construction of gravel augmentation projects may temporarily affect water quality due to the placement of gravel in active river channels. Placing gravel and driving heavy equipment in and near the river channel could result in a temporary increase in turbidity. Due to the limited nature and occurrence of construction activities during the dry season, it is not expected that water quality standards for the protection of fish and wildlife would be violated because the timing of work construction windows (i.e., June–October) would avoid the most sensitive life stages of special-status fish species. Additionally, turbidity would be monitored to maintain compliance with Basin Plan water quality objectives. Construction of gravel augmentation projects would not alter the capacity of existing or planned storm water drainage systems, and would not provide substantial additional sources of polluted runoff. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of gravel augmentation projects would not deplete groundwater supplies or interfere substantially with groundwater recharge because these projects would not require groundwater during construction or operation and would not result in an increase in impervious surfaces. Impacts would not occur. • Operation of the gravel augmentation sites could alter the existing drainage pattern of the site or area. However, it is not expected to cause an increase in substantial erosion or siltation or result in flooding on- or offsite. In addition, operation of gravel augmentation sites would not exceed the capacity of existing or planned storm water drainage systems, and would not provide substantial additional sources of polluted runoff. Site design would take into account existing hydrology and channel geomorphology and gravel placement would be done so no erosion or flooding would occur. An MMP, which is part of the permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers, would be implemented to ensure no erosion is occurring and the gravel placement is functioning successfully. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Gravel augmentation projects would not substantially increase the number of people exposed to the risk of flooding because these projects would not draw people to flood hazard locations. As such, these projects would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Construction and operation of gravel augmentation sites would not involve the construction of housing, and therefore this activity would not place housing within a 100-year flood hazard area. Impacts would not occur. • Gravel augmentation projects would entail the placement of spawning-sized gravel and/or hydraulic structures (e.g., large woody debris, boulder clusters, weirs) within stream channels. Neither gravel nor hydraulic structures would impede or redirect flood flows within a 100-year flood hazard area. Site design would take into account existing

Potential Environmental Effects of Gravel Augmentation	
Resource	Discussion
	hydrology and channel geomorphology and gravel placement would be done so no flooding would occur. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Gravel augmentation is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of gravel augmentation projects could result in a substantial degradation of water quality.
Land Use and Planning	• Construction and operation of gravel augmentation projects would not physically divide an established community because they would be located in the existing river channels, or immediately adjacent to them, and communities are not established in these areas. Impacts would not occur. • Construction and operation of gravel augmentation sites would occur in existing river channels, or immediately adjacent to them, and would not conflict with land use designations or zoning. Frequently these areas are designated natural resource or open space areas by land use plans and gravel augmentation would be consistent with those designations because it would enhance existing habitat for fish and wildlife species. Impacts would not occur. • The following habitat conservation plans cover parts of the Stanislaus, Tuolumne, and Merced Rivers: SJR Wildlife Refuge CCP and the SJMSCP. These plans protect special-status species within the Stanislaus, Tuolumne, and Merced Rivers. As described in the Biological Resources section of this table, there would be some temporary construction impacts on adjacent riparian areas, but lead agencies could mitigate these temporary impacts through measures identified in Table 16-39. As such, no conflicts are expected with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations. Impacts would not occur.
Mineral Resources	• As mentioned in the Mineral Resources section in Table 16-12, there are known aggregate mines along the three eastside tributaries (Clinkenbeard 1999, Clinkenbeard 2012a and 2012b, Higgins and Dupras 1993, Rapp et al. 1977, and Smith and Clinkenbeard 2012). While mining within the active river channel is not typically performed, aggregate sites may be located in close proximity to the active river channel. Construction and operation of gravel augmentation could have potential to affect access to state or locally designated mineral resource areas. This is because the gravel augmentation sites would be within existing river channels and could cover mineral areas located downstream of the augmentation if the gravel moves downstream within the river channel. As discussed under the Biological Resources section of this table, an MMP would be enforced after restoration is completed, which is part of permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. Until such time that the potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. After construction, the gravel augmented areas would need to be monitored using the MMP to determine if the quantity and location of gravel was correct and to ensure the augmented areas are functioning as designed and benefiting Chinook salmon and steelhead. Movement of gravel would also be monitored to ensure it was not covering or removing access to existing important or designated mineral resources. If gravel movement covers or removes

Potential Environmental Effects of Gravel Augmentation

Resource	Discussion
	access to mineral resource areas, gravel augmentation could be re-evaluated and discontinued at the site. However, if gravel augmentation is not discontinued, impacts would remain significant and unavoidable.
Noise	• Construction of the gravel augmentation sites would create noise related to the use of heavy construction equipment and rock placement. The sites would be located in river channels, or immediately adjacent to them, where people generally do not live. It is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies due to the limited duration of construction and the remote location of these projects from populated areas. Excessive ground-borne vibration or ground-borne noise levels are also not expected due to the small nature of the projects and the standard type of construction equipment that would be used. If there was temporary elevated noise in excess of standards established in local general plans, noise ordinance, or applicable standards, it would occur during the day (as construction is not expected to occur at night) and for short periods of time within the day over a short duration (e.g., 1–12 weeks). Given the limited exposure of potential sensitive receptors to this potential temporary increase and low likelihood of potential sensitive receptors to exist because of the remoteness of the project sites, it is expected impacts would be less than significant. Operation of gravel augmentation sites would not create noise. There may be some maintenance activities, but that would not create a permanent increase in ambient noise. Impacts would not occur. • Projects would not be constructed near airports or airstrips so people would not be exposed to excessive noise levels. Impacts would not occur.
Population and Housing	• The construction and operation of gravel augmentation sites would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Furthermore, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • The construction and operation of gravel augmentation sites would not displace substantial numbers of people or existing housing, or necessitate the construction of replacement housing elsewhere because the sites would be located in, or immediately adjacent to, river channels. No homes or people would be displaced. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed above, the construction and operation of gravel augmentation sites would not involve an increase in population or housing. In addition, these actions would not include new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.

Potential Environmental Effects of Gravel Augmentation

Resource	Discussion
Recreation	• Construction of gravel augmentation sites would occur within, or immediately adjacent to, river channels. It is possible that recreational facilities would be located in areas where gravel augmentation sites would be located. If recreational facilities were located within very close proximity, construction of gravel augmentation sites may affect them; however, it is unlikely that there would be significant impacts on recreational facilities because construction would be temporary and limited (e.g., 1–12 weeks). And once construction is complete the river would be returned to similar conditions prior construction because the gravel would be submerged in the channel on the bottom of the river. Impacts would be less than significant. • Construction and operation of gravel augmentation sites would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Construction of gravel augmentation sites could result in some additional trips associated with construction workers. Depending on the location of the site, there could be an increase in traffic from construction workers. The temporary increased traffic during construction would likely not exceed local or regional road trip thresholds because the number of construction workers that gravel augmentation projects typically require is less than 30. Additionally, the duration of construction would be very short (e.g., 1–12 weeks). This would be a less-than-significant impact. Operation of gravel augmentation sites would not generate additional trips beyond those needed to maintain the sites. If maintenance activities are needed, they would be temporary and infrequent in nature and would not increase traffic. Impacts would not occur. • Construction of gravel augmentation sites would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Construction and operation of gravel augmentation sites would not exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of wastewater. Impacts would not occur. • Construction and operation of gravel augmentation would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur. • Construction and operation of gravel augmentation sites would not need the construction of additional storm water drains because the facilities would likely be built within, or immediately adjacent to, river channels and would not generate storm water. Impacts would not occur. • Construction and operation of gravel augmentation sites would not generate an increase in solid waste because activities are limited to gravel placement into an existing river channel. Impacts would not occur. • Construction and operation of gravel augmentation sites would not require a water supply. Impacts would not occur.

16.3.4 Enhance In-Channel Complexity

Enhancement of in-channel complexity focuses on the placement of large wood or boulder structures to assist in the restoration of degraded river ecosystems. A major factor that has contributed to historical decline and current status of Central Valley salmon and steelhead populations is the lack of habitat complexity resulting from dam construction and operation, channelization, levee construction, bank stabilization, and major land uses along major tributaries and mainstem reaches of the Sacramento and San Joaquin Rivers. Historically, extensive clearing of large wood from rivers and streams for water conveyance, navigation, and fish passage, and loss of riparian forests have greatly diminished the primary sources of large wood in spawning and rearing areas below mainstem dams (Bilby and Ward 1991). The loss of riparian vegetation, instream cover, and river-floodplain connectivity have greatly simplified riverine habitat and disrupted the natural processes that promote habitat diversity and complexity in Central Valley rivers and streams (NMFS 2008, 2014a).

Structural methods for enhancing habitat complexity in rivers span a wide range of designs that depend on project objectives and site-specific hydraulic, geomorphic, and ecological conditions. Such structures may be used to address other high-priority stream management needs (e.g., scour protection) or used in conjunction with other enhancement actions (e.g., spawning gravel augmentation) to achieve the project objectives. Three general categories of commonly used instream structures are cover structures, boulder structures, and log structures.

- Cover structures are often incorporated into other stream enhancement structures (e.g., log or boulder weirs) and include logs, root wads, tree bundles, and boulders that are typically placed in pools to serve as a direct source of cover for salmonids.
- Boulder structures include weirs, clusters, and deflectors that are typically placed in the active channel to concentrate the flow and create a diversity of hydraulic conditions promoting deposition (spawning gravel retention) and scour (pool formation), facilitating fish passage, and/or providing cover and resting areas for juvenile and adult salmonids.
- Log structures have similar applications as boulder structures and include a range of weirs, barbs, and engineered log jams.

Cost Evaluation

The costs for enhancing in-channel complexity through the installation of cover structures, boulder structures and log structures depend primarily on the size of the stream, channel hydrology, complexity of the design, site accessibility, cost of materials, and equipment needed to transport and install the material. One of the primary costs associated with enhancing in-channel complexity is the cost for large woody materials, such as logs, which is highly dependent on the type of tree selected. For example, Washington Douglas Fir is $100 per 1,000 board ft while the California Redwood costs about $510 for the same amount. The National Resources Conservation Service cost share practice standard estimates that the material cost for large woody material ranges between approximately $1,900 per acre and $924 per acre (Guhin and Hayes 2015). Table 16-16, *Engineered Log Structures and Large Woody Debris – Cost Estimates*, shows the approximate costs (low–high) based on the stream size.

Table 16-16. Engineered Log Structures and Large Woody Debris – Cost Estimates

Stream Size (cfs)	Cost[a] (Low–High)
Small stream (1–100 cfs)	\$10–\$40K
Medium stream (101–2000 cfs)	\$20–\$70K
Large stream (2000+ cfs)	\$10–\$80K

Source: Thomson and Pinkerton 2008.

cfs = cubic feet per second.

[a] Estimates identified above include construction, design, permitting, basic monitoring and routine maintenance (up to 2 years), reestablishing site to prior conditions and project management costs. These estimates assume purchased materials.

In 2008, the Lower Mokelumne River Joint Settlement Agreement (JSA) between EBMUD, USFWS, and CDFW included approval of\$25,663 in funding to UC Davis to conduct a study along the Lower Mokelumne River to determine the effectiveness of large woody materials in aiding fish habitat (Partnership Steering Committee 2008). The project consisted of placing 542 large wood pieces along 4.8 miles on the Lower Mokelumne River directly below the Camanche Dam where the flows averaged 350 cfs (Pasternack and Senter 2008).

Environmental Evaluation

The primary sources of information for the following general description of in-channel habitat enhancement projects and associated environmental impacts were NMFS (2000) and USBR and U.S. Army Engineer Research and Development Center (ERDC) (2016). Additional references are cited below.

Summary of Potential Action

Pre-project assessment, planning, and design activities for in-channel habitat enhancement projects may include geomorphic surveys, topographic/bathymetric surveys, sediment sampling, hydrologic analyses, and hydraulic and sediment transport modeling. Major design considerations include long-term stability and viability of the proposed structures relative to site-specific hydraulic conditions, scour and depositional effects, and ecological performance objectives.

The magnitude of construction impacts on native fish and wildlife species, vegetation, soils, streambed substrates, and water quality during construction activities depends on site selection, type of structure, and installation methods. Potential construction activities include clearing of vegetation to construct temporary roads and staging areas; placement of temporary gravel berms, cofferdams, or other structures to provide construction access and isolate work areas from the river; excavation and grading of the channel and banks to anchor in-stream structures; and placement and anchoring of boulders, logs, and root wads. Typical construction equipment includes graders, excavators, and loaders. Common environmental commitments or BMPs to avoid, minimize, or offset potential environmental impacts may include seasonal work windows, preconstruction biological surveys; biological monitoring during construction; construction noise and light reduction measures; traffic control; SWPPP; spill prevention, control, and countermeasure plan; and turbidity compliance monitoring.

Operation and maintenance of in-channel enhancement projects may include periodic inspections, repairs, and replacement of structural elements. Post-project activities typically include monitoring and evaluation of key geomorphic, hydraulic, and biological parameters in an adaptive management framework.

Potential Environmental Effects

Construction of in-channel enhancing structures may result in temporary and localized effects typically associated with construction activities, including impacts on water quality, air quality effects, and ground and channel disturbance. River channels may be graded to facilitate structures to be anchored into the bank substrate and to stabilize the structures in areas that support special-status fish species such as Chinook salmon and steelhead. These areas would be located below the dams on the Stanislaus, Tuolumne, Merced, and San Joaquin Rivers, where the rivers may lack complexity of habitats such as riffles and pools. Aquatic and riparian special-status species would be the most affected by construction and installation of in-channel enhancing structures. Operation of the structures would benefit aquatic species and may require maintenance if the structures move or do not create the expected habitat.

It is reasonable to assume that installation of in-channel enhancing structures would be professionally installed by contractors familiar with such projects. Depending on the magnitude of the projects, construction could last anywhere from several weeks to up to 12 weeks (i.e., 3 months). Construction activities would occur during the dry season (typically June–October) to avoid the most sensitive spawning and rearing periods of anadromous fish. BMPs for controlling sediment and contaminant release into waterbodies would be used and minimize potential impacts on water quality associated with sediment and hazardous materials. In-channel enhancing structures would result in changes to hydraulics, channel substrate, and stream habitats. These structures would also increase habitat for special-status fish species. In-channel enhancing structures are expected to benefit aquatic biological resources.

Table 16-17, *Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures*, summarizes the potential environmental effects associated with installation and operation of in-channel enhancing structures. Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of these in-channel enhancing structures and is referenced in Table 16-17 where appropriate.

Table 16-17. Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures	
Resource	Discussion
Aesthetics	• Construction and operation of in-channel enhancing structures is not expected to significantly affect scenic vistas because they would be located within existing river channels. Construction and operation of the in-channel enhancing structures would not have a substantial adverse effect on a scenic vista. Construction may be observable for a temporary period of time when heavy equipment is used to grade banks, move sediment, and install structures around the project site. However, it is anticipated that the location of these projects would not be within close proximity to sensitive viewers (e.g., recreationists or residents) given the remote location of the projects within rivers. If sensitive viewers are located within close proximity, the temporary nature of construction would result in less-than-significant impacts because views would not be permanently changed. Operation of the project may be noticeable at first during the time it takes for re-establishment of vegetation and river channel natural movement. After that, the river channel may be more aesthetically pleasing. Lighting is not expected to be used during construction of in-channel enhancing structures since all construction would occur during the day. Impacts would be less than significant.
Agriculture and Forestry Resources	• Construction and operation of in-channel enhancing structures would occur within the footprint of existing river channels and not on lands used for agriculture or forestry. There would be no conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use, conflict with existing zoning for agriculture use or a Williamson Act contract, conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Construction of in-channel enhancing structures would likely result in emissions associated with construction equipment and construction worker vehicle trips. The quantity, duration, and the intensity of construction activities would have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since construction of in-channel enhancing structures does not require lengthy construction activities, the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the SJVAPCD regulations and established thresholds. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction of in-channel enhancing structures would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
	applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction of in-channel enhancing structures would not result in population or employment growth because these projects are habitat restoration projects for the benefit of special-status fish species. Therefore, construction of in-channel enhancing structures would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • Enhancing in-channel complexity would likely result in maintenance or monitoring trips by a few vehicles on a periodic schedule of limited duration. As such, emissions from maintenance vehicles are not expected to prevent compliance with regulations or exceed thresholds established by SJVAPCD, conflict or obstruct implementation of the applicable air quality plan, violate any air quality standard, contribute substantially to an existing or projected air quality violation, or result in a net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standards. Impacts would be less than significant. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). Enhancing in-channel complexity would not create objectionable odors affecting a substantial number of people. Impacts would be less than significant.
Biological Resources	• Construction of in-channel enhancing structures would release sediment and possibly hazardous materials (e.g., oil or fuel from construction equipment) into waterbodies, affecting water quality. Release of sediment can bury macroinvertebrates which are prey for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat. In addition, due to the effects of in-channel construction, the movement of native resident or migratory fish species and the associated migratory corridors may be temporarily impeded. This would result in a significant impact. Water quality measures such as monitoring turbidity during construction, to ensure compliance with Basin Plan water quality objectives, and construction BMPs, would be implemented as either mitigation measures under CEQA or permit requirements and conditions. Further, an MMP would be enforced after restoration is completed, which is part of permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. The enhanced areas would need to be monitored to determine that the structures were functioning as designed and benefiting Chinook salmon and steelhead once construction is complete, under operating conditions. However, operation of in-channel enhancing structures would change aquatic habitat by changing river width, river habitat types (riffles, pools, runs), and hydraulics. In-channel enhancing structures would have beneficial long-term effects on Chinook salmon and steelhead habitat, including migratory corridors. Impacts under operation would be less than significant. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction and operation of in-channel

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
	enhancing structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of in-channel enhancing structures would be located in river reaches that support special-status fish species such as Chinook salmon and steelhead. This would result in take of special-status species. It is reasonable to assume that construction of in-channel enhancing structures would occur during the least sensitive periods of special-status species life stages, (i.e., during the dry season, June–October), as this would reduce and minimize impacts on aquatic species and would be required through either the CEQA process or through permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. However, if construction of the in-channel enhancement requires the construction and installation of cofferdams, these can injure or kill fish. If pile driving is need to construct the cofferdam, it can create noise impacts harmful to fish. Stranding within the cofferdams can occur if special-status fish species become trapped inside a dewatered area. Fish rescue in the dewatered area (seining, electrofishing) could injure or kill fish. These activities could result in take of special-status fish species. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce potentially significant environmental impacts on special-status biological resources from construction of in-channel enhancing structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even with mitigation measures, significant and unavoidable impacts may occur if the potential for take cannot be avoided or reduced or take occurs during construction. • The surrounding habitat on river banks may include riparian vegetation and/or wetlands. Riparian vegetation may have to be removed to allow heavy equipment movement and wetlands may also be disturbed during construction. This would result in a temporary significant impact on riparian habitat and wetlands. Under operations, riparian habitat and wetlands would not be affected. Removal and/or disturbance of riparian and wetlands habitats during construction would be compensated for at a ratio appropriate for the disturbance per standard permit requirements or conditions from the U.S. Army Corps of Engineers and the Central Valley Water Board. This compensation would reduce and minimize impacts on fish and wildlife species and their habitats. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on biological resources associated with construction of in-channel enhancing structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • While construction may result in temporary localized significant impacts on special-status species, plants, and habitat, construction activities are highly unlikely to result in population level adverse effects for any species. Therefore, these activities are not expected to conflict with habitat conservation plans such as the SJR Wildlife Refuge CCP or the SJMSCP, which are meant to provide protection at the population level. In addition, conflicts with local policies as a result of

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
	construction are not considered significant because of the temporary and localized nature of the effects. Impacts would be less than significant.
Cultural Resources	• Construction and operation of in-channel enhancing structures would occur within existing river banks and channels. Typically the river channels have had high levels of disturbance because of hydraulic conditions and there is a low potential for significant cultural resources (significant historical, archaeological, or paleontological resources) or human remains to exist within the river channels or immediately adjacent. However, it is unknown if cultural resources or human remains would exist at locations that could be used for anchoring or installing in channel structures, if the design of the project required that type of installation. Operation of in-channel enhancing structures would have a very low potential to affect cultural resources or human remains because the in-channel structures would primarily be located in the river and would be monitored. Where construction within areas that may contain cultural resources or human remains cannot be avoided an assessment should be conducted of the potential for damage to cultural resources prior to construction; this may require hiring a qualified cultural resources specialist to determine the presence of significant cultural resources. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant effects on cultural resources associated with construction of in-channel enhancing structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.
Geology and Soils	• The locations of new in-channel enhancing structures could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, in-channel enhancing structures would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, loss of topsoil, or landslides. Impacts would not occur. • Project design would evaluate sites for the potential of soil erosion to minimize erosion or sediment release that would not support the objectives of in-channel enhancement during construction or operation. However, given, construction would likely take place along adjacent rivers and in riparian areas, erosion could take place depending on the soil characteristics, geology, and area of disturbance. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant erosion or sediment impacts associated with construction or operation of in-channel enhancement projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Enhancement of in-channel complexity would not bring people to the risk of earthquakes or geologic hazards, meaning the operation of the enhanced areas would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur.

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-12, construction of enhanced in-channel complexity would generate GHG emissions because heavy equipment would be used for up to 12 weeks. While construction activities would be limited, it is likely that enhancement activities could result in a potentially significant GHG impact beyond SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • During operation, some vehicles may be needed for monitoring the enhanced areas. However, the trips would be limited, of very short duration, and over a long period of time (e.g., one trip every year). As such, they would likely result in less than significant quantities of GHG emissions. However, GHG emissions may still exceed SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
Hazards and Hazardous Materials	• Construction and operation of in-channel enhancing structures would not be a hazard or provide a safety concern to public or public use airports or private airstrips because the structures would be constructed and operated within the river banks and channels and would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, construction and operation of in-channel enhancing structures would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road and within the river banks and channels. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • Construction of in-channel enhancement projects could involve the temporary use of small amounts of hazardous materials, such as fuel to power construction equipment. There is a low potential for a hazardous materials spill associated with construction equipment given the limited duration of construction and the generally small number of construction equipment that would be used. However, since construction work would occur within river channels, Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due to hazards and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The precise location of where in-channel enhancement projects would be constructed is not yet known; however, these projects could be constructed within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation or grading activities. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962. These sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the DTSC for Calaveras, Tuolumne, or Mariposa Counties (CalEPA 2016). There were a total of 17 sites identified for Merced, San Joaquin, and Stanislaus Counties. In addition to these sites

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
	identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 500 leaking underground storage tanks designated as open in these counties (CalEPA 2016). There are approximately 55 facilities in these counties that have received CDOs/CAOs not identified as non-hazardous wastes, domestic wastewater, or domestic sewage (CalEPA 2016). It is not yet known precisely where in-channel enhancement would occur and if it would require excavation. However, if it occurred on a Cortese Site and required excavation there would be potential for release of existing soil or groundwater contaminants because of the ground disturbance. Were this to occur, impacts could be significant. Table 16-39 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • Enhancing in-channel complexity could require excavation. Utilities may be underneath the sites or adjacent to a site and may need to be relocated or avoided. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potential hazards associated with excavation around utilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.
Hydrology and Water Quality	• Construction of in-channel enhancing structures may temporarily affect water quality due to grading the river banks and channels. Placing and anchoring the structures and driving heavy equipment in and near the river channel could result in a temporary increase in turbidity. By scheduling construction activities during the dry season and isolating the work areas from surface water with cofferdams or some other means, it is expected that water quality standards would not be violated. Additionally, turbidity would be monitored to maintain compliance with Basin Plan water quality objectives. Operation of in-channel enhancing structures would not have a significant impact on water quality. Construction of in-channel enhancing structures would not provide substantial additional sources of polluted runoff. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction of in-channel enhancing structures would not exceed the capacity of existing or planned storm water drainage systems because it would not contribute substantial runoff to a storm water drainage system. In addition, construction would not provide substantial additional sources of polluted runoff. Impacts would not occur.

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
	• Construction and operation of in-channel enhancing structures would not deplete groundwater supplies or interfere substantially with groundwater recharge because activities would not use groundwater and would not result in an increase in impervious surfaces. Impacts would not occur. • Operation of in-channel enhancing structures could alter the existing drainage pattern of the site or area and could cause an increase in substantial erosion or siltation or result in flooding on- or offsite. Site design would take into account existing hydrology and channel geomorphology and installation of the structures would be done so no erosion or flooding would occur. An MMP, which is part of the permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers, would be implemented to ensure erosion is minimized and the enhancing structures are functioning successfully. Table 16-39 lists potential mitigation measures in the Geology and Soils section that lead agencies can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of in-channel enhancing structures would not substantially increase the number of people exposed to the risk of flooding because these activities would not draw people to flood hazard locations. As such, construction and operation of in-channel enhancing structures would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not involve the construction of housing, and, therefore this activity would not place housing within a 100-year flood hazard area. Impacts would not occur. • Enhancement of in-channel complexity would focus on the placement of large wood or boulder structures within stream channels. Neither construction nor operation of in-channel enhancing structures would impede or redirect flood flows within a 100-year flood hazard area. Site design would take into account existing hydrology and channel geomorphology, and enhancement of in-channel complexity would be done so no flooding would occur. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction of in-channel enhancing structures is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of in-channel enhancing structures could result in a substantial degradation of water quality.

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
Land Use and Planning	• Construction and operation of in-channel enhancing structures would not physically divide an established community because they would be located within existing river banks and channels, or immediately adjacent to them, and communities are not established in these areas. Impacts would not occur. • Construction and operation of in-channel enhancing structures would occur in existing river banks and channels and would not conflict with land use designations or zoning. Frequently these areas are designated natural resource or open space areas by land use plans and in-channel enhancing structures would be consistent with those designations because they would enhance existing habitat for fish and wildlife species. Impacts would not occur. • The following habitat conservation plans cover parts of the Stanislaus, Tuolumne, and Merced Rivers: SJR Wildlife Refuge CCP and the SJMSCP. These plans protect special-status species within the San Joaquin, Stanislaus, Tuolumne, and Merced Rivers. As described in the Biological Resources section of this table, there would be some temporary construction impacts on adjacent riparian and/or wetland areas, but lead agencies would mitigate these temporary impacts through measures identified in Table 16-39. As such, no conflicts are expected with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations. Impacts would not occur.
Mineral Resources	• As mentioned in the Mineral Resources section of Table 16-12, there are known aggregate mines along the three eastside tributaries (Clinkenbeard 1999, Clinkenbeard 2012a and 2012b, Higgins and Dupras 1993, Rapp et al. 1977, and Smith and Clinkenbeard 2012). Construction and operation of in-channel enhancing structures are not likely to result in the removal or inability to access state or locally designated mineral resource areas. In-channel enhancing structures would be within existing river channels but would not be expected to cover existing mineral areas near operating mines. The locations selected for in-channel structures would be assessed to prevent them from being located within a state or locally designated mineral resource area. As such, construction and operation would not remove or result in significant impacts on these mineral resource areas. Impact would be less than significant.
Noise	• Construction of the in-channel enhancing structures would create noise related to the use of heavy construction equipment. The sites would be located where people generally do not live. It is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies. Excessive ground-borne vibration or ground-borne noise levels are also not expected due to the small nature of the projects and the type of construction equipment that would be used. If there was temporary elevated noise in excess of standards established in local general plans, noise ordinance, or applicable standards, it would occur during the day (as construction is not expected to occur at night) and for short periods of time within the day over a short duration (i.e., up to 12 weeks). However, given the temporary noise exposure to limited potential sensitive receptors, it is expected that noise impacts would be less than significant. Operation and maintenance of the in-channel enhancing structures would not create a permanent increase in ambient noise. This impact would be less than significant. • Projects would not be constructed near airports or airstrips so people would not be exposed to excessive noise levels. Impacts would not occur.

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
Population and Housing	• The construction and operation of in-channel enhancing structures would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Further, construction and operation of in-channel enhancing structures would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • The construction and operation of in-channel enhancing structures would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the sites would be located within river banks and channels. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location’s population increases, the need for additional or new public services and public service facilities generally increases. As discussed above, the construction and operation of in-channel enhancing structures would not involve an increase in population or housing. In addition, these actions would not include new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.
Recreation	• Construction of in-channel enhancing structures would occur within river banks and channels. It is possible that recreational facilities would be located in areas where in-channel enhancing structures would be placed. If recreational facilities were located within very close proximity, construction of in-channel enhancing structures may affect them; however, it is unlikely that there would be significant impacts on recreational facilities because construction would be temporary and limited in duration (i.e., up to 12 weeks). After construction is complete, in-channel enhancing structures would be located primarily submerged in the river channel. Impacts would be less than significant. • Construction and operation of in-channel enhancing structures would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Construction of in-channel enhancing structures could result in some additional trips associated with construction workers. Depending on the location of the site, there could be an increase in traffic from construction workers. The temporary increased traffic during construction would likely not exceed local or regional road trip thresholds, because the number of construction workers that in-channel enhancing structures typically require is less than 30. Impacts would be less than significant. • Operation of in-channel enhancing structures would not generate additional trips beyond those needed to maintain the sites. If maintenance activities are needed, it would be temporary and infrequent in nature and operation of the sites would not increase traffic. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.

Potential Environmental Effects of Installation and Operation of In-Channel Enhancing Structures

Resource	Discussion
Utilities and Service Systems	• Construction and operation of in-channel enhancing structures would not exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of wastewater. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not need the construction of additional storm water drains because the structures would be built within river channels and would not generate storm water. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not generate an increase in solid waste because activities are limited to modification of the river bank and channel. Impacts would not occur. • Construction and operation of in-channel enhancing structures would not require a water supply. Impacts would not occur.

16.3.5 Improve Temperature Conditions

Improving temperature conditions on the rivers can be done by operational and structural measures in upstream reservoirs. These have been identified as a priority conservation and recovery action in Central Valley rivers where coldwater reservoir supplies and operational flexibility may be sufficient to significantly improve water temperatures during critical migration, spawning, and rearing periods (NMFS 2014a). Currently, a number of naturally spawning populations of winter-run Chinook salmon, spring-run Chinook salmon, and steelhead populations in reaches below these dams (i.e., New Melones Dam, New Exchequer Dam) are artificially maintained by cool water releases from upstream reservoirs. However, warm water temperatures during critical spring, summer, and fall migration, spawning, and rearing periods continue to be a major threat to these populations, especially in dry years, and will likely exert increasing stress on these populations based on current climate change predictions (NMFS 2014a).

Key non-flow actions for managing water temperatures released from these dams include cold water pool management, installation or modification of selective withdrawal structures (e.g., temperature curtains or shutters), and floodplain and riparian restoration (discussed previously in Section 16.3.1, *Floodplain and Riparian Habitat Restoration*). While additional flows in the rivers can also contribute to reducing water temperatures, flows are not considered in this evaluation because they are not considered a non-flow measure.

Cost Evaluation

Costs associated with floodplain and riparian restoration are discussed in Section 16.3.1, *Floodplain and Riparian Habitat Restoration*. Availability of cost information regarding actions to improve temperature conditions, such as installation or modification of selective withdrawal structures, is limited. Considerations that contribute to the cost generally include high construction costs.

The Lake Natoma Temperature Curtains Pilot Project estimated the cost to be $1,960,196 for a 3-year study that included the installation of 2 curtains (one curtain 700-ft long with a depth of 15–20 ft, second curtain 600-ft long with a depth of 20–25 ft). Lake Natoma is located within the Lower American River, approximately 23 miles upstream of the American River’s confluence with the Sacramento River in Sacramento County. The costs associated with this pilot project included: design, permitting and environmental review, project management, temperature monitoring, project installation and removal, and completion of a project analysis and report (Winternitz and Washburn 2002).

In 2011, installation of a temperature curtain took place at Whiskeytown Lake for a cost of $3 million; Whiskeytown Lake is approximately 10 miles west of the city of Redding in Shasta County. The new temperature curtain replaced a curtain from 1993 that had deteriorated and was no longer functional. The new temperature curtain is 2,400 ft long and drops into the lake 110-ft and is anticipated to achieve a 2–4 degree drop in water temperature (Gee et al. 2012).

Environmental Evaluation

The primary sources of information for the following general description of water temperature control projects and associated environmental impacts were EBMUD (2008), NMFS (2000), and USBR (1991, 2013).

Summary of Potential Action

Planning and evaluation for water temperature control projects generally includes the development and evaluation of a number of conceptual alternatives, including both operational and structural measures, to identify the most effective means of optimizing the use of cold water for protection of salmon and steelhead populations while maintaining existing water supply and power generation capabilities. Planning and evaluation of cold water management operations typically requires initial water supply and temperature modeling to evaluate the feasibility and potential effectiveness of alternative measures. Following implementation, the continued use of modeling and forecasting tools is generally required to adaptively manage available cold water supplies under variable hydrologic, water demand, and operational conditions to achieve the best possible release temperatures for fisheries protection.

The use of shutters or other structural devices, typically in conjunction with operational measures, has been shown to be an effective means to seasonally control the temperature of water released from major storage reservoirs (deep, seasonally stratified reservoirs) to protect salmon and steelhead populations in a number of Central Valley rivers (e.g., Sacramento River, American River, Feather River). The magnitude of construction impacts of temperature control structures on native fish and wildlife species, aquatic and terrestrial habitat, water quality, and other resources depends on the type of device (e.g., curtains, shutters), construction methods and materials, and the location of the structure relative to protected or sensitive resources. Installation of temperature control devices typically requires minimal ground clearing; most structures can be assembled offsite, hauled to the dam, and lowered into place from the top of the dam by a mobile crane. The construction methods vary in intensity depending on the dam size and the type of water control temperature device being installed. Barges are typically not used during construction of temperature curtains or shutters (e.g., Cougar Dam, Shasta Lake Water Resources Investigation). Assembly or attachment of the new structural components may require underwater cutting and assembly by divers. Installation of temporary barriers or dewatering is typically not necessary. Common environmental commitments or BMPs to avoid, minimize, or offset potential environmental effects may include seasonal work windows (e.g., non-flood control periods), preconstruction biological surveys; biological monitoring; construction noise and light reduction measures; traffic control; SWPPP; and a spill prevention, control, and countermeasure plan. Post-construction evaluation activities may include testing and evaluation of mechanical and electrical systems; water temperature monitoring and evaluation; and adaptive management to address unforeseen issues and optimize water temperature management relative to water supply, power generation, and biological objectives. Long-term operations and maintenance activities may include regular or periodic inspections, repairs, cleaning, and sediment and debris management.

Potential Environmental Effects

Construction of water temperature control structures may result in temporary and localized effects typically associated with construction activities, including impacts on water quality and air quality. It is assumed water temperature control structures could be implemented on the dam structures of New Melones, New Don Pedro, and New Exchequer on the Stanislaus, Tuolumne, and Merced Rivers respectively, where the reservoirs store water above the mainstem rivers. Aquatic resources would be the most affected by installation or implementation of water temperature control measures, primarily during installation. Operation of the water temperature control structures would benefit aquatic species by reducing the temperature of water released from the reservoirs downstream in the Stanislaus, Tuolumne, and Merced Rivers. Maintenance would be required to ensure proper operation of the water temperature control structures.

It is reasonable to assume that installation of water temperature control structures would be professionally installed by contractors familiar with such projects. Depending on the magnitude of the structures, construction could last up to 4 years with activities occurring up to 5 months per year. Construction activities would be expected to occur during the dry season (e.g., typically June–October) to avoid the flood control season and minimize exposure of sensitive fish and wildlife species to disturbance. BMPs for controlling sediment and contaminant release into waterbodies would be used to minimize potential impacts on water quality associated with hazardous materials that may potentially be used during construction (e.g., fuels and oils for construction equipment). Water temperature control structures or a change in reservoir releases would result in decreases in water temperature. A decrease in water temperature would be beneficial for Chinook salmon and steelhead migratory, spawning, and rearing habitat.

Table 16-18, *Potential Environmental Effects of Improved Temperature Conditions*, summarizes the potential environmental effects associated with construction and operation of water temperature control structures. Those impacts associated with floodplain or habitat restoration are identified in Table 16-12, *Potential Environmental Effects of Floodplain and Riparian Habitat Restoration,* and are not incorporated into Table 16-18. Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this non-flow measure and is referenced in Table 16-18 where appropriate.

Table 16-18. Potential Environmental Effects of Improved Temperature Conditions

Potential Environmental Effects of Improved Temperature Conditions	
Resource	Discussion
Aesthetics	• Construction may be observable for a limited period of time when heavy equipment is used to install the structures behind the dams. While this could be visible around scenic areas around the reservoir, it would not permanently alter the scenic vistas or aesthetic experience of sensitive viewers because the construction equipment would be removed and the sites restored to their previous conditions once construction is complete. Lighting is not expected to be used during construction of water temperature control structures because generally most construction would occur during the day. However, there may be a need for 24-hour construction for a short period of time. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction lighting. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Operation of water temperature control structures would not be expected to have a significant impact on scenic vistas because they would be located underwater at existing dams. Impacts would be less than significant.
Agriculture and Forestry Resources	• Construction and operation of water temperature control structures are not expected to be located on lands used for agriculture or forestry because they would be located within the footprint of existing dams. There would be no conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use, conflict with existing zoning for agriculture use or a Williamson Act contract, conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Construction of water temperature control structures would likely result in emissions associated with construction equipment and construction worker vehicle trips, and fugitive dust emissions from ground disturbance, potentially at a laydown area. The quantity, duration, and the intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Similar to the discussion in Table 16-11b, *Potential Environmental Effects of New Surface Water Supplies,* emissions could be generated in the MCAB and GBVAB and depending on the air district and the criteria used, could exceed thresholds. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction of water temperature control structures would be

Potential Environmental Effects of Improved Temperature Conditions

Resource	Discussion
	inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction of water temperature control structures would not result in population or employment growth because these projects are habitat restoration projects for the benefit of special-status fish species. Therefore, construction of water temperature control structures would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • Construction and operation of water temperature control structures would not generate odors because the facility would exist behind a dam and not be located where people frequent. As such, impacts would not occur.
Biological Resources	• Construction of water temperature control structures would release sediment and possibly hazardous materials (e.g., oils or fuels from construction equipment) into waterbodies, temporarily affecting water quality. Dredging above the dam to clear sediment that may have settled against the dam would release sediment. Release of sediment into the river below the dam can bury macroinvertebrates which are prey for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat. Water quality measures such as monitoring turbidity and assessing water quality measurements (i.e., water temperature, dissolved oxygen) below the dam during construction should occur to avoid effects on aquatic resources and to ensure compliance with Basin Plan water quality objectives, and construction BMPs, would be implemented as either mitigation measures under CEQA or permit requirements and conditions. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on biological resources associated with construction of water temperature control structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction of water temperature control structures would not interfere with the movement of native residential or migratory fish species and associated migratory corridors, or impede the use of nursery sites because any work done in the water would occur during June to October when fish are not spawning or migrating. Impacts would not occur. • Operation of water temperature control structures would change aquatic habitat by changing water temperature. The change in water temperature is expected to be beneficial for Chinook salmon and steelhead. Overall, the project may have some temporary significant impacts during construction, but beneficial long-term effects. Water temperature control structures are not expected to have a substantial adverse effect, either directly or through habitat modifications on special-status species. Operation of water temperature control structures is expected to have a beneficial effect on special-status fish species by providing water temperatures that would create better conditions for migration, spawning, and rearing. During operation, an MMP would be implemented to ensure water temperatures are within appropriate ranges for special-status fish and other aquatic species. Monitoring is part of permitting requirements and conditions by

Potential Environmental Effects of Improved Temperature Conditions

Resource	Discussion
	resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. To ensure this, lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on biological resources associated with operation of water temperature control structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of water temperature control structures would be located in river reaches that support special-status fish species such as Chinook salmon and steelhead. These areas are expected to have high potential for special-status plant species, animal species, and habitat, and support biological resources. It is reasonable to assume that construction of water temperature control structures would occur during the least sensitive periods of special-status species life stages, (i.e., during the dry season, June–October), as this would reduce and minimize impacts on aquatic species and would be required through either the CEQA process or through permitting requirements and conditions by resource agencies including USFWS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce potentially significant environmental construction and operations impacts on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.
	• The surrounding habitat, outside of the area of reservoir fluctuation, may include riparian vegetation and/or wetlands. The areas around the reservoirs have maintenance roads and access areas for maintenance workers, which are cleared of vegetation. These areas could be used for construction staging and laydown and would not affect riparian vegetation or wetlands. If riparian vegetation or wetlands are removed or disturbed, they would be compensated for at a ratio appropriate for the disturbance per standard permit requirements or conditions from the U.S. Army Corps of Engineers and the Central Valley Water Board. This compensation would ensure fish and wildlife species and their habitats are protected. Under operations, wetlands and riparian vegetation would not be affected because the water temperature control device would be located in the reservoir. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental impacts associated with construction of water temperature control structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • While construction may result in temporary localized significant impacts on special-status species, plants, and habitat, construction activities are highly unlikely to result in population level adverse effects for any species. As such, these activities are not expected to conflict with habitat conservation plans such as the SJR Wildlife Refuge CCP or the SJMSCP, which are meant to provide protection at the population level. In addition, conflicts with local policies as a result of construction are not considered significant because of the temporary and localized nature of the effects. Because temperature control devices are expected to produce beneficial results for special-status fish species, ultimately the water

Potential Environmental Effects of Improved Temperature Conditions	
Resource	Discussion
	temperature devices would not conflict with local policies protecting biological resources or conflict with provisions of an adopted habitat conservation plan or natural community conservation plan, such as the SJR Wildlife Refuge CCP or the SJMSCP. This impact would be less than significant.
Cultural Resources	• Construction and operation of water temperature control structures would be within existing dam footprints. With the exception of the New Melones, New Don Pedro, and New Exchequer dams themselves, it is unlikely that cultural resources (significant historical, archaeological, or paleontological resources) exist in these locations, because the areas where the dams were constructed are highly disturbed and no further ground disturbing activities or excavation is required to install the temperature control structures. However, New Melones, New Don Pedro, and New Exchequer dams are reasonably within or beyond the 50-year threshold to be considered for evaluation for listing in either the National or state historical registers. While the temperature improvement devices could be considered needed as part of the normal operation of these dams, depending on the device selected, the design and the size of it, a determination may need to be made of the potentially significant historic or non-historic nature of the dams and whether the device would affect the significance of the potential historic nature and, in so doing, result in a significant impact. California Public Resources Code Section 21084.1 and California Code of Regulations Section 15064.5 subd. (a) maintain that the lead agency shall consider the eligibility of these structures for listing in the California Register of Historic Resources despite the addition of a temperature control device that may have no physical impact on the dam(s). Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on cultural resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Geology and Soils	• Because the dams are already constructed, the soils and geology are stable to support the existing dams. Water temperature control structures would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. Water temperature control structures would not bring people to the risk of earthquakes or geologic hazards, meaning the operation of the structures would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would be less than significant.
Greenhouse Gas Emissions	• Construction of water temperature control structures would result in increased GHG emissions because heavy equipment would be used. Given the duration of construction (up to 4 years with activities occurring up to 5 months per year). Similar to the discussion in Table 16-11b, the following APCDs do not have applicable GHG thresholds: CCAPCD, MCAPCD, TCAPCD. For air districts in which there is no adopted GHG threshold, the ZEL for SJVAPCD could be applied. While construction activities would be limited, it is likely that water temperature control structures construction activities could result in a potentially significant GHG impact beyond the SJVAPCD's ZEL. Depending on the level of construction activities and the potential operational lifespan of the project, construction-related GHG emissions could exceed these values and result in a potentially significant impact. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable,

Potential Environmental Effects of Improved Temperature Conditions

Resource	Discussion
	consistent with State CEQA Guidelines Section 15091. • During operation, vehicles may be needed for maintenance. The trips would be anticipated to be limited in number, of short distance and duration, and over a long period of time (e.g., one trip every year). As such, maintenance trips would likely result in small quantities of GHG emissions. However, GHG emissions may still exceed SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Potential Environmental Effects of Improved Temperature Conditions

Resource	Discussion
Hazards and Hazardous Materials	• Construction of water temperature control structures could possibly create a hazard if fuel trucks were used to transport fuel to the project sites. Gas and diesel are not acutely hazardous, and storage, handling, and disposal of these materials is regulated by local, county, and state laws. Although transportation and use of hazardous materials would occur, required safety protocols would be followed, mitigation measures and BMPs would be implemented, and the materials would be handled and transported appropriately to reduce the likelihood of a foreseeable accident involving the release of hazardous materials into the environment. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction of water temperature control structures would not emit hazardous emissions or handle hazardous materials, substances or waste within one-quarter mile (0.25 miles) of an existing school because all construction would occur near the dams. No schools are located within one-quarter mile of a dam. Impacts would not occur. • Construction and operation of water temperature control structures would not be located on a hazardous materials site, including a Cortese Site, because the structures would be located within the reservoirs or on the dam structure of the reservoirs. Impacts would not occur. • Construction and operation of water temperature control structures would not be a hazard or provide a safety concern to public or public use airports or private airstrips because the structures would be constructed and operated within the dams and would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, construction and operation of water temperature control structures would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Construction and operation of water temperature control structures would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road within the dams. Impacts would not occur. • Construction and operation of water temperature control structures would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur.
Hydrology and Water Quality	• Construction of water temperature control structures may temporarily affect water quality due to removing sediment buildup behind the dams before installation of the structures. Dredging could release sediments into the reservoir and could be discharged downstream of the dam. Resulting turbidity could cause a temporary exceedance of applicable water quality standards. Turbidity would be monitored to maintain compliance with Basin Plan water quality objectives. Operation of the water temperature control structures would decrease water temperatures and this would be a beneficial effect for Chinook salmon and steelhead in the mainstem of the river. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on water quality during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts

Potential Environmental Effects of Improved Temperature Conditions

Resource	Discussion
	could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of water temperature control structures would not deplete groundwater supplies or interfere substantially with groundwater recharge because these projects would not require groundwater supplies and would not result in an increase in impervious surfaces. Impacts would not occur. • Operation of the water temperature control structures would not alter the existing drainage pattern of the site or area nor cause an increase in substantial erosion or siltation, substantial runoff, or result in flooding on- or offsite because it would operate within the reservoir. Installation of the structures would be done so no erosion or flooding would occur because it is likely the reservoirs would be drawn down to allow construction in the dry areas as much as possible. Additionally, an MMP would be implemented after restoration is completed, which is part of permitting requirements and conditions by resource agencies including USFWS, NMFS, CDFW, Central Valley Water Board, and U.S. Army Corps of Engineers to ensure all of the structures are working as designed. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of water temperature control structures would not substantially increase the number of people exposed to the risk of flooding because these structures would not draw people to flood hazard locations. As such, construction and operation of water temperature control structures would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Construction and operation of water temperature control structures would not involve the construction of housing, and therefore this activity would not place housing within a 100-year flood hazard area. Impacts would not occur. • Construction and operation of water temperature control structures would occur within a reservoir and existing dams. The water temperature control structures would not impede or redirect flood flows within a 100-year flood hazard area. Impacts would be less than significant. • Construction and operation of water temperature control structures would occur in existing dams and would not create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems. Impacts would not occur. • Operation of water temperature control structures would not create or contribute runoff water. Impacts would not occur. • Construction of water temperature control structures is not expected to provide substantial additional sources of polluted runoff because these activities would occur primarily within existing dams. However, construction equipment would be required and, as a result, hazardous materials (e.g., fuels, lubricants, diesel) may be used during construction. While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it result in a significant impact. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water

Potential Environmental Effects of Improved Temperature Conditions

Resource	Discussion
	purveyors) can and should implement to reduce potentially significant impacts on water quality associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Although construction and operation of temperature control structures would occur at reservoirs, these activities would not cause in seismic ground shaking to generate in-reservoir seiches. Furthermore, these activities would not result in an increase in the potential for a seiche to occur, as the reservoirs could already experience a seiche under baseline conditions. Impacts would not occur. • There are no other ways in which construction or operation of temperature control structures could result in a substantial degradation of water quality.
Land Use and Planning	• Construction and operation of water temperature control structures would not physically divide an established community. Impacts would not occur. • Construction and operation of water temperature control structures would occur in existing dams and would not conflict with land use designations or zoning. Frequently these areas are designated natural resource or open space areas by land use plans and would be consistent with those designations because it would enhance existing habitat for fish species. Impacts would be less than significant. • The SJMSCP covers parts of the Stanislaus, Tuolumne, and San Joaquin Rivers. This plan protects special-status species within the San Joaquin, Stanislaus, and Tuolumne Rivers. Operation of water temperature control devices would not affect special-status species and would be beneficial. As such, no conflicts are expected with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations. Impacts would be less than significant.
Mineral Resources	• Construction and operation of water temperature control structures are not expected to result in the removal or inability to access state or locally designated mineral resource areas. This is because the water temperature control structures would be behind (i.e., upstream of) existing dams and would not affect mineral areas. Impacts would not occur.
Noise	• Construction of the water temperature control structures would create noise related to the use of heavy construction equipment. The sites would be located behind (i.e., upstream of) dams, and within the reservoirs, where people do not live. As such, it is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies. Excessive ground-borne vibration or ground-borne noise levels are also not expected due to the fact that construction would primarily be in the water with equipment on land. While there may be temporary elevated noise in excess of standards established in local general plans, noise ordinance, or applicable standards, it would occur during the day (as construction is not expected to occur at night) and for short periods of time within the day. Given the relatively limited exposure of potential sensitive receptors

Potential Environmental Effects of Improved Temperature Conditions	
Resource	Discussion
	to this potential temporary increase in noise, and low likelihood of potential sensitive receptors to exist because of the location of construction, it is expected impacts would be less than significant. While it is not anticipated that potential sensitive receptors would be subject to excessive noise, Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce noise impacts during construction. However, it is likely that impacts could be mitigated to less than significant once implemented. • Operation of the water temperature control structures would not create noise. There would be maintenance activities, but they would not create a permanent increase in ambient noise. This impact would be less than significant. • Water temperature control structures would not be constructed near airports or airstrips so people would not be exposed to excessive noise levels. Impacts would not occur.
Population and Housing	• The construction and operation of water temperature control structures would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Further, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • The construction and operation of water temperature control structures would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere. No homes or people would be displaced. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, the construction and operation of water temperature control structures would not involve an increase in population or housing. In addition, these actions would not include proposals for new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.
Recreation	• Construction and operation of water temperature control structures would occur behind (i.e., upstream of) dams. It is unlikely recreational facilities would be located near dams because recreational boating and fishing are typically not allowed near the dam structures. Impacts on recreational facilities are not anticipated. Construction and operation of water temperature control structures would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur.

Potential Environmental Effects of Improved Temperature Conditions

Resource	Discussion
Transportation and Traffic	• Construction of water temperature control structures could result in additional trips associated with construction workers. Depending on the location of the site, there could be an increase in traffic from construction workers. The temporary increased traffic during construction would likely not exceed local or regional road trip thresholds, because the number of construction workers that work on water temperature control structures typically is less than 30. This impact would be less than significant. • Operation of water temperature control structures would not generate additional trips beyond those needed to maintain the structure. If maintenance activities are needed, they would be temporary in nature and operation of the structures would not affect traffic. Impacts would be less than significant. • Construction and operation of water temperature control structures would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Construction and operation of water temperature control structures would not exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of wastewater. Impacts would not occur. • Construction and operation of water temperature control structures would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur. • Construction and operation of water temperature control structures would not need the construction of additional storm water drains because the structures would be built behind the dams and would not generate storm water. Impacts would not occur. • Construction and operation of water temperature control structures would not generate an increase in solid waste. Impacts would not occur. • Construction and operation of water temperature control structures would not require a water supply. Impacts would not occur.

16.3.6 Fish Passage Improvements – Fish Screens

NMFS (2014a) identified entrainment of juvenile salmonids at unscreened or inadequately screened water diversions as a major factor contributing to historical declines and current status of listed Central Valley Chinook salmon and steelhead. Consequently, a major focus of species protection and recovery efforts has been screening of water diversions, with a higher priority placed on the largest diversions. However, there are many smaller diversions (mostly agricultural) that remain unscreened (Herren and Kawasaki 2001). It is generally recognized that modern fish screens are effective in preventing entrainment of juvenile salmonids but information is lacking to evaluate the overall survival and population-level benefits of fish screens (Moyle and White 2002, Vogel 2013).

Fish screen design varies widely depending on site-specific engineering, hydraulic, and fish protection objectives and requirements. Common positive barrier screen types include flat plate, drum, traveling, cylindrical, and inclined screens. Fish screen projects where NMFS, USFWS, and CDFW have jurisdiction must be developed in consultation with these agencies and in accordance with established design, operational, and maintenance criteria and guidelines (e.g., NMFS 2011).

Cost Evaluation

The costs for fish screens vary significantly depending on the size of the existing intake. Typically, screening smaller or private intakes that primarily serve agricultural uses are less costly when compared to screening large intake projects that primarily serve municipal and industrial uses. Agricultural diversions (with an average diversion rate of 10 cfs) have an estimated cost of $75,000 per diversion (unit cost of $7,500/cfs) (URS Corporation and Jack R. Benjamin & Associates 2011). Capital costs for agricultural diversion screens in the western United States can range between $3,000 and $20,000 per cfs, with maintenance and operations costs ranging between $3,000 and $5,000 per year (FCA 2016).

The Anadromous Fish Screen Program (AFSP) under the Central Valley Project Improvement Act (CVPIA) has funded several fish screen projects in California. The most recent ones are listed below.

- Natomas Mutual Sankey Fish Screen Project (total cost $45.975 million) located off the left bank of the Sacramento River replaced existing unscreened diversions with a consolidated 434 cfs fish screen and intake facility (USBR and USFWS 2014).
- Reclamation District (RD) 2035/Woodland Davis Clean Water Agency Joint Intake and Fish Screen (estimated cost of $44 million) located off the right bank of the Sacramento River replacing unscreened diversion with a consolidated 400 cfs fish screen and intake facility to provide water to irrigate approximately 15,000 acres of crops and serve the cities of Davis, Woodland, and the University of California, Davis campus (USBR and USFWS 2014, Wilcox 2014).

Another large municipal intake that has been screened in the Central Valley is the Davis Ranches Fish Screen Project, located in Colusa County at RM 132.5. This fish screen consisted of installing a self-cleaning, cylindrical, brushed intake fish screen with a retrieving system. The cost for this project is $414,904 which includes planning, design, project management, construction, installation, and monitoring. Table 16-19, *Design and Construction Costs Davis Ranches Site 2 Pump 4 & 5 Project*, provides a more detailed breakdown of the costs for this project.

Table 16-19. Design and Construction Costs Davis Ranches Site 2 Pump 4 & 5 Project

Cost Category	Davis Ranches Site 2, Pumps 4 &5[a]
Design & construction of fish screen	$310,964.00
Eng. review, inspection & documentation, permit costs	$24,000.00
Accounting & project management & monitoring	$79,940.00
Total	**$414,904.00**

Source: Griffith 2001.

Costs represent the total costs over 2 years.

Environmental Evaluation

The primary sources of information for the following general description of fish screen projects and associated environmental impacts were USFWS (2004), USBR (2006b), NMFS (2004, 2011). Additional references are cited below.

Summary of Potential Action

The design process for fish screen projects may include hydrologic and hydraulic data collection and analysis, debris and sediment loading assessments, and biological investigations. Key design considerations include screen placement (e.g., in- or off-river); screen size, orientation to flow, and hydraulics; debris and sediment management (e.g., screen cleaning systems); size, life history, behavior, and swimming ability of the target species; ancillary fish guidance and protection facilities (e.g., bypass systems); and operation and maintenance schedules.

The magnitude of construction impacts of fish screen projects on native fish and wildlife species, aquatic and terrestrial habitat, water quality, and other resources depends on the type, size, and location of the intake; construction methods; and proximity of other protected or sensitive resources. There are 112 diversions on the Merced River, 51 on the Tuolumne River, 117 on the Stanislaus River, 36 diversions on the SJR between the Merced and Tuolumne Rivers, and 8 diversions on the SJR between the Tuolumne and Stanislaus Rivers and between the Stanislaus River and Vernalis. This is a total of 324 diversions that could be screened depending on project-specific circumstances. These diversions are used for hydropower and irrigation. The minimum diversion is 1 cfs (East Stanislaus Resources Conservation District) and ranges up to 6,000 cfs (hydropower at New Melones Dam). Replacing, relocating, or constructing new fish screens may include clearing of vegetation to construct temporary roads, staging, and storage areas; placement of temporary structures (e.g., cofferdams) to isolate work areas from flowing water; clearing, grading, and armoring of the channel and banks; and pile driving. Typical construction equipment includes excavators, pile drivers, bulldozers, dump trucks, and front-end loaders. Generally the projects are relatively small in size and only require a construction crew of 5–10 people.

Common environmental commitments or BMPs to avoid, minimize, or offset potential environmental effects may include seasonal work windows (e.g., low flow periods); preconstruction biological surveys; erosion and sediment control measures; biological monitoring; construction noise and light reduction measures; traffic control; SWPPP; spill prevention, control, and countermeasure plan; and turbidity compliance monitoring.

Post-construction evaluation activities may include testing and evaluation of mechanical and electrical systems, hydraulic evaluations, and biological evaluations (e.g., fish entrainment monitoring). Long-term operations and maintenance activities may include regular or periodic inspections, repairs, cleaning, and sediment and debris management to ensure the effectiveness of the screen over the design life of the facility.

Potential Environmental Effects

Some of the irrigation diversions in the Central Valley are relatively small (<5 cfs) and the scale and magnitude of potential impacts associated with screening these diversions are such that they could meet the requirements of a categorical exemption under CEQA. CEQA allows categorical exemptions for classes of projects which have been determined not to have a significant effect on the environment. (Pub. Res. Code, § 21084.) Specifically, the following types of facilities and activities are exempt under a Class 1 or Class 3 categorical exemption.

- Minor alterations of the existing public or private structure without expanding existing uses.
- Installation of small new equipment and facilities.

In addition, Class 2 categorical exemptions allow for the replacement or reconstruction of existing facilities where the new structure will be located on the same site and will have the same purpose and capacity as the structure replaced. Some fish screen projects could meet the requirements for this exemption.

If the screening project would not meet the requirements of a categorical exemption, depending on the size of the intake and the needed screen, construction of fish screens may result in temporary and localized effects typically associated with construction activities, including a change in water quality, air quality effects, and ground and channel disturbance. If cofferdam placement and dewatering is needed, this could result in special-status fish species becoming stranded within the cofferdam area. A rescue and relocation of all fish species would be needed within the isolated areas. This could result in injury or mortality of special-status fish species. Additionally, pile driving may be needed for structure and/or cofferdam installation. Noise levels could affect special-status fish species. River banks or channels may be graded to facilitate structures in areas that support special-status fish species such as Chinook salmon and steelhead. Riprap may need to be placed around the intake structures. These areas would be located below the dams on the Stanislaus, Tuolumne, Merced, and Lower San Joaquin Rivers, where unscreened diversions occur. Aquatic resources would be the most affected by installation of fish screens. Operation of the screens would benefit special-status fish species and would require maintenance. Maintenance would occur when needed and would include cleaning the screen and regular or periodic inspections.

It is reasonable to assume that installation of fish screens will be professionally installed by contractors familiar with such projects. Depending on the magnitude of the projects, construction could last anywhere from several weeks to several months, but generally less than 6 months. Construction activities would occur during the dry season (typically June–October), when anadromous fish would not be spawning. BMPs for controlling sediment and contaminant release into waterbodies would be used to minimize potential effects on water quality associated with sediment and hazardous materials. Mitigation measures to minimize stranding and protect fish from injury and mortality from pile driving noise, cofferdam installation, and riprap placement would be implemented. Operation of fish screens would result in changes to hydraulics and stream habitats by the addition of riprap around the intake structures. Fish screens would help decrease entrainment of special-status fish species and other fish species. Adding fish screens is expected to benefit aquatic biological resources.

Table 16-20, *Potential Environmental Effects of Fish Passage Improvements—Fish Screens*, summarizes the potential environmental effects associated with improving fish passage with fish screens. Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this non-flow measure and is referenced in Table 16-20 where appropriate.

Table 16-20. Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Potential Environmental Effects of Fish Passage Improvements—Fish Screens	
Resource	Discussion
Aesthetics	• Construction and operation of fish screens would not be expected to significantly affect scenic vistas because the screens would be located within existing river channels. Construction and operation of the fish screens would not have a substantial adverse effect on a scenic vista. Construction may be observable for a temporary period of time when heavy equipment is used to grade banks, move sediment, and install structures. Lighting is not expected to be used during construction of fish screens—all construction would occur during the day. This impact would be less than significant. • Operation has a low potential to substantially degrade the visual character and quality of the surrounding area, as the screen would be in the water and adjacent to the river channel. Further, a structure for diversion purposes is already part of the visual character and quality and the screen would be located in the same place. Impacts would be less than significant.
Agriculture and Forestry Resources	• Construction and operation of fish screens would not be expected to be located on lands used for agriculture or forestry but within the footprint of existing river channels. There would be no conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use, conflict with existing zoning for agriculture use or a Williamson Act contract, conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Construction of fish screens would likely result in emissions associated with construction equipment and construction worker vehicle trips, as well as fugitive dust emissions from ground disturbance. The quantity, duration, and the intensity of construction activity may have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be “diluted” relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since construction of fish screens does not require lengthy construction activities, the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the SJVAPCD regulations and established thresholds. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • SJVAPCD generally defines a sensitive receptor as a facility that houses or attracts children, the elderly, people with illnesses, or others who are especially sensitive to the effects of air pollutants, and where there is a reasonable expectation of continuous human exposure according to the averaging period for National AAQSs (e.g., 24-hour, 8-hour, or 1-hour) (SJVAPCD 2002). Sensitive receptors are primarily concentrated in urbanized areas, and their

Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Resource	Discussion
	proximity to construction or operational activities, the type of activity, and duration of activity, determines their potential exposure to pollutants. If criteria pollutant standards are exceeded during construction, and sensitive receptors are in proximity, mitigation measures identified in Table 16-38 would serve to reduce potentially significant air quality effects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, given the potential short term nature of construction and the required mitigation by the SJVAPC, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction of fish screens would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction of fish screens would not result in population or employment growth because these projects are intended only to benefit special-status fish species through improvement of fish passage. Therefore, construction of fish screens would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • Operation of fish screens would not result in direct emissions because they are passive structures. However, the fish screens would long-term operations and maintenance activities, which may include regular or periodic inspections, repairs, cleaning, and sediment and debris management to ensure the effectiveness of the screen over the design life of the facility, which would require maintenance vehicle trips. Because vehicle trips would be relatively limited in number, impacts on air quality and any sensitive receptors would be less than significant. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). Construction and operation of fish screens would not create objectionable odors affecting a substantial number of people. Impacts would not occur.
Biological Resources	• Construction of fish screens would release sediment and possibly hazardous materials (e.g., oil or fuel from construction equipment) into waterbodies, creating water quality issues. Release of sediment can bury macroinvertebrates, which are prey items for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat. Water quality measures such as monitoring turbidity to ensure compliance with Basin Plan water quality objectives and construction BMPs would be implemented. To ensure this, lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental

Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Resource	Discussion
	effects associated with construction of fish screens. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and installation of cofferdams can injure or kill fish, if cofferdams are needed, depending on the size of the diversion and the type and size of the screen. Pile driving can create noise impacts harmful to fish. Stranding within the cofferdams can occur if special-status fish species become trapped inside a dewatered area. Fish rescue in the dewatered area (seining, electrofishing) could injure or kill fish. These activities could result in take of special-status fish species. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction of fish screens. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even with mitigation measures, significant and unavoidable impacts may occur if the potential for take cannot be avoided or reduced or take occurs during construction. • Construction and operation of fish screens would be located in river reaches that support special-status fish species such as Chinook salmon and steelhead. These areas are expected to have high potential for special-status plant species, animal species, and habitat, and support biological resources. This could be a significant impact on special-status species and their habitats. It is reasonable to assume that construction of fish screens would occur during the least sensitive periods of special-status species life stages, (i.e., during the dry season, June–October), because this would reduce and minimize impacts on aquatic species and would be required through either the CEQA process or through permitting requirements and conditions by resource agencies including USFWS, CDFW, NMFS, Central Valley Water Board, and U.S. Army Corps of Engineers. As such, construction of fish screens would not interfere with the movement of native residential or migratory fish species and associated migratory corridors, or impede the use of nursery sites because any work done in the water would occur during June to October when fish are not spawning or migrating. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce potentially significant impacts on special-status biological resources from construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The surrounding habitat on river banks may include riparian vegetation and/or wetlands. Riparian vegetation may have to be removed to facilitate heavy equipment movement and wetlands may also be disturbed during construction activities. This would result in a temporary significant effect on riparian habitat and wetlands. Under operations, riparian habitat and wetlands would not be affected. Removal and/or disturbance of riparian and wetlands habitats would be compensated for at a ratio appropriate for the disturbance per standard permit requirements or conditions from the U.S. Army Corps of Engineers and Central Valley Water Board. This compensation would reduce and minimize impacts on fish and wildlife species and their habitats. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with

Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Resource	Discussion
	construction of fish screens. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Operation of fish screens would change aquatic habitat by installing riprap near the intakes and changing velocity near the fish screen. Velocities will be measured at the screen to ensure they fall into the correct range for the fish species that will be present near the fish screen (CDFW 2016). Overall, the project may have beneficial long-term effects. Operation of fish screens would keep fish from entering agricultural fields or other areas of diversion, therefore increasing survival. This impact would be less than significant. • While construction may result in temporary localized adverse effects on special-status species, plants, and habitat, construction activities are highly unlikely to result in population level adverse effects for any species. As such, these activities are not expected to conflict with habitat conservation plans such as the SJR Wildlife Refuge CCP or the SJMSCP, which are meant to provide protection at the population level. In addition, conflicts with local policies as a result of construction would be less than significant because of the temporary and localized nature of the effects. Because fish screens are expected to produce beneficial results for special-status fish species, they would not conflict with local policies protecting biological resources or conflict with provisions of an adopted habitat conservation plan or natural community conservation plan, such as the SJR Wildlife Refuge CCP or the SJMSCP. This impact would be less than significant.
Cultural Resources	• Construction and operation of fish screens would be within existing river banks and channels at the location of existing diversions. River banks could be excavated for installation of structures during construction. It is unknown if cultural resources (significant historical, archaeological, or paleontological resources) or human remains exist in these locations. Typically the river channels have had high levels of disturbance because of hydraulic conditions and the fish screen sites would have been previously disturbed to install diversions. As such, there is a low potential for significant cultural resources to exist within the river banks. Operation of fish screens would have a very low potential to affect cultural resources because operation would be along the river bank and channels. It is reasonable to assume that where construction within areas that may contain cultural resources cannot be avoided, an assessment would be conducted of the potential for damage to cultural resources or human remains prior to construction. This may require hiring a qualified cultural resources specialist to determine the presence of significant cultural resources. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant effects on cultural resources associated with construction of fish screen projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.

Potential Environmental Effects of Fish Passage Improvements—Fish Screens	
Resource	Discussion
Geology and Soils	• The locations of new fish screens could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, construction or operation of fish screens would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. Impacts would not occur. • Construction would likely take place along rivers and in riparian areas where erosion can take place depending on the soil characteristics, geology, and area of disturbance. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant erosion or sediment effects associated with construction of fish screens. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 175091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Fish screens would not bring people to the risk of earthquakes or geologic hazards, meaning the operation of the areas would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur.
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-12, construction of fish screen projects would generate GHG emissions because heavy equipment would be used for a period of up to 6 months. While construction activities would be limited, it is likely that construction could result in a potentially significant GHG impact beyond SJVAPCD's ZEL. Depending on the level of construction activities and the potential operational lifespan of the project, construction-related GHG emissions could exceed these values and result in a potentially significant impact. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • During operation, some vehicles may be needed for monitoring or maintenance of the fish screens. However, the trips would be limited, of very short duration, and over a long period of time (e.g., one trip every year). As such, they would likely result in extremely small quantities of GHG emissions. However, GHG emissions may still exceed SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources.

Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Resource	Discussion
	○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Construction and operation of fish screens would not be a hazard or trigger safety concerns to public or public use airports or private airstrips because the structures would be constructed and operated within the river banks and channels and would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, construction and operation of fish screens would not result in a safety hazard for people residing or working in or near the project area. Impacts would not occur. • Construction and operation of fish screens would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road within the river banks and channels. Impacts would not occur. • Construction and operation of fish screens would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • Construction of fish screens could involve the temporary use of small amounts of hazardous materials, such as fuel to power construction equipment. There is a low potential for a hazardous materials spill associated with construction equipment given the limited duration of construction and the generally small number of construction equipment that would be used. However, since construction work would occur within river channels, Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due to hazards and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The precise location of fish screens would be constructed is not yet known; however, these projects could be constructed within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation activities. Table 16-39 lists potential

Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Resource	Discussion
	mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962. These sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the DTSC for Calaveras, Tuolumne, or Mariposa Counties (CalEPA 2016). There were a total of 17 sites identified for Merced, San Joaquin, and Stanislaus Counties. In addition to these sites identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 500 leaking underground storage tanks designated as open in these counties (CalEPA 2016). There are approximately 55 facilities in these counties that have received CDOs/CAOs not identified as non-hazardous wastes, domestic wastewater, or domestic sewage (CalEPA 2016). The active and open leaking underground storage tank cases and the CDO/CAO facilities are located throughout these counties. Although it is not yet known precisely where fish screens would be constructed, if construction were to occur on a Cortese Site, because construction activities would likely entail some ground disturbance (e.g., excavation), there would be potential for release of existing soil or groundwater contaminants. Were this to occur, impacts could be significant. Table 16-39 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • Construction of fish screens could require excavation. Utilities may be underneath the sites or adjacent to a site and may need to be relocated or avoided. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potential hazards associated with excavation around utilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.

Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Resource	Discussion
Hydrology and Water Quality	• Construction of fish screens may temporarily affect hydrology and water quality due to grading along the river banks and channels. Turbidity resulting from construction activity on-bank and instream could cause a temporary exceedance of applicable water quality standards. Placing and anchoring the fish screens using pile driving or a crew in the water placing a screen, armoring the channel and banks with riprap and driving heavy equipment in and near the river channel could result in temporary turbidity. Due to the placement activities during the dry season, to avoid impacts on sensitive fish species, and isolation of the areas from surface water with cofferdams or some other means, it is expected that water quality impacts would be less than significant with mitigation incorporated. Turbidity should be monitored for Basin Plan objectives compliance during construction, reducing the impacts on water quality. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of fish screens would not deplete groundwater supplies or interfere substantially with groundwater recharge because these projects would not require groundwater supply and would not result in a substantial increase in impervious surfaces. Impacts would not occur. • Operation of the fish screens could alter the existing drainage pattern of the site or area but is not expected to cause an increase in substantial erosion or siltation, substantial runoff or result in flooding on- or offsite. Design would take into account existing hydrology and channel geomorphology and installation of the structures would be done so erosion or flooding would be controlled or would not occur. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of fish screens would not substantially increase the number of people exposed to the risk of flooding because these activities would not draw people to flood hazard locations. As such, construction and operation of fish screens would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Construction and operation of fish screens would not involve the construction of housing, and therefore this activity would not place housing within a 100-year flood hazard area. Impacts would not occur. • Construction and operation of fish screens would not impede or redirect flood flows because lead agencies would be required to comply with the requirements of USACE and the Central Valley Flood Protection Board to avoid increased flood potential. Impacts would be less than significant. • Construction of fish screens would not create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems because most activities would take place in the stream channel within a cofferdam. Impacts would not occur.

Potential Environmental Effects of Fish Passage Improvements—Fish Screens	
Resource	Discussion
	• Operation of fish screens would not create or contribute runoff water or provide substantial additional source of polluted runoff. Most of the fish screen would be in the river channel, and although there may be some impervious surfaces on land associated with the screen it would not be expected to increase runoff volume or contribute polluted runoff. Maintenance of fish screens would be expected to be periodic would likely primarily entail cleaning the screens of debris from the river, which would not increase runoff volume or contribute polluted runoff. Impacts would not occur. • Construction of fish screens is not expected to provide substantial additional sources of polluted runoff because these activities would occur primarily within the stream channel. However, construction equipment would likely be working from the river bank and, as a result, hazardous materials (e.g., fuels, lubricants, diesel) would be used during construction. While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it result in a significant impact. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts on water quality associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction of fish screens is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of fish screens could result in a substantial degradation of water quality.
Land Use and Planning	• Construction and operation of fish screens would not physically divide an established community because they would be located within existing river banks and channels where communities are not established. Impacts would not occur. • Construction and operation of fish screens would occur in existing river banks and channels and would not conflict with land use designations or zoning because the activities would take place at an existing diversion already allowed by local policies or plans. In addition, these areas may be designated natural resource or open space areas by land use plans and fish screens would be consistent with those designations because they would enhance existing habitat for fish and wildlife species. Impacts would be less than significant. • The SJMSCP covers parts of the San Joaquin, Stanislaus, and Tuolumne Rivers. This plan protects special-status species within the San Joaquin, Stanislaus, and Tuolumne Rivers. As described in the Biological Resources section of this table, there could be some temporary construction impacts on adjacent riparian and/or wetland areas, but lead agencies would mitigate these temporary impacts through measures identified in Table 16-39. As such, no conflicts are expected with habitat conservation plans, natural community conservation plans, or other plans, policies, and

Potential Environmental Effects of Fish Passage Improvements—Fish Screens	
Resource	Discussion
	regulations. Furthermore, the fish screens would help protect designated fish species that are identified within the habitat conservation plan as needing protection (e.g., splittail), and would ultimately support the purpose of the plan to protect these species. Impacts would be less than significant.
Mineral Resources	• Construction and operation of fish screens would not result in the removal or inability to access state or locally designated mineral resource areas. Fish screens would be located in areas that have already been modified by water diversions and there is a very low potential for mineral resources to exist. Impacts would not occur.
Noise	• Construction of fish screens would create noise related to the use of heavy construction equipment. The sites would be located within river banks and channels where people do not live. Of the 324 diversions that could be screened, the majority of them, 226, are located in areas with a population density of 0–100 people per square mile. Generally this would indicate they are located in fairly remote and sparsely populated areas, with a low likelihood of sensitive receptors to be located immediately adjacent to a project site. As such, for these diversions, it is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies due to the small nature of the projects and the remote location of these projects. Excessive ground-borne vibration or ground-borne noise levels are also not expected, unless pile driving is needed. If pile driving is needed it is not expected to cause excessive vibrations that would disturb sensitive receptors because of the remote location of the projects. Of the 324 diversions that could be screened, 104 are located in areas with a medium population density of 101–1,000 people per square mile and 2 are located in areas with a high population density of greater than 1,000 people per square mile. These are located in more urban areas and, as such, have a greater likelihood of having sensitive receptors located within relative close proximity to project site locations. As such, there may be temporary elevated noise in excess of standards established in local general plans, noise ordinance, or applicable standards that may affect sensitive receptors. These potential elevated noise levels would primarily occur during the day because construction is not expected to occur at night and for short periods of time within the day over a short duration (e.g., several weeks to several months, but generally less than 6 months). Given the potential for 106 locations to have sensitive receptors within relative close proximity, and the potential for pile driving, lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant effects associated with construction noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Operation of fish screens would not create noise. There may be some maintenance activities, but they would not create a permanent increase in ambient noise and impacts would be less than significant. • Projects would not be constructed near airports or airstrips so people would not be exposed to excessive noise levels. Impacts would not occur.

Potential Environmental Effects of Fish Passage Improvements—Fish Screens

Resource	Discussion
Population and Housing	• The construction and operation of fish screens would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Furthermore, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • The construction and operation of fish screens would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the sites would be located within river banks and channels. No homes or people would be displaced. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, and other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, the construction and operation of fish screens would not involve an increase in population or housing. In addition, these actions would not include new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.
Recreation	• Construction of fish screens would occur within river banks and channels. It is possible that recreational facilities would be located in areas where fish screens would be constructed. If recreational facilities were located within very close proximity, construction of fish screens may affect them; however, it is unlikely that there would be significant impacts on recreational facilities because construction would be temporary and limited (e.g., several weeks to several months, but generally less than 6 months). Construction and operation of fish screens would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Construction of fish screens could result in some additional trips associated with construction workers. Depending on the location of the site, there could be an increase in traffic from construction workers. The temporary increased traffic during construction would likely not exceed local or regional road trip thresholds, because the number of construction workers that fish screen projects typically require is 5–10 people. This would be a less-than-significant impact. • Operation of fish screens would not generate additional trips beyond those needed to maintain the sites. If maintenance activities during operation are needed, they would be temporary in nature and would not affect traffic. Impacts would not occur. • Construction and operation of fish screens would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.

Potential Environmental Effects of Fish Passage Improvements—Fish Screens	
Resource	Discussion
Utilities and Service Systems	• Construction and operation of fish screens would not exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of wastewater. Impacts would not occur. • Construction and operation of fish screens would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur. • The construction and operation of fish screens would not need the construction of additional storm water drains because the screens would be built within river channels and would not generate storm water. Impacts would not occur. • Construction and operation of fish screens would not generate an increase in solid waste because the activities would not generate large quantities of solid waste. Impacts would not occur. • Construction and operation of fish screens would not require a water supply. Impacts would not occur.

16.3.7 Fish Passage Improvements – Physical Barrier in the Southern Delta

Initiated by DWR in 1991, the South Delta Temporary Barriers Program (TBP) consists of seasonal installation of three rock barriers (Old River Near Tracy, Middle River, Grant Line Canal) designed to facilitate pumping by agricultural water diversions in the southern Delta, and a fourth barrier (Head of Old River [HOR]) designed to benefit SJR salmon and steelhead by improving attraction flows and passage conditions for adults in the fall, and survival of out-migrating smolts in the spring by blocking entry of smolts into Old River (See Section 16.4.5, *South Delta Temporary Barriers,* for more information regarding this program). Studies conducted by the Vernalis Adaptive Management Program (VAMP) demonstrated that increasing the volume of flow in the mainstem SJR and preventing smolts from entering Old River was effective in improving survival of SJR smolts through the Delta. Installation of the HOR barrier was prohibited in 2008 in response to a court order to protect delta smelt. In 2009 and 2010, USBR and DWR investigated the effectiveness of a non-physical barrier (bio-acoustic fish fence) in deterring juvenile salmonids from entering Old River. A permanent operable barrier at the HOR is currently proposed as part of the California WaterFix to prevent out-migrating salmonids from entering Old River in the spring and improve adult passage conditions and water quality (dissolved oxygen [DO]) in the SJR (particularly the Stockton Deep Water Ship Channel) in the fall. This section evaluates the construction and operation of a permanent operable barrier at HOR. It assumes the other temporary barriers under the TBP in the southern Delta would continue to be implemented as described in Section 16.4.5 as part of addressing the impacts of the CVP/SWP export operations on water levels and flow conditions that might affect salinity.

Cost Evaluation

DWR (2015a) produced a report in response to requirements of the NMFS 2009 Biological Opinion on the long-term operations of the CVP and SWP, discussing engineering solutions to reduce diversion of emigrating salmonids. This report discusses the potential engineering solutions for HOR and four other areas in the Delta. The HOR gate is estimated to cost $43,200,000 for construction and $200,000 for operation and maintenance.

Environmental Evaluation

The primary sources of information for the following description of physical barriers in the southern Delta and associated environmental impacts were NMFS's Biological Opinion for the 2012 South Delta Temporary Barriers Project (NMFS 2012), San Joaquin River Group Authority (SJRGA) Annual Technical Reports (2009, 2011), and the publicly available California WaterFix Draft Biological Assessment (USBR and DWR 2016).

Summary of Potential Action

As described in Section 16.4.5, *South Delta Temporary Barriers*, continued implementation of the TBP is currently part of baseline hydrologic, water quality, and biological conditions of the southern Delta. Because DWR would continue to work with the permitting and resource agencies to obtain the appropriate permits and conditions to operate the temporary barriers, there would be no change from baseline conditions or additional environmental assessment or regulatory requirements with future installation and operation of the temporary barriers. The barriers are typically installed in the spring and operated April–November. In general, installation of the barriers requires stockpiling of quarry rock on the waterside of the levee crown and use of heavy equipment (e.g., front loaders, dump trucks, excavators, cranes) to place the stockpiled rock and other structures (e.g., culverts, flashboard structures, concrete reinforcing mats) into the channel. As the rock barrier is extended into the channel, heavy equipment can use the top of the barrier to move farther into the channel to place additional material. Construction typically takes 1–3 weeks. The barriers are removed in the fall by reversing the installation procedure. The TBP includes a fish monitoring program employing the use of acoustic telemetry to assess the survival of salmon and steelhead with the south Delta barriers in place, and gain a better understanding of survival, migration behavior, and predator-prey interactions in the south Delta under various structural and operational water management conditions.

Foreseeable future barrier projects in the south Delta include the construction and operation of a permanent operable barrier at the HOR. The HOR is in San Joaquin County near the town of Lathrop. Currently proposed as part of the California WaterFix, the HOR gate would consist of five water control gates; a fish passage structure; a boat lock; and associated control, operations, and navigation facilities. Typical construction equipment for this type of project would include excavators, graders, cranes, pile drivers, bulldozers, dump trucks, and front-end loaders. The fish passage structure would be designed according to guidelines established by NMFS and USFWS. The barrier would be constructed with reinforced concrete within the confines of the existing channel with no levee relocation. To ensure stability of the levee, a sheet pile retaining wall would be installed in the levee where the operable barrier connects to it. Dredging of Old River and the placement of rock slope protection would be required upstream and downstream of the proposed structure. Cofferdams would be installed to create a dewatered area for construction of the foundation. Construction may last up to 3 years and may be conducted in two phases with half of the structure constructed in the first phase and the other half constructed in the second phase. A temporary work area would be established for storage and stockpiling of construction materials, fabrication of structural components, and construction of other temporary facilities and equipment. The operable barrier construction site, including the temporary work area, would be located in areas that were previously disturbed by construction and operation of the temporary rock barrier. Long-term operations and maintenance activities may include regular or periodic inspections, repairs, cleaning, and sediment and debris management to ensure the effectiveness of the barrier over the design life of the facility.

Potential Environmental Effects

Construction of the physical barrier in the southern Delta may result in temporary and localized effects typically associated with construction activities, including a change in water quality, air quality effects, and ground and channel disturbance. Placement of riprap and grading along the banks for the future HOR permanent barrier could change fish habitat in the area. Dredging would temporarily decrease macroinvertebrate density in the area of the barrier, resulting in a loss of prey for fish. Cofferdam placement and dewatering could result in special-status fish species becoming stranded within the cofferdam area. A rescue and relocation of all fish species would be needed within the isolated areas. The cofferdam and the rescue and relocation could result in injury or mortality of special-status fish species. Pile driving may be needed for structure and/or cofferdam installation. Noise levels could exceed injury/mortality ranges determined by NMFS and affect special-status fish species. Aquatic resources would likely be the most affected for a temporary period of time by the construction of the new HOR permanent operable barrier. Operation of the physical barrier could increase predation on juvenile special-status fish species (i.e., Chinook salmon and steelhead), but is also expected to benefit special-status fish species by directing them toward better migratory habitat. The new operable barrier would require maintenance. Maintenance would occur when needed and would include cleaning the barrier and regular or periodic inspections. Maintenance activities would be short term and not expected to have long-term effects on fish or other aquatic organisms.

It is reasonable to assume that the permanent physical barrier would be professionally installed by contractors familiar with such projects. Construction of the permanent barrier could last up to 3 years and may be conducted in two phases. Construction activities would occur during the dry season (typically June–October) when anadromous fish or other special-status fish species such as delta smelt would not be migrating or spawning. BMPs for controlling sediment and contaminant release into waterbodies would be used and minimize potential effects associated with water quality and hazardous materials. Mitigation measures to minimize stranding and protect against pile driving generated noise would be implemented. Operation of the permanent barrier would result in changes to hydraulics and aquatic habitats by the addition of riprap around the structure. They could also cause an increase in predation of special-status fish species due to the attraction of predatory fish to structures. Overall, operation of the barrier would help guide fish into better migratory habitat and increase survival. This is expected to benefit both special-status fish species and native fish species.

Table 16-21, *Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta*, summarizes the potential environmental effects associated with improving fish passage by use of a physical barrier in the southern Delta. Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this non-flow measure and is referenced in Table 16-21 where appropriate.

Table 16-21. Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta	
Resource	Discussion
Aesthetics	• Construction and operation of a physical barrier would not be expected to significantly affect scenic vistas because it would be located at the current site of the TBP at HOR and there are no scenic vistas identified in the San Joaquin County general plan (San Joaquin County 2014a). Construction may be observable for a temporary period of time when heavy equipment is used to grade banks, move sediment, and install structures around the project site. Operation would have limited impacts on the aesthetics of the area as it would be similar to the temporary barrier that can already be viewed within the existing channel. The barrier would generally not be near residential or roadway areas so no sensitive receptors would be present if lighting was used during construction for a temporary period of time. Impacts would be less than significant.
Agriculture and Forestry Resources	• Construction and operation of physical barriers would not be expected to be located on lands used for agriculture or forestry but within the footprint of where the barrier is currently located (i.e., in Old River). Some temporary disturbance of area along the channel or behind the levee may be required for construction equipment and storage. However, there would be no permanent conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use, conflict with existing zoning for agriculture use or a Williamson Act contract, conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would be less than significant.
Air Quality	• Construction of physical barrier would likely result in emissions associated with construction equipment and construction worker vehicles, as well as fugitive dust emissions from ground disturbance. The quantity, duration, and the intensity of construction activities have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since construction of physical barriers wells does not require lengthy construction activities, (i.e., multiple years) the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the SJVAPCD regulations and established thresholds. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction of a physical barrier in the southern Delta would be inconsistent with applicable air quality plans or local general plans. A project is deemed

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta

Resource	Discussion
	inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction of a physical barrier in the southern Delta would not result in population or employment growth because this project is intended only to benefit special-status fish species through improvement of fish passage. Therefore, construction a physical barrier in the southern Delta would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • The physical barrier would operate passively and, as such, would not result in emissions. However, the barrier would require regular or periodic inspections and repairs, which would entail a limited number of maintenance personnel vehicle trips. Given the limited number of trips expected annually and the fact that they would be spread over time and be of short duration, this impact would be less than significant. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). Construction and operation of a physical barrier in the southern Delta would not create objectionable odors affecting a substantial number of people. Impacts would not occur.
Biological Resources	• Construction and operation of the physical barrier would be located in the Old River, which supports special-status fish species such as Chinook salmon and steelhead. This area is expected to have high potential for special-status plant species, animal species, and habitat, and support biological resources. It is reasonable to assume that in-water work of constructing the physical barrier would occur during the least sensitive periods of special-status species life stages, (i.e., during the dry season, June–October), because this would reduce and minimize impacts on aquatic species. As such, construction of the physical barrier would not interfere with the movement of native residential or migratory fish species and associated migratory corridors, or impede the use of nursery sites because any work done in the water would occur June–October when fish are not spawning or migrating. However, Table 16-39 lists potential mitigation measures the lead agency can and should implement to reduce potentially significant environmental effects of construction and operations on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Construction of the physical barrier would release sediment and possibly hazardous materials (e.g., oil or fuel from construction equipment) into waterbodies, affecting water quality. Release of sediment can bury macroinvertebrates which are prey for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat. Water quality measures such as monitoring turbidity to ensure compliance with Basin Plan water

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta

Resource	Discussion
	quality objectives and construction BMPs would be implemented. To ensure this, lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and installation of cofferdams can injure or kill fish by noise generated through pile driving and stranding, if special-status fish species become trapped inside a dewatered area. Pile driving can create noise impacts harmful to fish, resulting in injury or death. Fish rescue in the dewatered area (seining, electrofishing) could injure or kill fish. This would result in take and be a significant and unavoidable impact. Water quality measures such as monitoring turbidity to ensure compliance with Basin Plan water quality objectives and construction BMPs should be implemented per Table 16-39. Measures for reducing stranding and pile driving noise would also be followed. Furthermore, a monitoring plan assessing the movements of salmonids around the barriers would be enforced after the barriers are completed, which is part of permitting requirements and conditions by resource agencies (e.g., NMFS, Central Valley Water Board). Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction of the physical barrier. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even with mitigation measures, significant and unavoidable impacts may occur if the potential for take cannot be avoided or reduced or take occurs during construction. • Operation of the physical barrier would change aquatic habitat by installing riprap and changing hydraulics near the barrier. The change in hydraulic conditions would be assessed before construction to ensure velocities would not cause a change that would be detrimental to special-status fish species. The barrier itself could increase predation of juvenile salmonids by attracting predatory fish, but predation effects are unknown. Overall, the project would be expected to have beneficial long-term effects by guiding fish toward better migratory habitat. Operation of the physical barriers would keep fish from entering poor habitat and direct them toward better migratory and spawning habitat, therefore increasing survival. This impact would be less than significant. • The HOR permanent barrier would be constructed in the same area that has already been used for the temporary barriers so disturbance of riparian vegetation or wetlands is not anticipated. Additionally, this area has been continuously disturbed by installing and removing the temporary barriers. However, the lead agency can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction and operation of physical barriers. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta	
Resource	Discussion
	• While there is not specific language in either the SJMSCP or the SJR Wildlife Refuge CCP about barriers, these documents do identify that San Joaquin County would work with CDFW and other agencies to promote restoration for anadromous fish. The physical barrier is expected to produce beneficial results for migrating special-status fish species and, as such, construction and operation would not conflict with local policies protecting biological resources or conflict with provisions of an adopted habitat conservation plan or natural community conservation plans. Impacts would be less than significant.
Cultural Resources	• Construction and operation of the physical barrier would be within an area that has been regularly disturbed for the installation and removal of the temporary barrier. Because this area has been previously disturbed by the TBP installation, there is a low potential for significant cultural resources (significant historical, archaeological, or paleontological resources) and human remain presence. However, Table 16-39 lists potential mitigation measures the lead agency can and should implement to reduce potentially significant environmental effects of construction on cultural resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, its likely impacts could be mitigated to less than significant once mitigation measures were implemented given the low potential for cultural resources. • Operation of a permanent physical barrier would have a very low potential to affect cultural resources because operation would be in the same footprint as the TBP. This impact would be less than significant.
Geology and Soils	• Construction or operation of the barrier would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, loss of topsoil, or landslides. Impacts would not occur. • Given construction and operation would occur in close proximity to existing waterways and within a waterway, the proposed project site would be evaluated before construction begins for the potential of soil erosion under construction and operating conditions. Depending on soil conditions and the design and construction of the barrier, erosion could occur. The lead agency can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant erosion effects associated with construction and operation of the barrier. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The physical barrier would not bring people to the risk of earthquakes or geologic hazards, meaning the operation of the physical barriers would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur.

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta

Resource	Discussion
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-12, construction of the physical barrier would generate GHG emissions because heavy equipment would be used for a period of time over 3 years. While construction activities would be limited, it is likely that construction could result in a potentially significant GHG impact beyond the SJVAPCD's ZEL. Depending on the level of construction activities and the potential operational lifespan of the project, construction-related GHG emissions could exceed these values and result in a potentially significant impact. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • During operation of the barrier, vehicles may be needed for monitoring and maintenance. The trips are expected to be limited, of very short duration, and over a long period of time (e.g., one trip every year). As such, they would likely result in extremely small quantities of GHG emissions. However, GHG emissions may still exceed SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. • Adopt early action measures to reduce GHGs. • Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. • Adopt mandatory report rules for significant GHG sources. • Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. • Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs. • AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta

Resource	Discussion
Hazards and Hazardous Materials	• Construction and operation of the physical barrier would not be a hazard or provide a safety concern to public or public use airports or private airstrips because the structure would be constructed and operated within river banks and channels and would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, construction and operation of the physical barrier would not result in a safety hazard for people residing or working in the project area. Impacts would not occur. • Construction and operation of the physical barrier would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road within river banks and channels. Impacts would not occur. • Construction and operation of the physical barrier would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • Construction of in the physical barrier could involve the temporary use of small amounts of hazardous materials, such as fuel to power construction equipment. Given the in-water location of the barriers and the potential for a spill, this impact would be significant. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due to hazards and hazardous materials. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • There are no schools within one-quarter mile of the barrier. Therefore, there would be no hazardous materials impact on schools related to construction or operation of the HOR physical barrier. • The location at which the barrier would be constructed and operated is not a Cortese Site. Therefore, construction and operation of a physical barrier at this location would not create a significant hazard to the public or the environment. Impacts would not occur.
Hydrology and Water Quality	• Construction of the physical barrier may temporarily change water quality due to the placement of rock, dredging, and grading near and at the river's banks and channels. Turbidity resulting from construction activity on-bank and instream could cause a temporary exceedance of applicable water quality standards. Placing and anchoring the barrier structures and driving heavy equipment in and near the channel could result in a temporary increase in turbidity. Following the isolation of construction areas from surface water with cofferdams or other means, it is not expected that water quality standards will be violated. Turbidity should be monitored during construction for compliance with Basin Plan requirements, minimizing the potential impacts on water quality, per Table 16-39. Operation of the physical barriers would change the hydrology of the river and may also affect water quality (i.e., turbidity). It is likely water quality would be monitored when the HOR permanent barrier is operable. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta	
Resource	Discussion
	Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of the physical barrier would not deplete groundwater supplies or interfere substantially with groundwater recharge because this project would not require a water supply during construction or operation and would not result in a substantial increase in impervious surfaces. Impacts would not occur. • Operation of the physical barrier could alter the existing drainage pattern of the site or area but is not expected to cause an increase in substantial erosion or siltation, substantial runoff, or result in flooding on- or offsite. Site design would be modeled before installation and would take into account existing hydrology and channel geomorphology. Installation of the structure would be done so no erosion or flooding would occur. Table 16-39 lists potential mitigation measures that the lead agency can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Operation of the physical barrier would not create or contribute runoff water because the barrier would be within the river channel. Therefore, operations would not would exceed the capacity of existing or planned storm water drainage systems. Impacts would not occur. • Construction of the physical barrier is not expected to provide substantial additional sources of polluted runoff because these activities would occur primarily within the stream channel. However, construction equipment and construction vehicles would be working from the river bank and, as a result, hazardous materials (e.g., fuels, lubricants, diesel) may be used during this activity. While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it result in a significant impact. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts on water quality associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • Construction and operation of the physical barrier would not substantially increase the number of people exposed to the risk of flooding because these activities would not draw people to flood hazard locations. As such, construction and operation of the physical barrier would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur.

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta	
Resource	Discussion
	• Construction and operation of the physical barrier would not involve the construction of housing, and therefore this activity would not place housing within a 100-year flood hazard area. Impacts would not occur. • Construction and operation of the physical barrier would not impede or redirect flood flows within a 100-year flood hazard area. A physical barrier would be within the river channel and not built within the floodplain, i.e., not within the actual flood hazard area. Lead agencies would be required to comply with the requirements of USACE and the Central Valley Flood Protection Board to avoid increased flood potential. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction and operation of the physical barrier would not occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of the physical barrier could result in a substantial degradation of water quality.
Land Use and Planning	• Construction and operation of the physical barrier would not physically divide an established community because it would be located within existing river banks and channels where communities are not established. Impacts would not occur. • Operation of the physical barrier would occur in existing river banks and channels and would not conflict with land use designations or zoning. It would occur within the general area that the current temporary barrier is installed and removed. The zoning in the area is shown as water, with city limits of Lathrop on one side and general agriculture on the other side within the county limits, which provides for natural open space area. Construction laydown areas may result in a temporary disturbance to existing land uses and but would not result in a permanent change or conflict with existing land uses or zoning. Impacts would be less than significant. • No conflicts are expected with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations because the land use designation is general agriculture and associated support uses are natural open space and the barrier would support natural open spaces uses (San Joaquin County 2014b). Impacts would not occur.
Mineral Resources	• Construction and operation of the physical barrier would be constructed in an area previously used for this purpose. This area is not used to extract state or locally designated mineral resources. Therefore, construction and operation of permanent physical barrier would not affect state or locally designated mineral resources or result in the removal or inability to access state or locally designated mineral resource areas. Impacts would not occur.

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta

Resource	Discussion
Noise	• Construction of the physical barrier would create noise related to the use of construction heavy equipment. The site is located within river banks and channels where people do not live. It is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies due to the remote location of the project from populous areas. Excessive ground-borne vibration or ground-borne noise levels are also not expected, unless pile driving is needed. If pile driving is needed it is not expected to cause excessive vibrations that would disturb sensitive receptors because of the remote location of the project. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due construction noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the limited exposure of potential sensitive receptors to this potential temporary impact and low likelihood of potential sensitive receptors to exist because of the remoteness. • Operation of the physical barrier would not create noise. There would be maintenance activities required during operation, but they would not create a permanent increase in ambient noise. This impact would be less than significant. • The barrier would not be constructed near airports or airstrips so people would not be exposed to excessive noise levels. Impacts would not occur.
Population and Housing	• Construction and operation of the physical barrier would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Further, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • The construction and operation of the physical barrier would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the site is located within river banks and channels. No homes or people would be displaced. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, or other public facilities and schools) or the deterioration of existing public services typically results from an increase in population. As a location’s population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, the construction and operation of the physical barrier would not involve an increase in population or housing. In addition, these actions would not include new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.

Potential Environmental Effects of Fish Passage Improvements—Physical Barrier in the Southern Delta

Resource	Discussion
Recreation	• Construction of the physical barrier would occur within river banks and channels and block access to boaters in certain areas depending on the needs of construction, duration of construction, and timing of construction. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce effects on recreation during construction and operation of the barriers. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Construction and operation of the physical barrier would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Construction of the physical barrier could result in additional trips associated with construction workers. The location of the site is along existing levee roads away from major roadways so even with an increased number of trips, it is unlikely traffic would exceed existing level of service standards. Heavy construction equipment may damage dirt levee roads, so maintenance of the roads may be necessary during or after construction is complete. This impact would be less than significant. • Operation of the physical barrier would not generate additional trips beyond those needed to maintain the barrier. If maintenance activities are needed, it would be temporary in nature and would not increase traffic. Impacts would not occur. • Construction and operation of the physical barrier would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Construction and operation of the physical barrier would not exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of wastewater. Impacts would not occur. • Construction and operation of the physical barrier would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur. • Construction and operation of the physical barrier would not need the construction of additional storm water drains because the barrier would be built within the river and would not generate storm water. Impacts would not occur. • Construction and operation of the physical barrier would not generate an increase in solid waste because the proposed activities would not generate large quantities of solid waste. Impacts would not occur. • Construction and operation of the physical barrier would not require a water supply. Impacts would not occur.

16.3.8 Fish Passage Improvements – Removal or Modification to Human-Made Barriers to Fish Migration

Blockage of migration of anadromous fish to historical habitat by dams and other human-made barriers is recognized as a major reason for historical declines and current status of ESA-listed salmon, steelhead, and sturgeon in the Central Valley (Moyle and White 2002, Lindley et al. 2007, NMFS 2014a). In the SJR system, NMFS identified re-establishment of steelhead in historic habitat upstream of impassable mainstem dams as a Priority 1 recovery action on the Stanislaus, Tuolumne, and Merced Rivers (NMFS 2014a). Such actions present unique technological challenges that require extensive engineering, biological, and environmental studies to evaluate the feasibility of potential fish passage methods as well as the suitability and potential capacity of upstream habitat to support the life history and habitat needs of the target species. Conceptual alternatives for adult fish passage at dams include fishways, ladders, lifts and locks, and trap and haul operations (DWR 2013b). Feasibility studies of downstream passage alternatives for juveniles and post-spawning adults (steelhead) at large dams and reservoirs typically focus on methods for capturing downstream migrants above the reservoirs and transporting these fish to release sites below the dam.

Implementation of fish passage or re-introduction programs that restore passage of anadromous salmonids to reaches above impassable dams on the SJR tributaries would not likely occur within an effective timeframe to contribute to the State Water Board's implementation program or other non-flow measures that may be implemented in the foreseeable future to improve anadromous fish production in the currently accessible reaches below the dams (e.g., floodplain and riparian habitat restoration). Therefore, the following evaluation addresses only the pre-project planning and evaluation actions that would be required to support implementation of such a program in the future.

Cost Evaluation

The primary goal of a feasibility study is to demonstrate the project is economically viable if it is designed, constructed, and operated in accordance with the concepts set forth in the study. The cost of a feasibility study can be expected in the range of 1.5–4 percent of the project costs (Mackenzie and Cusworth 2007).

Environmental Evaluation

The primary source of information for the following summary of fish passage planning and evaluation actions was DWR (2007, 2013b).

Summary of Potential Action

Fish passage or re-introduction programs typically include pre-project engineering feasibility studies, fish passage and barrier assessments, hydrologic and water quality monitoring, habitat surveys and suitability assessments, environmental and economic analyses, and evaluations of the potential effectiveness of the program (measured in terms of achieving the biological goals of the program) based on the quantity and quality of potential habitat above the dams and other factors that could limit the success of the program. Based on these studies, an experimental or pilot re-introduction program may be recommended prior to implementation of any long-term re-introduction program.

Potential Environmental Effects

Pre-project planning, evaluation actions, and habitat assessments that would be required to support implementation of fish passage or re-introduction programs that restore passage of anadromous salmonids to reaches above impassable dams are not likely to result in any significant effects on special-status species or other resources (e.g., aesthetics, transportation, air quality). CEQA allows categorical exemptions for classes of projects which have been determined not to have a significant effect on the environment (Pub. Res. Code, § 21084). Specifically, information collection is exempt from CEQA review under a Class 6 categorical exemption. The Class 6 categorical exemption consists of basic data collection, research, experimental management, and resource evaluation activities which do not result in a major disturbance to an environmental resource. These may be strictly for information gathering purposes or as part of a study leading to an action which a public agency has not yet approved, adopted, or funded. (Pub. Res. Code, § 21084.) In addition, a Class 7 categorical exemption consists of actions taken by regulatory agencies to assume the maintenance, restoration, or enhancement of natural resources where the regulatory process involves procedures for protection of the environment. (Pub. Res. Code, § 21084.) Examples include, but are not limited to, wildlife preservation activities by CDFW. Construction activities are not included in a Class 7 categorical exemption and the types of evaluation and feasibility studies would not require construction. As such, many of the field studies involving fish passage and barrier assessments and hydrologic and water quality monitoring may be exempt under Class 6 or Class 7 categorical exemptions.

Access to river banks and channels is necessary for implementing the studies but would not result in effects on special-status species or their habitats because a crew of several people could do the surveys and the work would only cause a small disturbance for a limited period of time (e.g., several days to several weeks). Several persons would use one to two vehicles to access monitoring sites. Emissions from the vehicles would not conflict with an applicable air quality plan or violate air quality standards because there would be very few vehicles traveling during short periods of time. Water quality could be affected if activities included in-water work. However, it would be short term and only one or two persons would be in the river channel. The assessments would not alter the existing drainage pattern of the site or area or alter the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or offsite. There would be no impacts on traffic because the activities would require less than 10 people and vehicles. Other resources such as aesthetics, agriculture, and others would not be affected by field studies because the field studies would not alter or substantively change these types of resources when compared to existing conditions. It is reasonable to assume that field studies would be implemented or supervised by professional biologists who are familiar with such studies and projects. The biologists would recognize special-status aquatic and terrestrial species and avoid them if encountered during the field studies. These studies would provide the data to assess the possibility of introducing anadromous salmonids above impassable dams. As such, impacts on biological resources would be less than significant. The other studies such as pre-project engineering feasibility studies and suitability assessments, environmental and economic analyses, and evaluations of the potential effectiveness of the program (measured in terms of achieving the biological goals of the program), would be desk-top studies and based on data collected in the field.

16.3.9 Predatory Fish Control

The primary purpose of predatory fish control is to increase the survival of migrating salmonids and other native fishes through localized reductions of targeted predatory fishes and/or elimination or modification of habitat for predatory fishes at locations of high predation risk (*hotspots*). Predation by non-native striped bass, largemouth bass, and other warm-water species is identified as a major stressor for juvenile salmonids in the three eastside tributaries and mainstem LSJR (NMFS 2014a, McBain and Trush 2002, Brown 2000, FishBio 2013). Sites within the Delta that are currently considered hotspots of predator aggregation or activity, and which may contribute to high mortality rates of migrating smolts, include HOR, Old and Middle Rivers, Clifton Court Forebay, CVP intakes, and Georgiana Slough (Gingras 1997, Clark et al. 2009, Castillo et al. 2012, Bowen et al. 2009, Bowen and Bark 2010). Predation by non-native fishes has been identified as a likely contributor to low survival of Chinook salmon smolts in the interior Delta (Perry et al. 2010). In addition, considerable variability in smolt survival and an apparent shift in the relationship between smolt survival and flow in the southern Delta since 1997 (SJRGA 2009) suggests changes in biological factors such as predation (Hankin et al. 2010). However, a literature review of predation effects in the Delta by Grossman et al 2013, indicates that, "Although it is assumed that much of the short-term (<30 d) mortality experienced by these fish is likely due to predation, there are few data establishing this relationship. Juvenile salmon are clearly consumed by fish predators and several studies indicate that the population of predators is large enough to effectively consume all juvenile salmon production. However, given extensive flow modification, altered habitat conditions, native and non-native fish and avian predators, temperature and limitations, and overall reduction in historical salmon population size, it is not clear what proportion of juvenile mortality can be directly attributed to fish predation."

Acceptable strategies for predatory fish control include direct removal methods and habitat modifications to reduce predator habitat. Direct removal methods include electrofishing, hook-and-line fishing, passive trapping (e.g., fyke nets, hoop nets, gillnets), and active capture methods (e.g., trawls, beach seines). Habitat modifications that may reduce local aggregations of predators or their feeding efficiency include the removal or modification of abandoned structures (e.g., dams, bridge piers, docks), water diversion facilities (e.g., water intakes, forebays), scour holes, and invasive aquatic vegetation. Varying the location and/or timing of releases or routing of fish that are salvaged or bypassed at water intake or pumping facilities may also reduce predation losses associated with fixed release sites.

Cost Evaluation

As discussed above, predatory fish control can be accomplished through direct removal, or the elimination/modification of habitat conducive to predators. Using the method of direct removal of predators is generally less expensive than the elimination/modification of habitat as described below.

No long-term predator removal programs are in effect in the Delta; however, such programs have been implemented in rivers located in the western United States. For example, the Upper Colorado Endangered Fish Recovery Program (Recovery Program), established in 1988, is a partnership of local, state, and federal agencies, water and power interests, and environmental groups working to recover endangered fish in the Upper Colorado River Basin (Upper Colorado River Endangered Fish Recovery Program 2016). The Recovery Program implements long-term non-native fish management by removing the most problematic non-native fish predators from rivers. Among the non-native fish management projects funded within the Recovery Program are the middle Yampa River northern pike and smallmouth bass removal and evaluation project and the removal of smallmouth bass in the Upper Colorado River between Price-Stubb Dam near Palisade, Colorado, and Westwater, Utah project (Upper Colorado River Endangered Fish Recovery Program 2016). The total annual cost of each project from 2010 to 2015 was between $157,000 and $214,000[16] (Upper Colorado River Endangered Fish Recovery Program 2010a, 2011a, 2012a, 2013a, 2014a, and 2015a; Upper Colorado River Endangered Fish Recovery Program 2010b, 2011b, 2012b, 2013b, 2014b, and 2015b).

The costs of the habitat modification projects discussed above, designed to reduce predator habitat in the Delta and upstream tributaries, have been estimated as part of several recovery programs including: the Golden Gate Salmon Association Salmon Rebuilding Plan, the NMFS Final Recovery Plan (Recovery Plan)[17] (NMFS 2014a), the Habitat Restoration Plan for the Lower Tuolumne River Corridor (USFWS 2000), and the San Francisco Estuary Project 2007 Comprehensive Conservation and Management Plan (SFEP 2007). The various projects are site specific, and are dependent on the extent of the modifications needed and can vary in cost from $100,000–$300,000 per site for reducing predator habitat at large screen structures, to over $4.6 million for filling a gravel pit to reduce/eliminate habitat favored by predatory bass species, and replacing with high quality Chinook salmon habitat (McBain and Trush 2000, SFEP 2007, GGSA 2013, NMFS 2014a). On a broader scale, the Recovery Plan estimated implementing projects to minimize predation at weirs, diversions, and related structures in the Delta at $50 million over a period of 50 years[18] (NMFS 2014a).

Environmental Evaluation

Summary of Potential Action

Acceptable predator reduction methods likely would be limited to active and passive capture methods such as electrofishing, hook-and-line fishing, nets, and traps. These methods are preferred because they have no water quality impacts, minimal effects on non-target organisms, a higher degree of feasibility in open channel environments compared to other fish population control measures (e.g., chemical treatment, dewatering), and a lower level of risk of unintended ecological consequences. Limitations include high levels of effort and funding to achieve meaningful or measurable benefits, and significant uncertainty associated with the complexities of predator–prey interactions (e.g., compensatory responses by other piscivores) (Ward and Zimmerman 1999, Finlayson et al. 2010, Cavallo et al. 2012, also see Hubbs 1940 and other cited literature). Recreational reward fisheries using hook-and-line methods may be a relatively cost-effective means of reducing local predator densities and improving survival of migrating salmonids by concentrating intensive angling pressure on targeted predatory fish species at key location and times (Rieman and Beamsderfer 1990, Ward and Zimmerman 1999).

---

[16] These costs are described in the Colorado River Recovery Program Annual Reports for 2010–2015.

[17] The National Marine Fisheries Service Final Recovery Plan targets the evolutionarily significant units of Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, and the distinct population segment of California Central Valley steelhead.

[18] This action originated from the Bay Delta Conservation Plan Administrative Draft (DWR 2013a), available: http://baydeltaconservationplan.com/Library/DocumentsLandingPage/BDCPDocuments.

Structural modifications aimed at reducing predator hotspots such as the removal or modification of human-made structures (e.g., removal of old pier pilings) and other forms of predator habitat (e.g., invasive aquatic vegetation) could result in effects on native fish and wildlife species, vegetation, soils, streambed substrates, and water quality. Structural modifications for predatory fish control do not include fish screen modifications which are discussed above in Section 16.3.6, *Fish Passage Improvements – Fish Screens*. The severity and magnitude of the impacts would vary depending on the timing, extent, and duration of these modifications; site conditions (e.g., presence of other sensitive resources); and the biological responses of individuals and populations to short- and long-term habitat changes. Potential construction activities include clearing of vegetation to construct temporary roads and staging areas; placement of temporary barriers or other structures to isolate active construction areas (e.g., cofferdams); and mechanical demolition, excavation, and extraction methods. Construction equipment may include excavators, hydraulic hammers, pile extractors, and cranes. Depending on the size of the structure to be removed or modified, construction could take between 6 months and 2 years. Common environmental commitments or BMPs to avoid, minimize, or offset potential construction-related effects may include seasonal work windows, preconstruction biological surveys; biological monitoring during construction; construction noise and light reduction measures; traffic control; SWPPP; spill prevention, control, and countermeasure plan; and turbidity compliance monitoring.

While there have been many studies determining the rate of predation on salmonids in the Central Valley and Delta (Clark et al. 2009, Garcia 1989, Gingras 1997, Holbrook et al 2009, Grossman et al 2013) the efficacy of predator control measures as an aid to rebuilding threatened and endangered salmonid populations and other native fish species remains unclear (Propst et al 2014, Grossman et al 2013). Recommended approaches to addressing these uncertainties and increasing the likelihood of desired outcomes include an experimental pilot program and an evaluation and refinement of the proposed measures.

Potential Environmental Effects

Active and passive capture methods are not expected to have significant impacts on aquatic or terrestrial sensitive-species habitat because the activities (hook-and-line fishing, nets, traps) would not modify habitat. However, if special-status fish species were caught with the active or passive capture methods, that could result in injury or mortality (i.e., *take*). Active and passive capture methods would harm individual non-native, predatory fish, because the purpose of the active and capture methods is to remove the predator fish once they are captured. Timing of the active or passive predatory control would vary depending on the species targeted and the design of the removal. It is reasonable to assume that active and passive capture methods would be done or supervised by professional fisheries biologists familiar with predatory fish and special-status species presence/absence in areas that would be fished.

CEQA allows categorical exemptions for classes of projects which have been determined not to have a significant effect on the environment. (Pub. Res. Code, § 21084.) Specifically, modification or demolition of existing structures can be exempt under a Class 1 categorical exemption. The Class 1 categorical exemption consists of the minor alteration of existing public or private structures, facilities, topographical features, involving negligible or no expansion of use beyond that existing at the time of the lead agency's determination. The types of "existing facilities" listed in the exemption are not intended to be all-inclusive of the types of projects which might fall within a Class 1 categorical exemption. The key to the consideration of this class of categorical exemptions is whether the project involves negligible or no expansion of an existing use. As structural modifications or removals for predatory control (e.g., removal of old pier pilings) would not expand an existing use, this type of predatory control may be eligible for a Class 1 categorical exemption depending on the project-specific circumstances. Structural modifications/removals of human-made structures could result in temporary and localized effects typically associated with construction activities, including water quality impacts and ground and channel disturbance. Depending on the size of the structure to be removed, placement of temporary barriers or other structures (e.g., cofferdams) may be required. This placement and dewatering could result in special-status fish species becoming stranded within the cofferdam area. A rescue and relocation of all fish species would be needed within the isolated areas if these types of construction activities are needed to remove structures. This could result in injury or mortality of special-status fish species. River banks or channels may need to be graded after removal of human-made structures in areas that support special-status fish species such as Chinook salmon and steelhead. Aquatic resources would be the most affected by structural modifications/removals. There would be no operation and maintenance activities for predatory fish control. For the structural modifications/removals, activities would be professionally done by contractors familiar with such projects. BMPs for controlling sediment and contaminant release into waterbodies would be used and minimize potential effects on water quality associated with sediment and hazardous materials. Mitigation measures to minimize stranding would be implemented.

Table 16-22, *Potential Environmental Effects of Predatory Fish Control*, summarizes the potential environmental effects associated with predatory fish control. Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of this non-flow measure and is referenced in Table 16-22 where appropriate.

Table 16-22. Potential Environmental Effects of Predatory Fish Control

Potential Environmental Effects of Predatory Fish Control	
Resource	Discussion
Aesthetics	• Passive and active capture methods would not significantly affect scenic vistas because construction would not be required and because activities would be limited to people in the rivers passively or actively removing fish. This would not result in a permanent or even temporary alteration of river views. Impacts would not occur. • Removal or modification of human-made structures would be located within existing river channels and may alter views if the structure is located within a scenic vista or view. For modification/removal of a structure, construction may be observable for a temporary period of time when heavy equipment is used to grade banks, move sediment, and remove structures around the project site. This impact would be less than significant. • Lighting is not expected to be used during passive and active capture methods or removal of human-made structures—all activities would occur during the day. Impacts would not occur.
Agriculture and Forestry Resources	• Predatory fish control, both passive and active control and removal of structures, would not be expected to be located on lands used for agriculture or forestry but within existing river channels or immediately adjacent to them. There would be no conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use, conflict with existing zoning for agriculture use or a Williamson Act contract, conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Predatory fish control would likely result in emissions associated with the removal or modification of human-made structures which would involve construction equipment and construction worker truck trips, as well as fugitive dust emissions from ground disturbance. The quantity, duration, and the intensity of construction activities have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since removal of the structures would not require lengthy construction activities, the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the SJVAPCD regulations and established thresholds. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects on air quality associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean implementation of predatory fish control projects would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth

Potential Environmental Effects of Predatory Fish Control

Resource	Discussion
	estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The implementation of predatory fish control projects would not result in population or employment growth because these projects are for the benefit of special-status fish species through improvement of fish passage. Therefore, predatory fish control projects would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • Passive or active predator fish control or the removal of in-water structures, would likely result in monitoring vehicle trips on a periodic schedule. Given the limited number of vehicles over a longer timeframe, emissions from the vehicles would not prevent compliance with regulations or exceed thresholds established by SJVAPCD, conflict with or obstruct implementation of the applicable air quality plan, violate any air quality standard, contribute substantially to an existing or projected air quality violation, result in a net increase of any criteria pollutant for which the project region is nonattainment under an applicable federal or state ambient air quality standards, or create objectionable odors. Impacts would not occur.
Biological Resources	• Removal or modification of human-made structures would be located in river reaches that support special-status fish species such as Chinook salmon and steelhead. These areas are expected to have high potential for special-status plant species, animal species, and habitat, and support biological resources. It is reasonable to assume that removal or modification of human-made structures would occur during the least sensitive periods of special-status species life stages, (i.e., during the dry season, June–October), because this would reduce and minimize impacts on aquatic species. However, passive and active capture techniques could occur during any time of the year and this could result in interference with movement of native residential or migratory fish species and associated migratory corridors. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce potentially significant environmental effects of removal or modification of human-made structures and passive and active capture techniques on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Removal or modification of human-made structures would release sediment and possibly hazardous materials (e.g., oil or fuel from construction equipment) into waterbodies, potentially affecting water quality. Release of sediment can bury macroinvertebrates which are prey for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat. Water quality measures such as monitoring turbidity to ensure compliance with Basin Plan water quality objectives and construction BMPs would be implemented. To ensure this, lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with construction of fish screens. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section

Potential Environmental Effects of Predatory Fish Control

Resource	Discussion
	15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Depending on the type of structure and location of structure to be removed or modified, removal or modification of human-made structures could require installation of cofferdams. Cofferdams can injure or kill fish by noise generated through pile driving and stranding, if special-status fish species become trapped inside a dewatered area. Fish rescue in the dewatered area (e.g., seining, electrofishing) could injure or kill fish. Passive and active capture methods could capture special-status fish species if they are present in the targeted sampling area. These methods could injure or cause mortality of fish. As such, construction of cofferdams, and passive and active capture methods could result in take of special-status fish species. Removal of predatory fish is targeted toward removing non-native fish (e.g., striped bass, largemouth bass, smallmouth bass). If non-native predatory fish are captured, they would be removed and killed. It is anticipated that the removal may have localized effects, but would not overall reduce the population of the non-native fish given their general prevalence and resilience (Cavallo et al. 2012). Given the need for evaluation and refinement of predatory control programs, a monitoring program would be implemented to determine if survival is increased by the removal of predatory fish and to determine the effectiveness of the programs (Ward and Zimmerman 1999, Finlayson et al. 2010, Cavallo et al. 2012). Overall, the project may have temporary significant impacts during the removal or modification of human-made structures, but beneficial long-term effects by allowing fish to access more and better habitat and decreasing predation. Removal or modification of structures are not expected to have a substantial adverse effect, either directly or through habitat modifications, on special-status species. Measures for reducing stranding and pile driving noise would also be followed. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with removal or modification of human-made structures and passive and active capture methods. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. Even with mitigation measures, significant and unavoidable impacts may occur if the potential for take cannot be avoided or reduced or take occurs during construction. • Passive capture methods would not result in disturbance or removal of riparian vegetation or wetlands as these methods would be implemented within existing river channels and would not temporarily or permanently remove habitat. No impact would occur.

Potential Environmental Effects of Predatory Fish Control	
Resource	Discussion
	• Removal or modification of human-made structures could affect riparian vegetation and/or wetlands. This is because the surrounding habitat on river banks may include riparian vegetation and/or wetlands. Riparian vegetation may have to be removed to facilitate heavy equipment movement and wetlands may also have to be disturbed during removal activities. This would result in a temporary significant impacts on riparian habitat and wetlands. Under operations, riparian habitat and wetlands would not be affected. Removal and/or disturbance of riparian and wetlands habitats would be compensated for at a ratio appropriate for the disturbance per standard permit requirements or conditions from the U.S. Army Corps of Engineers and the Central Valley Water Board. This compensation would reduce and minimize impacts on fish and wildlife species and their habitats. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with installation, removal, or modification of human-made structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The SJR NWR Comprehensive Conservation Plan includes activities that would benefit steelhead and Chinook salmon. It is unknown how effective the removal or modification of human-made structures are in reducing predatory fish and the potential benefits to special-status species. Overall, installation, removal, or modification of human-made structures to benefit special-status fish species would not conflict with local policies protecting biological resources or conflict with provisions of an adopted habitat conservation plan or natural community conservation plan. This would be a less-than-significant impact.
Cultural Resources	• Passive and active capture methods would not affect cultural resources (significant historical, archaeological, or paleontological resources) or human remains because they would not involve ground-disturbing activities or other construction activities that may disturb unknown cultural resources or human remains. Impacts would not occur. • Removal or modification of human-made structures would be within existing banks and channels or immediately adjacent. Typically river banks and channels have experienced a high level of disturbance as a result of hydrologic events and man-made alterations, resulting in a generally low likelihood of intact cultural resources or human remains. However, it is unknown if cultural resources or human remains exist in these locations, and river banks could be excavated for removal or modification of structures that contain unknown cultural resources or human remains. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on historic cultural resources during the removal or modification of existing structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • There would be no operational changes for either the removal or modification of the structures or passive and active capture methods and no ground-disturbing activity so there would be no impacts on cultural resources or human remains from operations. Impacts would not occur.

Potential Environmental Effects of Predatory Fish Control

Resource	Discussion
Geology and Soils	• Removal or modification of human-made structures and passive and active capture methods would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. Impacts would not occur. • The removal or modification of human-made structures and passive and active capture methods would not bring people to the risk of earthquakes or geologic hazards, and there would be no operational changes for the removal or modification of human-made structures and passive and active capture methods so they would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because the activities would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur.
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-12, removal or modification of human-made structures would result in increased GHG emissions because heavy construction equipment would be used. While construction activities would be limited, between 6 months and up to 2 years, it is likely that removal of structures could result in a potentially significant GHG impact beyond the SJVAPCD's ZEL. Depending on the level of construction activities and the potential operational lifespan of the project, construction-related GHG emissions could exceed these values and result in a potentially significant impact. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Passive and active control methods would not result in GHG emissions because there would be a very limited number of vehicles used to transport personnel to remove the predatory fish and the actions of removing the predatory fish do not produce GHGs. Some vehicles may also be needed for monitoring areas. However, the trips would be limited, of very short duration, and occur over a long period of time (e.g., one trip every year). As such, they would likely result in extremely small quantities of GHG emissions. However, GHG emissions may still exceed SJVAPCD's ZEL. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions.

Potential Environmental Effects of Predatory Fish Control

Resource	Discussion
	○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Passive and active capture methods would not be a hazard or provide a safety concern to public and public use airports or private airstrips because the structures would be removed or modified within river banks and channels and would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, passive and active capture methods would not result in a safety hazard for people residing or working in the project area. Impacts would not occur. • Removal or modification of human-made structures may release hazardous materials if the structures themselves contain hazardous materials (i.e., creosote pilings). It would be expected that any suspected structures would be tested prior to removal and disposed of in a proper facility. Additionally, fuel would be used in heavy equipment. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts associated with releasing hazardous materials by removing or modifying existing structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The precise location of where existing in-stream structures would be removed or modified is not yet known; however, these projects could be constructed within one-quarter mile (0.25 miles) of a school. Hazardous materials (e.g., fuels, lubricants, diesel) may be used during construction (i.e., grading near river banks and channels). While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction.

Potential Environmental Effects of Predatory Fish Control

Resource	Discussion
	• Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962. These sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the DTSC for Calaveras, Tuolumne, or Mariposa Counties (CalEPA 2016). There were a total of 17 sites identified for Merced, San Joaquin, and Stanislaus Counties. In addition to these sites identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 500 leaking underground storage tanks designated as open in these counties (CalEPA 2016). There are approximately 55 facilities in these counties that have received CDOs/CAOs not identified as non-hazardous wastes, domestic wastewater, or domestic sewage (CalEPA 2016). It is not yet known precisely where removal of or modification to structures would occur and removal or modification would require excavation. However, if it occurred on a Cortese Site and required excavation there would be potential for release of existing soil or groundwater contaminants because of the ground disturbance. Were this to occur, impacts could be significant. Table 16-39 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • Removal or modification of human-made structures and passive and active capture methods would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road within river banks and channels. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • Removal or modification of human-made structures could require excavation. Utilities may be underneath the sites or adjacent to a site and may need to be relocated or avoided. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potential hazards associated with excavation around utilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented.

Potential Environmental Effects of Predatory Fish Control	
Resource	Discussion
Hydrology and Water Quality	• Removal or modification of human-made structures may temporarily affect water quality as a result of increased turbidity due to the removal of in-water structures and any grading near the banks and channels. Driving heavy equipment in and near the channel could result in temporary turbidity. Turbidity resulting from these activities could cause a temporary exceedance of applicable water quality standards. Due to the removal or modification activities limited to the dry season and isolation of the areas from surface water with cofferdams or some other means, significant impacts on water quality are not anticipated. Turbidity should be monitored during construction to ensure compliance with Basin Plan water quality objectives and construction BMPs would be implemented to minimize potential impacts on water quality. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Active capture methods could disturb substrate and potentially affect water quality depending on the method used. Active capture methods require people to enter the water and set up nets and then retrieve the nets. These methods can result in a slight disturbance of the substrate; however given the limited number of people that would be in the water and the limited ability of people to disturb substantial amounts of substrate impacts on water quality would be less than significant. • Removal or modification of human-made structures and passive and active capture methods would not deplete groundwater supplies or interfere substantially with groundwater recharge because these projects would not require groundwater and would not result in an increase in impervious surfaces. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not alter the existing drainage pattern of the site or area and are not expected to cause an increase in substantial erosion or siltation or result in flooding on- or offsite. This would be a less-than-significant impact. • Removal or modification of human-made structures and passive and active capture methods would not substantially increase the number of people exposed to the risk of flooding because these activities would not draw people to flood hazard locations. As such, predatory fish control would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not involve the construction of housing, and, therefore this activity would not place housing within a 100-year flood hazard area. Removal or modification of human-made structures and passive and active capture methods would not impede or redirect flood flows within a 100-year flood hazard area. Impacts would not occur. • Passive and active capture methods would not create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff because these activities would occur primarily within the stream channel. Impacts would not occur.

Potential Environmental Effects of Predatory Fish Control	
Resource	Discussion
	• Removal or modification of human-made structures would not create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff because these activities would occur primarily within the stream channel. However, some grading near the banks and channels may be required and, as a result, hazardous materials (e.g., fuels, lubricants, diesel) may be used during this activity. While it is expected that these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it result in a significant impact. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts on water quality associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Removal or modification of human-made structures is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which predatory fish control projects could result in a substantial degradation of water quality.
Land Use and Planning	• Removal or modification of human-made structures and passive and active capture methods would not physically divide an established community because they would be located within existing river banks and channels, where communities are not established. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would occur in existing banks and channels and would not conflict with land use designations or zoning. Frequently these areas are designated natural resource or open space areas by land use plans and the removal or modification of human-made structures would be consistent with those designations because it would enhance existing habitat for fish and wildlife species. Impacts would not occur. • As discussed in the Biological Resources section of this table, no conflicts or changes with land use are expected due to the removal or modification of human-made structures or passive and active capture methods with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations. This impact would be less than significant.

Potential Environmental Effects of Predatory Fish Control	
Resource	Discussion
Mineral Resources	• Passive and active control methods would not result in a loss or lack of access to a state or locally designated mineral resource because river channels would not be disturbed. Impacts would not occur. • Removal or modification of human-made structures would not have the potential to result in the removal or inability to access state or locally designated mineral resource areas. This is because the structures that would be removed or modified already exist and are either currently preventing access to a state or locally designated mineral resource or are not in the area of mineral resources. If these structures were removed, there may be the potential to access state or locally designated mineral resources when compared to current conditions. Impacts would not occur.
Noise	• Passive and active capture methods would not generate noise. Additionally, sensitive receptors would likely not be present in the area (i.e., in the middle of a river). Impacts would not occur. • Removal or modification of human-made structures would create noise related to the use of heavy construction equipment. The sites would be located within river banks and channels where people do not live. It is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies due to the small nature of the projects and the remote location of the project from populous areas. Excessive ground-borne vibration or ground-borne noise levels are also not expected unless pile driving is needed if a cofferdam needs to be put in place. If pile driving is needed it is not expected to cause excessive vibrations that would disturb sensitive receptors. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due construction noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the limited exposure of potential sensitive receptors to this potential temporary increase in noise and low likelihood of potential sensitive receptors to exist because of the remoteness. • Removal or modification of human-made structures and passive and active capture methods would not be done near airports or airstrips so people would not be exposed to excessive noise levels. Impacts would not occur.
Population and Housing	• Removal or modification of human-made structures and passive and active capture methods would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Furthermore, they would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the sites would be located within banks and channels. No homes or people would be displaced. Impacts would not occur.

Potential Environmental Effects of Predatory Fish Control

Resource	Discussion
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, removal or modification of human-made structures and passive and active capture methods would not involve an increase in population or housing. In addition, these actions would not include new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.
Recreation	• Removal or modification of human-made structures and passive and active capture methods would occur within river banks and channels. It is possible that recreational facilities would be located in areas where the human-made structures and passive and active capture methods would be located. If recreational facilities were located within very close proximity, removal or modification of human-made structures may affect them; however, it is unlikely that there would be significant effects on recreational facilities because removal or modification of structures and passive and active capture methods would be limited in scope and duration. This would be a less-than-significant impact. • Removal or modification of human-made structures and passive and active capture methods would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur. • Removal or modification of human-made structures and passive or active capture methods would likely target recreational and sport fish species, including striped bass. While it is unknown the number of fish that might be removed through predatory control, the removal of these species from the rivers could result in a reduction in recreational and sport fishing opportunities for fishermen. However, a few selected areas (i.e., below dams, areas where juvenile hatchery fish are released) would be targeted for predatory removal and they could easily move back into the area (Cavallo et al. 2012). It is highly unlikely to affect sport fish on a population level. This would be a less-than-significant impact.

Potential Environmental Effects of Predatory Fish Control	
Resource	Discussion
Transportation and Traffic	• Removal or modification of human-made structures could result in additional vehicle trips associated with construction workers. Depending on the location of the site, there could be an increase in traffic from construction workers. The temporary increased traffic during removal or modification would likely not exceed local or regional road trip thresholds, because the typical number of construction workers that would be involved in this activity is less than 30. Passive and active capture methods would require only a few people to perform the surveys so an increase in traffic is not expected. This impact would be less than significant. • There are no operational activities associated with either the removal or modification of human-made structures or passive and active capture methods so no additional trips would be generated. Impacts would not occur. • Removal or medication of human-made structures and passive or active capture methods would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Removal or modification of human-made structures and passive and active capture methods would not exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of wastewater. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not require the construction of additional storm water drains because the activities would occur within river channels and would not generate storm water. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not generate an increase in solid waste because they would limit modification to the river banks and channels and those activities do not generate large quantities of solid waste. Impacts would not occur. • Removal or modification of human-made structures and passive and active capture methods would not require a water supply. Impacts would not occur.

16.3.10 Invasive Aquatic Vegetation Control

Invasive aquatic vegetation control measures include actions to prevent the introduction and control the spread of invasive aquatic species. Invasive aquatic vegetation represents a major threat to native fish species because of its large-scale ecosystem effects on aquatic habitat and biological communities in the Delta and estuary (Toft et al. 2003, Baskerville-Bridges et al. 2004, Nobriga et al. 2005, Nobriga and Feyrer 2007, Anderson 2008, Santos et al. 2009, Hestir 2010, Huenemann et al. 2012). Current methods for control of Brazilian waterweed (*Egeria densa*), water hyacinth (*Eichhornia crassipes*), and other invasive plant species include small-scale and large-scale applications of herbicides and mechanical removal depending on the target species, site conditions, and objectives (DBW 2006, 2008). The primary goal of these programs is control rather than eradication because of the widespread distribution of these species. Relevant ongoing research includes investigations of potential biological control methods, and restoration design studies that provide useful insights into the natural properties of riverine and estuarine environments (e.g., flow velocity, salinity) that can be manipulated to reduce invasion risk (Hestir 2010).

Cost Evaluation

The California Department of Boating and Waterways (DBW) implements an Aquatic Weed Control Program, which includes a water hyacinth control program (WHCP). Established in 1982, the California state legislature designated DBW as the lead state agency to cooperate with other state, local, and federal agencies in controlling water hyacinth in the Delta, its tributaries, and Suisun Marsh (DBW 2016a). The WHCP uses chemical and physical control (mechanical and hand removal) as control methods for water hyacinth (DBW 2016b). The DBW also operates an *Egeria densa* control program (EDCP) that uses chemical control (DBW 2016b). The EDCP was authorized by law in 1997, and treatment began in 2001 (DBW 2016a). The total annual cost of DBW's Aquatic Weed Control Program (both the WHCP and EDCP) for the years of 2001 through 2007 was between $6.2 and $7.9 million dollars (DBW 2006, CDFW 2008). These programs are actively implemented today; however, cost information is only readily available through 2007.

Environmental Evaluation

The primary sources of information for the following general description of invasive aquatic vegetation control projects and associated environmental impacts were USDA and DBW (2012a, 2012b). Additional references are cited below.

Summary of Potential Action

General methods and techniques of invasive aquatic vegetation control programs include early detection and response; application of chemical, mechanical, or biological control methods; monitoring of treatment efficacy; and research and development of new control methods.

Chemical control (herbicide applications) is the most feasible and effective control method because herbicides can be used to rapidly control invasive aquatic plants over large areas (hundreds or thousands of acres). However, a major concern is the potential for toxic effects on other aquatic plants and animals and on riparian plants adjacent to treated waterbodies. All herbicides currently in use by DBW have been approved for aquatic use and are subject to permit restrictions on timing, application methods, and concentrations to avoid or minimize potential adverse effects on water quality and federally listed fish and wildlife species. An initial EIR was written and distributed in 2001 and an addendum was written in 2003 to incorporate the use of the aquatic herbicide Sonar Precision Release. The 2001 EIR proposed a 5-year program and one of the requirements of the EIR was to submit supplemental environmental documentation in 2006 to support continued operations. The second addendum written in 2006 discussed the environmental monitoring results. Currently, annual reports for *Egeria densa* and water hyacinth are submitted detailing the monitoring results of aquatic vegetation control. Permits from NMFS, USFWS, and the Central Valley Water Board are required every 5 years. Biological opinions from USFWS and NMFS are required under the federal Endangered Species Act (ESA) before herbicide application as well as a National Pollutant Discharge Elimination System (NPDES) permit from the Central Valley Water Board. These permits also require extensive water quality monitoring and toxicity research.

Physical control, which can be successful at relatively small scales, involves the removal of invasive aquatic vegetation by hand or machine and disposal on land. Machine removal requires a mechanical harvester that cuts and collects aquatic plants. Cut plants are removed from the water by a conveyor belt system and stored on the harvester until ready for disposal. Removal and disposal of large amounts of aquatic vegetation can become prohibitive because of transportation costs and land requirements for disposal.

Biological control methods involve the release of organisms (typically invertebrates or pathogens that target invasive aquatic vegetation) into the environment with the goal of establishing sufficient numbers to reduce or limit the growth of the target species. Laboratory and limited field evaluations are underway to determine the efficacy of these organisms and the potential risk they pose to non-target species.

Implementation plans for invasive aquatic vegetation control programs will likely require compliance and effectiveness monitoring, research actions, and adaptive management.

Potential Environmental Effects

Invasive aquatic vegetation control programs could include early detection and response; application of chemical, mechanical, or biological control methods; monitoring of treatment efficacy; and research and development of new control methods. Application of chemical, mechanical, or biological control methods would result in effects on special-status fish species and existing aquatic habitat. Application of chemical controls would result in an effect on water quality and aquatic species if applied during the wrong time of year or concentrations are too high. Mechanical removal of aquatic vegetation would result in temporary and localized water quality effects including a change in water quality and ground and channel disturbance. Mechanical removal of certain species (e.g., *Egeria densa*) can also worsen infestations through dispersal and colonization by plant fragments. Small fish, invertebrates, amphibians, and turtles can be entrained and injured or killed. Also if the harvester is not properly disinfected, new exotic species could be introduced (Washington State Department of Ecology n.d.). Biological control methods, early detection and response to invasive aquatic species, and monitoring of treatment efficacy are not expected to affect special-status species because these methods would not involve herbicides, mechanical harvesters, or disturbance to waterbodies. Aquatic resources would be the most affected by invasive aquatic vegetation control programs because they are applied in the aquatic environment. Attempts to control aquatic invasive vegetation also can have a significant impact on the health and well-being of salmonids within the affected water systems. For example, the control programs for the invasive water hyacinth and Brazilian waterweed plants in the Delta must balance the toxicity of the herbicides applied to control the plants to the probability of exposure to listed salmonids during herbicide application. In addition, the control of the nuisance plants have certain physical parameters that must be accounted for in the treatment protocols, particularly the decrease in DO resulting from the decomposing vegetation left by plants that have died from the chosen control method (NMFS 2014a). After implementation of the invasive aquatic vegetation control programs, compliance monitoring, research actions, and adaptive management would be applied to the sites. This would require additional trips to the sites but are not expected to affect aquatic species or resources.

It is reasonable to assume that invasive aquatic vegetation control programs would be done by professionals that are familiar with control methods for invasive aquatic vegetation. It is likely that invasive aquatic vegetation would be targeted between June 1 and October 15 when anadromous fish or other special-status fish species would not be migrating or spawning. BMPs for controlling sediment and contaminant release into waterbodies would be used to minimize potential significant impacts on water quality associated with sediment and hazardous materials. Chemical spraying would be done and closely monitored by licensed professionals to ensure native aquatic species are not harmed. To determine if removing aquatic vegetation is successful, compliance monitoring, research actions, and adaptive management would be implemented.

Table 16-23, *Potential Environmental Effects of Invasive Aquatic Vegetation Control*, summarizes the potential environmental effects associated with invasive aquatic vegetation control.
Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*, at the end of this chapter, lists potential mitigation measures associated with the construction and operation of this non-flow measure and is referenced in Table 16-23 where appropriate.

Table 16-23. Potential Environmental Effects of Invasive Aquatic Vegetation Control

Potential Environmental Effects of Invasive Aquatic Vegetation Control	
Resource	Discussion
Aesthetics	• Invasive aquatic vegetation control is not be expected to significantly affect scenic vistas because invasive aquatic vegetation removal may be observable for a temporary period of time if a mechanical harvester is used to extract aquatic plants at the project site. Operation would not affect the aesthetics of the area because compliance monitoring activities would be of short duration and would not change the aesthetics of a channel. However, removal of aquatic vegetation could change the visual character of a location because the aquatic vegetation would no longer be there to be viewed by sensitive receptors. While this is a change to visual character, it would likely not be significant as the existing channel would be restored to its previous open water condition. Lighting is not expected to be used during invasive aquatic vegetation control or monitoring—all activities would occur during the day. This impact would be less than significant.
Agriculture and Forestry Resources	• Invasive aquatic vegetation control is not be expected to be located on lands used for agriculture or forestry but within or adjacent to existing water channels. There would be no conversion of farmland (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural use, conflict with existing zoning for agriculture use or a Williamson Act contract, conflict with existing zoning of forest land, or conversion of forest land to non-forest use. Impacts would not occur.
Air Quality	• Removal of invasive aquatic vegetation would likely result in emissions associated with mechanical harvesters, disposal trucks, and worker vehicle trips. The quantity, duration, and the intensity of removal activities have an effect on the amount of emissions and related pollutant concentrations occurring at any one time. However, it is anticipated that, given the type of equipment that would be used and low level of activity associated with removal of aquatic vegetation, emissions would not likely prevent compliance with regulations or exceed thresholds established by SJVAPCD. In addition, activities would be required to implement measures to reduce or minimize removal-related emissions. Impacts would be less than significant. • General plan assumptions of local jurisdictions inform local air quality plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. Removal of invasive aquatic vegetation would not result in population or employment growth and therefore would not result in a conflict with or obstruct implementation of the applicable air quality plan because activities that are associated with population growth (e.g., housing development, business centers, etc.) would not be implemented as a result. Impacts would not occur. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing

Potential Environmental Effects of Invasive Aquatic Vegetation Control	
Resource	Discussion
	facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). Removal of invasive aquatic vegetation would not create objectionable odors affecting a substantial number of people. Impacts would not occur.
Biological Resources	• Invasive aquatic vegetation control could release sediment and possibly hazardous materials (e.g., oil or fuel from equipment and herbicides) into waterbodies, affecting water quality. Release of sediment can bury macroinvertebrates which are prey for fish and other aquatic species, coat or bury eggs from frogs and fish, and fill in pool habitat, and potentially temporarily interfere with the movement of native resident or migratory fish species and associated migratory corridors, and impede the use of nursery sites. Herbicides can kill aquatic plant species, and if the plants are not removed, decompose and decrease DO in the water. Overall, implementing invasive aquatic vegetation control may have temporary significant impacts during plant removal, but beneficial long-term effects by allowing fish to access more and better habitat, and decrease predation. Removal of invasive aquatic vegetation is not expected to have a substantial adverse effect, either directly or through habitat modifications on special-status species. Timing restrictions, water quality measures such as monitoring turbidity and chemicals during removal and other water quality BMPs should be followed. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with invasive aquatic vegetation control. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The surrounding habitat on river banks may include riparian vegetation and/or wetlands. Riparian vegetation may be removed to facilitate equipment movement and wetlands may also be disturbed during vegetation removal activities. This would result in a temporary significant impact on riparian habitat and wetlands. Under operations, riparian habitat and wetlands would not be affected. Permanent removal and/or disturbance of riparian and wetlands habitats would be compensated for at a ratio appropriate for the disturbance per standard permit requirements or conditions from the U.S. Army Corps of Engineers, the Central Valley Water Board, and other conditioning agencies. This compensation would reduce and minimize impacts on fish and wildlife species and their habitats. Lead agencies can and should implement potential mitigation measures identified in Table 16-39 to reduce potentially significant environmental effects associated with implementing invasive aquatic vegetation removal projects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Invasive aquatic vegetation control would be conducted in channel reaches that support special-status fish species such as Chinook salmon and steelhead. These areas are expected to support biological resources. It is reasonable to assume that invasive aquatic vegetation control would occur during the least sensitive periods of special-status species life stages, (i.e., between June 1 and October 15), because this would reduce and minimize impacts on aquatic species. Table 16-39 lists potential mitigation measures lead agencies can and should implement to reduce

Potential Environmental Effects of Invasive Aquatic Vegetation Control

Resource	Discussion
	potentially significant environmental effects of invasive aquatic vegetation control on special-status biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Because invasive aquatic vegetation control is expected to produce beneficial results for special-status fish species, this activity would not conflict with local policies protecting biological resources or conflict with provisions of an adopted habitat conservation plan or natural community conservation plan. Impacts would be less than significant.
Cultural Resources	• Invasive aquatic vegetation control and compliance monitoring would not involve limited ground-disturbing activities to set up equipment adjacent to channels and therefore would have a very low potential for disturbing any unknown existing cultural resources (significant historical, archaeological, or paleontological resources) or human remains. Impacts would be less than significant.
Geology and Soils	• Invasive aquatic vegetation control would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, soil erosion, loss of topsoil, or landslides. No impact would occur. • Invasive aquatic vegetation control would not bring people to the risk of earthquakes or geologic hazards, and compliance monitoring would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because the activities would not draw people to earthquake areas or hazard locations not already frequented. No impact would occur.
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-12, invasive aquatic vegetation control would result in increased GHG emissions because heavy construction equipment would be used. Given the limited duration of removal activities (up to 1 week) and limited amount of equipment associated with invasive aquatic vegetation control, these activities would likely not exceed the SJVAPCD's ZEL. During compliance monitoring, trips would be by vehicle and of very short duration over a long period of time and would likely result in extremely small quantities of GHG emissions. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources.

Potential Environmental Effects of Invasive Aquatic Vegetation Control

Resource	Discussion
	○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Invasive aquatic vegetation control would not be a hazard or provide a safety concern to public and public use airports or private airstrips because it would not involve structures that could impede, interfere, or otherwise create a safety hazard to airports or air traffic. As such, invasive aquatic vegetation control would not result in a safety hazard for people residing or working in the project area. Impacts would not occur. • Invasive aquatic vegetation control would not physically interfere with an adopted emergency response plan or emergency evacuation plan because the sites would be located off-road within river banks and channels. Impacts would not occur. • Invasive aquatic vegetation control would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur. • As discussed in the Biological Resources section of this table, there are specific regulations regarding spraying of herbicides for controlling aquatic vegetation. Table 16-39 in the Biological Resources section, discusses mitigation measures that minimize impacts from herbicide application. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • The precise location(s) of where aquatic vegetation control would occur is not yet known; however, this activity could occur within one-quarter mile (0.25 miles) of a school. Hazardous materials (i.e., herbicides) may be used to control aquatic vegetation. While it is expected herbicides would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Table 16-39 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to that minimize impacts from herbicide application. Until such time that these potential mitigation measures are implemented, the

Potential Environmental Effects of Invasive Aquatic Vegetation Control	
Resource	Discussion
	impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented. • Aquatic vegetation control could entail limited ground disturbing activities (e.g., grading, excavation) in some circumstances, depending on the vegetation being controlled and the type of control mechanism selected. Lists of hazardous materials site are compiled by different state agencies under Government Code, § 65962. These sites are also known as Cortese Sites. There were no sites identified on the Hazardous Waste and Substance Site List compiled into the EnviroStor online database managed by the DTSC for Calaveras, Tuolumne, or Mariposa Counties (CalEPA 2016). There were a total of 17 sites identified for Merced, San Joaquin, and Stanislaus Counties. In addition to these sites identified by the EnviroStor database, CalEPA also identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facilities where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action for these counties (CalEPA 2016). There are approximately 500 leaking underground storage tanks designated as open in these counties (CalEPA 2016). There are approximately 55 facilities in these counties that have received CDOs/CAOs not identified as non-hazardous wastes, domestic wastewater, or domestic sewage (CalEPA 2016). It is not yet known precisely where invasive aquatic vegetation control would occur and removal would require excavation or ground disturbing activities. However, if it occurred on a Cortese Site and required excavation there would be potential for release of existing soil or groundwater contaminants because of the ground disturbance. Were this to occur, impacts could be significant. Table 16-39 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed.
Hydrology and Water Quality	• Invasive aquatic vegetation control may temporarily affect water quality due to the mechanical removal of aquatic plants within an active channel. Mechanical removal involves using a harvester and the harvester can hit the substrate and increase surface water turbidity. If aquatic vegetation is controlled with herbicides, water quality would be affected and water quality standards could potentially be violated. As a result, aquatic species including fish and invertebrates could be adversely affected. This is a significant impact. The DBW is the only agency authorized to use herbicides on invasive aquatic vegetation and they must receive biological opinions from USFWS and NMFS before applying herbicides. In addition, the Central Valley Water Board requires compliance with a statewide NPDES permit for residual aquatic pesticide discharges to surface waters from aquatic vegetation control application. The two biological opinions (USFWS and NMFS) and the NPDES permit requires a water monitoring program which involves a minimum of 10 percent of all treatment sites be sampled to collect and analyze Delta water quality data, and results of chemical residue and toxicity tests after applying herbicides (DBW 2009). Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts on water quality. Until such time that these potential mitigation measures are implemented, the

Potential Environmental Effects of Invasive Aquatic Vegetation Control	
Resource	Discussion
	impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Invasive aquatic vegetation control would not deplete groundwater supplies or interfere substantially with groundwater recharge because these projects would not require groundwater and would not result in an increase in impervious surfaces. Impacts would not occur. • Invasive aquatic vegetation control would not alter the existing drainage pattern of the site or area and is not expected to cause an increase in substantial erosion or siltation or result in flooding on- or offsite. Impacts would not occur. • Invasive aquatic vegetation control would not substantially increase the number of people exposed to the risk of flooding because these activities would not draw people to flood hazard locations. As such, Invasive aquatic vegetation control would not expose people to significant loss, injury, or death related to flooding. Impacts would not occur. • Invasive aquatic vegetation control would entail the application of chemical, mechanical, or biological control methods. Accordingly, this activity would not place housing within a 100-year flood hazard area or impede or redirect flood flows within a 100-year flood hazard area. Impacts would not occur. • Invasive aquatic vegetation control would not create or contribute runoff water, and therefore this activity would not exceed the capacity of existing or planned storm water drainage system. Impacts would not occur. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Invasive aquatic vegetation control is not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which aquatic vegetation control projects could result in a substantial degradation of water quality.
Land Use and Planning	• Invasive aquatic vegetation control would not physically divide an established community because aquatic plants would be located within existing river banks and channels where communities are not established. Impacts would not occur. • Invasive aquatic vegetation control would occur in existing river banks and channels and would not conflict with land use designations or zoning. Frequently these areas are designated natural resource or open space areas by land use plans and the removal of aquatic vegetation would be consistent with those designations because it would enhance existing habitat for fish and wildlife species. Impacts would not occur. • No conflicts are expected with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations. Impacts would not occur.

Potential Environmental Effects of Invasive Aquatic Vegetation Control

Resource	Discussion
Mineral Resources	• Invasive aquatic vegetation control would not result in the removal or inability to access state or locally designated mineral resource areas. This is because the removal of aquatic species would not involve activities that would limit access to or remove important locally or state designated mineral areas. Impacts would not occur.
Noise	• Invasive aquatic vegetation control would create noise related to the use of a mechanical harvester. However, the sites would be located within river banks and channels where people do not reside. It is unlikely people would be permanently exposed to noise levels in excess of standards established in the local general plan, noise ordinance, or applicable standards of other agencies due to the small nature of the projects and the remote location of the project from highly populated areas. Excessive ground-borne vibration or ground-borne noise levels are also not expected due to the type of equipment that would be used for mechanical or herbicide removal activities. While there may be temporary elevated noise in excess of standards established in local general plans, noise ordinance, or applicable standards, it would occur during the day because vegetation control activities are not expected to occur at night. Table 16-39 lists potential mitigation measures that lead agencies can and should implement to reduce potentially significant impacts due construction noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the limited exposure of potential sensitive receptors to this temporary noise increase and low likelihood of potential sensitive receptors to exist because of the remoteness. • Compliance monitoring would not create noise because only a few people would be performing the monitoring and sensitive receptors would not be present in the area. • Invasive aquatic vegetation control would not be done near airports or airstrips so people would not be exposed to excessive noise levels. Impacts would not occur.
Population and Housing	• Invasive aquatic vegetation control would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Furthermore, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people. Impacts would not occur. • Invasive aquatic vegetation control would not displace substantial numbers of people or existing housing or necessitate the construction of replacement housing elsewhere because the sites would be located within river banks and channels. No homes or people would be displaced. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, libraries, parks, schools, or other public facilities) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. Invasive aquatic vegetation control would not involve an increase in population or housing. In addition, these actions would not include proposals for new housing and would not generate students or increase demands for school services or facilities. Impacts would not occur.

Potential Environmental Effects of Invasive Aquatic Vegetation Control

Resource	Discussion
Recreation	• Invasive aquatic vegetation control would occur within river banks and channels. It is possible that areas may be temporarily restricted for recreational activities during primary application of chemicals or during mechanical removal; however, access would be restored and as such, significant effects on recreational facilities are not expected. Removal of thick aquatic vegetation may allow increased boat access to areas that previously were not accessible. Compliance monitoring would not affect recreational facilities because only a few people would be involved in the monitoring activities. This would be a less-than-significant impact. • Invasive aquatic vegetation control would not increase the use of existing parks or recreational facilities and would not result in the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Invasive aquatic vegetation control could result in a very few limited additional vehicle trips associated with workers. Depending on the location of the site, there could be a slight increase in traffic from workers. The temporary increase in traffic during aquatic vegetation control activities would likely not exceed local or regional road trip thresholds, because the number of workers that would be involved in these activities is less than 30. This would be a less-than-significant impact. • Invasive aquatic vegetation control would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Invasive aquatic vegetation control would not exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of wastewater. Impacts would not occur. • Invasive aquatic vegetation control would not involve construction or expansion of new or existing wastewater treatment facilities or water treatment facilities. Impacts would not occur. • Invasive aquatic vegetation control would not need the construction of additional storm water drains because the activity would occur within river channels and would not generate storm water. Impacts would not occur. • Invasive aquatic vegetation control would not generate an increase in solid waste because it involves activities that do not generate large quantities of solid waste. Impacts would not occur. • Invasive aquatic vegetation control activities would not require a water supply. Impacts would not occur.

16.4 Southern Delta Water Quality Alternatives – Reasonably Foreseeable Methods of Compliance

To achieve compliance with the numeric salinity objectives identified in the SDWQ alternatives, the Central Valley Water Board, in adopting or amending NPDES permits for point-source dischargers into the southern Delta (e.g., WWTPs), would have to implement the numeric objective (e.g., 1.0 deciSiemens per meter [dS/m] or 1.4 dS/m). This means that WWTPs with discharges that have a reasonable potential to cause or contribute to an excursion above the numeric objective would have effluent limitations in their NPDES permits to meet the revised objective.[19] In Chapter 13, *Service Providers*, it was identified that under SDWQ Alternative 2, the Cities of Tracy and Stockton, and Mountain House CSD may need to implement changes to their facilities. The regulated community (e.g., service providers of wastewater treatment services) who cannot comply with the revised effluent limitations may seek and obtain a variance for up to 10 years pursuant to Central Valley Water Board Resolution R5-2014-0074, which has the effect of delaying compliance. Ultimately, however, these service providers would have to comply and may choose to do one or a combination of actions to achieve compliance with potential NPDES permit changes as a result of the SDWQ alternatives. The reasonably foreseeable methods of compliance that service providers may take to comply with salinity requirements of SDWQ Alternative 2 are:

- Developing new source water supplies such that they have less salt
- Implementing salinity pretreatment programs that require CII facilities or residential salinity source controls, which would reduce the amount of salts that are discharged to the sewer system
- Implementing an effluent desalination process at the WWTP before treated effluent is discharged to the southern Delta

In addition, the Central Valley Water Board could adopt, revise or reissue waste discharge requirements (WDRs) or it could use the Irrigated Lands Program to require compliance with either SDWQ Alternative 2 or 3. As such, implementing salinity removal through agricultural return salinity control is considered a method of compliance.

Under the program of implementation for SDWQ Alternative 2 or 3, continued operations of the agricultural barriers at Grant Line Canal, Middle River, and Old River at Tracy, could occur to address the impacts of the CVP or SWP export operations on water levels and flow conditions that might affect salinity. This analysis assumes the existing temporary barriers would likely continue to operate in the southern Delta under the program of implementation because DWR determined it is essential to continue barrier installations to protect salmon migrating through the Delta, and to provide an adequate agricultural water supply for southern Delta farmers. The program of implementation for both SDWQ Alternatives 2 and 3 also requires additional studies and monitoring of the southern Delta circulation and water levels. It is possible that additional studying and monitoring would determine the need for modifications of the temporary barriers. If this

---

[19] Municipal WWTPs in the southern Delta are currently not subject to the existing numeric objective as a result of a superior court decision in *City of Tracy v. California State Water Resources Control Board*, Sacramento Superior Court, Case No. 34-2009-80000392.

determination is made by the State Water Board, DWR may be required to install low lift pumping stations at the temporary barriers as a method of compliance.

The regulated community (e.g., agriculture users or DWR) may choose to do one or a combination of many actions to achieve compliance related to either a reissuance of WDRs or the Irrigated Lands Program and the program of implementation. As such, the reasonably foreseeable methods of compliance for SDWQ Alternatives 2 and 3 are:

- Implementing salinity removal through agricultural return flow salinity control before treated effluent is discharged to the southern Delta
- Continuation of temporary barriers program
- Implementing low lift pumping stations in the southern Delta

The cost and environmental impacts of the actions associated with the methods of compliance that service providers, agricultural users, and DWR may implement are evaluated below. It should be noted that the regulated community could implement one or more than one of the methods of compliance evaluated. Because it is unknown which members of the regulated community would decide on which method(s) of compliance, for the purposes of this discussion, the methods of compliance are analyzed separately.

16.4.1 New Source Water Supplies

Water supplies with high salinity content can contribute to elevated salinity discharges to the southern Delta. Generally, water purveyors in the plan area (e.g., the Cities of Tracy and Stockton) rely on a combination of surface water and groundwater to meet potable water demand. Groundwater is typically more saline than surface water in the San Joaquin Basin.

Cost Evaluation

One method to reduce salinity discharges is to use more high-quality water (i.e., surface water) to meet water demands. To use more surface water, a water purveyor may need to enlarge existing structures (water intake, treatment facility, pipelines, and pumps), or build new structures.

One comparable project is the Davis-Woodland Water Supply Project (DWWSP). The DWWSP will construct a surface water intake, water treatment plant, pump stations, storage tanks, and associated transmission lines to develop 45,000 AF/y of new, high quality water from the Sacramento River. The DWWSP is in the construction phase, which began in April 2014, and is estimated to be completed in September 2016. The estimated project costs are detailed in Table 16-24, *Design and Construction Costs for the Davis-Woodland Water Supply Project and Delta Water Supply Project*.

The City of Stockton has completed its Delta Water Supply Project (DWSP) which will divert water pursuant to Water Code Section 1485. Water Code Section 1485 allows any municipality disposing of treated wastewater into the SJR to seek a water right to divert a like amount of water, less losses, from the river downstream of the point of its wastewater discharge. The DWSP will develop 33,600 AF/y of new water resources in the Delta. The DWSP has completed construction of a new surface water intake, water treatment plant, pump stations, and pipelines. The estimated project costs are also detailed in Table 16-24, *Design and Construction Costs for the Davis-Woodland Water Supply Project and Delta Water Supply Project*.

Table 16-24. Design and Construction Costs for the Davis-Woodland Water Supply Project and Delta Water Supply Project

Cost Category	DWWSP (millions)	DWSP (millions)
Design and Construct Intake	$15.6	$22.3
Design and Construct Treatment Facilities and Pipelines	$236.9	$176.6
Project Administration[a]	$33.1	$14.2
Other Local Costs[b]	$51.4	$21.6
Total	$337.0	$234.7

Sources: Woodland-Davis Clean Water Agency 2011; Price pers. comm.

Note: All costs are in in 2010 dollars.

DWWSP = Davis-Woodland Water Supply Project.

DWSP = Delta Water Supply Project.

[a] Project Administration includes environmental and construction permitting, land acquisitions, rights of way, pre-design, agency administration and contingency, program management, water rights permits, and water supply acquisition.

[b] Other Local Costs includes costs to the water purveyor not included in the project, but necessary to integrate the project into the existing infrastructure.

Based on information available for these two projects, it could cost $234.7–$337 million to plan, design, manage, and construct the required facilities to develop 33,600–45,000 AF/y of new surface water resources in the Delta.

Environmental Evaluation

Summary of Potential Action

Procuring and providing alternate low-salinity water source(s) to water users in a service area would reduce the salinity in the potable water used, ultimately lowering the salinity in the wastewater and treated effluent discharged from the WWTP. This action would require municipalities and/or water districts that serve customers in the southern Delta to obtain a new source of low-salinity water (e.g., purchasing surface water diversions from senior surface water users) and would likely require modifications to existing water supply distribution system(s) or the construction and operation of new water supply distribution system(s). The water supply distribution system(s) would take the new source of low-salinity water and distribute it within the water district service area. Municipalities and/or water districts with service areas within the southern Delta or that provide water to customers who ultimately discharge treated effluent into the southern Delta and could implement changes to their distribution system(s) include: City of Tracy, Mountain House CSD, and City of Stockton. These municipalities provide both water supply and wastewater treatment services.

The location, timing of construction, details of operation, and source of low-salinity water are all unknown. In addition, the size and scale of the facilities is unknown. These unknown factors would influence the type, magnitude and severity of impacts that could occur during construction and operation. It is expected that obtaining an alternative source of low-salinity water would require the construction and operation of underground pipelines and/or above-ground canals and pump stations to distribute water from one unknown location to another. Underground pipes would be typically located within existing road rights-of-way, adjacent to existing utility lines and approximately 3–8 ft below ground surface. If canals were to be used, the location and number of canals are unknown. If pump stations are used, they would likely be located adjacent to the canals or the pipelines, but the locations are unknown.

Potential Environmental Effects

Construction of new source water supply facilities would likely result in temporary and highly localized effects typically associated with similar construction activities, such as air quality effects and ground disturbance. As noted above, it is likely that such facilities would be constructed in areas that are already disturbed by urban development, and most facilities would be located within existing facility footprints and road rights-of-way. Depending on the precise location, new diversion facilities could have the potential to affect aquatic resources during construction and operation, which would need to be evaluated and mitigated as part of the project level analysis. Construction and operation of such facilities are highly regulated, and the project would be required to comply with applicable regulations. In addition, because such facilities are owned by water supply purveyors and service districts or WWTP service districts[20] and subject to CEQA review, any new projects would undergo project-level analysis under CEQA and other required regulatory compliance at the time they are proposed. Implementation of these potential methods of compliance would improve salinity conditions in the southern Delta.

Table 16-25, *Potential Environmental Effects of New Source Water Supply Facilities*, summarizes the potential environmental effects associated with new source water supply facilities. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Additional Compliance and Other Indirect Actions*, at the end of this chapter, lists potential mitigation measures associated with the construction or operation of the methods of compliance and is referenced in Table 16-25 where appropriate.

---

[20] Note: Cities or water districts that do not treat wastewater would have no obligation to try to reduce the salt levels in the water they provide.

Table 16-25. Potential Environmental Effects of New Source Water Supply Facilities

Potential Environmental Effects of New Source Water Supply Facilities	
Resource	Discussion
Aesthetics	• New source water supply facilities would require the construction of new infrastructure including pipelines, canals, small lift or pump stations, and tie-in stations to existing water treatment plant intakes. Construction of the new source water supply facilities could result in temporary impacts on the visual character or quality of the chosen sites and surroundings, likely within San Joaquin County, due to ground disturbance. Ground-disturbing construction activities would have the potential to disturb or remove mature vegetation (i.e., landscaping) and create dust clouds, which could affect views. In addition, construction may involve nighttime lighting for safety and potentially 24-hour construction. The severity of these impacts would depend on the location of sensitive receptors and scenic vistas relative to the construction site. For example, San Joaquin County has no designated scenic vistas and as such an impact may not occur (San Joaquin County 2014a). However, if 24-hour construction occurs, light and glare could be produced that could affect sensitive receptors. Table 16-38 identifies potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant environmental effects day and nighttime views associated with light and glare and aesthetics. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented depending on the possible location of potential sensitive receptors and the ability to reduce light and glare. • Operation of new source water supply facilities would not be expected to significantly affect the visual character or quality of the area in which it would likely occur (i.e., San Joaquin County) Generally, the infrastructure associated with new water supply facilities would be unobtrusive structures, with low profiles and a low potential to adversely affect the daytime view of existing sensitive receptors (e.g., residents or recreationists). However, if new intakes were operated on a waterway, the siting of concrete infrastructure could result in a substantial change to the visual character and quality of the area, depending on where the area is located (e.g., adjacent to a river). Furthermore, Certain facilities, such pump stations, may require permanent outdoor lighting, which could adversely affect viewers in rural areas where there is relatively limited outdoor lighting at night. Design and operation of lights would be expected to follow lighting guidelines and lighting plans of local jurisdictions approving the construction and operation of new source water supply facilities. Many of the facilities (such as pipelines) would likely be located below ground and, once operational, would not affect the visual quality or character of an area. Table 16-38 identifies potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant environmental effects day and nighttime views associated with aesthetics and light and glare. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	once mitigation measures were implemented depending on the possible location of potential sensitive receptors, the visual character and quality of the surrounding area, and the ability to reduce light and glare. • There are two state-designated scenic highways in San Joaquin County, Interstate 5 (I-5) and I-580 (San Joaquin County 2014a). Depending on the location, construction of new source water supply facilities may be visible from portions these highways and temporarily alter the existing views. However, because permanent water supply facility structures would be visually unobtrusive and because travelers on the interstates would be traveling at relatively high speeds, they are generally considered to have low visual sensitivity to changes in views. Moreover, it is not expected that the construction and operation of new source water supply facilities would substantially damage scenic resources (including trees, rock outcroppings, and historic buildings) within I-5 or I-580. Impacts would be less than significant.
Agriculture and Forestry Resources	• Construction and operation of new source water supply facilities such as pipelines, small lift or pump stations, and tie-in stations, would not be expected to be located on agricultural lands (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) because they are expected to be located along the rights-of-way of existing roads or close to existing water supply infrastructure. If canals are constructed and operated, there is the potential for canals to remove some amount of agricultural lands from production; however, the amount cannot be quantified in this analysis because the location of the canals is unknown. The extent of the impact would depend on the total acres removed from agricultural use, whether it was permanent removal, and whether they were in Williamson Act contracts. But it is expected that agricultural uses in the southern Delta would benefit from the reduction in salinity discharges provided by the new source water supplies and potentially offset any agricultural land that might be indirectly affected by the new source water supplies. Lead agencies can and should implement potential mitigation measures identified in Table 16-38 to mitigate for significant environmental effects associated with the potential permanent removal or conversion of agricultural lands. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Construction and operation of new source water supply facilities would not be expected to be located on forest land or timberland because these resources are limited in the southern Delta and because these facilities are expected to be located along the rights-of-way of existing roads or close to existing water supply infrastructure. Accordingly, there would be no conflict with existing zoning for, or cause rezoning or loss of these resources. Impacts would not occur.
Air Quality	• Construction and operation of new source water supply facilities would likely be located in the SJVAB, which generally covers San Joaquin, Stanislaus, Merced, and Madera Counties. USEPA has classified SJVAB as an extreme nonattainment area for the federal 8-hour ozone standard and a nonattainment area for the federal PM2.5 standard. For the federal CO standard, USEPA has classified most major population centers of the SJVAB as maintenance areas and rural areas of the SJVAB as unclassified/attainment areas. The SJVAB is classified as a serious maintenance area with regards to the federal PM10 standards. ARB has classified the SJVAB as a severe nonattainment area for the state 1-hour ozone standard and a nonattainment area for the state 8-hour ozone,

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	PM10, and PM2.5 standards. ARB has classified the SJVAB as an attainment area for the state CO standard. SJVAPCD's published guidelines, *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002) do not require the quantification of construction emissions. Rather, the guidelines require implementation of effective and comprehensive feasible control measures to reduce PM10 emissions (SJVAPCD 2002). SJVAPCD considers PM10 emissions to be the greatest pollutant of concern when assessing construction-related air quality impacts and has determined that compliance with its Regulation VIII, including implementation of all feasible control measures specified in its *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), constitutes sufficient mitigation to reduce construction-related PM10 emissions to less-than-significant levels and minimize adverse air quality effects. All construction projects must abide by Regulation VIII. Since the publication of its guidance manual, SJVAPCD has revised some of the rules comprising Regulation VIII. Guidance from SJVAPCD staff indicates that implementation of a Dust Control Plan would satisfy all of the requirements of Regulation VIII (Siong pers. comm.). Further consultation with SJVAPCD staff indicates that, though explicit thresholds for construction-related emissions of ozone precursors are not enumerated in the *Guide for Assessing and Mitigating Air Quality Impacts*, SJVAPCD considers it to be a significant impact when construction or operational emissions of ROG or NO_X exceed 10 tons per year or if PM10 or PM2.5 emissions exceed 15 tons per year (Siong pers. comm.). SJVAPCD's CEQA Guidelines indicate their numeric thresholds are project-level and cumulative: "Any proposed project that would individually have a significant air quality impact…would also be considered to have a significant cumulative air quality impact" (SJVAPCD 2002). Construction of new source water supply facilities would likely result in emissions associated with construction equipment and construction worker vehicle trips, as well as fugitive dust emissions from ground disturbance. Construction activities would temporarily increase emissions of ozone precursors and particulate matter. The quantity, duration, and intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations that occur at any one time. More emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Depending on the level of construction activities and amount of infrastructure built, construction of new source water supply facilities could exceed air quality thresholds established by SJVAPCD, which would be a significant impact. Implementation of measures to help reduce or minimize construction-related emissions and comply with regulations would be required. Lead agencies (e.g., municipalities or municipal water purveyors) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on air quality associated with construction emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the regulatory requirement to implement all required feasible measures to reduce emissions during construction and the potential for the duration and frequency of activities during construction to reduce overall emissions (e.g., diluting emissions over time).

Potential Environmental Effects of New Source Water Supply Facilities	
Resource	Discussion
	• Operation of new source water supply facilities could include facility inspection and maintenance activities, similar to the maintenance of existing water supply facilities. The need for additional energy to distribute the new water supply could result in increased criteria pollutant emissions at other power facilities. However, the power facilities that would compensate for the additional power are already built and permitted to emit a maximum amount of criteria pollutants. These facilities are required to offset additional power generation by the use of pollution credit. Therefore, if additional emissions are generated, they would be generated by facilities that are permitted to do so. Operation of new source water supplies may use nonelectric back up during intermittent emergency situations and their cumulative operation could result in exceedances of SJVAPCD's thresholds and potentially result in a cumulatively considerable net increase in criteria pollutants for which SJVAB is in nonattainment, as SJVAPCD's CEQA Guidelines indicate their numeric thresholds are project-level and cumulative: "Any proposed project that would individually have a significant air quality impact…would also be considered to have a significant cumulative air quality impact (SJVAPCD 2002)". However, the potential short term increase in criteria pollutant emissions during intermittent emergency situations would be potentially offset by reductions in the use of electric or fuel pumps being used to lift water into canals or pipelines. Operations could include periodic facility inspection and maintenance activities. However, emissions generated once operational would be minimal and are not anticipated to exceed SJVAPCD thresholds. Impacts would be less than significant. • SJVAPCD generally defines a sensitive receptor as a facility that houses or attracts children, the elderly, people with illnesses, or others who are especially sensitive to the effects of air pollutants, and where there is a reasonable expectation of continuous human exposure according to the averaging period for National ambient air quality standards (AAQSs [e.g., 24-hour, 8-hour, or 1-hour]) (SJVAPCD 2002). Sensitive receptors are primarily concentrated in urbanized areas and their proximity to construction or operational activities, the type of activity, and duration of activity, determines their potential exposure to pollutants. If criteria pollutant standards are exceeded during construction, and sensitive receptors are in proximity, mitigation measures identified in Table 16-38 would serve to reduce potentially significant effects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. It is not anticipated that operation of the facilities would expose sensitive receptors to substantial pollutant concentrations because operations would not generate toxic or diesel exhaust. If diesel generators were used, they would be limited in operation and would likely be subject to air district permitting requirements that would minimize health risks. In addition, operation of these facilities would not create objectionable odors. Impacts on sensitive receptors related to new source water supply facility operations would be less than significant. • The ARB traditionally has established state air quality standards, maintaining oversight authority in air quality planning, developing programs for reducing emissions from motor vehicles, developing air emission inventories, collecting air quality and meteorological data, and approving State Implementation Plan, as required by the Clean Air Act, provisions. Responsibilities of local air districts include overseeing stationary source emissions, approving permits, maintaining emissions inventories. SJVAPCD has adopted an air quality improvement plan that addresses

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	NO_X and ROGs, both of which are ozone precursors and contribute to the secondary formation of PM10 and PM2.5. The air quality improvement plan specifies that regional air quality standards for ozone and PM10 concentrations can be met through the use of additional source controls and trip reduction strategies. It also establishes emission budgets for transportation and stationary sources. Those budgets, developed through air quality modeling, reveal how much air pollution can be present in an area before AAQSs are violated. General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction and operation of new source water supply facilities would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with an air quality plan if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air quality plan(s). The construction and operation of new source water supply facilities would not result in growth because it would serve to provide alternate low-salinity water source(s) to water users and would not serve to satisfy an increase in demand or an increase in need. The construction and operation of new source water supply facilities would not result in population or employment growth that would result in a conflict with or obstruct implementation of the applicable air quality plan because they would not require activities that are associated with population growth (e.g., housing development, business centers, etc.). Accordingly, this impact is less than significant. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). New source water supplies are not included in one of these categories. Therefore, construction and operation of salinity source controls would not create objectionable odors affecting a substantial number of people. Impacts would be less than significant.
Biological Resources	• Construction and operation of new source water supply facilities, such as pipelines, lift pumps, and tie-ins, would primarily be underground, in the public rights-of-way in existing roads, or adjacent to existing water supply facilities, and are expected to have a low potential to disturb habitat (potentially including established native resident or migratory wildlife corridors, federally protected wetlands, riparian habitat, or other sensitive natural communities) or candidate, sensitive or special-status species (including interfering substantially with the movement of any native resident or migratory fish or wildlife species) above ground. It is unlikely construction and operation of these underground facilities would impede the use of native wildlife nursery sites given where the facilities would likely be located. Further, because new source water facilities would likely be located in the public rights-of-way in existing roads, or adjacent to existing water supply facilities, they are not likely to conflict

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	with local policies or ordinances protecting biological resources, or conflict with an adopted natural community conservation plan or habitat conservation plan. Impacts would be less than significant. • If canals are constructed and operated as part of new source water supply facilities, there is the potential for the canals to disturb habitat (potentially including federally protected wetlands, riparian habitat or other sensitive natural communities) and/or candidate, sensitive, or special-status species depending on the location of the canals. Similarly, if new intakes constructed and operated, there would be a high potential to affect these resources depending on its location and proximity to a waterway. However, the extent of potential disturbance cannot be quantified in this analysis because the locations of the canals are unknown. Construction and operation of canals associated with new source water supply facilities, depending on the location, could conflict with local policies or ordinances protecting biological resources. Further, construction and operation of canals or a new intake, depending on the location, could impede the use of native wildlife nursery sites. As specific source water supply facilities are designed, lead agencies (e.g., municipalities or municipal water purveyors) would be required to evaluate construction effects of new source water supply facilities, such as the potential for direct and indirect impacts on jurisdictional waters, habitat, and candidate, sensitive, or special-status species on a case-by-case basis in subsequent CEQA documents. Table 16-38 lists potential mitigation measures lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant environmental effects of construction and operation of new source water supply facilities on biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. If habitat is permanently removed as a result of constructing canals or a new intake, it is likely that impacts could not be mitigated and would remain significant and unavoidable. • Construction and operation of new source water supply facilities could occur within the SJMSCP Plan Area. The SJMSCP is administered by the San Joaquin Council of Governments (SJCOG), a non-profit corporation established by San Joaquin County and the cities of Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton and Tracy. Implementation of new source water supply facilities may be considered a covered activity under SJMSCP—a determination which would be made by SJCOG, in consultation with the lead agency. If an activity is determined to be covered, participation in the SJMSCP is voluntary except when conditioned to participate by a Permittee (i.e., SJCOG, Inc. San Joaquin County, and the cities of Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton and Tracy). If an activity is not covered, the lead agency can request coverage using one of the following four options: (1) payment of a fee, which is assessed depending on habitat type within which the project is located; (2) dedicate habitat lands as a conservation easement or fee title; (3) purchase mitigation bank credits from a SJCOG-approved mitigation bank; and (4) propose an alternative mitigation plan, consistent with the goals of the SJMSCP and equivalent in biological value. Participation in the SJMSCP fulfills ESA, CESA, NEPA, and CEQA requirements, provides mitigation and guarantees no additional mitigation, excepting for Incidental Take Minimization Measures required in limited cases (SJCOG 2016a). If the lead agency participates in the SJMSCP, construction and operation of the new source water supply facilities would not be considered in conflict with the SJMSCP, and impacts would be less than

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	significant. If the lead agency chooses to opt out of participation in the SJMSCP, that agency or agencies (e.g., municipalities or municipal water purveyors) can and should implement the mitigation measures identified in Table 16-38 to reduce potentially significant impacts on biological resources and to avoid conflict with the SJMSCP. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. If habitat is permanently removed as a result of constructing or operating new source water supply facilities, it is likely that impacts could not be mitigated and would remain significant and unavoidable. However, it is likely impacts could be reduced once mitigation was implemented because once a lead agency opts in or determines its action is covered, consistency would be determined and impacts would be less than significant. • Direct and indirect impacts on candidate, sensitive, or special-status biological resources or habitat are unlikely to occur during operation because the new source water supply facilities would primarily be underground and would convey water supplies from a currently unknown source to the water district or municipality water treatment plant. Further, since the water would likely come from an existing senior water right holder, it is assumed the senior water right holder is using the water for another purpose and, therefore, a change in use of the water for municipal purposes would not result in direct or indirect impacts on candidate, sensitive, or special-status species and habitat. Finally, lead agencies (e.g., municipalities or municipal water purveyors) would evaluate the operation of the new source water supply facilities and the potential for direct impacts on jurisdictional waters, habitat, and candidate, sensitive, or special-status species on a case-by-case basis in subsequent CEQA documents. Table 16-38 lists potential mitigation measures lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts on biological resources related to new source water supply facilities operations. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Cultural Resources	• Construction of the new water supply facilities could include installing pipeline generally along the rights-of-way of existing roads, new lift stations, and tie-ins to existing water supply facilities. There is the potential to encounter significant unknown buried cultural resources (significant historical, archeological, or paleontological resources) during construction because it is unknown if these resources are currently present within these sediments. At this time, no specific projects have been proposed, and the foreseeable future new source water supply facilities are unknown. Even so, given that most of the construction would occur within highly developed public rights-of-way or where much of the sediments have been previously disturbed, the potential to encounter significant buried cultural resources is greatly reduced. Construction of new water supply facilities such as canals or new intakes may involve the disturbance of ground not within the rights-of-way of existing roads, or the footprint of existing facilities, and could result in excavation at varying depths below ground surface; however, the location is unknown at this time and, therefore, it the potential to uncover unknown significant cultural resources cannot be determined. Lead agencies (e.g., municipalities or municipal water purveyors) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on cultural

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	resources associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • As described above, new water supply facilities would primarily be located within the rights-of-way of roads or at existing facilities. Therefore, it is highly unlikely human remains, would be disturbed during construction, because these areas have already been highly disturbed. However, canals may be located outside the rights-of-way of public roads and at varying depths below ground surface. In the event human remains are uncovered during construction, compliance with the State Health and Safety Code would be required. As specified by Section 7050.5 of the Health and Safety Code, and described in Table 16-38, no further disturbance would occur until the county coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code Section 5097.98. If such a discovery occurs, excavation or construction would halt in the area of the discovery, the area would be protected, and consultation and treatment would occur as prescribed by law. If the coroner recognizes the remains to be Native American, he or she would contact the NAHC, who would appoint the Most Likely Descendent. Additionally, if the human remains are determined to be Native American, a plan would be developed regarding the treatment of human remains and associated burial objects, and the plan shall be implemented under the direction of the Most Likely Descendent. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Geology and Soils	• The locations of the new source water supply facilities could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, these facilities would not bring people to the risk of earthquakes or geologic hazards, meaning the construction and operation new water supply facilities would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur. • New facilities would be required to follow all appropriate building codes and would be designed to withstand seismic-related activities as identified by the building codes. Geologic studies would also be required, and design guidelines would be incorporated into the design and build that would reduce the geologic risk to the structures. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to geology and soils associated with new structures. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the need to follow the building code and other state and federal building requirements. • Construction of the new source water supply facilities would result in limited ground-disturbing activities, which could cause soil erosion or loss of topsoil; however, ground-disturbing activities would be limited in duration and geography. Furthermore, ground-disturbing activities of 1 acre or greater would require the water district or

Potential Environmental Effects of New Source Water Supply Facilities	
Resource	Discussion
	municipality to prepare and implement a SWPPP, as required by the Central Valley Water Board. The SWPPP would require soil and erosion control mechanisms to reduce the effects of soil, erosion, and runoff that may be generated during construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to soil erosion and storm water runoff associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary. • The construction and operation of new source water supply facilities would not involve constructing or operating septic tanks and, therefore, septic tanks would not be affected by soils incapable of supporting the use of them or other alternative wastewater disposal systems. Impacts would not occur.
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-7, because construction and operation of new source water supply facilities would likely result in increased use of electricity and fuels there would be an increase in GHG emissions. However, the overall increased electrical demand would be small compared to the existing electrical demand and it is unlikely to require the construction of major new power generation or transmission facilities. Regardless, it is anticipated that this increased electricity-related GHG emissions could exceed applicable SJVAPCD ZEL threshold and result in a potentially significant impact. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs • AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be

Potential Environmental Effects of New Source Water Supply Facilities	
Resource	Discussion
	inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
Hazards and Hazardous Materials	• Construction of new water supply facilities would be short term and may involve the limited transport, storage, use, and disposal of hazardous materials such as fuel and lubricating grease for motorized heavy equipment. Some examples of typical hazardous materials handling are fueling and servicing construction equipment on the site and transporting fuels, lubricating fluids, solvents, and bonding adhesives. These types of materials are not acutely hazardous, and storage, handling, and disposal of these materials are regulated by local, county, and state laws. Furthermore, the quantities of these materials used during construction would be small (e.g., less than 100 gallons) because construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because construction and the use of hazardous materials would be temporary and relatively short in duration over the course of construction. • There are eight sites within San Joaquin County that are identified on the Hazardous Waste and Substance Site List (Cortese Site list) as being hazardous materials sites under Government Code, § 65962) (CalEPA 2016). Construction and operation of new source water supply facilities are not likely to be located on these eight sites or interfere with these sites because the construction and operation of new source water supply facilities would not involve activities at the sites on this list (e.g., Lawrence Livermore National Lab, McCormick and Baxter Creosoting Company). CalEPA identifies leaking underground storage tank sites, sites that have received CDOs or clean up and abatement orders, and hazardous waste facility sites where DTSC has taken corrective Action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action in San Joaquin County (CalEPA 2016). As such, construction of new source water supply facilities would not affect them. There are approximately 244 leaking underground storage cases in San Joaquin County designated as open (CalEPA 2016). Sixteen facilities in San Joaquin County have received CDOs or CAOs and have active cases, but may not be necessarily related to hazardous waste (CalEPA 2016). The location of construction of new source water supply facilities is unknown, but it is not anticipated to be located directly on these sites because they include locations such as gas stations, car washes, private lands with underground storage tanks. However, construction could occur along the rights of way of existing roads that could be in proximity to these sites. During excavation or soil disturbance potentially contaminated soil could be encountered. As such, Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • San Joaquin County has 14 school districts and more than 200 schools (San Joaquin County Office of Education n.d.). The location of construction of new surface water facilities is unknown; however, construction could be located within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected these materials would be handled, used, and stored properly in accordance with local, state, and federal laws and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation activities. As such, if a school existed within close proximity to construction of new source water facilities, those mitigation measures identified Table 16-38 applied to project-specific construction needs would reduce potentially significant impacts during construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction • Construction of new source water supply facilities, such as pipelines, lift stations, or tie-ins, would not physically interfere with an adopted emergency response plans or emergency evacuation plans since they would likely be located in the existing rights-of-way of public roads or within the footprint of other existing water supply infrastructure. During construction, road shoulders or lanes may be closed, but traffic construction workers would be employed to direct and control traffic as is typical during construction work that occurs in the rights-of-way of public roads. Road shoulders or lanes may be closed as a result of construction of canals if the canals are adjacent to roads or cross roads. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with traffic and potential conflicts with emergency response. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary. • Once new source water supply facilities are operational, they would either be underground, adjacent to existing water supply infrastructure, or contained in a canal and would not physically interfere with an emergency

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	response plan or emergency evacuation plan because they would not prevent road access. Furthermore, operation does not involve an increase in population that would necessitate reconsideration of how to evacuate people in an emergency. • Assuming construction and operation of new source water supply facilities would be located in San Joaquin County, there are six public access airports within the county (SJCOG n.d.[a]). The Stockton Metropolitan Airport and San Joaquin County Airport have approved Airport Land Use Compatibility Plans, which prescribe safety requirements and ensure land uses would not pose a safety hazard to the airports in accordance with the Federal Aviation Administration. Other airports, such as the City of Tracy, have either airport master plans or other planning documents outlining safety requirements and ensuring land uses would not pose a safety hazard, consistent with FAA requirements (City of Tracy 1998). The location of construction or operation of new source water supply facilities is unknown and could occur within 2 miles of an airport. However, construction and operation new source water supply facilities would not be a hazard or cause safety concerns to airports since the facilities would be relatively low profile and/or underground. Impacts would not occur. • Construction and operation of new source water supply facilities would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur.
Hydrology and Water Quality	• Construction of new source water supply facilities could result in temporary changes to storm water drainage, existing drainage patterns, erosion, or runoff associated with typical construction activities such as grading or preparation of land. As discussed earlier in this table (Geology and Soils), soil disturbance of over 1 acre would require water districts or municipalities to prepare and implement a SWPPP, which would include specific types and sources of storm water pollutants, determine the location and nature of potential impacts, and specify appropriate control measures to eliminate any potentially significant impacts from storm water runoff on receiving waters. In addition, as discussed in this table for Hazards and Hazardous Materials, construction of new source water supply facilities may involve the limited transport, storage, use, and disposal of hazardous materials, which, if spilled, could have adverse effects on water quality depending on the location and magnitude of the spill. However, storage, handling, and disposal of these materials is regulated by local, county, and state laws, and the quantities of these materials used during construction would be small (e.g., less than 100 gallons) and construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained and, as such, violations of water quality standards are not expected to occur. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary and the need to follow existing regulations requiring the handling, use and disposal of hazardous materials, and the need to prepare SWPPPs.

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	• Under operating conditions of a new source water supply facility, a water district or municipality would need to purchase water from a source such as an irrigation district. The source would have a water right to obtain water from various locations and allocate the amount of water as allowed by its water right(s). Therefore, impacts on hydrology and water quality are not expected to occur under operating conditions of new source water supplies because the water district or municipality could not obtain water from a source that was out of compliance with its water right. Impacts would be less than significant. • It is unknown if new source water supply facilities would be located in a 100-year flood hazard area. However, the new source water supply facilities would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to flood hazard locations or result in the construction of housing in a flood hazard area. Accordingly, new source water supply facilities would not expose people to significant loss, injury, or death related to flooding. Construction of new source water supply facilities would not result in flooding or otherwise cause flooding, including flooding as a result of the failure of a levee or dam. The new source water supply facilities are expected to be low in profile and/or underground and would, therefore, not impede or redirect flood flows. Impacts would be less than significant. • Construction and operation of new source water supply facilities would not result in a substantial depletion of groundwater supplies because surface water would be the supply source. The operation of the facilities and any impervious surfaces needed would be minimal from a regional groundwater basin perspective; therefore, new source water supply facilities would not interfere with groundwater recharge. Further, new source water supplies could actually reduce the amount of groundwater pumped because typically groundwater is saline, and the use of it increases the salinity concentration in the treated effluent discharged into the southern Delta. Impacts would be less than significant. • Construction and operation of new source water supply facilities would primarily be located in areas of relatively flat relief because pipelines and canals are typically not located on the side of steep slopes. Therefore, these locations would not support mudflows, which typically need very steep slopes and large amounts of precipitation to occur. Furthermore, these areas would not be adjacent to the ocean and, therefore, they would not be affected by tsunamis. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction and operation of new source water supply facilities are not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of new source water supply facilities could result in a substantial degradation to water quality.

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
Land Use and Planning	• Construction and operation of new source water supply facilities would not physically divide an established community because the facilities would be located either underground or on land likely designated for infrastructure. Impacts would not occur. • Typically, general land use designations and zoning designations allow for the development of infrastructure, such as pipelines or pumping stations. It is not anticipated that the construction or operation of the new source water supply facilities would result in a conflict with land use designations or zoning. If the new source water supply facilities were inconsistent with applicable land use plans, policies, or regulations, an amendment or variant from the local jurisdiction approving the discretionary action associated with the facilities would be required by the project proponent (e.g., water district or municipality) prior to project approval and construction. If no discretionary action were to occur as a result of the construction or operation of the facilities, it is assumed it would not result in a conflict with local land use plans, policies or regulations. Impacts would be less than significant. • Construction and operation of new source water supply facilities would likely take place in the Delta and may be considered covered activities under the Delta Plan. Only the lead CEQA state or local agency may determine whether that plan, program, or project is a covered action of the Delta Plan. If an action is covered, consistency with the Delta Plan would be determined. The consistency determination would include implementing mitigation from the Mitigation Monitoring or Reporting Program of the Delta Plan, as appropriate. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to consistency with the Delta Plan. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely impacts could be reduced once mitigation was implemented because once a lead agency determines an action is covered and complies with the Mitigation Monitoring or Reporting Program, consistency would be determined and impacts would be less than significant. • Potential conflicts with habitat conservation plans, natural community conservation plans, or other plans, policies and regulations protecting biological species and resources are evaluated in the Biological Resources section of this table.
Mineral Resources	• The California Surface Mining and Reclamation Act (SMARA) requires the State Geologist to classify land into mineral resource zones (MZ), according to the known or inferred mineral potential of existing land. The primary goal of mineral land classification is to ensure that the mineral potential of land is recognized by local government decision-makers and considered before land-use decisions are made that could preclude mining. Local general plans, specific plans, and other local plans refer to and use the information produced by the State Geologist, to identify mineral resources because they are specialized evaluations and because the California Geologic Survey is the designated agency to perform these surveys under SMARA. MZ are identified by the State to identify inferred mineral potential of an area. Areas designated MZ-1 have adequate information to determine no significant mineral resources exist, or indicate a very low likelihood; areas designated MZ-2 have adequate information to

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	identify significant mineral deposits or indicate a high likelihood of presence; and areas designated MZ-3 have inadequate information to determine significance of mineral deposits, but contain mineral deposits. Some gravel, sand, and aggregate resources (identified as MZ-1 or MZ-2) are found in close proximity to waterways and the LSJR in San Joaquin County (San Joaquin County 1998, City of Tracy 2005). Most of the city of Stockton is designated as MZ-1, with a small area of MZ-3 (City of Stockton 2007). Other mineral resources, such as gold or peat, have been previously extracted from the county (San Joaquin County 1998). • Construction and operation of new source water supply facilities would have a very low potential to result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state or result in the loss of availability of a locally designated mineral resource recovery site. This is because the new source water supply facilities would likely be located within the rights-of-way of existing public roads or adjacent to water supply facilities. Additionally, if the new source water supply facilities are located within a state or locally designated mineral resource area, construction and operation of the facilities would not permanently remove access to a mineral resource as there would be other locations around the facilities that could provide access to the mineral resource. Impacts would be less than significant.
Noise	• Construction would potentially take place in San Joaquin County, and the cities of Tracy and Stockton depending on the location of water supply facilities. But it could also take place within one of the other multiple cities within San Joaquin County, depending on whether the construction of pipelines or canals would occur and their specific location(s). Each of these jurisdictions have noise requirements in their general plans or zoning ordinances for construction and operation based on land use designations and timing restrictions. Noise requirements are typically based on land uses that are considered more sensitive to ambient noise levels than others due to noise exposure. Residences, motels and hotels, schools, libraries, churches, hospitals, nursing homes, and outdoor recreation or natural areas are typically more sensitive to noise than are commercial or industrial land uses. Therefore, local noise standards are typically more stringent for sensitive land uses in terms of level of noise generated, duration, and frequency than less sensitive uses. Given the wide ranges of land uses throughout San Joaquin County, noise levels can range from louder high density residential and industrial uses or roadway uses to more quiet open space and agricultural areas (San Joaquin County 1992). Frequently, the most common and loud noise generating activity in San Joaquin County affecting the overall permanent ambient noise setting is freeway traffic on I-5, I-205, and SR-4 and along railroads and in heavy industrial areas (e.g., Port of Stockton) or around airports (San Joaquin County 1992). It is unknown where construction or operation of the new source water supply facilities would take place, so it is unknown if construction or operation would occur within or in close proximity to a noise sensitive land use (e.g., residences) or in an area less sensitive to noise (e.g., industrial area). • The City of Tracy and the City of Stockton regulate generation of construction noise by restricting the timing that construction can occur (e.g., operating construction requirement from 10pm to 7pm is prohibited) and the land use or adjacent land uses under which the noise generating activity occurs (City of Stockton n.d., City of Tracy n.d.). San Joaquin County exempts noise sources associated with construction, provided they do not take place before 6am or after 9pm (San Joaquin County n.d.) Other local jurisdictions also either exempt construction noise from

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	noise standards or have restrictions as to when it can occur. Construction of new source water supplies could generate temporary noise and as such could expose people to noise levels in excess of standards. Construction of the new source water supply facilities could exceed noise standards established in local general plans or noise ordinances, depending on the location of sensitive receptors, the type of construction equipment used, and the duration of construction. As such, could result in the temporary increase in ambient noise levels and expose persons to noise levels in excess of applicable noise standards. While construction would generally occur within rights-of-way along public roads; however, it is unknown where certain facilities, such as canals, would be located. They could be located in residential neighborhoods or within immediate proximity to other sensitive receptors (e.g., schools, hospitals, parks). If sensitive receptors were adjacent to construction activities and experienced construction noise, construction would likely be temporary and it would be required to follow existing local noise ordinances limiting the timing of construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Construction activities that typical result in ground-borne vibrations or ground-borne noise are activities such as pile driving, where the ground is repeatedly struck and vibrations or noise can be generated. Given the nature of the facilities constructed (e.g., canals, pump stations, pipelines), it is likely that construction activities such as digging, excavating, and more standard practices and less vibration producing activities, would be used as opposed to pile driving. Furthermore, some local agencies (e.g., San Joaquin County) exempt vibrations associated with construction provided it is occurring within certain hours (San Joaquin County n.d). However, if pile driving is used, and there are sensitive receptors to noise (e.g., homes, hospitals, schools) within close proximity, Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant noise impacts related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the potential location of possible sensitive receptors the duration of the particular noise generating activities over the course of construction. • Once operational, the new source water supply facilities would be located underground and may include some lift stations. Although the location of the lift pump stations is unknown, it is unlikely they would generate sufficient permanent noise to exceed noise standards established by a local general plan or noise ordinance. This is because they would likely be enclosed for security purposes by some type of enclosed structure or fencing that would reduce noise generated. As such, a permanent increase in ambient noise under operating conditions is not expected. Impacts would be less than significant. • Assuming construction and operation of new source water supply facilities would be located in San Joaquin County, there are six public access airports within the county (SJCOG n.d.[a]). The Stockton Metropolitan Airport, San Joaquin County Airport have approved Airport Land Use Compatibility Plans, which identifies noise contours

Potential Environmental Effects of New Source Water Supply Facilities	
Resource	Discussion
	and where noise exposures may take place as a result of aircraft flight patterns consistent with Federal Aviation Administration requirements (SJCOG n.d.[a]). Other airports, such as the City of Tracy, have either airport master plans or other planning documents (e.g., general plans) that outline noise contours consistent with FAA requirements (City of Tracy 1998). While it is unknown where construction or operation of new source water supply facilities might occur, the construction and operation of new source water supply facilities would not bring new or additional people within close proximity to an airport or private airstrip or expose people to noise generated by air traffic on a regular basis. This is because new source water supply facilities would not result in an increased permanent work force cited within proximity to an airport or private airstrip. Nor would new source water supply facilities result in a population increase that would be exposed to airport noise. Impacts would not occur.
Population and Housing	• The construction and operation of new source water supply facilities would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area because the new water supply would be in lieu of higher-salinity water and would not result in a greater supply of water (i.e., source water supply facilities would not be constructed and operated to increase capacity to serve new users). New source water supply facilities would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people to the southern Delta. In addition, construction and operation of new source water supply facilities would not displace existing housing because the facilities would be located either underground or on land likely designated for infrastructure. Impacts would be less than significant.
Public Services	• The need for additional public services (e.g., fire protection, police protection, parks, libraries, schools) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, construction and operation of new source water supply facilities would not involve an increase in population or housing. In addition, construction and operation of new source water supply facilities would not include proposals for new housing and would not generate students or increased demands for school services or facilities. Impacts would not occur.
Recreation	• Construction of new source water supply facilities would likely occur in the rights-of-way of public roads or adjacent to water supply infrastructure. If recreational facilities were located within very close proximity to construction, recreation could be affected by noise levels or other temporary construction activities. An increase in use of existing recreational facilities is typically associated with a substantial increase in the population to accommodate new recreationists. Construction or operation of new source water supply facilities would not result in a substantial increase in population because it would not result in the development of housing or other population-inducing development (e.g., job centers). The purpose of the construction and operation of new source water supply facilities would be to comply with water quality objectives. Construction and operation of these facilities would satisfy existing demand, not meet new projected demand for wastewater treatment (Sections 16.4.2, *Salinity Pretreatment Programs*, and 16.4.3, *Desalination*) or water supply. If construction occurs within

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	close proximity to existing recreational resources, Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to construction noise, traffic, or air quality, if those types of impacts occur within close proximity to existing recreational facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the construction timeframe and the location of potential sensitive receptors and recreational resources, and also because construction if certain components (e.g., segments of pipelines) would generally temporary and relatively short in duration. • Construction and operation of new source water supply facilities would not include recreational facilities or require the construction or expansion of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Assuming construction and operation of new source water supplies would be located within San Joaquin County, projects would be subject to the SJCOG Regional Congestion Management Program (SJCOG 2016b). A total of 103 intersections have been designated as part of San Joaquin County Council of Governments Regional Congestion Management Program (SJCOG n.d.[b]). Designation of RCMP intersections allows for congestion monitoring and appropriately focuses attention at locations where operational constraints are typically experienced on arterial roadways (SJCOG n.d.[b]). As described in the Regional Congestion Management Program, projects are subject to a tiered review process, unless exempt from CEQA or unless considered as part of a previously. Projects that trigger 125 or more vehicle trips during weekday AM or PM peak-hours or 500 or more total vehicle daily trips on any day of the week would be required to perform a quantitative regional traffic analysis. The Regional Congestion Management Program provides for mitigation to reduce effects approved project (SJCOG 2016b) if trips occur at those levels. Trips that are exempted from the RCMP standards, and are removed from calculations of LOS standards under the RCMP include trips resulting from construction (SJCOG 2013). Regional deficiencies have been identified on portions of congestion management program roadway segments in San Joaquin County, including Intrastate-5 and State Routes (SR) 4, 88, 99, and 120 because they are operating at a level of service (LOS)[21] of E or F (Table 2 in Dowling Associates 2010). Several congestion management program roadway segments are also operating at LOS D (Table 3 in Dowling Associates 2010). Of approximately 1,500 congestion management roadway segment miles, 245 operate at LOS D, with approximately half of these in the County, and the remaining in the cities of Stockton, Lathrop, and Manteca and Tracy (Table 4 in Dowling Associates 2010). There are approximately 92 miles of CMP lanes operating at LOS E or F, with more than half located in county areas, and 16 percent in Stockton (Table 4 in Dowling Associates 2010). Operation of new source water supply

---

[21] Level of Service is a standard transportation evaluation term and is a qualitative measure of traffic operating conditions or system adequacy. It is typically defined on a scale using the letters A through F (best to worse). LOS A is free flowing conditions with little or no delay and LOS E is flow conditions at traffic volumes at or near design capacity. LOS F represents unstable forced flow exceeding capacity, resulting in greatly reduced travel speeds.

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	facilities would likely not generate additional trips beyond those required to maintain the existing facilities and would likely not exceed the thresholds identified in the RCMP (e.g., 125 or more vehicle trips during weekday AM or PM peak-hours or 500 or more total vehicle daily trips on any day of the week). This is because would be unlikely that operation of the facilities would result in a substantial increase in the number of water district or municipality employees. Therefore, construction and operation of new source water supply facilities is expected to comply with the RCMP. Impacts would be less than significant. • Construction and operation of new source water supply facilities could result in some additional trips. These facilities may be located in urban and suburban areas that could already experience some congestion on existing roadways. It is unknown the number of construction and operational trips that might be needed for these facilities and the location of these trips, but it is anticipated that construction would be relatively limited in duration and the number of operational trips would be limited, given a substantial increase in the number of water district or municipality employees is not expected. Typically, construction activities are exempt from local road trip thresholds because construction is considered temporary; however, depending on the quantity of trips, and the duration, a temporary increase in traffic during construction or under operating conditions could exceed local road trip thresholds (either vehicle miles traveled or level of service[22]). Projects would be required to evaluate trip generating activities through the respective jurisdiction traffic impact analysis guidelines, depending on the location and number of trips generated (City of Stockton n.d.). Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts of transportation and traffic related to construction or operation. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because construction impacts would be temporary and because operations are not expected to result in a substantial increase in employees. • Construction of new source water supplies is not expected to result in hazards to, or on, roadways because they would primarily be constructed within existing footprints of facilities or along the rights-of-way of roads. The development of project-specific construction traffic management plans, as identified in Table 16-38 would reduce potentially significant impacts if hazards on the roadway were temporarily created during construction due to

---

[22] In January of 2016, the Office of Planning and Research (OPR) prepared a revised proposal on updates to State CEQA Guidelines for evaluating transportation impacts. The proposed methodology to evaluate transportation impacts includes replacing the standard level of service (LOS) evaluation with vehicle miles traveled (VMT) as identified in Senate Bill 743 (Steinberg, 2013). In the proposal, OPR recommends the new procedures and methods remain optional for a two-year period. This would allow agencies that are ready to switch from LOS to VMT to do so, but gives time to other agencies that may need to adjust protocols and data sources. OPR formally closed comment period on the proposal at the end of February 2016. OPR will submit a draft of the proposed revisions based on vehicle miles traveled to the Natural Resources Agency, which would then commence with a formal rule making process. (OPR 2016.)

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	lane closures or other types of construction related activities. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts of transportation and traffic related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because construction impacts would be temporary. • Similar to the discussion in Hazards and Hazardous Materials, it is not expected that construction of new source water supplies to result in inadequate emergency access, given the location of the construction work would primarily be on the rights-of-way of roads or within the existing footprint of water supply facilities. However, Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with traffic and potential conflicts with emergency response. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. It is likely that impacts would be mitigated to less than significant once mitigation measures were implemented given construction would be temporary. • The Regional Congestion Management Program identifies multimodal corridors within the county where the operational performance of pedestrian, bicycle, transit passengers, and motorists are considered holistically (SJCOG 2012a). In addition, the Regional Congestion Management Program identifies a regional bikeway network throughout the county with existing and planned bikeways (SJCOG 2012b). Construction of new source water supplies may temporarily conflict with public transit or bicycle or pedestrian facilities if lane closures are required during construction. Depending on the location, this could temporarily remove these types of facilities, if construction activities need to occur immediately adjacent to them. However, the project-specific congestion management plans identified in Table 16-38 would include details of transit facility closures or relocations, and procedures for re-routing pedestrian or bicycle traffic, based on the particular circumstance of the project-specific location and construction activity. As such, Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts associated with public transit facilities, bicycle facilities, or pedestrian facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary. • Construction and operation of new source water supplies would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and is not related to air traffic or airports. Impacts would not occur. • Operation of new source water supply facilities is not expected to result in a permanent substantial increase in hazards due to a design feature or incompatible use, permanent inadequacy of emergency access, or a permanent

Potential Environmental Effects of New Source Water Supply Facilities

Resource	Discussion
	change that would decrease the performance or safety of public transit facilities, public biking facilities, or public pedestrian facilities because it is anticipated that some of the new source water supply facilities would be underground in operating conditions. For those facilities that would be above ground, they would comply with safety requirements and local building requirements ensuring access and safety. Impacts would be less than significant.
Utilities and Service Systems	• Construction and operation of new source water supply facilities is not be expected to exceed wastewater treatment requirements of the Central Valley Water Board because it would not involve the discharge of treated effluent. Instead, it would actually help comply with effluent limitations for salinity because it is expected the lower-salinity source water would result in lower-salinity treated effluent discharged into the southern Delta. Additionally, it would not increase the volume of wastewater delivered to the WWTP or result in a determination by the wastewater treatment provider that it has inadequate capacity to meet the service area's demand for wastewater treatment. Impacts would be less than significant. • Construction and operation of new source water supply facilities would not involve the construction of wastewater treatment facilities. Impacts would not occur. • Construction and operation of new source water supply facilities does involve the construction of water supply infrastructure. Environmental effects associated with water supply infrastructure are discussed earlier in this table (Aesthetics through Transportation and Traffic). Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant construction and operation impacts related to all environmental resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Construction and operation of new source water supply facilities are not expected to require construction of additional storm water drains because the facilities would either be underground (e.g., pipelines) or be conveyance canals that would not generate substantial volumes of runoff. Existing storm water infrastructure is expected to be sufficient. Impacts would be less than significant. • In order to operate the new source water supply facilities municipalities may need to enter into contracts to purchase surface water from senior surface water users. It is anticipated that the new source water would come from existing entitlements and either purchased through different contracted vehicles, or potentially transferred, to municipalities. As such, it is not expected new entitlements for surface water would be needed. Impacts would be less than significant. • Construction and operation of new source water supply facilities would be unlikely to generate substantial amounts or increase solid waste. The new source water supply facilities would move water from one location to another and would not generate solid waste. Solid waste generated during construction would be disposed of at landfills and would comply with all applicable laws related to construction debris recycling and solid waste disposal in California. Impacts would be less than significant.

16.4.2 Salinity Pretreatment Programs

A salinity pretreatment program would target salinity loading in a wastewater service provider's wastewater collection system from domestic (residential) and CII sources. It would provide salinity source controls at different locations within a service district to reduce the overall salt loading into the sewer system.

Domestic water similar to that found in the southern Delta may have a high concentration of minerals (typically magnesium and calcium). Water softeners are frequently used in residences to remove these minerals. During a water softener's recharge cycle, brine is used to clean the system and remove magnesium and calcium that accumulate in the mineral exchange tank. The recharge water, with suspended minerals, is then discharged to the wastewater collection system. This brine[23] and mineral solution is rarely treated at a wastewater treatment facility. By removing self-regenerating (or "automatic") water softeners, there would be a reduction of salinity discharged to the wastewater collection system, and as a result, salinity in the effluent discharged in the southern Delta would be reduced. Many wastewater treatment agencies operate a water softener buy-back program to remove water softeners from domestic use.

Salts also can enter the wastewater collection system as a byproduct commercial activities, industrial processes, and food preparation activities. CII dischargers can contribute to elevated salt loads entering the wastewater collection system and discharging into the southern Delta. Some CII sources of salinity are commercial laundry facilities, food processing operations, and industrial fabrication shops. To address salinity loading by CII dischargers, many wastewater treatment agencies prohibit CII users from discharging to the wastewater collection system or strictly regulate the quality of wastewater entering the wastewater collection system. To reduce the wastewater salt concentration from CII sources, a variety of pollution-control methods can be used, such as BMPs and desalination devices, depending on the activities conducted by the CII discharger. These methods are typically applied at the CII source generating the wastewater.

Cost Evaluation

Many wastewater treatment agencies offer rebate programs for removal of water softeners. Currently, the Inland Empire Utilities Agency (IEUA) and the Los Angeles County Sanitation Districts (LACSD) offer $206–$2,000 to homeowners to remove water softeners (Proctor pers. comm., Ghuman pers. comm.). Rules for each agency's programs differ, but in general, once a homeowner certifies that the water softener is removed (and it is later verified by the wastewater treatment agency), the wastewater treatment agency will reimburse the homeowner for the cost of removal.

To operate a water softener buy-back program, a wastewater treatment agency must advertise the program, coordinate inspections, process rebate claims, and conduct verification inspections. In some cases, the wastewater treatment agency will hire a plumber to remove water softeners. The administrative support for an in-home water softener rebate program varies. Table 16-26, *Inland Empire Utilities Agency Water Softener Buy-Back Program Costs*, and Table 16-27, *Los Angeles County Sanitation Districts Water Softener Buy-Back Program Costs,* offer general program costs for IEUA and LACSD.

---

[23] Brine is the saline solution prevented from traveling through an RO filter.

High and low estimates for water softener buy-back program costs were obtained by dividing the amount each entity spent on rebates by the upper and lower bounds of the eligible rebate amounts, which provided a high and low estimate of the number of rebates issued. The total program cost was divided by the estimated number of rebates issued to obtain a per rebate cost.

NA = not applicable.

Based on the information presented in Table 16-26, *Inland Empire Utilities Agency Water Softener Buy-Back Program Costs* and Table 16-27, *Los Angeles County Sanitation Districts Water Softener Buy-Back Program Costs*, if a wastewater treatment agency anticipates replacing 2,000 water softeners over 5 years, the agency can reasonably expect to pay $920,000–$9,020,000 over a period of 5 years.

Processes to pretreat CII wastewater vary due to discharger type and source. In some cases, an activity can be modified to reduce the amount of salts discharged to the wastewater collection system. Some general examples of BMPs that a wastewater treatment agency's pretreatment program could implement to reduce salinity are to conserve water, pretreat water, install a desalination device, reduce water runoff, use process water for landscape irrigation, or dispose of solids in landfills instead of in the wastewater collection system.

The costs of some BMPs (e.g., disposing of solids in landfills) have nominal costs (e.g., higher garbage removal cost). Other BMPs may save the CII discharger money (e.g., using process water for landscape irrigation could reduce the user's monthly water bill).

When a CII discharger decides to install a desalination device, costs vary based on what is being discharged, the volume, and the desired wastewater salt concentration entering the wastewater collection system. Some light commercial reverse osmosis (RO) filtration systems cost as little as $1,000 to install and $200 per year to operate. These systems would treat the domestic water supply for the specific discharger, but the waste brine from the RO process must be thrown away in a landfill and not discharged to the wastewater collection system. Other systems cost millions to install and tens of thousands to operate per year, per user. In some areas, the wastewater treatment agency will bear the cost of procuring and installing a CII pretreatment device; in other areas, the costs will be split between the CII discharger and the wastewater treatment agency.

Environmental Evaluation

Summary of Potential Action

Salinity pretreatment programs would provide salinity source controls at residential homes or existing CII facilities within a wastewater treatment service provider's service area. It is anticipated that the following municipalities and wastewater treatment service providers that discharge into the southern Delta could implement such programs: City of Tracy, City of Stockton, and Mountain House CSD. The decision to implement pretreatment programs would include many variables, such as the type and number of CII wastewater dischargers in the service area of each service provider and the availability of funding to implement a residential home program.

For residential homes, the program would request or compensate residential users to modify their activities. For CII users, a salinity pretreatment program would be expected to modify existing CII processes and/or require the construction and operation of salinity source controls, such as RO. These salinity source controls would be located at existing CII facilities. The location, timing of construction, and details of operation of CII salinity source controls is unknown. However, any new salinity source controls at an existing CII facility would likely be constructed and operated within an existing CII facility footprint or within close proximity. This is because salinity source controls would have to be integrated with the CII water supply connection or wastewater discharge to capture and treat the water either prior to the CII process or capture and treat it prior to discharge into the sewer system. It is expected that the CII facility would be located in urban areas with other CII uses because generally land uses such as these are located in appropriately designated and zoned areas of municipalities. It is anticipated these salinity source controls at CII facilities would not require additional employees and would not modify or change the volume of CII wastewater discharged into the sewer system. However, it is anticipated the salt concentration of the wastewater would be lower as the salinity source controls would reduce the salinity of the wastewater.

Potential Environmental Effects

For CII users, a salinity pretreatment program would be expected to modify existing CII processes and/or require the construction and operation of salinity source controls, as described above. These salinity source controls would be located at existing CII facilities because salinity source controls would have to be integrated with the CII water supply connection or wastewater discharge to capture and treat the water either prior to the CII process or capture and treat it prior to discharge into the sewer system. Depending on the scale and magnitude of the changes to CII facilities they could meet the requirements of a categorical exemption under CEQA. CEQA allows categorical exemptions for classes of projects which have been determined not to have a significant effect on the environment. (Pub. Res. Code, § 21084.) Specifically, the following types of facilities and activities are exempt under a Class 1 or Class 3 categorical exemption.

- Minor alterations of the existing public or private structure without expanding existing uses.
- Installation of small new equipment and facilities.

In addition, Class 2 categorical exemptions allow for the replacement or reconstruction of existing facilities where the new structure will be located on the same site and will have the same purpose and capacity as the structure replaced. Some fish screen projects could meet the requirements for this exemption.

If salinity control measures at CII facilities do not meet the requirements of a categorical exemption, depending on the size of disturbance, construction may result in temporary and localized effects typically associated with construction activities. As such, installation of salinity control equipment at existing CII facilities could involve short-term construction-related effects, such as air quality and ground-disturbing effects. Any construction of new facilities at existing CII locations would not be likely to affect natural or cultural resources (significant historical, archaeological, or paleontological resources) as those locations because these areas are already highly disturbed. Programs involving residential users would be expected to have less-than-significant environmental effects. There may be some highly concentrated salt waste as a result of the operation of the pretreatment salinity source controls. This concentrated waste could not be disposed of in the sewer and would likely need to be trucked offsite and disposed of in an appropriate landfill depending on the waste classification and in compliance with all applicable laws, ordinances, and regulations. To the extent such programs were successful in reducing salinity in the southern Delta, agricultural uses and aquatic resources would benefit.

Table 16-28, *Potential Environmental Effects of Salinity Source Controls*, summarizes the potential environmental effects associated with salinity source controls at CII facilities. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions,* at the end of this chapter, lists potential mitigation measures associated with the construction or operation of the methods of compliance and is referenced in Table 16-28 where appropriate.

Table 16-28. Potential Environmental Effects of Salinity Source Controls

Potential Environmental Effects of Salinity Source Controls	
Resource	Discussion
Aesthetics	• Construction and operation of salinity source controls at existing CII facilities would not be expected to substantially degrade the visual character or quality of areas, have a substantial adverse effect on a scenic vista, or substantially damage scenic resources within the state-designated scenic highways in San Joaquin County, I-5 and I-580, because the facilities would be located within the existing footprint of other CII facilities. The salinity source controls would be either much smaller than the existing CII facilities or similar in size and scale as the existing facilities so the wastewater generated by the CII process can be targeted and treated. Construction and operation of salinity source controls may involve operational and safety lights. Impacts associated with lighting would depend on the location of sensitive receptors to potential lighting; however, lights would be expected to follow lighting guidelines and lighting plans of local jurisdictions approving the construction and operation of the salinity source controls. In addition, as stated above, the salinity source controls would likely be within existing CII facilities and infrastructure, which may already have operational and safety lighting, and thus it would likely not be necessary to add additional lighting. If sensitive receptors are present, Table 16-38 identifies potential mitigation measures lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant environmental effects associated with lighting. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented depending on the possible location of potential sensitive receptors and the ability to reduce light and glare
Agriculture and Forestry Resources	• Construction and operation of salinity source controls would not be expected to be located on lands used for agriculture or directly or indirectly convert agricultural lands (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) to nonagricultural uses because the salinity source controls would be located within the footprint of existing CII facilities. Because salinity source controls would likely not be located on agricultural lands, there would not be a conflict with existing zoning for agricultural use, or a Williamson Act contract. Additionally, it is expected that agricultural uses in the southern Delta would benefit from the reduction in salinity and potentially offset any agricultural land that might be indirectly affected by the salinity source controls. Impacts would not occur. • Construction and operation of salinity source controls would not be expected to be located on forest land or timberland or result in the conversion of those resources because these resources are limited in the southern Delta, and because the salinity source controls would be located within the footprint of existing CII facilities. Therefore salinity source controls would not conflict with existing zoning for, or cause rezoning or loss of these resources. Impacts would not occur.
Air Quality	• CII facilities that would implement salinity source controls would likely be constructed and operated within the SJVAB, which generally covers San Joaquin, Stanislaus, Merced, and Madera Counties. USEPA has classified SJVAB as an extreme nonattainment area for the federal 8-hour ozone standard and a nonattainment area for the federal PM2.5 standard. For the federal CO standard, USEPA has classified most major population centers of the SJVAB as maintenance areas and rural areas of the SJVAB as unclassified/attainment areas. The SJVAB is classified as a serious maintenance area with regards to the federal PM10 standards. ARB has classified the SJVAB as a severe nonattainment area for the state 1-hour ozone standard

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	and a nonattainment area for the state 8-hour ozone, PM10, and PM2.5 standards. ARB has classified the SJVAB as an attainment area for the state CO standard. SJVAPCD's published guidelines, *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002) do not require the quantification of construction emissions. Rather, the guidelines require implementation of effective and comprehensive feasible control measures to reduce PM10 emissions (SJVAPCD 2002). SJVAPCD considers PM10 emissions to be the greatest pollutant of concern when assessing construction-related air quality impacts and has determined that compliance with its Regulation VIII, including implementation of all feasible control measures specified in its *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), constitutes sufficient mitigation to reduce construction-related PM10 emissions to less-than-significant levels and minimize adverse air quality effects. All construction projects must abide by Regulation VIII. Since the publication of SJVAPCD's guidance manual, the district has revised some of the rules comprising Regulation VIII. Guidance from SJVAPCD staff indicates that implementation of a Dust Control Plan would satisfy all of the requirements of SJVAPCD Regulation VIII (Siong pers. comm.). Further consultation with SJVAPCD staff indicates that, though explicit thresholds for construction-related emissions of ozone precursors are not enumerated in the *Guide for Assessing and Mitigating Air Quality Impacts*, SJVAPCD considers it a significant impact when construction or operational emissions of ROG or NO_X exceed 10 tons per year or if PM10 or PM2.5 emissions exceed 15 tons per year (Siong pers. comm.). SJVAPCD's CEQA Guidelines indicate their numeric thresholds are project-level and cumulative: "Any proposed project that would individually have a significant air quality impact…would also be considered to have a significant cumulative air quality impact (SJVAPCD 2002)" • Construction of salinity source controls would likely result in emissions associated with construction equipment, construction worker vehicle trips, and fugitive dust emissions from ground disturbance. The quantity, duration, and intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations that occur at any one time. More emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Depending on the level of activities and amount of infrastructure built, construction of salinity source controls could exceed air quality thresholds established by SJVAPCD and would be required to implement measures to help reduce or minimize construction-related emissions. Lead agencies (e.g., CII facilities or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on air quality associated with construction emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the regulatory requirement to implement all required feasible measures to • reduce emissions during construction and the potential for the duration and frequency of activities during construction to

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	reduce overall emissions (e.g., diluting emissions over time). • Prior to a project dealing with a stationary source of emissions (such as a CII facility), it is required to receive an ATC from SJVAPCD. The project is subject to the requirements of SJVAPD Rule 2201. As stated under Sections 1.1 and 1.2 of Rule 2201[24]: *The purpose of this rule is to provide for the following:* *1.1 The review of new and modified Stationary Sources of air pollution and to provide mechanisms including emission trade-offs by which Authorities to Construct such sources may be granted, without interfering with the attainment or maintenance of Ambient Air Quality Standards;* *1.2 No net increase in emissions above specified thresholds from new and modified Stationary Sources of all nonattainment pollutants and their precursors.* Rule 2201 applies to new stationary sources and all modifications to existing stationary sources that are subject to permit requirements and may emit one or more affected pollutant after construction. • Operation of salinity source controls could include facility inspection and maintenance activities, similar to the maintenance of existing CII facilities. Operation of salinity source controls would likely be electric because of their expected locations in urban and suburban areas and the expected location within the footprint of a CII facility. Salinity source controls may use nonelectric backup intermittently for emergency circumstances. Operations could include facility inspection and maintenance activities and are expected to be similar to or fewer activities than inspection and maintenance of existing wastewater treatment facilities. The need for additional energy could result in increased criteria pollutant emissions at other power facilities. However, the power facilities that would compensate for the additional power are already built and permitted to emit a maximum amount of criteria pollutants. These facilities are required to offset additional power generation by the use of pollution credit. Therefore, if additional emissions are generated, they would be generated by facilities that are permitted to do so. There would be an increased number of truck trips associated with the disposal of salt concentrate at landfills, and these trips would produce emissions. The number of truck trips would depend on the salinity of the wastewater, which is a function of the quality and volume of the influent and the CII process, which is unknown at this time, and therefore cannot be quantified in this analysis. However, depending on the amount of materials that would require disposal and number of haul trucks that would be required, operational activities associated with material hauling could result in exceedances of SJVAPCD's thresholds, as SJVAPCD's CEQA Guidelines indicate their numeric thresholds are project-level and cumulative: "Any proposed project that would individually have a significant air quality impact…would also be considered to have a significant cumulative air quality impact (SJVAPCD 2002)". This could result in a potentially significant impact. Lead agencies (e.g., CII facilities or municipalities) can and should implement potential mitigation

---

[24] Sources whose primary function is permitted by SJVAPCD through Rules 2010 and 2201 are not subject to SJVAPCD Rule 9510 (Indirect Source Review). Projects subject to Rule 9510 are required to quantify and reduce indirect (mobile source emissions), area-source (space heating, landscaping, and maintenance), and construction exhaust emissions.

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	measures identified in Table 16-38 to reduce potentially significant environmental effects associated with operational emissions and air quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.
	• SJVAPCD generally defines a sensitive receptor as a facility that houses or attracts children, the elderly, people with illnesses, or others who are especially sensitive to the effects of air pollutants, and where there is a reasonable expectation of continuous human exposure according to the averaging period for National AAQSs (e.g., 24-hour, 8-hour, or 1-hour) (SJVAPCD 2002). Sensitive receptors are primarily concentrated in urbanized areas and their proximity to construction or operational activities, the type of activity, and duration of activity, determines their potential exposure to pollutants. If criteria pollutant standards are exceeded during construction, and sensitive receptors are in proximity, mitigation measures identified in Table 16-38 would serve to reduce potentially significant air quality effects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. It is not anticipated that operation of the facilities would expose sensitive receptors to substantial pollutant concentrations because operations would not generate toxic or diesel exhaust. If diesel generators were used, they would be limited in operation and would likely be subject to air district permitting requirements that would minimize health risks. Impacts on sensitive receptors related to operation of salinity source controls would be less than significant. • The ARB traditionally has established state air quality standards, maintaining oversight authority in air quality planning, developing programs for reducing emissions from motor vehicles, developing air emission inventories, collecting air quality and meteorological data, and approving State Implementation Plan, as required by the Clean Air Act provisions. Responsibilities of local air districts include overseeing stationary source emissions, approving permits, maintaining emissions inventories. SJVAPCD has adopted an air quality improvement plan that addresses NO_X and ROGs, both of which are ozone precursors and contribute to the secondary formation of PM10 and PM2.5. The plan specifies that regional air quality standards for ozone and PM10 concentrations can be met through the use of additional source controls and trip reduction strategies. It also establishes emission budgets for transportation and stationary sources. Those budgets, developed through air quality modeling, reveal how much air pollution can be present in an area before national AAQSs are violated. General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction and operation of salinity source controls would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with air quality plans if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air plans. The construction and operation of salinity source controls would not result in growth because it would serve to provide salinity source controls at different locations within a service district to reduce the overall salt loading into the sewer system and would not serve to satisfy an increase in demand or an increase in need. The construction and operation of salinity source controls would not result in population or employment growth that would result in a conflict

Potential Environmental Effects of Salinity Source Controls	
Resource	Discussion
	with or obstruct implementation of the applicable air quality plan because they would not require activities that are associated with population growth (e.g., housing development, business centers, etc.). Accordingly, this impact is less than significant. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). While salinity source controls may be applied at one or more of these types of facilities, the salinity source controls would not contribute to any odors that would already be produced by the facilities. This is because the salinity source controls take the facilities' source water or wastewater and remove salt. Therefore, construction and operation of salinity source controls would not create objectionable odors affecting a substantial number of people. Impacts would be less than significant.
Biological Resources	• It is expected that construction and operation of salinity source controls would be in urban and suburban areas within the footprint of existing CII facilities. These areas are expected to have a low potential for candidate, sensitive, or special-status species, and habitat (including federally protected wetlands, riparian habitat, or other sensitive natural communities) because urban and suburban areas typically have buildings and impervious surfaces and would be very unlikely to support these biological resources. Because of their location, construction and operation of salinity source control facilities are unlikely to interfere with the movement of any native resident or migratory fish or wildlife species, or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites. Furthermore, it is expected that the treated effluent discharged from the WWTP would actually have lower concentration of salts due to the salinity source controls, and this would be beneficial to aquatic and other biological resources. If candidate, sensitive, or special-status species or habitats are identified within close proximity, Table 16-38 lists potential mitigation measures lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant environmental impacts on biological resources related to construction and operations of salinity source control facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the low potential for sensitive species and habitat to exist and the relatively short timeframe and duration of construction. • It is unlikely construction and operation of salinity source controls would conflict with local policies or ordinances protecting biological resources, or conflict with an adopted natural community conservation plan or habitat conservation plan because construction and operation would likely occur within existing facilities. However, construction and operation of salinity source control facilities would occur within the SJMSCP Plan Area. The SJMSCP is administered by the SJCOG, a non-profit corporation established by San Joaquin County and the cities of Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton and Tracy. Implementation of new salinity source controls may be considered a covered activity under SJMSCP—a determination which would be made by SJCOG, in consultation with the lead agency. If an activity is determined to be covered, participation in the SJMSCP is voluntary except when conditioned to participate by a Permittee (i.e., SJCOG, Inc. San Joaquin County, and the cities of Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton and Tracy). If an activity is not covered,

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	the lead agency can request coverage using one of the following four options: (1) payment of a fee, which is assessed depending on habitat type within which the project is located; (2) dedicate habitat lands as a conservation easement or fee title; (3) purchase mitigation bank credits from a SJCOG-approved mitigation bank; and (4) propose an alternative mitigation plan, consistent with the goals of the SJMSCP and equivalent in biological value. Participation in the SJMSCP fulfills ESA, CESA, NEPA, and CEQA requirements, provides mitigation and guarantees no additional mitigation, excepting for Incidental Take Minimization Measures required in limited cases (SJCOG 2016a). If the lead agency participates in the SJMSCP, construction and operation of salinity source control facilities would not be considered in conflict with the SJMSCP, and impacts would be less than significant. If the lead agency chooses to opt out of participation in the SJMSCP, that agency or agencies (e.g., municipalities or municipal water purveyors) can and should implement the mitigation measures identified in Table 16-38 to reduce potentially significant impacts on biological resources and to avoid conflict with the SJMSCP. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. If habitat is permanently removed as a result of constructing or operating salinity source control facilities, it is likely that impacts could not be mitigated and would remain significant and unavoidable. However, it is likely impacts could be reduced once mitigation was implemented because once a lead agency opts in or determines its action is covered, consistency would be determined and impacts would be less than significant. • The brine generated by salinity source controls would be disposed of at landfills, and would have a very low potential to affect biological resources because the brine would be contained within the landfill. Impacts would be less than significant.
Cultural Resources	• Construction and operation of salinity source control facilities would likely exist in urban and suburban areas within existing CII facilities. Construction may result in some ground-disturbing activities, which has the potential to disturb or destroy buried, unknown significant cultural resources (significant historical, archeological, or paleontological resources). While it is unknown if cultural resources exist in these locations, these areas would have likely been previously disturbed during the construction of the existing CII facilities, reducing the potential for significant unknown cultural resources to exist. Operation of salinity source controls has no potential to affect cultural resources because the facilities would simply remove salt and discharge wastewater of lower salinity into the sewer system. Lead agencies (e.g., CII facilities or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on cultural resources associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the low potential for cultural resources to exist and the relatively limited area of ground disturbance. • As described above, it is expected the CII facility locations would be previously disturbed. If, in the highly unlikely event human remains are uncovered during construction, compliance with the State Health and Safety Code would be required. As specified by Section 7050.5 of the Health and Safety Code, and described in Table 16-38, no further disturbance shall occur until the county coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code, Section 5097.98. If such a discovery occurs, excavation or construction shall halt in the area of the discovery, the

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	area shall be protected, and consultation and treatment shall occur as prescribed by law. If the coroner recognizes the remains to be Native American, he or she shall contact the NAHC, who shall appoint the Most Likely Descendent. Additionally, if the human remains are determined to be Native American, a plan shall be developed regarding the treatment of human remains and associated burial objects, and the plan shall be implemented under the direction of the Most Likely Descendent. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the low potential for human remains to exist and the relatively limited area of ground disturbance.
Geology and Soils	• Salinity source controls would not result in an impact on, or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, or landslides. Since the facilities would be located within existing CII facilities, the addition of the salinity source controls would not substantially add to the structure such that it would increase the exposure to potential substantial adverse effects, such as risk of loss to rupture of known earthquake fault, seismic ground shaking, or seismic ground-related failure. Furthermore, all new structures related to salinity source controls would be required to follow all appropriate building codes and be designed to withstand seismic-related activities as identified by the building codes. Finally, salinity source controls would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would be less than significant. • The construction and operation of salinity source controls would not involve constructing or operating septic tanks and, therefore, septic tanks would not be affected by soils incapable of supporting the use of them or other alternative wastewater disposal systems. Impacts would not occur. • Construction of salinity source control facilities could result in limited ground-disturbing activities, which could cause soil erosion or loss of topsoil; however, ground-disturbing activities would be limited in duration and geography and would most likely be contained within the site of an existing CII facility. Furthermore, ground-disturbing activities of 1 acre or greater would need the preparation and implementation of a SWPPP as required by the Central Valley Water Board. The SWPPP would require soil and erosion control mechanisms. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts related to soil erosion and storm water runoff and erosion associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented due to the temporary nature of construction and the relatively small scale of disturbance within or adjacent to an existing facility.

Potential Environmental Effects of Salinity Source Controls	
Resource	Discussion
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-7, because construction and operation of salinity source control facilities would likely result in increased use of electricity and fuels and there would be an increase in GHG emissions. Depending on the process used (e.g., RO) salinity source controls could be an energy-intensive process (e.g., RO energy use will vary depending on the salinity and temperature of the source water or wastewater; the higher the salinity or the colder the water temperature, the more energy it takes to remove the salt [Kennedy/Jenks Consultants 2013]). The overall increased electrical load would be extremely small compared to the existing electrical load of the service area and it is unlikely to require the construction of major new power generation or transmission facilities. However, it is anticipated that this increased electricity-related GHG emissions could exceed applicable SJVAPCD ZEL thresholds and result in a potentially significant impact. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Potential Environmental Effects of Salinity Source Controls	
Resource	Discussion
Hazards and Hazardous Materials	• Construction of salinity source controls would be short term in nature and may involve the limited transport, storage, use, and disposal of hazardous materials such as fuel and lubricating grease for motorized heavy equipment. Some examples of typical hazardous materials handling are fueling; servicing construction equipment on the site; and transporting fuels, lubricating fluids, solvents, and bonding adhesives. These types of materials are not acutely hazardous, and all storage, handling, and disposal of these materials are regulated by local, county, and state laws. Furthermore, the quantities of these materials used during construction would be small (e.g., less than 100 gallons) because construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction and the small amount of hazardous materials handled, used, or transported over the course of construction. • There are eight sites within San Joaquin County that are identified on the Hazardous Waste and Substance Site List (Cortese Site list) as being hazardous materials sites under Government Code, § 65962) (CalEPA 2016). Construction and operation of salinity source controls is not likely to be located on these eight sites or interfere with these sites because these sites are not CII facilities (e.g., commercial laundry facilities, food processing operations, and industrial fabrication shops) (CalEPA 2016). CalEPA identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facility sites where DTSC has taken corrective action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action in San Joaquin County (CalEPA 2016). As such, construction and operation of salinity source controls could not affect them. There are approximately 244 leaking underground storage cases in San Joaquin County designated as open (CalEPA 2016). Sixteen facilities in San Joaquin County have received CDOs or CAOs and have active cases, but may not be necessarily related to hazardous waste (CalEPA 2016). Some of these locations could be classified as CII facilities and may decide to implement salinity source controls (e.g., commercial laundry facilities, food processing operations, and industrial fabrication shops). During construction ground disturbing activities potentially contaminated soil could be encountered. As such, Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • San Joaquin County has 14 school districts and more than 200 schools (San Joaquin County Office of Education n.d.). The location of construction of salinity source controls is unknown; however, construction could be located within one-quarter mile (0.25 miles) of a school. Hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected these would be handled, used, and stored properly in accordance with local, state, and federal laws, and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school.

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation activities. As such, if a school existed within close proximity to a construction site, those mitigation measures identified table 16-38 applied to project-specific construction needs would reduce potentially significant impacts during construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • Operation of salinity source controls would not produce any new wastewater that would not already be produced and discharged to the sewer system and ultimately treated at the WWTP. If municipal wastewater already contains constituents, they should not be hazardous due to pretreatment requirements with which CII facilities must comply. Therefore, when compared to baseline, no new quantities of hazardous materials would be used, transported, or disposed of. There could be a new waste stream (e.g., salt concentrated waste) generated from the CII facility that would need to be removed and disposed of in accordance with applicable laws and regulations. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during operation. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the need to comply with state and federal regulations in order to conduct business and operate. • Assuming construction and operation of salinity source control measures would be located in San Joaquin County, there are six public access airports within the county (SJCOG n.d.[a]). The Stockton Metropolitan Airport and San Joaquin County Airport have approved Airport Land Use Compatibility Plans, which prescribe safety requirements and ensure land uses would not pose a safety hazard to the airports in accordance with the Federal Aviation Administration. Other airports, such as the City of Tracy, have either airport master plans or other planning documents outlining safety requirements and ensuring land uses would not pose a safety hazard, consistent with FAA requirements (City of Tracy 1998). The location of the CII facilities that may implement salinity source controls is unknown and these facilities could be located within 2 miles of an airport. However, construction and operation of salinity source controls would not be a hazard or provide a safety concern to airports since salinity source controls would be constructed and operated within the footprint of existing CII facilities and the CII facilities already exist. Impacts would not occur. • Construction and operation of salinity source controls would not physically interfere with an adopted emergency response plans or emergency evacuation plans since they would be located within exiting CII facilities and would not prohibit the mobility of people to escape potential emergencies. Furthermore, construction and operation does not involve an increase in population that would necessitate reconsideration of how to evacuate people in an emergency. Impacts would not occur. • Construction and operation of salinity source controls would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur.

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
Hydrology and Water Quality	• Construction of salinity source controls could result in temporary changes to storm water drainage, existing drainage patterns, erosion, or runoff associated with typical construction activities, such as grading or preparation of land. As discussed earlier in this table (Geology and Soils section), for soil disturbance of over 1 acre, wastewater treatment special districts or municipalities would be required to prepare and implement a SWPPP, which would include specific types and sources of storm water pollutants, determine the location and nature of potential impacts, and specify appropriate control measures to eliminate any potentially significant impacts from storm water runoff on receiving waters. In addition, as discussed in this table for Hazards and Hazardous Materials, construction of salinity source controls may involve the limited transport, storage, use, and disposal of hazardous materials, which, if spilled, could have adverse effects on water quality depending on the location and magnitude of the spill. However, storage, handling, and disposal of these materials is regulated by local, county, and state laws, and the quantities of these materials used during construction would be small (e.g., less than 100 gallons) and construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained and, as such, violations of water quality standards are not expected to occur. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary and the need to follow existing regulations requiring the handling, use and disposal of hazardous materials and the need to prepare SWPPPs. • It is unknown if CII facilities implementing salinity source controls would be located in a 100-year flood hazard area. However, since salinity source controls would be located within an existing CII facility footprint, the addition of salinity source controls would not substantially add to the existing structures such that flood flows would be impeded or redirected. Furthermore, salinity source controls would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to flood hazard locations or result in the construction of housing in a flood hazard area. Accordingly, salinity source controls would not expose people to significant loss, injury, or death related to flooding. Construction of salinity source controls would not result in flooding or otherwise cause flooding, including flooding as a result of the failure of a levee or dam. Impacts would be less than significant. • Under operating conditions, CII facilities would continue to discharge pretreated wastewater into the sewer and would have to comply with the pretreatment requirements of the receiving WWTP. The pretreatment requirements are in place such that the WWTP can meet the WDRs of its NPDES permit. While there could be an exceedance in wastewater treatment effluent by a CII facility due to an unforeseen circumstance, it would not be expected under normal operating procedures. Salinity source controls would not increase the volume of wastewater discharged from the CII facility but rather would reduce the salinity of the facility’s wastewater discharged into the sewer system. Therefore, it is expected that hydrology or water quality would not be affected as the CII facilities’ pretreated wastewater would have the same volume but lower salt concentration. Impacts would be less than significant.

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	• Salinity source controls would likely not result in the need for new storm water facilities because there is a low likelihood of new impervious surfaces being created as salinity source controls would likely be located in existing CII facility footprints. Impacts would be less than significant. • Increases in groundwater pumping are not expected under the construction and operation of salinity source controls because these types of control measures would not need to pump groundwater. Further, CII uses that would employ salinity source control already receive their source water from municipal sources and would not increase their demand. Therefore, groundwater supplies would not be substantially depleted. Construction of salinity source controls would not interfere with groundwater recharge because the controls would generally be within existing facility footprints. Impacts would be less than significant. • Construction and operation of salinity source controls would primarily be located in areas of relatively flat relief because they would be within the footprint of existing CII facilities, and these facilities typically are not located on the side of steep slopes. Therefore, these locations would not support mudflows, which typically need very steep slopes and large amounts of precipitation to occur. Furthermore, these areas would not be adjacent to the ocean and would not be affected by tsunamis. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction and operation of salinity source controls are not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of salinity source controls could result in a substantial degradation to water quality.
Land Use and Planning	• Construction and operation of salinity source controls would not physically divide an established community because they would likely be located in the existing footprint of CII facilities. Impacts would be less than significant. • Construction and operation of salinity source controls would take place on the footprint of existing CII facilities and would not conflict with land use designations or zoning because the CII facilities are allowed generally to update or modify their facilities and processes within their appropriate land use and zoning designations. Impacts would be less than significant. If the salinity source controls were inconsistent with applicable land use plans, policies, or regulations, an amendment or variant from the local jurisdiction approving the discretionary action associated with the salinity source controls would be required to be obtained by the project proponent prior to project approval and construction. If no discretionary action occurred as a result of the construction or operation of the salinity source controls, it is assumed it would not result in a conflict with local land use plans, policies, or regulations. Impacts would be less than significant. • Construction and operation of salinity source controls would likely take place in the Delta and may be considered covered activities under the Delta Plan. Only the lead CEQA state or local agency may determine whether that plan, program, or project is a covered action of the Delta Plan. If an action is covered, consistency with the Delta Plan would be determined. The consistency determination would include implementing mitigation from the Mitigation Monitoring or Reporting Program of the Delta Plan, as appropriate. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	related to consistency with the Delta Plan. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely impacts could be reduced once mitigation was implemented because once a lead agency determines an action is covered and complies with the Mitigation Monitoring or Reporting Program, consistency would be determined and impacts would be less than significant. • Potential conflicts with habitat conservation plans, natural community conservation plans, or other plans, policies and regulations protecting biological species and resources are evaluated in the Biological Resources section of this table.
Mineral Resources	• The California SMARA requires the State Geologist to classify land into MZs, according to the known or inferred mineral potential of existing land. The primary goal of mineral land classification is to ensure that the mineral potential of land is recognized by local government decision-makers and considered before land-use decisions are made that could preclude mining. Local general plans, specific plans, and other local plans refer to, and use the information produced by the State Geologist, to identify mineral resources because they are specialized evaluations and because the California Geologic Survey is the designated agency to perform these surveys under SMARA. Some gravel, sand, and aggregate resources are found in close proximity to waterways and the LSJR in San Joaquin County (San Joaquin County 1998, City of Tracy 2005). Most of the city of Stockton is designated as either not having mineral resources or a low likelihood of mineral resources (City of Stockton 2007). Other mineral resources, such as gold or peat, have been previously extracted from the county (San Joaquin County 1998). • Construction and operation of salinity source controls would have a very low potential to result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state or result in the loss of availability of a locally designated mineral resource recovery site. This is because salinity source controls would be within existing CII facilities, which are typically not located in the middle of mineral resource extraction areas. Furthermore, if the CII facilities are located within a state or locally designated mineral resource area, construction and operation of salinity source controls would not permanently remove access to a mineral resource as there would be other locations around the facilities that could provide access to the mineral resource. Impacts would be less than significant.
Noise	• Construction of salinity source controls would potentially take place in San Joaquin County, and the Cities of Tracy and Stockton depending on the location of the facilities that may implement salinity source control. Each of these jurisdictions have noise requirements in their general plans or zoning ordinances for construction and operation based on land use designations and timing restrictions. Noise requirements are typically based on land uses that are considered more sensitive to ambient noise levels than others due to noise exposure. Residences, motels and hotels, schools, libraries, churches, hospitals, nursing homes, and outdoor recreation or natural areas are typically more sensitive to noise than are commercial or industrial land uses. Therefore, local noise standards are typically more stringent for sensitive land uses in terms of level of noise generated, duration, and frequency than less sensitive uses. Given the wide ranges of land uses throughout San Joaquin County, noise levels can range from louder high density residential and industrial uses or roadway uses to more quiet open space and agricultural areas (San Joaquin County 1992). Frequently, the most common and loud noise generating activity in San Joaquin County affecting the overall permanent ambient noise setting is freeway traffic on I-

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	5, I-205, and SR-4 and along railroads and in heavy industrial areas (e.g., Port of Stockton) or around airports (San Joaquin County 1992). • The City of Tracy and the City of Stockton regulate generation of construction noise by restricting the timing that construction can occur (e.g., operating construction requirement from 10pm to 7pm is prohibited) and the land use or adjacent land uses under which the noise generating activity occurs (City of Stockton n.d., City of Tracy n.d.). San Joaquin County exempts noise sources associated with construction, provided they do not take place before 6am or after 9pm (San Joaquin County n.d.). Construction of salinity source controls could generate temporary noise and as such could expose people to noise levels in excess of standards. It is likely salinity source controls would be constructed in areas with suitable land use designations and zoning for CII uses because they would be within the footprint of existing CII facilities; therefore, it would be unlikely that sensitive receptors (e.g., homes, hospitals, schools) would be within close proximity. If sensitive receptors were adjacent to construction activities and experienced a temporary increase in ambient noise levels due to construction, construction would likely be temporary and would be required to follow existing local noise ordinances limiting the timing of construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts related to noise. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because construction impacts would be temporary and the low potential for sensitive receptors to be located within proximity to CII facilities. • Construction activities that typical result in ground-borne vibrations or ground-borne noise are activities such as pile driving, where the ground is repeatedly struck and vibrations or noise can be generated. Given the limited nature of the facilities being constructed for salinity source controls, it is unlikely that pile driving would be used. This is because these controls would be installed within existing facilities to the water supply connection or wastewater discharge to capture and treat the water either prior to the CII process or capture and treat it prior to discharge into the sewer system. As such, it would likely require finer mechanical installation than pile driving. Impacts would be less than significant. • The operation of salinity source controls may generate temporary noise when the CII facility is running. However, the existing facilities may already generate intermittent process noise (e.g., from alarm bells, pumps, and generators). Furthermore, it is anticipated there would be a very low probability that sensitive receptors (e.g., homes, hospitals, schools) would be located within close proximity to experience the operating noise generated because it is anticipated that the CII facilities would be located in areas with similar land uses (e.g., other CII facilities). Finally, it is expected that the salinity source controls would be enclosed within the CII buildings or enclosed with security fencing or barriers, which would reduce the operating noise. As such, a permanent increase in ambient noise under operating conditions is not expected. Impacts would be less than significant. • Assuming construction and operation of salinity source controls would be located in San Joaquin County, there are six public access airports within the county (SJCOG n.d.[a]). The Stockton Metropolitan Airport, San Joaquin County Airport have approved Airport Land Use Compatibility Plans, which identifies noise contours and where noise exposures may take place as a result of aircraft flight patterns consistent with Federal Aviation Administration requirements (SJCOG n.d.[a]).

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	Other airports, such as the City of Tracy, have either airport master plans or other planning documents that outline noise contours consistent with FAA requirements (City of Tracy 1998). While it is unknown where construction or operation of salinity source controls might occur, the construction and operation of salinity source controls would not bring new or additional people within close proximity to an airport or private airstrip or expose people to noise generated by air traffic on a regular basis. This is because salinity source controls would not result in an increased permanent work force cited within proximity to an airport or private airstrip. Nor would salinity source controls result in a population increase that would be exposed to airport noise. Impacts would not occur.
Population and Housing	• The construction and operation of salinity source controls would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Additionally, construction and operation of salinity source controls would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people to the southern Delta. Impacts would not occur. • The construction and operation of salinity source controls would not displace substantial numbers of people or housing, or necessitate the construction of replacement housing elsewhere because the facilities would be located in the existing footprint of CII buildings and not where people currently reside. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, parks, libraries, schools) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, the construction and operation of salinity source controls would not involve an increase in population or housing. In addition, these actions do not include proposals for new housing and would not generate students or increased demands for school services or facilities. Impacts would not occur.
Recreation	• An increase in use of existing recreational facilities is typically associated with a substantial increase in the population to accommodate new recreationists. Construction or operation of salinity source controls would not result in a substantial increase in population because it would not result in the development of housing or other population-inducing development (e.g., job centers). The purpose of the construction and operation of salinity source controls would be to comply with water quality objectives. Construction and operation of these facilities would satisfy existing demand, not meet new projected demand for wastewater treatment or water supply. Impacts would not occur. • Construction of salinity source controls would likely occur within the footprint of CII facilities. These facilities are typically located adjacent to other CII land uses, so it is unlikely recreational facilities would be located in areas where CII facilities currently exist. However, if recreational facilities were located within very close proximity to the salinity source controls, recreational facilities could be affected by noise levels or other temporary construction activities. If construction occurs within close proximity to existing recreational resources, Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to construction noise, traffic, or air quality if those types of impacts occur within close proximity. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than

Potential Environmental Effects of Salinity Source Controls	
Resource	Discussion
	significant once mitigation measures were implemented, depending on the construction timeframe and the location of potential sensitive receptors and recreational resources, and the need to implement existing regulatory requirements (e.g., feasible air quality emissions reduction measures). • Construction and operation of salinity source controls would not include recreational facilities, and would not require the construction or expansion of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Assuming the construction and operation of salinity source controls would be located within San Joaquin County, projects would be subject to the SJCOG Regional Congestion Management Plan (SJCOG 2016b). CII facilities may be located in urban and suburban areas, including the City of Tracy, the City of Stockton, and the County of San Joaquin, that could already experience some congestion. As described in the Regional Congestion Management Program, projects are subject to a tiered review process, unless exempt from CEQA or unless considered as part of a previously approved project (SJCOG 2016b). Projects that trigger 125 or more vehicle trips during weekday AM or PM peak-hours or 500 or more total vehicle daily trips on any day of the week would be required to perform a quantitative regional traffic analysis. The Regional Congestion Management Program provides for mitigation to reduce effects if trips occur at those levels. Trips that are exempted from the RCMP standards, and are removed from calculations of LOS standards under the RCMP include trips resulting from construction (SJCOG 2013). A total of 103 intersections have been designated as part of SJCOG Regional Congestion Management Program (SJCOG n.d.[b]). Designation of RCMP intersections allows for congestion monitoring and appropriately focuses attention at locations where operational constraints are typically experienced on arterial roadways (SJCOG n.d.[b]). Operation of salinity source controls would generate additional truck trips to dispose of the waste brine generated by the salinity source control process. The number of truck trips depends on the volume of wastewater treated per day and the salinity; therefore, the number of trucks that would be required is unknown. As discussed above, if a project exceeds the criteria established by the Regional Congestion Management Program on roads identified in that program (e.g., 125 or more vehicle trips during weekday AM or PM peak-hours or 500 or more total vehicle daily trips on any day of the week), mitigation would be applied through that program. The criteria are particularly high and generally applicable to development such as office parks, retail, or housing developments that would generate substantial numbers of trips. However, Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant transportation and traffic impacts related to operations, if indeed brine disposal resulted in exceedances of the Regional Congestion Management criteria. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented and consistency with the Regional Congestion Management Plan was determined. • Construction and operation of salinity source controls could result in some additional trips. It is unknown the number of construction and operational trips that might be needed and the location of these trips, but it is anticipated that construction would be relatively limited in duration. Typically, construction activities are exempt from local road trip thresholds because construction is considered temporary. However, depending on the quantity of trips and the duration, the temporary increased traffic during construction or the potential increase in operational trips associated with brine disposal could exceed local or regional road trip thresholds (either vehicle miles traveled or level of service, as discussed in Table 16-25, changes to the methodology and criteria for evaluations are occurring). Projects would be required to

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
	evaluate trip generating activities through the respective jurisdiction traffic impact analysis guidelines, depending on the location and number of trips generated (City of Stockton n.d.). Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant transportation and traffic impacts related to construction or operation. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction and because brine disposal trips could likely occur on an infrequent basis. • Construction of salinity source controls is not expected to result in hazards to, or on, roadways because they would primarily be constructed within existing footprints of facilities. Similarly, construction activities are not expected to conflict with public transit facilities, public bicycle facilities, or pedestrian facilities (e.g., sidewalks) because they would be constructed within existing footprints of facilities. The development of project-specific construction traffic management plans, as identified in Table 16-38 would reduce potentially significant impacts if hazards on the roadway were temporarily created during construction due to construction related activities. Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts of transportation and traffic related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant, given the low likelihood of occurring, and once mitigation measures were implemented because construction impacts would be temporary. • Similar to the discussion in the Hazards and Hazardous Materials section of this table, it is not expected that construction of salinity source controls would result in inadequate emergency access, given the location of the construction work would primarily within the existing footprint of CII facilities. As such, there is a low likelihood of interfering with emergency access. However, Table 16-38 lists potential mitigation measures that lead agencies (e.g., CII facilities or municipalities) can and should implement to reduce potentially significant impacts of transportation and traffic related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. It is likely that impacts could be mitigated to less than significant, given the low likelihood of occurring, and once mitigation measures were implemented because construction impacts would be temporary. • Construction and operation of salinity source controls would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and are not related to air traffic or airports. Impacts would not occur. • Operation of salinity source controls are not expected to result in a permanent substantial increase in hazards due to a design feature or incompatible use, permanent inadequacy of emergency access, or a permanent change that would decrease the performance or safety of public transit facilities, public biking facilities, or public pedestrian facilities because it is anticipated that these would be located within existing facility footprints. Trips associated with brine disposal would be done on existing roads and as such, would not result in permanent substantial hazards or conflicts with emergency access and public transit, bicycle, or pedestrian facilities. Impacts would be less than significant.

Potential Environmental Effects of Salinity Source Controls

Resource	Discussion
Utilities and Service Systems	• Construction and operation of salinity source controls would not be expected to affect wastewater treatment requirements of the Central Valley Water Board because it would actually reduce the salinity of the wastewater entering a WWTP. Therefore, the salinity source controls overall would reduce the salinity in the treated effluent that is discharged into receiving waters. Additionally, construction and operation of salinity source controls would not result in a determination by a wastewater treatment provider that it has inadequate capacity to meet the service area's demand because the salinity source controls would not increase the volume of wastewater from the CII facilities discharged into the sewer system; therefore, the WWTP would receive the same volume of wastewater. Impacts would be less than significant. • Construction and operation of salinity source controls would not require new entitlements because the controls would not require water. The controls target salinity in the wastewater collection system and implemented prior to wastewater entering the system to be treated. As such, impacts would not occur. • Construction and operation of salinity source controls would involve the construction of WWTP infrastructure. Environmental effects associated with the infrastructure are discussed earlier in this table (Aesthetics through Transportation and Traffic). Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant construction and operation impacts related to all environmental resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • The construction and operation of salinity source controls would not need the construction of additional storm water drains because they would likely be built within the footprint of the existing CII facilities, which currently have impervious surfaces that generate runoff. It is expected that existing storm water infrastructure would be used. Impacts would be less than significant. • Construction and operation of salinity source controls could generate solid waste in the form of waste brine. All waste would be disposed of in accordance with applicable laws and regulations. Impacts would be less than significant.

16.4.3 Desalination

Some wastewater treatment agencies may opt to remove salts at the WWTP before treated effluent is discharged to the southern Delta. Conventional wastewater treatment processes do not significantly remove salts from the wastewater. To remove salts, a discharger must desalinate treated wastewater effluent. Methods to desalinate water at WWTPs include thermal separation, electro-dialysis, and RO. This analysis is specific for RO because it is the most common desalination technology in California and is comparable or less expensive than other desalination methods (e.g., ion exchange, distillation) (DWR 2009). It is anticipated that the following municipalities and wastewater treatment service providers that discharge into the southern Delta could implement such programs: City of Tracy, City of Stockton, and Mountain House CSD.

Cost Evaluation

The costs of RO include the costs associated with the construction of the RO facilities and operation and maintenance costs associated with energy use and brine disposal. Brine's salinity is a function of the concentration and volume of the influent into the RO filter and the efficiency of the RO filter. For example, if the influent water had 75,000 pounds of salt per 10 mgd, and the RO filter was 85 percent efficient, the brine would contain 75,000 pounds of salt per 1.5 million gallons.

Brine disposal is an important consideration when evaluating wastewater treatment technologies used to reduce salinity. This is because of the associated costs and potential environmental effects of brine disposal. There are five major methods of brine disposal: (1) disposal to WWTPs, (2) disposal to surface waters, (3) deep-well injection, (4) evaporation ponds, and (5) evaporation to dryness (crystallization). Approximately 40 percent of all desalination facilities in the country discharge brine to an existing wastewater collection system (Sethi et al. 2006, USBR 2006c). Approximately 48 percent of all desalination facilities in the country discharge brine directly to surface water (Sethi et al. 2006, USBR 2006c). In some areas, brine may be discharged to a deep well, below potable water aquifers (TWDB 2009). Regulatory concerns associated with this deep-well injection method of brine disposal include the receiving water's transmissivity, the salinity of the receiving water, and the presence of a structurally isolating and confining layer between the receiving aquifer and any overlying source of drinking water (Sethi et al. 2006, USBR 2006c). Evaporation ponds can be used in relatively warm, dry climates with high evaporation rates, level terrain, and low land costs (Sethi et al. 2006). Evaporation ponds allow the brine to dewater, and then be hauled to a landfill for ultimate disposal. Thermal separators and vapor compression systems can completely remove water from brine, leaving a crystallized solid for disposal. These crystallization systems are very energy intensive. The capital, operations, and maintenance costs can exceed the cost of the desalination facility. This potential brine disposal method is used for very small flows where other discharge methods are not feasible (Sethi et al. 2006). Other methods that have been utilized are treatment wetlands and other developing technologies (TWDB 2009).

Evaporation ponds were selected for this cost evaluation because of their lower associated cost and regulatory constraints. The assumptions included in the cost evaluation are a portion or all of the wastewater treated effluent would be treated with RO at the wastewater facility, the brine would be dewatered in evaporation ponds located at the wastewater facility or adjacent to the wastewater facility, and solids remaining after evaporation would be transported and disposed of at a Class I/II landfill (non-hazardous waste landfill).

The cost to install a desalination system at a WWTP is highly variable. In general, important factors to consider are the quality and quantity of wastewater effluent entering the desalination system, the desired quality leaving the desalination system, energy costs, the chosen method of desalination, and the brine disposal method. Some WWTPs will only need to treat a portion of the wastewater effluent to achieve effluent limitations for salinity, which would reduce costs.

The California Water Plan Update 2009 discusses the cost of desalination. Table 16-29, *California Water Plan Update 2009 Unit Cost of Desalination*, provides a summary of costs.

Table 16-29. California Water Plan Update 2009 Unit Cost of Desalination

	Total Water Cost ($/AF)	
Type of Desalting	Low	High
Groundwater	$500	$900
Wastewater	$500	$2,000
Seawater	$1,000	$2,500

Source: DWR 2009.
AF = acre-feet.

Using this approximation, a 10 mgd discharger can expect to pay $5.6–$22.4 million to construct an RO system at the WWTP. Extrapolating this trend is nonlinear. The associated administrative, engineering, and legal costs do not generally decrease for smaller projects. Larger RO facilities cost more, but the typical unit price of water produced decreases due to the scale of construction costs compared to administrative, engineering, and legal costs.

Environmental Evaluation

Summary of Potential Action

The location, timing of construction, and details of operation of desalination facilities are unknown. In addition, the size and scale of the facilities is unknown. These unknown factors would influence the type, magnitude and severity of impacts that could occur during construction and operation. However, any modified or new desalination facilities would likely be constructed and operated in the existing footprint of, or within very close proximity to, a WWTP that discharges treated effluent into the southern Delta waterways or is physically located within the southern Delta. This is because the desalination process would have to be integrated with the wastewater treatment stream to capture the WWTP treated effluent, remove the salt, and release the RO effluent into receiving waters. Additionally, it is assumed WWTPs are located within close proximity to creeks or rivers because they must discharge treated effluent into receiving waters. It is also assumed WWTPs are located in more urbanized areas and adjacent to CII and urban uses because they must be located in an area to serve their existing municipal customers. Treatment plants are generally located on lands designated and zoned for public facilities and CII uses. Desalination would likely require the disposal of highly concentrated salt waste streams (e.g., brine). These waste streams are assumed to be trucked offsite and disposed of in a landfill for nonhazardous materials. Since the operation of the desalination facilities would be located within existing WWTPs or within close proximity, and the process is highly automated, it is anticipated that the current employees of the existing WWTP would maintain and operate the desalination facility and that a substantial number of additional employees would not be needed.

Potential Environmental Effects

Construction of wastewater desalination facilities would likely result in temporary and highly localized effects typically associated with similar activities, including air quality effects and ground disturbance. As noted above, it is likely that such facilities would be constructed in areas that are already disturbed by urban development, and most facilities would be located within existing WWTP footprints. Desalination facilities are typically relatively energy intensive. However, the overall increased electrical load for new treatment facilities would be very small compared to the existing electrical grid capacity and is unlikely to require the construction of major new power generation or transmission facilities. The operation of new RO treatment facilities may require a slight increase in chemical transport and storage, but this potential increase would likely be minimal because new RO facilities would likely be constructed within or adjacent to existing WWTPs. Therefore, the increase would be negligible compared to existing chemical use and transport.
New desalination facilities would result in the production of solid waste, which would be disposed of in accordance with applicable laws and regulations in landfills. To the extent such programs were successful in reducing salinity in the southern Delta, agricultural uses and aquatic resources would benefit. Construction and operation of such facilities are highly regulated, and the project would be required to comply with applicable regulations. In addition, because such facilities are owned by WWTP service districts[25] and subject to CEQA review, any new projects would undergo project-level analysis under CEQA and other required regulatory compliance at the time they are proposed.

Table 16-30, *Potential Environmental Effects of Wastewater Treatment Plant Desalination*, summarizes the potential environmental effects associated with desalination. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, at the end of this chapter lists potential mitigation measures associated with the construction or operation of the methods of compliance and is referenced in Table 16-30 where appropriate.

---

[25] Note: Cities or water districts that do not treat wastewater would have no obligation to try to reduce the salt levels in the water they provide.

Table 16-30. Potential Environmental Effects of Wastewater Treatment Plant Desalination

Potential Environmental Effects of Wastewater Treatment Plant Desalination	
Resource	Discussion
Aesthetics	• Construction and operation of WWTP effluent desalination facilities would not be expected to substantially degrade the visual character or quality of areas where these facilities would be constructed, or substantially damage scenic resources (including trees, rock outcroppings, and historic buildings) within the state-designated scenic highways in San Joaquin County (I-5 and I-580) because desalination facilities would be located within the existing footprint of WWTPs or within close proximity. These facilities would be similar in size, scale, and general appearance as the existing WWTP. The magnitude and severity of the aesthetic impacts would depend on the location of sensitive receptors and scenic vistas relative to the construction and operation site. For example, San Joaquin County has no designated scenic vistas and as such an impact may not occur (San Joaquin County 2014a). Construction of the facilities could create temporary light and glare during potentially needed nighttime construction periods, and once desalination facilities become operational, they may require permanent outdoor lighting. However, given that these facilities would likely be located within an existing WWTP footprint or within close proximity, it is unlikely that this light and glare would be substantial relative to existing outdoor lighting conditions. Impacts on aesthetic resources would depend on the location of sensitive receptors relative to potential lighting. Outdoor lighting would be expected to follow lighting guidelines and plans of local jurisdictions approving the construction and operation of the desalination facilities. Table 16-38 identifies potential mitigation measures lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant environmental effects associated with light and glare and aesthetics. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the potential location of possible sensitive receptors and the ability to reduce light and glare.
Agriculture and Forestry Resources	• Construction and operation of desalination facilities would not be expected to take place on lands used for agriculture (Prime Farmland, Unique Farmland or Farmland of Statewide Importance) or on lands under Williamson Act contract because the facilities would be located within the footprint of existing WWTPs or within very close proximity such that the desalination facilities can use the existing wastewater treatment stream. Additionally, it is expected that agricultural uses in the southern Delta would benefit from the reduction in salinity and potentially offset any losses of agricultural land that might be indirectly affected by the desalination facilities. Table 16-38 identifies potential mitigation measures lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant environmental effects on agricultural resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of

Potential Environmental Effects of Wastewater Treatment Plant Desalination	
Resource	Discussion
	potential disturbance during construction. It is also expected that desalination would result in higher water quality in the southern Delta, which could potentially offset impacts on agricultural land affected by the recycled water facilities. • Construction and operation of desalination facilities would not be expected to take place forest lands or timberland because the facilities would be located within the footprint of existing WWTPs or within very close proximity such that the desalination facilities can use the existing wastewater treatment stream. Furthermore, the southern Delta generally does not have timber resources or forestlands. As such, there would be no conflict with existing zoning for forest land or timberland, and there would be no rezoning or loss of these resources. Impacts would not occur.
Air Quality	• Desalination facilities would likely be located in the SJVAB, which generally covers San Joaquin, Stanislaus, Merced, and Madera Counties. USEPA has classified SJVAB as an extreme nonattainment area for the federal 8-hour ozone standard and a nonattainment area for the federal PM2.5 standard. For the federal CO standard, USEPA has classified most major population centers of the SJVAB as maintenance areas and rural areas of the SJVAB as unclassified/attainment areas. The SJVAB is classified as a serious maintenance area with regards to the federal PM10 standards. ARB has classified the SJVAB as a severe nonattainment area for the state 1-hour ozone standard and a nonattainment area for the state 8-hour ozone, PM10, and PM2.5 standards. ARB has classified the SJVAB as an attainment area for the state CO standard. SJVAPCD's published guidelines, *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002) do not require the quantification of construction emissions. Rather, the guidelines require implementation of effective and comprehensive feasible control measures to reduce PM10 emissions (SJVAPCD 2002). SJVAPCD considers PM10 emissions to be the greatest pollutant of concern when assessing construction-related air quality impacts and has determined that compliance with its Regulation VIII, including implementation of all feasible control measures specified in its *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), constitutes sufficient mitigation to reduce construction-related PM10 emissions to less-than-significant levels and minimize adverse air quality effects. All construction projects must abide by Regulation VIII. Since the publication of the SJVAPCD's guidance manual, the district has revised some of the rules comprising Regulation VIII. Guidance from SJVAPCD staff indicates that implementation of a Dust Control Plan would satisfy some requirements of SJVAPCD Regulation VIII (Siong pers. comm.). Further consultation with SJVAPCD staff indicates that, though explicit thresholds for construction-related emissions of ozone precursors are not enumerated in the *Guide for Assessing and Mitigating Air Quality Impacts*, SJVAPCD considers it a significant impact when construction or operational emissions of ROG or NO_X exceed 10 tons per year or if PM10 or PM2.5 emissions exceed 15 tons per year (Siong pers. comm.). SJVAPCD's CEQA Guidelines indicate their numeric thresholds are project-level and cumulative: "Any proposed project that would individually have a significant air quality impact…would also be considered to have a significant cumulative air quality impact (SJVAPCD 2002)" Construction of desalination facilities would likely result in emissions associated with construction equipment and construction worker vehicle trips as well as fugitive dust emissions from ground disturbance. The quantity, duration, and intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Depending on the level of activities and amount of infrastructure built, construction of desalination facilities could exceed air quality thresholds established by SJVAPCD and would be required to implement measures to help reduce or minimize construction-related emissions. Lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on air quality from construction-related emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Prior to a project dealing with a stationary source of emissions (such as a WWTP) it is required to receive an ATC from SJVAPCD. The project is subject to the requirements of SJVAPD Rule 2201. As stated under Sections 1.1 and 1.2 of Rule 2201[26]: *The purpose of this rule is to provide for the following:* *1.1 The review of new and modified Stationary Sources of air pollution and to provide mechanisms including emission trade-offs by which Authorities to Construct such sources may be granted, without interfering with the attainment or maintenance of Ambient Air Quality Standards;* *1.2 No net increase in emissions above specified thresholds from new and modified Stationary Sources of all nonattainment pollutants and their precursors.* Rule 2201 applies to new stationary sources and all modifications to existing stationary sources that are subject to permit requirements that may emit one or more affected pollutant after construction. The requirements of this rule would be in effect on the date the application is determined to be complete by the Air Pollution Control Officer shall apply to such application. Operation of desalination facilities would likely be electric because of their expected locations in urban and suburban areas and the expected location in close proximity to existing wastewater treatment infrastructure. They may use nonelectric backup for intermittent emergency circumstances. Operations could include facility inspection and maintenance activities and are expected to be similar to or fewer maintenance activities than inspection and maintenance of existing wastewater treatment facilities. The need for additional energy could result in increased criteria pollutant emissions at other power facilities. However, the power facilities that would compensate for the additional power are already built and permitted to emit a maximum amount of criteria pollutants. These facilities are required to offset additional power generation by the use of pollution credits. Therefore, if additional emissions

---

[26] Sources whose primary function is permitted by SJVAPCD through Rules 2010 and 2201 are not subject to SJVAPCD Rule 9510 (Indirect Source Review). Projects subject to Rule 9510 are required to quantify and reduce indirect (mobile source emissions), area-source (space heating, landscaping, and maintenance), and construction exhaust emissions.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	are generated, they would be generated by facilities that are permitted to do so. • The increased number of truck trips that would be associated with the disposal of brine at landfills would produce emissions. The brine would be dewatered in evaporation ponds and then transported offsite to landfills. The number of truck trips cannot be fully quantified because it would depend on the salinity of the wastewater, which is a function of the concentration, volume of the RO influent, and the time the brine would need to spend in the evaporation ponds. However, depending on the amount of materials that would require disposal and number of haul trucks that would be required, operational activities associated with material hauling could result in exceedances of SJVAPCD's thresholds and potentially result in a cumulatively considerable net increase in criteria pollutants for which SJVAB is in nonattainment, as SJVAPCD's CEQA Guidelines indicate their numeric thresholds are project-level and cumulative: "Any proposed project that would individually have a significant air quality impact…would also be considered to have a significant cumulative air quality impact (SJVAPCD 2002)". Impacts due to operation of the desalination facilities could result in potentially significant impacts. Lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on air quality associated with operational emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • SJVAPCD generally defines a sensitive receptor as a facility that houses or attracts children, the elderly, people with illnesses, or others who are especially sensitive to the effects of air pollutants, and where there is a reasonable expectation of continuous human exposure according to the averaging period for National AAQSs(e.g., 24-hour, 8-hour, or 1-hour) (SJVAPCD 2002). Sensitive receptors are primarily concentrated in urbanized areas and their proximity to construction or operational activities, the type of activity, and duration of activity, determines their potential exposure to pollutants. If criteria pollutant standards are exceeded during construction, and sensitive receptors are in proximity, mitigation measures identified in Table 16-38 would serve to reduce potentially significant air quality effects. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. It is not anticipated that operation of the facilities would expose sensitive receptors to substantial pollutant concentrations because operations would not generate toxic or diesel exhaust. If diesel generators were used, they would be limited in operation and would likely be subject to air district permitting requirements that would minimize health risks. • The ARB traditionally has established state air quality standards, maintaining oversight authority in air quality planning, developing programs for reducing emissions from motor vehicles, developing air emission inventories, collecting air quality and meteorological data, and approving State Implementation Plan, as required by the Clean Air Act, provisions. Responsibilities of local air districts include overseeing stationary source emissions, approving permits, maintaining emissions inventories. SJVAPCD has adopted an air quality improvement plan that addresses NO_X and ROGs, both of which are ozone precursors and contribute to the secondary formation of PM10 and PM2.5. The air quality improvement plan specifies that regional air quality standards for ozone and PM10 concentrations

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	can be met through the use of additional source controls and trip reduction strategies. It also establishes emission budgets for transportation and stationary sources. Those budgets, developed through air quality modeling, reveal how much air pollution can be present in an area before AAQSs are violated. General plan assumptions of local jurisdictions inform local air quality plans. The exceedance of air quality thresholds, or the net increase of emissions, does not necessarily mean construction and operation of new source water supply facilities would be inconsistent with applicable air quality plans or local general plans. A project is deemed inconsistent with an air quality plan if it would result in population and/or employment growth that exceeds growth estimates included in the applicable air quality plan or local general plan, which, in turn, would generate emissions not accounted for in the applicable air quality plan emissions budget. Therefore, projects are evaluated to determine whether they would generate population and employment growth and, if so, whether that growth and associated emissions would exceed those included in the relevant air quality plan(s). The construction and operation of desalination facilities would not result in growth because it would serve to provide alternate low-salinity water source(s) to water users and would not serve to satisfy an increase in demand or an increase in need. The construction and operation of desalination facilities would not result in population or employment growth that would result in a conflict with or obstruct implementation of the applicable air quality plan because they would not require activities that are associated with population growth (e.g., housing development, business centers, etc.). Accordingly, this impact is less than significant.
	• SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants. Construction and operation of desalination facilities would not involve the type of facility identified by, for example, SJVAPCD, as a known odor source (SJVAPCD 2002). The desalination facilities would be located at the WWTP but would not produce additional odors beyond what currently may be produced at the WWTP. This is because the desalination process typically uses the existing volume of wastewater which is already treated to secondary or tertiary levels (as required by state law). The desalination process further processes the wastewater effluent. Therefore, the additional processing of the wastewater does not produce further odors as the odors are typically generated during primary treatment and biosolids production. Furthermore, many WWTPs contain any odors by enclosing primary treatment and biosolids production and by scrubbing odor-generating emissions. Consequently, it is expected desalination would not create objectionable odors affecting a substantial number of people. Impacts would be less than significant.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
Biological Resources	• It is expected that construction and operation of desalination facilities would be in urban and suburban areas within the footprint of existing WWTPs. These areas are expected to have a low potential for candidate, sensitive, or special-status species, and habitat (including federally protected wetlands, riparian habitat, or other sensitive natural communities). Additionally, the footprints of WWTPs are expected to have a very low potential for special-status biological resources because typically WWTPs are industrial facilities with buildings and impervious surfaces, which would be unlikely to support these biological resources. As such, construction and operation of desalination facilities are unlikely to interfere substantially with the movement of any native resident or migratory fish or wildlife species, or impede the use of native wildlife nursery sites. Furthermore, it is expected that the treated effluent discharged from the WWTP would actually be improved from baseline conditions because the desalination facilities would remove salinity prior to discharge into the receiving water. This would be considered beneficial to aquatic resources. If special status species and habitat are present, construction could result in short term, temporary, indirect effects. Table 16-38 lists potential mitigation measures lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant environmental effects of construction and operations on biological resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction and depending on the ability to schedule construction for particular seasons and durations. • It is expected that construction or operation of desalination facilities would not result in a conflict with an existing local policies or ordinances protecting biological resources, or an adopted habitat conservation plan or natural community conservation plan. However, construction and operation of desalination facilities would occur within the SJMSCP Plan Area. The SJMSCP is administered by the SJCOG, a non-profit corporation established by San Joaquin County and the cities of Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton and Tracy. Implementation of new desalination facilities may be considered a covered activity under SJMSCP—a determination which would be made by SJCOG, in consultation with the lead agency. If an activity is determined to be covered, participation in the SJMSCP is voluntary except when conditioned to participate by a Permittee (i.e., SJCOG, Inc. San Joaquin County, and the cities of Escalon, Lathrop, Lodi, Manteca, Ripon, Stockton and Tracy). If an activity is not covered, the lead agency can request coverage using one of the following four options: (1) payment of a fee, which is assessed depending on habitat type within which the project is located; (2) dedicate habitat lands as a conservation easement or fee title; (3) purchase mitigation bank credits from a SJCOG-approved mitigation bank; and (4) propose an alternative mitigation plan, consistent with the goals of the SJMSCP and equivalent in biological value. Participation in the SJMSCP fulfills ESA, CESA, NEPA, and CEQA requirements, provides mitigation and guarantees no additional mitigation, excepting for Incidental Take Minimization Measures required in limited cases (SJCOG 2016a). If the lead agency participates in the SJMSCP, construction and operation of desalination facilities would not be considered in conflict with the SJMSCP, and impacts would be less than significant. If the lead agency chooses to opt out of participation in the SJMSCP, that agency or agencies (e.g., municipalities or municipal water purveyors)

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	can and should implement the mitigation measures identified in Table 16-38 to reduce potentially significant impacts on biological resources and to avoid conflict with the SJMSCP. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. If habitat is permanently removed as a result of constructing or operating desalination facilities, it is likely that impacts could not be mitigated and would remain significant and unavoidable. However, it is likely impacts could be reduced once mitigation was implemented because once a lead agency opts in or determines its action is covered, consistency would be determined and impacts would be less than significant. • Disposal of the brine generated by the desalination facilities would occur at landfills and would have a very low potential to affect sensitive biological resources because the brine would be contained in the landfill. Impacts would be less than significant.
Cultural Resources	• Construction and operation of desalination facilities would likely take place in urban and suburban areas adjacent or within close proximity to existing wastewater treatment facilities and infrastructure. Construction may result in some ground-disturbing activities which have the potential to disturb or destroy buried, unknown, significant cultural resources (significant historical, archeological, or paleontological resources). While it is unknown if cultural resources exist in these locations, these areas would likely have been previously disturbed during the construction of the existing wastewater treatment facilities, reducing the potential for significant unknown cultural resources to exist. Lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on cultural resources associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented the low potential for resources to exist. • Operation of desalination facilities have no potential to affect cultural resources because the facilities would simply remove salt, and discharge treated effluent into receiving waters. Under baseline conditions, discharges are already occurring and an increase in discharge would not occur. Impacts would be less than significant. • As described above, it is expected that wastewater treatment sites would have been previously disturbed. Therefore, it is highly unlikely that human remains, typically buried at depths of 6 ft, would be disturbed during construction. If, in the highly unlikely event human remains are uncovered during construction, compliance with the State Health and Safety Code would be required. As specified by Section 7050.5 of the Health and Safety Code, and described in Table 16-38, no further disturbance would occur until the county coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code Section 5097.98. If such a discovery occurs, excavation or construction would halt in the area of the discovery, the area would be protected, and consultation and treatment would occur as prescribed by law. If the coroner recognizes the remains to be Native American, he or she would contact the NAHC, who would appoint the Most Likely Descendent. Additionally, if the human remains are determined to be Native American, a plan would be developed regarding the treatment of human remains and associated burial objects, and the plan would be implemented under the direction of the Most Likely Descendent.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the low potential for resources to exist.
Geology and Soils	• Desalination facilities could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, desalination facilities would not result in an impact on or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, expansive soils, or landslides. Since the facilities would be located within or in close proximity to existing WWTPs, the addition of the desalination facilities would not substantially add to the structure such that it would increase the exposure of the structure to potential substantial adverse effects, as the risk of loss to rupture of known earthquake faults, seismic ground shaking, or seismic ground-related failure. Furthermore, new structures would be required to follow all appropriate building codes and would be designed to withstand seismic-related activities as identified by the building codes. Finally, desalination facilities would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts related to geology and soils associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the need to follow the building code and other state and federal building requirements. • The construction and operation of desalination facilities would not involve constructing or operating septic tanks and, therefore, septic tanks would not be affected by soils incapable of supporting the use of them or other alternative wastewater disposal systems. Impacts would not occur. • Construction of desalination facilities would result in limited ground-disturbing activities that could cause soil erosion or loss of topsoil; however, ground-disturbing activities would be limited in duration and geography. Furthermore, ground-disturbing activities of 1 acre or greater would require the need for preparation and implementation of a SWPPP, as required by the Central Valley Water Board. The SWPPP would require soil and erosion control mechanisms. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts on soil erosion and storm water runoff associated with construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-7, because construction and operation of desalination facilities would likely result in increased use of electricity and fuels there would be an increase in GHG emissions. The desalination process is an energy-intensive process (e.g., RO energy use will vary depending on the salinity and temperature of the source water or wastewater; the higher the salinity or the colder the water temperature, the more energy it takes to remove the salt [Kennedy/Jenks Consultants 2013]). The overall increased electrical load would be extremely small compared to the existing electrical demand of the service area and it is unlikely to require the construction of major new power generation or transmission facilities. However, it is anticipated that this increased electricity-related GHG emissions could exceed applicable SJVAPCD ZEL threshold and result in a potentially significant impact. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts of construction and operations from GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
Hazards and Hazardous Materials	• Construction of desalination facilities would be short term and may involve the limited transport, storage, use, and disposal of hazardous materials such as fuel and lubricating grease for motorized heavy equipment. Some examples of typical hazardous materials handling are fueling and servicing construction equipment on the site, and transporting fuels, lubricating fluids, solvents, and bonding adhesives. These types of materials are not acutely hazardous, and storage, handling, and disposal of these materials are regulated by local, county, and state laws. Further, the quantities of these materials used during construction would be small (e.g., less than 100 gallons) because construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction. • Schools are not located within one-quarter mile of the WWTPs of Tracy, Stockton, or Mountain House CSD (California Department of Education 2016a, 2016b). As such, impacts would not occur. • There are eight sites within San Joaquin County that are identified on the Hazardous Waste and Substance Site List (Cortese Site list) as being hazardous materials sites under Government Code, § 65962) (CalEPA 2016). Construction and operation of desalination facilities is not likely to be located on these eight sites or interfere with these sites because these sites are not located on the WWTPs of Tracy, Stockton, or Mountain House CSD and are not located within close proximity (CalEPA 2016). CalEPA identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facility sites where DTSC has taken corrective Action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action in San Joaquin County (CalEPA 2016). As such, construction and operation of desalination facilities would not affect them. There are approximately 244 leaking underground storage cases in San Joaquin County designated as open (CalEPA 2016). Sixteen facilities in San Joaquin County have received CDOs or CAOs and have active cases, but may not be necessarily related to hazardous waste (CalEPA 2016). The location of construction and ground disturbing activities is anticipated to be within existing WWTPs or within close proximity. However, construction could occur within proximity to leaking underground storage tanks. In addition, Stockton WWTP is included on the list of cease and desist or clean up and abatement for domestic sewage and industrial purposes. As such, during construction of desalination facilities ground disturbing activities potentially contaminated soil could be encountered. As such, Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	• Operation of desalination facilities would not produce any new wastewater that would not already be discharged. Municipal wastewater is not expected to contain hazardous materials due to CII facility pretreatment requirements. Therefore, when compared to baseline, no new quantities of hazardous materials would be used, transported, or disposed. However, there would be a new waste stream (e.g., brine) generated from the WWTP that would need to be removed. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts associated with hazardous materials during operations. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented. • Assuming construction and operation of desalination would be located in San Joaquin County, there are six public access airports within the county (SJCOG n.d.[a]). The Stockton Metropolitan Airport and San Joaquin County Airport have approved Airport Land Use Compatibility Plans, which prescribe safety requirements and ensure land uses would not pose a safety hazard to the airports in accordance with the Federal Aviation Administration. Other airports, such as the City of Tracy, have either airport master plans or other planning documents outlining safety requirements and ensuring land uses would not pose a safety hazard, consistent with FAA requirements (City of Tracy 1998). While it is unknown where construction or operation of desalination might occur, the WWTPs for the City of Tracy and Stockton and Mountain House CSD are not located within 2 miles of an airport (SJCOG n.d.[a]). Further, construction and operation of desalination facilities would not be a hazard or cause safety concerns to airports since the facilities would be constructed and operated within the footprint of existing WWTPs or within close proximity. Impacts would not occur. • Construction and operation of desalination facilities would not physically interfere with an adopted emergency response plans or emergency evacuation plans since they would be located within existing WWTPs or in close proximity to them and therefore would not prohibit the mobility of people to escape potential emergencies. Standard practices and protocols with respect to emergencies that are currently implemented by the WWTPs would apply and desalination facilities would be incorporated into the standard practices and protocols. Furthermore, construction and operation does not involve an increase in population that would necessitate reconsideration of how to evacuate people in an emergency. Impacts would not occur. • Construction and operation of desalination facilities would not involve the construction of housing or an increase in population and would not expose people or structures to wildland fires. Impacts would not occur.

Potential Environmental Effects of Wastewater Treatment Plant Desalination	
Resource	Discussion
Hydrology and Water Quality	• Construction of desalination facilities could result in temporary changes to drainages, erosion, or runoff associated with typical construction activities, such as grading or preparation of land. As discussed earlier in this table (Geology and Soils section), for soil disturbance of over 1 acre, wastewater treatment special districts or municipalities would be required to prepare and implement a SWPPP, which would include specific types and sources of storm water pollutants, determine the location and nature of potential impacts, and specify appropriate control measures to eliminate any potentially significant impacts from storm water runoff on receiving waters. In addition, as discussed in this table for Hazards and Hazardous Materials, construction of desalination facilities may involve the limited transport, storage, use, and disposal of hazardous materials, which, if spilled, could have adverse effects on water quality depending on the location and magnitude of the spill. However, storage, handling, and disposal of these materials is regulated by local, county, and state laws, and the quantities of these materials used during construction would be small (e.g., less than 100 gallons) and construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained and, as such, violations of water quality standards are not expected to occur. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts of construction on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction. • It is likely that the desalination facilities would be located in a flood hazard area because wastewater treatment facilities are typically located adjacent to rivers and streams so they can discharge treated effluent into receiving waters. Since the desalination facilities would be located within the existing WWTP footprint (or in close proximity), the addition of the desalination facilities would not substantially add to the existing structures such that flood flows would be impeded or redirected. Additionally, the desalination facilities would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to flood hazard locations or result in the construction of housing in a 100-year flood hazard area. Accordingly, desalination facilities would not expose people to significant loss, injury, or death related to flooding. Construction of desalination facilities would not result in flooding or otherwise cause flooding, including flooding as a result of the failure of a levee or dam because it would not involve construction or operation of levees or dams. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given construction would be temporary and the need to comply with existing building code requirements if building in flood hazard areas were to occur. • Desalination in conjunction with the wastewater treatment process would not increase the volume of treated effluent discharged into receiving waters. This is because the amount of wastewater entering the facilities and

Potential Environmental Effects of Wastewater Treatment Plant Desalination	
Resource	Discussion
	leaving the facilities would be the same, and only salts would be removed. Therefore, it is expected that hydrology would not be affected. Desalination would ensure that the treated effluent released to surface waters would be of lower salinity, and support compliance with beneficial use standards, objectives, and WDRs of NPDES permits. Impacts would be less than significant. • Increases in groundwater pumping are not expected to occur under the construction and operation of desalination facilities because wastewater treatment facilities do not pump groundwater. Furthermore, it is anticipated that evaporation ponds would be lined such that salts could not enter the groundwater system. Therefore, construction and operation of desalination facilities would not substantially deplete groundwater supplies or interfere substantially with groundwater recharge. Impacts would be less than significant. • Construction and operation of desalination facilities would primarily be located in areas of relatively flat relief because they would be within the footprint of existing WWTPs or within relatively close proximity, and WWTPs typically are not located on the side of steep slopes. Therefore, these locations would not support mudflows, which typically need very steep slopes and large amounts of precipitation to occur. Furthermore, these areas would not be adjacent to the ocean and would not be affected by tsunamis. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction and operation of desalination facilities are not expected to occur near a lake or reservoir. Impacts would not occur. • There are no other ways in which construction or operation of desalination facilities could result in a substantial degradation to water quality.
Land Use and Planning	• Construction and operation of desalination facilities would not physically divide an established community because they would likely be located in the footprint of the existing WWTP or closely adjacent. Impacts would not occur. • Construction and operation of desalination facilities would likely take place within the footprint of an existing WWTP or within close proximity and therefore would not likely conflict with land use designations or zoning since WWTPs are typically located in areas that are for public facilities. Mountain House CSD WWTP is located in an area zoned for public facilities with a land use designation of “Public”. The WWTP for the City of Stockton is in an area zoned as “Port” and with a land use designation of “Industrial”, and the City of Tracy’s WWTP is located in a “Light Industrial” zone with a land use designation of “Public Facilities”. If the desalination facilities were inconsistent with applicable land use plans, policies, or regulations, an amendment or variant from the local jurisdiction approving the discretionary action associated with the desalination facilities would be required to be obtained by the project proponent prior to project approval and construction. If no discretionary action occurred as a result of the construction or operation of the desalination facilities, it is assumed they would not result in a conflict with local land use plans, policies, or regulations. Impacts would be less than significant. • Construction and operation of desalination facilities would likely take place in the Delta and may be considered covered activities under the Delta Plan. Only the lead CEQA state or local agency may determine whether that plan,

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	program, or project is a covered action of the Delta Plan. If an action is covered, consistency with the Delta Plan would be determined. The consistency determination would include implementing mitigation from the Mitigation Monitoring or Reporting Program of the Delta Plan, as appropriate. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to consistency with the Delta Plan. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely impacts could be reduced once mitigation was implemented because once a lead agency determines an action is covered and complies with the Mitigation Monitoring or Reporting Program, consistency would be determined and impacts would be less than significant. • Potential conflicts with habitat conservation plans, natural community conservation plans, or other plans, policies and regulations protecting biological species and resources are evaluated in the Biological Resources section of this table.
Mineral Resources	• The California SMARA requires the State Geologist to classify land into MZs, according to the known or inferred mineral potential of existing land. The primary goal of mineral land classification is to ensure that the mineral potential of land is recognized by local government decision-makers and considered before land-use decisions are made that could preclude mining. Local general plans, specific plans, and other local plans refer to, and use the information produced by the State Geologist, to identify mineral resources because they are specialized evaluations and because the California Geologic Survey is the designated agency to perform these surveys under SMARA. MZs are identified by the State to identify inferred mineral potential of an area. Areas designated MZ-1 have adequate information to determine no significant mineral resources exist, or indicate a very low likelihood; areas designated MZ-2 have adequate information to identify significant mineral deposits or indicate a high likelihood of presence; and areas designated MZ-3 have inadequate information to determine significance of mineral deposits, but contain mineral deposits. Some gravel, sand, and aggregate resources (identified as MZ-1 or MZ-2) are found in close proximity to waterways and the LSJR in San Joaquin County (San Joaquin County 1998, City of Tracy 2005). Most of the city of Stockton is designated as MZ-1, with a small area of MZ-3 (City of Stockton 2007). Other mineral resources, such as gold or peat, have been previously extracted from the county (San Joaquin County 1998). • Construction and operation of desalination facilities would have a very low potential to result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state or result in the loss of availability of a locally designated mineral resource recovery site. This is because the desalination facilities would likely be within existing WWTPs. If the desalination facilities are located within a state or locally designated mineral resource area, construction and operation of the desalination facilities would not permanently remove access to a mineral resource because there would be other locations around the facilities that could provide access to the mineral resource. Impacts would be less than significant.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
Noise	• Construction would potentially take place in Mountain House (San Joaquin County), and the Cities of Tracy and Stockton, since desalination facilities would likely be within or adjacent to existing WWTPs. Each of these jurisdictions have noise requirements in their general plans or zoning ordinances for construction and operation based on land use designations and timing restrictions. Noise requirements are typically based on land uses that are considered more sensitive to ambient noise levels than others due to noise exposure. Residences, motels and hotels, schools, libraries, churches, hospitals, nursing homes, and outdoor recreation or natural areas are typically more sensitive to noise than are commercial or industrial land uses. Therefore, local noise standards are typically more stringent for sensitive land uses in terms of level of noise generated, duration, and frequency than less sensitive uses. Given the wide ranges of land uses throughout San Joaquin County, noise levels can range from louder high density residential and industrial uses or roadway uses to more quiet open space and agricultural areas (San Joaquin County 1992). Frequently, the most common and loud noise generating activity in San Joaquin County affecting the overall permanent ambient noise setting is freeway traffic on I-5, I-205, and SR-4 and along railroads and in heavy industrial areas (e.g., Port of Stockton) or around airports (San Joaquin County 1992). • The City of Tracy and the City of Stockton regulate generation of construction noise by restricting the timing that construction can occur (e.g., operating construction requirement from 10pm to 7pm is prohibited) and the land use or adjacent land uses under which the noise generating activity occurs (City of Stockton n.d., City of Tracy n.d.). San Joaquin County exempts noise sources associated with construction, provided they do not take place before 6am or after 9pm (San Joaquin County n.d.). Construction of desalination facilities could generate temporary noise and as such could expose people to noise levels in excess of standards. It is likely desalination facilities would be constructed in areas with suitable land use designations and zoning for infrastructure (e.g., public facilities or industrial) and would be unlikely to have sensitive receptors (e.g., homes, hospitals, schools) within close proximity. If sensitive receptors were adjacent to construction activities and experienced a temporary increase in ambient noise levels due to construction, and the noise generating activities would be required to follow existing local noise ordinances limiting the timing of construction. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant noise impacts related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, depending on the potential location of possible sensitive receptors and the duration of the particular noise generating activities over the course of construction. • Construction activities that typical result in ground-borne vibrations or ground-borne noise are activities such as pile driving, where the ground is repeatedly struck and vibrations or noise can be generated. Pile driving may be needed to construct desalination facilities. Some local agencies (e.g., San Joaquin County) exempt vibrations associated with construction provided it is occurring within certain hours (San Joaquin County n.d). However, if pile driving is used, and there are sensitive receptors to noise (e.g., homes, hospitals, schools) within close proximity, Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant noise impacts related to construction.

Potential Environmental Effects of Wastewater Treatment Plant Desalination	
Resource	Discussion
	Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • Desalination facilities would generate constant noise during operation. Existing WWTPs already generate intermittent noise (e.g., from alarm bells, pumps, and generators). It is anticipated there would be a low probability that sensitive receptors (e.g., homes, hospitals, schools) would be located within close proximity to experience the operating noise generated because it is anticipated that the WWTPs would be located in areas with similar land uses (e.g., other public facilities or CII facilities). Additionally, most of the wastewater treatment facilities are enclosed within buildings or behind walls that can reduce the operating noise. As such, a permanent increase in ambient noise under operating conditions is not expected. Impacts would be less than significant. • Assuming construction and operation of desalination facilities would be located in San Joaquin County, there are six public access airports within the county (SJCOG n.d.[a]). The Stockton Metropolitan Airport, San Joaquin County Airport have approved Airport Land Use Compatibility Plans, which identifies noise contours and where noise exposures may take place as a result of aircraft flight patterns consistent with Federal Aviation Administration requirements (SJCOG n.d.[a]). Other airports, such as the City of Tracy, have either airport master plans or other planning documents that outline noise contours consistent with FAA requirements (City of Tracy 1998). While it is unknown where construction or operation of salinity source controls might occur, the construction and operation of desalination facilities would not bring new or additional people within close proximity to an airport or private airstrip or expose people to noise generated by air traffic on a regular basis. This is because desalination facilities are expected to be automated and would not result in an increased permanent work force cited within proximity to an airport or private airstrip. Nor would desalination facilities result in a population increase that would be exposed to airport noise. Impacts would not occur.
Population and Housing	• The construction and operation of desalination facilities would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property or population growth in an area. Further, it would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people to the southern Delta. Finally, they would not be constructed and operated increase capacity to serve new users. Impacts would not occur. • The construction and operation of desalination facilities would not displace substantial numbers of people or housing, or necessitate the construction of replacement housing elsewhere because the facilities would be located in the existing footprint of WWTPs or closely adjacent in industrial or public land use type areas. As such, it is not expected people would reside in these areas. Impacts would not occur.
Public Services	• The need for additional public services (e.g., fire protection, police protection, parks, libraries, schools) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, the construction and operation of desalination facilities would not involve an increase in population or housing. In addition, these actions do not include proposals for new housing, and would not generate students or increase demands for school services or facilities. Impacts would not occur.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
Recreation	• Construction of desalination facilities would likely occur within the footprint or immediately adjacent to existing wastewater treatment facilities. These facilities are typically located adjacent to receiving waters and in CII or urban areas to provide wastewater service to urban, suburban, and CII users of the wastewater system. So it is unlikely recreational facilities would be located in areas where wastewater treatment facilities currently exist. However, if recreational facilities were located within very close proximity, recreational facilities could be affected by noise levels or other temporary construction activities. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to construction. • An increase in use of existing recreational facilities is typically associated with a substantial increase in the population to accommodate new recreationists. Construction or operation of desalination facilities would not result in a substantial increase in population because it would not result in the development of housing or other population-inducing development (e.g., job centers). The purpose of the construction and operation of desalination facilities would be to comply with water quality objectives. Construction and operation of these facilities would satisfy existing demand, not meet new projected demand for wastewater treatment or water supply (Section 16.4.1, *New Source Water Supplies*). Impacts would be less than significant. • Construction and operation of desalination facilities would not include recreational facilities or require the construction or expansion of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Assuming construction and operation of desalination facilities would occur in San Joaquin County, because that is where the cities of Tracy and Stockton are located, as well as Mountain House CSD, the project(s) would be subject to the SJCOG Regional Congestion Management Program (SJCOG 2016b). As described in the Regional Congestion Management Program, projects are subject to a tiered review process, unless exempt from CEQA or unless considered as part of a previously approved project (SJCOG 2016b). Projects that trigger 125 or more vehicle trips during weekday AM or PM peak-hours or 500 or more total vehicle daily trips on any day of the week would be required to perform a quantitative regional traffic analysis. The Regional Congestion Management Program provides for mitigation to reduce effects if trips occur at those levels and these are included in Table 16-38. Trips that are exempted from the RCMP standards, and are removed from calculations of LOS standards under the RCMP include trips resulting from construction (SJCOG 2013). A total of 103 intersections have been designated as part of SJCOG Regional Congestion Management Program (SJCOG n.d.[b]). Designation of RCMP intersections allows for congestion monitoring and appropriately focuses attention at locations where operational constraints are typically experienced on arterial roadways (SJCOG n.d.[b]). Of approximately 1,500 congestion management roadway segment miles, 245 operate at a LOS D, with approximately half of these in the county, and the remaining in the cities of Stockton, Lathrop, and Manteca and Tracy (Table 4 in Dowling Associates 2010). There are approximately 92 miles of CMP lanes operating at LOS E or F, with more than half located in county areas, and 16 percent in Stockton (Table 4 in Dowling Associates 2010). Operation of desalination facilities would generate additional truck trips to dispose of the waste brine generated by the desalination process. The number of truck trips depends on the volume and salt concentration of the wastewater treated; therefore, the number of trucks that would be required is

Potential Environmental Effects of Wastewater Treatment Plant Desalination	
Resource	Discussion
	unknown, as is the roads they would travel or their ultimate destination (i.e., landfill or other facility). Trucks would likely not be required every day because the evaporation ponds would first dewater the brine solution. As discussed above, if a project exceeds the criteria established by the Regional Congestion Management Program on roads identified in that program (e.g., 125 or more vehicle trips during weekday AM or PM peak-hours or 500 or more total vehicle daily trips on any day of the week), mitigation would be applied through that program. The criteria is particularly high and is generally applicable to development such as office parks, retail, or housing developments that would generate substantial numbers of trips. However, Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant transportation and traffic impacts related to operations, if indeed disposal resulted in exceedances of the Regional Congestion Management criteria. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented and consistency with the Regional Congestion Management Plan was determined. • Construction and operation of desalination facilities could result in some additional trips. It is unknown the number of construction and operational trips that might be needed and the location of these tips, but it is anticipated that construction would be relatively limited in duration. Typically, construction activities are exempt from local road trip thresholds because construction is temporary. However, depending on the quantity of trips and the duration, the temporary increased traffic during construction or the increase in operational trips associated with brine disposal could exceed local or regional road trip thresholds (either vehicle miles traveled or level of service, as discussed in Table 16-25, changes to the methodology and criteria for evaluations are occurring). Projects would be required to evaluate trip generating activities through the respect jurisdiction traffic impact analysis guidelines depending on the location and number of trips generated (City of Stockton n.d.). Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts on transportation and traffic related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction. • Construction of desalination facilities is not expected to result in hazards to, or on, roadways because they would primarily be constructed within existing footprints of facilities or in close proximity. Similarly, construction activities are not expected to conflict with public transit facilities, public bicycle facilities, or pedestrian facilities (e.g., sidewalks). The development of project-specific construction traffic management plans, as identified in Table 16-38 would reduce potentially significant impacts if hazards on the roadway were temporarily created during construction due to construction related activities. Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts of transportation and traffic related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable,

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
	consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant, given the low likelihood of occurrence and because construction impacts would be temporary. • Similar to the discussion in Hazards and Hazardous Materials, it is not expected that construction of desalination facilities would result in inadequate emergency access, given the location of the construction work would primarily within the existing footprint of existing WWTPs or in close proximity to them. Similarly, construction activities are not expected to conflict with public transit facilities, public bicycle facilities, or pedestrian facilities (e.g., sidewalks) because they would be constructed within existing footprints of facilities. As such, there is a low likelihood of interfering with emergency access, public transit facilities, public bicycle facilities, or pedestrian facilities. However, Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts of transportation and traffic related to construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. It is likely that impacts could be mitigated to less than significant, given the low likelihood of occurrence and because construction impacts would be temporary. • Construction and operation of desalination facilities would not result in an increase demand for air traffic or the need for airports because this type of project would not result in an increase in population and is not related to air traffic or airports. Impacts would not occur. • Operation of desalination facilities is not expected to result in a permanent substantial increase in hazards due to a design feature or incompatible use, permanent inadequacy of emergency access, or a permanent change that would decrease the performance or safety of public transit facilities, public biking facilities, or public pedestrian facilities because it is anticipated that these would be located within existing facility footprints or within close proximity. Trips associated with brine disposal would be done on existing roads and as such, would not result in permanent substantial hazards or conflicts with emergency access and public transit, bicycle, or pedestrian facilities. Impacts would be less than significant.

Potential Environmental Effects of Wastewater Treatment Plant Desalination

Resource	Discussion
Utilities and Service Systems	• The construction and operation of desalination facilities would not be expected to exceed wastewater treatment requirements of the Central Valley Water Board because, by removing salts, it would actually improve the treated effluent quality. Additionally, it would not result in a determination by the wastewater treatment provider that it has inadequate capacity to meet the service area's demand because the desalination facilities would not increase the actual volume of wastewater generated in the service area. Impacts would be less than significant. • The construction and operation of desalination facilities involve construction at wastewater treatment facilities. Environmental effects associated with implementation of desalination facilities are discussed throughout this table (Aesthetics through Transportation and Traffic). Table 16-38 lists potential mitigation measures that lead agencies (e.g., wastewater treatment special districts or municipalities) can and should implement to reduce potentially significant impacts related to construction and operation of desalination facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • The construction and operation of desalination facilities would involve processing treated wastewater to remove additional salts before discharge into receiving waters. It is not anticipated that the demand for water would increase because desalination would be treating wastewater already generated by the service area. Further, it is not expected that this process would require new entitlements for water because it is at the end of the wastewater treatment process. As such, impacts would be less than significant. • The construction and operation of desalination facilities would not need the construction of additional storm water drains because desalination facilities would likely be built within the footprints of existing wastewater treatment facilities, which currently have impervious surfaces that generate runoff; therefore, it is expected that existing storm water infrastructure would be used. Impacts would be less than significant. • The construction and operation of desalination facilities could generate solid waste in the form of brine. This type of solid waste is not considered hazardous, and the disposal of brine would follow all regulations and guidelines of solid waste in Class I/II landfills (non-hazardous waste landfills). Impacts would be less than significant.

16.4.4 Agricultural Return Flow Salinity Control

Real-time management of agricultural return flow, such as changing the timing of the release of agricultural discharge to receiving waters, is a reasonably foreseeable method of compliance for agricultural water users that must comply with numeric salinity objectives. This method may reduce salinity entering the southern Delta.

Cost Evaluation

Agricultural dischargers could monitor receiving water's assimilative capacity on a real-time basis, and time discharges to coincide with periods of high flow (i.e., more assimilative capacity). This potential method of compliance with proposed salinity standards would require dischargers to establish a network of monitoring stations and a discharge schedule. When there is no assimilative capacity, irrigators would either recycle water that would otherwise be discharged or would discharge to a detention pond until discharges to the receiving waters are permitted. This method of compliance could be integrated with other BMPs, such as water recycling, to reduce salinity entering the plan area.

Temporary discharge basin sizing was estimated in the Central Valley Water Board's *Amendments to the Water Quality Control Plan for the Sacramento River and San Joaquin River Basins for the Control of Salt and Boron Discharges into the Lower San Joaquin River, July 2004* (Basin Plan Amendments 2004). The Basin Plan Amendments analyzed a project area that included 1.4 million acres of irrigated agricultural land. The Central Valley Water Board estimated that for this irrigated area, 50,000 AF of water may need to be stored annually when there is no assimilative capacity in the river (Central Valley Water Board 2004). For this plan area, it is assumed that there are roughly 137,000 acres of irrigated agricultural land (roughly the size of the South Delta Water Agency [SDWA]). Using the relationship of detention volume to agricultural land developed in the Basin Plan Amendments 2004 and this plan area's assumed irrigated land acreage, it is estimated that this method of compliance would need 4.9 TAF of detention basin storage. If each detention basin is 10 ft deep, approximately 490 acres could be used for this potential method of compliance.

Enhanced monitoring equipment, modeling, and forecasting capability would be needed to forecast assimilative capacity in the LSJR. Control gates and conveyance systems would also be needed to divert drainage from river discharge to permanent treatment structures when assimilative capacity is not available. Personnel would be needed to manage real-time systems and coordinate discharges from multiple subareas in the LSJR Watershed (Central Valley Water Board 2004). It is assumed that there would be multiple subareas within the plan area that would manage discharges in real time, creating a real-time monitoring system. Table 16-31, *Costs and Components of a Real-Time Management System*, estimates the components needed and costs associated with constructing a real-time management system.

Table 16-31. Costs and Components of a Real-Time Management System

Construction	Cost
Computer and Software	$ 5,000
Control Gates (10)	$ 100,000
Floats, Weirs, and EC Monitoring Equipment	$ 50,000
Installation of Monitoring Components	$ 75,000
Conveyance to River	$ 100,000
Subtotal	$ 330,000
Contingency (30%)	$ 99,000
Total Construction Cost	$ 429,000
Operations and Maintenance	
Operations and Maintenance (Including Coordinating Discharges)	$100,000 per year

Source: Central Valley Water Board 2004.
EC = electrical conductivity (salinity).
EC is electrical conductivity, which is generally expressed in deciSiemens per meter (dS/m) in this document. Measurement of EC is a widely accepted indirect method to determine the salinity of water, which is the concentration of dissolved salts (often expressed in parts per thousand or parts per million).

The costs in Table 16-31, *Costs and Components of a Real-Time Management System,* were adapted from the Central Valley Water Board's Basin Plan Amendments 2004. Costs for a real-time management system in the plan area were assumed to be the same as those in Table 16-31, but the contingency was increased to 30 percent of construction costs based on best professional judgment. It is assumed that 11 systems would need to be constructed to effectively cover the major water users in the plan area (Central Valley Water Board 2004). The total estimated construction cost for 11 systems is $4,719,000, with an operations and maintenance budget of $1,100,000 per year.

Environmental Evaluation

Summary of Potential Action

Real-time management is a reasonable foreseeable salinity control measure that would include shifting the agricultural discharge timing to allow agricultural return flows released from agricultural lands to occur during times of high assimilative capacity for the receiving waters. This would require agricultural dischargers to hold or contain their discharge in detention ponds and release it at different times of the year. The agricultural dischargers could hold salt in the soil column for a period of time and then leach it by applying water. The leached water (e.g., agricultural return flow) could be held in a detention pond or released directly into the receiving water, depending on the assimilative capacity of the receiving water at the time of leaching. While assimilative capacity can increase in receiving waters during higher flows, the relationship between assimilative capacity and flow is not always linear. The construction of detention ponds on the agricultural discharger property would likely be contained in close proximity to the discharge point and the generation source (e.g., fields and orchards in the southern Delta). The location, timing of construction, and details of operation for the detention ponds are unknown. However, detention ponds for these types of purposes would likely be less than 0.5 acre and take a few months to construct. The volume of agricultural discharge would essentially remain the same, and discharges would be expected to occur from current outfall locations along the receiving waters.

Potential Environmental Effects

The most likely potential effect of a change in discharge timing and the use of detention ponds would be the repurposing of lands currently used for agriculture. Discharge timing or the use of detention ponds would not result in the loss of agricultural land (Prime Farmland, Unique Farmland, or Farmland of Statewide Importance) but only a reuse of that land. While there may be economic effects for individuals, the amount of land temporarily taken out of production would be small compared to the amount of agricultural land in the southern Delta (primarily located in San Joaquin County). There is some potential that natural and cultural resources (significant historical, archaeological, or paleontological resources) adjacent to existing agricultural lands could be affected. However, construction and operation of detention pond facilities on farmland would be subject to county code and potential county permit requirements (e.g., agricultural excavation permit), which could minimize potential construction- and operation-related effects on natural and cultural resources. San Joaquin County, as part of the county permitting process for agricultural excavation, determines if a proposed project would result adverse environmental effects. If the County determines that there is no potential for adverse effect(s) from a proposed project, a permit is issued. However, if it is determined that there is potential for a project to result in adverse effects, the County would require environmental review under CEQA to issue the permit.

CEQA allows categorical exemptions for classes of projects which have been determined not to have a significant effect on the environment. (Pub. Res. Code, § 21084.) Specifically, modification or demolition of existing facilities can be exempt from CEQA under a Class 1 categorical exemption. The Class 1 categorical exemption consists of the minor alteration of existing public or private structures, facilities, topographical features, involving negligible or no expansion of use beyond that existing at the time of the lead agency's determination. The types of "existing facilities" listed in the exemption are not intended to be all-inclusive of the types of projects which might fall within the CEQA exemption. The key to the consideration of this class of categorical exemptions is whether the project involves negligible or no expansion of an existing use. As construction and operation of detention ponds on agricultural land would not expand an existing use, the detention ponds may be eligible for a Class 1 categorical exemption depending on the project-specific circumstances. Table 16-32, *Potential Environmental Effects of Agricultural Return Flow Salinity Controls*, summarizes the potential environmental effects associated with agricultural return flow salinity controls. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, at the end of this chapter lists potential mitigation measures associated with the construction or operation of the methods of compliance and is referenced in Table 16-32 where appropriate.

Table 16-32. Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Potential Environmental Effects of Agricultural Return Flow Salinity Controls	
Resource	Discussion
Aesthetics	• The detention ponds that may store agricultural discharge would be on private agricultural property in the southern Delta. There are relatively few sensitive receptors to views in the southern Delta, but receptors may include boaters on southern Delta waterways. Because the detention ponds would be relatively small and below grade, are not expected to involve large buildings or facilities, and would not likely require permanent lighting, the potential to substantially adversely affect a scenic vista or substantially degrade the existing visual character or quality of the sites where they are to be installed would be low. The detention ponds may be fenced for security purposes, and this fencing would serve as a screen from viewers. The detention ponds would not substantially detract from the existing view of agricultural activities and facilities in the southern Delta. Further, detention ponds would not substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic building within view of the two state-designated scenic highways in San Joaquin County, I-5 and I-580, because the ponds would be installed and operated on existing actively farmed land where these resources are not likely to occur or can be easily avoided. Impacts would be less than significant.
Agriculture and Forestry Resources	• The detention ponds would likely be constructed and operated within existing agricultural land (including Prime Farmland, Unique Farmland, or Farmland of Statewide Importance). They would be relatively small in size when compared to the overall amount of agricultural land in production in the southern Delta. Therefore, they would have a low potential to convert large amounts of agricultural land. Furthermore, using agricultural land for agricultural ponds would be considered an agricultural use and would be supporting existing agricultural lands by reducing salinity of the discharge used for irrigation and improving the water quality of the southern Delta. Because of this, detention ponds would likely be included within agricultural land use designations and zoning. If the construction and operation of detention ponds were inconsistent with local land use plans, policies and regulations, and required a discretionary action by a local government agency, the project would obtain an amendment or variant from the local jurisdiction prior to operation. The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects on agricultural resources. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the small area of disturbance and the purpose of detention ponds to support agricultural uses. • Construction and operation of the detention ponds would not be located on forest land or timberland because they would likely be constructed and operated within existing agricultural lands. Impacts would not occur.

Potential Environmental Effects of Agricultural Return Flow Salinity Controls	
Resource	Discussion
Air Quality	• Construction of detention ponds would likely result in emissions associated with construction equipment and construction vehicles, as well as fugitive dust emissions from ground disturbance. The quantity, duration, and the intensity of construction activity have an effect on the amount of construction emissions and related pollutant concentrations occurring at any one time. As such, more emissions are typically generated by relatively large amounts of relatively intensive construction. SJVAPCD's published guidelines, *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002) do not require the quantification of construction emissions. Rather, the guidelines require implementation of effective and comprehensive feasible control measures to reduce PM10 emissions (SJVAPCD 2002). SJVAPCD considers PM10 emissions to be the greatest pollutant of concern when assessing construction-related air quality impacts and has determined that compliance with its Regulation VIII, including implementation of all feasible control measures specified in its *Guide for Assessing Air Quality Impacts* (SJVAPCD 2002), constitutes sufficient mitigation to reduce construction-related PM10 emissions to less-than-significant levels and minimize adverse air quality effects. All construction projects must abide by Regulation VIII. Since the publication of SJVAPCD's guidance manual, the district has revised some of the rules comprising Regulation VIII. Guidance from SJVAPCD staff indicates that implementation of a Dust Control Plan would satisfy all of the requirements of SJVAPCD Regulation VIII (Siong pers. comm.). However, if construction is conducted over a longer time period, emissions could be "diluted" relative to construction that would occur over a shorter time period because of a less intensive buildout schedule (i.e., total daily or yearly emissions would be averaged over a longer time interval). Since construction of detention ponds does not require lengthy construction activities, the potential for significant environmental effects is minimal. Further, construction emissions generated would need to comply with the SJVAPCD regulations and established thresholds. Impacts would be less than significant. • Operation of detention ponds would not release air quality emissions because changing the timing of the release of discharge into receiving waters would not generate air quality emissions. As such, operations would not have the potential to emit criteria pollutants, result in a net increase of criteria pollutants, conflict with an applicable air quality plan, or contribute to objectionable odors. Impacts would not occur. • SJVAPCD has determined some common types of facilities that have been known to produce odors in the SJVAB. Some of these facilities are wastewater treatment facilities, sanitary landfills, transfer stations, composting facilities, petroleum refineries, asphalt batch plants, chemical manufacturing facilities, fiberglass manufacturing facilities, painting/coating operations, food processing facilities, feed lots/dairies, and rendering plants (SJVAPCD 2002). Construction and operation of detention ponds would not involve the type of facility identified by, for example, SJVAPCD, as a known odor source. Consequently, it is not expected detention ponds would create objectionable odors affecting a substantial number of people. Impacts would be less than significant.

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
Biological Resources	• Construction of detention ponds would result in soil disturbance and alteration of drainage in areas of active agricultural management. There is generally a low potential for candidate, sensitive, or special-status species, or habitat (including federally protected wetlands, riparian habitat, or other sensitive natural communities) in these areas because of ongoing farming activities and the changing landscape. Similarly, because detention ponds would be located on existing, actively farmed agricultural land, it is unlikely that construction of detention ponds would substantially interfere with the movement of any native resident or migratory fish or wildlife species or associated migratory corridors, or impede the use of native wildlife nursery sites. The lead agency with permitting approval over the ponds can and should implement the mitigation measures listed in Table 16-38 to reduce potentially significant environmental effects on biological resources, if it is determined that sensitive species or habitat is present. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because of the small area of disturbance and the low likelihood of special status species to exist. • Because detention ponds would be located on existing, actively farmed agricultural land, it is unlikely that construction and operation of the ponds would conflict with local policies and ordinances protecting biological resources, or conflict with an adopted natural community conservation plan or habitat conservation plan. Construction and operation of detention ponds would occur within the SJMSCP Plan Area; however, agricultural activities located on agriculturally zoned land are not covered (SJCOG 2016a). As discussed above, the lead agency with permitting approval over the ponds can and should implement the mitigation measures listed in Table 16-38 to reduce potentially significant environmental effects on biological resources, if it is determined that sensitive species or habitat is present. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because of the small area of disturbance and the low likelihood of special status species to exist. • Operation of detention ponds would be expected to discharge agricultural flow into receiving waters when salinity levels in the river are below the designated salinity objective and with high assimilative capacity (i.e., ability for the receiving waters to increase salt concentration without exceeding salinity objectives). Salinity concentration in the receiving waters would not result in significant impacts on fish and wildlife. Additionally, these fish and wildlife are adapted to tidally influenced environments which exhibit a wide range of salinity levels. Impacts would be less than significant.
Cultural Resources	• Construction of detention ponds would result in ground disturbance in existing managed and active agricultural lands in the southern Delta. It is likely managed and active agricultural lands have been disturbed before; however, cultural resources (significant historical, archeological, or paleontological resources) could exist depending on the location of disturbance and depth of disturbance. The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant environmental effects associated with construction of detention ponds should unknown significant cultural resources be discovered during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
	impacts could be mitigated to less than significant once mitigation measures were implemented because of the small area of disturbance and the low likelihood of cultural resources to exist. • Construction of detention ponds would result in ground-disturbing activities at depths greater than 6 ft. It is considered highly unlikely human remains, typically buried at depths of 6 ft, would be disturbed during construction, because these lands have been in agricultural production and have been regularly disturbed. In the event human remains are uncovered during construction, compliance with the State Health and Safety Code would be required. As specified by Section 7050.5 of the Health and Safety Code, and described in Table 16-38, no further disturbance shall occur until the county coroner has made the necessary findings as to origin and disposition pursuant to Public Resources Code Section 5097.98. If such a discovery occurs, excavation or construction shall halt in the area of the discovery, the area shall be protected, and consultation and treatment shall occur as prescribed by law. If the coroner recognizes the remains to be Native American, he or she shall contact the NAHC, who shall appoint the Most Likely Descendent. Additionally, if the human remains are determined to be Native American, a plan shall be developed regarding the treatment of human remains and associated burial objects, and the plan shall be implemented under the direction of the Most Likely Descendent. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because of the small area of disturbance and the low likelihood of human remains to exist. • Operation of detention ponds would result in a change in timing of release of water or a change in the volume of agricultural return flow released and would not involve ground-disturbing activities. Therefore, it is highly unlikely any known or unknown cultural resources would be affected because of the lack of ground-disturbing activities during operation. Impacts would be less than significant.
Geology and Soils	• The new detention ponds could occur in areas known to have an earthquake fault, experience strong seismic ground shaking, experience seismic-related ground failure, experience landslides, or be located on a geologic unit or soil that is unstable or be located on expansive soil. However, construction and operation of a detention pond would not result in an impact on, or be affected by: Alquist-Priolo faults, strong seismic shaking, seismic-related ground failure, unstable geologic units, expansive soils or landslides. Furthermore, storing agricultural return flow in a detention pond would not bring people to the risk of earthquakes or geologic hazards, meaning construction or operation of detention ponds would not substantially increase the number of people exposed to the risk of earthquakes or geologic hazards because it would not draw people to earthquake areas or hazard locations not already frequented. Impacts would not occur. • Construction of detention ponds would result in ground-disturbing activities that could result in soil erosion or loss of topsoil; however, ground-disturbing activities would be limited in duration and geography. The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant impacts related to soil erosion and storm water runoff. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented because of the small area of disturbance and the limited duration of disturbance.

Potential Environmental Effects of Agricultural Return Flow Salinity Controls	
Resource	Discussion
	• Operation of detention ponds would involve the release of agricultural return flow into receiving waters. It is expected the releases would occur at existing discharge points and the releases would not result in erosion or topsoil loss. Impacts would be less than significant. • Construction and operation of detention ponds would not involve constructing or operating septic tanks and, therefore, they would not be affected. Impacts would not occur.
Greenhouse Gas Emissions	• Similar to the discussion in Table 16-7, construction of detention ponds would likely result in increased use of electricity and fuels and, therefore, an increase in GHG emissions that could exceed SJVAPCD's ZEL and result in a potentially significant impact. The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant impacts related to construction and operation activities and GHG emissions. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • In September 2006, the California State Legislature adopted AB 32. AB 32 establishes a cap on statewide GHG emissions and sets forth the regulatory framework to achieve the corresponding reduction in statewide emission levels. Under AB 32, the ARB is required to take the following actions. ○ Adopt early action measures to reduce GHGs. ○ Establish a statewide GHG emissions cap for 2020 based on 1990 emissions. ○ Adopt mandatory report rules for significant GHG sources. ○ Adopt a scoping plan indicating how emission reductions would be achieved through regulations, market mechanisms, and other actions. ○ Adopt regulations needed to achieve the maximum technologically feasible and cost-effective reductions in GHGs AB 32 establishes a statewide GHG reduction target from which most local GHG thresholds are based and substantial evidence is taken for these established GHG thresholds. Therefore, if GHG emissions are in excess of a relevant threshold, then it would conflict with the reduction targets established by AB 32 and would be inconsistent with the AB 32 Scoping Plan. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts from GHG emissions associated with construction and operation of the facilities. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. • The release of agricultural return flow into receiving waters from detention ponds does not have the potential to emit GHGs. Impacts would not occur.

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
Hazards and Hazardous Materials	• Construction of detention ponds would be short term and may involve the limited transport, storage, use, and disposal of hazardous materials such as fuel and lubricating grease for motorized heavy equipment. Some examples of typical hazardous materials handling are fueling and servicing construction equipment on the site, and transporting fuels, lubricating fluids, solvents, and bonding adhesives. These types of materials are not acutely hazardous, and storage, handling, and disposal of these materials are regulated by local, county, and state laws. Furthermore, the quantities of these materials used during construction would be small (e.g., less than 100 gallons) because construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained. The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant impacts associated with hazardous materials during construction of detention ponds. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented, given the temporary nature of construction, the short duration of construction, and the relatively small quantities of hazards handled. • There are eight sites within San Joaquin County that are identified on the Hazardous Waste and Substance Site List (Cortese Site list) as sites being hazardous materials sites under Government Code Section 65962 (CalEPA 2016). Construction and operation of detention ponds are not likely to be located on these eight sites or interfere with these sites because the construction and operation of detention ponds would be in agricultural areas and would not involve activities at the sites on this list (e.g., Lawrence Livermore National Lab, McCormick and Baxter Creosoting Company). CalEPA identifies leaking underground storage tank sites, sites that have received CDOs or CAOs, and hazardous waste facility sites where DTSC has taken corrective Action (CalEPA 2016). There are no hazardous waste facility sites where DTSC has taken corrective action in San Joaquin County (CalEPA 2016). As such, construction of detention ponds would not affect them. There are approximately 244 leaking underground storage cases in San Joaquin County designated as open (CalEPA 2016). Sixteen facilities in San Joaquin County have received CDOs or CAOs and have active cases, but may not be necessarily related to hazardous waste (CalEPA 2016). The location of construction of detention ponds is unknown, but could occur on one of these sites as some of the sites are agriculturally related land uses. During excavation or soil disturbance potentially contaminated soil could be encountered. As such, the lead agency with permitting approval over the ponds can and should implement potential mitigation measures in Table 16-38 to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed. • Assuming construction of detention ponds would be located in San Joaquin County, there are six public access airports within the county (SJCOG n.d.[a]). While it is unknown where construction of detention ponds might occur, they would occur within agricultural areas. Furthermore, they would not result in the construction of structures that would result in a safety conflict with airport land use plans. As such, impacts would be less than significant. San Joaquin County has 14 school districts and more than 200 schools (San Joaquin County Office of Education n.d.). The location of

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
	construction of detention ponds unknown. They are likely to occur in primarily agricultural lands and the likelihood of a school being within one-quarter mile (0.25 miles) is low. However, hazardous materials may be used during construction (e.g., fuels, lubricants, diesel). While it is expected materials would be handled, used, and stored properly in accordance with local, state and federal regulation, and contained in the event of an accidental release, if an accidental release occurred, it could occur within proximity to a school. Additionally, depending on the location of construction, remediation may be needed to address soil contamination during excavation activities. As such, if a school existed within close proximity to a construction site, those mitigation measures identified table 16-38 applied to project-specific construction needs would reduce potentially significant impacts during construction. The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 to reduce potentially significant impacts associated with hazardous materials during construction. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once implemented because hazardous materials contamination could be remediated and removed and because the measures would ensure the appropriate handling of hazardous materials during construction. • Construction and operation of detention ponds would not physically interfere with an adopted emergency response plans or emergency evacuation plans since they would be located on existing agricultural lands and therefore would not prohibit the mobility of people to escape potential emergencies. Furthermore, construction and operation does not involve an increase in population that would necessitate reconsideration of how to evacuate people in an emergency. Impacts would not occur. • Operation of detention ponds would result in a change in timing or volume of agricultural return flow discharged into receiving waters. The activity of discharging agricultural return flow would not result in the use, transport, or disposal of hazardous materials, nor would it interfere with an airport or result in an increased risk of wildland fire exposure. Impacts would not occur.
Hydrology and Water Quality	• Construction of detention ponds would entail ground-disturbing activities, such as grading, that could result in temporary changes to existing drainages (including any storm water drainage), erosion, or runoff. However, ground-disturbing activities would be limited in duration and geography (i.e., detention ponds would generally be constructed on approximately 0.5 acre of land or less). Further, it is assumed that as part of adhering to city and/or county grading/excavation permits or other applicable permit requirements, detention pond construction would be such that changes to drainage and erosion or runoff are minimized, and existing drainage patterns would not be substantially altered such that onsite flooding would occur. In addition, as discussed in this table for Hazards and Hazardous Materials, construction of detention ponds may involve the limited transport, storage, use, and disposal of hazardous materials, which, if spilled, could have adverse effects on water quality depending on the location and magnitude of the spill. However, storage, handling, and disposal of these materials is regulated by local, county, and state laws, and the quantities of these materials used during construction would be small (e.g., less than 100 gallons) and construction would be limited in duration. Therefore, if a spill occurred, it could be readily and easily contained and, as such, violations of water quality standards are not expected to occur. The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 to reduce

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
	potentially significant impacts on hydrology and water quality. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction, the short duration of construction, and the relatively small area of ground disturbance. • Operation of a detention pond is expected to change the seasonal fluctuations of agricultural return flow by changing the timing of the discharge from agricultural lands to receiving waters. Although the discharge could have a different salinity concentration than the discharge previously released, the change in timing of the release would allow the receiving water to have higher assimilative capacity. Thus the discharge would not be considered polluted runoff. The same volume of discharge would be released under baseline conditions when compared to being released from detention ponds. It is likely that the discharges would occur during higher flows or normal flows when there may be more assimilative capacity. Water quality standards would be maintained because the discharge would have to comply with the Central Valley Water Board's water quality requirements. Impacts would be less than significant. • Detention ponds could be located within a 100-year flood hazard area; however, these structures are of low relief, and/or below ground surface, and would not impede or redirect flood flows. Additionally, the detention ponds would not substantially increase the number of people exposed to the risk of flooding because they would not draw people to flood hazard locations or result in the construction of housing in a 100-year flood hazard area. Accordingly, detention ponds would not expose people to significant loss, injury, or death related to flooding. Impacts would be less than significant. • Detention ponds would be constructed in areas of low land relief. Therefore, these locations would not support mudflows, which typically need very steep slopes and large amounts of precipitation to occur. Furthermore, these areas would not be adjacent to the ocean and would not be affected by tsunamis. Impacts would be less than significant. • A seiche is an oscillation of the surface of a landlocked body of water that varies in period from a few minutes to several hours that is caused by ground movement generated by meteorological effects (e.g., wind) or earthquakes. Construction and operation of detention ponds are not expected to occur near a lake or reservoir. Impacts would not occur. • Construction and operation of the detention ponds would not substantially deplete groundwater supplies because groundwater would not be pumped. In addition, construction and operation of the detention ponds would not interfere with groundwater recharge because no impervious surfaces would be constructed. Impacts would not occur. • There are no other ways in which construction or operation of detention ponds could result in a substantial degradation to water quality.

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
Land Use and Planning	• Construction and operation of detention ponds is not expected to physically divide an established community because the ponds would be developed on existing agricultural land, support existing agricultural practices, and because the discharge locations already exist on the agricultural lands. Detention ponds would be considered agricultural infrastructure and likely included within agricultural land use designations and zoning. If the construction and operation of detention ponds were inconsistent with local land use plans, policies and regulations, and required a discretionary action by a local government agency, the project would obtain an amendment or variant from the local jurisdiction prior to operation. Impacts would be less than significant. • Construction and operation of detention ponds would likely take place in the Delta and may be considered covered activities under the Delta Plan. Only the lead CEQA state or local agency may determine whether that plan, program, or project is a covered action of the Delta Plan. If an action is covered, consistency with the Delta Plan would be determined. The consistency determination would include implementing mitigation from the Mitigation Monitoring or Reporting Program of the Delta Plan, as appropriate. Table 16-38 lists potential mitigation measures that lead agencies (e.g., municipalities or municipal water purveyors) can and should implement to reduce potentially significant impacts related to consistency with the Delta Plan. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely impacts could be reduced once mitigation was implemented because once a lead agency determines an action is covered and complies with the Mitigation Monitoring or Reporting Program, consistency would be determined and impacts would be less than significant. • Potential conflicts with habitat conservation plans, natural community conservation plans, or other plans, policies, and regulations protecting biological species and resources are evaluated in the Biological Resources section of this table.
Mineral Resources	• The California SMARA requires the State Geologist to classify land into MZs, according to the known or inferred mineral potential of existing land. The primary goal of mineral land classification is to ensure that the mineral potential of land is recognized by local government decision-makers and considered before land-use decisions are made that could preclude mining. Local general plans, specific plans, and other local plans refer to, and use the information produced by the State Geologist, to identify mineral resources because they are specialized evaluations and because the California geologic survey is the designated agency to perform these surveys under SMARA. Some gravel, sand, and aggregate resources are found in close proximity to waterways and the LSJR in San Joaquin County (San Joaquin County 1998, City of Tracy 2005, City of Manteca 2003, City of Lathrop 2004). Most of the City of Stockton is designated as either not having mineral resources or a low likelihood of mineral resources (City of Stockton 2007). Other mineral resources, such as gold or peat, have been previously extracted from the county (San Joaquin County 1998). • Construction and operation of detention ponds would have a very low potential to result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state or result in the loss of availability of a locally designated mineral resource recovery site. This is because these uses would be located within existing agricultural lands that are not used for mineral extraction. Impacts would not occur.

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
Noise	• Construction and operation of the detention ponds would occur in agricultural areas where there are limited sensitive receptors (e.g., schools, hospitals). Agricultural activities, which generate noise, are part of the existing noise conditions in actively farmed agricultural lands. Construction of detention ponds would be temporary and limited to ground-disturbing activities, and would be required to comply with existing local noise ordinances limiting the timing of construction (e.g., generally Mondays–Fridays, 7am–6pm). The lead agency with permitting approval over the ponds can and should implement potential mitigation measures identified in Table 16-38 or comparable to reduce potentially significant impacts associated with noise during construction of detention ponds. Until such time that these potential mitigation measures are implemented, the impacts would remain significant and unavoidable, consistent with State CEQA Guidelines Section 15091. However, it is likely that impacts could be mitigated to less than significant once mitigation measures were implemented given the temporary nature of construction, the short duration of construction, and the relatively small area of ground disturbance. • Construction activities that typical result in ground-borne vibrations or ground-borne noise are activities such as pile driving, where the ground is repeatedly struck and vibrations or noise can be generated. Given nature of construction to build a detention pond (e.g., digging and excavating) it is highly likely that pile driving would not occur or be needed. Impacts would be less than significant • Once operational, detention ponds would not produce noise as they would discharge agricultural return flows into receiving waters, which is not a noise-producing activity. As such, a permanent increase in ambient noise under operating conditions is not expected. Impacts would not occur. • While it is unknown where construction or operation of detention ponds might occur, the construction and operation of detention ponds would not bring new or additional people within close proximity to an airport or private airstrip or expose people to noise generated by air traffic on a regular basis. This is because detention ponds would not result in an increased permanent work force cited within proximity to an airport or private airstrip. Nor would detention ponds result in a population increase that would be exposed to airport noise. Impacts would not occur.
Population and Housing	• Construction and operation of detention ponds would not involve the construction of new homes or businesses, the extension of roads, or other actions that may induce substantial property growth in an area. Construction and operation of detention ponds would not develop any amenities (e.g., malls, amusement parks, hotels, recreation areas) that would attract people to the southern Delta. Impacts would not occur. • Construction and operation of detention ponds would not displace substantial numbers of people or housing, or necessitate the construction of replacement housing elsewhere because the change in volume of water (and timing of release of water) would take place at existing discharge points and agricultural lands, and not where people currently reside. Impacts would not occur.

Potential Environmental Effects of Agricultural Return Flow Salinity Controls

Resource	Discussion
Public Services	• The need for additional public services (e.g., fire protection, police protection, parks, libraries, schools) or the deterioration of existing public services typically results from an increase in population. As a location's population increases, the need for additional or new public services and public service facilities generally increases. As discussed in Population and Housing, above, construction and operation of the detention ponds would not involve an increase in population or housing. In addition, construction and operation of the ponds would not include proposals for new housing, and would not generate students or increase demands for school services or facilities. Impacts would not occur.
Recreation	• Recreational facilities are not typically located in agricultural fields, and construction and operation of detention ponds in agricultural lands would not result in impacts on recreational facilities or lead to the construction of recreational facilities. Impacts would not occur.
Transportation and Traffic	• Construction of detention ponds may involve construction vehicle trips. However, due to the limited geographic scale and limited duration of construction, it is not expected truck or worker trips would exceed local or regional road trip thresholds. Impacts would be less than significant. • Construction and operation of detention ponds would occur on existing agricultural land, which is generally not heavily trafficked and access would likely be restricted to the public. As such, it is not expected construction or operation would conflict with a regional congestion management program, would result in inadequate emergency access, conflict with existing public transit, public bicycle facilities, or public pedestrian facilities (e.g., sidewalks) or result in a hazard to on-road traffic. Once operational, they would not generate trips beyond what currently is generated on existing agricultural lands and as such would not conflict with the Regional Congestion Management Plan or local or regional trip thresholds. Impacts would not occur. • Construction and operation of detention ponds would not result in an increase demand for air traffic or the need for airports because these projects would not result in an increase in population and is not related to air traffic or airports. Impacts would not occur.
Utilities and Service Systems	• Construction and operation of detention ponds would not involve the need for utilities or service systems because it would not require the construction or operation of wastewater treatment facilities or water treatment supply facilities. It would not increase the demand for water and therefore new entitlements would not be needed. It would not result in the generation of solid waste. Impacts would not occur.

16.4.5 South Delta Temporary Barriers

The program of implementation for the SDWQ alternatives requires continued operations of the agricultural barriers at Grant Line Canal, Middle River, and Old River at Tracy, or other reasonable measures, to address the impacts of the CVP or SWP export operations on water levels and flow conditions that might affect salinity. The existing temporary barriers would likely to continue to operate in the southern Delta under the program of implementation. DWR determined it is essential to continue barrier installations to protect salmon migrating through the Delta, and to provide an adequate agricultural water supply for southern Delta farmers (DWR 2015b). An adequate agricultural water supply must satisfy quantity, quality, and channel water levels to meet the reasonable and beneficial needs of water users in the SDWA (DWR 2015b).

The purpose of operating the temporary barriers is to protect salmon migrating through the Delta and provide an adequate agricultural water supply in terms of quantity, quality, and channel water levels to meet the reasonable and beneficial needs of water users in the southern Delta area. The program is operated by DWR and also takes actions to protect agricultural diversions that are affected from the operations of the barriers. The program consists of four rock barriers across southern Delta channels that primarily benefit migrating fish or benefit agricultural water users.

- HOR – fish barrier
- Old River Near Tracy (ORT) – agricultural barrier
- Middle River (MR) – agricultural barrier
- Grant Line Canal (GLC) – agricultural barrier

The HOR barrier and has been in place most years since 1963 between September 15 and November 30. It was also installed in the spring between April 15 and May 30 of 1992, 1994, 1996, 1997, 2000, 2001, 2002, 2003, and 2004 and 2007 (high SJR flows prohibited installation in 1993, 1995, 1998, 1999, 2005, and 2006). The remaining three barriers and are installed between April 5 and September 30 of each season. The ORT barrier has been installed since 1991 and the MR barrier has been installed since 1987. A rock barrier in GLC was first installed in spring 1996, and has since been installed in 1997, 1999, and 2000 through the present. The four rock barriers were not installed in 1998 due to high SJR flows (DWR 2015c).

DWR maintains a publicly available schedule for the operation of the barriers. The schedule for 2015 is described in Table 16-33, *Temporary Barrier 2015 Schedule*, and generally follows seasonal timeframes and restrictions associated with fish and agriculture (DWR 2015d).

Table 16-33. Temporary Barrier 2015 Schedule

Barrier	Beginning of Onsite Work	Beginning of In-Water Work	Closure	Complete Removal
Spring Head of Old River	March 16, 2015	March 16, 2015	April 8, 2015	June 2015
Middle River	March 30, 2015	March 30, 2015	April 3, 2015	Early to Mid November 2015
Old River at Tracy	March 16, 2015	March 16, 2015	April 7, 2015	Mid to Late November 2015
Grant Line Canal	April 2, 2015	April 2, 2015	June 2015	Mid to Late November 2015
Fall Head of Old River	September 2015	September 2015	September 2015	Mid to Late November 2015

Source: DWR 2015d.

DWR identifies that water levels and water circulation in the southern Delta have improved with agricultural barrier installation. Migration conditions for salmon have improved when the HOR barrier was installed. As such, DWR determined it is essential to continue barrier installations to protect salmon migrating through the Delta, and to provide an adequate agricultural water supply for southern Delta farmers. An adequate agricultural water supply must satisfy quantity, quality, and channel water levels to meet the reasonable and beneficial needs of water users in the SDWA (DWR 2015c).

The temporary agricultural barriers maintain higher water elevations during ebb tides (water moving downstream towards the estuary) by blocking the tidal flow once the water elevation falls below the barrier crest. The crest elevation of the ORT and MR barriers are 1 foot higher than the GLC barrier, to create a slight upstream net flow towards Grant Line Canal as the tide elevation drops below the barrier crests. The minimum tidal elevations upstream of the barriers are thereby constrained by the GLC barrier crest, although the slight flow through the barriers allows a slowly decreasing elevation. The general effects of the barriers are such that the minimum daily elevations increase by about 2–3 ft during the period when the temporary barriers are installed.

The tidal flow during each ebb tide moves water one direction (towards the estuary) and the tidal flow during each flood tide moves water in the opposite direction (away from the estuary). Salinity will increase in a tidal channel having a higher salinity discharge (e.g., treated wastewater or agricultural drainage) both upstream and downstream; the increase in salinity will be less if the tidal flows are higher (from a greater tidal mixing volume) or if the net flow is higher (from greater dilution). The combination of tidal flows (mixing) with a net channel flow is sometimes called circulation; a null zone refers to a portion of a channel that has limited tidal flows and a small net flow, allowing salinity to accumulate from local drainage discharges. Tidal flow measurements at each of the temporary agricultural barriers show similar effects; the tidal flows upstream of the barriers are reduced to about 50 percent of the full tidal flows.

The salinity in the SJR at Vernalis is generally controlled by releases from New Melones Reservoir to meet the existing water quality objectives as described by the 2006 Bay-Delta Plan. Salinity generally increases downstream of Vernalis from the effects of agricultural drainage and treated wastewater discharges. Salinity along Old River between the SJR near Mossdale and Tracy Boulevard also generally increases from the City of Tracy wastewater discharge and many local discharges of agricultural drainage. Below is the cost evaluation and environmental evaluation for continuing to operate the South Delta Temporary Barriers, as described by the program of implementation for the SDWQ alternatives.

Cost Evaluation

The primary cost for the temporary barriers is driven by the activities, materials and equipment required to construct and remove them. Based on the DWR's multi-year (2016–2018) construction contract for the temporary barriers, DWR's estimated cost for constructing and removing the barriers for the 3-year period was approximately $11.8 million (DWR 2015e). This cost estimate includes labor, materials, equipment for construction and removal of the temporary rock barriers at MR, ORT, and GLC, and maintenance, refurbishment and/or replacement of appurtenances (e.g., temporary agricultural pumping facilities), as well as other related tasks, which could include furnishing, installing, and removing a non-physical barrier at Delta divergence locations (DWR 2015f). The contract was awarded for the lowest bid of $9.5 million (DWR 2015e).

Environmental Evaluation

The temporary barriers have been installed during their respective seasons for decades as described above. They are currently part of the baseline hydrology, water quality, and biological conditions of the southern Delta. They may continue to operate as they have been to maintain water levels and circulation in the southern Delta under the program of implementation. As such, DWR would continue to work with permitting agencies (e.g., U.S. Army Corps of Engineers) and resource agencies (e.g., Central Valley Water Board, NMFS, USFWS) to obtain the appropriate permits and conditions to operate the temporary barriers. As such, there would be no change from baseline conditions and there would be no environmental impacts with the continued operation of the temporary barriers.

16.4.6 Low Lift Pumping Stations

The program of implementation for the SDWQ alternatives requires additional studies and monitoring of the southern Delta circulation and water levels. It is possible that additional study and monitoring would determine the need for modifications of the existing South Delta Temporary Barriers Project. If this determination is made by the State Water Board, DWR may be required to install low lift pumping stations at the temporary barriers as a method of compliance.

Modifications could include providing additional lift stations at the barriers. DWR prepared the *Low-Head Pumping Conceptual Plan* (2011c) describing potential modifications to the operations of these barriers. Below is the cost evaluation and environmental evaluation performed by the *Low Head Pumping Conceptual Plan* for the installation of either permanent or temporary pumps at the South Delta Temporary Barriers.

Cost Evaluation

Cost evaluations were based on a number of layouts and scenarios. Costs were evaluated for stand-alone pumping sites or *single pumping sites* on each of the agricultural barriers in the southern Delta (ORT, MR, GLC). Costs were also evaluated for two pumping sites, or pumping sites on two of the three agricultural barriers (MR and ORT or MR and GLC). Three intake structure types were analyzed: temporary cylindrical, permanent cylindrical, and permanent flat intake screens. Lastly, pumping capacities were also analyzed with the above variables. The three analyzed pumping capacities were 250, 1,000, and 1,500 cfs. Tables 16-34, *Single Pumping Sites Estimated Initial Capital Costs*, through Table 16-37, *Two Pumping Sites Estimated Annual Costs*, show the costs of these potential methods of compliance.

The cost ranges are based on different site layout configurations analyzed in DWR's *Low-Head Pumping Conceptual Plan*. The site layout that would provide the greatest reduction in water quality violations is a two-pumping site alternative with 1,000 cfs pumping capacity combined pumping at MR and ORT barriers (DWR 2011c). The estimated cost of this layout is $55.5–$540.7 million; the estimated annual costs are $4.5–$62.7 million.

Table 16-34. Single Pumping Sites Estimated Initial Capital Costs

	Pump Capacity (cfs)		
Pump Facility Intake Screen Design	250	500	1,000
Temporary Cylindrical	$5.5–$20.7	$9.8–$40.9	$19.6–$80.9
Permanent Cylindrical	$20.2–$60.8	$40.9–$112.9	$81.7–$234.3
Permanent Flat	$120– $161.4	$214.5–$286.6	$391.7–$551

Source: DWR 2011c.
Note: All cost values in millions of dollars.
cfs = cubic feet per second.

Table 16-35. Two Pumping Sites Estimated Initial Capital Costs

	Pump Capacity (cfs)		
Pump Facility Intake Screen Design	250	500	1,000
Temporary Cylindrical	$14.9	$28.4	$55.5
Permanent Cylindrical	$49.5	$87.6	$168.1
Permanent Flat	$186.9	$301.0	$540.7

Note: All cost values in millions of dollars.

cfs = cubic feet per second.

Environmental Evaluation

As part of the *Low-Head Pumping Conceptual Plan* (2011b), DWR prepared an environmental checklist documenting potential impacts on environmental resources should the conceptual plan be implemented. The environmental checklist and analysis identified environmental commitments and/or potential mitigation measures to be implemented by DWR, should the project move forward, to reduce potentially significant impacts for the following resources associated with either construction or operation: aesthetics, agriculture, air quality, biological resources, cultural resources, geology and soils, GHG emissions, hazards and hazardous materials, hydrology and water quality, land use and planning, noise, transportation and traffic, and utilities and service systems. The environmental checklist identified less-than-significant impacts for the following resources: mineral resources, population and housing, public services, and recreation. Attachment 4 of Appendix H, *Supporting Materials for Chapter 16*, contains the environmental checklist of the conceptual plan and is incorporated into this evaluation. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, at the end of this chapter, lists potential mitigation measures that DWR can and should implement to reduce potentially significant environmental effects on environmental resources. It is likely that those impacts related to construction could be mitigated to less than significant once mitigation measures were implemented due to the temporary nature of construction, the relative short duration of construction, and the relatively small area of ground disturbance. However, given the potential need to construct a cofferdam and dewater, there is the potential for take of listed fish species (similar to coffer dams required and described in Section 16.3.6, *Fish Passage Improvements – Fish Screens*, Section 16.3.7, *Fish Passage Improvements – Physical Barriers in the Southern Delta*, and Section 16.3.9, *Predatory Fish Control*). As such, even with mitigation measures, significant and unavoidable impacts may occur if the potential for take cannot be avoided or reduced or take occurs during construction. In addition, as described in Tables 16-12 and 16-21, the generation of GHGs during construction and operation may not be lessened with mitigation measures and as such, may result in exceedances of existing air quality management basin thresholds that cannot be mitigated to less-than-significant levels.

16.5 Sources of Funding

There are many financial assistance programs designed to assist agencies implement water supply and water quality projects. The federal and state governments manage these programs. Often, these funding programs can leverage each other to make a project more feasible. Below is a brief description of some pertinent funding programs.

16.5.1 Federal Sources

U.S. Department of Agriculture

Water and wastewater loans and grants are offered through U.S. Department of Agriculture (USDA) Rural Development. Eligible applicants are public entities, nonprofit organizations, federally recognized tribes, and mutual water companies located outside cities, with a population under 10,000 people. Financial assistance recipients may receive a grant and loan component. The grant component cannot exceed 75 percent of the total financial assistance requested. Loans are offered up to a 40-year term at an interest rate updated quarterly, based on nonmetropolitan median household income (CFCC 2012).

U.S. Department of the Interior, Bureau of Reclamation

The Water Sustain and Manage America's Resources for Tomorrow (Water SMART) Program is an umbrella program that manages many grant programs for water supply research and implementation projects. The core focus of Water SMART is sustainable management and water efficiency. Typical projects include projects to reduce water losses in distribution systems, water recycling projects, and the creation of new water sources for agricultural irrigation purposes. Water SMART has multiple funding opportunities for municipal and agricultural water users. Typical grant awards range from $200,000 to $1,500,000 (CFCC 2012).

The U.S. Department of the Interior, Bureau of Reclamation (USBR) also offers grant programs targeted at improving the Bay-Delta's water resources and water quality through the Bay-Delta Restoration Water Use Efficiency Grants Program. Funds are available for improving water supply reliability and for increasing water use efficiency. Eligible applicants are public entities with authority over water delivery located within the CALFED solution area as identified in the 1999 *CALFED Programmatic Environmental Impact Statement/ Environmental Impact Report* (CALFED 2000a, CFCC 2012).

16.5.2 State Sources

California Infrastructure and Economic Development Bank

The Infrastructure State Revolving Fund finances water supply and water quality projects. Financial assistance is available in the form of lower-than-market interest rate loans. Based on a project description and applicant's credit score, an interest rate is computed. The term of the loan can be up to 30 years. Eligible applicants include public entities, such as cities, counties, and special districts (CFCC 2012).

California Department of Water Resources

The Agricultural Water Use Efficiency Grant Program provides funds for projects that improve agricultural water use efficiency. Projects must result in water savings, increased in-stream flow, increased water quality, or increased energy efficiency in water systems. Sample projects include: feasibility studies, research, development, training, education, public outreach, and pilot projects (CFCC 2012).

Integrated Regional Water Management (IRWM) provides funds for many types of water quality activities. Current IRWM grant programs include: planning, implementation, and storm water flood management. IRWM grants focus on holistic watershed management activities and regional coordination of water supplies. Eligible applicants include cities, counties, districts, and nonprofit organizations (CFCC 2012).

DWR manages the Delta and San Joaquin and Sacramento Rivers Water Quality Grant Program to assist agencies with projects that protect drinking water supplies. Eligible projects include: (1) projects that reduce or eliminate discharges of salt, dissolved organic carbon, pesticides, pathogens, and other pollutants to the SJR; (2) projects that reduce or eliminate discharges of bromide, dissolved organic carbon, salt, pesticides, and pathogens from discharges to the Sacramento River; (3) projects at Franks Tract and other locations in the Delta that will reduce salinity or other pollutants at agricultural and drinking water intakes; and (4) projects identified in the June 2005 *Delta Region Drinking Water Quality Management Plan*, prioritizing design and construction of the relocation of drinking water intake facilities for in-Delta water users (CFCC 2012).

State Water Resources Control Board

The Clean Water State Revolving Fund provides low-interest loans for water quality improvement projects, including water recycling and desalination. The loan term is up to 30 years, and the interest rate is between 0 percent and half the general obligation bond rate (2.4–3 percent) depending on the applicant's population and median household income. Principal forgiveness is available for small disadvantaged communities. Typical loans are for 20 years at half the State's general obligation bond rate. Eligible applicants are cities, counties, special districts, and joint powers authorities (CFCC 2012).

Water recycling projects that offset potable water supplies are eligible to apply for financial assistance from the Water Recycling Funding Program (WRFP). WRFP has funds available to assist with planning and implementation of water recycling projects. Only public entities (e.g., cities, counties, special districts) are eligible to apply for these funds. The WRFP offers both grants and loans (CFCC 2012).

The Agricultural Drainage Loan and Agricultural Drainage Management Loan Programs provide funding for projects that address treatment, storage, conveyance, or disposal of agricultural drainage that threatens waters of the State. An example project is the installation of tailwater recirculation systems and drip irrigation systems to reduce the volume of tailwater and contaminants discharged to a receiving waterbody. Eligible applicants include public entities (e.g., cities, counties), districts, joint powers authority, or other political subdivisions of the State involved with water management (CFCC 2012).

Department of Public Health

The Safe Drinking Water State Revolving Fund provides low-interest loans for projects that correct and upgrade drinking water infrastructure. The loan term is up to 30 years, and the interest rate is between 0 percent and half the general obligation bond rate (2.4–3 percent) depending on the applicant's population and median household income. Principal forgiveness is available for small disadvantaged communities. Typical loans are for 20 years at half the State's general obligation bond rate. Eligible applicants are cities, counties, special districts, and joint powers authorities (CFCC 2012).

16.6 Potential Mitigation Measures

This section summarizes potential mitigation measures that could be applied by lead agencies or other entities to reduce potentially significant impacts identified in the environmental evaluations of Sections 16.2, *Lower San Joaquin River Alternatives – Other Indirect Actions*, 16.3, *Lower San Joaquin River Alternatives – Non-Flow Measures,* and 16.4, *Southern Delta Water Quality Alternatives – Reasonably Foreseeable Methods of Compliance*. These potential mitigation measures were developed based on a review of similar projects. The scope, scale, and location of a particular project would dictate the need for, and the type of, mitigation. While the particular circumstances and location of a project may result in significant and unavoidable impacts post mitigation, lead agencies and entities may be able to fully mitigate impacts to a less-than-significant level (using one or more of the potential mitigation measures identified in Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions,* and Table 16-39, *Potential Mitigation Measures for Construction and Operation Activities Related to Non-Flow Measures*). In addition, as required by CEQA (State CEQA Guidelines § 15126.2) lead agencies and entities would describe a reasonable range of alternatives based on project-specific conditions and project-specific objectives, and one of the alternatives may, in and of itself reduce significant environmental impacts. The effectiveness of mitigation is contingent upon several other factors, such as those listed below.

- The ability of lead agencies and entities to implement the mitigation.
- The other responsible agencies involved in the project.
- The thresholds lead agencies use to evaluate the impact.
- Site-specific conditions.

This section first summarizes those mitigation measures that could be applied to other indirect actions and methods of compliance and then summarizes mitigation measures that could be applied to non-flow measures.

16.6.1 Other Indirect Actions and Methods of Compliance

The other indirect actions that could occur under the LSJR alternatives and the reasonably foreseeable methods of compliance that could occur under the SDWQ alternatives, discussed herein, would be subject to project-specific CEQA review prior to approval. The project-specific analysis would be required to identify potentially significant environmental impacts. The lead agency would be required to require the implementation of all feasible mitigation measures to reduce impacts to less than significant or be responsible for providing a statement of overriding considerations for significant impacts that cannot be mitigated to a level of less than significant. Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, identifies the potential mitigation measures that lead agencies could implement should they determine a discretionary action they approve has significant impacts. These mitigation measures are based, in part, on mitigation measures presented in the following documents.

- *Proposed Amendment to the Water Quality Control Plan for the North Coast Region to Establish Exception Criteria to Point Source Waste Discharge Prohibition by Raising the Action Plan for Storm Water Discharges and Adding a New Action Plan for Low Threat Discharges* (North Coast Regional Water Quality Control Board 2009).
- *Amendments to the Water Quality Control Plan for the Sacramento River and San Joaquin River Basins for the Control of Methylmercury and Total Mercury in the Sacramento and San Joaquin Delta Estuary* (Central Valley Water Board 2010a).
- *Substitute Environmental Document for Toxic Pollutants in the Dominguez Chanel and Greater Los Angeles and Long Beach Waters Total Maximum Daily Load* (California Regional Water Quality Control Board, Los Angeles Region 2011).
- *Initial Study and Mitigated Negative Declaration for the Tracy Desalination and Green Energy Project* (City of Tracy 2011).
- *Irrigated Lands Regulatory Program Environmental Impact Report* (Central Valley Water Board 2010b).
- Low Head Pump Salinity Control Study Prepared to Meet Requirements of the State of California State Water Resources Control Board Water Rights Order WR 2010-0002, Condition A.7. Appendix C: Environmental Considerations for South Delta Low Head Pump Station (DWR 2011c).
- *Water Supply Options* (SFPUC 2007).

An SED must identify feasible mitigation measures for each significant environmental impact identified in the SED. (Cal. Code Regs., tit. 23, § 3777, subd. (b)(d).) Feasible mitigation measures are intended to avoid, reduce, or compensate for adverse impacts on a resource and can include actions such as implementation of plans to minimize impacts. For each impact identified as significant, a mitigation measure to reduce that impact to a less-than-significant level is described, if appropriate, or the infeasibility of mitigation is discussed. One legal factor that may render a mitigation measure infeasible is the limited authority of the lead agency. CEQA does not grant agencies new, discretionary powers independent of the powers granted to the agencies by other laws. (Pub. Resources Code, § 21004; Cal. Code Regs., tit. 14, § 15040.) Accordingly, a mitigation measure may be legally infeasible if the lead agency does not have the discretionary authority to implement it. In addition, economic considerations may render mitigation measures infeasible. (Pub. Resources Code, § 21004; Cal. Code Regs., tit. 14, §§ 15040, 15041, 15126.4, 15364.) The authority to require project-level mitigation lies with the lead agencies undertaking or approving the individual projects, not the State Water Board. These agencies can and should impose the mitigation measures presented in Table 16-38, *Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions*, and until such time that these mitigation measures are imposed, impacts would remain significant, consistent with State CEQA Guidelines Section 15091. Potential mitigation measures associated with water transfers discussed in Section 16.2.1, *Transfer/Sale of Surface Water*, are summarized in Attachment 1 of Appendix H, *Supporting Materials for Chapter 16*. Potential mitigation measures associated with Water Supply Desalination discussed in Section 16.2.6, *Water Supply Desalination*, are summarized in Attachment 3 of Appendix H, *Supporting Materials for Chapter 16*.

Table 16-38. Potential Mitigation Measures for Construction and Operation Activities Related to Other Indirect and Additional Actions[a]

Resource	Potential Mitigation Measure	Substituting Surface Water with Groundwater	Aquifer Storage and Recovery	Recycled Water Sources	In-Delta Diversion	New Surface Water Storage	New Source Water Supplies	Salinity Pretreatment Programs	Wastewater Treatment Plant Desalinization	Agricultural Return Flow Salinity Control	Low Lift Pump Station(s)
Construction											
Aesthetics	• Direct construction lighting away from residential and roadway areas if sensitive receptors are present.[2]	X	—	X	—	X	X	X	X	—	X
	• Implement a revegetation plan to revegetate areas where construction-related ground disturbance has occurred.	—	—	X	—	X	X	X	X	—	X
	• Design facility to blend with surrounding land uses.	—	—	—	X	X	X	—	X	—	X
	• Use appropriate architectural treatment and landscaping.	—	—	—	X	X	X	—	X	—	X
	• Reservoir management plan to incorporate elevation/storage levels to accommodate recreational access to the extent practicable.	—	—	—	—	X	—	—	—	—	—
Agriculture and Forestry Resources	• If forest or vegetation is removed by a qualified forester or restoration ecologist and reviewed by the appropriate agencies, develop and implement a reforestation and/or revegetation plan.[2]	—	—	—	—	—	X	—	X	—	—
	• Restrict ground-disturbing mechanical operations around sensitive forested or agricultural areas.[2]	—	—	X	X	X	X	—	X	—	X
	• Preserve or replace onsite trees as a means of maintaining forest resource(s) and providing carbon storage (afforestation/reforestation).[2]	—	—		—	X	X	—	X	—	X
	• Avoid agricultural lands (including Prime Farmland, Unique Farmland, and Farmland of Statewide Importance) or timber production zone lands or National Forest System lands to the greatest extent possible.[6]	—	—	X	X	X	X	X	X	X	X
	• Develop a plan that mitigates to the maximum extent practicable for lands inundated by new surface water storage to reduce impacts on forestry resources.	—	—	—	—	X	—	—	—	—	—
	• Coordinate with applicable counties and local jurisdictions to determine if there is an agricultural mitigation program and comply with mitigation the program to the extent required by law. For example, San Joaquin County's agricultural mitigation ordinance (Title 9, Division 10, Chapter 9-1080) requires agricultural mitigation for an amendment to the general plan or a zoning reclassification that changes the designation of any land from agricultural to nonagricultural use. Mitigation is satisfied by granting a farmland conservation easement or other farmland conservation mechanism, and the number of acres of agricultural mitigation land must be at least equal to the number of acres converted to a nonagricultural use (1:1 ratio). The City of Tracy, pursuant to an agricultural mitigation fee ordinance (Municipal Code Title 13, Chapter 13.28), requires payment of a fee for each acre of farmland to be developed for private urban uses. The fees are used for the purchase of conservation easements on agricultural lands. Similarly, the City of Stockton's Agricultural Land Mitigation Program requires that all projects under the City's jurisdiction that would result in the conversion of agricultural land to nonagricultural uses to either dedicate an in-kind direct	—	—	—	—	—	X	—	X	—	—

Resource	Potential Mitigation Measure	Substituting Surface Water with Groundwater	Aquifer Storage and Recovery	Recycled Water Sources	In-Delta Diversion	New Surface Water Storage	New Source Water Supplies	Salinity Pretreatment Programs	Wastewater Treatment Plant Desalinization	Agricultural Return Flow Salinity Control	Low Lift Pump Station(s)
	purchase/acquisition of an agricultural conservation easement at a 1:1 ratio or pay an in-lieu agricultural land mitigation fee.										
Air Quality	• Apply appropriate construction mitigation measures from the applicable air district (e.g., SJVAPCD) to reduce construction emissions. These measures will be applied on a project-level basis and may be tailored in consultation with the appropriate air district, depending on the severity of anticipated construction emissions. [5] ○ CCAPCD: – The applicant shall be responsible for ensuring that all adequate dust control measures are implemented in a timely manner during all phases of project development and construction. – All material excavated, stockpiled, or graded shall be sufficiently watered, treated, or covered to prevent fugitive dust from leaving the property boundaries and causing a public nuisance or a violation of an AAQS. Watering should occur at least twice daily, with complete site coverage. – All areas with vehicle traffic shall be watered or have dust palliative applied as necessary for regular stabilization of dust emissions. – All onsite vehicle traffic shall be limited to a speed of 15 miles per hour on unpaved roads. – All land clearing, grading, earth moving, or excavation activities on a project shall be suspended as necessary to prevent excessive windblown dust when winds are expected to exceed 20 miles per hour. – All inactive portions of the development site shall be covered, seeded, or watered until a suitable cover is established. Alternatively, the applicant may apply County-approved nontoxic soil stabilizers (according to manufacturer's specifications) to all inactive construction areas (previously graded areas which remain inactive for 96 hours) in accordance with the local grading ordinance. – All material transported offsite shall be either sufficiently watered or securely covered to prevent public nuisance, and there must be a minimum of 6 inches of freeboard in the bed of the transport vehicle. – Paved streets adjacent to the project shall be swept or washed at the end of each day, or more frequently if necessary, to remove excessive or visibly raised accumulations of dirt and/or mud which may have	X	—	X	X	X	X	X	X	—	X

	resulted from activities at the project site. – Prior to final occupancy, the applicant shall re-establish ground cover on the site through seeding and watering in accordance with the local grading ordinance. – In addition, the CCAPCD recommends the following mitigation measures, which may be applicable to a proposed project: o Mitigation for Use during Design and Construction Phases: – Grid power shall be used (as opposed to diesel generators) for job site power needs where feasible during construction. – Temporary traffic control shall be provided during all phases of construction to improve traffic flow as deemed appropriate by local transportation agencies and/or Caltrans. – Construction activities shall be scheduled to direct traffic flow to off-peak hours as much as practicable. – During initial grading, earth moving, or site preparation, larger projects may be required to construct a paved, coarse gravel, or dust palliative treated apron, at least 100 ft in length, leading onto the paved road(s). – Wheel washers may be required where project vehicles and/or equipment enter and/or exit onto paved streets from unpaved roads on larger projects. – All self-propelled off-road diesel-powered equipment and vehicles greater than 25 bhp shall be equipped with an engine meeting at least Tier 1 emission standards (typically manufactured 1996 or later). o GBUAPCD: – Use, where possible, of water or chemicals for control of dust in the demolition of existing buildings or structures, construction operations, the grading of roads or the clearing of land. – Application of asphalt, water, or suitable chemicals on dirt roads, material stockpiles, and other surfaces which can give rise to airborne dusts. – Installation and use of hoods, fans, and fabric filters, to enclose and vent the handling of dusty materials. Adequate contaminant methods shall be employed during such handling operations. – Use of water, chemicals, chuting, venting, or other precautions to prevent particulate matter from
