Impact WQ-19h (CP2): Delta Salinity on the San Joaquin River at Brandt Bridge Impact WQ-19h (CP2) would be similar to Impact WQ-19h (CP1). On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years, as shown in Table 7-84. CP2 would not measurably change EC on the San Joaquin River at Brandt Bridge. This impact would be less than significant.

Table 7-85 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Brandt Bridge in the period of simulation. CP2 would not change the existing compliance level for salinity standards for the San Joaquin River at Brandt Bridge. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19j (CP2): Delta Salinity on the Old River at Tracy Road Bridge
Impact WQ-19j (CP2) would be similar to Impact WQ-19j (CP1). On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP2 would not measurably change EC on the Old River at Tracy Road Bridge, as shown in Table 7-88. This impact would be less than significant.

Table 7-89 shows the number of months simulated EC values exceeded the standards for the Old River near Tracy Road Bridge. Although exceedence would occur during August, under future conditions, on an annual average basis, the compliance of salinity standards under CP2 would not change from the existing conditions. Overall, CP2 would not change the baseline compliance levels under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP2): X2 Position CP2 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the existing condition or future condition. Although several months may be out of compliance individually under the bases of comparison, the impact would be less than significant.

Impact WQ-20 (CP2) would be similar to Impact WQ-20 (CP1). Table 7-90 shows the simulated monthly average X2 position for CP2 as compared to the existing condition and future condition baselines. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-90. Simulated Monthly Average X2 Position Under Baseline Conditions and CP2

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3 focuses on increasing agricultural water supply reliability while also increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 18.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded CWP. Because CP3 focuses on increasing agricultural water supply reliability, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, with the additional storage retained for water supply reliability and to expand the CWP for downstream anadromous fisheries.

Simulations of CP3 did not involve any changes to the modeling logic for deliveries or flow requirements; all rules for water operations were updated to include the new storage, but were not otherwise changed.

Shasta Lake and Vicinity

Impact WQ-1 (CP3): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-1 (CP1). However, the construction-related activities described in Chapter 2, "Alternatives," would result in about 1,270 more acres of exposed shoreline than CP1. Relocation activities under CP3 would expose a similar but greater acreage to erosion than would CP2 (up to 698 acres). This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP3): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses Similar to CP1, construction activities associated with enlarging Shasta Dam as well as the relocation actions would result in sizeable areas that would be subject to surface disturbance, including jurisdictional waters within the influence zone of CP3. Efforts to document jurisdictional waters associated with relocation areas are described in Chapter 12, "Botanical Resources and Wetlands." This information has been updated since the DEIS was circulated for public review. If the SLWRI is authorized, Reclamation will work closely with its cooperating agencies to ensure compliance with the CWA (e.g., Section 401 and 404) consistent with the development of the LEDPA.

Environmental commitments and BMPs for the various construction and relocation activities (e.g., bridge replacement, boat ramp construction, demolition of facilities) have been incorporated into CP3. These activities could include removal of riparian vegetation, thereby exposing water bodies to increased solar radiation for various time periods. As described in Chapter 2, "Alternatives," and the "Preliminary Environmental Commitments and Mitigation Plan Appendix," riparian revegetation would be implemented at all construction and relocation sites as applicable to ensure that shade is quickly reestablished after construction is completed. As described in Chapter 2, "Alternatives," although the TCD may not be operational for some period of time during construction, project sequencing would ensure that changes to water temperature in Shasta Lake and downstream in the upper Sacramento River, as well as associated limnological conditions in Shasta Lake would be consistent with those that occur periodically under the No-Action Alternative typically associated with maintenance and outage periods.

Because of the large water surface area of Shasta Lake, coupled with the isolated and discrete nature of the relocation activities on the tributaries, temporary construction-related effects are not expected to modify water temperature in a manner that would have a negative effect on beneficial uses or result in a water quality violation. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP3): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-3 (CP1). No construction activities would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP3): Long-Term Sediment Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to WQ4 (CP1), except that the exposure of about 2,498 acres of shoreline surrounding Shasta Lake would result in a potential for increased wave-related shoreline erosion compared to the No-Action Alternative (see Attachment 1, "Shoreline Erosion Technical Memorandum," to Appendix 7, "Geologic Technical Report"). As the reservoir is lowered during summer and fall, the exposed surface area would also be subject to surficial erosion processes that could mobilize and transport sediment to the newly expanded Shasta Lake. Although environmental commitments and BMPs are incorporated into the project description, the project would result in an incremental increase in the delivery of suspended sediment and turbidity to the receiving waters. The amount of sediment that could be delivered is not entirely quantifiable because of the size of the lake and the number of variables that influence sediment transport and delivery. Chapter 4, "Geology, Geomorphology, Minerals, and Soils," does provide information on the estimated volume of sediment that may be introduced into Shasta Lake as a result of increases in shoreline erosion. Under CP3, it's estimated that about 767,000 cubic yards per year would be delivered to Shasta Lake as a result of shoreline erosion. Therefore, this impact is potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP3): Long-Term Temperature Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, this alternative would increase storage on a monthly basis, although it would vary by water year. This impact would be less than significant.

Table 7-91 illustrates the monthly change in simulated storage for CP3 as a percent increase above the existing condition. On average, CP3 represents an approximately 14 percent increase in the end-of-month storage on an annual basis.

Table 7-91. Simulated Average Increased End-of-Month Shasta Lake Storage – CP3

Month	Existing Conditions (TAF)	CP3 Change (TAF)	CP3 % Increase
October	2,592	399	15.4%
November	2,568	390	15.2%
December	2,722	424	15.6%
January	2,995	440	14.7%
February	3,267	457	14.0%
March	3,625	468	12.9%
April	3,916	459	11.7%
May	3,941	459	11.7%
June	3,639	455	12.5%
July	3,160	442	14.0%
August	2,834	431	15.2%
September	2,669	420	15.7%

Key:
% = percent
CP = Comprehensive Plan
TAF = thousand acre-feet

Under CP3, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-91 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Similar to CP1, the increase in storage provided by CP3 fluctuates greatly throughout a year. A key indicator of water temperature benefits of CP3 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake before the water temperature operation season, about May through October. Similar to CP1, the CWP volume in the lake accumulates during winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP3 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52°F for the existing condition and the change in CWP volume for CP3 is shown, by SVI, in Table 7-92.

Table 7-92. Simulated Average Volume of Water Less than 52°F in Shasta Lake at the End of April – CP3

SVI Year Type	Existing Conditions (TAF)	CP3 Change (TAF)	% Increase
Average of All Years	2,609	385	15%
Wet	2,916	520	18%
Above Normal	2,972	432	15%
Below Normal	2,699	382	14%
Dry	2,542	322	13%
Critical	1,601	151	9%

Year types as defined by the Sacramento Valley Index

Key:
°F = degrees Farenheit
% = percent
CP = Comprehensive Plan
SVI = Sacramento Valley Index
TAF = thousand acre-feet

In addition to illustrating the average change in available CWP, Table 7-92 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall, would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although an increase in active storage and carryover storage of the CWP would occur, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP3): Long-Term Metals Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, the increase in storage associated with this alternative would not result in modifying the depth and thickness of the thermocline that persists in Shasta Lake. This impact would be potentially significant.

Within the Squaw Creek Arm, two depositional features associated with historic copper mining and smelting operations are immediately adjacent to the shoreline of Shasta Lake in the general vicinity of the Bully Hill Mine. As mapped, these two sites appear to have about 7,300 cubic yards of material that could be subjected to shoreline and surficial erosional processes with an increase in reservoir elevations related to CP3.

The impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (CP3): Temporary Construction-Related Sediment Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

This impact would be the same as Impact WQ-7 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP3): Temporary Construction-Related Temperature Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

This impact would be identical to Impact WQ-8 (CP1). For the same reasons as described for Impact WQ-8 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP3): Temporary Construction-Related Metal Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

This impact would be identical to Impact WQ-9 (CP1). For the same reasons as described for Impact WQ-9 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP3): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment, because modeling results have indicated that CP3 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. This impact would be less than significant.

This impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP3 on sediment would be similar to that for CP1. For the same reasons as described for Impact WQ-10 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP3): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP3 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the CWP in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact on water quality measured as temperature would be beneficial.

CP3 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critical years. Raising Shasta Dam 18.5 feet would increase the CWP and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, "Fisheries and Aquatic Resources."

Analysis of temperature modeling results indicates that CP3 would have a beneficial effect on temperature within the upper Sacramento River, with a slight decrease in average monthly water temperature during summer under both existing and future conditions. Decreased temperatures would improve compliance with the temperature objectives for the upper Sacramento River in the 2009 NMFS BO. CP3 would reduce temperature exceedences at Balls Ferry by 18 percent under existing conditions and 24 percent under future conditions. At the Bend Bridge compliance station, CP3 would reduce temperature exceedences by 8 percent under existing conditions and 11 percent under future conditions. Table 7-38 summarizes the temperature modeling results.

The impact on water quality measured as temperature would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP3): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes related to historic mining and smelting operation features. This impact would be potentially significant.

This impact would be similar to Impact WQ-12 (CP3) because the extent of the effect of CP3 on metals would be similar to that for CP1. For the same reasons as described for Impact WQ-12 (CP1), the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact WQ-13 (CP3): Temporary Construction-Related Sediment Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

This impact would be similar to Impact WQ-13 (CP1). For the same reasons described for Impact WQ-13 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP3): Temporary Construction-Related Temperature Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-14 (CP1). For the same reasons described for Impact WQ-14 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP3): Temporary Construction-Related Metal Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-15 (CP1). For the same reasons described for Impact WQ-15 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP3): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended study area, but effects would diminish with distance. This impact would be less than significant.

This impact would be similar to Impact WQ-16 (CP1). For the same reasons as described for Impact WQ-16 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP3): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-17 (CP1). Analysis of temperature modeling shows little to no change in temperature at RBPP caused by CP3. This suggests that no changes in temperature would occur beyond RBPP. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP3): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-18 (CP1). For the same reasons as described for Impact WQ-18 (CP1), the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP3): Delta Salinity on the Sacramento River at Collinsville Similar to WQ-19a (CP1) and WQ-19a (CP2), and as shown in Table 7-93, operations for CP3 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 5 percent. The impact would be less than significant.

Table 7-94 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The operation of CP3 would not result in any violation of the salinity standards under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP3): Delta Salinity on the San Joaquin River at Jersey Point
Impact WQ-19b (CP3) would be similar to Impact WQ-19b (CP1). Operations for CP3 would result in both increases and decreases in salinity in comparison with baseline conditions; however, none of the increases would be sufficient to change compliance for the San Joaquin River at Jersey Point. On a percentage basis, all increases in salinity would be less than 5 percent. The impact would be less than significant.

As shown in Table 7-95, the basis of comparison would meet the requirement on an average basis in both average years and in dry and critical years. Furthermore, all changes during April through August would be less than 1 percent.

Table 7-96 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Jersey Point in the period of simulation. No exceedences were shown, and CP3 would actually result in a decrease in the frequency of violations under existing conditions during July: by 2 percent in all years and 4.5 percent during dry and critical years.

Overall, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP3): Delta Salinity on the Sacramento River at Emmaton
On an average monthly basis, EC would meet the requirements in all months on an average annual basis; moreover, CP3 would not increase the EC at Emmaton during this period by more than 2.8 percent. This impact would be less than significant.

Impact WQ-19c (CP3) would be similar to Impact WQ-19c (CP1). Although Table 7-97 shows EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, EC would meet the requirements in all months on an average annual basis. Table 7-98 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. CP3 would result in an increase in the frequency of violations under existing and future conditions during May, by up to 33.3 percent in all years and dry and critical years. However, CP3 would result in a decrease in the frequency of violations under existing and future conditions during April, June, and August by up to 50 percent in the average of all years and dry and critical years. Overall, the compliance of salinity standards for the Sacramento River at Emmaton would be very similar to the baseline levels under both existing and future conditions.

The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19d (CP3): Delta Salinity on the Old River at Rock Slough Impact WQ-19d (CP3) would be similar to Impact WQ-19d (CP1). On an average annual basis, chloride levels under both the existing condition and future condition would be less than 150 mg/L from February through July. This impact would be less than significant.

Table 7-99 shows that in average annual years, CP3 would not increase chlorides by more than 1.2 percent. For dry and critical years, a maximum change of 2.5 percent in chloride concentration would occur. Change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. This impact would be less than significant.

Table 7-100 shows the number of days in a year when simulated chloride values exceeded the standards of 150 mg/L for Contra Costa Canal Pumping Plant No. 1. No daily violations of the chloride standards would occur under both existing and future conditions under CP3. Overall, CP3 would not alter the compliance level observed under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19e (CP3): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant This impact would be similar to Impact WQ-19e (CP1). The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. Tables 7-101 and 7-102 show that CP3 would not cause exceedence of chloride thresholds. All increases in chloride concentrations would be less than 5 percent. Chloride values under CP3 would be similar to the baseline values under both existing and future conditions. Tables 7-103 and 7-104 show that increases in EC would be less 5 percent under CP3 and would not exceed the EC threshold. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19f (CP3): Delta Water Quality in the West Canal at the Mouth of the Clifton Court Forebay Impact WQ-19f (CP3) would be similar to Impact WQ-19f (CP1). The 250-mg/L chloride concentration standard at the West Canal would not be exceeded on an average annual or dry and critical year basis under CP3. CP3 would also not exceed EC thresholds. This impact would be less than significant.

Table 7-105 shows that maximum chloride concentrations under both existing and future project conditions are lower for CP3 than the 250 mg/L threshold. Maximum changes under both existing and future projection conditions are less than 1.5 percent. As shown in Table 7-106, CP2 the maximum change in EC values under existing and future project conditions would be less than 1.5 percent.

Table 7-107 shows the average number of days simulated chloride values exceeded the standards of 250 mg/L for the West Canal at the Clifton Court Forebay in a year. There would be no additional violations throughout the year under both existing and future project conditions. CP3 would not change the baseline compliance levels under both existing and future conditions.

As shown in Table 7-108, CP3 would not result in any additional violations of the salinity standards. CP3 would actually result in decreases in EC during several months of the year. CP3 would not change the baseline compliance levels under both existing and future conditions.

Overall, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19i (CP3): Delta Salinity on the Old River near the Middle River
Impact WQ-19i (CP3) would be similar to Impact WQ-19i (CP1). On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP3 would not measurably change EC on the Old River near the Middle River, as shown in Table 7-113. This impact would be less than significant.

Table 7-114 shows the number of months simulated EC values exceeded the standards for the Old River near the Middle River in the period of simulation. Compliance with salinity standards for the Old River near the Middle River would not change under CP3 when compared to the existing conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-113. Simulated Monthly Average Salinity and Percent Change for the Old River near the Middle River Under Baseline Conditions and CP3

Month	Existing Condition (2005)				Future Conditions (2030)			
	Average All Years		Dry and Critical Years		Average All Years		Dry and Critical Years	
	Existing Condition (mmhos/cm)	CP3 Change (mmhos/cm (%))	Existing Condition (mmhos/cm)	CP3 Change (mmhos/cm (%))	No-Action Alternative (mmhos/cm)	CP3 Change (mmhos/cm (%))	No-Action Alternative (mmhos/cm)	CP3 Change (mmhos/cm (%))

Impact WQ-19j (CP3): Delta Salinity on the Old River at Tracy Road Bridge
Impact WQ-19j (CP3) would be similar to Impact WQ-19j (CP1). On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP3 would not measurably change EC on the Old River at Tracy Road Bridge, as shown in Table 7-115. This impact would be less than significant.

Table 7-116 shows the number of months simulated EC values exceeded the standards for the Old River near Tracy Road Bridge in the period of simulation. Although salinity level would be alternately exceeded and improved during several months, on an annual average basis, the compliance of salinity standards under CP2 would not change from the existing conditions. Overall, CP3 would not change the baseline compliance levels under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP3): X2 Position CP3 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the existing condition or future condition. Although several months may be out of compliance individually under the bases of comparison, the impact would be would be less than significant.

This impact would be similar to Impact WQ-20 (CP1). Table 7-117 shows the simulated monthly average X2 position for CP3 compared to the existing condition and future condition baselines. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 and CP4A focus on increasing anadromous fish survival while also increasing water supply reliability. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP4 and CP4A would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded CWP. The additional storage created by the 18.5-foot dam raise would be used to improve the ability to meet temperature objectives and habitat requirements for anadromous fish during drought years and increase water supply reliability. CP4 and CP4A also include the augmentation of spawning gravel and the restoration of riparian, floodplain, and side channel habitat in the upper Sacramento River for fisheries benefit.

CP4A is identical to CP4 except for Shasta Dam and reservoir operations. Both alternatives have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for fisheries purposes; however, the portion of this dedicated storage varies. For CP4, approximately 378,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1, with 70,000 acre-feet and 35,000 acre-feet reserved to specifically focus on increasing M&I deliveries during dry and critical years, respectively. For CP4A, approximately 191,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2 where Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved for M&I deliveries.

Shasta Lake and Vicinity

Impact WQ-1 (CP4 and CP4A): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses For CP4 or CP4A, this impact would be similar to Impact WQ-1 (CP3). The nature of inundation and relocation impacts is consistent with those described for CP3 in Chapter 2, “Alternatives.”

The impact for CP4 would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

The impact for CP4A would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP4 and CP4A): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses For CP4 or CP4A, this impact would be similar to Impact WQ-2 (CP3). The nature of inundation and relocation impacts is consistent with those described for WQ-2 (CP3).

For CP4, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP4 and CP4A): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses For CP4 or CP4A, this impact is similar to WQ-3 (CP1). No construction activities would disturb locations known to contain elevated metal concentrations in either sediments or the water column.

For CP4, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP4 and CP4A): Long-Term Sediment Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries For CP4 or CP4A, this impact would be similar to Impact WQ-4 (CP3). The nature of inundation and relocation impacts is consistent with those described for CP3.

For CP4, the impact would be a potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

For CP4A, the impact would be a potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP4 and CP4A): Long-Term Temperature Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries For CP4, similar to CP1, this alternative would increase storage on a monthly basis, although it would vary by water year. Table 7-118 illustrates the monthly change in simulated storage for CP4 as a percent increase above the existing condition. On average, CP4 represents an approximately 17-percent increase in the end-of-month storage on an annual basis.

Under CP4, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-118 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Table 7-118. Simulated Average Increased End-of-Month Shasta Lake Storage – CP4 and CP4A

Month	Existing Conditions (TAF)	CP4 Change (TAF)	CP4 % Increase	CP4A Change (TAF)	CP4 % Increase
October	2,592	526	20.3%	473	18.2%
November	2,568	520	20.2%	462	18.0%
December	2,722	539	19.8%	486	17.9%

TAF = thousand acre-feet

Similar to CP1, the increase in storage provided by CP4 fluctuates greatly throughout a year. A key indicator of water temperature benefits of CP4 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake before the water temperature operation season, about May through October. Similar to CP1, the CWP volume in the lake accumulates during the winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP4 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52˚F for the existing condition and the change in CWP volume for CP4 is shown, by SVI, in Table 7-119.

Table 7-119. Simulated Average Volume of Water Less than 52˚F in Shasta Lake at the End of April – CP4

SVI Year Type	Existing Conditions (TAF)	CP4 Change (TAF)	% Increase	CP4A Change (TAF)	% Increase

Notes:
Simulation period: 1922-2003. Change as measured from Existing Condition.
Year types as defined by the Sacramento Valley Index

Key:
˚F = degrees Farenheit
% = percent
CP = Comprehensive Plan
SVI = Sacramento Valley Index
TAF = thousand acre-feet

In addition to illustrating the average change in available CWP, Table 7-119 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall, would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although a meaningful increase in active storage and carryover storage of the CWP would occur, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, similar to CP4, this alternative would increase storage on a monthly basis, although it would vary by water year. Table 7-118 illustrates the monthly change in simulated storage for CP4A as a percent increase above the existing condition. On average, CP4A represents an approximately 16-percent increase in the end-of-month storage on an annual basis.

Under CP4A, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-118 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Similar to CP4, the increase in storage provided by CP4A fluctuates greatly throughout a year. A key indicator of water temperature benefits of CP4A to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake before the water temperature operation season, about May through October. Similar to CP4, the CWP volume in the lake accumulates during the winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP4A should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52°F for the existing condition and the change in CWP volume for CP4A is shown, by SVI year type, in Table 7-119.

In addition to illustrating the average change in available CWP, Table 7-119 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. An increase in active storage and carryover storage of the CWP would occur. However, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP4 and CP4A): Long-Term Metals Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries For CP4, this impact is similar to CP1. The nature of inundation impacts is consistent with those described for CP3. The impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

For CP4A, this impact is similar to CP2. The nature of inundation impacts is consistent with those described for CP3. The impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact WQ-7 (CP4 and CP4A): Temporary Construction-Related Sediment Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. Construction impacts are identical for CP4 and CP4A. This impact would be potentially significant for CP4 or CP4A.

Ground-disturbing activities associated with construction could cause soil erosion and sedimentation of local drainages and eventually the Sacramento River. Construction activities could also discharge waste petroleum products or other construction-related substances that could enter these waterways/facilities in runoff. In addition, transportation, handling, and placement of materials used for gravel augmentation as well as clearing, grubbing, and grading during construction could also adversely affect water quality and temporarily increase turbidity and sedimentation downstream from the gravel augmentation sites. In-water construction work at some gravel augmentation sites could also result in temporary increases in turbidity, downstream sedimentation, and accidental discharge of construction-related substances into the river channel.

In addition, riparian, floodplain, and side channel habitat restoration as part of CP4 or CP4A would involve breaching the levee using an excavator, loader, and compaction equipment, excavation of approximately 15,650 cubic yards of earthen material for off-site disposal, and potential vegetation clearing along 0.8 mile of channel. Invasive aquatic vegetation would be removed as well. Although in-water construction is expected to take place during periods of low flow in the Sacramento River (October to November) to minimize effects on water quality, construction activities related to habitat restoration and vegetation clearing could adversely affect water quality and temporarily increase turbidity and sedimentation downstream, or result in the accidental discharge of construction-related substances into the river channel. In addition, excavated sediments could be contaminated with pesticides and metals. Development and implementation of a SWPPP as part of the environmental commitments described in Chapter 2, "Alternatives," would reduce potential impacts related to pesticides and metals.

For CP4, the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

For CP4A, the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP4 and CP4A): Temporary Construction-Related Temperature Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. Construction impacts are identical for both CP4 and CP4A. This impact would be less than significant for CP4 or CP4A.

For CP4, this impact would be similar to Impact WQ-8 (CP1). For the same reasons as described for Impact WQ-8 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-8 (CP1). For the same reasons as described for Impact WQ-8 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP4 and CP4A): Temporary Construction-Related Metal Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. Construction impacts are identical for both CP4 and CP4A. This impact would be less than significant for CP4 or CP4A.

For CP4, this impact would be similar to Impact WQ-9 (CP1). For the same reasons as described for Impact WQ-9 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-9 (CP1). For the same reasons as described for Impact WQ-9 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP4 and CP4A): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River For CP4, this impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP4 on sediment would be similar to that for CP1. For the same reasons as described for Impact WQ-10 (CP1), the impact would be less than significant.

No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment because modeling results have indicated that CP4 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. For CP4, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-10 (CP2), which would be similar to, but slightly greater than that for CP1 (i.e., CP2 would have greater potential to reduce erosional processes and sediment transport in the upper Sacramento River). For the same reasons as described for Impact WQ-10 (CP1), this impact would be less than significant.

No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment because modeling results have indicated that CP4A would cause little change in average mean monthly winter flows during some years, which could slightly reduce sediment transport. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP4 and CP4A): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP4 and CP4A would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the CWP in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact on water quality measured as temperature would be beneficial.

CP4 and CP4A would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critical years. Raising Shasta Dam 18.5 feet would increase the CWP and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, "Fisheries and Aquatic Resources."

Analysis of temperature modeling results indicates that CP4 would have a beneficial effect on temperature within the upper Sacramento River with a measurable decrease in average monthly water temperature during summer months under both existing and future conditions. For instance, at the Balls Ferry compliance station in September, average monthly water temperature would be reduced by 1.4°F under CP4 for both existing and future conditions. During October at Balls Ferry, the average monthly temperature would decrease by 1.6°F under CP4 for both existing and future conditions. For more information on modeling results and monthly water temperature, see Chapter 11, "Fisheries and Aquatic Resources."

Decreased temperatures would improve compliance with the temperature objectives for the upper Sacramento River in the 2009 NMFS BO. Analysis of modeling results indicates that CP4 would reduce temperature exceedences at Balls Ferry by 29 percent under existing conditions and 32 percent under future conditions. At the Bend Bridge compliance station, CP4 would reduce temperature exceedences by 13-percent under existing conditions and 13 percent under future conditions. Table 7-38 summarizes the temperature modeling results.

The impact of CP4 would be beneficial; CP4 would have the greatest beneficial effect on water temperature of all alternatives evaluated. Mitigation for this impact is not needed, and thus not proposed.

Analysis of temperature modeling results indicates that CP4A would have a beneficial effect on temperature within the upper Sacramento River with a measurable decrease in average monthly water temperature during summer months under both existing and future conditions. For instance, at the Balls Ferry compliance station in September, average monthly water temperature would be reduced by 1.2°F under CP4A for both existing and future conditions. During October at Balls Ferry, the average monthly temperature would decrease by 1.4°F under CP4A for both existing and future conditions. For more information on modeling results and monthly water temperature, see Chapter 11, "Fisheries and Aquatic Resources."

Decreased temperatures would improve compliance with the temperature objectives for the upper Sacramento River in the 2009 NMFS BO. Analysis of modeling results indicates that CP4A would reduce temperature exceedences at Balls Ferry by 25 percent under existing conditions and 25 percent under future conditions. At the Bend Bridge compliance station, CP4A would reduce temperature exceedences by 11 percent under existing conditions and 11 percent under future conditions. Table 7-38 summarizes the temperature modeling results.

The impact of CP4A would be beneficial; CP4A would be only slightly less beneficial than CP4, which has the greatest beneficial effect on water temperature of all alternatives evaluated. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP4 and CP4A): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant for CP4 or CP4A.

For CP4, this impact is similar to Impact WQ-12 (CP1) because the extent of the effect of CP4 on metals would be similar to that for CP1. For the same reasons as described for Impact WQ-12 (CP1), the impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 7.3.5.

For CP4A, this impact would be similar to Impact WQ-12 (CP2) because the extent of the effect of CP4A on metals would be similar to but slightly greater than that for CP1. For the same reasons as described for CP2, this impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact WQ-13 (CP4 and CP4A): Temporary Construction-Related Sediment Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction of CP4 or CP4A is not anticipated to affect water quality conditions in the extended study area. Construction impacts are identical for CP4 and CP4A. This impact would be less than significant for CP4 or CP4A.

For CP4, this impact would be similar to Impact WQ-13 (CP1). For the same reasons as described for Impact WQ-13 (CP1), the impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-13 (CP1). For the same reasons as described for Impact WQ-13 (CP1), the impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP4 and CP4A): Temporary Construction-Related Temperature Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact for CP4 or CP4A would be similar to Impact WQ-14 (CP1). For the same reasons as described for Impact WQ-14 (CP1), the impact would be less than significant for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP4 and CP4A): Temporary Construction-Related Metal Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact for CP4 or CP4A would be similar to Impact WQ-15 (CP1). For the same reasons as described for Impact WQ-15 (CP1), the impact would be less than significant for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP4 and CP4A): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended study area, but effects would diminish with distance. This impact would be less than significant for CP4 or CP4A.

For CP4, this impact would be similar to Impact WQ-16 (CP1). For the same reasons described for Impact WQ-16 (CP1), the impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-16 (CP1). For the same reasons described for Impact WQ-16 (CP1), the impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP4 and CP4A): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area For CP4, this impact would be similar to Impact WQ-17 (CP1). Analysis of temperature modeling shows little to no change in temperature at RBPP caused by CP4. This suggests that there would be no changes in temperature beyond RBPP as a result of CP4. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-17 (CP1). Analysis of temperature modeling shows little to no change in temperature at RBPP caused by CP4A. This suggests that there would be no changes in temperature beyond RBPP as a result of CP4A. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP4 and CP4A): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact for CP4 or CP4A would be similar to Impact WQ-18 (CP1). For the same reasons described for Impact WQ-18

(CP1), the impact would be potentially significant for CP4 or CP4A. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP4 and CP4A): Delta Salinity on the Sacramento River at Collinsville This impact would be the same as Impact WQ-19a (CP1) for CP4. Operations for CP4 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 5 percent. The operation of CP4 would not result in any violations of the salinity standards for the Sacramento River at Collinsville under both existing and future conditions. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-19a (CP2). Operations for CP4A would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 5 percent. The operation of CP4A would not result in any violation of the salinity standards under both existing and future conditions. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP4 and CP4A): Delta Salinity on the Sacramento River at Jersey Point This impact would be the same as Impact WQ-19b (CP1) for CP4. On an average monthly basis, EC would meet the requirements in all months in an average year. On a percentage basis, all increases in salinity would be less than 5 percent. Furthermore, all changes during April through August would be less than 2 percent. Overall, the frequency of exceedence of salinity standards for the San Joaquin River at Jersey Point under CP4 would be similar to those under existing and future conditions. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, the impact would be similar to Impact WQ-19b (CP2). On an average basis, EC would meet the requirements in in both average years and in dry and critical years. Furthermore, all changes during April through August would be less than 2 percent. CP4A would result in an increase in the frequency of violations under existing conditions during June, by 10 percent in all years and 12.5 percent during dry and critical years. However, the EC standards are not violated on an average monthly basis. Overall, frequency of violation of salinity standards for the San Joaquin River at Jersey Point under CP4A would be similar to those under existing and future conditions. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP4 and CP4A): Delta Salinity on the Sacramento River at Emmaton This impact would be the same as Impact WQ-19c (CP1) for CP4. On an average monthly basis, EC would meet the requirements in all months on an average annual basis. On a percentage basis, all increases in salinity would be less than 5 percent. Operations of CP4 would not result in any additional violation of salinity standards between October and March. CP4 would result in an increase in the frequency of violations under existing and future conditions during May, by up to 100 percent in all years and dry and critical years. However, CP4 would result in a decrease in the frequency of violations under existing and future conditions during August and April, by up to 11.5 percent in all years and up to 50 percent during dry and critical years. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, the impact would be similar to Impact WQ-19c (CP2). Operations for CP2 would result in both increases and decreases in salinity in comparison to baseline conditions; however, none of the increases would be sufficient to change compliance for the Sacramento River at Emmaton. On a percentage basis, all increases in salinity would be less than 5 percent. On an average monthly basis, EC requirements would be satisfied in all months in an average year under CP4A operations. Maximum change in monthly EC would not be greater than 5 percent under both existing and future conditions. Operations of CP4A would not result in any violation of salinity standards between October and March. CP4A would result in an increase in the frequency of violations under existing and future conditions during May, by up to 100 percent in all years and dry and critical years. However, CP4A would result in a decrease in the frequency of violations under existing and future conditions during August and April, by up to 50 percent in all years and dry and critical years. On an average monthly basis, the standards are not violated. Overall, the compliance of salinity standards for the Sacramento River at Emmaton would be very similar to the baseline levels under both existing and future conditions. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19d (CP4 and CP4A): Delta Salinity on the Old River at Rock Slough This impact would be similar to Impact WQ-19d (CP1) for CP4. On an average annual basis, all months except October through January under both the existing condition and future condition would be less than 150 mg/L. In average annual years, CP4 would not increase chlorides by more than 1.1 percent. Maximum change in chloride concentrations under the CP4 are less than 2.1 percent for dry and critical years. The change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, the impact would be similar to Impact WQ-19d (CP1), and the same as WQ-19d (CP2). On an average annual basis, chloride levels under both the existing condition and future condition would be less than 150 mg/L from February through July. In average annual years, CP4A would not increase chlorides by more than 1.3 percent. For dry and critical years, a maximum change of 2.3 percent in chloride concentration would occur. Change in chloride concentration would not affect compliance with the standard as it would already be exceeded under the basis of comparison. CP4A would result in no daily violations of the chloride standards under both existing and future conditions for CP4A. Overall, CP4A would not alter the compliance level observed under the existing and future conditions. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19e (CP4 and CP4A): Delta Salinity on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement.

For CP4, this impact would be the same as impact WQ-19e (CP1). CP4 would not cause exceedence of chloride thresholds. All increases in chloride concentrations would be less than 5 percent. Chloride values under CP4 would be similar to the baseline values under both existing and future conditions. Increases in EC would be less than 5 percent under CP4 and would not exceed the EC threshold. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, the impact would be the same as impact WQ-19e (CP2), which is similar to Impact WQ-19e (CP1). CP4A would not cause exceedence of chloride thresholds. All increases in chloride concentrations would be less than 5 percent. Chloride values under CP4A would be similar to the baseline values under both existing and future conditions. Increases in EC would be less than 5 percent under CP4A and would not exceed the EC threshold. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19f (CP4 and CP4A): Delta Salinity on the West Canal at Clifton Court Forebay This impact would be the same as WQ-19f (CP1) for CP4. The 250 mg/L chloride concentration standard at the West Canal would not be exceeded on an average annual or dry and critical year basis under CP1. CP4 would also not exceed EC thresholds. This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as WQ-19f (CP2). The 250 mg/L chloride concentration standard at the West Canal would not be exceeded on an average annual or dry and critical year basis. CP4A would also not exceed EC thresholds. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19g (CP4 and CP4A): Delta Salinity on the San Joaquin River near Vernalis This impact would be the same as Impact WQ-19g (CP1) for CP4, where CP1 would not change the baseline compliance levels under both existing and future conditions. On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP4 would not exceed EC thresholds on the San Joaquin River at Vernalis. CP4 would not change the baseline compliance levels under both existing and future conditions. This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact WQ-19g (CP2), which is similar to Impact WQ-19g (CP1). On an average monthly basis, EC would meet requirements in all months, in both average years and in dry and critical years. CP4A would not exceed EC thresholds on the San Joaquin River at Vernalis. CP4A would not change the baseline compliance levels under both existing and future conditions. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19h (CP4 and CP4A): Delta Salinity on the San Joaquin River at Brandt Bridge This impact would be the same as Impact WQ-19h (CP1) for CP4, where CP1 would not change the existing compliance level under both existing and future project conditions. On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP4 would not change EC on the San Joaquin River at Brandt Bridge. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact WQ-19h (CP2), where, on an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years, and EC would not measurably change on the San Joaquin River at Brandt Bridge. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19i (CP4 and CP4A): Delta Salinity on the Old River near the Middle River This impact would be similar to Impact WQ-19i (CP1) for CP4. On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP4 would not measurably change EC on the Old River near the Middle River. Compliance with salinity standards for the Old River near the Middle River would not change under CP4. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar Impact WQ-19i (CP2), which is similar to Impact WQ-19i (CP1), for CP4A. On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. Compliance with salinity standards for the Old River near the Middle River would not change under CP4A when compared to the existing conditions. CP4A would not measurably change EC on the Old River near the Middle River. This impact would be less than significant CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19j (CP4 and CP4A): Delta Salinity on the Old River near Tracy Road Bridge This impact would be similar to Impact WQ-19j (CP1) for CP4. On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP4 would not measurably change EC on the Old River at Tracy Road Bridge. The impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact WQ-19j (CP2), which is similar to Impact WQ-19j (CP1), for CP4A. On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP4A would not change the baseline compliance levels under both existing and future conditions. CP4A would not measurably change EC on the Old River at Tracy Road Bridge. Therefore, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP4 and CP4A): X2 Position This impact would be the same as WQ-20 (CP1) for CP4. CP4 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the existing condition or future condition. Although several months may be out of compliance individually under the bases of comparison, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as WQ-20 (CP2), which would be similar to similar to Impact WQ-20 (CP1), for CP4A. CP4A would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the existing condition or future condition. Although several months may be out of compliance individually under the bases of comparison, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily focuses on increasing water supply reliability, anadromous fish survival, Shasta Lake area environmental resources, and recreation opportunities. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP5 would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would be extended to achieve efficient use of the expanded CWP. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 150,000 acre-feet and 75,000 acre-feet, respectively, of the increased storage capacity in Shasta

Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP5 also includes constructing additional fish habitat in and along the shoreline of Shasta Lake and along the lower reaches of its tributaries; augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River; and increasing recreation opportunities at Shasta Lake.

CP5 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the CWP in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact WQ-1 (CP5): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-1 (CP3). However, CP5 includes several ecosystem restoration projects that would require temporary construction-related activities, as described in Chapter 2, “Alternatives.”

Although the environmental protection measures and BMPs described in Chapter 2, “Alternatives,” are intended to reduce the potential effects of introducing sediment into Shasta Lake and its tributaries, CP5 would affect water quality by increasing the levels of turbidity and suspended sediment in the receiving waters at levels that could be inconsistent with the Basin Plan. These increased levels of turbidity and suspended sediment could affect the beneficial uses of Shasta Lake and/or its tributaries. Therefore, the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP5): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-2 (CP3). The nature of inundation impacts is consistent with those described for CP3. However, relocation activities under CP5 would expose a similar but greater acreage to erosion than would CP3 (up to 3,337 acres). The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP5): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-3 (CP1). No construction activities would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP5): Long-Term Sediment Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to WQ-4 (CP3). Although some ecosystem enhancement measures (i.e., road restoration) are expected to reduce the long-term sediment delivery to Shasta Lake and its tributaries, CP5 would nonetheless result in increased levels of suspended sediment and turbidity that could affect beneficial uses. The amount of sediment that could be delivered is not quantifiable because of the size of the lake and the number of variables that influence sediment transport and delivery. The impact would be a potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP5): Long-Term Temperature Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to the discussion in CP3, this alternative would increase storage on a monthly basis although it would vary by water year. Table 7-120 illustrates the monthly change in simulated storage for CP5 as a percent increase above the existing condition. On average, CP5 represents an approximately 13 percent increase in the end-of-month storage on an annual basis. This impact would be less than significant.

Table 7-120. Simulated Average End-of-Month Shasta Lake Storage – CP5

Month	Existing Conditions (TAF)	CP5 Change (TAF)	CP5 % Increase
October	2,592	383	14.8%
November	2,568	373	14.5%
December	2,722	409	15.0%
January	2,995	428	14.3%
February	3,267	449	13.7%
March	3,625	460	12.7%
April	3,916	451	11.5%
May	3,941	452	11.5%
June	3,639	447	12.3%
July	3,160	428	13.6%
August	2,834	422	14.9%
September	2,669	404	15.1%

Simulation period: 1922-2003. Change as measured from Existing Condition.
Key:
% = percent
CP = Comprehensive Plan
TAF = thousand acre-feet

Consistent with the discussion presented under CP3, existing water temperature requirements would typically be met in most years. The simulated end-of-April volume of water with a temperature lower than 52°F for the existing condition and the change in CWP volume for CP5 is shown, by SVI, in Table 7-121.

Table 7-121. Simulated Average Volume of Water Less than 52°F in Shasta Lake at the End of April – CP5

SVI Year Type	Existing Conditions (TAF)	CP5 Change (TAF)	% Increase
Average of All Years	2,609	378	15%
Wet	2,916	520	18%
Above Normal	2,972	439	15%
Below Normal	2,699	357	13%
Dry	2,542	317	12%
Critical	1,601	142	9%

Notes:
Simulation period: 1922-2003. Change as measured from Existing Condition.
Year types as defined by the Sacramento Valley Index

Key:
°F = degrees Farenheit
% = percent
CP = Comprehensive Plan
SVI = Sacramento Valley Index
TAF = thousand acre-feet

In addition to illustrating the average change in available CWP, Table 7-121 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall, would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although a meaningful increase in active storage and carryover storage of the CWP would occur, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP5): Long-Term Metals Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to CP1. The nature of inundation impacts is consistent with those described for CP3. The impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (CP5): Temporary Construction-Related Sediment Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

Ground-disturbing activities associated with construction could cause soil erosion and sedimentation of local drainages and eventually the Sacramento River. Construction activities could also discharge waste petroleum products or other construction-related substances that could enter these waterways/facilities in runoff. As described for Impact WQ-7 (CP4 and CP4A), gravel augmentation construction activities could also adversely affect water quality and temporarily increase turbidity and sedimentation downstream from the gravel augmentation sites.

In addition, riparian, floodplain, and side channel habitat restoration activities as part of CP5 would involve breaching the levee using an excavator, loader, and compaction equipment, excavation of approximately 15,650 cubic yards of earthen material for off-site disposal, and potential vegetation clearing along 0.8 mile of channel. Invasive aquatic vegetation would be removed as well. As described for Impact WQ-7 (CP4 and CP4A), construction activities related to habitat restoration and vegetation clearing could adversely affect water quality and temporarily increase turbidity and sedimentation downstream, or result in the accidental discharge of construction-related substances into the river channel. In addition, excavated sediments could be contaminated with pesticides and metals. Development and implementation of a SWPPP as part of the environmental commitments described in Chapter 2, "Alternatives," would reduce potential impacts related to pesticides and metals. However, the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP5): Temporary Construction-Related Temperature Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

This impact would be similar to Impact WQ-8 (CP1). For the same reasons described for Impact WQ-8 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP5): Temporary Construction-Related Metal Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

This impact would be similar to Impact WQ-9 (CP1). For the same reasons described for Impact WQ-9 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP5): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment because modeling results have indicated that CP5 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. This impact would be less than significant.

This impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP5 on sediment would be similar to that for CP1. For the same reasons as described for Impact WQ-10 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP5): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP5 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the CWP in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact on water quality measured as temperature would be beneficial.

CP5 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critical years. Raising Shasta Dam 18.5 feet would increase the CWP and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, "Fisheries and Aquatic Resources."

CP5 is the same as CP3 for both flow and temperature characteristics. Therefore, separate temperature modeling was not completed for CP5. See Impact WQ-11 (CP3) for a more complete discussion on temperature modeling analysis. For the same reasons as described for Impact WQ-11 (CP3), the impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP5): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

This impact would be similar to Impact WQ-12 (CP1) because the extent of the effect of CP5 on metals would be similar to that for CP1. For the same reasons as described for Impact WQ-12 (CP1), the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact WQ-13 (CP5): Temporary Construction-Related Sediment Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

This impact is similar to Impact WQ-13 (CP1). For the same reasons as described for Impact WQ-13 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP5): Temporary Construction-Related Temperature Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to Impact WQ-14 (CP1). For the same reasons as described for Impact WQ-14 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP5): Temporary Construction-Related Metal Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to Impact WQ-15 (CP1). For the same reasons as described for Impact WQ-15 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP5): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended study area, but effects would diminish with distance. This impact would be less than significant.

This impact is similar to Impact WQ-16 (CP1). For the same reasons as described for Impact WQ-16 (CP1), the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP5): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact is similar to Impact WQ-17 (CP1). Analysis of temperature modeling shows little to no change in temperature at RBPP caused by CP5. This suggests that no changes in temperature would occur beyond RBPP as a result of CP5. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP5): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact is similar to Impact WQ-18 (CP1). For the same reasons as described for CP1, the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP5): Delta Salinity on the Sacramento River at Collinsville Impact WQ-19a (CP5) would be similar to Impact WQ-19a (CP1). This impact would be less than significant.

As shown in Table 7-122, operations for CP5 result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. Similarly, on a percentage basis, all increases in salinity would be less than 1 percent; this would be within the range of natural variability. Table 7-123 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The operation of CP5 would not result in any violation of the salinity standards under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP5): Delta Salinity on the San Joaquin River at Jersey Point
Impact WQ-19b (CP5) would be similar to Impact WQ-19b (CP1). On an average monthly basis, EC would meet the requirements in all months in an average year. Moreover, CP5 would not increase the EC at Jersey Point. On a percentage basis, all increases in salinity would be less than 5 percent. This impact would be less than significant.

As shown in Table 7-124, the basis of comparison would meet the requirement on an average basis in both average years and in dry and critical years. Furthermore, all changes during April through August would be less than 2 percent. Table 7-125 shows the number of months simulated EC values exceeded the standards for San Joaquin River at Jersey Point in the period of simulation. CP5 would result in an increase in the frequency of violations under future conditions during July, by 2 percent in all years and 4.8 percent during dry and critical years. However, CP5 would result in a decrease in the frequency of violations under future conditions during August, by 1.3 percent in all years and 3.7 percent during dry and critical years. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP5): Delta Salinity on the Sacramento River at Emmaton
On an average monthly basis, EC would meet the requirements in all months on an average annual basis; moreover, CP5 would not increase the EC at Emmaton during this period by more than 1.4 percent. This impact would be less than significant.

Impact WQ-19c (CP5) would be similar to Impact WQ-19c (CP1). Although Table 7-126 shows EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, EC would meet requirements in all months on an average annual basis. Table 7-127 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. Operations of CP5 would not result in any violation of salinity standards between October and March. CP5 would result in an increase in the frequency of violations under existing and future conditions during May, by up to 33.3 percent in all years and dry and critical years. However, CP5 would result in a decrease in the frequency of violations under existing and future conditions during April and August, by up to 50 percent in the average of all years and dry and critical years. Overall, the compliance of salinity standards for the Sacramento River at Emmaton would be very similar to the baseline levels under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-126. Simulated Monthly Average Salinity and Percent Change for the Sacramento River at Emmaton Under Baseline Conditions and CP5

Source: Version 8.0.6, DSM2 Existing and Future simulations (Node RSAC092)

Note:
Simulation period: 1922-2003. Change as measured from either Existing Condition or No-Action Alternative. Dry and critical years as defined by the Sacramento Valley Index.

Key:
% = percent
CP = Comprehensive Plan

Impact WQ-19d (CP5): Delta Salinity on the Old River at Rock Slough Impact WQ-19d (CP5) would be similar to Impact WQ-19d (CP1). On an average annual basis, all months except September through January under both the existing condition and future condition would be less than 150 mg/L. This impact would be less than significant.

Table 7-128 shows simulated monthly average chloride concentrations and percent change for Contra Costa Canal Pumping Plant No. 1. In average annual years, CP5 would not increase chlorides by more than 1.0 percent. Maximum change in chloride concentrations under the CP5 are less than 1.2 percent for dry and critical years. Change in chloride concentration would not affect compliance with the standard; it would already be exceeded under the basis of comparison.

Table 7-129 shows the number of days simulated chloride values exceeded the standards of 150 mg/L for Contra Costa Canal Pumping Plant No. 1 in the period of simulation. No daily violations of the chloride standards would occur under both existing and future conditions for CP5. Overall, CP5 would not alter the compliance level observed under the existing and future conditions.

Impact WQ-19e (CP5): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant This impact would be similar to Impact WQ-19e (CP1). The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. Tables 7-130 and 7-131 show that CP5 would not cause exceedence of chloride thresholds. All increases in chloride concentrations would be less than 5 percent. Chloride values under CP5 would be similar to the baseline values under both existing and future conditions. Tables 7-132 and 7-133 show that increases in EC would be less than 1.0 percent and would not exceed the EC threshold. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19f (CP5): Delta Water Quality in the West Canal at the Mouth of the Clifton Court Forebay This impact would be similar to Impact WQ-19f (CP1). The 250-mg/L chloride concentration standard at the West Canal would not be exceeded on an average annual or dry and critical year basis under CP5. CP5 would also not exceed EC thresholds. This impact would be less than significant.

Table 7-134 shows that maximum chloride concentrations under both existing and future project conditions are lower for CP5 than the 250 mg/L threshold. Maximum changes under both existing and future projection conditions are less than 1.5 percent. As shown in Table 7-135, the maximum change in EC values under existing and future project conditions would be less than 1 percent.

mmhos/cm = millimhos per centimeter

Table 7-136 shows the average number of days simulated chloride values exceeded the standards of 250 mg/L for the West Canal at the Clifton Court Forebay in a year. There would be no additional violations throughout the year under both existing and future project conditions. CP5 would not change the baseline compliance levels under both existing and future conditions.

As shown in Table 7-137, CP5 would not result in any additional violations of the salinity standards. CP5 would actually result in decreases in EC during several months of the year. CP5 would not change the baseline compliance levels under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19g (CP5): Delta Salinity on the San Joaquin River at Vernalis

This impact would be similar to Impact WQ-19g (CP1). On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP5 would not exceed EC thresholds on the San Joaquin River at Vernalis, as shown in Tables 7-138 and 7-139. CP5 would not change the baseline compliance levels under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19h (CP5): Delta Salinity on the San Joaquin River at Brandt Bridge This impact would be the same as Impact WQ-19h (CP1). On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. Moreover, CP5 would not measurably change EC on the San Joaquin River at Brandt Bridge. This impact would be less than significant.

This impact also would be similar to Impact WQ-19h (CP1). On an average monthly basis, EC would meet the requirements in all months in both average years and in dry and critical years. Moreover, CP5 would not measurably change EC on the San Joaquin River at Brandt Bridge, as shown in Table 7-140. Table 7-141 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Brandt Bridge in the period of simulation. CP5 would not change the existing compliance level for salinity standards for the San Joaquin River at Brandt Bridge. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19i (CP5): Delta Salinity on the Old River near the Middle River
On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP5 would not measurably change EC on the Old River near the Middle River, as shown in Table 7-142. This impact would be less than significant.

Table 7-143 shows the number of months simulated EC values exceeded the standards for the Old River near the Middle River in the period of simulation. Compliance with salinity standards for the Old River near the Middle River would not change under CP5 when compared to the existing conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19j (CP5): Delta Salinity on the Old River at Tracy Road Bridge
This impact would be similar to Impact WQ-19j (CP1). On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP5 would not measurably change EC on the Old River at Tracy Road Bridge, as shown in Table 7-144. This impact would be less than significant.

Table 7-145 shows the number of months simulated EC values exceeded the standards for the Old River near Tracy Road Bridge in the period of simulation. Although exceedence would occur during August, under future conditions, on an annual average basis, the compliance of salinity standards under CP2 would not change from the existing conditions. Overall, CP5 would not change the baseline compliance levels under both existing and future conditions. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP5): X2 Position This impact would be similar to Impact WQ-20 (CP1). CP5 would not change average monthly X2 in either average years or in dry and critical years by more than 0.1 km under either the existing condition or future condition. Although several months may be out of compliance individually under the bases of comparison, the impact would be less than significant.

Table 7-146 shows the simulated monthly average X2 position for CP5 as compared to the existing condition and future condition baselines. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month.

CP5 would not change average monthly X2 in either average years or in dry or critical years by more than 0.1 km under either the existing condition or the future condition. Although several months may be out of compliance under the bases of comparison, the change resulting from CP5 would not increase the amount out of compliance. The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

LTS = less than significant
NI = no impact
PS = potentially significant
SU = significant and unavoidable

No-Action Alternative

Under the No-Action Alternative, no action would be taken, including implementation of mitigation measures; rather, existing conditions would continue to change into the future. No mitigation measures are required for the No-Action Alternative. Thus, Impact WQ-20 (No-Action) would be significant and unavoidable.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are needed for Impacts WQ-2 (CP1), WQ-3 (CP1), WQ-5 (CP1), WQ-8 (CP1) through WQ-11 (CP1), WQ-13 (CP1) through WQ-17 (CP1), WQ-19a (CP1) through WQ-19j (CP1), and WQ-20 (CP1). Mitigation is provided below for the remaining impacts of CP1 on water quality.

Mitigation Measure WQ-1 (CP1): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area. The type and nature of actions described in Chapter 2 of the EIS will require a wide array of mitigation activities to reduce sediment impacts to Shasta Lake and the upper Sacramento River. Watershed analysis and assessments prepared for most of the watersheds tributary to these water bodies consistently document that roads and modified fire regimes have increased sediment contributions to receiving waters, particularly in those watersheds that have been subjected to mining, forest management, and other types of large-scale developments (CVWRCB 2011, The River Exchange 2010).

This mitigation measure focuses on proactive activities intended to reduce sediment delivery to receiving waters using a framework approach. At this point in Reclamation’s planning process, there is substantial uncertainty with respect to the specific location and types of mitigation activities that may be appropriate and/or effective. At a minimum, the framework includes four fundamental components intended to meet the primary objectives of reducing sediment impacts and improving water quality. These components are generally consistent with the type of management opportunities identified in the Upper Sacramento River Watershed Assessment and Management Strategy (The River Exchange 2010):

- Stabilize and/or remediate localized point-source locations that are directly affecting waters tributary to Shasta Lake and/or the upper Sacramento River (e.g., active landslides).

- Reduce road-related sediment and improve hydrologic functions by implementing erosion prevention and sediment control and stormproofing measures at the appropriate scale (5th-field watersheds).

- Use fuels and vegetation management techniques to manage fuel loads in a manner that restores ecological processes with the intention of reducing the potential for large-scale, high-intensity wildfires (like the Bagley fire) that often result in wide-spread erosion and water quality impacts. This mitigation element may be implemented at multiple scales, but likely planning efforts would focus on the scale of 5th-field watersheds to effectively mitigate impacts to water quality and other landscape values.

- Stabilize and/or restore channels using both active (construction) and passive (revegetation) measures that reestablish form and function in a manner that improves water quality. This component is consistent with the objectives for Mitigation Measure Geo-2 (Chapter 4).

The following discussion is intended to demonstrate Reclamation's commitment to using the best science available to fully develop and implement this mitigation measure in a manner that fully mitigates impact WQ-1 for CP1. Reclamation acknowledges that efforts are ongoing to fully develop this mitigation measure; however the approach outlined below describes efforts to date to identify a number of site-specific actions intended to reduce road-related sediment and improve the hydrologic function of existing roads within the watersheds encompassed by BLM's Shasta-Chappie Off-Highway Vehicle (OHV) area – drainages that enter the Main Arm of Shasta Lake. Reclamation is committed to inventorying road-related sediment sources, prioritizing corrective actions, and implementing mitigation projects in other watersheds tributary to the arms of Shasta Lake (e.g., McCloud, Squaw Creek).

With an understanding that off-site, out-of-kind mitigation would be required for WQ-1, Reclamation initiated a Sediment Source Inventory (SSI) of 113 miles of road and OHV trails throughout the OHV area (Reclamation 2013) in cooperation with the BLM and other land owners. This SSI included a road analysis process (RAP) developed by the USFS (USFS 1999) that was used to prioritize road-related projects intended to reduce sediment impacts and improve water quality in the watersheds contributing to Shasta Lake.

Using this RAP approach, 32-miles of road segments inventoried were considered a moderate-high to high risk. Seven out of the 19 moderate-high to high risk roads are located within the South Fork Squaw Creek and Dry Creek drainages that are tributary to the Main Arm of Shasta Lake. Within these drainages, approximately 20 miles of roads received a high risk rating. The amount of sediment reduction that occurs through road stabilization, stormproofing, and/or decommissioning can be assessed through the WEPP model developed for the USFS (USFS 2010).

The WEPP model provides a tool that can be used to characterize the benefits of Mitigation Measure WQ-1 for various types of mitigation components. An example of this has been developed for the road restoration and stabilization opportunities identified in the Westside Lands SSI.

For example, for each mitigation treatment an "x" amount of sediment reduction occurs with "y" number of mitigation treatments. In the sediment budget approach, the amount of sediment produced as a result of short-term construction impacts and long-term shoreline erosion would be offset by a combination of the mitigation of these disturbances with various types of mitigation treatments in high priority areas identified through the RAP process and other applicable criteria developed through the mitigation planning process.

Implementation of this mitigation measure would reduce Impact WQ-1 (CP1) to a less-than-significant level.

Mitigation Measure WQ-4 (CP1): Implement Mitigation Measure WQ-1 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce long-term effects related to sediment. The SWPPP may be customized to address long-term construction-related impacts associated with this impact. Implementation of this mitigation measure would reduce Impact WQ-4 (CP1) to a less-than-significant level.

Customization of Mitigation Measure WQ-4 (CP1) to address long-term construction-related impacts will be completed in a similar manner to Mitigation Measure WQ-1 (CP1), described above. The application of the shoreline erosion model with WEPP can be used to customize Mitigation Measure WQ-4 (CP1). The mitigation activities and treatments would be modified to address long-term construction impacts as predicted by the models.

Mitigation Measure WQ-6 (CP1): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines Reclamation will prepare and implement a plan to remove or otherwise remediate two sites related to historic mining activities that have the potential to introduce metals into Shasta Lake, a Section 303(d)-listed water body. This plan will include requirements to coordinate with Federal, State, and local agencies and landowners to ensure that measures taken will reduce the potential for a discharge of metals into Shasta Lake. Reclamation will obtain any required permits, approvals, and authorizations before any ground-disturbing remediation activity occurs.

Implementation of this mitigation measure would reduce Impact WQ-6 (CP1) to a less-than-significant level.

Mitigation Measure WQ-7 (CP1): Implement Mitigation Measure WQ-1 (CP1) to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce temporary construction-related effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-7 (CP1) to a less-than-significant level.

Mitigation Measure WQ-12 (CP1): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP1) to a less-than-significant level.

Mitigation Measure WQ-18 (CP1): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP1) to a less-than-significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are needed for Impacts WQ-2 (CP2), WQ-3 (CP2), WQ-5 (CP2), WQ-8 (CP2) through WQ-11 (CP2), WQ-13 (CP2) through WQ-17 (CP2), WQ-19a (CP2) through WQ-19j (CP2), and WQ-20 (CP2). Mitigation is provided below for the remaining impacts of CP2 on water quality.

Mitigation Measure WQ-1 (CP2): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area. This mitigation measure is similar to Mitigation Measure WQ-1 (CP1); however, it will be modified to increase the number of mitigation activities and treatments to address the predicted increase in erosional impacts associated with CP2. Implementation of this mitigation measure would reduce Impact WQ-1 (CP2) to a less-than-significant level.

Mitigation Measure WQ-4 (CP2): Implement Mitigation Measure WQ-4 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-4 (CP1) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP2) to a less-than-significant level.

Mitigation Measure WQ-6 (CP2): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP2) to a less-than-significant level.

Mitigation Measure WQ-7 (CP2): Implement Mitigation Measure WQ-1 (CP1) to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce temporary construction-related effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-7 (CP2) to a less-than-significant level.

Mitigation Measure WQ-12 (CP2): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP2) to a less-than-significant level.

Mitigation Measure WQ-18 (CP2): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP2) to a less-than-significant level.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation measures are needed for Impacts WQ-2 (CP3), WQ-3 (CP3), WQ-5 (CP3), WQ-8 (CP3) through WQ-11 (CP3), WQ-13 (CP3) through WQ-17 (CP3), WQ-19a (CP3) through WQ-19j (CP3), and WQ-20 (CP3). Mitigation is provided below for the remaining impacts of CP3 on water quality.

Mitigation Measure WQ-1 (CP3): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area. This mitigation measure is similar Mitigation Measure WQ-1 (CP1); however, it will be modified to increase the number of mitigation activities and treatments to address the predicted increase in erosional impacts associated with CP3. Implementation of this mitigation measure would reduce Impact WQ-1 (CP3) to a less-than-significant level.

Mitigation Measure WQ-4 (CP3): Implement Mitigation Measure WQ-4 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-4 (CP1) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP3) to a less-than-significant level.

Mitigation Measure WQ-6 (CP3): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the

Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP3) to a less-than-significant level.

Mitigation Measure WQ-7 (CP3): Implement Mitigation Measure WQ-1 (CP1) to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement Mitigation Measure WQ-1 (CP1) as described above to reduce temporary construction-related effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-7 (CP3) to a less-than-significant level.

Mitigation Measure WQ-12 (CP3): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP3) to a less-than-significant level.

Mitigation Measure WQ-18 (CP3): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP3) to a less-than-significant level.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation measures are needed for Impacts WQ-2 (CP4 and CP4A), WQ-3 (CP4 and CP4A), WQ-5 (CP4 and CP4A), WQ-8 (CP4 and CP4A) through WQ-11 (CP4 and CP4A), WQ-13 (CP4 and CP4A) through WQ-17 (CP4 and CP4A), WQ-19a (CP4 and CP4A) through WQ-19j (CP4 and CP4A), and WQ-20 (CP4 and CP4A). Mitigation is provided below for the remaining impacts of CP4 or CP4A on water quality.

Mitigation Measure WQ-1 (CP4 and CP4A): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area. This mitigation measure is identical to Mitigation Measure WQ-1 (CP3). Implementation of this mitigation measure would reduce Impact WQ-1 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure WQ-4 (CP4 and CP4A): Implement Mitigation Measure WQ-4 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-4 (CP3) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure WQ-6 (CP4 and CP4A): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure WQ-7 (CP4 and CP4A): Implement Mitigation Measure WQ-1 (CP1) and Gravel Augmentation BMPs to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment Reclamation will implement (a) Mitigation Measure WQ-1 (CP3) as described above; and (b) specific BMPs for the gravel augmentation program. Gravel augmentation BMPs will include, but will not be limited to:

- **Construction Work Windows** – All gravel augmentation construction activities will be conducted outside of the flood season (e.g., June 15 to September 15).

- **Source and Handle Gravel So As to Minimize Potential Water Quality Impacts** – Gravel will be sorted and transported in a manner that minimizes potential water quality impacts (e.g., management of fine sediments). Gravel will be washed at least once and have a cleanliness value of 85 or higher based on California Department of Transportation Test No. 227. Gravel will also be completely free of oils, clay, debris, and organic material.

- **Minimize Potential Impacts Associated with Equipment Contaminants** – For in-river work, all equipment will be steam cleaned every day to remove hazardous materials before the equipment enters the water.

- **Implement Feasible Spill Prevention and Hazardous Materials Management** – The accidental release of chemicals, fuels, lubricants, and non-storm drainage water into channels will be prevented to the extent feasible. Spill prevention kits will always be in close proximity when using hazardous materials (e.g., crew trucks and other logical locations). Feasible measures will be implemented to ensure that hazardous materials are properly handled and the quality of aquatic resources is protected by all reasonable means. No fueling will be done within the ordinary high-water mark or immediate floodplain, unless equipment stationed in these locations is not readily relocated (i.e., pumps, generators). For stationary equipment that must be fueled on site, containments will be provided in such a manner that any accidental spill of fuel will not be able to enter the water or contaminate sediments that may come in contact with water. Any equipment that is readily moved out of the channel will not be fueled in the channel or immediate floodplain. All fueling done at the construction site will provide containment to the degree that any spill will be unable to enter the channel or damage wetland or riparian vegetation. No equipment servicing will be done within the ordinary high-water mark or immediate floodplain, unless equipment stationed in these locations cannot be readily relocated (i.e., pumps, generators). Additional BMPs designed to avoid spills from construction equipment and subsequent contamination of waterways will also be implemented.

- **Minimize Potential Impacts Associated with Access and Staging** – Existing access roads will be used. Equipment staging areas will be located outside of the ordinary high-water mark and away from sensitive resources.

- **Remove Temporary Fills as Appropriate** – Temporary fill, such as for access, side channel diversions, and/or side channel cofferdams, will be completely removed upon the completion of construction.

Implementation of this mitigation measure would reduce Impact WQ-7 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure WQ-12 (CP4 and CP4A): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure WQ-18 (CP4 and CP4A): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP4 and CP4A) to a less-than-significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation measures are needed for Impacts WQ-2 (CP5), WQ-3 (CP5), WQ-5 (CP5), WQ-8 (CP5) through WQ-11 (CP5), WQ-13 (CP5) through WQ-17 (CP5), WQ-19a (CP5) through WQ-19j (CP5), and WQ-20 (CP5). Mitigation is provided below for the remaining impacts of CP5 on water quality.

Mitigation Measure WQ-1 (CP5): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area. This mitigation measure is identical to Mitigation Measure WQ-1

(CP3). Implementation of this mitigation measure would reduce Impact WQ-1 (CP5) to a less-than-significant level.

Mitigation Measure WQ-4 (CP5): Implement Mitigation Measure WQ-4 (CP1) to Reduce Long-Term Effects on Shasta Lake and Its Tributaries Related to Sediment Reclamation will implement Mitigation Measure WQ-4 (CP3) as described above to reduce long-term effects related to sediment. Implementation of this mitigation measure would reduce Impact WQ-4 (CP5) to a less-than-significant level.

Mitigation Measure WQ-6 (CP5): Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines This mitigation measure is identical to Mitigation Measure WQ-6 (CP1). Implementation of this mitigation measure would reduce Impact WQ-6 (CP5) to a less-than-significant level.

Mitigation Measure WQ-7 (CP5): Implement Mitigation Measure WQ-1 (CP1) and Gravel Augmentation BMPs to Reduce Temporary Construction-Related Effects on the Upper Sacramento River Related to Sediment This mitigation measure is identical to Mitigation Measure WQ-7 (CP4 and CP4A). Implementation of this mitigation measure would reduce Impact WQ-7 (CP5) to a less-than-significant level.

Mitigation Measure WQ-12 (CP5): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Upper Sacramento River Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-12 (CP5) to a less-than-significant level.

Mitigation Measure WQ-18 (CP5): Implement Mitigation Measure WQ-6 (CP1) to Reduce Long-Term Metals Effects on the Extended Study Area Reclamation will implement Mitigation Measure WQ-6 (CP1) as described above to reduce long-term metals effects. Implementation of this mitigation measure would reduce Impact WQ-18 (CP5) to a less-than-significant level.

7.3.6 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This section analyzes the overall cumulative impacts of the action alternatives with other past, present, and reasonably foreseeable future projects that would produce related impacts.

Actions which are included quantitatively in this cumulative effects analysis are those that are reasonably foreseeable, including actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete. As described in Chapter 2, "Alternatives," Section 2.2, "No-Action Alternative," the NEPA No-Action alternative includes all reasonably foreseeable actions included quantitatively in the cumulative effects analysis, but excludes effects for project actions. The future with-project conditions combine project actions with the actions included in the No-Action Alternative (2030 baseline). Therefore, quantitative impact assessments for the future with-project conditions presented in this chapter in Section 7.3, "Environmental Consequences and Mitigation Measures." With mitigation, none of the action alternatives would combine with the projects considered for quantitative cumulative impact analysis to contribute to a cumulatively considerable water quality impact.. Therefore, this section evaluates only those projects listed in Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," that are qualitatively considered in this EIS.

Past effects to water quality in the primary and extended study area include land uses, water diversions, wastewater discharge, non-point source pollution, and historic mining activities. Because of the substantial degradation in water quality in the primary and extended study areas when considering past, present, and reasonably foreseeable projects, and as identified in the existing conditions presented in this chapter, a significant cumulative impact would occur on water quality overall under both existing and future conditions. These cumulative impacts are occurring without the proposed action (e.g., 2012 Bagley fire). Several factors could substantially affect water quality in both the primary and extended study areas as an outcome of reasonably foreseeable future actions, but the potential effects are highly uncertain and may result in either beneficial or adverse short-term or long-term impacts on water quality in the study areas. Example projects listed in Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," that could contribute to cumulative impacts in the primary and extended study areas include, but are not limited to, the San Joaquin River Restoration Program, Bay-Delta Conservation Plan, Iron Mountain Mine Restoration Plan, North of Delta Offstream Storage Facility, and Delta Islands and Levees Feasibility Study.

The effect of climate change on operations at Shasta Lake could potentially result in changes to water quality. As described in the Climate Change Projection Appendix, climate change could result in higher inflows to Shasta Lake in the winter and early spring due to a shift from precipitation falling as snow to rain. This change could result in both higher Shasta Lake releases in the winter and spring to manage the increased potential for flood events, and an increase in water temperature for Shasta Lake inflows. A corresponding decrease in Shasta Lake releases in the summer and fall and a decrease in operable cold-water volume could result in warmer flows downstream.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 would not result in adverse changes to sediment, metals, and temperature, and therefore would not make a cumulatively considerable incremental contribution to an overall significant cumulative impact on water quality.

Without mitigation, CP1 could cause potentially significant effects on water quality in the primary study area. These effects could be caused temporarily or for the short term by construction-related activities that cause sediment, petroleum, or other substances to enter waterways in runoff. Mitigation measures would eliminate these effects or reduce them to a less-than-significant level.

CP1 would also affect water quality by increasing the volume of water in the reservoir and by altering downstream river flows. The effects on water quality resulting from these hydrologic alterations would be long term and much greater than the temporary and short-term effects related to construction.

Hydrologic modeling output predicts that hydrologically, CP1 would result in a small change in reservoir storage and minimal change in river flows relative to the No-Action Alternative. A small increase in the volume of water stored in the reservoir under CP1 could result in additional inputs of metals from shoreline erosion of historical mining deposits and would result in a slight dilution of inputs of sediment and metals relative to existing and future No-Action conditions. The potential for additional inputs of metals would be substantially reduced or eliminated by Mitigation Measure WQ-6 (CP1). Changes in Sacramento River flows can be best characterized as a small decrease in monthly average winter and early spring flows in some years as measured below Keswick Dam, RBPP, Wilkins Slough, and Freeport, and a slight increase in summer flows in most years. This redistribution of flows would have little effect on water quality as measured by metals, sediment, salinity, and temperature.

The small reduction in winter flows caused by CP1 would slightly reduce potential sediment loading and discharge rates, and would also slightly reduce transport of heavy metals. Therefore, the water quality impact of CP1 related to metals and sediment would not be adverse.

Monthly mean water temperatures at all modeling locations (below Shasta Dam, below Keswick Dam, above Bend Bridge, and above Red Bluff) within the upper Sacramento River under CP1 would be essentially equivalent or slightly decreased (i.e., beneficial). Therefore, the effects of CP1 on water quality measured as water temperature would be beneficial, not adverse.

Implementing Mitigation Measure WQ-1 (CP1) would substantially reduce adverse effects from CP1, and the incremental contribution of CP1 to cumulative effects on water quality would no longer be cumulatively considerable. In summary, effects of CP1 on water quality measured as water temperature, metals, and sediment would be less than significant, and CP1 would not cause an incremental cumulatively considerable contribution to an overall significant cumulative impact on water quality in the primary study area.

In the extended study area, CP1 could also influence water quality in the Delta by altering the quality, volume, or timing of Sacramento River flows. However, because changes in Sacramento River flows relative to the No-Action Alternative would be minimal and effects would diminish with distance from Shasta Dam, the effects would be very minor. Water quality effects are attenuated by multiple factors, including flow from tributaries, stormwater runoff, and municipal and agricultural discharges. Furthermore, the Central Valley's reservoirs and diversions are managed as a single integrated system, and the opearional requirements for this system and have been designed to maintain standards for Delta inflow and water quality. Therefore, water quality impacts of CP1 at the Delta would not make a cumulatively considerable incremental contribution to the overall significant cumulative impact on Delta water quality.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP1 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP1. Therefore, even with the addition of anticipated effects of climate change, CP1 would not have a significant cumulative effect, and could be potentially beneficial.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The cumulative effects of CP2 would be similar to those of CP1, except that the greater increase in reservoir storage and river flow alteration under CP2 would result in greater beneficial effects on water temperature in the upper Sacramento River. Effects on sediments and metals in the Upper Sacramento River, and on Delta water quality, would be effectively the same as CP1. Therefore, water quality impacts of CP2 would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP2 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP2. Therefore, even with the addition of anticipated effects of climate change, CP2 would not have a significant cumulative effect, and could be potentially beneficial.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

The cumulative effects of CP3 would be similar to those of CP1 and CP2, except that the greater increase in reservoir storage and river flow alteration under CP3 would result in greater beneficial effects on water temperature in the upper Sacramento River. Effects on sediments and metals in the upper Sacramento River, and on Delta water quality, would be effectively the same as CP1. Therefore, water quality impacts of CP3 would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP3 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP3. Therefore, even with the addition of anticipated effects of climate change, CP3 would not have a significant cumulative effect, and could be potentially beneficial.

CP4 or CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

With the exception of water quality measured as water temperature, the cumulative effects of CP4 or CP4A would be the same as those of CP1 or CP2. Effects of CP4 or CP4A on water quality measured as water temperature would be beneficial and greater than those of other alternatives. Therefore, water quality impacts of CP4 or CP4A would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP4 or CP4A could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP4 or CP4A. Therefore, even with the addition of anticipated effects of climate change, CP4 or CP4A would not have a significant cumulative effect, and could be potentially beneficial.

CP5 – 18.5-Foot Dam Raise, Combination Plan

With the exception of water quality measured as water temperature, the cumulative effects of CP5 would be the same as those of CP1. Effects of CP5 on water quality measured as water temperature would be beneficial and effectively the same as CP3. Therefore, water quality impacts of CP5 would not make a cumulatively considerable incremental contribution to the overall significant cumulative water quality impact in the primary study area or extended study area, including the Delta.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased releases with potentially increased water temperatures at other times. The additional storage associated with CP5 could potentially reduce these effects, allowing Shasta Lake to capture some of the increased runoff in the winter and early spring for both cold-water storage and release in summer and fall. This would benefit both Sacramento River water temperatures and Delta water quality. Potential impacts associated with Sacramento River water temperatures and Delta water quality would be less than significant under CP5. Therefore, even with the addition of anticipated effects of climate change, CP5 would not have a significant cumulative effect, and could be potentially beneficial.

Chapter 8
Noise and Vibration

8.1 Affected Environment

This section describes the affected environment related to noise and vibration for the dam and reservoir modifications proposed under SLWRI action alternatives.

8.1.1 Acoustic Fundamentals

Noise is generally defined as sound that is loud, disagreeable, or unexpected. Sound, as described in more detail below, is an audible vibration of an elastic medium.

Sound Properties

A sound wave is introduced into a medium (e.g., air) by a vibrating object. The vibrating object (e.g., vocal cords, the string and sound board of a guitar, or the diaphragm of a radio speaker) is the source of the disturbance that sets the medium to vibrate and then propagates through the medium. Regardless of the type of source creating the sound wave, the particles of the medium through which the sound moves are vibrating in a back-and-forth motion at a given frequency, tone, or pitch. The frequency of a wave refers to how often the particles vibrate when a wave passes through the medium. Wave frequency is measured as the number of complete back-and-forth vibrations of a particle per unit of time. If a particle of air undergoes 1,000 longitudinal vibrations in 2 seconds, then the frequency of the wave would be 500 vibrations per second. A commonly used unit for frequency is Hertz (Hz).

Each particle vibrates as a result of the motion of its nearest neighbor. For example, the first particle of the medium begins vibrating at 500 Hz and sets the second particle of the medium into motion at the same frequency (500 Hz). The second particle begins vibrating at 500 Hz and thus sets the third particle into motion at 500 Hz. The process continues throughout the medium; hence each particle vibrates at the same frequency, which is the frequency of the original source. Subsequently, a guitar string vibrating at 500 Hz will set the air particles in the room vibrating at the same frequency (500 Hz), which carries a sound signal to the ear of a listener that is detected as a 500 Hz sound wave.

The back-and-forth vibration motion of the particles of the medium would not be the only observable phenomenon occurring at a given frequency. Because a sound wave is a pressure wave, a detector could be used to detect oscillations in pressure from high to low and back to high pressure. As the compression (high-pressure points) and rarefaction (low-pressure points) disturbances move through the medium, they would reach the detector at a given frequency. For example, a compression would reach the detector 500 times per second if the frequency of the wave were 500 Hz. Similarly, a rarefaction would reach the detector 500 times per second if the frequency of the wave were 500 Hz. Thus, the frequency of a sound wave refers not only to the number of back-and-forth vibrations of the particles per unit of time but also to the number of compression or rarefaction disturbances that pass a given point per unit of time. A detector could be used to detect the frequency of these pressure oscillations over a given period of time. The period of the sound wave can be found by measuring the time between successive compressions or the time between successive rarefactions. The frequency is simply the reciprocal of the period; thus an inverse relationship exists so that as frequency increases, the period decreases, and vice versa.

A wave is a disturbance through some medium (e.g., air, water, space) that typically transfers energy. Waves travel and transfer energy from one point to another, often with little or no permanent displacement of the particles of the medium. For example, in an ocean wave, the seawater appears to be move along the path of the wave. However, the water particles themselves are nearly stationary—it is the energy transferred through those particles (the wave) causing displacement that makes it appear that the water itself is moving.

In the case of sound (and noise), the “wave” is a vibration or disturbance moving through air particles and, at a certain range of frequencies, is audible to the human ear. The amount of energy carried by a wave is related to the amplitude (loudness) of the wave. A high-energy wave is characterized by high amplitude; a low-energy wave is characterized by low amplitude. The amplitude of a wave refers to the maximum amount of displacement of a particle from its rest position. The energy transported by a wave is directly proportional to the square of the amplitude of the wave. This means that a doubling of the amplitude of a wave indicates a quadrupling of the energy transported by the wave.

Sound and the Human Ear

Because of the ability of the human ear to detect a wide range of sound-pressure fluctuations, sound-pressure levels are expressed in logarithmic units called decibels (dB). The sound-pressure level in decibels is calculated by taking the log of the ratio between the actual sound pressure and the reference sound pressure squared. The reference sound pressure is considered the absolute hearing threshold (Caltrans 1998). Use of this logarithmic scale reveals that the total sound from two individual sources of 65 A-weighted decibels (dBA) each (see explanation of the A-weighting scale below) is 68 dBA, not 130 dBA; that is, doubling the source strength increases the sound pressure by 3 dBA.

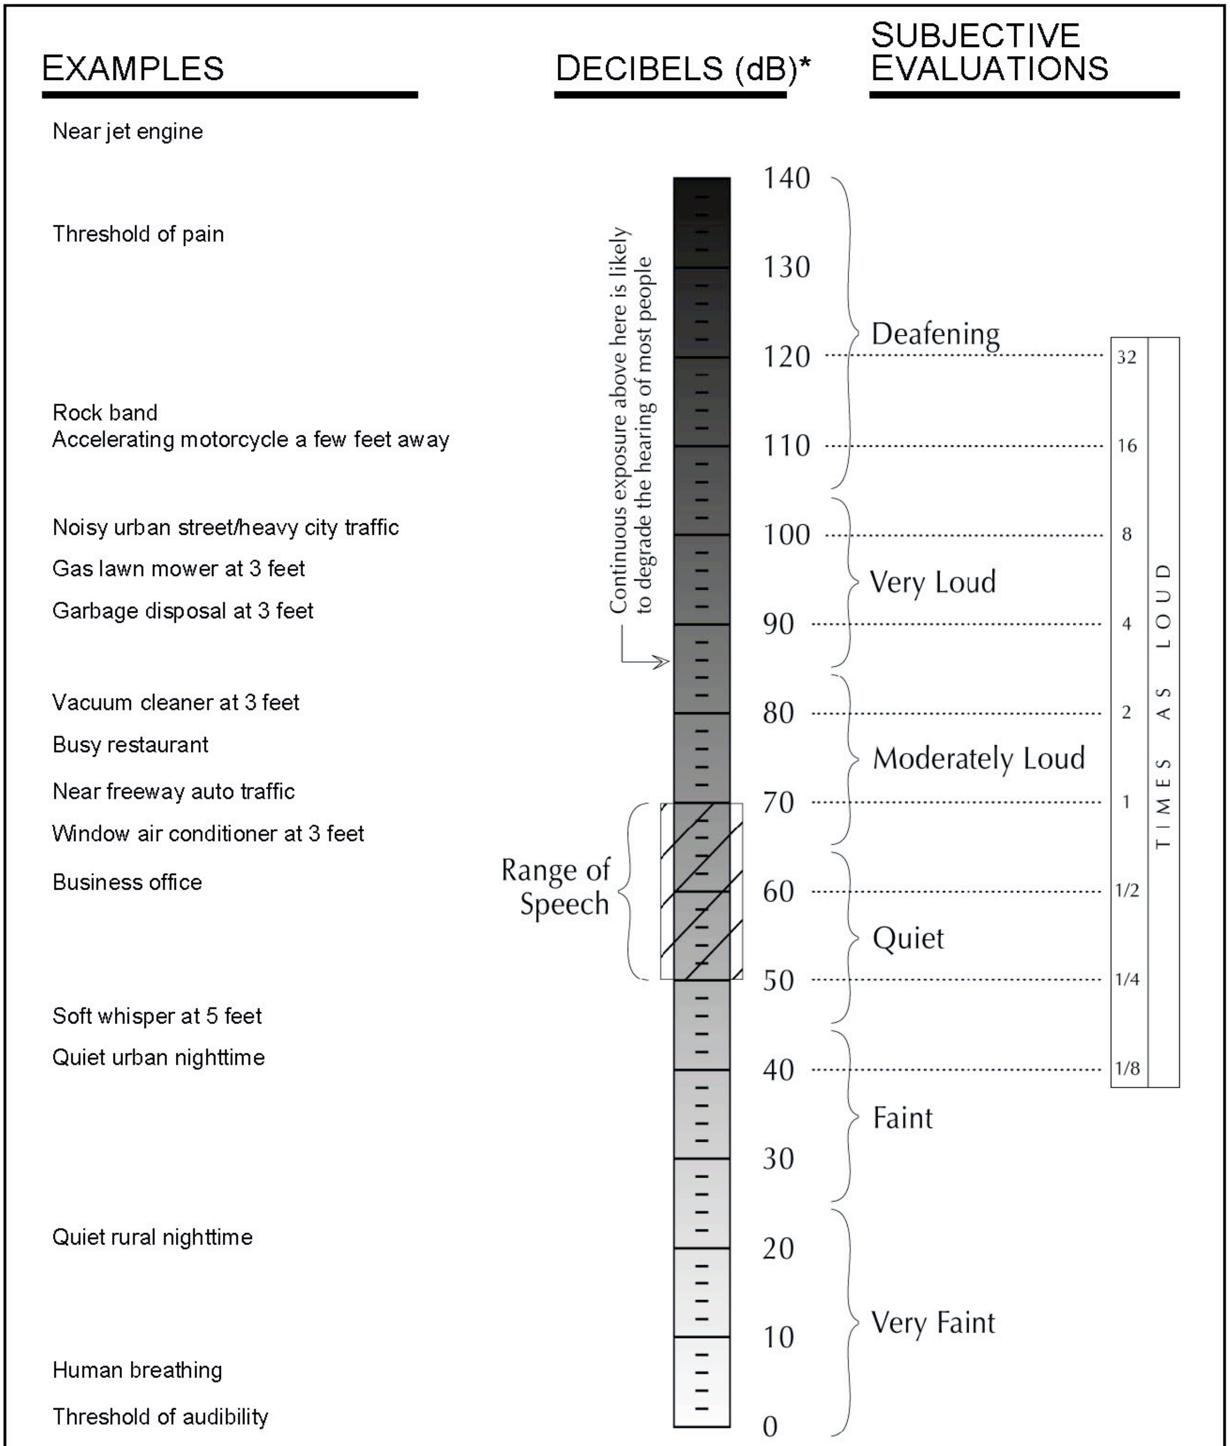
The human ear is sensitive to frequencies from 20 Hz to 20,000 Hz (the audible range) and can detect the vibration amplitudes that are comparable in size to a hydrogen atom (EPA 1974). When damaged by noise, the ear is typically affected at the 4,000-Hz frequency first; therefore, this can be considered the most noise-sensitive frequency. The averaged frequencies of 500 Hz, 1,000 Hz, and 2,000 Hz have traditionally been employed in hearing conservation criteria because of their importance to the hearing of speech sounds (ASA 1997).

The human ear is not equally sensitive to all sound frequencies, depending on the amplitude of the sound; therefore, a specific frequency-dependent rating scale was devised to relate noise to human sensitivity. This called the weighting scale or function. The A-weighting scale is the most commonly used and is noted as A-weighted dB, dB(A), or dBA. The dBA scale discriminates against frequencies in a manner approximating the sensitivity of the human ear when a source is at 50 dB. The basis for compensation is a comparison of the "loudness" of tones played one at a time with a reference tone producing 50 dB. This dBA scale has been chosen by most authorities for the purpose of regulating environmental noise. Typical indoor and outdoor noise levels are presented on Figure 8-1.

With respect to how humans perceive increases in noise levels, for pure tones or some broadband tones, a 1-dBA increase is imperceptible, a 3-dBA increase is barely perceptible, a 6-dBA increase is clearly perceptible, and a 10-dBA increase is subjectively perceived as approximately twice as loud (Egan 1988). For this reason, an increase of 3 dBA or more is generally considered a degradation of the existing noise environment for this type of source. For more complex sources, that is, where the tones differ substantially between sources, such as for the sound of a heavy truck versus a new car or a kitchen blender, the ear perceives differences much more quickly.

Sound Propagation

As sound (noise) propagates from the source to the receptor, the attenuation, or manner of noise reduction in relation to distance, depends on surface characteristics, atmospheric conditions, and the presence of physical barriers. The inverse-square law describes the attenuation when sound travels from a point source such as an air-conditioning unit to the receptor. Sound travels uniformly outward from a point source in a spherical pattern with an attenuation rate of 6 dBA per doubling of distance (dBA/DD). However, from a line source, such as a long line of traffic on a freeway, sound travels uniformly outward in a cylindrical pattern with an attenuation rate of 3 dBA/DD. The surface characteristics between the source and the receptor may result in additional sound absorption and/or reflection. Atmospheric conditions such as wind speed, temperature, and humidity may affect noise levels. Furthermore, the presence of a barrier between the source and the receptor may also attenuate noise levels. The actual amount of attenuation depends on the size of the barrier and the frequency of the noise. A noise barrier may be any natural or human-made feature such as a hill, building, wall, or berm (Caltrans 1998).



* dB are "average" values as measured on the A-scale of a sound-level meter.
From Concepts in Architectural Acoustics: M. David Egan, McGraw Hill, 1972 and U.S. Department of Housing and Urban Development, Office of Community Planning and Development "The Noise Guidebook."

Figure 8-1. Typical Noise Levels

Noise Descriptors

The selection of a proper noise descriptor for a specific source depends on the spatial and temporal distribution, duration, and fluctuation of the noise. The noise descriptors most often encountered when dealing with traffic, community, and environmental noise are defined below (Caltrans 1998; Lipscomb and Taylor 1978):

- **L_{max} (maximum noise level) –** The maximum noise level during a specific period of time. The L_{max} may also be referred to as the "highest (noise) level."
- **L_{min} (minimum noise level) –** The minimum noise level during a specific period of time.
- **L_x (statistical descriptor) –** The noise level exceeded X percent of a specific period of time.
- **L_{eq} (equivalent noise level) –** The energy mean (average) noise level. The instantaneous noise levels during a specific period of time in dBA are converted to relative energy values. From the sum of the relative energy values, an average energy value is calculated, which is then converted back to dBA to determine the L_{eq}.
- **L_{dn} (day-night noise level) –** The 24-hour L_{eq} with a 10-dBA "penalty" for the noise-sensitive hours between 10 p.m. and 7 a.m. The L_{dn} attempts to account for the fact that noise during this specific period of time is a potential source of disturbance with respect to normal sleeping hours.
- **CNEL (community noise equivalent level) –** A noise level similar to the L_{dn} described above, but with an additional 5-dBA "penalty" for the noise-sensitive hours between 7 p.m. and 10 p.m., which are typically reserved for relaxation, conversation, reading, and television. If the same 24-hour noise data are used, the CNEL is typically approximately 0.5 dBA higher than the L_{dn}.
- **SEL (single-event (impulsive) noise level) –** A receiver's cumulative noise exposure from a single impulsive-noise event, which is defined as an acoustical event of short duration and which involves a change in sound pressure above some reference value.

Negative Effects of Noise on Humans

Negative effects of noise exposure include physical damage to the human auditory system, speech interference, sleep interference, activity interference, and disease. Exposure to noise may result in physical damage to the auditory system, which may lead to gradual or traumatic hearing loss. Gradual hearing loss is caused by sustained exposure to moderately high noise levels over a period of time; traumatic hearing loss is caused by sudden exposure to extremely high noise levels over a short period. However, gradual and traumatic hearing loss both may result in permanent hearing damage. In addition, noise may interfere with or interrupt sleep, relaxation, recreation, and communication. Although most interference may be classified as annoying, the inability to hear a warning signal may be considered dangerous. Noise may also be a contributor to diseases associated with stress, such as hypertension, anxiety, and heart disease. The degree to which noise contributes to such diseases depends on the frequency, bandwidth, and level of the noise, and the exposure time (Caltrans 1998).

Vibration Fundamentals

Vibration is sound radiated through the ground. The rumbling sound caused by the vibration of room surfaces is called groundborne noise. Sources of groundborne vibrations include natural phenomena (e.g., earthquakes, volcanic eruptions, sea waves, and landslides) and human-made causes (e.g., explosions, machinery, traffic, trains, and construction equipment). Vibration sources may be continuous, such as factory machinery, or transient, such as explosions. As is the case with airborne sound, groundborne vibrations may be described by amplitude and frequency.

Vibration amplitudes are usually expressed in peak particle velocity (PPV) or root mean squared (RMS), as in RMS vibration velocity. The PPV and RMS velocity are normally described in inches per second (in/sec). PPV is defined as the maximum instantaneous positive or negative peak of a vibration signal. PPV is often used in monitoring of blasting vibration because it is related to the stresses that are experienced by buildings (FTA 2006; Caltrans 2002a).

Although PPV is appropriate for evaluating the potential for building damage, it is not always suitable for evaluating human response. It takes some time for the human body to respond to vibration signals. In a sense, the human body responds to average vibration amplitude. The RMS of a signal is the average of the squared amplitude of the signal, typically calculated over a 1-second period. As with airborne sound, the RMS velocity is often expressed in decibel notation, expressed as vibration decibels (VdB), which serves to compress the range of numbers required to describe vibration (FTA 2006).

The background vibration-velocity level in residential areas is usually approximately 50 VdB. Groundborne vibration is normally perceptible to humans at approximately 65 VdB. For most people, a vibration-velocity level of 75 VdB is the approximate dividing line between barely perceptible and distinctly perceptible levels (FTA 2006).

Typical outdoor sources of perceptible groundborne vibration are construction equipment, steel-wheeled trains, and traffic on rough roads. If a roadway is smooth, the groundborne vibration is rarely perceptible. The range of interest is from approximately 50 VdB, which is the typical background vibration-velocity level, to 100 VdB, which is the general threshold where minor damage can occur in fragile buildings. Construction activities can generate groundborne vibrations, which can pose a risk to nearby structures. Constant or transient vibrations can weaken structures, crack facades, and disturb occupants (FTA 2006).

Construction vibrations can be transient, random, or continuous. Transient construction vibrations are generated by blasting, impact pile driving, and wrecking balls. Continuous vibrations result from vibratory pile drivers, large pumps, and compressors. Random vibration can result from jackhammers, pavement breakers, and heavy construction equipment. Table 8-1 describes the general human response to different levels of groundborne vibration-velocity levels.

Table 8-1. Human Response to Different Levels of Groundborne Noise and Vibration

Vibration-Velocity Level	Human Reaction
65 VdB	Approximate threshold of perception.
75 VdB	Approximate dividing line between barely perceptible and distinctly perceptible. Many people find that transportation-related vibration at this level is unacceptable.
85 VdB	Vibration acceptable only if there are an infrequent number of events per day.

Source: FTA 2006

Key:
VdB = vibration decibels

8.1.2 Existing Noise Sources and Levels

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Existing sources of noise and vibration in the primary study area associated with roadway traffic and aircraft noise are outlined below. Noise is also generated by watercraft on Shasta Lake and stationary noise sources such as mechanical equipment at the existing dam facility. Additional sites that would be affected by the project are existing bridges, roads, and structures that would be inundated with implementation of the proposed dam rise and would need to be modified, demolished, or reconstructed. Sensitive receptors in these areas consist of residences, transient lodging, and recreational facilities.

Roadway Traffic Interstate 5 (I-5) and State Routes 36, 44, 151, 273, and 299 contribute the majority of roadway noise in the greater Shasta area. The Federal Highway Administration’s Highway Traffic Noise Prediction Model was used to predict existing traffic noise levels for these routes. Table 8-2 shows existing average daily traffic volumes for Shasta County’s major roadways, modeled vehicle distribution characteristics, and the modeled distance from the roadway centerline to the various noise-level contours for each affected roadway segment in the study area under existing conditions. The modeling presented was based on 2006 traffic data from California Department of Transportation (Caltrans). These data are also representative of current information from Caltrans (Caltrans 2012) that show minor fluctuations in overall traffic volumes. The traffic noise levels shown in the table assume no shielding or reflection from structures or topography. Actual noise levels would vary from day to day.

Railway traffic in Shasta County is served by the Union Pacific Railroad single-track main line, which travels north/south through the primary study area, paralleling I-5. (The McCloud Railway Company, a single-track short line, runs from McCloud to Burney, but because its activity is limited, noise measurements were not conducted for this line.) Noise measurements were conducted at two sites near Redding and Cottonwood for the *Shasta County General Plan* Noise Element. Table 8-3 presents noise levels associated with railroad noise in the Shasta Lake area.

Aircraft The three existing airports in the primary study area are described below.

Redding Municipal Airport In the 12-month period ending April 2012, there were approximately 104,674 total aircraft operations at Redding Municipal Airport (FAA 2012). As shown in the background report for the *Shasta County General Plan* Noise Element, the 65-dB CNEL contour is confined primarily to the airport property. The 60-dB CNEL contour extends outside of the property, but does not encroach on existing residential uses. According to the *Redding Municipal Airport Master Plan*, aviation growth at the airport will affect the surrounding area. The total number of aircraft operations is estimated to increase to 162,400 by 2015.

Fall River Mills Airport In 2001, there were approximately 6,000 total aircraft operations at Fall River Mills Airport. Based on the *Environmental Assessment for the Fall River Mills Airport Layout Plan* (April 2003), the existing 65-dB CNEL contour is contained within the existing airport boundary. Aviation growth at Fall River Mills Airport can also affect the area surrounding the airport. The number of aircraft operations is expected to increase to 15,000 by 2021. The future (2021) 65-dB CNEL contour is confined to Public Facility and Agriculture lands. The 60-dB CNEL contour also encompasses Urban Residential lands.

Table 8-2. Summary of Modeled Existing Traffic Noise Levels (Year 2006)[1]

Roadway Segment	Modeling Assumptions				Distance (feet) from Roadway Edge to CNEL/L_{dn} (dBA)[1]				CNEL/L_{dn} (dBA) from Roadway Edge
	Average Daily Traffic Volume	Speed (mph)	Traffic Distribution Percentages (%)		70 CNEL	65 CNEL	60 CNEL	55 CNEL	50 Feet
			Auto/Medium Truck/Heavy Truck	Day/ Evening/ Night					
SR 36, north of Red Bluff	12,000	45	79/9/12	79/11/10	64	138	298	641	72
SR 44, junction with I-5	51,000	65	81/9/10	79/11/10	235	507	1,093	2354	80
SR 151, Shasta Lake	5,500	45	81/9/10	79/11/10	36	77	165	356	68
SR 273, Redding	23,800	35	81/9/10	79/11/10	74	160	345	742	73
SR 299, Redding	19,900	35	81/9/10	79/11/10	66	142	306	659	72
I-5, Bridgebay	27,500	70	81/9/10	79/11/10	171	368	792	1,706	78
I-5, Shasta Lake	37,000	70	81/9/10	79/11/10	208	448	965	2,080	79
I-5, Redding	67,000	70	81/9/10	79/11/10	309	666	1,434	3,090	82
I-5, Anderson	50,000	70	81/9/10	79/11/10	254	548	1,180	2,542	81
I-5, Cottonwood	46,500	70	81/9/10	79/11/10	242	522	1,124	2,422	80
I-5, Red Bluff	40,500	70	79/9/12	79/11/10	231	498	1,073	2,313	80

Source: Average daily traffic volumes from CalTrans (2006). Modeling performed by EDAW (now AECOM) in 2007

Note:

[1a] 2006 and 2012 traffic volumes modeled on these roadways produce the same levels of noise.

Key:

% = percent
Caltrans = California Department of Transportation
CNEL = community noise equivalent level
dBA = A-weighted decibels
I-5 = Interstate 5
L_{dn} = day-night noise level
mph = miles per hour
SR = State Route

Table 8-3. Approximate Distance to Union Pacific Railroad Noise Contours

L_{dn}, Based on Distance from Railroad Tracks				Distance to L_{dn} Contour (feet)

Key:
dB = decibel
L_{dn} = day-night noise level

Benton Airpark In the 12-month period ending December 2011, there were approximately 35,000 total aircraft operations at this Airpark (FAA 2012). Based on the *Benton Airpark Master Plan* (March 2005), the existing 65-dB CNEL contour is contained within the existing airport boundary. Aviation growth at Benton Airpark can also affect the area surrounding the airport. The number of aircraft operations is expected to increase to 38,000 by 2021. The future (2021) 65-dB CNEL contour is confined to airport property and vacant land.

Other Aircraft Activities In addition to the aircraft facilities listed above, helipads from medical facilities in Redding are also in use. Usage of these helipads would be reserved for emergencies and would be intermittent in comparison to usage by full-time facilities such as the Benton Airpark. In the fire season, aircraft, operated by the California Department of Forestry and Fire Protection or under contract with the USFS, use Shasta Lake as a source of water for fighting wildfires. Fire helicopters and tankers use the lake as needed during emergencies. Because firefighting is intermittent, no consistent noise levels would result from firefighting operations.

Fixed Noise Sources Industrial, light industrial, commercial, and public service facilities that could produce objectionable noise levels at nearby noise-sensitive uses are dispersed throughout the primary study area. Among these fixed noise sources are lumber mills, auto maintenance shops, car washes, loading docks, recycling centers, electricity generating stations, landfills, and athletic fields.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Noise sources within the extended study area would be similar to the general descriptions provided for the primary study area.

8.1.3 Existing Noise-Sensitive Land Uses

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Noise-sensitive land uses (sensitive receptors) are uses where exposure to noise would result in adverse effects and uses where quiet is essential. Residential dwellings are of primary concern. Other noise-sensitive land uses are schools, hospitals, convalescent facilities, parks, hotels, places of worship, and libraries. No sensitive land uses are immediately adjacent to (within 0.5 mile of) the dam. Sensitive land uses in the proximity of the dam raise site would be the vacant on site residence at the fish hatchery approximately one-half mile downstream. The nearest occupied residence is the horse camp located approximately 7,000 feet downstream; residents on Lake Boulevard are located approximately 4,500 feet east. Other sensitive receptors would include any residences within one-half mile of other construction work being done as a result of the dam raise. Bridge construction would occur at Charlie Creek, Doney Creek, McCloud River, Pit River, Fenders Ferry, Didallas Creek, and other Union Pacific Railroad bridges. Major road construction would occur on Lakeshore Drive, in the Turntable Bay Area, on Gillman Road, in Jones Valley and the Silverthorn Area, and on Salt Creek Road. The nearest school to construction activities would be the Smithson School in Lakehead (approximately 500 feet); the nearest place of worship would be Canyon Community Church also in Lakehead (approximately 800 feet).

Lower Sacramento River and Delta and CVP/SWP Service Areas

Noise receptors within the extended study area would be similar to those generally described above for the primary study area.

8.2 Regulatory Framework

8.2.1 Federal

No Federal plans, policies, regulations, or laws related to noise are applicable to the project. The environmental review of Federal projects generally defers to State of California (State), county, or other local guidelines.

To address the human response to groundborne vibration, the Federal Transit Administration (FTA) of the U.S. Department of Transportation has set forth guidelines for maximum-acceptable vibration criteria for different types of land uses. These criteria include 65 VdB for land uses where low ambient vibration is essential for interior operations (e.g., hospitals, high-tech manufacturing, and laboratory facilities), 80 VdB for residential uses and buildings where people normally sleep, and 83 VdB for institutional land uses with primarily daytime operations (e.g., schools, churches, clinics, and offices) (FTA 2006).

Standards have also been established to address the potential for groundborne vibration to cause structural damage to buildings. These standards were developed by the Committee of Hearing, Bio Acoustics, and Bio Mechanics at the request of the U.S. Environmental Protection Agency (FTA 2006). For fragile structures, Committee of Hearing, Bio Acoustics, and Bio Mechanics recommends a maximum limit of 0.25 in/sec PPV (FTA 2006).

8.2.2 State

Governor's Office of Planning and Research

The Governor's Office of Planning and Research published the *State of California General Plan Guidelines* (OPR 2003), which provides guidance for the acceptability of projects within specific L_{dn} contours. Table 8-4 summarizes acceptable and unacceptable community noise exposure limits for various land use categories.

Generally, residential uses (e.g., mobile homes) are considered to be acceptable in areas where exterior noise levels do not exceed 60 dBA L_{dn}. Residential uses are normally unacceptable in areas exceeding 70 dBA L_{dn} and conditionally acceptable within 55–70 dBA L_{dn}. Schools are normally acceptable in areas up to 70 dBA L_{dn} and normally unacceptable in areas exceeding 70 dBA L_{dn}. Commercial uses are normally acceptable in areas up to 70 dBA CNEL. Between 67.5 and 77.5 dBA L_{dn}, commercial uses are conditionally acceptable, depending on the noise insulation features and the noise reduction requirements. With respect to water recreation uses, exterior noise levels that do not exceed 75 dBA CNEL/L_{dn} are considered normally acceptable, levels between 70 and 80 dBA CNEL/L_{dn} are normally unacceptable, and levels that exceed 80 dBA CNEL/L_{dn} are clearly unacceptable. The guidelines also present adjustment factors that may be used to arrive at noise-acceptability standards that reflect the noise-control goals of the community, the particular community's sensitivity to noise, and the community's assessment of the relative importance of noise issues.

California Department of Transportation

For the protection of fragile, historic, and residential structures, Caltrans recommends a threshold of 0.2 in/sec PPV for normal residential buildings and 0.08 in/sec PPV for old or historically significant structures (Caltrans 2002a). These standards are more stringent than the Federal standard established by Committee of Hearing, Bio Acoustics, and Bio Mechanics, presented above.

Table 8-4. State Noise-Compatibility Guidelines by Land-Use Category

Land-Use Category	Community Noise Exposure (CNEL/L_{dn}, dBA)			
	Normally Acceptable [1]	Conditionally Acceptable [2]	Normally Unacceptable [3]	Clearly Unacceptable [4]
Residential – Low-Density Single-Family, Duplexes, Mobile Homes	< 60	55–70	70–75	75+
Residential – Multifamily	< 65	60–70	70–75	75+
Transient Lodging – Motels, Hotels	< 65	60–70	70–80	80+
Schools, Libraries, Churches, Hospitals, Nursing Homes	< 70	60–70	70–80	80+
Auditoriums, Concert Halls, Amphitheaters		< 70	65+	
Sports Arenas, Outdoor Spectator Sports		< 75	70+	
Playgrounds, Neighborhood Parks	< 70		68–75	72.5+
Golf Courses, Riding Stables, Water Recreation, Cemeteries	< 75		70–80	80+
Office Buildings, Businesses, Commercial and Professional	< 70	68–78	75+	
Industrial, Manufacturing, Utilities, Agriculture	< 75	70–80	75+	

Source: OPR 2003

Notes:

[1] Specified land use is satisfactory, based on the assumption that any buildings involved are of normal conventional construction, without any special noise-insulation requirements.

[2] New construction or development should be undertaken only after a detailed analysis of the noise-reduction requirements is made and needed noise-insulation features are included in the design. Conventional construction, but with closed windows and fresh-air supply systems or air conditioning, will normally suffice.

[3] New construction or development should generally be discouraged. If new construction or development does proceed, a detailed analysis of the noise-reduction requirements must be made and needed noise-insulation features included in the design. Outdoor areas must be shielded.

[4] New construction or development should generally not be undertaken.

Key:
< = less than
+ = and greater
CNEL = community noise equivalent level
dBA = A-weighted decibels
L_{dn} = day-night noise level

8.2.3 Regional and Local

All major project-related construction activities would occur in Shasta County. However, haul trucks and employee trips could also occur in Tehama County and, thus, related information is also provided. In any note, the regulations provided are very similar for both.

Shasta County

Shasta County General Plan Noise Element The Noise Element of the *Shasta County General Plan* includes goals, standards, and policies designed to ensure that county residents are not subjected to noise beyond acceptable levels (Shasta County 2004). Policies that may be applicable to the project include the following:

- **Policy N-b –** Noise likely to be created by a proposed non-transportation land use shall be mitigated so as not to exceed the noise level standards of Table 8-5 as measured immediately within the property line of adjacent lands designated as noise-sensitive.

- **Policy N-c –** Where proposed non-residential land uses are likely to produce noise levels exceeding the performance standards of Table 8-5 upon existing or planned noise-sensitive uses, an acoustical analysis shall be required as part of the environmental review process so that appropriate noise mitigation may be included in the project design. The requirements for the content of an acoustical analysis are given by Table 8-5.

- **Policy N-d –** The feasibility of proposed projects with respect to existing and future transportation noise levels shall be evaluated by comparison to Tables 8-5 and 8-6.

- **Policy N-f –** Noise created by new transportation sources shall be mitigated to satisfy the levels specified in Table 8-5 at outdoor activity areas and/or interior spaces of existing noise-sensitive land uses. Transportation noise shall be compared with existing and projected noise levels.

- **Policy N-g –** Existing noise-sensitive uses may be exposed to increased noise levels due to future roadway improvement projects as a result of increased traffic capacity and volumes and increases in travel speeds. In these instances, it may not be practical to reduce increased traffic noise levels consistent with those contained in Table 8-5. Therefore, as an alternative, the following criteria may be used as a test of significance for increases in the ambient outdoor activity areas of the noise level of noise-sensitive uses created as a result of a new roadway improvement project:

  – Where existing traffic noise levels are less than 60 dB Ldn, a +5 dB Ldn increase will be considered significant,

– Where existing traffic noise levels range between 60 and 65 dB Ldn, a +3 dB Ldn increase will be considered significant, and

– Where existing traffic noise levels are greater than 65 dB Ldn, a + 1.5 dB Ldn increase will be considered significant.

Table 8-5. Noise Level Performance Standards for New Projects Affected by or Including Nontransportation Sources

Noise Level Descriptor	Daytime (7 a.m. to 10 p.m.)	Nighttime (10 p.m. to 7 a.m.)
Hourly L_{eq}, dB	55	50

The noise levels specified above shall be lowered by 5 dB for simple tone noises, noises consisting primarily of speech or music, or for recurring impulsive noises. These noise level standards do not apply to residential units established in conjunction with industrial or commercial uses (e.g., caretaker dwellings).

The County can impose noise level standards which are more restrictive than those specified above based upon determination of existing low ambient noise levels.

In rural areas where large lots exist, the exterior noise level standard shall be applied at a point 100 feet away from the residence.

Industrial, light industrial, commercial, and public service facilities which have the potential for producing objectionable noise levels at nearby noise-sensitive uses are dispersed throughout the County. Fixed-noise sources which are typically of concern include, but are not limited to, the following:

HVAC Systems	Heavy Equipment
Cooling Towers/Evaporative Condensers	Conveyor Systems
Pump Stations	Transformers
Lift Stations	Pile Drivers
Emergency Generators	Grinders
Boilers	Drill Rigs
Steam Valves	Gas or Diesel Motors
Steam Turbines	Welders
Generators	Cutting Equipment
Fans	Outdoor Speakers
Air Compressors	Blowers

Source: Shasta County 2004

Notes:

The types of uses which may typically produce the noise sources described above include, but are not limited to: industrial facilities including lumber mills, trucking operations, tire shops, auto maintenance shops, metal fabricating shops, shopping centers, drive-up windows, car washes, loading docks, public works projects, batch plants, bottling and canning plants, recycling centers, electric generating stations, race tracks, landfills, sand and gravel operations, and athletic fields.

For the purposes of the Noise Element, transportation noise sources are defined as traffic on public roadways, railroad line operations, and aircraft in flight. Control of noise from these sources is preempted by Federal and State regulations. Other noise sources are presumed to be subject to local regulations, such as a noise control ordinance. Non-transportation noise sources may include industrial operations, outdoor recreation facilities, heating, ventilation, and air conditioning units, loading docks, etc.

Key:
County = Shasta County
dB = decibels
HVAC = heating, ventilation, and air conditioning
L_{eq} = equivalent noise level

Table 8-6. Requirements for an Acoustical Analysis

An acoustical analysis prepared pursuant to the Noise Element shall:
A. Be the financial responsibility of the applicant.
B. Be prepared by a qualified person experienced in the fields of environmental noise assessment and architectural acoustics.
C. Include representative noise level measurements with sufficient sampling periods and locations to adequately describe local conditions and the predominant noise sources.
D. Estimate existing and projected cumulative (20 years) noise levels in terms of L_{dn} or CNEL and/or the standards of Table [8-5], and compare those levels to the adopted policies of the Noise Element.
E. Recommend appropriate mitigation to achieve compliance with the adopted policies and standards of the Noise Element, giving preference to proper site planning and design over mitigation measures which require the construction of noise barriers or structural modifications to buildings which contain noise-sensitive land uses.
F. Estimate noise exposure after the prescribed mitigation measures have been implemented.
G. Describe a post-project assessment program which could be used to evaluate the effectiveness of the proposed mitigation measures.

Source: Shasta County 2004
Key:
CNEL = community noise equivalent level
L_{dn} = day-night noise level

- **Policy N-i –** Where noise mitigation measures are required to achieve the standards of Tables 8-5 and 8-6, the emphasis of such measures shall be placed upon site planning and project design. The use of noise barriers shall be considered a means of achieving compliance with the noise standards only after all other practical design-related noise mitigation measures have been integrated into the project.

- **Policy N-j –** Encourage railroad officials to install noise-mitigation features on trains, equipment, and at fixed-based facilities whenever possible, and instruct railroad engineers to limit their use of air horns to reduce rail-related noise impacts on cities, towns, and rural community centers.

- **Policy N-k –** All County airports lacking adopted noise level contours consistent with the General Plan forecast year of 2025 should update their respective Master Plans or Comprehensive Land Use Plans to reflect aircraft operation noise levels for existing and future operations.

- **Policy N-l –** The use of site planning and building materials/design as primary methods of noise attenuation is encouraged.

- **Policy N-m –** The County should adopt noise control guidelines to assist staff and project applicants in determining the appropriate methods for reducing transportation and non-transportation generated noise.

- **Policy N-n –** The State Noise Insulation Standards (California Code of Regulations, Title 24) and Chapter 35 of the Uniform Building Code shall be enforced.

- **Policy N-o** – As the County updates the geographic information system (GIS) mapping data base, the traffic, airport, and railroad noise contour information contained within the Background Report for the Noise Element shall be included as a part of the mapping data base. Noise contours for transportation and fixed noise sources should be periodically updated and any subsequent revisions of the data shall be incorporated into the General Plan and adopted for noise control planning purposes, as appropriate (see Tables 8-7 and 8-8).

Table 8-7. Maximum Allowable Noise Exposure Transportation Noise Sources

Land Use	Outdoor Activity Areas[1] L_{dn}/CNEL, dB	Interior Spaces	
		L_{dn}/CNEL, dB	L_{eq}, dB[2]
Residential	60 [3]	45	–
Transient Lodging	60 [4]	45	–
Hospitals, Nursing Homes	60 [3]	45	–
Theaters, Auditoriums, Music Halls	–	–	35
Churches, Meeting Halls	60 [3]	–	40
Office Buildings	–	–	45
Schools, Libraries, Museums	–	–	45
Playgrounds, Neighborhood Parks	70	–	–

Source: Shasta County 2004

Notes:

[1] Where the location of outdoor activity areas is unknown, the exterior noise level standard shall be applied to the property line of the receiving land use. Where it is not practical to mitigate exterior noise levels at patio or balconies of apartment complexes, a common area such as a pool or recreation area may be designated as the outdoor activity area.

[2] As determined for a typical worst-case hour during periods of use.

[3] Where it is not possible to reduce noise in outdoor activity areas to 60 dB L_{dn}/CNEL or less using a practical application of the best-available noise reduction measures, exterior noise levels of up to 65 dB L_{dn}/CNEL may be allowed provided that available exterior noise level reduction measures have been implemented and interior noise levels are in compliance with this table.

[4] In the case of hotel/motel facilities or other transient lodging, outdoor activity areas such as pool areas may not be included in the project design. In these cases, only the interior noise level criterion will apply.

Key:

CNEL = community noise equivalent level

dB = decibels

L_{dn} = day-night noise level

Table 8-8. Transportation Noise–Related Land Use Compatibility Guidelines for Development in Shasta County

Land Use Category	Community Noise Exposure (L_{dn} or CNEL, dB)

Source: Shasta County 2004

Key:

CNEL = community noise equivalent level

dB = decibels

G.A. = Generally Acceptable. Specified land use is satisfactory. No noise mitigation measures are required.

C.A. = Conditionally Acceptable. Use should be permitted only after careful study and inclusion of protective measures as needed to satisfy the policies of the Noise Element.

G.U. = Generally Unacceptable. Development is usually not feasible in accordance with the goals of the Noise Element.

L_{dn} = day-night noise level

Shasta County Code The Shasta County Code has one provision related to noise:

> *13.04.170: Unnecessary Noise Prohibited. No person shall operate any aircraft in flight or on the ground in such a manner as to cause unnecessary noise as determined by applicable Federal or State or local laws and regulations. (Prior code Section 2112.)*

Tehama County

Tehama County General Plan The Noise Element of the *Tehama County General Plan* provides a basis for comprehensive local policies to control and abate environmental noise and to protect the citizens of the county from excessive noise exposure (Tehama County 2009). The fundamental goals of the Noise Element are as follows:

- **Goal N-1 –** Provide sufficient information concerning the community noise environment so that noise may be effectively considered in the land use planning process.

  – **Policy N-1.1 –** The County shall require an acoustical analysis for new projects anticipated to generate excessive noise located adjacent, or near, to noise-sensitive land uses. The acoustical analysis shall be prepared in accordance with Table 8-9, Requirements for Acoustical Analysis Prepared in Tehama County.

Table 8-9. Requirements for an Acoustical Analysis Prepared In Tehama County

An acoustical analysis prepared pursuant to the Noise Element shall:	
(1)	Be the responsibility of the applicant.
(2)	Be prepared by qualified persons experienced in the fields of environmental noise assessment and architectural acoustics.
(3)	Include representative noise level measurements with sufficient sampling periods and locations to adequately describe local conditions.
(4)	Estimate existing and projected cumulative noise levels in terms of the standards of Tables 9-6 and 9-7 of this General Plan and compare those levels to the adopted policies of the Noise Element.
(5)	Recommend appropriate mitigation to achieve compliance with the adopted policies and standards of the Noise Element. Where the noise source in question consists of intermittent single events, the report must address the effects of maximum noise levels in sleeping rooms evaluating possible sleep disturbance.
(6)	Estimate interior and exterior noise exposure after the prescribed mitigation measures have been implemented.
(7)	Describe the post-project assessment program that could be used to evaluate the effectiveness of the proposed mitigation measures.

Source: Tehama County 2009

- **Goal N-2 –** Develop strategies for abating excessive noise exposure through cost-effective mitigation measures in combination with appropriate zoning to avoid incompatible land uses.

  – **Policy N-2.4 –** The County shall restrict construction activities to the hours as determined in the Countywide Noise Control Ordinance, if such an Ordinance is adopted.

    ▪ **Implementation Measure N-2.4a –** Restrict construction activities to the hours as determined by the County's Noise Control Ordinance unless an exemption is received from the County to cover special circumstances. Special circumstances may include emergency operations, short-duration construction, etc.

    ▪ **Implementation Measure N-2.4b –** Require all internal combustion engines that are used in conjunction with construction activities be muffled according to the equipment manufacturer's requirements.

- **Goal N-3 –** Protect those existing regions of the planning area whose noise environments are deemed acceptable, and also those locations throughout the community deemed "noise sensitive."

- **Goal N-4 –** Protect existing noise-producing commercial and industrial uses in Tehama County from encroachment by noise-sensitive land uses.

  - **Policy N-4.1 –** The County shall require review for discretionary industrial, commercial, or other noise-generating land uses for compatibility with adjacent and nearby noise-sensitive land uses.

  - **Policy N-4.2 –** The interior and exterior noise level standards for noise-sensitive areas of new uses affected by non-transportation noise sources within Tehama County are depicted in Table 8-10.

Lower Sacramento River and Delta

General plan noise elements and noise ordinances from all counties in the lower Sacramento River and Delta and communities in Tehama, Butte, Glenn, Colusa, Sutter, Yolo, Sacramento, Solano, and Contra Costa counties would be applicable to affected areas within their jurisdictions. The general plans and codes in these jurisdictions would be similar to the Shasta and Tehama county regulations outlined above. Construction, land use, and acceptable levels for various land uses would be defined and outlined.

CVP/SWP Service Areas

All community and county plans and ordinances in the CVP and SWP service areas would be applicable to affected areas within their jurisdictions. The general plans and codes in these jurisdictions would be similar to the Shasta and Tehama county regulations outlined above. Construction, land use, and acceptable levels for various land uses would be defined and outlined.

Table 8-10. Noise Standards for New Uses Affected By Nontransportation Noise in Tehama County

New Land Use	Outdoor Activity Area—L_{eq}, dB		Interior—L_{eq}, dB	
	Daytime	Nighttime	Day and Night	Notes
All Residential	50	45	35	a, b, g
Transient Lodging	55	–	40	c
Hospitals and Nursing Homes	50	45	35	d
Theaters and Auditoriums	–	–	35	
Churches, Meeting Halls, Schools, Libraries, etc.	55	–	40	
Office Buildings	55	–	45	e, f
Commercial Buildings	55	–	45	e, f
Playgrounds, Parks, etc.	65	–	–	f
Industry	65	65	50	e

Source: Tehama County 2009

Notes:

[a] Outdoor activity areas for single-family residential uses are defined as back yards. For large parcels or residences with no clearly defined outdoor activity area, the standard shall be applicable within a 100-foot radius of the residence.

[b] For multi-family residential uses, the exterior noise level standard shall be applied at the common outdoor recreation area, such as at pools, play areas or tennis courts. Where such areas are not provided, the standards shall be applied at individual patios and balconies of the development.

[c] Outdoor activity areas of transient lodging facilities include swimming pool and picnic areas, and are not commonly used during nighttime hours.

[d] Hospitals are often noise generating uses. The exterior noise level standards for hospitals are applicable only at clearly identified areas designated for outdoor relaxation by either hospital staff or patients.

[e] Only the exterior spaces of these uses designated for employee or customer relaxation have any degree of sensitivity to noise.

[f] The outdoor activity areas of office, commercial and park uses are not typically used during nighttime hours.

[g] It may not be possible to achieve compliance with this standard at residential uses located immediately adjacent to loading dock areas of commercial uses while trucks are unloading. The daytime and nighttime noise level standards applicable to loading docks shall be 55 and 50 dB Leq, respectively.

General: The Table 9-7 standards shall be reduced by 5 dB for sounds consisting primarily of speech or music, and for recurring impulsive sounds. If the existing ambient noise level exceeds the standards of Table 9-7, then the noise level standards shall be increased at 5 dB increments to encompass the ambient.

Key:
dB = decibels
L_{eq} = equivalent noise level

8.3 Environmental Consequences and Mitigation Measures

8.3.1 Methods and Assumptions

Land use types and major noise sources in the project vicinity were identified based on existing documentation (e.g., the Shasta County Zoning Code) and site reconnaissance data. To assess potential short-term construction noise impacts, sensitive receptors and their relative exposure (considering topographic barriers and distance) were identified. Noise levels of specific construction equipment were determined and resultant noise levels at those receptors were calculated.

Potential long-term (operational) traffic, area-source, and stationary-source noise impacts were qualitatively assessed based on the number of vehicle trips and other potential operational noise sources introduced to the project area.

Groundborne vibration impacts were qualitatively assessed based on existing documentation (e.g., vibration levels produced by specific construction equipment) and the distance of sensitive receptors from the given source.

Predicted noise levels were compared with applicable standards for determination of significance. Mitigation measures were developed for significant and potentially significant noise impacts.

8.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, other Federal, State, and local guidance, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on noise would be significant if project implementation would do any of the following:

- Expose persons to or generate noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.

- Expose persons to or generate excessive groundborne vibration or groundborne noise levels.

- Permanently increase ambient noise levels in the project vicinity substantially above levels existing without the project.

- Temporarily or periodically increase ambient noise levels in the project vicinity substantially above levels existing without the project.

- Expose people residing or working in the project area to excessive aircraft-generated noise levels.

8.3.3 Topics Eliminated from Further Consideration

None of the project alternatives would expose people residing or working in the project area to excessive aircraft-generated noise levels because of the distance of existing airports to the project area. In addition, none of the alternatives would place new sensitive receptors near any aircraft-related facilities. There would also be no change in railway traffic as a result of any of the alternatives. Therefore, potential effects on the primary and extended study areas related to these issues are not discussed further in this EIS.

This analysis assumes that the operation of any of the project alternatives would not generate any new significant long-term noise sources because operation and maintenance of Shasta Dam and current or relocated recreational facilities would be relatively unchanged compared to existing conditions. Relocated recreational facilities would presumably generate the same levels and types of noise, but in a slightly different location than currently exists. After completion of the dam raise, bridge and levee construction, and relocation of recreational facilities, the number of personnel serving at all sites during construction would be reduced to approximately the number currently serving to operate and maintain the facilities. Therefore, no further analysis is needed and these issues are not discussed further in this EIS.

No effects on the current ambient noise environment would occur in the lower Sacramento River and Delta and the CVP and SWP service areas; no construction activities would occur in these geographic regions, and there would be no long-term noise sources from dam operation, modified flows in the Sacramento River and other tributaries, or water storage and conveyance throughout the CVP and SWP service areas. Therefore, potential effects related to project noise in those geographic regions are not discussed further in this EIS.

8.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (No-Action): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise No construction activities would occur and current operations would continue. Recreational use, population, and traffic would all increase but these increases and the effect on the noise environment would not be substantial. This impact would be less than significant.

No construction activities would occur and the dam would continue to function as it currently functions. Because no construction activities would occur under this alternative, implementation of the No-Action Alternative would not contribute toward a temporary change in the ambient noise environment. Generally, ambient noise levels could likely increase under the No-Action Alternative because greater recreational use, population growth, and traffic would occur; however, these increases would not be substantial. As a result, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Noise-2 (No-Action): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction No construction activities would occur and current operations would continue. Recreational use, population, and traffic could increase, but such source types are not considered to be major vibration sources. This impact would be less than significant.

This impact is similar to Impact Noise-1 (No-Action) for the primary study area. For the same reasons as described under Impact Noise-1 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Noise-3 (No-Action): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations No construction activities would occur and current operations would continue. Recreational use, population, and traffic would all increase, but these increases and the effect on the noise environment would not be substantial. This impact would be less than significant.

This impact is similar to Impact Noise-1 (No-Action) for the primary study area. For the same reasons as described under Impact Noise-1 (No-Action), this impact would be less than significant.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects in those geographic regions are not discussed further in this EIS.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP1): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise from activities at Shasta Dam, including site preparation (e.g., excavation, grading, and clearing), raising, tree removal, material handling, blasting, demolition, site restoration and cleanup, would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Increases in truck traffic from construction would also not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. However, related activities at other construction sites (e.g., bridges, roads, recreation facilities) could result in noise levels that exceed applicable standards resulting in substantial increases at nearby sensitive receptors. This temporary impact would be significant.

Construction activities at the Shasta Dam site under CP1 would include site preparation (e.g., excavation, grading, and clearing), the proposed dam raise, blasting, tree removal, material handling, site restoration and clean-up, and other miscellaneous activities. Temporary noise effects of the operation of heavy-duty construction equipment at the dam, blasting activities, operation of heavy-duty construction equipment at other project sites, and off-site construction traffic are addressed separately below.

Operation of Heavy-Duty Construction Equipment at the Dam The construction activities mentioned above would require the use of scrapers, excavators, bulldozers, compactors, loaders, trucks, crushers, pumps, pavers, concrete mixers, cranes, generators, and other miscellaneous pieces of equipment based on similar projects. According to the U.S. Environmental Protection Agency, noise levels generated by individual pieces of these types of equipment can range from 76 to 94 dBA at 50 feet without feasible noise control (Table 8-11). Simultaneous operation of the heavy-duty construction equipment could result in combined intermittent noise levels of approximately 94 dBA at 50 feet from the project site. Based on these noise levels and a typical noise-attenuation rate of 6.0 dBA/DD, exterior noise levels at noise-sensitive receptors located within 4,000 feet of construction activity could exceed 55 dBA Leq (the Shasta County standard for daytime hours) without noise control. However, there is a 450-foot elevation increase spanning 4,500 feet of intervening topography between the nearest receptors (residences on Lake Boulevard) and Shasta Dam. Accounting for the intervening topography attenuation, the vegetation, and the distance between the dam and receptors, an attenuation rate of approximately -100 dBA can be applied (-40 dBA for distance, -10 dBA for trees and vegetation, and -50 dBA for topographic elevation change). Thus, noise levels at the nearest sensitive receptor would be less than 50 dBA L_{dn}.

Table 8-11. Typical Construction Equipment Noise Levels

Type of Equipment	Noise Level at 50 feet (dBA)
Scraper	89
Excavator	89
Bulldozer	85
Compactor	82
Loader	85
Truck	88
Crusher	94
Pump	76
Paver	89
Concrete Pump	82
Concrete Mixer	85
Derrick Crane	88
Pile Driving (sonic)	96
Generator	81

Source: FTA 2006

Key:
dBA = A-weighted decibels

Additional residential receptors are approximately 7,000 feet down the Sacramento River from Shasta Dam. The construction-related noise level at this location would be approximately 45 dBA (95 dBA at 50 feet from construction site minus 45 dBA attenuation for distance, and minus 5 dBA attenuation from vegetation and topography). Thus, project construction noise generated by on-site construction equipment at Shasta Dam under CP1 would not expose sensitive receptors to or generate noise levels in excess of applicable standards (55 dBA daytime, 50 dBA nighttime), or to a substantial temporary increase in noise levels above existing conditions.

Blasting Activities at the Dam Construction of the Shasta Dam crest raise increase would require blasting during excavation of rock for the concrete tie-in to adjacent rock. Specific blast design parameters such as explosive type and amount (charge weight), drill pattern, and time scheme are not known at this time. However, it is anticipated that few blasts would occur each day. Blasting operations would result in airborne noise caused by the energy released in the explosion, which creates an air overpressure (airblast) in the form of a propagating wave. Still, as currently planned, SELs could exceed 110 dBA (FTA 2006). However, based on the above attenuation rates (i.e., distance between source and receptors, intervening topography and vegetation) coupled with the intermittent nature of blasting, such activities would not be anticipated to exceed applicable hourly standards.

Operation of Heavy-Duty Construction Equipment at Other Project Sites Multiple construction activities would occur at the other project-related sites (Pit River Bridge, the lakeshore area, and other areas where bridges and roads would require relocation; recreation facilities that would require removal and reconstruction; and inundation areas that would require clearing). Among the anticipated construction activities are site preparation (e.g., excavation, grading, demolition, and clearing), paving, pile driving, laying of railroad tracks, bridge relocation, removal of trees and vegetation, material handling, and site restoration and cleanup.

Based on similar projects, the on-site construction equipment required for the activities would likely include but not be limited to an excavator, bulldozer, front-end loader, grader, compactor, cranes, pile drivers, trucks, and other large pieces of equipment as necessary. According to the U.S. Environmental Protection Agency, noise levels from individual pieces of these types of equipment, when operated without feasible noise control, can range from 79 to 96 dBA at 50 feet (Table 8-11). Simultaneous operation of the three noisiest pieces of heavy-duty construction equipment, including pile driving, could result in combined intermittent noise levels of approximately 97 dBA at 50 feet from the project site. Based on these noise levels and a typical noise-attenuation rate of 6.0 dBA/DD, exterior noise levels at noise-sensitive receptors located within 75 feet of construction activity (i.e., sensitive receptors along Lakeshore Drive) could exceed 94 dBA L_{eq} without noise control. Such noise levels could exceed Shasta County standards (55 dBA daytime, 50 dBA nighttime).

Helicopters would also be used for vegetation removal during the spring and fall, when helicopters are not in use for firefighting. Helicopter noise levels range from 80 to 90 dBA at 250 feet (Caltrans 2002b). Noise levels from helicopters would be similar to those of other construction equipment described above.

Construction in areas away from the dam site would occur primarily during the daytime; however, the exact hours of construction are not specified at this time, nor has Shasta County adopted a noise ordinance that exempts construction noise from the provisions of the standard. If construction activities were to occur during the more noise-sensitive hours (evening, nighttime, and early morning), or if equipment were not properly equipped with noise-control devices, construction noise could exceed applicable noise-level standards (i.e., Shasta County's nighttime standard of 50 dBA L_{eq}) at existing noise-sensitive receptors located within 7,000 feet. In addition, any project-related construction noise generated during these more noise-sensitive hours may annoy and/or disrupt the sleep of occupants of the nearby existing noise-sensitive land uses, and temporarily but substantially increase ambient noise levels in the project vicinity. As a result, this impact would be significant.

Off-Site Construction Traffic Project construction would require approximately 350 on-site employees at any given time. Assuming two total trips per day per employee and 81 round trips per day for the transport of equipment and materials, project construction would result in a maximum of approximately 862 one-way daily trips at the dam site. Typically, traffic volumes must double before the associated increase in noise levels is noticeable (3 dBA CNEL/L_{dn}) along roadways. Given that the average daily traffic volumes are 5,500 for State Route 151, 37,000 for I-5, and 2,000 for the Lakeshore Community, traffic would not double. Therefore, adding these daily trips on the local roadway system to existing volumes would be a minor change. Consequently, project construction under CP1 would not noticeably change the traffic-noise contours of area roadways.

Summary Implementing CP1 would not result in noise levels that exceed applicable standards related to operation of heavy-duty construction equipment and blasting at Shasta Dam and off-site construction traffic. However, the impact of this alternative related to the operation of heavy-duty construction equipment at other project sites would be significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP1): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this temporary impact would be less than significant.

According to FTA, vibration levels associated with the use of trucks, dozers, and other heavy-duty construction equipment such as the equipment types used at project construction sites are 0.076 to 0.089 in/sec PPV and 86–87 VdB at 25 feet, and vibration levels from pile driving can reach 0.73 in/sec PPV (Table 8-10). Vibration levels generated during project construction under CP1 could exceed Caltrans's recommended standard with respect to the prevention of structural damage (0.2 in/sec PPV for buildings) and FTA's maximum-acceptable constant vibration standard of 80 VdB with respect to human annoyance for residential uses within 65 feet of the impact zone. Because there are no sensitive receptors within these distances from any of the construction sites (the nearest residences would be along Lakeshore Drive and approximately 75 feet from road and bridge construction activities taking place in the area), implementing CP1 would not generate excessive groundborne vibration or groundborne noise levels, nor would it expose persons or buildings to such groundborne vibration or noise. As a result, this temporary impact would be less than significant.

Blasting at the Shasta Dam site would result in ground vibration from the creation of seismic waves that radiate along the earth's surface. As discussed previously, no noise-sensitive receptors are located near the dam site. Receptors would need to be within 250 feet of the blasts to be affected (greater than 80 VdB) by groundborne vibration. No sensitive receptors are within this range of the dam. Therefore, this temporary impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP1): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic noise create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant.

Relocating Lakeshore Drive would move traffic noise closer to sensitive receptors in the Lakeshore Community. Based on roads of this size and service, it is estimated that the maximum average daily traffic in this area would be approximately 2,000 vehicles per day. Modeling by the Federal Highway Administration for a 2,000-average daily traffic two-lane roadway places the 60-dBA L_{dn} contour (Shasta County's transportation standard) at 70 feet from the roadway centerline. With the additional noise emanating from the adjacent railroad line (Shasta County 2004) and the nearest receptors farther than 75 feet from the new roadway centerline, the ambient noise level would not increase by more than 3 dBA or exceed 60 dBA (Shasta County 2004). Thus, project-generated long-term traffic noise would not result in an exceedence of the Shasta County standards. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Implementing CP1 would not generate any new long-term noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP1 in those geographic regions are not discussed further in this EIS.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The direct and indirect impacts of CP2 related to noise and vibration would be essentially the same as those described for CP1 because construction activities, and equipment and workforce needs, would be similar under both alternatives. Also, the long-term impact of CP2 on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact of CP1. Thus, as described below, the impacts described for CP1 would generally also apply to CP2.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Noise-1 (CP2): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise

from activities at Shasta Dam including site preparation (e.g., excavation, grading, and clearing), raising, tree removal, material handling, blasting, demolition, site restoration and cleanup would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Increases in truck traffic from construction would also not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. However, related activities at other construction sites (e.g., bridges, roads, recreation facilities) could result in noise levels that exceed applicable standards resulting in substantial increases at nearby sensitive receptors. This impact would be the same as Impact Noise-1 (CP1) and would be significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP2): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1) where no sensitive receptors are within this range of the dam. Therefore, this temporary impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP2): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-3 (CP1) where the ambient noise level would not increase by more than 3 dBA or exceed 60 dBA (Shasta County 2004). Thus, project-generated long-term traffic noise would not result in an exceedence of the Shasta County standards. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1, implementing CP2 would not generate any new long-term noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP2 in those geographic regions are not discussed further in this EIS.

CP3 –18.5-Foot Dam Raise, Agricultural Water Supply Reliability with Anadromous Fish Survival

The direct and indirect impacts of CP3 related to noise and vibration would be essentially the same as those described for CP1 and CP2 because construction activities, and equipment and workforce needs, would be similar under these alternatives. Also, the long-term impact of CP3 on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact of CP1 and CP2. Thus, as described below, the impacts described for CP1 and CP2 would generally also apply to CP3.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP3): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise from activities at Shasta Dam including site preparation (e.g., excavation, grading, and clearing), raising, tree removal, material handling, blasting, demolition, site restoration and cleanup would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Increases in truck traffic from construction would also not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. However, related activities at other construction sites (e.g., bridges, roads, recreation facilities) could result in noise levels that exceed applicable standards resulting in substantial increases at nearby sensitive receptors.

This impact would be the same as Impact Noise-1 (CP1) where implementing CP3 would not result in noise levels that exceed applicable standards related to operation of heavy-duty construction equipment and blasting at Shasta Dam and off-site construction traffic. However, the impact of this alternative related to the operation of heavy-duty construction equipment at other project sites would be significant. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP3): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1) where no sensitive receptors are within this range of the dam. Therefore, this temporary impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP3): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-3 (CP1) where the ambient noise level would not increase by more than 3 dBA or exceed 60 dBA (Shasta County 2004). Thus, project-generated long-term traffic noise would not result in an exceedence of the Shasta County standards. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1 and CP2, implementing CP3 would not generate any new long-term noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP3 in those geographic regions are not discussed further in this EIS.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

The direct and indirect impacts of CP4 or CP4A related to noise and vibration would be essentially the same as those described for CP1 through CP3 because construction activities, and equipment and workforce needs, would be similar under these alternatives. Also, the long-term impact of CP4 or CP4A on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact of CP1 through CP3. Thus, as described below, the impacts described for CP1 through CP3 would generally also apply to CP4 and CP4A.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP4 and CP4A): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise from activities at Shasta Dam including site preparation (e.g., excavation, grading, and clearing), raising, tree removal, material handling, blasting, demolition, site restoration and cleanup would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Gravel augmentation under CP4 or CP4A would increase the total number of construction-related truck trips, but not enough to result in a violation of traffic noise standards or a substantial increase in traffic noise. However, related activities at other construction sites (e.g., bridges, roads, recreation facilities) could result in noise levels that exceed applicable standards resulting in substantial increases at nearby sensitive receptors. This temporary impact would be significant for CP4 or CP4A.

This impact would be similar to Impact Noise-1 (CP1), but slightly greater because of the addition of gravel augmentation along the upper Sacramento River that is proposed under CP4 and CP4A. The proposed gravel augmentation would result in approximately 800 truck trips per year. Assuming 44 work days, approximately 18 truck trips per day would be added to the local roadway network. In addition, the upper Sacramento River restoration sites would also be included under CP4 and CP4A. Upper Sacramento River restoration site construction would include an excavator, loader, and compaction equipment. Noise levels would be similar to those described under CP1 and CP2 (see Table 8-11). Approximately 350 haul trips would be needed to remove material from the site, resulting in approximately eight trips per day over a 2-month period. As discussed above under Impact Noise-1 (CP1), to generate a substantial increase in traffic noise, the traffic volume must double. Because adding 26 truck trips would not double roadway traffic volumes, no violation of traffic noise standards or substantial increase in traffic noise would occur.

For the same reasons as described for Impact Noise-1 (CP1), this impact would be significant for CP4. Mitigation for this impact is proposed in Section 8.3.5.

For the same reasons as described for Impact Noise-1 (CP1), this impact would be significant for CP4A. Mitigation for this impact is proposed in Section 8.3.5.

Impact Noise-2 (CP4 and CP4A): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1) where blasting at the Shasta Dam site would result in ground vibration from the creation of seismic waves that radiate along the earth's surface. As discussed previously, no noise-sensitive receptors are located near the dam site. Receptors would need to be within 250 feet of the blasts to be affected (greater than 80 VdB) by groundborne vibration. No sensitive receptors are within this range of the dam.

Therefore, this temporary impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Therefore, this temporary impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP4 and CP4A): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. As a result, this impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Noise-3 (CP1) where the ambient noise level would not increase by more than 3 dBA or exceed 60 dBA (Shasta County 2004). Thus, project-generated long-term traffic noise would not result in an exceedence of the Shasta County standards.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1, the implementation of CP4 or CP4A would not generate any new long-term noise sources outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP4 or CP4A in those geographic regions are not discussed further in this EIS.

CP5 – 18.5-Foot Dam Raise, Combination Plan

The direct and indirect impacts of CP5 related to noise and vibration would be essentially the same as those described for CP1 through CP4 because construction activities, and equipment and workforce needs, would be similar under these alternatives. Also, the long-term impact of CP5 on traffic levels associated with relocating Lakeshore Drive would be expected to be similar to the corresponding impact under CP1 and CP2. Thus, as described below, the impacts described for CP1 and CP2 would generally also apply to CP5.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Noise-1 (CP5): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise Temporary construction noise from activities at Shasta Dam including site preparation (e.g., excavation, grading, and clearing), raising, tree removal, material handling, blasting, demolition, site restoration and cleanup would not exceed applicable noise-level standards at nearby noise-sensitive receptors. Construction activities at Shasta Dam would consist of site preparation (e.g., excavation, grading, and clearing), the dam raise, blasting, tree removal, material handling, demolition, and site restoration and cleanup. Gravel augmentation under CP5 would increase the total number of construction-related truck trips, but not enough to result in a violation of traffic noise standards or a substantial increase in traffic noise.

However, related activities at other construction sites (e.g., bridges, roads, recreation facilities) could result in noise levels that exceed applicable standards resulting in substantial increases at nearby sensitive receptors. This temporary impact would be significant.

Like CP4 and CP4A, CP5 would involve gravel augmentation and restoration at sites along the upper Sacramento River, neither of which would occur under CP1, CP2, or CP3. Upper Sacramento River restoration site construction would include an excavator, loader, and compaction equipment. Noise levels would be similar to those described under CP1 and CP2 (see Table 8-11). Approximately 350 haul trips would be needed to remove material from the site, resulting in approximately eight trips per day over a 2-month period. As discussed above under Impact Noise-1(CP1), to generate a substantial increase in traffic noise, a doubling of traffic volume would be required. Because adding 26 truck trips would not double roadway traffic volumes, no violation of traffic noise standards or substantial increase in traffic noise would occur. Noise levels from construction equipment, however, would still likely exceed noise standards. Therefore, temporary, construction-related impacts would be significant.

Thus, this impact would be the same as Impact Noise-1 (CP4 and CP4A) and would be significant. Mitigation for this impact is proposed in Section 8.3.5. Increases in truck traffic from construction would also not cause a perceptible increase in current traffic noise levels or a noticeable difference in ambient noise levels. However, related activities at other construction sites (e.g., bridges, roads, recreation facilities) could result in noise levels that exceed applicable standards resulting in substantial increases at nearby sensitive receptors. This temporary impact would be significant.

Impact Noise-2 (CP5): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction Temporary construction-related activities would not expose persons to or generate excessive groundborne vibration or groundborne noise. The additional habitat development included in CP5 would occur in uninhabited areas of Shasta-Trinity National Forest, would not affect sensitive receptors, and would be temporary. As a result, this impact would be less than significant.

This impact would be the same as Impact Noise-2 (CP1). CP5 would also involve development of additional habitat; however, habitat development would occur in an uninhabited area managed by the U.S. Bureau of Land Management, would not be expected to affect any sensitive receptors, and would be temporary. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Noise-3 (CP5): Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile-Source Noise During Operations Traffic associated with project operations would not expose persons to or generate noise in excess of applicable mobile-source noise standards, nor would such traffic create a substantial increase in ambient noise levels in the project vicinity. The additional habitat development included in CP5 would occur in uninhabited areas of Shasta-Trinity National Forest, would not create new operational traffic, and would not affect sensitive receptors. This impact would be less than significant.

This impact would be the same as Impact Noise-3 (CP1). CP5 would also involve development of additional habitat; however, habitat development would occur in an uninhabited area managed by the U.S. Bureau of Land Management, would not create any new operational traffic, and is not expected to affect any sensitive receptors. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas Similar to CP1 and CP2, implementing CP5 would not generate any new long-term noise outside of the primary study area. Furthermore, no construction work would occur in the extended study area; as a result, no project noise would be temporarily added to the current noise environment. No effects related to noise and vibration are expected to occur in the lower Sacramento River and Delta and the CVP/SWP service areas; therefore, potential effects of CP5 in those geographic regions are not discussed further in this EIS.

8.3.5 Mitigation Measures

Table 8-12 presents a summary of mitigation measures for noise and vibration.

	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS

Key:
CP = Comprehensive Plan
LOS = level of significance
LTS = less than significant
S = significant

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Noise-2 (CP1) and Noise-3 (CP1). Mitigation is provided below for the remaining noise impact of CP1.

Mitigation Measure Noise-1 (CP1): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites Reclamation and its primary construction contractors will implement the measures listed below during construction:

- Construction activities producing high impact noise at non-dam sites will be limited to the less noise-sensitive daytime hours and days (7 a.m. to 10 p.m., Monday through Friday). Nighttime (10 p.m. to 7 a.m.) construction activities at non-dam sites noise levels shall not exceed county standards.

- All contractors and subcontractors shall be specific in their contracts and purchase orders for equipment, gravel, aggregate, and other building supplies, as well as for debris removal, that all truck deliveries and debris removal trips that use roadways that pass within 50 feet of inhabitable rooms of residential dwellings shall be limited to the less noise-sensitive daytime hours (7 a.m. to 10 p.m.). Applicable roadways where nighttime truck travel shall be prohibited include the segment of Shasta Dam Boulevard (State Route 151) between Interstate 5 and Lake Boulevard (Road 415) and/or the segments of

Lake Boulevard immediately north and south of Shasta Dam Boulevard.

- All construction equipment and staging areas will be located at the farthest distance feasible from nearby noise-sensitive land uses.
- All construction equipment will be properly maintained and equipped with noise-reduction intake and exhaust mufflers and engine shrouds, in accordance with manufacturers' recommendations. Equipment engine shrouds will be closed during equipment operation.
- All motorized construction equipment will be shut down when not in use to prevent idling.
- A temporary barrier will be placed as close to the noise source or receptor as possible and will break the line of sight between the source and receptor.
- A disturbance coordinator will be designated and the person's telephone number conspicuously posted around the project sites and supplied to nearby residences. The disturbance coordinator will receive all public complaints and be responsible for determining the cause of the complaint and implementing any feasible measures to alleviate the problem.

Implementation of Mitigation Measure Noise-1, as revised above, would reduce temporary project generated construction source noise levels and limit them to the less sensitive daytime hours, thus preventing exposure of sensitive receptors to temporary construction noise at dam and non-dam sites. Implementation of this mitigation measure would also eliminate exposure of off-site residential uses to truck-generated SELs that would cause substantial levels of sleep disturbance. As a result, Impact Noise-1 would be reduced to a less-than-significant level for all the action alternatives.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Noise-2 (CP2) and Noise-3 (CP2). Mitigation is provided below for the remaining noise impact of CP2.

Mitigation Measure Noise-1 (CP2): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP2) to a less-than-significant level.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability with Anadromous Fish Survival

No mitigation is needed for Impacts Noise-2 (CP3) and Noise-3 (CP3). Mitigation is provided below for the remaining noise impact of CP3.

Mitigation Measure Noise-1 (CP3): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP3) to a less-than-significant level.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

No mitigation is needed for Impacts Noise-2 (CP4 and CP4A) and Noise-3 (CP4 and CP4A). Mitigation is provided below for the remaining noise impact of CP4 and CP4A.

Mitigation Measure Noise-1 (CP4 and CP4A): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP4 and CP4A) to a less-than-significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Noise-2 (CP5) and Noise-3 (CP5). Mitigation is provided below for the remaining noise impact of CP5.

Mitigation Measure Noise-1 (CP5): Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites This mitigation measure is identical to Mitigation Measure Noise-1 (CP1). Implementation of this mitigation measure would reduce Impact Noise-1 (CP5) to a less-than-significant level.

8.3.6 Cumulative Effects

Chapter 3, “Considerations for Describing the Affected Environment and Environmental Consequences,” discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, “Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area,” lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level.

Past and present projects within Shasta and Tehama counties have affected noise conditions in the primary study area through the use of heavy construction equipment and the increase in traffic resulting from construction activities. Other transient noise sources (e.g., railroads, traffic on existing highways) also contribute to ambient noise in the primary study area.

The action alternatives would not combine with any of the quantitatively assessed projects listed in Table 3-1 to have a cumulatively considerable impact on noise and vibration; therefore, this section evaluates only those projects listed in Table 3-1 that are qualitatively considered in this EIS.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Projects that could influence ambient noise levels in areas where the SLWRI could contribute noise include projects listed within the *Shasta-Trinity National Forest Land and Resource Management Plan, Iron Mountain Mine Restoration Plan, and Mendocino National Forest Land and Resource Management Plan;* and construction of the Antlers Bridge replacement. If the listed projects were to occur concurrently with construction of any of the project alternatives under the SLWRI (CP1–CP5), combined noise generation during construction would be unlikely to be substantial because noise is generally a local phenomenon and is minimal beyond 0.5 mile. Noise from SLWRI construction activities would not combine with other noise sources, such as construction from the projects listed above. After project construction is completed, the ambient noise environment relative to SLWRI construction activities would return to existing conditions. Therefore, none of the project alternatives would make a cumulatively considerable incremental contribution to cumulative noise effects.

Lower Sacramento and Delta and CVP/SWP Service Areas

Raising Shasta Dam would not result in any short-term or long-term effects on the ambient noise environment in the extended study area under any of the project alternatives. Therefore, there would be no cumulatively considerable incremental contribution to cumulative noise effects under any of the project alternatives.

Chapter 9
Hazards and Hazardous Materials and Waste

9.1 Affected Environment

This chapter describes the affected environment related to hazards and hazardous materials for the dam and reservoir modifications proposed under SLWRI action alternatives. Because of the potential influence of the proposed modification of Shasta Dam and water deliveries over a rather large geographic area, the SLWRI includes both a primary study area and an extended study area. The primary study area has been further divided into Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). The extended study area has been further divided into the lower Sacramento River and Delta and the CVP/SWP service areas.

This section describes hazards and hazardous materials, defined as hazardous waste and hazardous substances, in the primary and extended study areas. The discussion of hazards focuses primarily on wildland fire and its related effects on the human environment and natural resources, and water safety hazards, particularly those related to Shasta Lake. Other relevant hazards, such as flooding, dam failure, and issues related to hydropower generation, public services (e.g., fire protection, law enforcement, emergency services), roadways and bridges, and recreation, are addressed in separate chapters. The effects of proposed fuels treatments, such as pile burning, on air quality are addressed in Chapter 5, "Air Quality and Climate."

The hazards and hazardous waste setting for the primary study area consists of the portion of Shasta County above Shasta Dam and the upper Sacramento River from the dam downstream to the Red Bluff Pumping Plant (RBPP), including the lands within the boundary of the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). This area encompasses parts of the Pit River, Squaw Creek, McCloud River, and Sacramento River watersheds. The hazards and hazardous waste setting for the upper Sacramento River portion of the primary study area consists of lands draining to the Sacramento River between Shasta Dam and Red Bluff.

The hazards and hazardous waste setting for the extended study area includes the Sacramento River basin downstream from the RBPP to the Delta, the Delta itself, the San Joaquin River basin to the Delta, portions of the American River basin, and the CVP/SWP service areas.

9.1.1 Hazards

Shasta Lake and Vicinity

Water Safety Hazards The surface waters of Shasta Lake and, to a lesser extent, Keswick Reservoir and other surface waters in the vicinity pose hazards to persons engaging in boating and other water-based activities (see Chapter 18, “Recreation and Public Access,” for a detailed discussion of water safety hazards related to recreational activities). Water safety hazards are related to equipment operations, flow velocity, morphology, instream or submerged material, accessibility, and water temperature. Working in and adjacent to water bodies also poses risks to workers.

Fluctuations in the reservoir’s pool level affect the pattern of submerged obstacles, which poses a risk to boaters, water skiers, operators of personal watercraft, and workers. Reservoir drawdowns can leave rocks, shoals, and islands submerged below the water surface, where watercraft or skiers can strike them. Conversely, increases in the reservoir’s pool level conceal obstacles beneath the water surface that may be visible one day and submerged the next. Most of these hazards are not marked; however, the USFS public information program warns water-based recreationists via signage and various media to use caution when operating watercraft on the lake.

Although USFS manages Shasta Lake and adjacent Federal lands comprising the NRA’s Shasta Unit, law enforcement and emergency services are provided through a partnership between the Shasta-Trinity National Forest (STNF) and the Shasta County Sheriff’s Office (SCSO) (see Chapter 22, “Public Services,” for a detailed discussion of fire, law enforcement, and emergency services in Shasta Lake and vicinity). SCSO provides safety patrols and emergency response on Shasta Lake and its associated recreational areas and manages a Boating Safety Unit at the Bridge Bay Resort. SCSO staff consists of 4 full-time personnel and 22 seasonal deputies. An organized citizen volunteer patrol also assists with boater safety on Shasta Lake.

Fire Hazards Wildland fires pose a hazard to rural development, infrastructure, and natural resources. Climate, topography, vegetation characteristics, and ignition sources in a given area influence the degree of fire hazard. The California Department of Forestry and Fire Protection (Cal Fire) and STNF have delineated most of the primary study area as being at very high risk for wildland fire; some areas, such as Lakehead, are at extreme risk for fire (Figure 9-1) (Cal Fire 2005, 2008; USFS 1995; WSRCD 2010).

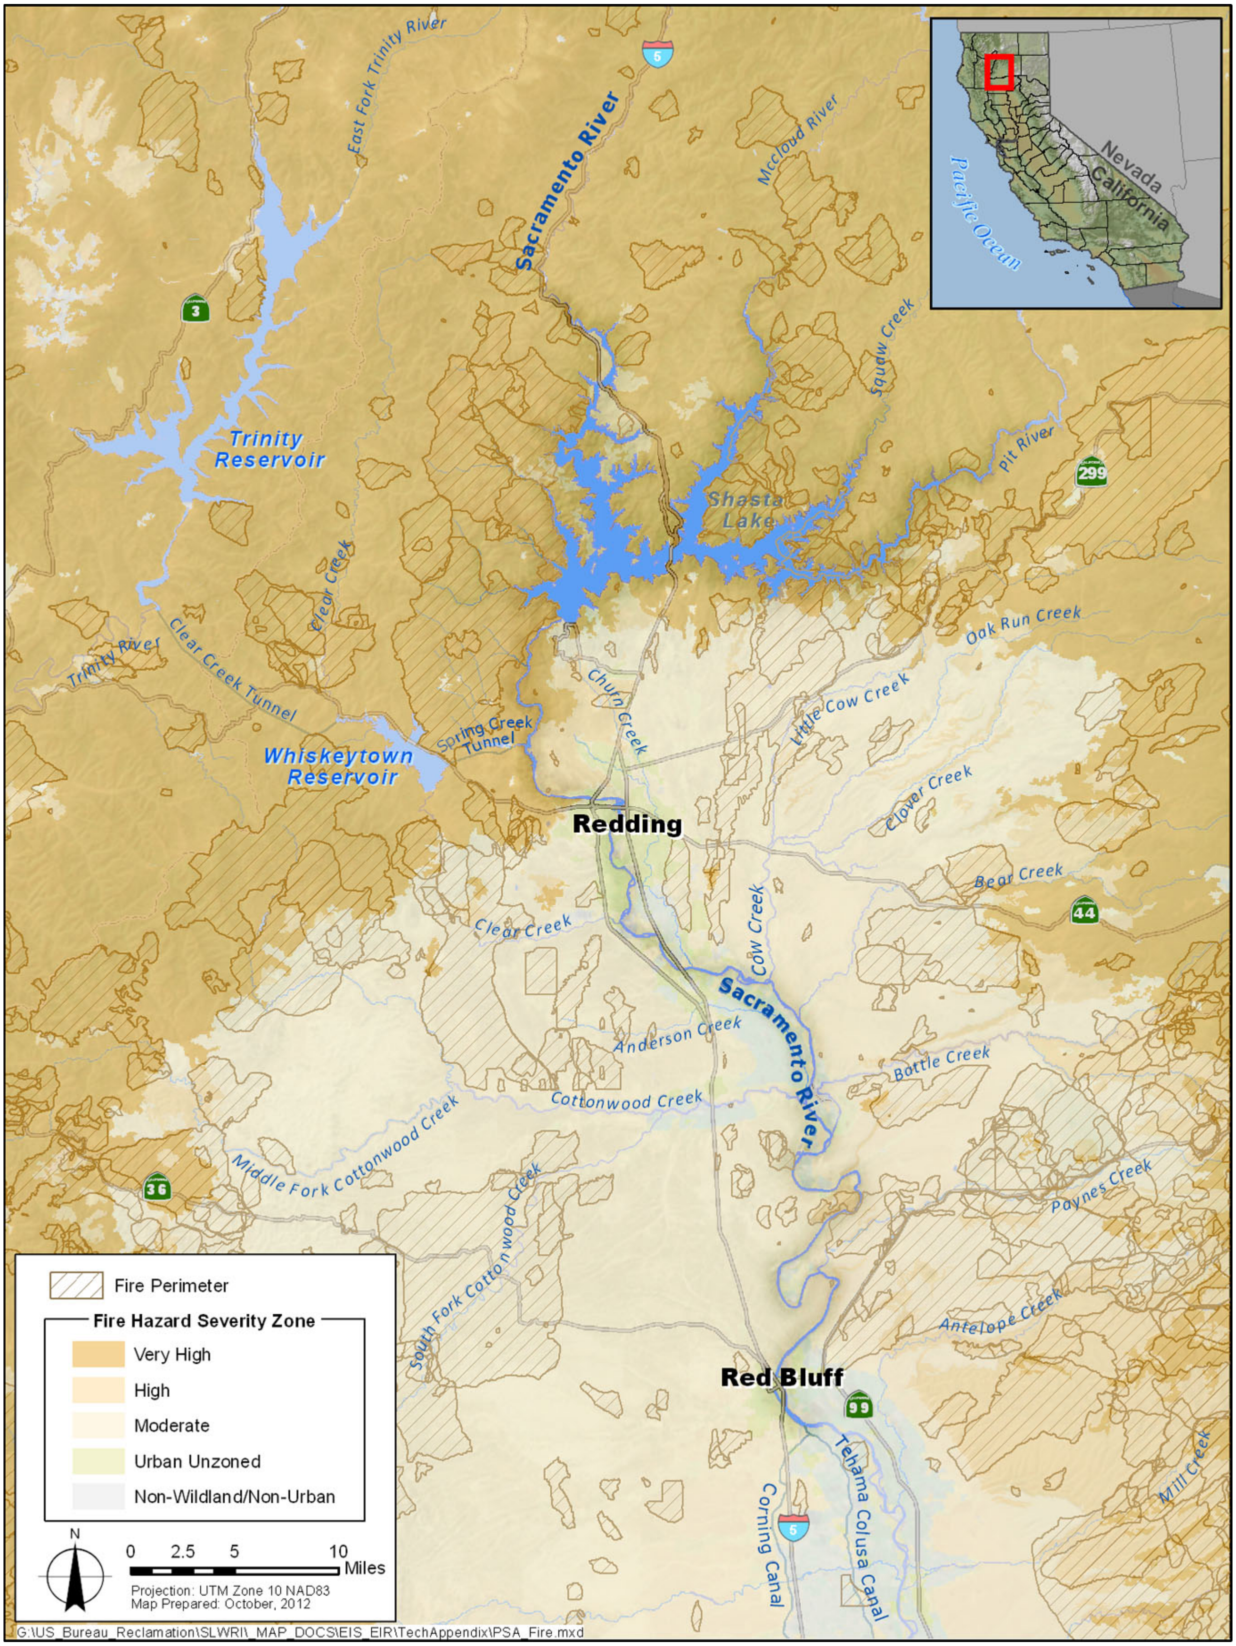

Figure 9-1. Fire Hazard Severity and Historic Fires

Historic fire data show that high-intensity, stand-replacing fires commonly occur at the lower elevations surrounding Shasta Lake. Major transportation corridors cross the NRA and the area receives high recreational use, resulting in numerous human-caused fires each year (USFS 1996). During the 5-year period from 2000 through 2004, the Shasta and Trinity units of the NRA experienced 1,545 vegetation fires affecting 40,352 acres (Cal Fire 2005). Roadside fires, abandoned campfires, and fireworks are common causes of these fires. Lightning from summer thunderstorms also causes a significant number of wildfires in and adjacent to the NRA. Large fires (more than 300 acres) that have occurred in the primary study area since 1950 are shown in Figure 9-1.

Rural and urban development has increasingly influenced the wildland fire hazard potential. Development in grasslands, oak woodlands, and forests (generally referred to as the wildland-urban interface (WUI)) and population growth have increased the risk to humans of wildland fire hazards. Cal Fire and other fire protection agencies expect this trend to continue.

Fire suppression has had a significant effect on the volume and types of fuels across the Shasta Lake region. Extreme fire weather conditions are perpetuated by high summer temperatures and dry lightning storms; particularly along the Sacramento and McCloud arms of Shasta Lake, frequent strong zonal north winds occur during the late summer and fall months. In the past 30 years, the Lakehead area, which is along the Sacramento Arm, has experienced several major fires, including the 1999 High Complex Fire, which was eventually contained at 39,000 acres, and numerous smaller fires that were suppressed in their initial stages (WSRCD 2010).

The concentration of human activity along the McCloud Arm of Shasta Lake prompted STNF to prepare a fire analysis as part of the McCloud Arm Watershed Analysis (USFS 1998). The fire analysis concludes that, at the time it was prepared (1998), more than 17,500 acres of forest surrounding the McCloud Arm was considered at high risk for a catastrophic fire. Cal Fire has designated the fire hazard severity potential in the McCloud Arm as very high (Cal Fire 2008).

The Jones Valley/Silverthorn area adjacent to the Pit Arm of Shasta Lake is another interface area with recognized fire hazards. In the last 12 years, two large fires have greatly affected residential and commercial developments in this area. In 2004, the Bear Fire burned 10,484 acres and destroyed 80 homes in the Jones Valley community, and the 1999 Jones Fire burned 26,020 acres and consumed 900 structures.

Cal Fire has devised a fire hazard severity scale that considers fuel load (vegetation is the major source of fuel), climate, and topography (fire hazards increase with slope) to evaluate the level of wildfire hazard in areas where the State of California (State) is primarily responsible for fire suppression (these are known as State Responsibility Areas). Cal Fire designates three levels of fire hazard severity zones – moderate, high, and very high – to indicate the severity of fire hazard in a particular geographical area. Based on a review of Cal Fire's statewide map of fire hazard severity zones, the primary study area includes lands designated as high and very high (Figure 9-1) (Cal Fire 2007).

Fuels management actions are conducted with some frequency on Federal lands in the Shasta Lake and vicinity portion of the study area. Since 2009, USFS has completed, or is currently proposing, several fuels management projects along the various arms of Shasta Lake, including the Bear Hazardous Fuels Project (Pit Arm), the Green-Horse Habitat Restoration and Maintenance Project (between the Pit and McCloud arms), the Interstate-5 Corridor Fuels Reduction Project (upper Sacramento Arm), and the Packers Bay Invasive Plant Species Removal Project (Sacramento Arm) (USFS 2009, 2011).

Upper Sacramento River (Shasta Dam to Red Bluff)

Water Safety Hazards Water safety hazards in the upper Sacramento River are similar to those in Shasta Lake and vicinity. Surface waters (i.e., Keswick Reservoir and the Sacramento River) pose hazards to persons engaging in boating and other water-based activities on these water bodies. Water hazards are posed by equipment operations, flow velocity, morphology, instream or submerged material, accessibility, and water temperature. Working in and adjacent to water bodies also poses risks to workers.

Fire Hazards Wildland and nonwildland fires present hazard risks to rural and urban development in the upper Sacramento River area. Based on a review of Cal Fire's statewide map of fire hazard severity zones, the upper Sacramento River area includes lands designated as high and very high risk (Figure 9-1) (Cal Fire 2007).

Human activities such as smoking, debris burning, and equipment operation cause 90 percent of the wildland fires in Shasta County, and lightning causes the remaining 10 percent. Wildland fires present a major safety hazard to rural development located in forest, brush, and grass-covered areas. Between 1992 and 2003, an average of 333 wildland fires per year occurred in Shasta County; the majority of these fires were in upland areas, where fire hazards are extreme because of an abundance of highly flammable vegetation and long, dry summers (Shasta County 2004). Large fires (more than 300 acres) that have occurred in the primary study area since 1950, including the upper Sacramento River near Shasta Dam, are shown in Figure 9-1.

Much of Tehama County, outside of the valley floor, is classified as wildland and contains substantial forest fire risks and hazards (Tehama County 2009). Outside of urbanized areas, fire hazard is considered to be moderate (Cal Fire 2007). Encroachment by development into previously uninhabited areas has expanded the WUI, compounding the challenges of wildland fire management. In the portion of the project area that is in Tehama County, no large fires (greater than 300 acres) have occurred in the last 60 years (Figure 9-1) (Cal Fire

2009), because vegetation adjacent to the Sacramento River is not conducive to carrying wildland fire.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Water safety hazards are similar to those described for the primary study area. Fire hazard in the extended study area varies, with risk increasing proportionally with the degree of WUI. As noted previously, Cal Fire maintains a map-based program that identifies fire hazard severity zones throughout the state. The program differentiates between State Responsibility Areas and Local Responsibility Areas. Most of the extended study area is mapped as local (or Federal) responsibility areas with moderate or unzoned fire hazard severity classifications (Cal Fire 2008).

9.1.2 Hazardous Materials and Waste

For purposes of this section, the term “hazardous materials” refers to both hazardous substances and hazardous wastes. A hazardous material is defined in the Code of Federal Regulations (CFR) as “a substance or material that … is capable of posing an unreasonable risk to health, safety, and property when transported in commerce” (49 CFR 171.8). California Health and Safety Code Section 25501 defines a hazardous material as follows:

> *“Hazardous material” means any material that, because of its quantity, concentration, or physical or chemical characteristics, poses a significant present or potential hazard to human health and safety or to the environment if released into the workplace or the environment. “Hazardous materials” include, but are not limited to, hazardous substances, hazardous waste, and any material which a handler or the administering agency has a reasonable basis for believing that it would be injurious to the health and safety of persons or harmful to the environment if released into the workplace or the environment.*

Hazardous wastes are defined in California Health and Safety Code Section 25141(b) as wastes that

> *…because of their quantity, concentration, or physical, chemical, or infectious characteristics, [may either] cause, or significantly contribute to an increase in mortality or an increase in serious illness [or] pose a substantial present or potential hazard to human health or the environment when improperly treated, stored, transported, disposed of, or otherwise managed.*

Potential sources of hazardous materials and wastes may exist in the urbanized, rural, industrial, and agricultural portions of the study areas. Hazardous materials may be present in a variety of common contexts, including the following:

- Construction and demolition debris
- Drums
- Landfills or solid waste disposal sites
- Pits, ponds, or lagoons
- Wastewater and wastewater treatment plants
- Fill, dirt, depressions, and mounds
- Herbicides, pesticides, and fungicides
- Contaminated aggregate (mercury, dioxin)
- Explosives
- Fish hatcheries (e.g., Livingston Stone, Coleman)
- Underground and above ground storage tanks
- Stormwater runoff structures
- Transformers that may contain polychlorinated biphenyls (PCB)
- Utility poles
- Abandoned mines

Shasta Lake and Vicinity

Facilities used to store, generate, and transport hazardous materials and hazardous waste are present upstream from Shasta Dam. In addition, several inactive or abandoned mines contribute hazardous materials to Shasta Lake or its tributaries. The following discussion describes these features and facilities.

Reclamation operates the Shasta Dam facility and controls the use and movement of hazardous materials and associated hazardous waste in and out of the Shasta Dam administrative compound. Operation and maintenance of the dam and the water project facility require the use of many of the hazardous materials listed in the previous section. In addition, utility poles, transformers, and associated power transmission facilities typically contain hazardous materials.

A number of recreational facilities are located on or adjacent to Shasta Lake. These facilities include marinas, campgrounds, day use facilities, and residences for recreational use. Although several of these are privately owned, most are operated under special use permits issued by USFS. Operation and maintenance of recreational facilities involve the use of a number of substances that are considered hazardous under Federal or State statutes. The STNF administrative facility at Turntable Bay contains substances used for maintenance of the facility, STNF boats, and recreation facilities throughout the NRA. Access to these substances is controlled by STNF in accordance with Federal, State, and local requirements. Additionally, public facilities that service and/or repair watercraft (e.g., marinas) generate wastes that are considered hazardous (e.g., oil, grease, solvents).

Currently, there are three underground fuel storage tanks permitted by the State Water Resources Control Board in the primary study area, all of which are in the Shasta Lake and vicinity portion of the primary study area: Holiday Harbor, Sugarloaf Marina, and Digger Bay Marina (State Water Board 2012). Also in the Shasta Lake and vicinity portion are four underground fuel storage tanks that are no longer in use due to regulatory actions resulting from documented occurrences of fuel leaks (State Water Board 2012).

The project would include the decommissioning/abandonment and/or relocation of a number of features and facilities on or adjacent to Shasta Lake. Underground and aboveground fuel storage tanks – including tanks in use and tanks no longer used – would be permanently removed from areas that would be inundated by the project. Above- and belowground fuel pipelines within the inundation area would be relocated/removed. Relocated fuel storage tanks would be designed and constructed in accordance with Title 23 of the California Code of Regulations (CCR) (Division 3, Chapter 15, Underground Tank Regulations); the Uniform Fire Code; California Air Resources Board; Shasta County Development Standards, Section 6.7; and Shasta County Environmental Health Division requirements. Additionally, the age of some buildings suggests that substances such as asbestos or lead paint may be included in demolition debris.

A records search of the Federal Superfund National Priorities List (NPL) (USEPA 2013) identified no sites in the Shasta Lake and vicinity portion of the study area. In its scoping comments, the Central Valley Regional Water Quality Control Board (CVRWQCB) identified three sites that are currently subject to some degree of remediation. These sites are associated with the Bully Hill/Rising Star Mine and the Digger Bay and Sugarloaf marinas. All three sites may be influenced by fluctuating water levels in Shasta Lake. An additional site near the Bully Hill Mine complex contains depositional features with elevated metal concentrations that are exposed to surficial and wave erosion processes. The CVRWQCB has also identified an abandoned mine complex west of Shasta Dam as a source of heavy metals and acid mine discharge that enters Shasta Lake via Dry Creek.

Interstate 5 (I-5) and Union Pacific Railroad transportation corridors are in close proximity to Shasta Lake and its tributaries. The potential exists for the accidental spill of chemicals and hazardous materials transported along these travel corridors. Transport through mountainous terrain and over water bodies, equipment failure, and improper storage and handling of hazardous materials contribute to the risk of accidental chemical spills.

The Cantara Spill is a prime example of the hazards associated with the transport of hazardous materials through the region. On July 14, 1991, a Southern Pacific train derailed upstream from Dunsmuir, sending several cars into the Sacramento River, including a tank car containing the herbicide/pesticide metam sodium (a potent chemical used principally to sterilize soil for agricultural purposes). A rupture in one of the tank cars resulted in the catastrophic spill of approximately 19,000 gallons of the soil fumigant into the river. When mixed with water, metam sodium breaks down into several highly toxic compounds. Although the toxins formed by the mixing of metam sodium with water dissipated in a matter of hours or weeks, the immediate effects of the spill were staggering. In the upper Sacramento River, every living aquatic creature downstream from the spill died over the 20-mile stretch of river between the spill and Shasta Lake (Cantara Trustee Council 2007). On July 17, 1991, the plume, estimated to have traveled at just under 1 mile per hour, entered Shasta Lake, where the chemical was reduced to undetectable levels approximately 2 weeks later. As a result of the Cantara Spill, more than $14 million in settlement funds – administered by the Cantara Trustee Council – was used for ecosystem restoration efforts throughout the primary study area.

Historic mining activities in the Shasta Lake and vicinity portion of the primary study area have left mine tailing deposits scattered throughout the uplands surrounding the lake. These deposits often contain high concentrations of various metals, including iron, copper, zinc, and mercury. The discharge of these dissolved metals into waterways can have an adverse effect on water quality, aquatic ecosystems, and human health. The historic Bully Hill Mine, located along the Squaw Arm, is the only mine site that would be inundated by the project. The effects on water quality that could result from the inundation of mine tailings are discussed in detail in Chapter 7, "Water Quality."

Upper Sacramento River (Shasta Dam to Red Bluff)

A number of business and industrial land uses downstream from Shasta Dam use and transport hazardous materials as part of their operations. Existing land uses that may have a hazardous material component include mining operations, heavy and light industrial uses, propane/petroleum fueling and/or storage facilities, and commercial and retail operations. Businesses that require storage of hazardous materials must submit a Hazardous Materials Business Plan (HMBP) to the Shasta County Environmental Health Department. I-5, Union Pacific Railroad lines, and several major surface routes are used for the transportation of hazardous materials throughout the region.

Hazardous waste sites associated with agricultural activities include storage facilities and agricultural ponds or pits contaminated with fertilizers, pesticides, herbicides, or insecticides. Petroleum products and other materials may also be present in the soil and groundwater near leaking underground tanks used to store these materials. However, there are no permitted underground fuel storage tanks – including tanks currently in use or tanks that have been subject to regulatory actions – within the project boundaries for the upper Sacramento River portion of the primary study area (State Water Board 2012).

Metals such as cadmium, copper, mercury, and zinc are present in inactive and abandoned mines in the upper Sacramento River area. Landfills and commercial activities, such as dry cleaning, could also be sources of contamination in this region. The project would not result in the inundation of any of these potentially hazardous locations.

A records search of the U.S. Environmental Protection Agency's (EPA) NPL identified one site in the upper Sacramento River area: Iron Mountain Mine. The mine is a privately owned site southwest of Shasta Dam and 9 miles northwest of Redding. The entire mine area, which encompasses about 2,000 acres, is drained by Boulder Creek and Slickrock Creek, tributaries to Spring Creek. Spring Creek enters Keswick Reservoir several miles downstream from Shasta Dam.

From the 1860s through 1963, the 4,400-acre Iron Mountain Mine was periodically mined for iron, silver, gold, copper, zinc, and pyrite. Although mining operations were discontinued in 1963, underground mine workings, waste rock dumps, piles of mine tailings, and an open mine pit remain at the site. Historic mining activity at Iron Mountain Mine has fractured the rock units, exposing minerals to surface water, rainwater, and oxygen. Acidic mine drainage typically contains high concentrations of copper, cadmium, zinc, and other heavy metals. Much of the acidic mine drainage ultimately is channeled into Spring Creek Reservoir via adjacent creeks and constructed diversion facilities. The low pH level and the heavy metal contamination from the mine have virtually extirpated aquatic life in sections of Slickrock Creek, Boulder Creek, and Spring Creek. (Project effects on potentially contaminated historic mine waste are discussed in Chapter 7, "Water Quality.")

Reclamation periodically releases water from Spring Creek Reservoir into Keswick Reservoir. Planned releases are timed to coincide with the presence of diluting releases of water from Shasta Dam. On occasion, uncontrolled spills and excessive waste releases have occurred when Spring Creek Reservoir reaches capacity. Without sufficient dilution, these events have resulted in the release of harmful quantities of heavy metals into the Sacramento River downstream from Keswick Dam. Acid mine drainage and associated heavy-metal contamination from the Spring Creek drainage and other abandoned mine sites are among the principal water quality issues in the upper Sacramento River portion of the primary study area (EPA 2008). In 2009, EPA began the removal of approximately 200,000 cubic yards of contaminated sediment from the Spring Creek Arm of Keswick Reservoir for disposal in an engineered disposal cell. The project was completed in 2010 and restored active storage space to Reclamation's Keswick Reservoir.

The Livingston Stone National Fish Hatchery facility, located at the foot of Shasta Dam, is used to propagate adult winter-run Chinook salmon collected from the mainstem Sacramento River. Water from Shasta Dam is used to supply the hatchery and waste is discharged to the Sacramento River downstream from the dam. The facility's discharge is regulated under CVRWQCB General Order R5-2010-0018 (National Pollutant Discharge Elimination System No. GAG135001) Waste Discharge Requirements for Cold-Water Concentrated Aquatic Animal Production Facility Discharges to Surface Waters (CVRWQCB 2010).

Lower Sacramento River and Delta and CVP/SWP Study Areas

Many of the land uses in the extended study area are similar to those in the primary study area. Thus, contamination is possible from agricultural, urban, industrial, commercial, landfill, and military land uses in the region. Because the extended study area covers many counties and regions, a records search of the NPL and the California Department of Toxic Substances Control list was not conducted. Although many sites in the extended study area undoubtedly are on these lists, it is not expected that these sites would be affected by project implementation.

Facilities created by CVP/SWP for the purposes of water conservation and management include dams, power plants, and an extensive canal system. Operation of these facilities involves the use of a variety of hazardous materials such as lubricants.

The Sacramento National Wildlife Refuge Complex consists of 5 national wildlife refuges and 3 wildlife management areas covering over 35,000 acres of wetlands and uplands, in addition to more than 30,000 acres of conservation easements. Many of the wetlands in the Sacramento Valley receive water not only from the Sacramento River, but also from agricultural runoff. Urban, industrial, agricultural, and natural sources of toxins contribute to water quality problems in the lower Sacramento River and Delta and can pose a hazard to fish and wildlife through processes such as bioaccumulation in the food chain.

A discussion of the current water quality and potential hazards to water quality associated with the project is presented in Chapter 7, "Water Quality."

9.2 Regulatory Framework

9.2.1 Federal

Federal Resource Conservation and Recovery Act

The Resource Conservation and Recovery Act (RCRA) is a Federal statute designed to provide “cradle to grave” control of hazardous waste by imposing management requirements on generators and transporters of hazardous wastes, and on owners and operators of treatment, storage, and disposal facilities. The EPA is responsible for administering the RCRA.

Federal Comprehensive Environmental Response, Compensation, and Liability Act

The Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA), also known as the Superfund Act, provides for the liability, compensation, cleanup, and emergency response for hazardous substances released into the environment and the cleanup of inactive hazardous waste disposal sites. CERCLA authorized the NPL, which identifies contaminated sites that are eligible for remedial action. The scope of CERCLA is broad; it holds current and prior owners and operators of contaminated sites responsible, and its definition of a hazardous substance incorporates definitions from the Clean Air Act, the Clean Water Act, the Toxic Substances Control Act, and the RCRA (CERCLA Section 101(14)). EPA is the agency responsible for administering CERCLA.

Occupational Safety and Health Act

The Occupational Safety and Health Act defines occupational health and safety standards with the goal of providing employees with a safe working environment. The California Occupational Safety and Health Administration (Cal/OSHA) is the agency responsible for administering this Federal act. The Occupational Safety and Health Administration (OSHA) regulations apply to the workplace and cover activities ranging from confined space entry to toxic chemical exposure. Employers are required to provide a workplace free of recognized hazards that could cause serious physical harm. OSHA regulates workplace exposure to hazardous chemicals and activities through workplace procedures and equipment requirements (29 U.S. Code 651–678).

Hazardous Materials Transportation Act

The Hazardous Materials Transportation Act regulates interstate transport of hazardous materials and wastes. This act specifies driver training requirements, load labeling procedures, and container design and safety requirements. Transporters of hazardous wastes must also meet the requirements of other statutes, such as the RCRA. The Hazardous Materials Transportation Act requires that carriers report accidental releases of hazardous materials to the U.S. Department of Transportation at soon as is practical (49 CFR Subchapter C). Incidents that must be reported include deaths, injuries requiring hospitalization, and property damage exceeding $50,000. The U.S. Department of Transportation, the Federal Highway Administration, and the Federal Railroad Administration are the agencies responsible for administering the Hazardous Materials Transportation Act.

Code of Federal Regulations, Title 36

Title 36 of the CFR governs parks, forests, and public property in the United States. Chapter 2, Section 260, pertains to prohibited activities within the boundaries of Federally owned lands and waters administered by USFS. USFS is responsible for administering the regulations described as follows.

Section 261.5 Fire (General Prohibitions) The following are prohibited:

- Carelessly or negligently throwing or placing any ignited substance or other substance that may cause a fire
- Firing any tracer bullet or incendiary ammunition
- Causing timber, trees, slash, brush, or grass to burn except as authorized by permit
- Leaving a fire without completely extinguishing it
- Allowing a fire to escape from control
- Building, attending, maintaining, or using a campfire without removing all flammable material from around the campfire adequate to prevent its escape

Section 261.52 Fire (Prohibitions in Areas Designated by Order) When provided by an order, the following are prohibited:

- Building, maintaining, attending or using a fire, campfire, or stove fire
- Using an explosive
- Smoking, except within an enclosed vehicle or building, a developed recreation site, or while stopped in an area at least 3 feet in diameter that is barren or cleared of all flammable material
- Possessing, discharging, or using any kind of firework or other pyrotechnic device

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF Land and Resource Management Plan (LRMP) contains goals, standards, and guidelines designed to guide the management of STNF. The following goals, standards, and guidelines relative to hazards and/or hazardous materials issues associated with the project area were excerpted from the LRMP (USFS 1995).

Facilities Goals (LRMP, p. 4-17)

- Provide and maintain those administrative facilities that effectively and safely serve the public and USFS work force.

Facilities Standards and Guidelines (LRMP, p. 4-17)

- Upgrade the surfacing on the forest's road system as necessary to protect the road and other resource values.
- Trails will be maintained as needed for specific management objectives. Erosion control and primary access will receive priority.
- Trails and trail bridges will be located, designed, constructed, and maintained so that they are suitable for the type of travel being served.
- Consider volcanic, seismic, flood, and slope stability hazards in the location and design of administrative and recreation facilities.
- Manage, construct, and maintain buildings and administrative sites to meet applicable codes and to provide the necessary facilities to support resource management.
- Monitor potable water sources and designated swimming areas according to the Safe Drinking Water Act and other regulatory health requirements.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The NRA Management Guide (USFS 2014) contains management strategies intended to achieve or maintain a desired condition. These strategies take into account opportunities and general management and mitigation measures to achieve specific goals. STNF is responsible for administering the following strategies related to hazards and/or hazardous materials issues associated with the project area.

Fire and Fuels

- Hazardous fuels management issues are primarily focused in wildland-urban interface (WUI) areas. It is recommended that more than 75 percent of the fuels-reduction efforts take place in relation to these areas. Consideration is given to implementing one Community at Risk fuels reduction project each year. The non-WUI areas are focused on creating and maintaining a vegetative mosaic that reduces the potential for resource-damaging fire effects, improving forest health, and maintaining and improving habitat for associated animal and plant species.
- Fuels created by other management actions should be evaluated for further fuels treatment. For fuels management projects, all treatment

options should be evaluated during the planning process. Fuel treatment types should be considered in the context of the environment in which they will be located. Included in this decision should be location in reference to other past and future treatments, effects on wildlife, watersheds, and plant life, as well as the impacts on communities and infrastructure.

- Fuel breaks or Modified Fuel Profile Zones (MFPZ) are considered in areas where values at risk are very high and other options are limited due to proximity to those risks. These treatments are made in conjunction with other treatments to allow for a higher chance of success during a suppression event. Maintenance is a consideration in the planning of all MFPZs.

Health and Safety

- Resorts/marinas are responsible for inspecting their own facilities to ensure that they comply with applicable laws, ordinances, and codes and standards for health and safety and are safe for public use. Copies of all health and safety inspections must be incorporated in the operation and maintenance plan annually and be available to STNF.

- Marinas are required to anchor docks using underwater cables and anchor systems. Minor exceptions may be made, with STNF approval, in areas where low-speed boating is required, such as behind a marina in a semi-enclosed, restricted waterway. If cables and anchors are positioned in main travel-ways where they can come in contact with boats or people, the cables must be flagged and have warning lights so that they are visible day and night.

- Buoys and floats placed and maintained by marinas must meet the following criteria:

  – If the float or buoy is constructed of a material that will not damage a boat or cause personal injury on contact, the float or buoy must be of a contrasting color that can be easily seen. Examples are floats and buoys made of lightweight Styrofoam and plastic.

  – If the float or buoy is made of a material that could damage a boat or cause personal injury on contact, it must be of a contrasting color that can be easily seen, and must have a blinking yellow light visible from 360 degrees for night boating safety. Examples are floats and buoys made of steel or aluminum.

  – Log booms may be installed around marinas to suppress wave action at the docks. Log booms must not infringe on the main boating channels. Log booms must have yellow blinking lights installed every 100 feet on or immediately adjacent to the boom so that the boom's location is visible at night. Boating entrances through log booms or other breakwaters will display red and green navigation lights on either side of the log boom or breakwater for nighttime navigation.

  – All docks that are approved to extend out into a main boating travel-way, and are not protected by a lighted breakwater or other lighting system, must have at least one blinking yellow light for nighttime boating safety every 100 feet.

- No work that would leave pollutants in the lake when the area is inundated is permitted below the lake high-water line. Examples of this are water blasting and sand blasting pontoons and mechanical repairs that would allow oil and grease to drain on the ground.

- Resorts/marinas may restrict vehicle nighttime land access to their facilities if they can display to STNF that such action is needed to protect people and property.

Vegetation

- Prescribed burning, fuel break construction, and other forms of vegetation manipulation will be used to reduce fire hazards and improve forest health.

- Hazard trees in traditionally high-use recreation areas that pose safety hazards to people or property will be identified and removed if consistent with other resource objectives.

U.S. Bureau of Land Management Resource Management Plan

The U.S. Department of the Interior, Bureau of Land Management (BLM) manages a number of public lands adjacent to the Sacramento River corridor downstream from Shasta Dam. The study area falls under two BLM districts (Northern California and Central California) and the resource management plans of three BLM field offices: Redding, Ukiah, and Mother Lode (BLM 2006a). The purpose of BLM's resource management plans is to provide an overall direction for managing and allocating public resources in each planning area. BLM is responsible for administering the following strategies related to hazards and/or hazardous materials issues common to the districts in the study area (BLM 1992, 2006b, 2008).

Wildfire Suppression Goal

- Provide an appropriate management response for all wildland fires, emphasizing firefighter and public safety.

Fuels Management Goals

- Reduce fire risk to the WUI communities.

- Protect riparian and wetland areas.
- Improve ecological conditions and reduce the risk of catastrophic wildfire through the use of prescribed burning.
- Improve ecological conditions and reduce the risk of catastrophic wildfire through mechanical treatments.
- Increase the public's knowledge of the natural role of fire in the ecosystem, and hazards and risks associated with living in the WUI.

Hazardous Materials

- Land use authorizations will not be issued for uses that would involve the disposal or storage of materials that could contaminate the land (e.g., hazardous waste disposal sites, landfills, rifle ranges).
- Minimize hazardous conditions on BLM lands to reduce risks to the public and ensure environmental health and safety.

9.2.2 State

Strategic Fire Plan

The 2010 Strategic Fire Plan for California (State Board of Forestry and Fire Protection and Cal Fire 2010) is a broad strategic document that guides fire policy for much of California. It was authorized under California Public Resources Code Section 4114 and Section 4130 to establish, among other things, the levels of statewide fire protection services for State Responsibility Area lands. The plan is a cooperative effort between the State Board of Forestry and Fire Protection and Cal Fire. It emphasizes what needs to be done long before a fire starts, and looks at ways to reduce firefighting costs and property losses, increase firefighter safety, and contribute to ecosystem health. The plan serves as the basis for assessing California's complex and dynamic natural and human-made environment, and identifies a variety of actions to minimize the negative effects of wildland fire.

The mission of the State Board of Forestry and Fire Protection is to lead California in developing policies and programs that serve the public interest in environmentally, economically, socially sustainable forest and rangeland management, and a fire protection system that protects and serves the people of the state. Its statutory responsibilities are to:

- Establish and administer forest and rangeland policy for the State
- Protect and represent the State's interest in all forestry and rangeland matters

- Provide direction and guidance to Cal Fire on fire protection and resource management
- Accomplish a comprehensive regulatory program for forestry and fire protection
- Conduct its duties to inform and respond to the people of the State

Hazardous Waste Control Act

The California Hazardous Waste Control Act governs hazardous waste management and cleanup in the State (Health and Safety Code, Chapters 6.5–6.98). The act mirrors the RCRA and imposes a “cradle to grave” regulatory system for handling hazardous waste in a manner that protects human health and the environment. It requires all businesses to report the quantity and locations of hazardous materials on an annual basis if the business stores (a) more than 55 gallons of a liquid or 500 pounds of a solid hazardous material, (b) more than 200 cubic feet of a compressed gas, or (c) a radioactive material that is handled in quantities for which an emergency plan is required. Businesses falling within these limits must prepare an HMBP, which includes spill prevention, containment and emergency response measures and a contingency plan.

County Environmental Health Departments and the California Environmental Protection Agency’s (CalEPA) Certified Unified Program Agencies assume responsibility for enforcing local hazardous waste reporting requirements. Sites that store, handle, or transport specified quantities of hazardous materials are inspected annually. The California Department of Toxic Substances Control, part of CalEPA, regulates the generation, transportation, treatment, storage, and disposal of hazardous waste under the RCRA and the State Hazardous Waste Control Act.

Hazardous Substances Account Act

California enacted the Hazardous Substances Account Act (1981) to establish State authority to clean up hazardous substances releases, compensate persons injured from exposure to hazardous substances, and provide funds for payment of the State’s mandatory 10 percent share of cleanup costs under the Federal Superfund law. CalEPA administers the State Superfund program and receives assistance from the California Department of Public Health.

Emergency Response Plan

California developed an Emergency Response Plan to facilitate and coordinate responses to emergencies. Emergency prevention and response to hazardous materials incidents are part of the State plan that is administered by the California Emergency Management Agency (formerly Governor’s Office of Emergency Services). Coordinating agencies include CalEPA, the California Highway Patrol (CHP), Cal Fire, local fire departments, the California National

Guard, the California Department of Transportation (Caltrans), CDFW, regional water quality control boards, and other emergency service providers.

California Code of Regulations, Title 13, Vehicle Code

In addition to the RCRA hazardous waste transportation standards, California regulates the transportation of hazardous waste originating or passing through the state. State regulations are contained in the CCR, Title 13, Vehicle Code. Hazardous waste must be regularly removed from generating sites by licensed hazardous waste transporters. Transported materials must be accompanied by hazardous waste manifests.

CHP and Caltrans are responsible for enforcing Federal and State regulations pertaining to the transport of hazardous materials through California. CHP enforces materials and hazardous waste labeling and packaging regulations that prevent leakage and spills of material in transit and provides information to cleanup crews in the event of an incident. Vehicle and equipment inspection, shipment preparation, container identification, and shipping documentation are all part of the responsibility of CHP. CHP conducts regular inspections of licensed transporters to assure regulatory compliance. CHP and Caltrans also respond to hazardous materials transportation emergencies. Caltrans has emergency chemical spill identification teams at locations throughout the state.

Worker Safety Requirements

Regulations pertaining to the use of hazardous materials in California workplaces are provided in CCR Title 8 and include requirements for safety training, availability of safety equipment, accident and illness prevention programs, hazardous substance exposure warnings, and emergency action and fire prevention plan preparation. Cal/OSHA standards are more stringent than Federal OSHA regulations.

As described above, Cal/OSHA assumes primary responsibility for developing and enforcing workplace safety regulations in the state. Cal/OSHA enforces hazard communication program regulations that contain training and information requirements, including procedures for identifying and labeling hazardous substances, communicating information related to hazardous substances and their handling, and preparing health and safety plans to protect workers and employees at hazardous waste sites. The hazard communication program requires that material safety data sheets be available to employees and that employee information and training programs be documented.

Government Planning

California law requires that each county and city in the state adopt a general plan (Government Code Section 65300). The State-mandated general plans consist of development policies and objectives for the long-term physical development of counties and cities. Each general plan must include a safety element that addresses a variety of natural and human-caused hazards. At a minimum, the safety element must adopt policies related to fire safety, flooding, and geologic and seismic hazards (Government Code Section 65302(g)).

California Building Code

In 2007, the California Building Code was amended to include regulations pertaining to fire safety. The amendments provide safety standards for new construction located in WUI areas. The building code requires landowners to maintain an area of defensible space around structures and requires the use of fire-resistant building materials. County building inspectors, Cal Fire, and local fire agencies are responsible for enforcing the requirements (CCR Title 24, Part 2). On Federal lands, the Federal agency is responsible for ensuring that buildings and facilities meet public health and safety standards.

9.2.3 Regional and Local

County General Plans

The general plans for the counties in the primary and extended study areas contain general policies aimed at reducing the use of hazardous substances and the generation of hazardous waste and ensuring safe use and storage of hazardous materials and management of hazardous waste.

County Fire Management Plans

Fire Management Plans have been prepared for Tehama County and Shasta County (Cal Fire and Tehama Fire-Safe Council 2005; SCFD 2007; Cal Fire 2005). The plans tier from the California Fire Plan and are intended to be used for prefire planning, prioritization, and implementation. The plans outline cooperative efforts of local fire agencies, Cal Fire, and fire safe councils.

9.3 Environmental Consequences and Mitigation Measures

9.3.1 Methods and Assumptions

This analysis addresses potential impacts associated with implementation of the project with respect to hazards and hazardous materials. This analysis is based on a review of planning documents applicable to the project area, consultation with appropriate agencies, and field reconnaissance.

9.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A “[s]ignificant effect on the environment” means a substantial, or potentially substantial, adverse change in any of the physical conditions in the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria are based on guidance provided by CEQA Guidelines (AEP 2010) and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on hazards and hazardous materials would be significant if project implementation would do any of the following:

- Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials
- Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment
- Emit hazardous emissions or involve the handling of hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school
- Be located on a site that is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would create a significant hazard to the public or the environment
- Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan
- Expose people or structures to a significant risk of loss, injury, or death involving wildland fires

9.3.3 Topics Eliminated from Further Consideration

Water safety hazards posed by the project alternatives to water-based recreationists are assessed in Chapter 18; therefore, this topic has been eliminated from further analysis in this chapter. Similarly, the effects of hazardous materials on water quality are assessed in Chapter 7.

9.3.4 Direct and Indirect Effects

Information on fire risk and severity was obtained from USFS and Cal Fire. This information was used to identify specific types and locations of activities that could present a threat to the human environment as a result of wildland fires.

A regulatory database search was conducted for portions of the primary study area. The purpose of such a search was to identify sites that are associated with the documented use, generation, storage, or release of hazardous materials or petroleum products. The results also include regulatory lists of known or potential hazardous waste sites, landfills, hazardous waste generators, and disposal facilities, in addition to sites under investigation. Information provided in the database search was obtained from publicly available sources, including the following:

- Cortese List (DTSC 2012)
- Leaking Tanks (State Water Board 2012)
- Comprehensive Environmental Response, Compensation and Liability Information System: EPA Superfund Sites (USEPA 2013)
- Annual Work Plan (State Water Board et al. 2008)

No-Action Alternative

Shasta Lake and Vicinity, Upper Sacramento River (Shasta Dam to Red Bluff), Lower Sacramento and Delta, and CVP/SWP Service Areas

Impact Haz-1 (No-Action): Wildland Fire Risk Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in the risk of wildland fire in the project area. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Haz-2 (No-Action): Release of Potentially Hazardous Materials or Hazardous Waste Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in hazards, hazardous materials, or hazardous waste in the project area. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Haz-3 (No-Action): Exposure of Workers to Hazardous Materials Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in exposure of workers to hazards, hazardous materials, or hazardous waste in the project area. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Haz-4 (No-Action): Exposure of Sensitive Receptors to Hazardous Materials Under the No-Action Alternative, no new facilities would be constructed in the primary or extended study areas and no changes in Reclamation's existing facilities or operations would occur that would directly or indirectly result in any increase in hazards, hazardous materials, or hazardous waste in the project area. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP1): Wildland Fire Risk Project implementation could contribute to wildland fire risk. Project construction and operation, and the anticipated postconstruction human activity in the primary study area would increase the potential for fire ignition. Therefore, this impact would be potentially significant.

Wildland fire in the primary study area would expose people, structures, infrastructure, and other resources to a significant risk of loss, injury, or death. Project design, implementation, and operation incorporate safety measures that prevent fire hazards. Although the construction details have not been finalized, this conclusion is based on the scope of activities involved and the fire hazard ratings (i.e., very high risk and extreme risk) in the primary study area and the relocation sites where project construction activities would occur. Construction activities would likely occur during the summer and fall months, which are generally considered a time of high fire hazard in Northern California. Reclamation and its contractors would follow fire safety regulations and procedures to prevent accidental fires.

Project activities associated with the removal and relocation of utilities could pose a wildland fire hazard in the primary study area, although it is anticipated that 100 percent vegetation clearance beneath high-voltage power transmission lines (typically 60-230 kilovolts) would be maintained. Under CP1, approximately 30,300 feet (5.7 miles) of power transmission lines and 59,400 feet (11.3 miles) of telecommunications lines would require demolition and relocation to prevent inundation by the new reservoir elevation resulting from project implementation. In addition, six power towers would be demolished, and six new towers would be constructed in new locations. CP1 also involves several miles of road construction and demolition of several vehicle and railroad bridges.

Other utility relocations and/or construction proposed under CP1 include potable water facilities, gas/petroleum facilities, and wastewater facilities. Vegetation clearing would be required to varying degrees for most utility relocation/construction, some of which would be located in densely vegetated areas. During construction/relocation, the potential would exist for the ignition of fire by construction equipment operating in the area. Although the increased risk of ignition would be short term (i.e., during implementation), it would be significant. CP1 would also include demolition and construction of recreational and public service facilities.

Relevant safety standards/procedures related to fire prevention would be incorporated into the project design, and would be used during construction activities and project operation and maintenance. Safety standards and procedures include the California Building Code; the Shasta County Fire Plan; USFS safety requirements regarding fire hazards; California Public Utilities Code General Order 95, which provides procedures for proper removal, disposal, and placement of poles, wires, and associated infrastructure; and the National Electric Safety Code (a voluntary code that provides safety procedures for electric utility installation and operation). Precautionary measures to prevent construction-related fires include locating utilities a safe distance from vegetation and structures, proper construction of power lines, and construction worker safety training. Postconstruction infrastructure operation and maintenance would follow current safety practices associated with fire prevention and would include clearing vegetation from power utility facilities and other sources using combustion engines (e.g., water pumps) on a regular basis.

Right-of-way easements obtained for transmission lines would be cleared of vegetation to provide for public and worker safety, and to provide reliable operations. The California Building Code, the National Electric Safety Code, and the Shasta County Fire Plan clearance requirements for power distribution facilities would be incorporated into the project design.

No new facilities or project construction would occur in the upper Sacramento River area. However, for purposes of the project, some aggregate material extraction may occur downstream from Shasta Dam. Construction activities downstream from Shasta Dam would increase the potential for fire starts due to the presence of highly flammable vegetation. In addition, vegetation below Shasta Dam would be susceptible to fires started elsewhere within the primary study area or surrounding areas.

Project materials and workers traveling to the construction sites from the upper Sacramento River area could also increase the risk of fire hazard over their route. Operation of motor vehicles throughout the region, particularly when vegetation adjacent to roadways is dry, imparts a certain level of fire potential from accidental combustion (e.g., sparks), hot metal (e.g., tail pipes, motors), or traffic accidents which could result in fire.

Project activities, including those intended to mitigate impacts on vegetation, are expected to reduce the overall fuel loading around the Shasta Lake and vicinity portion of the primary study area, thereby reducing the long-term fire hazard. In addition, the project could result in additional water supplies in the primary study area, which could assist future fire responses in the primary study area.

Project activities would increase the risk of wildland fires. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP1): Release of Potentially Hazardous Materials or Hazardous Waste Project construction and operation would involve the transportation, use, or storage of hazardous materials. Local, State, and Federal safety codes and procedures related to hazardous material transport, handling, and disposal would be followed for project construction and operation to minimize the risk of a hazardous materials release. However, an accidental release resulting from project activities could expose the public and the environment to a significant safety hazard. Therefore, this impact would be potentially significant.

Project facilities proposed for construction under CP1 would be located in the Shasta Lake and vicinity portion of the primary study area. Certain hazardous materials needed for construction and operation would need to be stored at the Shasta Dam facility and at other utility and infrastructure relocation sites around the primary study area. Certain hazardous materials would be used to operate equipment both during and after construction, and the construction, and operation, and maintenance of project facilities and infrastructure would require the use of potentially hazardous materials such as paint, concrete, and wood preservatives. In addition, industrial uses associated with the operation and maintenance of the modified Shasta Dam compound would require the use, storage, and routine transport of small quantities of hydraulic fluids, solvents, and other standard mechanical maintenance fluids.

Construction staging, and equipment and materials storage, including storage of possible contaminants, and equipment maintenance in the primary study area would occur in areas specified by Reclamation. Staging areas would likely be located in disturbed areas or existing facilities that would be inundated after the dam is raised, such as campgrounds, recreation parking facilities, the top of Shasta Dam, and the parking area along the left wing dam. All staging areas would be located at least 100 feet from bodies of water, wherever possible. Equipment refueling and maintenance would not occur within 100 feet of water bodies, wherever possible.

Seven existing gas/petroleum facilities would be subject to inundation under CP1 and would be relocated subsequent to demolition. The existing fuel tanks would be excavated and all associated piping would be removed. Hazardous material tests and removal would be performed, as required, in accordance with Title 23 CFR, Division 3, Chapter 16: Underground Tank Regulations, and in accordance with Shasta County Environmental Health Division requirements. In addition to adherence to the directives of Title 23, relocated tanks would be designed and constructed in accordance with the Uniform Fire Code; California Air Resources Board; Shasta County Development Standards, Section 6.7 (December 1997); and Shasta County Environmental Health Division requirements. Relocated tanks would be located in cleared areas with code-mandated clearances from other facilities.

Aggregate material for the project could originate from the drawdown portion of Shasta Lake and from areas downstream from Shasta Dam (e.g., Churn Creek bottom, Clear Creek confluence, Keswick Reservoir). These materials could contain hazardous substances such as mercury or selenium. Hazardous materials released into area waterways, including Shasta Lake and many upper Sacramento River tributaries, come from past land use activities (e.g., mining) or natural sources (e.g., asbestos, selenium) and are likely to be trapped in lake-bottom, river, or floodplain sediments.

Aggregate extraction could also require operation of heavy equipment next to and in Shasta Lake or the upper Sacramento River. Reclamation may use aggregate supplies from Shasta Lake or the upper Sacramento River floodplain for dam construction materials in the general vicinity of Bridge Bay Marina and Lakeshore Drive. Several additional aggregate sources near the existing shoreline of Shasta Lake are also being considered (e.g., Bass Mountain, Stillwater Creek valley, Gray Rocks). Excavation and extraction of aggregate from these sources, or the augmentation of gravel in the Sacramento River, would require the use of construction equipment, which would involve the use of various hazardous materials such as fuel, oils, grease, and other petroleum products. These contaminants could be introduced into water systems, either directly or through surface runoff.

Project implementation could result in dam operations that would inundate abandoned or inoperative mines located next to Shasta Lake. Areas adjacent to the Bully Hill/Rising Star property contain hazardous materials that would affect Shasta Lake. The effects of CP1 on mines in the primary study area and the upper Sacramento River are discussed in Chapter 7.

Four vehicle bridges would be removed under CP1: Charlie Creek Bridge, Doney Creek Bridge, McCloud River Bridge, and Didallas Creek Bridge. A fifth bridge, the Fender's Ferry Bridge, would be retained and modified to accommodate Shasta Dam raises. Bridge demolition or modification, as well as the demolition of other structures and facilities that would be inundated under CP1, could require handling of hazardous waste including asbestos, lead paint, and wood preservatives. This hazardous waste, along with any additional forms of hazardous waste materials generated by project construction, would be removed to an approved landfill for disposal per permit requirements. Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code Section 32000, which requires proper packaging and licensing by hazardous materials haulers.

The environmental commitments for all action alternatives include the development and implementation of a construction management plan, erosion and sediment control plan, stormwater pollution prevention plan, and revegetation plan, as well as water quality and fisheries conservation measures and compliance with all required permit terms and conditions. However, the accidental release of hazardous materials or waste could expose the public and the environment to a significant safety hazard. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP1): Exposure of Workers to Hazardous Materials Project implementation could result in the exposure of workers to hazardous materials. The project would require the use of potentially hazardous materials to operate construction equipment and to construct various facilities. Reclamation and project contractors would follow local, State, and Federal regulations and procedures for properly transporting, handling, and storing hazardous materials and hazardous waste to decrease the risk of exposure; however, there is a possibility of accidents that could expose project workers to hazardous materials. Structures proposed for demolition, such as bridges, may contain asbestos, lead paint, toxic wood preservatives, or other hazardous substances. Fuel tanks and utility infrastructure (e.g., transformers containing PCBs) proposed for relocation also would involve some risk of exposure to hazardous substances. However, at this time it appears that the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous waste sites in the primary study area. Therefore, this impact would be less than significant.

Project workers would be required to transport hazardous materials at various times, in various quantities, and for various stages of project development. I-5 and local roadways would be used to transport hazardous materials and hazardous waste to and from Shasta Lake and vicinity during construction and dam operations. Traffic accidents or equipment failure could expose project workers to hazardous materials. Reclamation and contractors would follow appropriate safety procedures to minimize these risks.

Project construction activities associated with utility line removal and relocation could expose workers to health risks associated with wood preservatives used on wooden utility poles and PCBs, which are commonly found in transformers. Approximately 53,600 feet (10.2 miles) of power and telecommunication lines and six power towers would be demolished and relocated to avoid inundation resulting from the proposed change in Shasta Lake’s elevation. A large number of wooden utility poles would be demolished and relocated outside of the inundation area. Construction activities associated with utility demolition and relocation are estimated to take up to 5 years. During that time, workers handling utility poles and transformers would follow protocols to minimize exposure to hazardous material and hazardous waste.

Aggregate extraction from sites in the primary study area that may contain hazardous materials entrained in sediments, such as mercury, could result in the exposure of workers to toxic substances. During construction, workers involved in gravel extraction activities would follow protocols to minimize exposure to hazardous materials.

Shasta Dam operations could expose workers at the facility to hazardous materials. Dam operations require the use of fuels, oils, greases, and solvents. Additional amounts of hazardous materials, beyond the volumes required for operation of the existing structure, may be needed to operate the expanded raised dam structure. Reclamation would update its HMBP and would ensure that its employees follow CalEPA and OSHA standards for handling hazardous waste.

In summary, the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous waste sites in the primary study area. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP1): Exposure of Sensitive Receptors to Hazardous Materials
Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. A school and park, as well as numerous homes, are located in Shasta Lake City about 4 miles from Shasta Dam. Project activity would occur while school is in session, and the park is open to the public year round. Although Reclamation would implement measures to lessen the risk of hazardous materials exposure to sensitive receptors, this impact would be potentially significant.

Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. Travel routes to and from the primary study area are limited (i.e., there are few roads); thus, construction traffic would have to use I-5 and local roads, such as Shasta Dam Boulevard and/or Lake Boulevard. A school and park, as well as numerous homes, are located in Shasta Lake City at the intersection of Shasta Dam Boulevard and Lake Boulevard, about 4 miles from Shasta Dam. Project activity would occur while school is in session. The park is open to the public year round. This park is the primary venue for a number of youth and adult sport programs.

Aside from scattered residential and recreation areas throughout the primary study area, it does not appear that any other sensitive receptors (e.g., hospitals, schools) in the primary study area would be placed at risk of exposure to hazardous materials as a result of the project. Project implementation would follow local, State, and Federal regulations and procedures regarding the transport of hazardous materials.

Although Reclamation would implement measures to lessen the risk of hazardous materials exposure to sensitive receptors, this impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Haz-5 (CP1): Wildland Fire Risk No new facilities or project construction in the extended study area would affect the potential for wildland fire. Construction materials would be transported and workers would travel to the extended study area via I-5. However, the typical quick response to traffic accidents and fires ignited along roadways significantly decreases the potential for a wildland fire being accidentally ignited by project-related traffic. Therefore, this impact would be less than significant.

No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. Construction materials would be transported and workers would travel to the extended study area from outlying areas via I-5. The potential would exist for truck and vehicular traffic associated with the project to ignite a fire as the result of an accident, a spark, or overheating. However, traffic accidents and fires ignited along roadways typically receive quick local emergency assistance, which includes fire protection. This typical response significantly decreases the potential for a wildland fire being accidentally ignited by project-related traffic. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and is thus not proposed.

Impact Haz-6 (CP1): Release of Potentially Hazardous Materials or Hazardous Waste No new facilities or project construction in the extended study area would result in the release of hazardous material or waste. Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code Section 32000, which requires proper packaging and licensing by hazardous materials haulers and approved by Caltrans. Therefore, this impact would be less than significant.

No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the release of hazardous material or waste. Although hazardous materials used for or generated by the project in the primary study area may be transported through the extended study area, the potential for their release into the environment is less than significant. Hazardous waste generated by the project in the primary study area would likely be disposed of in landfills in the extended study area, and would likely include utility poles, transformers, asbestos, or lead-based paint. Construction equipment would also generate petroleum product waste. Petroleum products would likely be reclaimed in the primary study area. Other hazardous waste would go to one of three EPA-certified commercial hazardous waste landfills in the state. They are all located in Kings, Kern, and Imperial counties.

Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code Section 32000, which requires proper packaging and licensing by hazardous materials haulers and approved by Caltrans. Highly explosive hazardous waste and large amounts of liquid hazardous waste or are not anticipated to be transported out of the primary study area for disposal. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP1): Exposure of Workers to Hazardous Materials Project implementation would not result in new facilities or construction in the extended study area. Hazardous material transport and safety procedures for hazardous material transported through the extended study area would be sufficient to minimize risks to workers. Therefore, this impact would be less than significant.

Project implementation would not result in new facilities or construction in the extended study area. Workers may be required to transport hazardous materials through the extended study area for project purposes and could be exposed to the materials in the case of an accidental spill. However, hazardous material transport and safety procedures for hazardous material transported through the extended study area would be sufficient to minimize risks to workers. Workers involved in hazardous waste disposal activities would follow CalEPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP1): Exposure of Sensitive Receptors to Hazardous Materials or Hazardous Waste No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact would be less than significant.

Hazardous materials needed for construction or operation of the project and hazardous waste generated in the primary study area would be transported through the extended study area. Accidental spills of hazardous materials or waste during transport are possible; however, hazardous waste haulers and hazardous materials suppliers would adhere to all safety precautions and regulations pertaining to hazardous material and hazardous waste transport. These actions would minimize the risk of exposure to hazardous materials or hazardous waste by sensitive receptors in the extended study area. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP2): Wildland Fire Risk Project implementation could contribute to wildland fire risk. Project construction and operation, and the anticipated postconstruction human activity in the primary study area would increase the potential for fire ignition. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Haz-1 (CP1). Activities that could result in wildland fire risks would be the same as those discussed for Impact Haz-1 (CP1). However, the larger inundation area proposed under CP2 would require that more utilities, public service, and recreational facilities be demolished and relocated than under CP1, and would require that more vegetation be cleared within the inundation area. The additional construction and mechanized vegetation clearing associated with CP2 would require prolonged operation of construction equipment in vegetated areas and increase the potential for fire ignition from motor vehicle operation and the presence of charged utility lines in areas with a high fire hazard potential. A proposed increase in the number of campground/day use recreation areas (261 versus 202 for CP1) would increase the potential for wildfire ignition. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP2): Release of Potentially Hazardous Materials or Hazardous Waste Project construction and operation would involve the transportation, use, or storage of hazardous materials. Local, State, and Federal safety codes and procedures related to hazardous material transport, handling, and disposal would be followed for project construction and operation to minimize the risk of a hazardous materials release. However, an accidental release resulting from project activities could expose the public and the environment to a significant safety hazard. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Haz-2 (CP1). However, the amount of potentially hazardous materials required for construction and operation of the project, and the volume of hazardous waste generated by project construction, could be greater for CP2 than for CP1. The number of bridge relocations, aggregate extraction or augmentation actions, and operations and maintenance of CP2 would be similar to but greater than those of CP1. Infrastructure relocation actions would require that land- and water-based construction and maintenance equipment operate in and adjacent to Shasta Lake and other potentially sensitive areas. Hazardous materials from leaking equipment, improper handling, or accidental spills could enter the lake, waterways, or adjacent land. Also under CP2, 10 gas/petroleum tanks would be excavated and relocated to avoid inundation. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP2): Exposure of Workers to Hazardous Materials Project implementation could result in the exposure of workers to hazardous materials. The project would require the use of potentially hazardous materials to operate construction equipment and to construct various facilities. Reclamation and project contractors would follow local, State, and Federal regulations and procedures for properly transporting, handling, and storing hazardous materials and hazardous waste to decrease the risk of exposure; however, there is a possibility of accidents that could expose project workers to hazardous materials. Structures proposed for demolition, such as bridges, may contain asbestos, lead paint, toxic wood preservatives, or other hazardous substances. Fuel tanks and utility infrastructure (e.g., transformers containing PCBs) proposed for relocation also would involve some risk of exposure to hazardous substances. However, at this time it appears that the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous waste sites in the primary study area. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-3 (CP1). CP2 would require the use of potentially hazardous materials during construction, operation, and maintenance of the project. The larger scale of CP2 compared to CP1 would also generate a larger volume of hazardous waste resulting from utility line and infrastructure demolition. However, workers involved in hazardous waste disposal activities would follow CalEPA and OSHA hazardous material and waste handling rules and regulations. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP2): Exposure of Sensitive Receptors to Hazardous Materials Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. A school and park, as well as numerous homes, are located in Shasta Lake City about 4 miles from Shasta Dam. Project activity would occur while school is in session, and the park is open to the public year round. Although Reclamation would implement measures to lessen the risk of hazardous materials exposure to sensitive receptors, this impact would be potentially significant.

This impact would be similar to Impact Haz-4 (CP1). Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. Travel routes to and from the primary study area are limited (i.e., there are few roads); thus, construction traffic would have to use I-5 and local roads, such as Shasta Dam Boulevard and/or Lake Boulevard. A school and park, as well as numerous homes are located in Shasta Lake City at the intersection of Shasta Dam Boulevard and Lake Boulevard, about 4 miles from Shasta Dam. Although the scale of project actions proposed under CP2 would be larger than that of CP1, the primary study area would remain the same. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Haz-5 (CP2): Wildland Fire Risk No new facilities or project construction in the extended study area would affect the potential for wildland fire. Construction materials would be transported and workers would travel to the extended study area via I-5. However, the typical quick response to traffic accidents and fires ignited along roadways significantly decreases the potential for a wildland fire being accidentally ignited by project-related traffic. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-5 (CP1). No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. The potential for an increased risk of fire resulting from haul trucks associated with the project would be negligible. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP2): Release of Potentially Hazardous Materials or Hazardous Waste No new facilities or project construction in the extended study area would result in the release of hazardous material or waste. Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code Section 32000, which requires proper packaging and licensing by hazardous materials haulers and approved by Caltrans. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-6 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. The potential for an increased risk of hazardous materials spills resulting from haul trucks associated with the project would be negligible. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP2): Exposure of Workers to Hazardous Materials Project implementation would not result in new facilities or construction in the extended study area. Hazardous material transport and safety procedures for hazardous material transported through the extended study area would be sufficient to minimize risks to workers. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-7 (CP1). Project implementation would not result in new facilities or construction in the extended study area. Workers involved in hazardous waste disposal activities would follow CalEPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP2): Exposure of Sensitive Receptors to Hazardous Materials or Hazardous Waste No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-8 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. The potential for the exposure of sensitive receptors to hazard materials or waste associated with the project would be negligible. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP3): Wildland Fire Risk Project implementation could contribute to wildland fire risk. Project construction and operation, and the anticipated postconstruction human activity in the primary study area would increase the potential for fire ignition. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Haz-1 (CP1). However, the larger inundation area proposed under CP3 would require that more utilities, public service, and recreational facilities be demolished and relocated than under CP1, and would require that more vegetation be cleared within the inundation area. The larger scale of utility line and road construction, and the vegetation clearing and grubbing associated with CP3 would require prolonged operation of construction equipment in vegetated areas and increase the potential for fire ignition that comes from motor vehicle operation and the presence of charged utility lines in areas with a high fire hazard potential. A proposed increase in the number of campground/day use recreation areas (328 versus 202 (CP1) or 261 (CP2)) would also increase the potential for wildfire ignition. This impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP3): Release of Potentially Hazardous Materials or Hazardous Waste Project construction and operation would involve the transportation, use, or storage of hazardous materials. Local, State, and Federal safety codes and procedures related to hazardous material transport, handling, and disposal would be followed for project construction and operation to minimize the risk of a hazardous materials release. However, an accidental release resulting from project activities could expose the public and the environment to a significant safety hazard. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Haz-2 (CP1). However, the amount of potentially hazardous materials required for construction and operation of the project and the volume of hazardous waste generated by project construction could be greater for CP3 than either CP1 or CP2. The number of bridge relocations, aggregate extraction or augmentation actions, and operations and maintenance of CP3 would be similar to but greater than those of CP1 and CP2. However, infrastructure relocation actions would require that land- and water-based construction and maintenance equipment operate in and adjacent to Shasta Lake and other potentially sensitive areas. Hazardous materials from leaking equipment, improper handling, or accidental spills could enter the lake, waterways, or adjacent land. Under CP3, 10 gas/petroleum tanks would be excavated and relocated to avoid inundation. This impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP3): Exposure of Workers to Hazardous Materials Project implementation could result in the exposure of workers to hazardous materials. The project would require the use of potentially hazardous materials to operate construction equipment and to construct various facilities. Reclamation and project contractors would follow local, State, and Federal regulations and procedures for properly transporting, handling, and storing hazardous materials and hazardous waste to decrease the risk of exposure; however, there is a possibility of accidents that could expose project workers to hazardous materials. Structures proposed for demolition, such as bridges, may contain asbestos, lead paint, toxic wood preservatives, or other hazardous substances. Fuel tanks and utility infrastructure (e.g., transformers containing PCBs) proposed for relocation also would involve some risk of exposure to hazardous substances. However, at this time it appears that the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous waste sites in the primary study area. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-3 (CP1). CP3 would require the use of potentially hazardous materials during construction, operation, and maintenance of the project. The larger scale of CP3 compared to CP1 or CP2 would also generate a larger volume of hazardous waste resulting from utility line demolition. However, workers involved in hazardous waste disposal activities would follow CalEPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP3): Exposure of Sensitive Receptors to Hazardous Materials Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. A school and park, as well as numerous homes, are located in Shasta Lake City about 4 miles from Shasta Dam. Project activity would occur while school is in session, and the park is open to the public year round. Although Reclamation would implement measures to lessen the risk of hazardous materials exposure to sensitive receptors, this impact would be potentially significant.

This impact would be similar to Impact Haz-4 (CP1). Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. Travel routes to and from the primary study area are limited (i.e., there are few roads); thus, construction traffic would have to use I-5 and local roads, such as Shasta Dam Boulevard and/or Lake Street. A school and park, as well as numerous homes, are located in Shasta Lake City at the intersection of Shasta Dam Boulevard and Lake Boulevard, about 4 miles from Shasta Dam. Although the scale of project actions proposed under CP3 would be larger than that of CP1 or CP2, the primary study area would remain the same. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Haz-5 (CP3): Wildland Fire Risk No new facilities or project construction in the extended study area would affect the potential for wildland fire. Construction materials would be transported and workers would travel to the extended study area via I-5. However, the typical quick response to traffic accidents and fires ignited along roadways significantly decreases the potential for a wildland fire being accidentally ignited by project-related traffic. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-5 (CP1). No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. The potential for an increased risk of fire resulting from haul trucks and construction traffic associated with the project would be negligible. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP3): Release of Potentially Hazardous Materials or Hazardous Waste No new facilities or project construction in the extended study area would result in the release of hazardous material or waste. Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code Section 32000, which requires proper packaging and licensing by hazardous materials haulers and approved by Caltrans. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-6 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. The potential for an increased risk of hazardous materials spills resulting from haul trucks associated with the project would be negligible. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP3): Exposure of Workers to Hazardous Materials Project implementation would not result in new facilities or construction in the extended study area. Hazardous material transport and safety procedures for hazardous material transported through the extended study area would be sufficient to minimize risks to workers. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-7 (CP1). Project implementation would not result in new facilities or construction in the extended study area. Workers involved in hazardous waste disposal activities would follow CalEPA and OSHA hazardous material and waste handling rules and regulations. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP3): Exposure of Sensitive Receptors to Hazardous Materials or Hazardous Waste No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-8 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. The potential for the exposure of sensitive receptors to hazardous materials or waste associated with the project would be negligible. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP4 and CP4A): Wildland Fire Risk Project implementation could contribute to wildland fire risk. Project construction and operation, and the anticipated postconstruction human activity in the primary study area would increase the potential for fire ignition. Therefore, this impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Haz-1 (CP3), except that vehicles and equipment involved in the gravel augmentation and habitat restoration actions in the upper Sacramento River habitat restoration project would slightly increase the potential for wildland fires.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 9.3.5.

This impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP4 and CP4A): Release of Potentially Hazardous Materials or Hazardous Waste Project construction and operation would involve the transportation, use, or storage of hazardous materials. Local, State, and Federal safety codes and procedures related to hazardous material transport, handling, and disposal would be followed for project construction and operation to minimize the risk of a hazardous materials release. However, an accidental release resulting from project activities could expose the public and the environment to a significant safety hazard. Therefore, this impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Haz-2 (CP3), except that vehicles and equipment involved in the gravel augmentation and habitat restoration actions in the upper Sacramento River would slightly increase the potential for release of hazardous materials or waste.

Under CP4 or CP4A, the major components described for CP3 would be implemented, with additional measures for increasing habitat for anadromous fish. These measures include the placement of spawning-sized gravel at multiple locations along the Sacramento River between Keswick Dam and the RBPP. Under CP4 and CP4A, riparian, floodplain, and side channel habitat restoration would be implemented at up to six potential sites on the upper Sacramento River to restore habitat for anadromous salmonids.

Aggregate extraction and/or augmentation activities under CP4 or CP4A could release hazardous substances (e.g., mercury) entrained in these gravels into the water. The gravel augmentation or the construction of habitat restoration actions could cause hazardous materials to enter nearby waterways or adjacent land from leaking equipment, improper handling, or accidental spills.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 9.3.5.

This impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP4 and CP4A): Exposure of Workers to Hazardous Materials Project implementation could result in the exposure of workers to hazardous materials. The project would require the use of potentially hazardous materials to operate construction equipment and to construct various facilities. Reclamation and project contractors would follow local, State, and Federal regulations and procedures for properly transporting, handling, and storing hazardous materials and hazardous waste to decrease the risk of exposure; however, there is a possibility of accidents that could expose project workers to hazardous materials. Structures proposed for demolition, such as bridges, may contain asbestos, lead paint, toxic wood preservatives, or other hazardous substances. Fuel tanks and utility infrastructure (e.g., transformers containing PCBs) proposed for relocation also would involve some risk of exposure to hazardous substances. However, at this time it appears that the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous waste sites in the primary study area. Therefore, this impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Haz-3 (CP3), with additional measures for increasing habitat for anadromous fish, which would slightly increase the potential for the exposure of workers to hazardous materials or hazardous waste.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP4 and CP4A): Exposure of Sensitive Receptors to Hazardous Materials Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. A school and park, as well as numerous homes, are located in Shasta Lake City about four miles from Shasta Dam. Project activity would occur while school is in session, and the park is open to the public year round. Although Reclamation would implement measures to lessen the risk of hazardous materials exposure to sensitive receptors, this impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impacts Haz-4 (CP1) and Haz-4 (CP3), with additional measures for increasing habitat for anadromous fish. However, no additional actions are proposed that would affect the potential for the exposure of sensitive receptors to hazardous materials or hazardous waste.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 9.3.5.

This impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Haz-5 (CP4 and CP4A): Wildland Fire Risk No new facilities or project construction in the extended study area would affect the potential for wildland fire. Construction materials would be transported and workers would travel to the extended study area via I-5. However, the typical quick response to traffic accidents and fires ignited along roadways significantly decreases the potential for a wildland fire being accidentally ignited by project-related traffic. Therefore, this impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Haz-5 (CP1). No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. The potential for an increased risk of fire resulting from haul trucks or construction traffic associated with the project would be negligible.

Therefore, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Therefore, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP4 and CP4A): Release of Potentially Hazardous Materials or Hazardous Waste No new facilities or project construction in the extended study area would result in the release of hazardous material or waste. Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code Section 32000, which requires proper packaging and licensing by hazardous materials haulers and approved by Caltrans. Therefore, this impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Haz-6 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. The potential for an increased risk of hazardous materials spills resulting from haul trucks associated with the project would be negligible.

Therefore, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Therefore, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP4 and CP4A): Exposure of Workers to Hazardous Materials Project implementation would not result in new facilities or construction in the extended study area. Hazardous material transport and safety procedures for hazardous material transported through the extended study area would be sufficient to minimize risks to workers. Therefore, this impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Haz-7 (CP1). Project implementation would not result in new facilities or construction in the extended study area. Workers involved in hazardous waste disposal activities would follow CalEPA and OSHA hazardous material and waste handling rules and regulations.

Therefore, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Therefore, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP4 and CP4A): Exposure of Sensitive Receptors to Hazardous Materials or Hazardous Waste No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Haz-8 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. The potential for the exposure of sensitive receptors to hazard materials or waste associated with the project would be negligible.

Therefore, this impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Therefore, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Haz-1 (CP5): Wildland Fire Risk Project implementation could contribute to wildland fire risk. Project construction and operation, and the anticipated postconstruction human activity in the primary study area would increase the potential for fire ignition. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Haz-1 (CP4 and CP4A). This impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-2 (CP5): Release of Potentially Hazardous Materials or Hazardous Waste Project construction and operation would involve the transportation, use, or storage of hazardous materials. Local, State, and Federal safety codes and procedures related to hazardous material transport, handling, and disposal would be followed for project construction and operation to minimize the risk of a hazardous materials release. However, an accidental release resulting from project activities could expose the public and the environment to a significant safety hazard. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Haz-2 (CP4 and CP4A). Under CP5, the major components described for CP3 would be implemented, but as described under CP4 and CP4A, the project focus would be a combination of increasing water supply availability, enhancing environmental resources in the primary study area, and maintaining the existing level of recreational opportunities. No additional actions are proposed that would affect the potential for the release of hazardous materials or hazardous waste. This impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Impact Haz-3 (CP5): Exposure of Workers to Hazardous Materials Project implementation could result in the exposure of workers to hazardous materials. The project would require the use of potentially hazardous materials to operate construction equipment and to construct various facilities. Reclamation and project contractors would follow local, State, and Federal regulations and procedures for properly transporting, handling, and storing hazardous materials and hazardous waste to decrease the risk of exposure; however, there is a possibility of accidents that could expose project workers to hazardous materials. Structures proposed for demolition, such as bridges, may contain asbestos, lead paint, toxic wood preservatives, or other hazardous substances. Fuel tanks and utility infrastructure (e.g., transformers containing PCBs) proposed for relocation also would involve some risk of exposure to hazardous substances. However, at this time it appears that the quantities and types of hazardous materials and possible exposure levels to these materials in the workplace would not pose a significant risk to worker health and safety. Furthermore, there are no known hazardous waste sites in the primary study area. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-3 (CP3). Under CP5, the major components described for CP3 would be implemented, but the project focus would be a combination of increasing water supply availability, enhancing environmental resources in the primary study area, and maintaining the existing level of recreational opportunities. No additional actions are proposed that would affect the potential for the exposure of workers to hazardous materials or hazardous waste. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-4 (CP5): Exposure of Sensitive Receptors to Hazardous Materials Project implementation could expose sensitive receptors to hazardous materials and waste that would be transported through the primary study area. A school and park, as well as numerous homes, are located in Shasta Lake City about 4 miles from Shasta Dam. Project activity would occur while school is in session, and the park is open to the public year round. Although Reclamation would implement measures to lessen the risk of hazardous materials exposure to sensitive receptors, this impact would be potentially significant.

This impact would be similar to Impact Haz-4 (CP3). Under CP5, the major components described for CP3 would be implemented, but the project focus would be a combination of increasing water supply availability, enhancing environmental resources in the primary study area, and maintaining the existing level of recreational opportunities. No additional actions are proposed that would affect the potential for the exposure of sensitive receptors to hazardous materials or hazardous waste. This impact would be potentially significant. Mitigation for this impact is proposed in Section 9.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Haz-5 (CP5): Wildland Fire Risk No new facilities or project construction in the extended study area would affect the potential for wildland fire. Construction materials would be transported and workers would travel to the extended study area via I-5. However, the typical quick response to traffic accidents and fires ignited along roadways significantly decreases the potential for a wildland fire being accidentally ignited by project-related traffic. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-5 (CP1). No new facilities or project construction would occur in the extended study area that would affect the existing potential for wildland fire. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-6 (CP5): Release of Potentially Hazardous Materials or Hazardous Waste No new facilities or project construction in the extended study area would result in the release of hazardous material or waste. Transport of hazardous materials would be conducted in accordance with CCR Title 26 and would be licensed by the CHP, pursuant to California Vehicle Code Section 32000, which requires proper packaging and licensing by hazardous materials haulers and approved by Caltrans. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-6 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect release of hazardous material or waste. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-7 (CP5): Exposure of Workers to Hazardous Materials Project implementation would not result in new facilities or construction in the extended study area. Hazardous material transport and safety procedures for hazardous material transported through the extended study area would be sufficient to minimize risks to workers. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-7 (CP1). Project implementation would not result in new facilities or construction in the extended study area. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Haz-8 (CP5): Exposure of Sensitive Receptors to Hazardous Materials or Hazardous Waste No new facilities or project construction would occur in the extended study area that would directly or indirectly result in the exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact would be less than significant.

This impact would be similar to Impact Haz-8 (CP1). No new facilities or project construction would occur in the extended study area that would result in the direct or indirect exposure of sensitive receptors to hazardous materials or hazardous waste. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

9.3.5 Mitigation Measures

Table 9-1 presents a summary of mitigation measures for hazards and hazardous materials and waste.

Table 9-1. Summary of Mitigation Measures for Hazards and Hazardous Materials and Waste

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/ CP4A	CP5
Impact Haz-1: Wildland Fire Risk (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Haz-2: Release of Potentially Hazardous Materials or Hazardous Waste (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Haz-3: Exposure of Workers to Hazardous Materials (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Haz-4: Exposure of Sensitive Receptors to Hazardous Materials (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	Mitigation Measure Haz-4: Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Haz-5: Wildland Fire Risk (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS

Table 9-1. Summary of Mitigation Measures for Hazards and Hazardous Materials and Waste (contd.)

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/ CP4A	CP5
Impact Haz-6: Release of Potentially Hazardous Materials or Hazardous Waste (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Haz-7: Exposure of Workers to Hazardous Materials (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Haz-8: Exposure of Sensitive Receptors to Hazardous Materials (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS

Key:
CP = Comprehensive Plan
CVP = Central Valley Project
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
SWP = State Water Project

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impact Haz-3 (CP1) or Impacts Haz-5 (CP1) through Haz-8 (CP1). Mitigation is provided below for other impacts of CP1 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP1): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards Reclamation will coordinate all proposed road closures, detours, and traffic control measures with SCSO and the Tehama County Sheriff’s Office, which are the designated offices of emergency services for the primary study area.

Reclamation will also coordinate all proposed road closures, detours, and traffic control measures with USFS, Caltrans, the CHP, the City of Shasta Lake, and the surrounding Shasta Lake communities.

Reclamation will appoint a public liaison to communicate construction schedules, road closures, and project activities with the public. The liaison will organize and conduct public meetings for communicating project information. The liaison will meet with all affected public services agencies to coordinate public meetings and information exchanges.

Reclamation will meet with public services agencies to determine that traffic controls for infrastructure, utility, and structure relocation do not impede emergency access for wildland fire response capabilities.

Reclamation will require that all project workers receive fire prevention safety training, which identifies local wildland fire hazards and informs workers of the relevant fire prevention procedures, rules, and regulations.

Implementation of this mitigation measure would reduce Impact Haz-1 (CP1) to a less-than-significant level.

Mitigation Measure Haz-2 (CP1): Reduce Potential for Release of Hazardous Materials and Waste Reclamation will update the Shasta Dam facilities HMBP (or like document). The update will provide information regarding the hazardous materials used for project implementation and hazardous waste that would be generated.

Reclamation will coordinate hazardous materials and waste information with SCSO and the Tehama County Sheriff’s Office (the designated offices of emergency services for the primary study area), USFS, the City of Shasta Lake, and the surrounding Shasta Lake communities. Transportation coordination efforts will also include the CHP and Caltrans, and will include disclosing and planning proposed hazardous material transportation routes to ensure use of the route(s) having the least impact.

Reclamation will appoint a public liaison to communicate hazardous material transportation routes related to project activities with the public. The liaison will organize and conduct public meetings, which will include discussions of hazardous waste transport in the primary and extended study areas. The liaison will meet with all affected public services agencies to coordinate public meetings and information exchanges.

Project workers who may come into contact with hazardous materials or waste will be required to receive hazardous material safety training, which identifies hazardous materials on the project site and informs workers of the relevant safety procedures, rules, and regulations that address hazardous waste handling, storage, and transportation.

Reclamation will ensure that project construction sites have staging areas that minimize potential hazardous waste releases and that meet best management practices for short-term construction site hazardous material storage.

Implementation of this mitigation measure would reduce Impact Haz-2 (CP1) to a less-than-significant level.

Mitigation Measure Haz-4 (CP1): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste Reclamation will coordinate hazardous materials transportation routes with SCSO and the Tehama County Sheriff's Office (which are the designated offices of emergency services for the primary study area), USFS, Caltrans, CHP, the City of Shasta Lake, a representative from the Shasta Lake Elementary School, and other affected local agencies within the primary and extended study areas. Coordination efforts will include disclosing and planning proposed hazardous material transportation routes and schedules to allow for site-specific modifications that would lessen the potential impact on sensitive receptors.

Reclamation will appoint a public liaison to communicate hazardous material transportation routes related to project activities with the public. The liaison will organize and conduct public meetings, which will include a discussion of hazardous waste transport near local sensitive receptors. The liaison will meet with all affected public services agencies to coordinate public meetings and information exchanges.

Reclamation will identify sensitive receptor sites for all project workers who would use, handle, or transport hazardous materials, and require workers transporting hazardous materials past the sensitive receptors to proceed with extreme caution.

Reclamation will place road signs identifying sensitive receptor sites for hazardous material haulers and post reduced speed limits if local jurisdictions find it necessary to prevent potential impacts.

Implementation of this mitigation measure would reduce Impact Haz-4 (CP1) to a less-than-significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impact Haz-3 (CP2) or Impacts Haz-5 (CP2) through Haz-8 (CP2). Mitigation is provided below for other impacts of CP2 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP2): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to

Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure would reduce Impact Haz-1 (CP2) to a less-than-significant level.

Mitigation Measure Haz-2 (CP2): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure would reduce Impact Haz-2 (CP2) to a less-than-significant level.

Mitigation Measure Haz-4 (CP2): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure would reduce Impact Haz-4 (CP2) to a less-than-significant level.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation is required for Impact Haz-3 (CP3) or Impacts Haz-5 (CP3) through Haz-8 (CP3). Mitigation is provided below for other impacts of CP3 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP3): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure would reduce Impact Haz-1 (CP3) to a less-than-significant level.

Mitigation Measure Haz-2 (CP3): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure would reduce Impact Haz-2 (CP3) to a less-than-significant level.

Mitigation Measure Haz-4 (CP3): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure would reduce Impact Haz-4 (CP3) to a less-than-significant level.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for Impact Haz-3 (CP4 and CP4A) or Impacts Haz-5 (CP4 and CP4A) through Haz-8 (CP4 and CP4A). Mitigation is provided below for other impacts of CP4 or CP4A on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP4 and CP4A): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure would reduce Impact Haz-1 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Haz-2 (CP4 and CP4A): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure would reduce Impact Haz-2 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Haz-4 (CP4 and CP4A): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure would reduce Impact Haz-4 (CP4 and CP4A) to a less-than-significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impact Haz-3 (CP5) or Impacts Haz-5 (CP5) through Haz-8 (CP5). Mitigation is provided below for other impacts of CP5 on hazards and hazardous materials. Mitigation is provided for the wildland fire hazard, the risk of hazardous material or hazardous waste releases, and the risk of exposing sensitive receptors to hazardous materials.

Mitigation Measure Haz-1 (CP5): Coordinate and Assist Public Services Agencies to Reduce Fire Hazards This mitigation measure is identical to Mitigation Measure Haz-1 (CP1). Implementation of this mitigation measure would reduce Impact Haz-1 (CP5) to a less-than-significant level.

Mitigation Measure Haz-2 (CP5): Reduce Potential for Release of Hazardous Materials and Waste This mitigation measure is identical to Mitigation Measure Haz-2 (CP1). Implementation of this mitigation measure would reduce Impact Haz-2 (CP5) to a less-than-significant level.

Mitigation Measure Haz-4 (CP5): Reduce Potential for Exposure of Sensitive Receptors to Hazardous Materials or Waste This mitigation measure is identical to Mitigation Measure Haz-4 (CP1). Implementation of this mitigation measure would reduce Impact Haz-4 (CP5) to a less-than-significant level.

9.3.6 Cumulative Effects

Chapter 3, “Considerations for Describing the Affected Environment and Environmental Consequences,” discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria.. Table 3-1, “Present and Reasonably

Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," in Chapter 3, lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level.

Past projects and activities that have affected hazardous materials, potential exposure of sensitive receptors to hazardous materials or hazardous waste, and wildland fire risk in the study area are land use development, recreation activities, construction activities and accidental spills of hazardous materials.

The action alternatives would not combine with any of the quantitatively assessed projects listed in Table 3-1 to have a cumulatively considerable impact related to hazards or hazardous materials and waste; therefore, this section evaluates only those projects listed in Table 3-1 that are qualitatively considered in this EIS.

Potentially significant effects for SLWRI were identified in the areas of increased wildland fire risk, accidental releases of hazardous materials or hazardous waste, and potential exposure of sensitive receptors to hazardous materials or hazardous waste. The potential effects would be of greater magnitude and duration with the larger dam raises (i.e., CP3 through CP5 would have greater potential effects than CP1 and CP2).

Reasonably foreseeable actions in the Shasta Lake and vicinity area, such as the construction of Antlers Bridge or the Iron Mountain Mine Restoration Plan, may result in increased potential for wildland fire hazards or accidental releases of hazardous materials or hazardous waste within the primary study area. In addition, as described in the Climate Change Modeling Appendix, climate change could result in less precipitation through the 2050s and warmer air temperature, thereby increasing the risk of wildland fire hazard near Shasta Lake.

Implementation of the proposed SLWRI alternatives would result in potentially significant impacts to wildland fire hazards, accidental releases of hazardous materials or hazardous waste, and exposure of sensitive receptors to hazardous materials or hazardous waste. Additive and interactive/multiplicative effects of implementing the proposed SLWRI alternatives with past, present, and reasonably foreseeable probable future projects could result in cumulatively considerable impacts. However, mitigation would be implemented to reduce impacts associated with the project to a less-than-significant level. Therefore, the potential for project-related impacts to be cumulatively considerable after mitigation would be less than significant.

The exposure of workers to hazards, hazardous materials, or hazardous waste would not be a cumulatively considerable effect. Implementation of the proposed SLWRI alternatives would not be likely to involve the same workers or occur in the same place or time as other reasonably foreseeable actions. Therefore, project implementation would not likely be associated with significant cumulative effects in terms of exposing workers and other sensitive receptors to hazards, hazardous materials, or hazardous waste.

This page left blank intentionally.

Chapter 10
Agriculture and Important Farmland

10.1 Affected Environment

This section describes the affected environment related to existing agricultural land uses, Important Farmland, Williamson Act contract lands, and forest resources in the primary and extended study areas. See Chapter 12, "Botanical Resources and Wetlands," for detailed definitions of forest land habitats and Chapter 13, "Wildlife Resources," for a discussion of the relationship between agricultural land uses and wildlife uses. See Chapter 17, "Land Use and Planning," for a discussion of existing land uses within the primary and extended study areas and the project's consistency with existing land uses.

10.1.1 Agriculture

Shasta Lake and Vicinity

The setting for agricultural resources in the Shasta Lake and vicinity portion of the primary study area consists of areas in Shasta County north of Shasta Dam, including lands surrounding the lake, that would be subject to inundation and areas where infrastructure would be removed, modified, or relocated under the action alternatives.

Shasta Lake is surrounded by mountainous and rugged terrain. There are no known agricultural uses adjacent to the lake or in its immediate vicinity above Shasta Dam.

Upper Sacramento River (Shasta Dam to Red Bluff)

The upper Sacramento River portion of the primary study area consists of the portion of Shasta County south of Shasta Dam and downstream to Red Bluff in Tehama County. The valleys of the Sacramento River and its tributaries (Churn, Cottonwood, Anderson, Stillwater, Cow, Bear, Battle, and Clover creeks) contain some of the most productive agricultural land in Shasta and Tehama counties. In addition to the high quality of their soils, agricultural lands in this area enjoy a long growing season of 172 to 205 days. Water from the Anderson-Cottonwood Irrigation District (ACID), surface diversions of streams, or groundwater is available and good transportation access exists (Shasta County 2004). As of 2007, Shasta County's 1,473 farms encompassed a total of almost 390,812 acres and Tehama County's 1,752 farms were located on 532,206 acres (USDA 2007a, 2007b). About 253,000 acres of Important Farmland are located in the Sacramento River corridor between Shasta Dam and the Red Bluff

Pumping Plant. Please see Section 10.1.2, "Important Farmland," below for further discussion.

The majority of agricultural activity is located on the Sacramento Valley floor in the south-central portion of Shasta County and across central Tehama County. Small pockets of pastureland exist throughout Shasta County, including mountainous regions. Based on production value, the largest use of agricultural land in Shasta County is field crops, followed by livestock (Shasta County 2011). Nursery stock is the third largest use. Approximately 13 percent of Shasta County land is devoted to some type of agricultural use.

Agricultural uses in the Tehama County portion of the Sacramento Valley consist mostly of orchard and nursery plant operations. The primary crops of Tehama County orchards are walnuts, prunes, almonds, and olives. These crops are largely concentrated in the floodplain alongside the Sacramento River (within and below the upper Sacramento River portion of the primary study area) and are irrigated with groundwater, as well as surface water from local creek diversions and the Sacramento River.

A drastic increase in orchard acreage has occurred since orchard production was initially reported by the National Agricultural Statistics Service in 1930. A combination of factors is responsible for this increase: the availability of irrigation water, advances in irrigation technologies, relatively good commodity prices for orchard crops, and the availability of processing facilities.

The upper Sacramento River portion of the primary study area (areas below Shasta Dam) is largely serviced by ACID. ACID's service area of approximately 32,000 acres extends south from the city of Redding in Shasta County into northern Tehama County. ACID does not provide water for municipal and industrial uses in these areas. Approximately 90 percent of ACID's customers irrigate pasture for haying or livestock; however, in most of the river corridor the water is used to irrigate orchard and other food crops. In total, ACID's service area accounts for about two-thirds of all irrigated pasture in the Redding basin.

ACID uses a rotation schedule to deliver irrigation water to its customers. Very little groundwater is used within the district for agricultural purposes, except occasionally during drought years. Water requirements are typically highest during summer (June, July, and August) because of the area's hot, dry climate. A groundwater management program is being developed; by 2005, 12 dual-completion groundwater monitoring wells had been installed within ACID boundaries. The small portion of groundwater used is limited primarily to deciduous crops and is pumped by privately owned wells. ACID's facilities and irrigation are important contributors to groundwater recharge in the Redding basin. Annual seepage associated with the ACID Main Canal is estimated to be approximately 44,000 acre-feet.

Agricultural use within ACID's service area is primarily pasture, in addition to alfalfa and some deciduous orchard crops. Pasture use is typically in the range of 75 percent of the total crop mix served by ACID. Annual cropping patterns have not varied substantially since the mid-1970s. Therefore, associated on-field water requirements and diversions for crops have been more a function of water-year type and climate than changes in cropping.

Agriculture thus accounts for an important segment of the economic base of Shasta and Tehama counties. In 2011, for example, the total market value of farm products in Shasta County was $76,328,000, a slight increase from the $70,760,000 produced in 2010. Minor increases in the annual production value of orchard crops and apiary products accounted for this increase. Field crops accounted for nearly 46 percent of this total, with livestock sales providing nearly one-third (32.2 percent) of the county's total agricultural production value. In 2010, Shasta County ranked only 37th among the 58 California counties in the value of total agricultural production – $110,283,000, as reported by the California Department of Food and Agriculture (Shasta County 2011).

In addition to its economic contribution, the agriculture industry is in large part responsible for the rural character of Shasta and Tehama counties. Farmland can also play an important role in the support of wildlife values through the effects it has on conservation of wildlife habitats. As more farmland is developed for urban and suburban uses, the available habitat for most field and woodland edge species decreases, resulting in a subsequent decline in or potential elimination of their populations. Agricultural lands also provide productive, privately maintained open space that contributes to the open, natural landscape of much of Shasta and Tehama counties.

Lower Sacramento River and Delta

The Sacramento River below the Red Bluff Pumping Plant and the river's tributaries continue to provide water to crops grown in the river's floodplain and the valley floor, which broadens as it expands into the Central Valley. The Sacramento River crosses Tehama, Butte, Glenn, Colusa, Sutter, Yolo, and Sacramento counties and is an important source of water for the irrigation and agricultural districts in those counties.

California's Central Valley is home to more than 4 million people; agriculture is the most important segment of the region's robust economy. The Sacramento and San Joaquin river basins provide drinking water for more than two-thirds of Californians and irrigation water for California's crops. The availability of irrigation water makes the Central Valley a major source of reliable, high-quality crops, such as almonds, walnuts, grapes, tomatoes, rice, and other orchard, vineyard, and field crops, marketed to the nation and the world (Reclamation and DWR 2005; DWR and Reclamation 2006).

As of 2007, California's 81,033 farms included a total of 25.4 million acres (USDA 2007c). Of that acreage, the Sacramento Valley had more than 11,000 farms with about 4.3 million acres. Sacramento Valley portions of the Central Valley's watersheds support a wide variety of agricultural uses, including livestock grazing, irrigated grain and vegetable crops, and orchards (DWR and Reclamation 2006).

Most agricultural water demands in the Sacramento Valley are met in average water years. Farmers have been growing more crops per acre-foot of applied water by improving productivity and efficiency. However, in some areas, water sources once used for agriculture are now used for urban needs, environmental restoration, and groundwater replenishment. During droughts, water supplies are less reliable, heightening competition and at times leading to conflicts among water users. Water quality is degraded, making it difficult and costly to make the water drinkable. Irrigated agriculture and related businesses are adversely affected, in turn affecting California's economy. During droughts, groundwater levels decline, pumping costs increase, and many rural residents who depend on small water systems or wells run short of water (DWR and Reclamation 2006).

Table 10-1 provides examples of water supply distribution among uses in wet, above-normal, and dry years.[1] Delta agricultural lands were "reclaimed" when levees were constructed and marshy areas were drained. In less than 100 years, from 1850 to 1930, hundreds of thousands of acres of land went into agricultural production. Historically, asparagus, corn, alfalfa, and sugar beets were the Delta's dominant crops. However, a wide variety of crops have been grown in the Delta. In 2008, the Delta's main crops were corn, alfalfa, tomatoes, and wine grapes (DWR 2009).

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

Notes:

[1] Percentage of normal precipitation. Water year 1998 was classified as a wet water year; 2000 was an above-normal water year; 2001 was a dry water year.

[2] Environmental water includes instream flows, wild and scenic river flows, required Delta outflow, and managed wetlands water use. Some environmental water is reused by agricultural and urban water users.

Key:

% = percent

DWR = California Department of Water Resources

MAF = million acre-feet

Reclamation = U.S. Department of Interior, Bureau of Reclamation

TAF = thousand acre-feet

CVP/SWP Service Areas

The CVP is the largest water storage and delivery system in California, covering 29 of the State of California's (State) 58 counties. Operated by Reclamation, the CVP consists of 21 reservoirs capable of storing 12 million acre-feet (MAF) of water, 11 powerplants, 500 miles of major canals and aqueducts, and many tunnels, conduits, and power transmission lines. The CVP irrigates about 3.25 million acres of farmland and supplies water to more than 2 million people through more than 250 water districts, individuals, and companies through water service contracts, Sacramento River water rights, and San Joaquin River exchange contracts. Most of the CVP service area is inside the Central Valley. About 90 percent of the south-of-Delta contractual delivery is for agricultural uses (Reclamation 2007).

The CVP plays a key role in California's economy, providing water for 6 of the top 10 agricultural counties in the nation's top farming state. The CVP provides about 5 MAF of water for farms, which is enough to irrigate about 3 million acres, or approximately one-third of the agricultural land in California (Reclamation 2009).

Most of the population of the CVP service area is concentrated in urban areas. The CVP service area includes various municipal and industrial water contractors and water districts that serve portions of the Sacramento and Stockton metropolitan areas and the San Francisco Bay Area (Reclamation 2007).

Outside of the fast-growing population centers, most of the CVP service area is rural, with irrigated agriculture being the predominant land use and driver of the local and regional economies (Reclamation 2007). As California's population continues to grow at a notable pace, water and power supplies have become more scarce and expensive; as a result, existing supplies have become more valuable.

Through contracts with 29 water agencies, the SWP provides water to Butte, Solano, Kings, and Kern counties in the Central Valley; to several Southern California counties; to Alameda and Santa Clara counties in the south San Francisco Bay Area; and to Napa and Solano counties in the north San Francisco Bay Area. In addition, the SWP provides water rights deliveries to water rights holders along the Feather River (Butte and Plumas counties). Of the total water delivered throughout California, the SWP provides water to about 600,000 acres of farmland. The SWP supplies about 10 percent of the total agricultural water used in the extended study area (DWR 2011).

Local surface water supplies (those not delivered by either the CVP or SWP) provide about 40 percent of all agricultural water used in the extended study area. More local surface water supplies are available on the east side of the valley because of the larger amount of precipitation in the Sierra Nevada. Locally owned water projects are especially important on the Yuba, Stanislaus, Tuolumne, Kings, and Merced rivers; but local sources on the west side, such as the Federal Solano Project, also are important.

As surface water flows through the San Joaquin Valley, numerous turnouts convey the water to farmland within the service areas of the SWP and CVP. The remaining water conveyed by the California Aqueduct is delivered to Southern California, home to about two-thirds of California's population (DWR 2011).

Groundwater provides an important supply of water for agriculture in normal years and often is used to reduce or eliminate shortages of surface water supplies during drought years. On average, groundwater provides about 20 percent of the total agricultural water used in the extended study area. Declining groundwater tables, subsidence, and loss of aquifer storage continue to be costly problems, particularly in the western and southern parts of the San Joaquin River region and the San Francisco Bay region, where less surface water is available.

10.1.2 Important Farmland

Important Farmland is classified by the California Department of Conservation (DOC) as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance (see Section 10.2, "Regulatory Framework," for further discussion). The following discussion of Important Farmland is derived from DOC's *California Farmland Conversion Report 2006–2008*, published in January 2011 (DOC 2011).

In 2008, DOC estimated that California had approximately 31.6 million acres of agricultural land, of which approximately 12.4 million acres were identified as Important Farmland and 19.2 million acres were identified as Grazing Land. During the 12 biennial reporting cycles since DOC's Farmland Mapping and Monitoring Program (FMMP) was established, more than 1.3 million acres of agricultural land in California have been converted to nonagricultural purposes.

Losses of irrigated farmland (Prime Farmland, Farmland of Statewide Importance, and Unique Farmland) have accelerated, as shown in updates to Important Farmland maps. Irrigated farmland decreased by 203,000 acres in 2008, a 30 percent greater decrease than in 2006. Idling of irrigated farmland became a major factor in 2008, exceeding the effect of urbanization for the first time in FMMP history. Losses of irrigated farmland have resulted in part from two factors: (1) drought-related reductions in water supply and (2) reclassification to Grazing Land or Farmland of Local Importance of those lands left idle for three or more update cycles, some of which may have been idled in anticipation of development.

Urban development decreased by 29 percent relative to the 2004–2006 period and the 2008 urbanization rate was the lowest rate recorded since the late 1990s. Nonetheless, between 2006 and 2008, 72,300 acres of agricultural land in the State were lost to urbanization, with irrigated farmland making up 20,400 acres, or 28 percent of all new urban land. Housing developments were the most frequent and largest category of newly urbanized land. The increase was associated mostly with construction of single-family homes at the periphery of existing cities, and to a lesser degree, with construction of apartment complexes. Retail and commercial developments and community infrastructure supporting new residential development also contributed substantially to urbanization.

The vast majority of the Important Farmland in California is located in the Central Valley, fed by the Sacramento and San Joaquin rivers and their tributaries.

Shasta Lake and Vicinity

According to the Shasta County Important Farmland map, published by DOC's Division of Land Resource Protection, no lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated as Important Farmland (Figure 10-1).

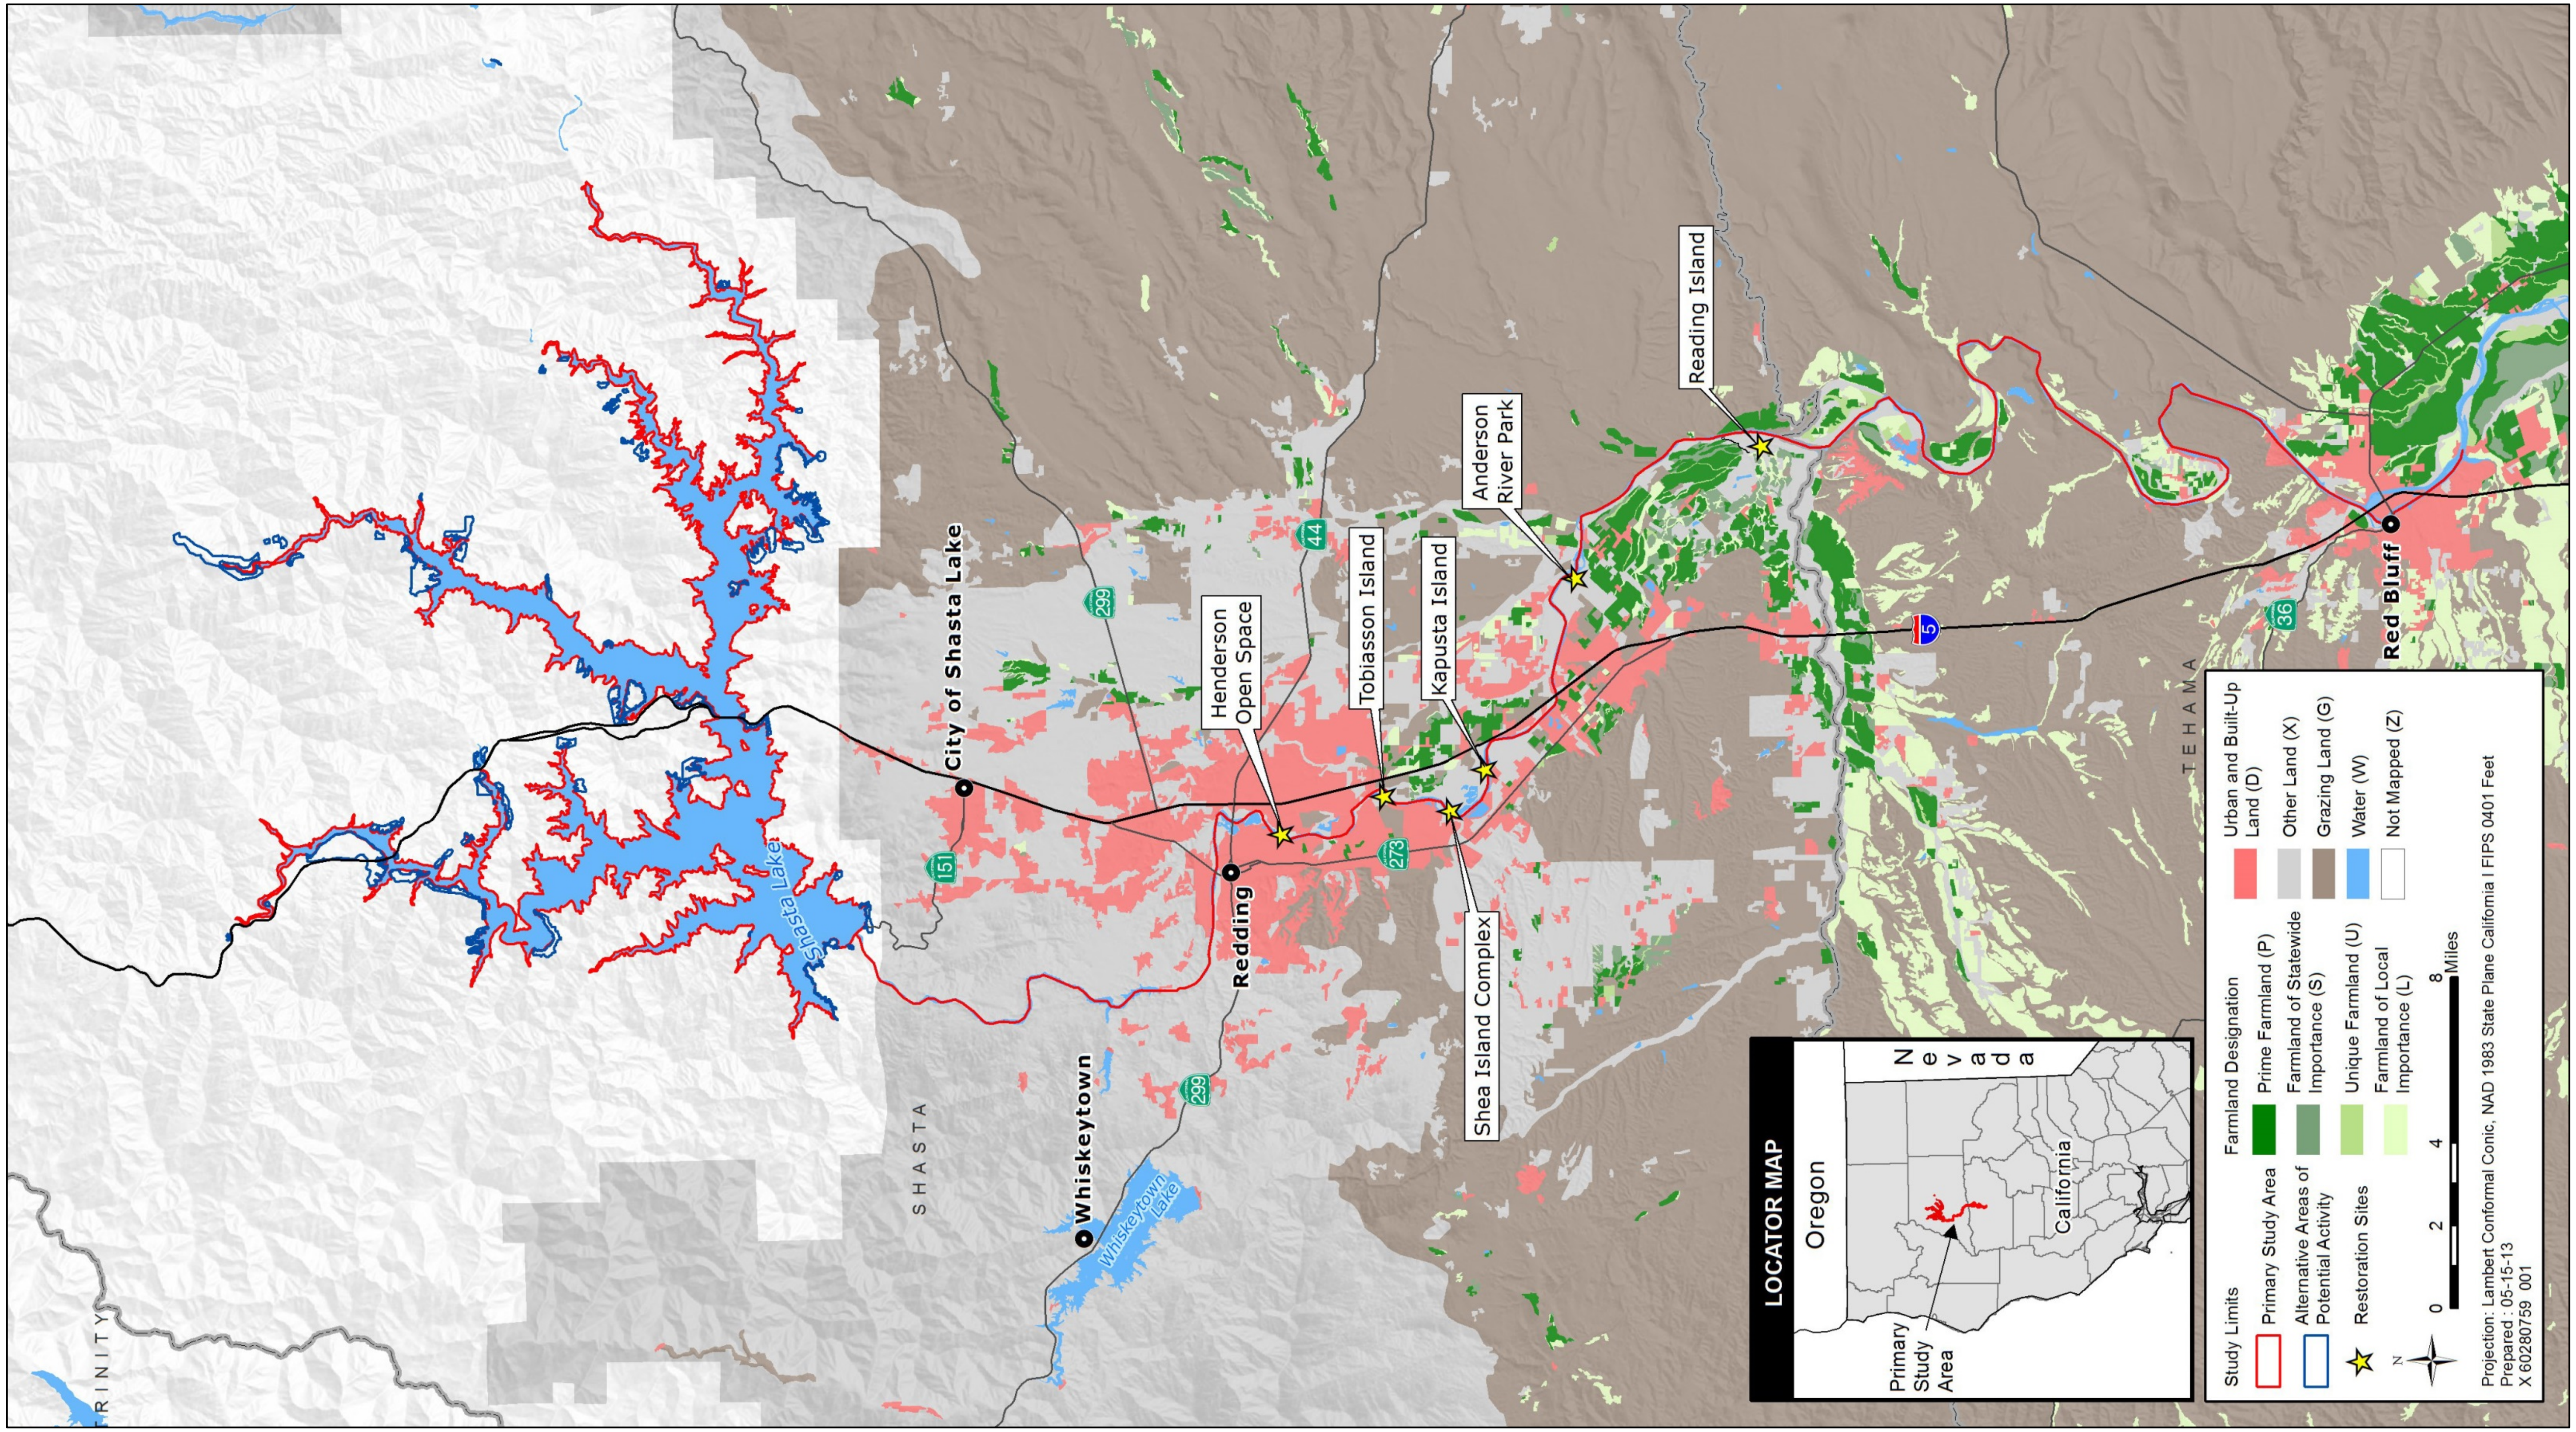

Figure 10-1. Important Farmland in the Primary Study Area

This page left blank intentionally.

Upper Sacramento River (Shasta Dam to Red Bluff)

The majority of Important Farmland in the primary study area is clustered in the former floodplain of the Sacramento River. As of 2008, Shasta County had 22,191 acres and Tehama County had 230,932 acres of Important Farmland (Table 10-2). The potential restoration and gravel augmentation sites described as part of CP4, CP4A, and CP5 are not located on Important Farmland.

Table 10-2. Acreage of Important Farmland in Shasta and Tehama Counties

Important Farmland Category	Shasta County	Tehama County	Total
Prime Farmland	12,290	63,037	75,327
Farmland of Statewide Importance	3,288	17,232	20,520
Unique Farmland	510	18,055	18,565
Farmland of Local Importance	6,103	132,608	138,711
Total	**22,191**	**230,932**	**253,123**

Source: DOC 2011

Key:
DOC = California Department of Conservation

According to the Important Farmland maps for Shasta and Tehama counties, the primary study area includes 432 acres of Important Farmland. Of this total, 90 acres are located in Shasta County and 342 acres are located in Tehama County (Table 10-3).

Table 10-3. Acreage of Important Farmland in Portions of Shasta and Tehama Counties Within the Primary Study Area

Important Farmland Category	Shasta County	Tehama County	Total
Prime Farmland	69	30	99
Farmland of Statewide Importance	8	–	8
Unique Farmland	8	38	46
Farmland of Local Importance	5	274	279
Total	**90**	**342**	**432**

Lower Sacramento River and Delta

Urbanization in the Sacramento Valley between 2006 and 2008 resulted in a decrease of 5,300 acres of irrigated farmland, which accounted for 33 percent of the statewide net decrease. Housing was the largest component of new urban acreage in the lower Sacramento River portion of the extended study area. Most of the increase was associated with single-family homes located at the periphery of existing cities, retail and commercial developments, and community infrastructure supporting new residential development. It is anticipated that current and future population growth will increase the demand for developable land, particularly near the Bay Area, Stockton, and Sacramento. This demand results in the conversion of open space, primarily agricultural land, to residential and commercial uses.

Overall, the Sacramento Valley saw the largest drop in urbanization between 2006 and 2008—63 percent—with a rate that fell below that of the San Francisco Bay Area for the first time since 2002. Much of this decrease was caused by the slowdown in Sacramento County's growth between the two updates. While urbanization in the Sacramento Valley dropped substantially, ecological restoration remained a factor. Most wetland restoration projects in the region were adjacent to existing wildlife refuges and river channels.

Other factors besides conversion to urban or other land uses (e.g., habitat restoration) also affect the acreage of irrigated farmland. Regionally, complex factors related to availability of surface and groundwater supplies, crop markets, and anticipation of urban development affect the acreage of irrigated farmland. More locally, changes in annual water supplies, drainage, access, and compatibility with adjacent land uses also affect the productivity and value, and thus use, of agricultural land. Potential conflicts of adjacent land uses with agricultural production include traffic, vandalism, dumping, and provision of habitat for pest organisms (EDAW 2006; Sokolow et al. 2010).

The periphery of the Delta is undergoing rapid urbanization associated with substantial population growth. In 2008, declines of irrigated farmland in the Delta occurred primarily in Contra Costa and Solano counties, as each lost more than 4,100 acres of irrigated land during the update. Urbanization accounted for more than half the decrease in Contra Costa County, while Solano County was affected by restoration projects in the south county (Liberty Island area) and land idling near Vacaville. Between 2000 and 2008, about 75,000 acres of agricultural land in the Delta were converted to urban and conservation uses. As of 2008, approximately 550,100 acres of Important Farmland were located in the Delta.

CVP/SWP Service Areas

Declines in Important Farmland in the CVP/SWP service areas have been similar to those discussed above for the lower Sacramento River and Delta. Urbanization was responsible for 77 percent (55,670 acres) of the total losses of Important Farmland in the CVP/SWP service areas between 2006 and 2008. Twenty-one percent of the newly developed land in the CVP/SWP service areas was located in Riverside County alone. Southern California led all regions with 50 percent of the developed acres, while the San Joaquin Valley ranked second at 27 percent of the total. Overall, both regions showed a decline in urbanization relative to the 2004–2006 period. Southern California's decrease was larger—24 percent compared to the 17-percent drop in urbanization in the San Joaquin Valley.

In addition, the San Joaquin Valley lost 66 percent of its irrigated farmland to long-term land idling in Fresno, Kings, and Kern counties. The Fresno County decrease—more than 56,000 acres—was particularly notable and is associated with salinity and drought-related land retirement on the west side of the valley.

10.1.3 Williamson Act

As of January 1, 2008, 16.6 million acres were enrolled under the Williamson Act statewide. (Figure 10-2 shows Williamson Act lands in the primary study area.) This represents approximately half of California's farmland and nearly one-third of its privately owned land. The nonrenewal process is the most common mechanism for terminating Williamson Act contracts. Nonrenewal trends may be seen as an indicator of likely farmland conversion in particular locations. Statewide, nonrenewal initiations have increased each year since 2001 and reached a new high in 2007, with the San Joaquin Valley accounting for the largest increase in nonrenewal initiations. Overall, a total of 520,550 acres of contracted land was at some stage of the nonrenewal process in 2008 (DOC 2009, 2010b).

10.1.4 Forest Land

Forest land is defined as native tree cover greater than 10 percent that allows for management of timber, aesthetics, fish and wildlife, recreation, and other public benefits (California Public Resources Code (PRC) Section 12220(g)). Natural forest and woodland vegetation types in the study area typically have greater than 10 percent cover by native trees. (Figures 12-2a through 12-2f in Chapter 12, "Botanical Resources and Wetlands," display the distribution of natural forest and woodland vegetation.)

Forests serve as high-quality habitat for fish and wildlife species, sequester carbon to mitigate effects of climate change, capture vital runoff for agricultural and domestic water supply, and provide a variety of outdoor recreation and education opportunities. Many rural communities depend on income and employment opportunities that result from working timber industries or on amenity values to attract new residents seeking a better lifestyle. In metropolitan areas, urban forests contribute to improved air quality, cooling of heat islands for energy conservation, and local employment (Cal Fire 2010).

This page left blank intentionally.

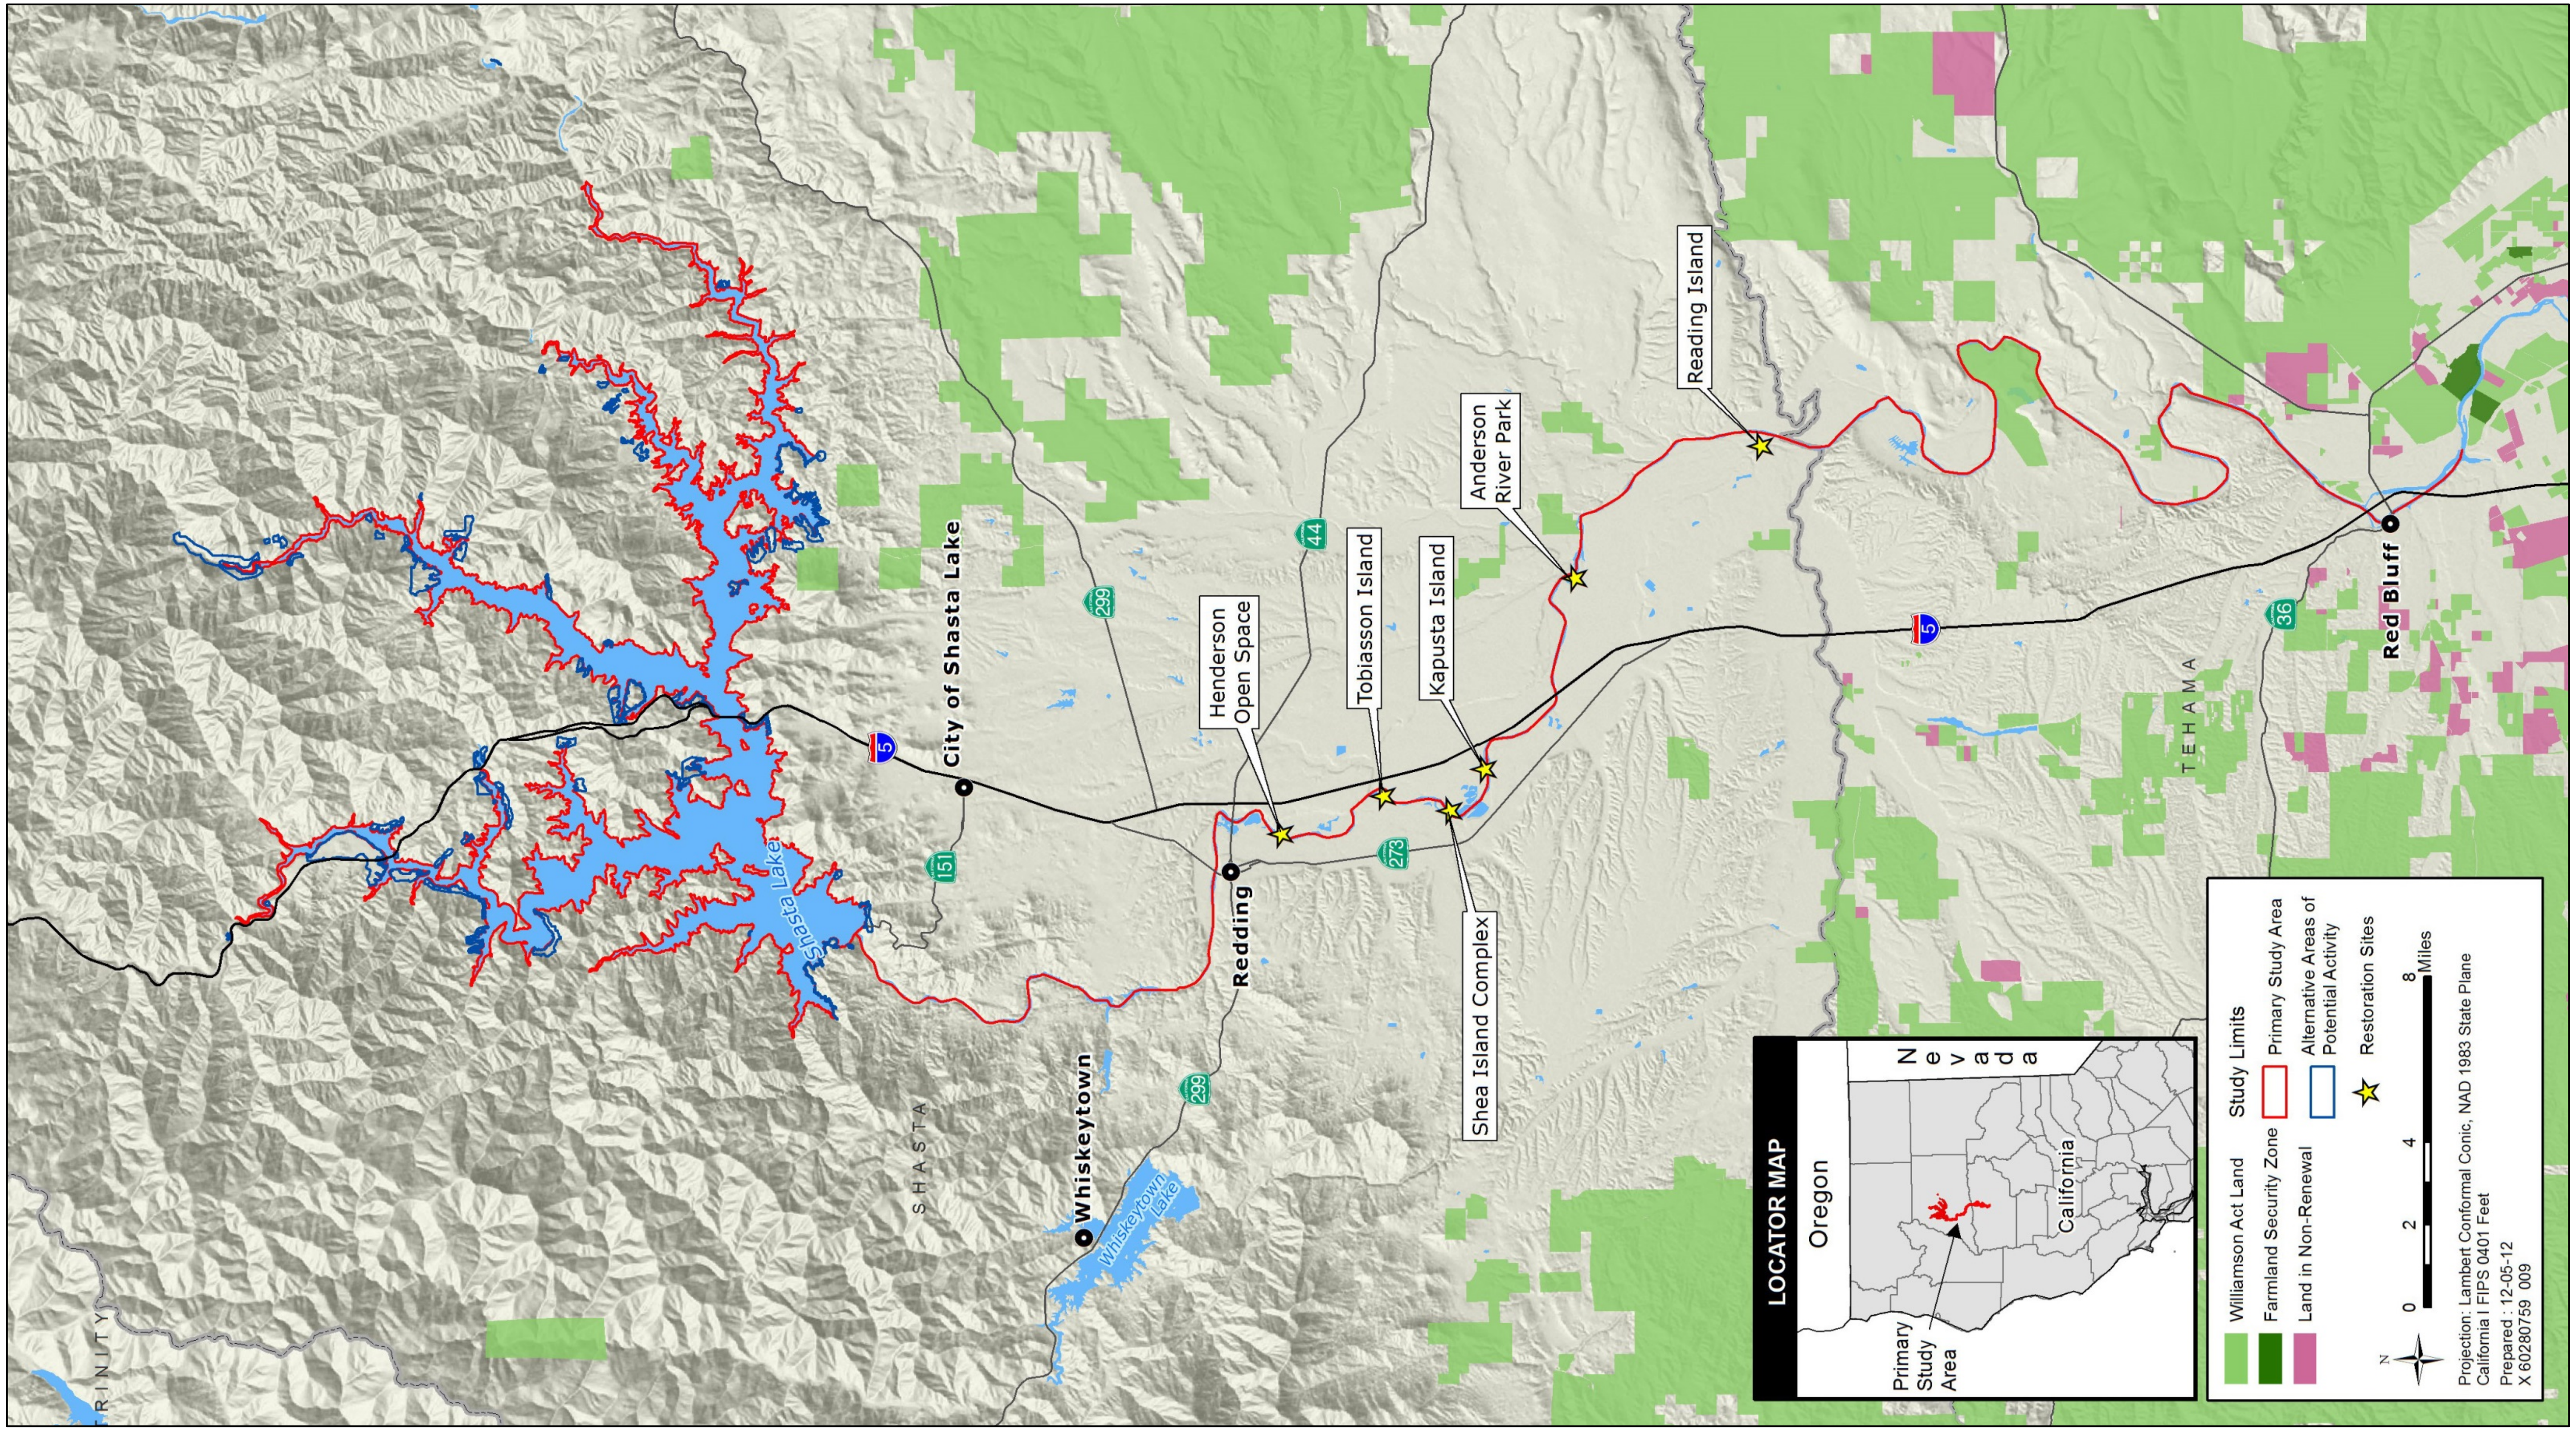

Figure 10-2. Williamson Act Lands in the Primary Study Area

This page left blank intentionally.

Shasta Lake and Vicinity

The study area for forest resources in the Shasta Lake and vicinity portion of the primary study area consists of the *impoundment areas* and the *relocation areas*. The impoundment areas are the areas that would be subject to inundation by the five arms and Main Body of Shasta Lake under the proposed dam enlargement scenarios. The relocation areas are those areas proposed as relocation sites for roadways, bridges, utilities, marinas, and campgrounds that could be inundated after the enlargement of Shasta Dam, as well as proposed dike locations.

The impoundment areas and relocation areas are characterized by a variety of forest lands typical of transitional mixed woodland and low-elevation forests: blue oak woodland, Brewer's oak, California black oak forest, canyon live oak forest, Fremont cottonwood forest, ghost pine woodland, interior live oak woodland, knobcone pine forest, Oregon white oak woodland, ponderosa pine-Douglas fir forest, ponderosa pine forest, and valley oak woodland (see Figures 12-2a through 12-2f and Table 12-1 in Chapter 12, "Botanical Resources and Wetlands"). As discussed in Chapter 12, "Botanical Resources and Wetlands," approximately 4,675 acres of forest land in the impoundment areas and relocation areas could potentially be affected by the alternatives (Table 10-4).

The exact combination of vegetation varies, with dramatic changes often occurring in relation to aspect, slope, geologic substrate, or juxtaposition with other habitats.

Table 10-4. Maximum Amount of Forest Land in the Impoundment and Relocation Areas

Forest Land	Area (Acres)
Blue oak woodland	11
Brewer oak scrub	151
California black oak forest	663
Canyon live oak forest	408
Fremont cottonwood forest	<1
Ghost pine woodland	456
Interior live oak woodland	6
Knobcone pine forest	293
Oregon white oak woodland	8
Ponderosa pine-Douglas fir forest	502
Ponderosa pine forest	2,176
Valley oak woodland	1
Total	**4,675**

Key:
< = less than

Upper Sacramento River (Shasta Dam to Red Bluff)

Forest land in the upper Sacramento River portion of the primary study area consists of riparian forest and oak woodland and savanna. Oak woodlands present in the primary study area include blue oak woodland, blue oak savanna, foothill pine-oak woodland, and valley oak woodland. Much of the Sacramento River from Shasta Dam to Redding is deeply entrenched in bedrock, which precludes development of extensive areas of riparian vegetation. The river corridor between Redding and Red Bluff, however, still maintains extensive areas of riparian forest communities.

Riparian plant communities present in the primary study area are located within the floodplain of the Sacramento River. These communities include Great Valley cottonwood riparian forest, Great Valley mixed riparian forest, and Great Valley valley oak riparian forest. Cottonwood- and willow-dominated riparian forest and woodland are present along active channels and on the lower flood terraces, whereas valley oak-dominated communities occur on higher flood terraces. In general, only narrow remnants of these riparian forests remain, often because levees are located close to river channels and the remaining riparian forest habitat is primarily confined to levee slopes. Riparian vegetation exists at Reading Island and some of the potential gravel augmentation sites.

Lower Sacramento River and Delta

Almost all of the forest land in the lower Sacramento River and Delta consists of riparian forests, including cottonwood-willow woodland and Valley oak riparian woodland. These areas are typically found in the lower Sacramento River and Delta as long, linear patches bordering waterways and agricultural or urban land. Riparian vegetation is most extensive on the water side of levees, but patches of riparian vegetation are also found on the interior of Delta islands along levee toes; along drainage channels; along pond margins; and in abandoned, low-lying fields. Forest land in riparian areas is managed primarily for habitat and water quality values, and to a lesser extent for recreation and other public benefits.

CVP/SWP Service Areas

Forest resources in the CVP/SWP service areas are similar to those discussed above for the upper Sacramento River and the lower Sacramento River and Delta. Agricultural and urban land uses have substantially reduced the area and connectivity of forest land in the CVP/SWP service areas. The region’s natural landscape changed substantially in the late 1800s and early 1900s as land uses were converted to agriculture. In Southern California, however, the land use pattern shifted more dramatically than in the Central Valley, as urban growth in the region that started in the 1900s began to convert large areas of forest land to developed land uses.

10.2 Regulatory Framework

10.2.1 Federal

Farmland Protection Policy Act

The Farmland Protection Policy Act is intended to minimize the effect of Federal programs with respect to the conversion of farmland to nonagricultural uses. It ensures that, to the extent possible, Federal programs are administered to be compatible with State, local, and private programs and policies to protect farmland. The U.S. Natural Resources Conservation Service (NRCS), part of the U.S. Department of Agriculture, is the agency primarily responsible for implementing the Farmland Protection Policy Act.

The Farmland Protection Policy Act established the Farmland Protection Program and the Land Evaluation and Site Assessment system. The Farmland Protection Program, a voluntary program administered by NRCS, provides funds to help purchase development rights to keep productive farmland in agricultural uses. The program provides matching funds to State, local, and tribal entities and nongovernmental organizations with existing farmland protection programs to purchase conservation easements. Participating landowners agree not to convert the land to nonagricultural uses and retain all rights to the property for future agriculture. A minimum 30-year term is required for conservation easements, and priority is given to applications with perpetual easements. NRCS provides up to 50 percent of the fair market value of the easement (NRCS 2006).

The Land Evaluation and Site Assessment system is a tool used to rank lands for suitability and inclusion in the Farmland Protection Program. The Land Evaluation and Site Assessment evaluates several factors: soil potential for agriculture, climate, location, market access, and adjacent land use. These factors are used to numerically rank land parcels based on local resource evaluation and site considerations (NRCS 2006).

10.2.2 State

California Important Farmland Inventory System and Farmland Mapping and Monitoring Program

DOC's Office of Land Conservation maintains a statewide inventory of farmlands, which are mapped by the DOC Division of Land Resource Protection as part of the FMMP. The FMMP was established by the State in 1982 to continue the Important Farmland mapping efforts begun in 1975 by the U.S. Soil Conservation Service (now called NRCS). The intent of the U.S. Soil Conservation Service was to produce agricultural-resource maps based on soil quality and land use across the nation. DOC sponsors the FMMP and is also responsible for establishing agricultural easements in accordance with PRC Sections 10250-10255. The maps are updated every 2 years with the use of aerial photographs, a computer mapping system, public review, and field reconnaissance.

As part of the nationwide effort to map agricultural land uses, the U.S. Soil Conservation Service/NRCS developed a series of definitions known as Land Inventory and Monitoring criteria. These criteria classify the land's suitability for agricultural production. Suitability includes both the physical and chemical characteristics of soils and the actual land use. Important Farmland maps are derived from NRCS soil survey maps using the Land Inventory and Monitoring criteria and are available by county. The maps prepared by NRCS classify land into one of eight categories, defined as follows (DOC 2011):

- **Prime Farmland –** Land that has the best combination of physical and chemical characteristics for crop production. This land has the soil quality, growing season, and moisture supply needed to produce sustained high yields of crops when treated and managed.

- **Farmland of Statewide Importance –** Land other than Prime Farmland that has a good combination of physical and chemical characteristics for crop production. This land has minor shortcomings, such as greater slopes or less ability to store soil moisture than Prime Farmland.

- **Unique Farmland –** Land that does not meet the criteria for Prime Farmland or Farmland of Statewide Importance, but that has been used for the production of specific crops with high economic value. This land is usually irrigated, but may include nonirrigated orchards or vineyards as found in some climatic zones in California.

- **Farmland of Local Importance –** Land that either is currently producing crops or has the capability of production, but does not meet the criteria of the categories above. Farmland of Local Importance is defined by each county's local advisory committee and adopted by its board of supervisors.

- **Grazing Land –** Land on which the vegetation is suited to the grazing of livestock. The minimum mapping unit for Grazing Land is 40 acres.

- **Urban and Built-up Lands –** Land occupied by structures with a density of at least one dwelling unit per 1.5 acres.

- **Land Committed to Nonagricultural Use –** Vacant areas; existing lands that have a permanent commitment to development but have an existing land use of agricultural or grazing lands.

- **Other Lands –** Land that does not meet the criteria of the remaining categories. This optional designation allows local governments to provide detail on the nature of changes expected to occur in the future.

Important Farmland is classified by DOC as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, or Farmland of Local Importance. The total acreages of Urban and Built-up Lands and Other Lands are calculated by DOC and are defined by DOC as agricultural land.

The designations for Prime Farmland, Farmland of Statewide Importance, Unique Farmland, and Farmland of Local Importance are defined together under the terms "Agricultural Land" and "Important Farmland" in CEQA (PRC Sections 21060.1 and 21095) and Appendix G of the State CEQA Guidelines. The conversion of these types of farmland could be considered an environmental impact.

Williamson Act Contracts

The California Land Conservation Act of 1965, commonly known as the Williamson Act, is the principal method for encouraging the preservation of agricultural lands in California. The Williamson Act enables local governments to enter into contracts with private landowners for the purpose of restricting specific parcels of land to agricultural or related open-space use for 10 years. In return, landowners receive property tax assessments that are based on farming and open-space uses as opposed to full market value. Local governments receive an annual subvention (subsidy) of forgone property tax revenues from the State via the Open Space Subvention Act of 1971.

The Williamson Act empowers local governments to establish "agricultural preserves" consisting of lands devoted to agricultural uses and other uses that are compatible with agriculture. Upon establishing such a preserve, the locality may offer to the owner of included agricultural land the opportunity to enter into an annually renewable contract that restricts the land to agricultural use for at least 10 years. (The contract continues to run for 10 years after the first date upon which the contract is not renewed.) In return, the landowner is guaranteed a relatively stable tax base, founded on the value of the land for agricultural/open space use only and unaffected by its development potential.

Canceling a Williamson Act contract involves an extensive review and approval process, in addition to payment of fees of up to 12.5 percent of the property value. The local jurisdiction approving the cancellation must find that the cancellation is consistent with the purpose of the California Land Conservation Act or is in the public interest. Several subfindings must be made to support either finding, as defined in Section 51282 of the California Government Code.

Farmland Security Zones

Farmland Security Zones (FSZ), also known as Super Williamson Act lands, were established by DOC with the same general intent as Williamson Act contracts. Agricultural landowners in FSZs may enter into contracts with the county for 20-year increments, with an additional 35 percent tax benefit over and above the standard Williamson Act contract. The FSZ program has been adopted by 25 counties, although not all of those counties have executed contracts. FSZ contracts constitute nearly 2 percent of statewide Williamson Act enrollment.

An FSZ must be located in an agricultural preserve (area designated as eligible for a Williamson Act contract) and designated as Prime Farmland, Farmland of Statewide Importance, Unique Farmland, or Farmland of Local Importance. Land protected in an FSZ cannot be annexed by a city or county government or school district.

An FSZ contract can be terminated through a nonrenewal or cancellation. The nonrenewal allows a rollout process to occur over the remainder of the term of the contract, when the tax rates would gradually rise to the full rate by the end of the 20-year term. A cancellation must be applied for and approved by the DOC director and must meet specific criteria. The cancellation must be in the public interest and consistent with Williamson Act criteria. If a cancellation is approved, fees equal to 25 percent of the full market value of the property must be paid.

Agricultural Water Management Plans

By the end of 2004, 62 water districts, 3 environmental interest groups, and more than 53 other interested groups had signed the Agricultural Water Management Memorandum of Understanding as members of the Agricultural Water Management Council. The agricultural signatories represent more than 4.75 million acres of irrigated agricultural land statewide.

In 2004, the council endorsed an additional three agricultural water management plans that had been submitted by agricultural water suppliers to the council. These plans have since become the basis for the districts' water conservation efforts. The districts with endorsed agricultural water management plans are expected to prepare and submit a biannual progress report to the Agricultural Water Management Council, starting from the date their plan was endorsed. DWR staff members provide technical review and evaluation of these plans. DWR also reviewed two biannual progress reports for the council. DWR staff also provided technical assistance to water districts to prepare water management plans and helped implement efficient water management practices, as well as administrative and programmatic assistance to both the Agricultural Water Management Council and water districts.

1992 Delta Protection Act

The 1992 Delta Protection Act identified the Delta as a natural resource of statewide significance, formalized the State's commitment to preserve its diverse values, and established the Delta Protection Commission. The purpose of the Delta Protection Act is to ensure protection, maintenance, and enhancement of the Delta environment; ensure orderly and balanced use of Delta land resources; and improve flood protection to increase public health and safety. The Delta Protection Commission has planning jurisdiction over portions of five counties: Contra Costa, Sacramento, San Joaquin, Solano, and Yolo.

In Section 29703a of the Delta Protection Act, the Delta Primary Zone is designated as an area for protection from intrusion of nonagricultural uses. In 1995, the Delta Protection Commission adopted its regional plan, *Land Use and Resource Management Plan for the Primary Zone of the Delta* (also known as the Delta Plan). The current Delta Plan was approved by the California Office of Administrative Law on October 7, 2010, and became effective November 6, 2010. Policies in the Delta Plan are developed to project the conversion of agricultural resources. Policy P-2 states that conversion of land to non-agriculturally oriented uses should occur first where productivity and agricultural values are lowest. Policy P-6 encourages acquiring agricultural conservation easements from willing sellers as mitigation for projects within each county. Use of environmental mitigation is to be promoted in agricultural areas only when it is consistent and compatible with ongoing agricultural operations and when developed in appropriate locations designated on a countywide or Deltawide habitat management plan (DPC 2010).

10.2.3 Regional and Local

Shasta and Tehama Counties

The general plans of Shasta and Tehama counties contain goals, policies, and implementation measures to protect agricultural lands, as summarized below.

Shasta County General Plan The *Shasta County General Plan* (Shasta County 2004) identifies goals, policies, and implementation measures aimed at conserving large contiguous areas of productive agricultural land, providing opportunities for the future expansion of such uses, and protecting them from development pressures that would adversely affect or hinder existing or future agricultural operations. This includes the objective to protect water resources and supply systems vital for the continuation of agriculture.

Tehama County General Plan The *Tehama County General Plan* (2009) encourages and supports agriculture and forest resources in Tehama County. The policies are within the Agriculture and Timber Element of the general plan and divided into the Land Use, Open Space and Conservation, and Economic Development elements to aid in implementation of the general plan, but focus on agriculture nonetheless.

Other

Sacramento River Conservation Area The Sacramento River Conservation Area seeks to promote the reestablishment of the 100-year floodplain along the Sacramento River. In 1986, the California Legislature passed Senate Bill 1086, which called for a management plan for the Sacramento River that would help restore, protect, and enhance the riparian and aquatic habitat. After much debate, the *Upper Sacramento River Fisheries and Riparian Habitat Management Plan* was developed (Resources Agency 1989). This plan called for fish bypass structures on the Sacramento River and its tributaries, as well as the Shasta Dam temperature control structure. After implementation of these projects began, the advisory council reconvened to complete additional work. This effort led to the *Sacramento River Conservation Area Handbook* (Resources Agency 2003), which would guide riparian habitat management along the river. In 1999, a memorandum of agreement was signed by most entities involved in management activities along the river. The U.S. Bureau of Land Management has acquired roughly 15,000 acres of riparian lands along the Sacramento River.

10.3 Environmental Consequences and Mitigation Measures

10.3.1 Methods and Assumptions

Implementation of the project would result in construction-related, maintenance-related, and operational impacts that could substantially affect agricultural and forest resources. This analysis evaluates potential construction-related and operational activities that could directly or indirectly affect existing agricultural and forest resources in the primary study area. Indirect impacts on the extended study area could result from alteration of flow regimes downstream from Shasta Lake and downstream from other reservoirs with altered operations, as well as increased inundation width of the Sacramento River during the growing season. In addition, water supply reliability in the CVP/SWP service areas could increase, which in turn could reduce limitations on growth and increase development that could adversely affect agricultural and forest resources.

Evaluation of the project's potential impacts on agricultural resources was based on a review of the planning documents pertaining to the study area, including goals and policies from the general plans of Shasta and Tehama counties. DOC's Important Farmland and Williamson Act maps were used to determine the agricultural significance of the lands in the primary study area. In addition, the results of CalSim-II simulations were reviewed to assess changes in flow regime in the primary and extended study areas.

Forest land that could be inundated or otherwise affected by implementation of any of the action alternatives was determined from vegetation mapping as described in Chapter 12, "Botanical Resources and Wetlands." These forest lands consist of blue oak-foothill pine, blue oak, and closed-cone pine-cypress woodlands; and Douglas-fir, montane hardwood, montane hardwood-conifer, montane riparian, Ponderosa pine, and valley-foothill riparian forests. The following analysis summarizes information provided in Chapter 12, "Botanical Resources and Wetlands," as it relates to the potential conversion of forest land to nonforest uses.

10.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on agriculture and Important Farmland would be significant if project implementation would do any of the following:

- Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance, as shown on the maps prepared pursuant to the FMMP of the Resources Agency, to nonagricultural use
- Conflict with existing zoning for agricultural use, or a Williamson Act contract
- Conflict with existing zoning for, or cause rezoning of, forest land (as defined in PRC Section 12220(g)), timberland (as defined in PRC Section 4526), or timberland zoned Timberland Production (as defined in PRC Section 51104(g))
- Result in the loss of forest land or conversion of forest land to nonforest use
- Involve other changes in the existing environment that, because of their location or nature, could result in conversion of farmland, to nonagricultural use or the conversion of forest land to nonforest use

10.3.3 Topics Eliminated from Further Consideration

None of the lands in the primary study area are zoned as forest land, timberland, or timberland zoned Timberland Production by the *Shasta County General Plan* (2004) or *Tehama County General Plan* (2009). Increasing water supply reliability within the lower Sacramento River to the Delta and within the CVP/SWP service areas would not conflict with existing zoning or directly result in the rezoning of forest land, timberland, or timberland zoned Timberland Production. Therefore, no effects related to conflicts with existing zoning or causing rezoning of forest land are expected to occur in the study area. Potential effects related to this issue area are not discussed further in this EIS.

10.3.4 Direct and Indirect Effects

No-Action Alternative

Under the No-Action Alternative, the existing Shasta Dam would be operated in the same manner as under current operations. Shasta Dam would not be enlarged and no infrastructure would be removed, modified, or relocated. Changes to the reservoir flow regime caused by changes in demand and other factors would be small, with a reduction in Shasta Lake storage of 2–4 percent during the fall of some years. Shasta Lake storage under the No-Action Alternative would be within -2 percent and 1 percent of existing Shasta Lake storage at most times.

Changes to the flow regime of the upper Sacramento River caused by changes in demand and other factors would be small under the No-Action Alternative; mean monthly flows in the Sacramento River would be within 5 percent of existing flows at most times. (Flows could increase by a greater amount during late summer and early fall of below-normal, dry, and critical years.)

In addition, Shasta Lake operations under the No-Action Alternative would not change the flow regime in the lower Sacramento River and Delta. If none of the project alternatives were implemented, CVP and SWP operations would likely continue under existing regulatory requirements. CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. Overall, CalSim-II modeling results suggest that only a very small decrease in flows greater than 15,000 cubic feet per second would occur.

Shasta Lake and Vicinity

Impact Ag-1 (No-Action): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No new facilities would be constructed at Shasta Lake and no operational changes would occur that would directly convert Important Farmland to nonagricultural uses or result in the cancellation of Williamson Act contracts in the vicinity of Shasta Lake. However, California's demand for water for irrigation and other uses is expected to continue to increase while the water supply will likely become less reliable. This trend could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts, resulting in an indirect impact. Therefore, this impact would be potentially significant.

Under the No-Action Alternative, Shasta Dam would not be enlarged; no infrastructure would be removed, modified, or relocated; and Reclamation's

Shasta operations would not change. Changes to the reservoir flow regime and reservoir storage caused by changes in demand and other factors would be small, and generally the same as under existing conditions at most times. Therefore, implementing the No-Action Alternative would not directly convert agricultural land to nonagricultural uses or result in the cancellation of Williamson Act contracts.

The demand for water for irrigation and other uses in California is expected to continue to increase in the future. At the same time, the water supply may become less reliable because of increasing environmental water requirements for special-status species, decreasing water quality, and climate change. Therefore, the No-Action Alternative could have an indirect, adverse impact on agricultural land uses and Important Farmland in the primary study area. Insufficient water supply, especially during drought periods, could indirectly lead to increased pressure on farmers to convert Important Farmland to other nonagricultural uses, or could cause land designated as Important Farmland to be fallowed. Additionally, the conversion of Important Farmland could involve cancellation or expiration of many Williamson Act contracts.

The magnitude and extent of the agricultural land that could be converted from changes in water supply is unknown; however, any loss of Important Farmland would be significant because there are no measures to fully mitigate the loss of Important Farmland. Based on a review of future demand projections used in CalSim-II modeling and estimated deliveries under the No-Action Alternative, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Ag-2 (No-Action): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake No new facilities would be constructed at Shasta Lake and no operational changes would occur that would result in the direct or indirect conversion of forest land to nonforest uses. No impact would occur.

Under the No-Action Alternative, Shasta Dam would not be enlarged; no infrastructure would be removed, modified, or relocated; and Reclamation's Shasta operations would not change. Changes to the reservoir flow regime and reservoir storage caused by changes in demand and other factors would be small and generally the same as under existing conditions at most times. Therefore, the No-Action Alternative would not result in the direct or indirect conversion to nonforest uses of blue oak-foothill pine, blue oak, and closed-cone pine-cypress woodlands; Douglas-fir, montane hardwood, montane hardwood-conifer, montane riparian, Ponderosa pine, and valley-foothill riparian forests; or other forest land. No impact would occur. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (No-Action): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Changes to the flow regime of the upper Sacramento River caused by changes in demand and other factors would be small under the No-Action Alternative; mean monthly flows in the Sacramento River would be within 5 percent of flows under existing conditions at most times. Implementing the No-Action Alternative would not directly convert Important Farmland to nonagricultural uses or result in the cancellation of Williamson Act contracts in the upper Sacramento River portion of the primary study area. However, California's demand for water for irrigation and other uses is expected to continue to increase while the water supply will likely become less reliable. This trend could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts, resulting in an indirect impact. Therefore, this impact would be potentially significant.

Changes to the flow regime of the upper Sacramento River resulting from changes in demand and other factors would be small under the No-Action Alternative; mean monthly flows in the Sacramento River would be within 5 percent of flows under existing conditions at most times. Therefore, implementing the No-Action Alternative would not directly convert agricultural land to nonagricultural uses or result in the cancellation of Williamson Act contacts.

California's demand for water for irrigation and other uses is expected to continue to increase in the future. At the same time, the water supply may become less reliable because of increasing environmental water requirements for special-status species, population growth that places further demands on existing water supply resources, decreasing water quality, and climate change. Therefore, the No-Action Alternative could have an indirect adverse impact on agricultural land uses and Important Farmland in the primary study area. Insufficient water supply, especially during drought periods, could indirectly lead to increased pressure on farmers to convert Important Farmland to other nonagricultural uses or cause land designated as Important Farmland to be fallowed. Additionally, conversion of Important Farmland could involve canceling many Williamson Act contracts or allowing such contracts to expire.

The magnitude and extent of the agricultural land that could be converted from changes in water supply is unknown; however, any loss of Important Farmland would be significant because there are no measures to fully mitigate the loss of Important Farmland. Based on a review of future demand projections used in CalSim-II modeling and estimated deliveries under the No-Action Alternative, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Ag-4 (No-Action): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River No operational changes would occur that would directly convert forest land to nonforest uses along the upper Sacramento River. However, water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. The resulting changes in the flow regime would likely result in minimal adverse effects on riparian forest and oak woodland habitats. Furthermore, management and restoration plans and programs would implement actions that would largely offset those adverse effects. Therefore, this impact would be less than significant.

Under the No-Action Alternative, no changes in Reclamation's Shasta operations would occur that would directly convert riparian and oak woodland habitats along the upper Sacramento River to nonforest uses. However, water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. As a consequence of these actions, the flow regime of the upper Sacramento River would change between 2005 and 2030. As described in Chapter 12, "Botanical Resources and Wetlands," this change in flow regime would likely result in minimal adverse effects on forest land, which along the upper Sacramento River consist of riparian forest and oak woodlands, and these effects would not be sufficient to alter the extent of these forest lands.

As also discussed in Chapter 12, several management and restoration plans and programs would be implemented under the No-Action Alternative. These actions would cause beneficial effects likely to be of a magnitude similar to or greater than the anticipated adverse effects of small changes in flow regime; thus, implementation of the plans and programs would largely offset those adverse effects. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (No-Action): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Changes to the flow regime of the lower Sacramento River, Delta, and CVP/SWP service areas caused by changes in demand and other factors would be small under the No-Action Alternative; mean monthly flows in the Sacramento River would be within 5 percent of flows under existing conditions at most times. Implementing the No-Action Alternative would not directly convert Important Farmland to nonagricultural uses or result in the cancellation of Williamson Act contracts along the lower Sacramento River, in the Delta, or in the CVP/SWP service areas. However, California's demand for water for irrigation and other uses is expected to continue to increase while the water supply will likely become less reliable. This trend could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts, resulting in an indirect impact. Therefore, this impact could be potentially significant.

This impact would be similar to Impact Ag-3 (No-Action) for the upper Sacramento River (Shasta Dam to Red Bluff). For the same reasons as described above for Impact Ag-3 (No-Action), this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Ag-6 (No-Action): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area No operational changes would occur under the No-Action Alternative that would directly convert forest land to nonforest uses in the extended study area. However, water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. The resulting changes in the flow regime would likely result in minimal adverse effects on forest land, which consists of riparian forest and oak woodlands along the lower Sacramento River and in the Delta. Management and restoration plans and programs would implement actions that would largely offset those adverse effects. Therefore, this impact would be less than significant.

This impact would be similar to Impact Ag-4 (No-Action) for the upper Sacramento River (Shasta Dam to Red Bluff). For the same reasons as described above for Impact Ag-4 (No-Action), this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

By increasing storage at Shasta Lake, this alternative would change the full pool elevation and seasonal pool elevations at Shasta Lake, and the flow regime downstream in the Sacramento River and potentially several other reservoirs and downstream waterways. By raising Shasta Dam 6.5 feet, CP1 would increase the height of the reservoir's full pool elevation by 8.5 feet, enlarge the total storage capacity in the reservoir by 256,000 acre-feet, and increase the reservoir's surface area at full pool by about 1,110 acres (4 percent). Areas at this elevation could be periodically inundated; existing facilities within the inundation zone would be relocated to higher areas to accommodate the periodic inundation. In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

Shasta Dam's operational guidelines would continue essentially unchanged, except during dry and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. Implementing CP1 would help reduce estimated future agricultural water shortages in the CVP/SWP service areas by increasing water supplies for agricultural deliveries by at least 22,500 acre-feet per year in dry and critical years and increasing average annual deliveries by about 20,300 acre-feet per year.

Potential impacts of CP1 on the upper Sacramento River's flow and stages and on deliveries of water supplies to the CVP/SWP service areas would be small. On average, in each month, changes in mean monthly flow relative to existing (2005) and No-Action Alternative (2030) conditions would be reductions or increases of about 5 percent or less. Generally, the relative magnitude of effects on river flows diminishes with distance downstream because of the influence of inflows from tributaries and the effects of diversions and flood bypasses.

Shasta Lake and Vicinity

Impact Ag-1 (CP1): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. Therefore, inundation of land and removal, modification, or relocation of infrastructure under CP1 would not directly or indirectly convert agricultural land to nonagricultural uses or result in the cancellation of Williamson Act contacts. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP1): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP1 would result in the conversion of forest land to nonforest uses. This impact would be significant.

A total of 1,032 acres of forest land would be affected by inundation under CP1 (Table 10-5). Also, up to 844 acres of land in the relocation areas would be affected by removal, modification, relocation, or inundation of roadways, bridges, utilities, and campgrounds under CP1 (Table 10-6); most of this acreage would be converted from forest land to nonforest uses. This impact would be significant. Mitigation for this impact is not proposed in Section 10.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Table 10-5. Acreage of Forest Land that Would Be Affected by Inundation Under CP1

Forest Land	Area (Acres)
Blue oak–foothill pine	10
Blue oak woodland	1
Closed-cone pine–cypress	247
Douglas-fir	<1
Montane hardwood	190
Montane hardwood–conifer	239
Ponderosa pine	345
Total	**1,032**

CP = Comprehensive Plan

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP1): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Agricultural lands in the upper Sacramento River portion of the primary study area, including Important Farmland and Williamson Act contract lands, could be inundated as a result of increases in mean monthly river flows. The flow increases that would occur in some years would generally be small (5 percent or less) and would affect areas periodically inundated under existing conditions or the No-Action Alternative. The effects of increased flows would diminish with distance downstream as tributary inflows, and the effects of diversions and flood bypasses, affect flows in the Sacramento River. CP1 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years.

Therefore, implementing CP1 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

Agricultural lands in the upper Sacramento River portion of the primary study area, including Important Farmland and Williamson Act contract lands, could be inundated or could undergo soil saturation as a result of project-related increases in mean monthly river flows. Based on CalSim-II model simulations, the flow increases that would occur in some years under CP1 would likely be small (5 percent or less) relative to existing (2005) and No-Action Alternative (2030) conditions. These increased flows would affect small areas periodically inundated under existing conditions or the No-Action Alternative. In addition, the effects would diminish with distance downstream because of the influence of inflows from tributaries and the effects of diversions and flood bypasses. As a result, implementing CP1 would not directly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts.

Implementing CP1 would increase the reliability of the water supply by increasing water supplies in the upper Sacramento River portion of the primary study area for irrigation purposes, primarily during dry and critical years. A substantial portion of this water would be used instead of groundwater, would allow for changes in agricultural irrigation practices, or would enable farmers to return idle cropland to production. Therefore, implementing CP1 would not indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP1): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River   Altered flow regimes associated with project implementation under CP1 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future. However, changes in the flow regime would not reduce the extent of riparian forest. Therefore, implementing CP1 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

Forest land along the upper Sacramento River consists of riparian forest and oak woodlands. These habitats could be affected by changes in river flow and stage in some years. In most years, changes in mean monthly flow would be reductions or increases of 5 percent or less. The areas affected would be areas periodically inundated under existing conditions and the No-Action Alternative. Generally, these effects diminish with distance downstream because of the influence of inflows from tributaries, and the effects of diversions and flood bypasses.

The altered flow regime of the upper Sacramento River associated with implementation of CP1 could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture. This effect would occur during years when mean monthly stage during March–October would differ from existing and No-Action Alternative conditions. Implementing CP1 could slightly increase the average elevation of the water surface in this zone (but would not increase the zone’s elevation range). Because of the important influence of water availability and soil aeration on plant growth and survival, these changes have the potential to result in the loss of oak woodlands. These effects are unclear, however, and may not all prove to be adverse.

The flow regime of a river or stream strongly influences the structure and species composition of riparian forests. Implementing CP1 would not alter the general annual pattern of flows but would reduce the magnitude, duration, and frequency of intermediate and large flows. Reductions in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River; however, changes in the flow regime would not reduce the extent of riparian forest.

For the reasons described above, implementing CP1 would not result in the conversion of forest land to nonforest uses. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Ag-5 (CP1): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Agricultural lands in the extended study area, including Important Farmland and Williamson Act contract lands, could be inundated or undergo soil saturation as a result of increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP1 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. Therefore, implementing CP1 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

Agricultural lands in the extended study area, including Important Farmland and Williamson Act contract lands, could experience more extensive inundation or soil saturation during some months as a result of project-related increases in mean monthly river flows. However, these increased flows would affect areas periodically inundated or saturated under existing conditions and/or the No-Action Alternative. In addition, the effects of inundation would diminish with distance downstream because of the influence of inflows from tributaries and the effects of diversions and flood bypasses. As a result, the direct conversion of agricultural land to nonagricultural uses or cancellation of Williamson Act contacts is unlikely to be substantial.

During dry and critical years, 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. Implementing CP1 would help reduce estimated future agricultural water shortages in the CVP/SWP service areas by increasing water supplies for agricultural deliveries by at least 22,500 acre-feet per year in dry and critical years and increasing average annual deliveries by about 20,300 acre-feet per year. The majority of increased dry and critical year water supplies would be for south-of-Delta agricultural deliveries. A substantial portion of this water would be used instead of groundwater, would allow for changes in agricultural irrigation practices, or would enable farmers to return idle cropland to production. Therefore, implementing CP1 would not indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts.

For the reasons described above, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP1): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP1 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future. However, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP1 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1) for the upper Sacramento River. For the same reasons as described above for Impact Ag-4 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, CP2 would increase storage at Shasta Lake, thus changing the reservoir's full pool elevation and seasonal pool elevations, and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

By raising Shasta Dam 12.5 feet, CP2 would increase the reservoir's full pool elevation by 14.5 feet and enlarge its total storage capacity by 443,000 acre-feet. Raising the dam 12.5 feet would increase the reservoir's surface area at full pool by about 1,900 acres (6 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

Shasta Dam's operational guidelines would continue essentially unchanged, except during dry and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. Implementing CP2 would help reduce estimated future agricultural water shortages in the CVP/SWP service areas by increasing water supplies for agricultural deliveries by at least 37,600 acre-feet per year in dry and critical years and increasing average annual deliveries by about 31,400 acre-feet per year.

In general, the proposed changes in flow and river stage on the upper Sacramento River associated with CP2 would be similar to but slightly greater than the changes associated with CP1, as outlined above.

Shasta Lake and Vicinity

Impact Ag-1 (CP2): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP2): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP2 would result in the conversion of forest land to nonforest uses. This impact would be significant.

A total of 1,440 acres of forest land would be affected by inundation under CP2 (Table 10-7). Also, up to 844 acres of land in the relocation areas would be affected by removal, modification, relocation, or inundation of roadways, bridges, utilities, and campgrounds under CP2 (Table 10-6); most of this acreage would be converted from forest land to nonforest uses. This impact would be significant. Mitigation for this impact is not proposed in Section 10.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Table 10-7. Acreage of Forest Land that Would Be Affected by Inundation Under CP2

Forest Land	Area (Acres)
Blue oak–foothill pine	15
Blue oak woodland	2
Closed-cone pine–cypress	343
Douglas-fir	<1
Montane hardwood	263
Montane hardwood–conifer	329
Ponderosa pine	488

< = less than
CP = Comprehensive Plan

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP2): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Agricultural lands in the upper Sacramento River portion of the primary study area, including Important Farmland and Williamson Act contract lands, could be inundated as a result of increases in mean monthly river flows. The flow increases that would occur in some years would generally be small and would affect areas periodically inundated under existing conditions or the No-Action Alternative. The effects of increased flows would diminish with distance downstream. CP2 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. Therefore, implementing CP2 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-3 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP2): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP2 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future. However, changes in the flow regime would not reduce the extent of riparian forest. Therefore, implementing CP2 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-4 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (CP2): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Agricultural lands in the extended study area, including Important Farmland and Williamson Act contract lands, could be inundated or undergo soil saturation as a result of increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP2 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. Therefore, implementing CP2 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-5 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. In addition, CP2 would include reserving more storage capacity in Shasta Reservoir to specifically focus on increasing M&I deliveries during dry and critical years and a greater volume of dry and critical year and average annual water supply for agricultural water deliveries for the CVP/SWP service areas. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP2): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP2 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future. However, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP2 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to but slightly greater than Impact Ag-6 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

Like both of the alternatives discussed above, CP3 would increase storage at Shasta Lake, thus changing the reservoir's full pool elevation and seasonal pool elevations and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

By raising Shasta Dam 18.5 feet, CP3 would increase the reservoir's full pool elevation by 20.5 feet and enlarge its total storage capacity by 634,000 acre-feet. Raising the dam 18.5 feet would increase the reservoir's surface area at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

Implementing CP3 would increase water supply reliability by increasing dry and critical year water supplies for CVP irrigation deliveries. None of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. However, CP3 would help reduce estimated future water shortages for CVP agricultural water users by increasing the reliability of water supplies for agricultural deliveries by at least 70,600 acre-feet per year in dry and critical years and increasing average annual deliveries by about 62,200 acre-feet per year.

In general, the changes in flow and river stage on the upper Sacramento River associated with CP3 would be more substantial than the changes associated with CP1 and CP2. However, these anticipated changes would still be within a few percentage points of the changes associated with CP1 and CP2, as outlined above.

Shasta Lake and Vicinity

Impact Ag-1 (CP3): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP3): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP3 would result in the conversion of forest land to nonforest uses. This impact would be significant.

A total of 2,069 acres of forest land would be affected by inundation under CP3 (Table 10-8). Also, up to 844 acres of land in the relocation areas would be affected by removal, modification, or relocation of infrastructure under CP3 (Table 10-6); most of this acreage would be converted from forest land to nonforest uses. This impact would be significant. Mitigation for this impact is not proposed in Section 10.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Table 10-8. Acreage of Forest Land that Would Be Affected by Inundation Under CP3

Forest Land	Area (Acres)
Blue oak–foothill pine	17
Blue oak woodland	7
Closed-cone pine–cypress	485
Douglas-fir	<1
Montane hardwood	376
Montane hardwood–conifer	481
Ponderosa pine	703
Total	**2,069**

Key:
< = less than
CP = Comprehensive Plan

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP3): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Agricultural lands in the upper Sacramento River portion of the primary study area, including Important Farmland and Williamson Act contract lands, could be inundated as a result of increases in mean monthly river flows. The flow increases that would occur in some years would generally be small (5 percent or less) and would affect areas periodically inundated under existing conditions or the No-Action Alternative. The effects of increased flows would diminish with distance downstream. CP3 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. Therefore, implementing CP3 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-3 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because alteration of the flow regime of the Sacramento River would be greater. This impact

would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP3): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP3 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future. However, changes in the flow regime would not reduce the extent of riparian forest. Therefore, implementing CP3 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because alteration of the flow regime of the Sacramento River would be greater. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (CP3): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Agricultural lands in the extended study area, including Important Farmland and Williamson Act contract lands, could be inundated or undergo soil saturation as a result of increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP3 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes primarily during dry and critical years. Therefore, implementing CP3 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-5 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because alteration of the flow regime of the Sacramento River would be greater. In addition, CP3 would not include reserving storage capacity in Shasta Reservoir for increasing M&I deliveries during dry and critical years. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP3): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP3 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future. However, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP3 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-6 (CP1); however, the extent of the impact would be greater under CP3 than under CP1 and CP2 because alteration of the flow regime of the Sacramento River would be greater. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Like each of the alternatives discussed above, CP4 or CP4A would increase storage at Shasta Lake, thus changing the reservoir's full pool elevation and seasonal pool elevations, and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

As under CP3, raising Shasta Dam 18.5 feet under CP4 or CP4A would increase the reservoir's full pool elevation by 20.5 feet and enlarge the reservoir's total storage capacity by 634,000 acre-feet. Raising the dam 18.5 feet would increase the reservoir's surface area at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years. CP4A is identical to CP4 with the exception of Shasta Dam and reservoir operations. CP4 and CP4A have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for fisheries purposes; however, the portion of this dedicated storage varies.

Approximately 378,000 acre-feet of the increased reservoir storage space of CP4 would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. For CP4, operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1, with 70,000 acre-feet reserved in dry years and 35,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries. Water supply reliability under CP4 would be the same as under CP1. Implementing CP4 would help reduce estimated future agricultural water shortages in the CVP/SWP service areas by increasing water supplies for agricultural deliveries by at least 22,500 acre-feet per year in dry and critical years and increasing average annual deliveries by about 20,300 acre-feet per year.

Similarly, approximately 191,000 acre-feet of the increased reservoir storage space of CP4A would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. For CP4A, operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2, with 120,000 acre-feet reserved in dry years and 60,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries. Water supply reliability under CP4A would be the same as under CP2. Implementing CP4A would help reduce estimated future agricultural water shortages in the CVP/SWP service areas by increasing water supplies for agricultural deliveries by at least 37,600 acre-feet per year in dry and critical years and increasing average annual deliveries by about 31,400 acre-feet per year.

The changes in flow and river stage on the upper Sacramento River associated with CP4 would be the same as the changes associated with CP1. The changes in flow and river stage on the upper Sacramento River associated with CP4A would be the same as the changes associated with CP2. CP4 and CP4A also would involve augmenting spawning gravel and restoring riparian, floodplain, and side-channel habitat at up to six potential locations in the upper Sacramento River.

Shasta Lake and Vicinity

Impact Ag-1 (CP4 and CP4A): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1) for CP4. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact Ag-1 (CP2) for CP4A. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP4 and CP4A): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP4 or CP4A would result in the conversion of forest land to nonforest uses. This impact would be significant for CP4 or CP4A.

This impact would be the same as Impact Ag-2 (CP3) and would be significant for CP4. Mitigation for this impact is not proposed in Section 10.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

This impact would be the same as Impact Ag-2 (CP3) and would be significant for CP4A. Mitigation for this impact is not proposed in Section 10.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Ag-3 (CP4 and CP4A): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Agricultural lands in the upper Sacramento River portion of the primary study area, including Important Farmland and Williamson Act contract lands, could be inundated as a result of increases in mean monthly river flows. The flow increases that would occur in some years would generally be small (5 percent or less) and would affect areas periodically inundated under existing conditions or the No-Action Alternative. The effects of increased flows would diminish with distance downstream. Both CP4 and CP4A would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. In addition, there is no Important Farmland or Williamson Act contract land in the area proposed for gravel augmentation or within any of the potential restoration areas. Therefore, implementing CP4 or CP4A would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Ag-3 (CP1) for CP4. This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to but slightly greater than Impact Ag-3 (CP1), because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP4 and CP4A): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP4 or CP4A could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future. However, changes in the flow regime would not reduce the extent of riparian forest. Therefore, the implementation of CP4 or CP4A would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1) for CP4 and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to but slightly greater than Impact Ag-4 (CP1) for CP4, because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact Ag-5 (CP4 and CP4A): Direct and Indirect Conversion of Important Farmland and Cancellation of Williamson Act Contracts to Nonagricultural Uses in the Extended Study Area Agricultural lands in the extended study area, including Important Farmland and Williamson Act contract lands, could be inundated or undergo soil saturation as a result of increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP4 and CP4A would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. Therefore, the implementation of CP4 or CP4A would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Ag-5 (CP1) for CP4 and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to but slightly greater than Impact Ag-5 (CP1) for CP4A, because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. In addition, CP2 would include reserving more storage capacity in Shasta Reservoir to specifically focus on increasing M&I deliveries during dry and critical years and a greater volume of dry and critical year and average annual water supply for agricultural water deliveries for the CVP/SWP service areas. Therefore, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP4 and CP4A): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP4 or CP4A could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future. However, changes in flow regime would not reduce the extent of riparian forest. Therefore, the implementation of CP4 or CP4A would not result in the conversion of forest land to nonforest uses. This impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Ag-6 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to but slightly greater than Impact Ag-6 (CP1) for CP4A, because alteration of the flow regime of the Sacramento River would be slightly greater under CP2 than under CP1. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Like each of the alternatives discussed above, CP5 would increase storage at Shasta Lake, thus increasing the reservoir's full pool elevation and seasonal pool elevations and changing the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways.

As under CP3, raising Shasta Dam 18.5 feet under CP5 would increase the reservoir's full pool elevation by 20.5 feet and enlarge its total storage capacity by 634,000 acre-feet. Raising the dam 18.5 feet would increase the reservoir's surface area at full pool by about 2,570 acres (9 percent). In general, the effect of this increase would be slight, given that the reservoir would exceed the current full pool elevation only during wetter-than-normal years.

Shasta Dam's operational guidelines would continue essentially unchanged, except during dry and critical years, when 150,000 acre-feet and 75,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. Implementing CP5 would help reduce estimated future agricultural water shortages in the CVP/SWP service areas by increasing water supplies for agricultural deliveries by at least 66,100 acre-feet per year in dry and critical years and increasing average annual deliveries by about 50,900 acre-feet per year. Of all the alternatives, CP5 would provide the greatest water supply reliability for the CVP/SWP service areas and the largest amount of storage capacity reserved for increasing M&I deliveries. CP5 also would involve augmenting spawning gravel and restoring riparian, floodplain, and side-channel habitat at up to six potential locations in the upper Sacramento River. CP5 would also involve constructing additional fish habitat in and along the shoreline of Shasta Lake and along the lower reaches of its tributaries and increasing recreation opportunities at Shasta Lake.

Shasta Lake and Vicinity

Impact Ag-1 (CP5): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Vicinity of Shasta Lake No lands adjacent to Shasta Lake or in the immediate vicinity above Shasta Dam are designated by DOC as Important Farmland or under Williamson Act contracts. No impact would occur.

This impact would be the same as Impact Ag-1 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-2 (CP5): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Vicinity of Shasta Lake Inundation of land and removal, modification, or relocation of infrastructure under CP5 would result in the conversion of forest land to nonforest uses. This impact would be significant.

This impact would be similar to Impact Ag-2 (CP3) and would be significant. Mitigation for this impact is not proposed in Section 10.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Ag-3 (CP5): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts Along the Upper Sacramento River Agricultural lands in the upper Sacramento River portion of the primary study area, including Important Farmland and Williamson Act contract lands, could be inundated as a result of increases in mean monthly river flows. The flow increases that would occur in some years would generally be small (5 percent or less) and would affect areas periodically inundated under existing conditions or the No-Action Alternative. The effects of increased flows would diminish with distance downstream. CP5 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. There is no Important Farmland or land under Williamson Act contract within the areas proposed for gravel augmentation, restoration, and improvements to recreational facilities. Therefore, implementing CP5 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-3 (CP1). In addition, none of the land in the areas proposed for gravel augmentation, restoration areas, and recreational facility improvements are Important Farmland or Williamson Act contract lands. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-4 (CP5): Direct and Indirect Conversion of Forest Land to Nonforest Uses Along the Upper Sacramento River Altered flow regimes associated with project implementation under CP5 could adversely affect forest land along the upper Sacramento River. The altered flow regime could affect oak woodland communities by prolonging inundation and changing the availability of soil moisture; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of forests in the riparian corridor along the upper Sacramento River in the future. However, changes in the flow regime would not reduce the extent of riparian forest.

Therefore, implementing CP5 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact Ag-5 (CP5): Direct and Indirect Conversion of Important Farmland to Nonagricultural Uses and Cancellation of Williamson Act Contracts in the Extended Study Area Agricultural lands in the extended study area, including Important Farmland and Williamson Act contract lands, could be inundated for undergo soil saturation as a result of increased mean monthly river flows. Increases in Sacramento River stage (elevation) would be small. These increased flows would affect areas periodically inundated or saturated under existing conditions or the No-Action Alternative. The effects of this inundation would diminish with distance downstream. CP5 also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. Therefore, implementing CP5 would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant.

This impact would be similar to Impact Ag-5 (CP1); however, CP5 would provide the greatest water supply reliability for the CVP/SWP service areas and the largest amount of storage capacity in Shasta Reservoir reserved to focus on increasing M&I deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Ag-6 (CP5): Direct and Indirect Conversion of Forest Land to Nonforest Uses in the Extended Study Area Altered flow regimes associated with project implementation under CP5 could adversely affect riparian forest and oak woodlands. The altered flow regime could affect oak woodlands by prolonging inundation and changing soil moisture in some years; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forests along the upper Sacramento River in the future. However, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing CP5 would not result in the conversion of forest land to nonforest uses. This impact would be less than significant.

This impact would be similar to Impact Ag-6 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

10.3.5 Mitigation Measures

Table 10-9 presents a summary of mitigation measures for agricultural and forest resources.

No-Action Alternative

Under the No-Action Alternative, no action would be taken, including implementation of mitigation measures; rather, existing conditions would continue to change into the future. No mitigation measures are required for the No-Action Alternative. Thus, Impacts Ag-1 (No-Action), Ag-3 (No-Action), and Ag-5 (No-Action) would be significant and unavoidable.

Table 10-9. Summary of Mitigation Measures for Agriculture and Important Farmland

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/CP4A	CP5

Key:
CP = Comprehensive Plan
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
S = significant
SU = significant and unavoidable

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impact Ag-1 (CP1) or for Impacts Ag-3 (CP1) through Ag-6 (CP1). No feasible mitigation measures are available at the time of preparation of this EIS to reduce Impact Ag-2 (CP1) to a less-than-significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP1) would be significant and unavoidable.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impact Ag-1 (CP2) or for Impacts Ag-3 (CP2) through Ag-6 (CP2). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this EIS to reduce Impact Ag-2 (CP2) to a less-than-significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP2) would be significant and unavoidable.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation is required for Impact Ag-1 (CP3) or for Impacts Ag-3 (CP3) through Ag-6 (CP3). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this EIS to reduce Impact Ag-2 (CP3) to a less-than-significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP3) would be significant and unavoidable.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for Impact Ag-1 (CP4 and CP4A) or for Impacts Ag-3 (CP4 and CP4A) through Ag-6 (CP4 and CP4A). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this EIS to reduce Impact Ag-2 (CP4 and CP4A) to a less-than-significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP4 and CP4A) would be significant and unavoidable.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impact Ag-1 (CP5) or for Impacts Ag-3 (CP5) through Ag-6 (CP5). As discussed above for CP1, no feasible mitigation measures are available at the time of preparation of this EIS to reduce Impact Ag-2 (CP5) to a less-than-significant level (i.e., to mitigate conversion of forest land to nonforest uses in the vicinity of Shasta Lake). Therefore, Impact Ag-2 (CP5) would be significant and unavoidable.

10.3.6 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria.. Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," in Chapter 3, lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level.

Past and present impacts on agriculture and forest lands are from changes in land use, oversubscription of surface and groundwater supplies, economic drivers, pests and disease, and wildland fires. All of the projects listed in Table 3-1 under Quantitative Analysis, would affect agriculture in the future, some beneficially, some adversely, and some both beneficially and adversely. These projects affect agriculture by altering water supplies available for agricultural uses, either directly or indirectly. However, because the SLWRI would improve agricultural water supplies, none of the action alternatives would contribute to a cumulative impact on agricultural resources in the primary or extended study area. Also, none of the projects listed in Table 3-1 under Quantitative Analysis, would have an adverse effect on forest resources, therefore there would be no quantitative cumulative impact on these resources from any of the action alternatives.

The projects listed in Table 3-1 for Qualitative Analysis also both benefit and adversely affect agricultural and forest land resources through alteration of waters supplies and converting agricultural land to other land uses. Example projects include, but are not limited to North Delta Flood Control and Ecosystem Restoration Project, Bay-Delta Conservation Plan, Dutch Slough Tidal Marsh Restoration Project, In-Delta Storage Program, and San Luis Drainage Reevaluation Program. California's demand for water for irrigation and other uses is expected to continue to increase, while the water supply will likely become less reliable. Future implementation of the related projects considered in this analysis of cumulative impacts would convert agricultural land, including Important Farmland, to nonagricultural uses. With or without implementation of the proposed action, the significant cumulative losses of agricultural resources, including Important Farmland, that have occurred in the primary and extended study areas from past projects—and that would continue as a result of planned future projects—are considerable.

Agricultural lands in the upper Sacramento River portion of the primary study area and in the extended study area, including Important Farmland and

Williamson Act contract lands, could be inundated as a result of increases in mean monthly river flows under any of the project alternatives. The flow increases that would occur in some years would generally be expected to be small (5 percent or less) and would affect areas periodically inundated under existing conditions or the No-Action Alternative. The effects of increased flows would diminish with distance downstream. Any of the project alternatives also would increase the reliability of the water supply by increasing water supplies for irrigation purposes, primarily during dry and critical years. Therefore, implementing any of the project alternatives would not directly or indirectly result in the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts. This impact would be less than significant. Implementation of any of the project alternatives would not result in a considerable incremental contribution to a cumulatively significant impact associated with the conversion of Important Farmland to nonagricultural uses or the cancellation of Williamson Act contracts.

No operational changes would occur that would directly convert forest land to nonforest uses along the upper Sacramento River. However, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlargement of Shasta Dam. The resulting changes in flow regime would likely result in minimal adverse effects on riparian forest and oak woodlands. Several management and restoration plans and programs would implement actions that would largely offset those adverse effects. Although there would be reasonably foreseeable projects that would restore forest land or put land into agricultural production, there would be an overall significant cumulative effect on Important Farmlands and forest lands. The effects of climate change on operations at Shasta Lake could potentially cause changes in conditions for agricultural land and forest land in downstream areas. As described in the Climate Change Modeling Appendix, climate change could affect future demand for agricultural water by leading to increased rates of evapotranspiration and increasing the length of the growing season. On the other hand, increased precipitation could decrease overall water demand, depending on which adaptation strategies are used by agriculture and municipalities and how much more efficiently plants use water when carbon dioxide concentrations are higher. Crop types, planting cycles, time of planting, and crop productivity may change as a result of climate change, although a consensus has not been reached on how changes will occur. As stated previously in this section, increases in California’s demand for water and forecast reductions in water supply could lead to increased pressure to convert Important Farmland to other nonagricultural uses and cancel Williamson Act contracts.

In addition, changes to forest land and land cover could affect climate change. As stated in the Climate Change Modeling Appendix, deforestation and land cover conversion have also been identified as contributing to global warming by reducing the Earth’s capacity to remove carbon dioxide from the air and altering the Earth's albedo or surface reflectance, allowing more solar radiation to be absorbed.

In the primary study area, forest land would be affected by inundation of land and removal, modification, or relocation of infrastructure in the vicinity of Shasta Dam. Implementing any of the project alternatives (CP1–CP5) would result in the conversion of forest land to nonforest uses in the vicinity of Shasta Dam. No feasible mitigation exists to create a similar area of forest land to replace the area of forest land that would be inundated or converted to nonforest uses by relocation of facilities. Although reforestation could occur at a small scale over hundreds of years, the acreage of forest land converted to nonforest uses, including by reservoir inundation, is too large of a scale for successful and feasible reforestation. Therefore, implementing any of the project alternatives would result in a cumulatively considerable incremental contribution to a cumulative impact related to conversion of forest land to nonforest uses. However, most of this area remains substantially in forest land and has not been converted to nonforest uses. Therefore, the overall impact would not be cumulatively significant.

In the extended study area, altered flow regimes associated with implementation of any of the project alternatives could affect forest land. The altered flow regime could affect oak woodlands by prolonging inundation and changing the availability of soil moisture in some years; however, these effects are unclear and may not all prove to be adverse. Changes in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian forest along the upper Sacramento River in the future. However, changes in flow regime would not reduce the extent of riparian forest. Therefore, implementing any of the project alternatives would not result in the conversion of forest land to nonforest uses. Therefore, the project alternatives would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to conversion of forest land to nonforest uses.

As stated previously, climate change could result in changes to conditions for agricultural land and forest land in downstream areas. However, implementing any of the project alternatives would promote improvements in the reliability of CVP water supply deliveries. Thus, the project alternatives would not result in a cumulatively considerable incremental contribution to a significant cumulative impact related to future demands for, and availability of, agricultural water.

Implementing any of the project alternatives would result in a cumulatively considerable incremental contribution to a cumulative impact related to conversion of forest land to nonforest uses. However, most of this area remains substantially in forest land and has not been converted to nonforest uses. Thus, when added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect on climate change resulting from changes to forest land and land cover.

Chapter 11
Fisheries and Aquatic Ecosystems

11.1 Affected Environment

This section describes the affected environment related to fisheries and aquatic ecosystems for the dam and reservoir modifications proposed under SLWRI action alternatives. For a more in-depth description of the affected environment, see the *Fisheries and Aquatic Ecosystems Technical Report*.

11.1.1 Aquatic Habitat

Shasta Lake and Vicinity

Water resources development, including the construction of dams and diversions, has affected the hydrology, geomorphology, and ecology of the watershed. Before the construction of Shasta Dam, the Sacramento River typically experienced large fluctuations in flow driven by winter storms, with late-summer flows averaging 3,000 cubic feet per second (cfs) or less. These fluctuations and periodic flows moved large amounts of sediment and gravel out of the mountainous tributaries and down the Sacramento River. The completion of Shasta Dam in 1945 resulted in general dampening of historic high and low flows, reducing the timing, magnitude, and duration of winter floods while maintaining higher summer flows between 7,000 and 13,000 cfs. The annual volume of flow in the Sacramento River continues to vary significantly from year to year. However, average monthly flows following the construction of Shasta Dam no longer exhibit pronounced seasonal winter highs and summer lows. This is primarily because of winter flood control operations that have reduced peak flood flows, and summer releases made for water supply purposes.

The current composition and distribution of fish species inhabiting the study area reflect habitat conditions, the historic fishery, the operational effects of Shasta Dam, effects of dams on several of the upstream tributaries, and the introduction of nonnative species.

The distribution and productivity of organisms and aquatic habitats of Shasta Lake are greatly affected by the reservoir's dynamic seasonal surface elevation fluctuations and thermal stratification. The reservoir's flood control, water storage, and water delivery operations typically result in declining water elevations during the summer through the fall months, rising or stable elevations during the winter months, and rising elevations during the spring months and sometimes into the early-summer months, while storing precipitation and snowmelt runoff. During summer months, the relatively warm surface layer within the lake favors warm-water fishes such as bass and catfish. Deeper layers are cooler and are suitable for cold-water species. Shasta Lake is classified as a cool-water, mesotrophic, monomictic reservoir because it is moderately productive and has one period of mixing each year, although it never completely turns over (Bartholow et al. 2001). Shasta Lake tributary fish species comprise several native and nonnative species and have been managed to favor naturally produced ("wild") and stocked (hatchery-cultured) native and nonnative trout species (Rode 1989, Moyle 2002, Rode and Dean 2004). Major assemblages of non-fish aquatic animal species include benthic macroinvertebrates and zooplankton communities. Climate conditions and reservoir storage volume are the two most influential factors affecting cold-water habitat and primary productivity in Shasta Lake (Bartholow et al. 2001). Cold-water habitat provided by Shasta Lake is a function of the total storage and associated surface area provided by Shasta Lake. This relationship is influenced by variation in the water surface elevation (WSEL) throughout the year. Variation in WSEL is a function of water demand, water quality requirements, and inflow, and WSEL can change based on the water year type.[1] Typically, primary production in reservoirs is associated with storage volumes when all other factors are held constant (Stables et al. 1990). Increased storage and the corresponding increase in surface area results in a greater total biomass and a greater abundance of plankton and fish, because available habitat area is increased.

Upper Sacramento River (Shasta Dam to Red Bluff)

The reach of the Sacramento River between Shasta Dam and Red Bluff has cool water temperatures because releases from Shasta and Keswick dams are regulated, and because the channel is stable and largely confined, with little meander. Riffle habitat with gravel substrates and deep pool habitats are more abundant than in reaches downstream, although they are still insufficient to support healthy salmonid populations. Immediately below Keswick Dam, the river is deeply incised in bedrock, with very limited riparian vegetation and limited functioning riparian ecosystems. Water temperatures are generally cool even in late summer because of the regulated dam releases. The reaches of the Sacramento River immediately downstream from Shasta Dam support populations of resident rainbow trout and other resident fish while the reach immediately downstream from Keswick Dam supports an abundant resident rainbow trout population, other resident fish, and provides holding habitat, spawning habitat, and juvenile rearing habitat for Chinook salmon (*Oncorhynchus tshawytscha*) and steelhead (*O. mykiss*).

Near Redding, the river flows into the valley and the floodplain broadens. Historically, this area appears to have had wide expanses of riparian forests, but

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

much of the river's riparian zone is currently subject to urban encroachment and noxious-weed problems. This encroachment becomes quite extensive in the Anderson/Redding area, with homes placed directly within or adjacent to the riparian zone.

Despite net losses of gravel since construction of Shasta Dam, substrates in much of this reach contain gravel needed for spawning by salmonids. This gravel is derived mostly from the Central Valley Project Improvement Act (CVPIA) gravel augmentation program. This reach provides much of the remaining spawning and rearing habitat of several listed anadromous salmonids (i.e., species that spawn in freshwater after migrating as adults from marine habitat). The Livingston Stone Hatchery, located immediately downstream from Shasta Dam produces winter-run Chinook salmon while the Coleman National Fish Hatchery, located on Battle Creek at tributary to the Sacramento River downstream from Keswick Dam, produces both Chinook salmon and steelhead. The reach of the Sacramento River downstream from Keswick Dam provides spawning and juvenile rearing habitat for winter-run, spring-run, fall-run, and late fall-run Chinook salmon and Central Valley steelhead. For this reason, the Sacramento River between Shasta Dam and Red Bluff is one of the most sensitive and important stream reaches in California.

Three water control structures – Keswick Dam, the Anderson-Cottonwood Irrigation District Dam, and Red Bluff Pumping Plant (RBPP) – are located along the Sacramento River in this reach. A new state-of-the-art positive barrier fish screen for the RBPP was completed in 2012. The fish screen allows the Red Bluff Diversion Dam gates to remain open most of the year to facilitate upstream and downstream passage by adult and juvenile Chinook salmon, steelhead, sturgeon, and other fish. A temperature control structure has been installed at Shasta Dam to improve cold-water pool management for salmonids spawning and rearing in the main stem river downstream from Keswick Dam. Instream flow regulation to meet habitat requirements and seasonal water temperatures for salmonids and other fish, flood control, and water supply deliveries are controlled primarily through managed releases of water from Shasta Dam that subsequently pass downstream through Keswick Dam into the main stem Sacramento River.

The main tributaries to the Sacramento River between Shasta Dam and Red Bluff are Battle, Bear, Clear, Cow, and Cottonwood creeks. The primary land uses along the Sacramento River between Shasta Dam and RBPP are urban, residential, and agricultural.

Lower Sacramento River and Delta

The roughly 300 miles of the Sacramento River can be subdivided into distinct reaches. The reaches in the lower Sacramento River and Delta area are discussed separately because of differences in morphology, water temperature, and aquatic habitat functions.

Sacramento River from Red Bluff to Colusa In this reach, the Sacramento River functions as a large alluvial river with active meander migration through the valley floor. The river is classified as a meandering river, where relatively stable, straight sections alternate with more sinuous, dynamic sections (Resources Agency 2003). The active channel is fairly wide in some stretches and the river splits into multiple braided channels at many different locations, creating gravel islands, often with riparian vegetation. Historic bends in the river are visible throughout this reach and appear as scars of the historic channel locations; the riparian corridor and oxbow lakes are still present in many locations. The channel remains active and has the potential to migrate during times of high water. Point bars, islands, high and low terraces, instream woody cover, growth of early successional riparian plants, and other evidence of river meander and erosion are common in this reach. The channel has varying widths, and aquatic habitats consist of shallow riffles, deep runs, deep pools at meander bends, glides, and willow vegetated floodplain areas that become inundated during high flows.

Sacramento River from Colusa to the Delta The general character of the Sacramento River changes drastically downstream from Colusa from a dynamic and active meandering channel to a confined, narrow channel restricted from migration. Setback levees exist along portions of the river upstream from Colusa; however, the levees become much narrower along the river’s edge as the river continues south to the Delta. Agricultural lands are located directly adjacent to the levees, which have cut the river off from most of its riparian corridor, especially on the east side of the river. Between Colusa and the Delta, Sacramento River levees are mostly lined with riprap, allowing the river no erodible substrate. Because the river is confined by levees, the trapezoidal channel width is fairly uniform (typically around 500 and 600 feet wide) and river bends are static. Depth profiles and substrate composition are fairly uniform throughout the reach, so aquatic habitats are fairly homogenous.

Several major flood control bypass facilities, including the Sutter and Yolo bypasses, are managed to provide flood protection for local municipalities and agricultural areas, and also provide important seasonal floodplain habitat that support juvenile salmonid rearing, habitat for Sacramento splittail (*Pogonichthys macrolepidotus*) spawning and larval rearing, and food production that passes downstream into the Sacramento River and Delta. Multiple water diversion structures move floodwaters into floodplain bypass areas during high-flow events. A large number of screened and unscreened agricultural irrigation diversions occur within the reach.

Tributaries to the Lower Sacramento River The lower reaches of primary tributaries to the lower Sacramento River are characterized here because of the potential for project effects on flows and associated flow-related effects on fish species of management concern. These potential flow changes, however, are minimized by upstream CVP and SWP reservoir operations and flow increases from tributary inflows and return flows from diversions and flood bypasses.

Lower Feather River Aquatic habitats found in the lower Feather River vary as the river flows from its release at the DWR Oroville Dam facilities down to the confluence with the Sacramento River at Verona. Included in the Oroville facilities are a low-flow channel and a high-flow channel. Under the Federal Energy Regulatory Commission license, DWR maintains an approximate 8-mile low-flow channel at 700 to 800 cfs. The low-flow channel at the upper extent of the lower Feather River contains mainly riffles and runs, which provide spawning habitat for the majority of Chinook salmon and steelhead. Also present in the low-flow channel is a series of remnant gravel pit pools/ponds that connect to the main channel.

This stretch of the Feather River is mostly confined by levees as it flows through the city of Oroville. Instream flows and water temperature management in the low-flow section of the river are managed by releases from Oroville Dam in compliance with the Federal Energy Regulatory Commission (Project 2100) requirements, and NMFS biological opinion (BO), and other regulatory requirements. From the downstream end of the low-flow channel, the river is fairly active and meanders its way south to Marysville. However, the high flow channel is bordered by active farmland, which confines the river to an incised channel in certain stretches. Some areas of adjacent farmlands have been restored to floodplain habitat with the construction of setback levee. The high flow channel that extends downstream to the Sacramento River also provides habitat for a variety of resident and migratory fish, as well as a migratory corridor, on the lower Feather River. The Feather River also supports wetland habitat for resident fish and wildlife. The Feather River Fish Hatchery, located immediately downstream from Oroville Dam, produces fall-run and spring-run Chinook salmon and steelhead.

Lower American River Flows in the lower American River (below Folsom and Nimbus dams) provide habitat for anadromous and resident fish species. The lower American River supports spawning and juvenile rearing by fall-run Chinook salmon and steelhead (although oversummering water temperatures limit juvenile steelhead rearing habitat) as well as a variety of resident fish and migratory fish, including American shad (*Alosa sapidissima*). The river is fairly low gradient and is composed of riffle, run, glide, and pool habitats. Folsom and Nimbus Dams, as well as a number of impoundments located further upstream in the watershed have reduced gravel inputs to the system, but the lower American River contains large gravel bars and forks in many locations, leaving gravel/cobble islands within the channel. Instream flows in the lower American River are managed by Reclamation through operations of Folsom and Nimbus Dams to provide instream flows for fishery habitat, maintenance of stream temperatures, flood control, and downstream water supplies and water quality management in the Delta.

Hatcheries located on the lower American River produce fall-run Chinook salmon, steelhead, and resident trout. Most of the lower American River is surrounded by the American River Parkway, preserving the surrounding riparian zone. The river channel does not migrate to a large degree because the geologic composition has allowed the river to incise deep into sediments, leaving tall cliffs and bluffs adjacent to the river.

Sacramento River Floodplain Bypasses There are three major floodplain bypasses – the Butte Basin, Sutter Bypass, and Yolo Bypass – along the main stem Sacramento River. These bypasses operate with a total of 10 overflow structures (6 weirs, 3 flood relief structures, and an emergency overflow roadway) primarily to provide flood control and secondarily to provide access to broad, inundated floodplain habitat for salmon rearing and splittail spawning during wet years. In high-flow periods, the stage of the Sacramento River is elevated and water flows over the weirs into the bypasses. Although the bypasses serve as important seasonal habitat for juvenile salmonid rearing and splittail spawning, an alternative migration pathway, and for the production and transport of organic matter downstream into the river and Delta, the bypasses are primarily operated and managed for flood control during the winter and for agricultural production during the spring and summer.

Unlike other Sacramento River and Delta habitats, floodplains and floodplain bypasses are dewatered seasonally as high flows recede between late spring and autumn. This prevents introduced fish species from establishing year-round dominance except in perennial water sources (Sommer et al. 2003). Moreover, many of the native fish, such as Sacramento splittail, are adapted to spawn and rear in winter and early spring (Moyle 2002) during the winter flood pulse. Introduced fish typically spawn between late spring and summer, when most of the floodplain is not available to them.

Butte Basin The Butte Basin lies east of the Sacramento River and extends from the Butte Slough outfall gates near Meridian to Big Chico Creek near Chico Landing. Flood flows are diverted out of the Sacramento River into the Butte Basin and Sutter Bypass via several designated overflow areas (i.e., low points along the east side of the river) that allow high flood flows to exit the Sacramento River channel.

Sutter Bypass The Sutter Bypass is a narrow floodwater bypass that conveys Sacramento River flood flows from the Butte Basin and the Tisdale Weir. The bypass area is an expansive land area in Sutter County used mainly for agriculture. In times of high water (when the stage exceeds 45.5 feet), Sacramento River water enters the bypass through the Butte Slough outfall and the Tisdale Weir and inundates the bypass with as much as 12 feet of water. The Sutter Bypass, in turn, conveys flows to the lower Sacramento River region at the Fremont Weir near the confluence with the Feather River and into the Sacramento River and the Yolo Bypass (USACE and The Reclamation Board 2002).

Yolo Bypass The Yolo Bypass is an approximately 59,000-acre land area that conveys Sacramento River floodwaters around Sacramento during times of high runoff. Sacramento River flow is diverted into the bypass when the river stage exceeds 33.5 feet (corresponding to 56,000 cfs at Verona). Diversion of most floodwaters from the Sacramento River, Sutter Bypass, and Feather River into the Yolo Bypass from Fremont Weir controls Sacramento River flood stages at Verona. During large flood events, up to 80 percent of Sacramento River flows are diverted into the bypass. The Yolo Bypass subsequently drains back into the Sacramento River in the vicinity of Cache Slough, which is located just upstream from Rio Vista. Cache Slough and the adjacent Sacramento Deep Water Ship Channel have been found to provide habitat year-round for delta smelt (*Hypomesus transpacificus*) as well as other fish. Efforts are currently underway to enhance aquatic habitat for juvenile salmonids, delta smelt, and other fish in the Yolo Bypass/Cache Slough complex.

Sacramento Deep Water Ship Channel The Sacramento Deep Water Ship Channel is a tidally influenced canal that is about 30 feet deep, 200 feet wide, and 43 miles long. It flows from the Port of Sacramento into the Sacramento River, which flows into San Francisco Bay. The channel was completed in 1969 and is primarily used to transport agricultural products. Due to manipulations to the channel, such as dredging, it tends to have low dissolved oxygen (DO) concentrations. Delta smelt spawn in and around the Sacramento Deep Water Ship Channel, and juvenile delta smelt are found in the channel (Baxter 2010).

Lower San Joaquin and Stanislaus Rivers The lower San Joaquin River is characterized by a relatively wide (approximately 300-foot) channel with little canopy or overhead vegetation and minimal bank cover. Aquatic habitat in the San Joaquin River is characterized primarily by slow-moving glides and pools, is depositional in nature, and has limited water clarity and habitat diversity. The Stanislaus River provides habitat for fall-run Chinook salmon spawning and juvenile rearing as well as a small population of resident trout and steelhead. Instream flows on the river are managed by Reclamation through releases from New Melones Reservoir for fishery habitat, water temperature management, flood control, and water supplies. Many of the fish species using the lower San Joaquin River use this lower segment of the river to some degree, even if only as a migratory pathway to and from upstream spawning and rearing areas. The lower river also is used by certain fish species (e.g., delta smelt) that make little to no use of areas in the upper segment of the river (see the Delta discussion below).

Aquatic habitats in the lower Stanislaus River vary longitudinally and provide fish spawning, rearing, and/or migratory habitat for a diverse assemblage of common Central Valley native and nonnative fish species. Aquatic habitats include riffles, runs, pools, and glides. Floodplain and associated riparian habitat also varies with the development of levees and encroachment of agriculture and urban uses. There is no fish hatchery located on the Stanislaus River although salmonids produced in hatcheries on other rivers (e.g., Merced River Fish Hatchery) have periodically been released into the Stanislaus River.

Water temperature and flows in both the lower San Joaquin and Stanislaus river systems are highly altered and are managed for flood control and water supply purposes.

Sacramento-San Joaquin Delta The Delta and Suisun Bay, on the western edge of the Delta, are located at the confluence of the Sacramento and San Joaquin rivers and may be considered to represent the most important, complex, and controversial geographic area for both anadromous and resident fisheries production and distribution of California water resources for numerous beneficial uses. The Delta's channels are used to transport water from upstream reservoirs to the south Delta, where Federal and State export facilities (Jones Pumping Plant and Harvey O. Banks Delta Pumping Plant, respectively) pump water into CVP and SWP canals, respectively.

Environmental conditions in the Delta depend primarily on the physical structure of Delta channels, inflow volume and source, Delta Cross Channel (DCC) operations, Delta exports and diversions, and tides. The CVP affects Delta conditions primarily through control of upstream storage and diversions, Delta exports and diversions, and DCC operations. These factors also determine outflow and the location of the low salinity zone (LSZ), which is an area of high organic carbon that is critically important to a number of fish and invertebrate species, as well as to the overall ecology of the Delta and Suisun Bay. The location of the LSZ in the estuary is typically denoted as the distance in kilometers upstream from the Golden Gate Bridge where the 2-practical-salinity-unit bottom salinity isohaline is located which is commonly referred to as the X2 location. The location of X2 is downstream in the Suisun Bay area (e.g., adjacent to Chipps or Roe Islands) when Delta outflow is relatively high and further upstream in the lower Sacramento and San Joaquin Rivers (e.g., Collinsville) when Delta outflow is reduced (Kimmerer 2004, Cloern and Jassby 2012). The location of X2 during the late winter and spring is managed in accordance with provisions of State Water Board Water Right Decision 1641 (D-1641). In addition to these physical factors, environmental conditions such as water temperature, predation, food production and availability, competition with introduced exotic fish and invertebrate species, and pollutant concentrations all contribute to interactive, cumulative conditions that have substantial effects on Delta fish populations.

Water development has changed the volume and timing of freshwater flows through the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta). Over the past several decades, the volume of the Bay-Delta's freshwater supply and Delta outflow from the estuary has been reduced by upstream diversions, in-Delta use, and Delta exports. As a result, the proportion of Delta outflow depleted by upstream and Delta diversions has grown substantially (Kimmerer 2004).

Water development has also altered the seasonal timing of flows passing into and through the Bay-Delta. Flows have decreased in April, May, and June and have increased slightly during the summer and fall (State Water Board 2012). Seasonal flows influence the transport of eggs and young organisms (e.g., zooplankton, fish eggs, larvae) through the Delta and into San Francisco Bay. Flows during the late winter and spring (e.g., February to June) play an especially important role in determining the reproductive success and survival of many estuarine species, including salmon, striped bass, American shad, delta smelt, longfin smelt (*Spirinchus thaleichthys*), splittail, and others (Stevens and Miller 1983, Stevens et al. 1985, Herbold 1994, Meng and Moyle 1995, Rosenfield 2010, Rosenfield and Baxter 2007, MacNally et al. 2010, Thomson et al. 2010).

An estimated 25 percent of all warm-water and anadromous sport fishing and 80 percent of California's commercial fishery depend on species that live in or migrate through the Delta. The Delta serves as a migration path for all Central Valley anadromous species returning to their natal rivers to spawn. Adult Chinook salmon move through the Delta during most months of the year. Salmon and steelhead juveniles depend on the Delta as transient rearing habitat during migration through the system to the ocean and could remain for several months, feeding in marshes, tidal flats, and sloughs. In addition, Delta outflow has been correlated to changes in the abundance and distribution of fish, such as green sturgeon and longfin smelt, and invertebrates in the bay through changes to salinity, currents, nutrient levels, and pollutant concentrations (Thomson et al. 2010, Mac Nally et al. 2010, Kimmerer 2002, Rosenfield and Baxter 2007, Rosenfield 2010). Delta smelt is a key species driving many of the ongoing water management decisions in the Delta (USFWS 2008).

Trinity River Sacramento River flow is augmented in average water years by the transfer of up to 1 million acre-feet of Trinity River water through Clear Creek and Spring Creek tunnels to Keswick Reservoir (Reclamation 2004). Flows in the Trinity River (below Lewiston Dam) are generally cold, providing habitat for anadromous and resident fish species. Aquatic habitats in the river consist of riffle, run, glide, and pool habitats. Fish habitat values have increased in quantity and quality through restoration activities that have taken place over the last several years. Implementation of the Trinity River Restoration Program is expected to further increase the value of the habitat below Lewiston Dam over the next 10 to 15 years (NMFS 2000).

CVP/SWP Service Areas

The CVP/SWP service areas contain primarily highly altered aquatic habitat types, including reservoirs, canals, ditches, and other manmade water conveyance structures/facilities. Agricultural land and urban development are the dominate land uses within these service areas. As a result of all these factors, the aquatic communities that occupy the habitats are highly adapted to these disturbed environments and are dominated by nonnative species.

11.1.2 Fish Species

Special-status aquatic species within the primary and extended study areas are listed in Table 11-1. These include animals that are legally protected or are otherwise considered sensitive by Federal, State, or local resource conservation agencies and organizations, and fish species of primary management concern (recreationally and/or commercially important species). The *Fisheries and Aquatic Ecosystems Technical Report* describes life histories and environmental/habitat requirements of special-status species, and information on seasonal timing of important life stages. The following text describes the fishes in the primary and extended areas that include special-status fish as well as other important species.

Table 11-1. Special-Status Aquatic Species Potentially Occurring in the Primary and Extended Study Areas

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas
	USFWS/ NMFS	CDFW	USFS	MSCS Goals		
River lamprey *Lampetra ayresi*		SSC			Anadromous species that spends relatively little time in the ocean. Spawns in freshwater gravel substrates from February through May.	Occurs in the extended study areas in the Delta and Sacramento River and tributaries.
Pacific lamprey *Entosphenus tridentatus*			S		Anadromous species that spends 1-3 years in the ocean. Spawns in freshwater gravel substrates from March through July.	Occurs in portions of the primary study area in the Sacramento River below Keswick Dam and throughout the extended study area, including the Delta and major tributaries.
Central Valley steelhead *Oncorhynchus mykiss*	T			R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Central California Coast steelhead *Oncorhynchus mykiss*	T				Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the extended study area in the lower Delta, Suisun Bay, and San Francisco Bay.

Table 11-1. Special-Status Aquatic Species Potentially Occurring in the Primary and Extended Study Areas (contd.)

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas

Sacramento winter-run Chinook salmon *Oncorhynchus tshawytscha*	E	E		R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Central Valley spring-run Chinook salmon *Oncorhynchus tshawytscha*	T	T		R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Central Valley fall/late fall-run Chinook salmon *Oncorhynchus tshawytscha*		SSC	S	R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.
Southern Oregon Northern California Coasts Coho salmon *Oncorhynchus kisutch*	T	T			Requires cold, freshwater streams with suitable gravel for spawning; rears in inundated floodplains, edgewater, off-channel habitat, rivers, tributaries, and estuaries.	Occurs in the extended study area in the Trinity River.
Klamath Mountain Province steelhead *Oncorhynchus mykiss*			S		Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta	Occurs in the extended study area in the Trinity River.
Southern DPS of the North American Green sturgeon *Acipenser medirostris*	T			R	Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, tributaries, and Delta.	Occurs in the primary and extended study areas in the Sacramento River, tributaries, and Delta.

Table 11-1. Special-Status Aquatic Species Potentially Occurring in the Primary and Extended Study Areas (contd.)

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas
	USFWS/ NMFS	CDFW	USFS	MSCS Goals		
Delta smelt *Hypomesus transpacificus*	T	E		R	Spawns in tidally influenced freshwater wetlands and seasonally submerged uplands; rears in tidal marsh and Delta.	Occurs in the extended study area in the lower Sacramento River and the Delta.
Longfin smelt *Spirinchus thaleichthys*	P	T		R	Primary habitat is the open water of estuaries, both in seawater and freshwater areas, typically in the middle or deeper areas of the water column; spawn in estuaries in fresh or slightly brackish water over sandy or gravel substrates.	Occurs in the extended study area in the Delta.
Sacramento splittail *Pogonichthys macrolepidotus*	DT	SSC		R	Spawning and juvenile rearing occur from winter to early summer in shallow weedy areas inundated during seasonal flooding in the lower reaches and flood bypasses of the Sacramento River, including the Yolo Bypass.	Occurs in the primary and extended study areas in the Delta and Sacramento River, tributaries, and the Delta.
Hardhead *Mylopharodon conocephalus*		SSC	S	m	Spawning occurs in pools and side pools of rivers and creeks; juveniles rear in pools of rivers and creeks, and shallow to deeper water of lakes and reservoirs.	Occurs in the primary and extended study areas in freshwater portions of Sacramento River and tributaries.
San Joaquin roach *Lavinia symmetricus* sp.		SSC			Spawning occurs in pools and side pools of small rivers and creeks; juveniles rear in pools of small rivers and creeks.	Occurs in the extended study area in the San Joaquin River and tributaries and Delta.

Species	Status[1]				Habitat	Potential to Occur in the Primary and Extended Study Areas
	USFWS/ NMFS	CDFW	USFS	MSCS Goals		
Rough sculpin *Cottus asperrimus*		FP			Prefers sand or gravel substrate in cool streams or reservoirs. Spawns in streams.	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in the Pit River and tributaries upstream from Shasta Lake.
Rainbow trout *Oncorhynchus mykiss*					Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, and tributaries.	Occurs in Shasta Lake, Keswick Reservoir, tributaries, and lakes.
Redband trout *Oncorhynchus mykiss stonei*			S		Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, and tributaries.	Occurs upstream from McCloud Dam.
Bull trout *Salvelinus confluentus*	T	E			Requires cold, freshwater streams with suitable gravel for spawning; rears in seasonally inundated floodplains, rivers, and tributaries.	Previously found in the McCloud River. Now considered extirpated from California.
California floater *Anodonta californiensis*			S		Potentially occurs in shallow areas of clean, clear ponds, lakes and rivers with sandy and silty substrate.	Potentially occurs in Shasta Lake, Keswick Reservoir, and tributaries.
Kneecap lanx *Lanx patelloides*			S		Potentially occurs in shallow areas of ponds, lakes, and rivers with sandy and silty substrate.	Potentially occurs in Shasta Lake, Keswick Reservoir, and tributaries.
Nugget pebblesnail *Fluminicola seminalis*			M		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats).	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in large creeks and rivers tributary to Shasta Lake.

Potem pebblesnail *Fluminicola* sp. 14			M		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats)	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in tributaries to Shasta Lake.
Flat-top pebblesnail *Fluminicola* sp. 15			M		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats).	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in tributaries to Shasta Lake.
Shasta pebblesnail *Fluminicola* sp. 16			M		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats).	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in spring complexes associated with the Sacramento River upstream from Shasta Lake.
Disjunct pebblesnail *Fluminicola* sp. 17			M		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats).	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in spring complexes associated with the Sacramento River upstream from Shasta Lake.
Globular pebblesnail *Fluminicola* sp. 18			M		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats).	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in tributaries to Shasta Lake.
Cinnamon juga *Juga* (*Orebasis*) sp. 3			M		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats).	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in spring complexes associated with the Sacramento River upstream from Shasta Lake.
Black Juga *Juga nigrina*			S		Potentially occurs in mixed conifer and conifer/woodland habitats (seeps, springs, and/or riverine habitats).	Potentially occurs in the Shasta Lake and vicinity portion of the primary study area in spring complexes associated with the Sacramento River upstream from Shasta Lake.

Shasta Lake and Vicinity

Shasta Lake fish species include native and nonnative species, which are dominated by mostly introduced warm-water and cold-water species (Weidlein 1971) (Table 11-2). Major assemblages of non-fish aquatic animal species include benthic macroinvertebrates and zooplankton communities.

Table 11-2. Fish Species Known to Occur in the Primary Study Area

RBPP = Red Bluff Pumping Plant

Cold-Water Species Shasta Lake and its tributaries provide very productive habitats for cold-water fish species, which typically prefer or require temperatures cooler than 70 degrees Fahrenheit (°F). During the cooler months, cold-water species such as rainbow trout, brown trout (*Salmo trutta*), and landlocked Chinook salmon may be found rearing throughout the lake; these species do not spawn in the lake, preferring to spawn in tributary streams though few Chinook salmon stocked in Shasta Lake have ever been observed to spawn in the reservoir tributaries (Zustak 2009). During the summer months, these cold-water species may be found rearing in association with the cold, deep hypolimnion and metalimnion layers within the reservoir, although the fish may make frequent forays into the epilimnion to feed on small prey fish and return to cooler depths to digest their prey (Finnell and Reed 1969, Koski and Johnson 2002, Moyle 2002, Quinn 2005).

Native species such as white sturgeon (*Acipenser medirostris* and *A. transmontanus*), hardhead (*Mylopharodon conocephalus)*, riffle sculpin (*Cottus gulosus*), Sacramento sucker (*Catostomus occidentalis*), and Sacramento pikeminnow (*Ptychocheilus grandis*) tend to reside in cooler water strata in the reservoir and in and near tributary inflows (Moyle 2002). Trout may also congregate near the mouths of the reservoir's tributaries, including the Sacramento River (upstream from Shasta Lake), McCloud River, Pit River, and Squaw Creek, at various times of the year seeking thermal refuge, foraging, and spawning, when conditions are favorable for these species.

Hatchery- and pen-reared trout and salmon are stocked in Shasta Lake several times each year to support the sport fishery. About 60,000 pounds of juvenile rainbow trout (*Oncorhynchus mykiss*) and about 50,000 subcatchable Chinook salmon are planted annually (Baumgartner 2008).

Climate conditions and reservoir storage volume are the two most influential factors affecting cold-water habitat and primary productivity in Shasta Lake (Bartholow et al. 2001). Cold-water habitat provided by Shasta Lake is a function of the total storage and associated surface area provided by Shasta Lake. This relationship is influenced by variation in the WSEL throughout the year. Variation in WSEL is a function of water demand and downstream instream flow releases, water quality requirements, and inflow. WSEL can change within and among years based on hydrology within the watershed, based on the water year type. Typically, primary production in reservoirs is associated with storage volumes when all other factors are held constant (Stables et al. 1990). Increased storage and the corresponding increases in surface area and aquatic habitat results in a greater total biomass and a greater abundance of plankton and fish, because available aquatic habitat area is increased.

Warm-Water Species The warm-water fish habitats of Shasta Lake occupy two ecological zones: the littoral (shoreline/rocky/vegetated) and the pelagic (open water) zones. The littoral zone lies along the reservoir shoreline down to the maximum depth of light penetration on the reservoir bottom, and supports populations of spotted bass (*Micropterus punctulatus*), smallmouth bass (*M. dolomieui*), largemouth bass (*M. salmoides*), black crappie (*Pomoxis nigromaculatus*), bluegill (*Lepomis macrochirus*), channel catfish (*Ictalurus punctatus*), and other warm-water species. Warm-water fish species are generally structure oriented and mostly occupy the littoral zone, however, some warm-water species like spotted bass will forage in the pelagic zone of Shasta Lake.

The upper, surface layer of the pelagic zone is the principal plankton-producing region of the reservoir. Plankton comprises the base of the food web for most of the reservoir's fish populations. Operation of the Shasta Dam temperature control device (TCD), which helps conserve the reservoir's cold-water pool by accessing warmer water for storage releases in the winter, spring, and early summer, may reduce zooplankton biomass in the epilimnion. However, operations of the TCD may result in some increased plankton production at deeper levels as a result of a slight warming of the hypolimnetic layers within the reservoir during the fall months (Bartholow et al. 2001).

Warm-water species, such as largemouth bass, smallmouth bass, spotted bass, and other sunfishes, were introduced into Shasta Lake and have become well established with naturally sustaining populations. Spotted bass are currently the dominant warm-water species in Shasta Lake (Baumgartner 2006). These warm-water fishes feed primarily on invertebrates while young and become predaceous on other fishes, including engaging in some cannibalism, as they grow. In Shasta Lake, threadfin shad (*Dorosoma petenense*), crayfish, and other invertebrates are most abundant in the diets of these fish (Saito et al. 2001). Spawning activity usually begins during late March or April when temperatures rise to around 60°F. Males generally build the nests in sand, fine gravel, rubble, or debris-covered bottoms at depths between 1 and 20 feet, which varies by species. Spotted bass and catfishes typically spawn at greater depths than the other warm-water species in Shasta Lake. Eggs generally hatch in 3 to 5 days at the predominant springtime water temperatures in Shasta Lake, and males guard the eggs and larvae for up to 4 weeks (Moyle 2002). Fry and juveniles disperse into shallow water and prefer areas with vegetation and large rubble as protective cover from predators (Moyle 2002, Ratcliff 2006).

The primary factors affecting warm-water fish abundance and production in Shasta Lake include seasonal reservoir fluctuations, availability of high-quality littoral habitat, and annual climate variations (Ratcliff 2006). The effect of sport fishery harvests on Shasta Lake warm-water fish populations is not well understood but is believed to be small with catch-and-release practices, although it is generally thought that overfishing of naturally reproducing populations by sport fisheries seldom limits fish abundance (Moyle 2002).

Reservoir level fluctuations, associated shoreline erosion, and suppression of shoreline and emergent vegetation are thought to generally be the most significant factors affecting warm-water fish production in reservoirs, including Shasta Lake (Moyle 2002, Parkos and Wahl 2002, Ratcliff 2006). Water level variations influence physical, chemical, and biological processes, which in turn affect fish populations. Reservoir drawdowns reduce water depths and influence thermal stratification and the resulting temperature, DO, and water chemistry profiles.

The typical seasonality of reservoir fluctuations on Shasta Lake can affect year-to-year reproductive success of littoral-spawning fishes, especially the black bass species, by influencing nesting behavior (e.g., abandonment of nests) and dewatering of nests containing eggs in years when reservoir levels decline during the spring and early summer months. Under these same conditions, juveniles may be forced to move to areas with less protection from predation or lower food production. In years when the reservoir rises rapidly and/or extensively during the spring and early summer months, submergence of active bass nests by more than 15 to 20 feet often results in high egg mortality (Stuber, Gebhart, and Maughan 1982, Lee 1999, Moyle 2002).

Shoreline and littoral vegetation are important warm-water fish habitat components for sustainable fishery production (Ratcliff 2006). Structural diversity (e.g., submerged trees, brush, rock, boulders, and rubble) provides shelter and feeding areas for fish. During construction of the reservoir, many trees and brush fields were cleared before inundation. Portions of the Pit River and Squaw Creek arms were not cleared, as evidenced by the large number of inundated trees observable in certain areas. Clearing efforts reduced the potential structural diversity of the inundated habitat. Vegetative clearing in many reservoirs has resulted in rocks, boulders, and man-made features (e.g., bridge pilings, riprap, marinas) being the only structural habitat features available, especially for bass and other warm-water fishes.

Annual reservoir fluctuations create highly variable conditions for establishment and maintenance of shoreline and littoral-zone vegetation and aquatic invertebrate communities that subsequently impose limitations on warm-water fish production. Exposed shoreline reservoir areas generally require 3 to 4 years to reestablish terrestrial vegetation. The absence of established, rooted aquatic vegetation is a common aquatic habitat factor that limits populations and fishery production for many fish species in reservoirs (Ploskey 1986, Moyle 2002).

The Shasta-Trinity National Forest (STNF), in cooperation with other Federal and State agencies and local nongovernmental organizations, has implemented a habitat improvement program at Shasta Lake. The objective of this program is to increase cover for warm-water fish. As the fishery management agency for Shasta Lake, CDFW prepared a Draft Management Plan for Shasta Lake in 1991. This plan, which has not been finalized, acknowledges the benefit to warm-water fish of structural enhancement projects.

STNF, CDFW, and nongovernmental organizations have used a variety of materials and techniques to construct structural enhancements (e.g., willow planting, brush structures) to provide warm-water fish habitat within the drawdown zone of Shasta Lake. The materials and techniques have varied because of differences in funding, available materials, site conditions (reservoir levels), longevity, and desired outcome.

According to Shasta-Trinity National Forest (STNF) aquatic biologists, brush structures constructed from whiteleaf manzanita (*Arctostaphylos manzanita)* have been the STNF's preferred means of structural enhancement since about 1990. These structures have been constructed in areas where manzanita is available near the shoreline, typically in a manner that provides varying degree of structural habitat as water levels change over time. The biologists have indicated that these structures have typically resulted in a threefold to tenfold increase in the abundance of warm-water fish in the treated areas (Ratcliff 2006; Zustak 2007).

Tributary Species The lower reaches of the tributaries draining to the reservoir provide spawning habitat for adfluvial fishes (i.e., fish that spawn in streams, but rear and grow to maturity in lakes) residing in Shasta Lake, as well as stream-resident fishes, with rainbow trout the principal game species. Accessible and suitable cold-water fish spawning habitat, including appropriate seasonal flows, depths, and gravel substrates, was observed in 5 percent of intermittent tributaries and nearly 70 percent of perennial tributaries to Shasta Lake surveyed in 2011 and 2012 (see *Fisheries and Aquatic Ecosystems Technical Report* for details). Most native fish species found in Shasta Lake may also inhabit the lower reaches of the tributaries. Several tributaries to Shasta Lake (e.g., Little Squaw Creek,[2] Little Backbone Creek) have been subjected to discharge from abandoned upslope copper mines. The Shasta Lake West Watershed analysis (Bachmann 2000) suggests that these creeks are "biologically dead" as a result of acid mine discharge from these mines. This watershed analysis also stated that "fish kills" have occurred in Shasta Lake in the vicinity of such tributaries during high runoff conditions. No fish were observed during 2012 in watersheds known to be affected by a legacy of mining and acidic, metal-laden mine drainage, including Little Squaw Creek and Little Backbone Creek, both located in the watershed to the immediate northwest of Shasta Dam, and Town Creek, near the Bully Hill Mine located in the Squaw Creek arm (Reclamation 2014).

The four main tributaries to Shasta Lake, which include the Sacramento River, McCloud River, Squaw Creek, and Pit River, are renowned for their high-quality recreational trout fisheries. Each of these streams drains considerable watershed areas comprising mixed conifer forests in the reaches above Shasta Lake. With the exception of the Pit River, which has a series of hydroelectric project dams that begin immediately upstream from Shasta Lake, each of these tributaries has more than 30 miles of high-quality, fish-bearing riverine habitat between the Shasta Lake and upstream dams on the Sacramento and McCloud rivers and steep headwater reaches on Squaw Creek.

For the most part, land use along the main Shasta Lake tributaries upstream from the reservoir is a mix of Federal and privately managed forest and

[2] This refers to a stream draining the terrain and entering Shasta Lake northwest of Shasta Dam, a historic mining district; not to be confused with the Squaw Creek drainage forming the "Squaw Creek Arm" of the lake.

timberlands and except for sparse residential development, several small municipalities, and the hydropower projects on the Pit, McCloud, and Sacramento rivers much of the area is lightly developed. The Sacramento River above Shasta Lake is paralleled by a major interstate highway and railroad transportation corridor. In July 1991, a railroad accident spilled 19,000 gallons of the fumigant pesticide metam sodium into the Sacramento River near the town of Dunsmuir, approximately 35 stream miles upstream from Shasta Lake. Metam sodium is highly toxic and killed aquatic and riparian vegetation, aquatic macroinvertebrates, and fish and amphibians along the entire length of the river to Shasta Lake, where a massive chemical containment and neutralization effort was mounted. Ecological recovery efforts were implemented shortly after this spill incident and populations of fish, aquatic macroinvertebrates, and the vegetation adjacent to the stream have attained levels that appear to be in a natural dynamic equilibrium consistent with full recovery, although some amphibian and mollusk population remained depressed at least 15 years later (Cantara Trustee Council 2007).

In addition to the four primary tributaries, there are 1,232 intermittent and perennial stream channels totaling about 2,962 miles of channel that contribute seasonal or year-round flows to Shasta Lake. Most of these channels are relatively short and steep and may be classified as confined headwater channels that contribute water, sediment, and organic and inorganic material to Shasta Lake. Many (64 percent) of these channels are intermittent and have stream slopes greater than 10 percent (mean gradient of 27 percent). Net Trace model results indicate that about 33 percent of these stream channels are perennial. About 20 percent of these channels (716) have gradients less than 10 percent and are likely to support fish and other aquatic organisms. In the Klamath Mountain and Cascade geomorphic provinces, stream channels with gradients up to about 4 percent to 7 percent and possessing sufficient flows typically exhibit a good potential to support habitation by fish and other aquatic organisms although steeper slopes do not necessarily, in and of themselves, preclude habitation by fish, particularly trout, sculpins, and dace (Naiman 1998; Reeves, Bisson, and Dambacher 1998). Of the channels surveyed, about 79 percent of those that appeared to have good fish-bearing potential flow into the Sacramento, Squaw, and Pit Arms of Shasta Lake (see Chapter 4, “Geology, Geomorphology, Minerals, and Soils,” for more detail).

Aquatic habitat for resident and adfluvial fishes is generally limited in intermittent tributaries to Shasta Lake because a large percentage (92 percent) of these channels does not possess suitable hydrologic conditions (i.e., sufficient duration and amount of discharge) and/or are too steep to provide accessible habitat, even seasonally, for fish. The gradient of most of these tributaries rapidly increases upstream from the shoreline, and natural barriers to fish are common. These barriers are most often created by cascades, waterfalls, and steep reaches of stream channel (i.e., greater than 7 percent slope) that are more than one-quarter mile in length. Stream channel data generated from field inventories and analysis using Net Trace based on Reclamation’s geographic information system (GIS) Digital Elevation Model (DEM) indicate that most barriers on the perennial tributaries occur near the reservoir. Fifty-four percent of all of the intermittent and 30 percent of the perennial tributaries surveyed in 2011 and 2012 contained partial or complete barriers to fish migration within the varial zones of the proposed reservoir enlargement. However, the estimated number of these perennial streams with complete passage barriers located between 1,070 feet and 1,090 feet msl is only 15, or 10 percent, of the 154 perennial tributaries to Shasta Lake (see Fisheries and Aquatic Ecosystems Technical Report for details).

The aquatic habitat composition of Shasta Lake's perennial tributaries is more diverse than in intermittent tributaries. Consequently, two percent of intermittent and 87 percent of perennial tributaries to Shasta Lake sampled in 2011 and 2012 were found to be inhabited by fish (see Fisheries and Aquatic Ecosystems Technical Report for details). Only cold-water species (trout) were observed in intermittent streams during periods of surface flow and in isolated pools after cessation of flow. Cold-water species inhabited 83 percent and warm-water species inhabited 48 percent of the sampled perennial tributaries. Warm-water species were mostly confined to portions of tributary channels within that portion of currently inundated areae. In the few perennial tributaries (less than 10 percent) where warm-water species were found upstream from the reservoir in 2012, the streams had low gradient channels (less than or equal to 2 percent) with an abundance of flatwater habitat (see Fisheries and Aquatic Ecosystems Technical Report for details).

The only special-status aquatic vertebrate species observed in some of these tributaries was the foothill yellow-legged frog; no special-status fish (e.g., hardhead) or invertebrate species were detected, although hardhead have previously been detected in some perennial tributaries (i.e., Sacramento and Pit rivers) (see *Fisheries and Aquatic Ecosystems Technical Report* for details).

Upper Sacramento River (Shasta Dam to Red Bluff)

Keswick Reservoir USFWS conducts a propagation and captive broodstock program for endangered winter-run Chinook salmon at the Livingston Stone National Fish Hatchery, located at the base of Shasta Dam on the Sacramento River upstream from Keswick Reservoir. The program consists of collecting adult winter-run Chinook salmon from the mainstem Sacramento River, holding and spawning the adults, rearing the juveniles in the hatchery environment, and then releasing them back into the mainstem Sacramento River downstream from Keswick Dam. The overriding goal of the program is to supplement the endangered population and provide an insurance policy against extinction. The propagation program (initiated in 1989), and the captive broodstock program (initiated in 1991) are recognized in the Recovery Plan for Sacramento River winter-run Chinook salmon (NMFS 2014)). Water is supplied to the hatchery from Shasta Dam.

Keswick Reservoir is operated by Reclamation as a reregulating facility. Water levels in Keswick Reservoir are subject to operational changes at Whiskeytown and Shasta lakes. The reservoir provides habitat for a variety of aquatic organisms, including native and nonnative fish. Table 11-2 includes the fish species known to occur in Keswick Reservoir. The aquatic habitat is mostly riverine in character in the upper reach of Keswick Reservoir and slow current, run-of-the-river habitat in the lower half of the reservoir. In addition to water released from Shasta Dam and Whiskeytown Lake, this reservoir is the recipient of surface flows and sediment from Spring Creek, as well as groundwater, emanating from the Iron Mountain Mine. Additional information on the relationship between Spring Creek and Keswick Reservoir is provided in Chapter 9, "Hazards and Hazardous Materials."

Keswick Dam to Red Bluff The upper Sacramento River (Keswick Dam to Red Bluff) provides vital fish spawning, rearing, and/or migratory habitat for a diverse assemblage of native and nonnative species (Table 11-2).

Native species present in this reach of the river can be separated into anadromous and resident species. Native anadromous species include four runs of Chinook salmon, steelhead, green sturgeon (*Acipenser medirostris*), white sturgeon, and Pacific lamprey. Native resident species include Sacramento pikeminnow, Sacramento splittail, Sacramento sucker, hardhead, California roach (*Lavinia symmetricus*), and rainbow trout.

Nonnative resident species present in the upper Sacramento River include largemouth bass, smallmouth bass, white and black crappie (*Pomoxis annularis* and *P. nigromaculatus*), channel catfish (*Ictalurus punctatus*), white catfish (*Ameiurus catus*), black bullhead (*A. melas*), brown bullhead (*A. nebulosus*), bluegill (*Lepomis macrochirus*), green sunfish (*L. cyanellus*), and golden shiner (*Notemigonus crysaleucas*).

See Table 11-1 for a list of special-status species with the potential to occur in the upper Sacramento River.

Lower Sacramento River and Delta Like habitats in the primary study area, habitats in the extended study area provide vital fish spawning, rearing, and/or migratory habitat for a diverse assemblage of native and nonnative species. Many of those species are the same as those found in the primary study area, including Chinook salmon, steelhead, and sturgeon (see the *Fisheries and Aquatic Ecosystems Technical Report*).

Trinity River The Trinity River provides habitat for Southern Oregon/Northern California Coast Coho salmon (*Oncorhynchus kisutch*), Southern Oregon/Northern California Coast Chinook salmon, Klamath Mountains Province steelhead, green sturgeon, white sturgeon, Pacific lamprey, resident rainbow trout, speckled dace, three-spine stickleback, Klamath small scale sucker (*Catostomus rimiculus*), prickly sculpin, riffle sculpin, brook trout

(*Salvelinus fontinalis*), brown trout, American shad, brown bullhead, golden shiner, and green sunfish. Coho salmon and Klamath Mountains Province steelhead are included in this discussion because they are special-status species, while CVP and SWP operations in response to changes at Shasta Dam have the potential to affect Trinity River flows.

See Table 11-1 for a list of special-status species with the potential to occur in the Trinity River.

CVP/SWP Service Areas

See Table 11-1 for a list of special-status species with the potential to occur in the CVP/SWP Service Areas.

11.1.3 Aquatic Macroinvertebrates

The constant flow of water in river systems provides an energetically convenient and economical way for aquatic macroinvertebrates to disperse to new habitats; this movement downstream is known as drift. Some invertebrates passively enter the drift (e.g., benthic organisms may be entrained in the water column when a large current sweeps through), and others exhibit active drift behavior (individuals actively enter the water column by voluntary actions) (Waters 1965, 1972; Müller 1974; Wiley and Kohler 1984). Macroinvertebrates drift to colonize new habitats (for dispersal of various life stages or to find suitable resources), or leave unsuitable habitats (in response to habitat quality or predation pressure). Drift is one of the most important downstream dispersal mechanisms for macroinvertebrates. Macroinvertebrates drift more commonly in the evening, usually at dusk (Waters 1972, Müller 1974, Wiley and Kohler 1984, Smock 1996).

Drifting invertebrates are the primary source of prey for juvenile fish, including salmonids (Chapman and Bjornn 1969). Juvenile Chinook salmon will often seek refuge in slow-velocity habitats where they can rest and drifting invertebrates will tend to be deposited.

Shasta Lake and Vicinity

Aquatic macroinvertebrates provide an important food base for many fish and wildlife species. Benthic macroinvertebrates (BMI) consist primarily of the larvae and nymphal forms of aquatic insects, mollusks, and worms, and serve as an important element of ecological communities and food chains for aquatic invertebrates, such as fish and amphibians. These organisms possess a wide array of life histories and preferences and tolerance of poor water quality. In general, published information on the taxonomy, distribution, and abundance of macroinvertebrates in the Sacramento River drainage is limited. In Shasta Lake, seasonal fluctuations in phytoplankton biomass regulate the abundance of the zooplankton, which form the base of the food chain for the lake's fisheries. Typically, the spring phytoplankton bloom peaks in late-March and April at the on-set of thermal stratification, when nutrients are abundant in surface waters and available to the algae, and again in the fall coincident with the breakdown of the thermocline and mixing of the water column (Lieberman and Horn 1998). The zooplankton community of Shasta Lake is dominated by cladoceran and copepod species, with lower abundance of several rotifer species. Cladocera are most abundant during algae blooms and their abundance wanes, with a corresponding increase in copepod abundance, during the mid-summer (Lieberman and Horn 1998).

Surveys conducted in 2011 and 2012 in tributaries of Shasta Lake found that BMI communities, with a few exceptions, were generally indicative of good habitat and water quality conditions capable of supporting healthy, functioning, and productive ecosystems. The BMI community was largely dominated by cool/warm (eurythermal) taxa, which is expected as a function of the region's Mediterranean climate; taxa representing both pool and riffle specialists; and taxa representing the collector-filterer and collector-gatherer functional feeding guilds, which is also expected based on the relative position and trophic status of the tributary sampling sites within the watersheds (see *Fisheries and Aquatic Ecosystems Technical Report* for details). Tributaries to the Sacramento River arm exhibited among the highest BMI abundances and taxa richness and diversity, although Pit River arm tributaries also exhibited relatively high taxa diversity. Tributaries in legacy mining districts immediately north of Shasta Dam and in portions of the Squaw Creek arm exhibited very depauperate BMI communities, with a high proportion of taxa tolerant of polluted conditions (see *Fisheries and Aquatic Ecosystems Technical Report* for details).

A number of different aquatic mollusks (e.g., snails, limpets, mussels, and clams) are known to inhabit the principal tributaries and general vicinity of Shasta Lake, including several species of management importance (Frest and Johannes 1995, 1999; Howard 2010). Several species of hydrobiid "spring snails" are known to inhabit the upper reaches of the Sacramento and McCloud rivers upstream from Shasta Lake (Frest and Johannes 1995, 1999) in spring complexes and associated headwater areas. These snails require clear, cold-water streams with cobbly gravel beds and tend to be associated with submergent vegetation; however, none of these species has been reported in the reaches of tributaries near Shasta Lake. A number of these spring snails and other stream-dwelling snails are ecologically important and are managed by the USFS and BLM under guidelines for Survey and Manage Species (see Table 11-1).

The USFS sensitive freshwater mussel, the California floater (*Anodonta californiensis*), is also known historically to have occurred in Shasta Lake tributaries near the head of the lake (Howard 2010; Zustak 2007). However, surveys of historically occupied sites around Shasta Lake failed to find this species (Howard 2010) nor was it detected by casual surveys and benthic sampling of the smaller perennial and intermittent tributaries to Shasta Lake in 2012 (Reclamation 2014). This species has experienced significant population declines throughout its range, primarily because of hydromodification of its habitat (Howard 2010). Its preferred habitat is unpolluted, slow-moving rivers and large streams, with beds composed of balanced mixtures of gravel, sand, and silt; however, California floaters are sometimes found in lake shore areas with stable water levels and suitable water currents and substrates (Pennak 1989). Other freshwater mollusks commonly observed in the tributaries of Shasta Lake include another freshwater mussel of the genus *Gonidea* and freshwater limpets of the genus *Lanx* (Howard 2010). The kneecap lanx (*Lanx Patelloides*) has been recently added to the USFS sensitive species list and is known to occur in the vicinity of the McCloud River Bridge. Another mollusk, Black juga (*Juga nigrina*) was recently added to the USFS sensitive species list. It was not detected during the 2014 field surveys but Shasta Lake and its tributaries are within the known range of this species (Cordeiro and Perez 2011). The western pearlshell (*Margaritifera falcata*) is also historically known from the McCloud River, but its close dependence on migratory salmonids for its life cycle has undoubtedly resulted in a decline in its abundance since construction of Shasta Dam blocked anadromous fish migrations (Howard 2010).

Invasive Species

New Zealand Mudsnail The New Zealand mudsnail (*Potamopyrgus antipodarum*), known to have been introduced to North America since about 1987 (Bowler 1991), was identified in Shasta Lake at the Bridge Bay Marina on September 10, 2007 (Benson and Kipp 2011). New Zealand mudsnail have also been found lower in the Central Valley, including Sacramento River near Red Bluff, and the American, Mokelumne and Calaveras rivers (Benson and Kipp 2011). This invasive aquatic mollusk is known from a number of other locations within California and can reach densities of over 500,000 snails per square meter. Densities can fluctuate seasonally, with lowest densities coinciding with the freezing winter months (Proctor et al. 2007). New Zealand mudsnails are highly effective competitors and predators of many native North American benthic macroinvertebrates, including other mollusks, crustaceans, and important aquatic insects. Predators of the New Zealand mudsnail include rainbow trout, brown trout, sculpins, and mountain whitefish (*Prosopium williamsoni*) (Proctor, Kerans, and Clancey 2007). Unfortunately, snails are capable of passing through the digestive system of fish alive and intact (Bondesen and Kaiser 1949).

Possible pathways of introduction into Shasta Lake include contaminated recreational watercraft and trailers and recreational water users (Proctor, Kerans, and Clancey 2007). Introduced snails may also be transported in the feathers and mud adhering to waterbirds and wildlife as they move from one waterbody to another. Other vectors known to spread the snails, such as contaminated livestock, commercial ships, and dredging/mining equipment, are less likely in the case of Shasta Lake’s invasion given the lack of commercial activities on the lake. If the particular clone detected in Shasta Lake is tolerant of the local conditions, a rapid colonization of the lake and its tributaries could occur through a variety of vectors.

The potential involvement of recreational watercraft and trailers and recreational water users in the translocation of New Zealand mudsnails between State waters is of immediate concern. Enlargement of Shasta Lake could provide a larger perimeter of shoreline accessibility for the snail, but not necessarily increase preferred lake habitats. In lakes in North America, New Zealand mudsnails do not commonly occupy shoreline habitats. Highest densities of New Zealand mudsnails occur at depths of between 20 and 25 meters (m) in Lake Ontario (Proctor, Kerans, and Clancey 2007).

Quagga and Zebra Mussel Quagga mussels (*Dressenia bugensis*) and zebra mussels (*Dressenia polymorpha*), are invasive European aquatic mollusks introduced to North America in ship ballast water and first discovered in Lake Erie in 1989 (Spidle, Marsden, and May 1994), have not been found in Shasta Lake, to date, but were discovered in California at Lake Havasu in 2007 (Cohen 2007). The CDFW has begun monitoring at Lake Shasta for adult mussels and veligers (Baumgartner 2008). Possible pathways of introduction into Shasta Lake include contaminated recreational watercraft and trailers and recreational water users. The potential involvement of recreational watercraft and trailers and recreational water users in the translocation of dressenid mussels between State waters is of immediate concern. Enlargement of Shasta Lake could provide a greater area of deepwater and littoral habitat available for occupation by quagga and zebra mussels.

In a 2007 report produced for CDFW, Cohen (2007) described the temperature, calcium, pH, DO, and salinity tolerances of quagga mussels in an effort to assess the vulnerability of various California waters to invasion by quagga mussels and zebra mussels. Cohen identified calcium thresholds as the most important environmental factor influencing distribution of zebra mussels in North America and applied similar thresholds for quagga mussels. In an investigation of the portion of the Sacramento River watershed including Whiskeytown Reservoir and the watersheds above Shasta Dam, Cohen found that the McCloud River above Shasta Lake and the Pit River near Canby have the proper range of salinity, DO, temperature and calcium (at less than or equal to 12 milligrams per liter to be of low and moderate suitability to invasion by quagga mussels.

Upper Sacramento River (Shasta Dam to Red Bluff)

A large-scale monitoring effort on the Sacramento River from Keswick Dam to Verona, coordinated by DWR in 2001, found that benthic macroinvertebrate diversity and richness decreased as the river moved downstream. Oligochaetes, chironomids, and mollusks became more prominent in this reach than in the reach from Keswick Dam to Red Bluff (Sacramento River Watershed Program 2002).

Petrusso and Hayes (2001) examined the diurnal feeding habits of juvenile Chinook salmon in the Sacramento River between RM 193 and RM 275 (downstream and upstream from Red Bluff, respectively) in relation to drifting invertebrates. Chironomids and baetids dominated both the drift and stomach contents. Diets of 153 juvenile salmonids were examined; more than 63 percent of the diet was made up of chironomids of all life stages. Baetids composed 14 percent of the total diet. It was concluded that based on measurements of mean stomach fullness and availability of drifting organisms, there was reasonable feeding opportunity during the sampling period in spring 1996. Mean drift densities ranged from 211 to 2,100 organisms per 100 cubic meters, with an overall mean of 617 organisms per 100 cubic meters (Petrusso and Hayes 2001). Daily mean drift density appeared to show no spatial patterns across the several sites sampled.

Lower Sacramento River and Delta

Aquatic macroinvertebrates provide an important food base for many fish and wildlife species. In general, published information on the taxonomy, distribution, and abundance of macroinvertebrates in the Sacramento River and Delta are limited.

Current macroinvertebrate monitoring efforts on the Sacramento River have focused on large-basin scale patterns, and survey sites on the mainstem have been at various locations along the study reach. As part of the Sacramento River Watershed Program, CDFW collected snag samples at two sites, one site near Colusa and one site near Hamilton City. Dominant taxa found in the fall of 1999 at the Hamilton City site included Orthocladiinae, Naididae, Ephemeroptera (*Baetis* and *Acentrella* sp.), and Trichoptera (*Hydropsyche* sp.) (Sacramento River Watershed Program 2002). Schaffter, Jones, and Karlton (1983) found no substantial difference in abundance of drifting invertebrates near riprapped and natural habitats on the Sacramento River. More than 50 percent of the drift was composed of chironomids, baetids, and aphids. Analysis of fish diets found the same 3 families in 72 percent of the guts sampled.

As mentioned above under "Upper Sacramento River (Shasta Dam to Red Bluff)," a large-scale monitoring effort by DWR on the river from Keswick Dam to Verona found that benthic macroinvertebrate diversity and richness decreased as the river moved downstream. Oligochaetes, chironomids, and mollusks became more prominent in this reach than in the reach from Keswick Dam to Red Bluff (Sacramento River Watershed Program 2002).

Also, as described previously, Petrusso and Hayes (2001) examined the diurnal feeding habits of juvenile Chinook salmon in the river between River Mile (RM) 193 and RM 275 (downstream and upstream from Red Bluff, respectively) in relation to drifting invertebrates. Petrusso and Hayes found that chironomids and baetids dominated both the drift and stomach contents; they concluded that there was reasonable feeding opportunity during the sampling period and that daily mean drift density appeared to show no spatial patterns.

The lower rivers and Delta support a diverse assemblage of zooplankton and macroinvertebrates. Many of these invertebrates are native to the Bay-Delta while many have been introduced into the estuary through ship ballast water discharges, oyster planting, and other processes. Many of the fish species forage on small zooplankton (e.g., copepods) during their early lifestages or throughout their life, while larger macroinvertebrates such as amphipods, shrimp, and crabs provide a forage source for many of the other fish species. Sturgeon and many of the flatfish, for example, forage extensively on shrimp (e.g., Cangon) while other fish such as largemouth bass forage extensively on crawfish. The macroinvertebrate communities are affected by changes in salinity gradients and other habitat factors as well as by filter feeding by other introduced nonnative species such as the Asian overbite clam that has extensively colonized areas of the estuary such as Suisun Bay.

Macroinvertebrate monitoring in the Delta has been focused on impacts to food web dynamics as a result of increases in phosphorous and nitrogen, and on loss of macroinvertebrate species diversity due to nonnative species introductions. The macroinvertebrate communities of the Delta are characterized by low diversity and are dominated by a minimal number of species (less than 10) (Nichols 1980). This is in part because of the predominately soft, silty substrate found throughout the Delta, and an ever-changing fresh and salt water (brackish) water mix (Nichols 1980).

11.2 Regulatory Framework

Several Federal, State, and local agencies have regulatory authority or responsibility over activities that affect aquatic and fisheries resources. These regulatory authorities are described in the following sections.

11.2.1 Federal

Federal Endangered Species Act

Pursuant to the Federal Endangered Species Act (ESA), USFWS and NMFS have authority over projects that may result in take of a federally listed species or adversely affect its designated critical habitat. Under the ESA, the definition of "take" is to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct." Under Federal regulation, "take" is further defined to include habitat modification or degradation where it would be expected to result in death or injury to listed fish and wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. If the project may affect a federally listed species, either an incidental take permit, under Section 10(a) of the ESA through a Habitat Conservation Plan (HCP), or a Federal interagency consultation, under Section 7 of the ESA, is required. Section 7(a)(2) states that each Federal agency shall, in consultation with the Secretary of the Interior, ensure that any action they authorize, fund, or carry out is not likely to jeopardize the continued existence of a listed species or result in the destruction or adverse modification of designated critical habitat. In the primary and extended study area, USFWS has regulatory jurisdiction over freshwater and estuarine fishes (such as delta smelt), while NMFS has jurisdiction over anadromous fish species that include Chinook salmon, steelhead, and green sturgeon, as well as marine fish and mammals.

Protection of these listed species is typically addressed through issuance of BOs and incidental take authorization by USFWS and NMFS, as well as designation of critical habitat. BOs have been issued for delta smelt by USFWS (2008) and for winter-run and spring-run Chinook salmon, Central Valley steelhead, and green sturgeon by NMFS (2009). These two most recent BOs were challenged in Federal court and remanded to the agencies for revisions. USFWS and NMFS have requested extensions on the deadlines for completing the revisions to the BOs required by the Federal court rulings.

NMFS Recovery Plan

Under Section 4(f) of the ESA, both NMFS and USFWS are required to publish a recovery plan for each species it lists as threatened or endangered. These plans must have objective and measureable criteria that would help the species be removed from the ESA list, a description of site-specific management actions necessary for the species recovery, and estimates of time and cost to carry out the recommended recovery measures.

In 2014, NMFS published the *Final Recovery Plan for Evolutionarily Significant Units of Sacramento River Winter-Run Chinook Salmon and Central Valley Spring-Run Chinook Salmon and Distinct Population Segments of Central Valley Steelhead* (NMFS 2014). In this Recovery Plan, NMFS indicates that the recovery of winter-run Chinook salmon is affected by the Shasta cold-water pool by stating:

> *"Currently, winter-run Chinook salmon spawning is limited to the mainstem Sacramento River downstream of Shasta and Keswick dams where the naturally-spawning population is artificially maintained by cool water releases from the dams. Within the Sacramento River, the spatial distribution of spawners is largely governed by water year type and the ability of the CVP to manage water temperatures.*
>
> *The fact that this ESU is comprised of a single population with very limited spawning and rearing habitat increases its risk of extinction due to local catastrophe or poor environmental conditions. There are no other natural populations in the ESU to buffer it from natural fluctuations. A single catastrophe with effects persisting for four or more years could result in extinction of the Sacramento River winter-run Chinook salmon ESU (Lindley et al. 2007). Such potential catastrophes include volcanic eruption of Lassen Peak, prolonged drought which*

> *depletes the cold water pool in Shasta Reservoir or some related failure to manage cold water storage, a spill of toxic materials with effects that persist for four years, or a disease outbreak.*
>
> *After two years of drought, Shasta Reservoir storage would be insufficient to provide cold water throughout the winter-run Chinook salmon spawning and embryo incubation season, resulting in partial or complete year class failure. A severe drought lasting more than 3 years would likely result in the extinction of winter-run Chinook salmon. The probability of extended droughts is increasing as the effects of climate change continue (see Chapter 6).”*

While the action plans surrounding this issue of cold-water pool are focused primarily on reintroduction into the upper watershed (upstream from Shasta Dam), these actions for upstream reintroduction may not be achievable. Improving the cold-water pool could reduce impacts to the species recovery if the reintroduction process is not successful. Additionally, NMFS includes management actions to improve gravel augmentation programs downstream from Keswick Dam.

Sustainable Fisheries Act (Essential Fish Habitat)

In response to growing concern about the status of United States fisheries, Congress passed the Sustainable Fisheries Act of 1996 (Public Law 104-297) to amend the Magnuson-Stevens Fishery Conservation and Management Act (Public Law 94-265), the primary law governing marine fisheries management in the Federal waters of the United States. Under the Sustainable Fisheries Act, consultation is required by NMFS on any activity that might adversely affect essential fish habitat. Essential fish habitat includes those habitats that fish rely on throughout their life cycles. It encompasses habitats necessary to allow sufficient production of commercially valuable aquatic species to support a long-term sustainable fishery and contribute to a healthy ecosystem. Fish species managed under Essential Fish Habitat by NMFS within the Bay-Delta include Pacific salmon, starry flounder, and English sole.

Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act requires Federal agencies to consult with USFWS, NMFS, and State fish and wildlife resource agencies before undertaking or approving projects that control or modify surface water. The recommendations made by these agencies must be fully considered in project plans by Federal agencies.

Federal Clean Water Act, Section 404

Section 404 of the Federal Clean Water Act (CWA) requires project proponents to obtain a permit from USACE before performing any activity that involves any discharge of dredged or fill material into “waters of the United States,” including wetlands. Waters of the United States include navigable waters of the United States, interstate waters, all other waters where the use or degradation or destruction of the waters could affect interstate or foreign commerce, tributaries to any of these waters, and wetlands that meet any of these criteria or that are adjacent to any of these waters or their tributaries. Many surface waters and wetlands in California, including those in the primary and extended study area, meet the criteria for waters of the United States.

Federal Clean Water Act, Section 402

CWA Section 402 regulates construction-related stormwater discharges to surface waters through the National Pollutant Discharge Elimination System (NPDES) program, which is administered by the U.S. Environmental Protection Agency (EPA). In California, the State Water Resources Control Board (State Water Board) is authorized by the EPA to oversee the NPDES program through the regional water quality control boards (regional water boards), in this case, the Central Valley Regional Water Quality Control Board (CVRWQCB).

Federal Clean Water Act, Section 401

CWA Section 401(a)(1) specifies that any applicant for a Federal license or permit to conduct any activity that may result in any discharge into navigable waters will provide the Federal licensing or permitting agency with a certification that any such discharge will not violate State water quality standards. The RWQCBs administer the Section 401 program with the intent of prescribing measures for projects that are necessary to avoid, minimize, and mitigate adverse impacts on water quality and ecosystems.

Central Valley Project Improvement Act

Reclamation’s evolving mission was written into law on October 30, 1992, with the passage by Congress and signing by President George H.W. Bush, of Public Law 102-575, the Reclamation Projects Authorization and Adjustment Act of 1992. Included in the law was Title 34, the CVPIA. The CVPIA amended previous authorizations of the CVP to include fish and wildlife protection, restoration, and mitigation as project purposes having equal priority with irrigation and domestic water supply uses, and fish and wildlife enhancement having equal priority with power generation. The following are among the changes mandated by the CVPIA:

- Dedicating 800,000 acre-feet annually to fish, wildlife, and habitat restoration.
- Authorizing water transfers outside the CVP service area.
- Implementing the Anadromous Fish Restoration Program (AFRP).
- Creating a restoration fund financed by water and power users.
- Providing for the Shasta TCD.

- Implementing fish passage measures at RBPP.
- Planning to increase water supplies for CVP deliveries.
- Mandating firm water supplies for Central Valley wildlife refuges.
- Meeting the Federal trust responsibility to protect fishery resources on the Trinity River.

The CVPIA is being implemented on a broad front. The Final Programmatic Environmental Impact Statement for the CVPIA analyzes projected conditions in 2022, 30 years from the CVPIA's adoption in 1992. The Final Programmatic Environmental Impact Statement was released in October 1999, and the CVPIA Record of Decision (ROD) was signed on January 9, 2001.

Operations of the CVP reflect provisions of the CVPIA, particularly Sections 3406(b)(1), (b)(2), and (b)(3). The U.S. Department of the Interior's Decision on Implementation of Section 3406(b)(2) of the CVPIA, October 5, 1999, provides the basis for implementing upstream and Delta actions with CVP delivery capability. The AFRP assumes that Sacramento River water will be acquired under Section 3406(b)(2).

Ecosystem Restoration Program

CDFW, USFWS, and NMFS are the implementing agencies for the Ecosystem Restoration Program (ERP). The ERP is a multi-agency effort to improve the ecological health of the Bay-Delta watershed by restoring and protecting habitats, ecosystem functions, and native species. Since the program's inception, ERP agencies have identified more than 600 programmatic actions and 119 milestones throughout the Bay-Delta watershed. The strategic plan objectives of the ERP include the following:

- Recover endangered and other at-risk species and native biotic communities.
- Rehabilitate ecological processes.
- Maintain or enhance populations of selected species for sustainable commercial or recreational harvest.
- Protect or restore functional habitat types.
- Prevent or reduce harmful impacts from nonnative species.
- Improve or maintain water quality and sediment quality conditions that support healthy ecosystems.

Bay Delta Conservation Plan The State and Federal water agencies are currently developing the Bay Delta Conservation Plan (BDCP). The BDCP consists of conservation measures that include components for water conveyance facilities combined with water conveyance operations; conservation components including land acquisition for major habitat restoration efforts in the Delta; and components related to reducing other stressors on the Bay-Delta ecosystem. The BDCP conservation measures are specific actions that would be implemented to achieve the biological goals and objectives of the proposed plan, and are a component of the BDCP conservation strategy. The conservation measures and effects assessment related to achieving the BDCP's overall planning goals are incorporated by reference into the EIR/EIS, which was publicly released in December 2013. The BDCP conservation strategy consists of multiple components that are designed to collectively achieve the overall BDCP planning goals of ecosystem conservation and water supply reliability. The conservation strategy includes biological goals and objectives; conservation measures; avoidance and minimization measures; and a monitoring, research, and adaptive management program.

Four broad concepts have been studied to address urban water quality, water supply reliability, and environmental concerns in the Delta: physical barriers, hydraulic barriers, through-Delta facilities, and isolated facilities. Several alternative Delta conveyance facilities are being evaluated as part of the plan. Depending on the alternative, the water conveyance facility components would create a new conveyance mechanism to divert water from the north Delta to existing SWP and CVP export facilities in the south Delta, interacting with operational guidelines to achieve the planning goal outlined above.

Operating Agreements and Constraints

Coordinated Operations Agreement With the goal of using coordinated management of surplus flows in the Delta to improve Delta export and conveyance capability, the Coordinated Operations Agreement (COA) received Congressional approval in 1986 and became Public Law 99-546. The COA, as modified by interim agreements, coordinates operations between the CVP and SWP and provides for the equitable sharing of surplus water supply. The COA requires that the CVP and SWP operate in conjunction to meet State objectives for water quality in the Bay-Delta estuary, except as specified. Under this agreement the CVP and SWP can each contract for the purchase of surplus water supplies from the other, potentially increasing the efficiency of water operations.

The COA specifies two basic conditions for operational purposes: balanced conditions and excess conditions. Balanced water conditions occur when releases from upstream reservoirs plus unregulated flow equal the water supply needed to meet Sacramento Valley in-basin uses plus exports. During balanced water conditions, storage releases required to meet the Sacramento in-basin uses are made 75 percent from the CVP and 25 percent from the SWP. If unstored water is available during balanced conditions, this water is allocated 55 percent to the CVP and 45 percent to the SWP. Excess water conditions occur when Delta inflows (combined releases from upstream reservoirs and unregulated flow) are greater than needed to meet in-basin uses plus export. Under this condition, flow through the Delta is adequate to meet all needs and no coordinated operation between the CVP and SWP is required.

Since 1986, the COA principles have been modified to reflect changes in regulatory standards, facilities, and operating conditions. At its inception, the COA water quality standards were those of the 1978 Water Quality Control Plan; these were subsequently modified in the 1991 Water Quality Control Plan. The adoption of the 1995 Bay-Delta Plan by the State Water Board superseded those requirements. Evolution of the CWA over time has also impacted the implementation of the COA.

ESA Consultation on CVP and SWP Long Term Operation In June 2004, Reclamation prepared the 2004 Operations Criteria and Plan (OCAP) to provide a description of facilities and the operating environment of the CVP and SWP. Using operational information presented in the 2004 OCAP, Reclamation and DWR developed the 2004 OCAP Biological Assessment (BA), prepared as part of the consultation process required by Section 7 of the ESA.

Reclamation consulted with NMFS and USFWS on the 2004 OCAP, and the two agencies issued the 2004 NMFS BO (NMFS 2004) and 2005 USFWS BO (USFWS 2005), respectively. In 2007, the District Court for the Eastern District of California (District Court), in *Natural Resources Defense Council v. Kempthorne*, found the 2005 USFWS BO to be unlawful and inadequate. In May 2008, in *Pacific Coast Federation of Fishermen's Associations v. Gutierrez,* the District Court found the 2004 NMFS BO to be unlawful and inadequate. The District Court remanded both BOs to the agencies.

In 2008, Reclamation provided the USFWS and NMFS the *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP* (2008 Long-Term Operation BA). USFWS and NMFS released their BOs in 2008 and 2009, respectively.

In the 2008 USFWS BO, the USFWS concluded that the long-term operations of the CVP and SWP would jeopardize the continued existence of delta smelt and adversely modify its critical habitat. Consequently, the USFWS developed a Reasonable and Prudent Alternative (RPA) to avoid jeopardy.

In the 2009 NMFS BO, NMFS similarly concluded that the long-term operations of the CVP and SWP would jeopardize the continued existence of listed salmonids, steelhead, green sturgeon, and killer whales; it also developed an RPA to avoid jeopardy to the species. The RPA included conditions for revised water operations, habitat restoration and enhancement actions, and fish passage actions. Actions were brought challenging the USFWS and NMFS BOs (2008 and 2009) under ESA and the Administrative Procedure Act (APA), concerning the effects of the CVP and SWP on endangered fish species.

2008 USFWS BO Litigation On December 27, 2010, the District Court entered an "Amended Order on Cross-Motions for Summary Judgment" (Doc. 761), remanding the 2008 USFWS BO to the USFWS without vacatur. On May 4, 2011, the District Court issued an amended Final Judgment, ordering the USFWS to complete a final revised BO by December 1, 2013.

In August 2011, the District Court enjoined implementation of USFWS RPA Component 3 (Action 4), the fall X2 requirements, which require a monthly average position of not greater than 74 km in wet years or 81 km in above normal water years eastward of the Golden Gate Bridge. That injunction is no longer in-effect.

The United States and NRDC appealed the District Court's decision invalidating the 2008 USFWS BO. NRDC also challenged the District Court's finding that Reclamation was required to prepare an EIS on its provisional acceptance of the RPA included in the 2008 USFWS BO. Water user plaintiffs cross-appealed the District Court's opinion. On March 13, 2014, the Ninth Circuit Court of Appeals reversed that part of the District Court's opinion that questioned the validity of the 2008 USFWS BO, but affirmed the District Court's finding that Reclamation violated in NEPA in failing to prepare an EIS on its provisional acceptance of the RPA included in the 2008 USFWS BO.

2009 NMFS BO Litigation In September 2011, the District Court remanded the 2009 BO to NMFS, without vacatur, finding in favor of the Federal government on some counts and in favor of water contractor plaintiffs on other counts. The District Court has ordered NMFS to prepare a draft BO no later than October 1, 2016. To meet that schedule, Reclamation must issue a draft EIS evaluating the environmental impacts associated with implementing the draft NMFS BO by April 1, 2017 (six months after receiving the draft BO), and a final EIS no later than March 28, 2018. Reclamation must prepare an EIS on any RPA included in the draft NMFS BO by February 1, 2018; NMFS must release a final BO by that same date. Reclamation must issue a ROD, deciding whether to accept the RPA or an alternative, by April 29, 2018. The United States has appealed the District Court's decision, and that appeal is still pending in the Ninth Circuit Court of Appeals.

Summary In February 2013, Reclamation requested reinitiation of ESA Section 7 consultation, to which USFWS and NMFS agreed.

Currently, although the Ninth Circuit Court of Appeals upheld the validity of the 2008 USFWS BO, the USFWS is obligated to issue (or reissue) a BO by December 1, 2015. On that same date, Reclamation must issue a Final EIS analyzing the environmental impacts associated with operating the CVP and SWP under the USFWS BO.

On the NMFS side, NMFS must issue a draft BO to Reclamation no later than October 1, 2016. Reclamation must issue a final EIS no later than February 1,

2018. On that same date, February 1, 2018, NMFS must release a final BO. Reclamation has until April 29, 2018 to issue a ROD.

Real-Time Decision-Making to Assist Fishery Management

Reclamation and DWR work closely with USFWS, NMFS, CDFW, and other agencies to coordinate the operation of the CVP and SWP with fishery needs. This coordination is facilitated through several forums, as discussed below.

CALFED Water Operations Management Team The Water Operations Management Team (WOMT) was established to facilitate decision making at the appropriate levels and provide timely support of decisions. This team, which first met in 1999, consists of management-level participants from Reclamation, DWR, USFWS, NMFS, and CDFW. The WOMT meets frequently to provide oversight and decision making that must routinely occur within the CALFED Bay-Delta Program (CALFED) Ops Group process. The WOMT relies heavily on other teams and work groups for recommendations on fishery actions. It also uses the CALFED Ops Group (see below) to communicate with stakeholders about its decisions. Although the goal of the WOMT is to achieve consensus on decisions, the agencies retain their authorized roles and responsibilities.

Delta Operations for Salmonids and Sturgeon Group The Delta Operations for Salmonids and Sturgeon (DOSS) was established from Action IV.5 in the NMFS BO. The responsibilities of DOSS are to provide advice to the WOMT and NMFS on measures to reduce adverse effects from Delta operations of the CVP and the SWP to salmonids and green sturgeon. DOSS coordinates the work of other technical teams to provide expertise on issues pertinent to Delta water quality, hydrology, and environmental parameters. The 2009 NMFS BO states the DOSS will:

1. Provide recommendations for real-time management of operations to WOMT and NMFS, consistent with implementation procedures provided in this RPA;

2. Review annually project operations in the Delta and the collected data from the different ongoing monitoring programs;

3. Track the implementation of Actions IV.1 through IV.4;

4. Evaluate the effectiveness of Actions IV.1 through IV.4 in reducing mortality or impairment of essential behaviors of listed species in the Delta;

5. Oversee implementation of the acoustic tag experiment for San Joaquin fish provided for in Action IV.2.2;

6. Coordinate with the Smelt Working Group to maximize benefits to all listed species; and

7. Coordinate with the other technical teams identified in this RPA to ensure consistent implementation of the RPA.

CALFED Ops Group The CALFED Ops Group consists of participants from Reclamation, DWR, USFWS, NMFS, CDFW, State Water Board, and EPA. The CALFED Ops Group generally meets 11 times a year in a public setting to discuss CVP and SWP operations, CVPIA implementation, and coordination with efforts to protect endangered species. The CALFED Ops Group held its first public meeting in January 1995, and during the next 6 years the group developed and refined its process. The CALFED Ops Group is recognized within D-1641 and elsewhere as a forum where agencies can consult and achieve consensus on coordinating CVP and SWP operations with endangered species, water quality, and CVPIA requirements. Decisions made by the CALFED Ops Group have been incorporated into the Delta standards to protect beneficial uses of water (e.g., export/inflow ratios and some closures of DCC gates).

Several teams were established as part of the Ops Group. These teams are described below.

Operations and Fishery Forum The stakeholder-driven Operations and Fishery Forum disseminates information about recommendations and decisions regarding CVP and SWP operations. Forum members are considered the contact people for their respective agencies or interest groups when the CALFED Ops Group needs to provide information about take of listed species or address other topics or urgent issues. Alternatively, the CALFED Ops Group may direct the Operations and Fishery Forum to recommend operational responses to issues of concern raised by member agencies.

Data Assessment Team The Data Assessment Team consists of technical staff members from the agencies and stakeholders. The team meets frequently during the fall, winter, and spring to review and interpret data relating to fish movement, location, and behavior. Based on its assessments and information about CVP and SWP operations, the Data Assessment Team recommends potential changes in operations to protect fish.

B2 Interagency Team The B2 Interagency Team was established in 1999 and consists of technical staff members from the agencies. The team meets weekly to discuss implementation of Section 3406(b)(2) of the CVPIA, which defines the dedication of CVP water supply for environmental purposes. It communicates with the WOMT to ensure coordination with the other operational programs or resource-related aspects of project operations.

Fisheries Technical Teams Several fisheries-specific teams have been established to provide guidance on resource management issues. These teams are described below.

Interagency Fish Passage Steering Committee The Interagency Fish Passage Steering Committee (IFPSC) was established in 2010 because of the NMFS 2009 BO, and consists of members from Reclamation, NMFS, USFWS, CDFW, DWR, RWQCB, USFS, and academia. The IFPSC's role is to provide insight and technical, management, and policy direction for a Fish Passage Program to evaluate the potential reintroduction of listed fish species upstream from Shasta, Folsom, and New Melones dams. The IFPSC provides a stabilizing influence so organizational concepts and directions are established and maintained with a visionary view, and provides insight on long-term strategies in support of implementation of the fish passage RPA.

The Sacramento River Temperature Task Group The Sacramento River Temperature Task Group (SRTTG) is a multiagency group formed pursuant to State Water Board Water Right Orders 90-5 and 91-1 to help improve and stabilize the Chinook salmon population in the Sacramento River. Reclamation develops temperature operation plans each year for the Shasta and Trinity divisions of the CVP. These plans consider impacts of CVP operations on winter-run and other races of Chinook salmon. The SRTTG meets in the spring to discuss biological and operational information, objectives, and alternative operations plans for temperature control, and then recommends an operations plan for temperature control to the WOMT. Reclamation then submits a report to the State Water Board, generally on or before June 1 each year.

After the operations plan is implemented, the SRTTG may perform additional studies and hold meetings to revise the plan based on updated biological data, reservoir temperature profiles, and operations data. Updated plans may be needed for summer operations to protect winter-run Chinook salmon, or in fall for the fall-run spawning season. If any changes are made to the plan, Reclamation submits a supplemental report to the State Water Board.

Delta Smelt Working Group The Delta Smelt Working Group was established in 1995 to resolve biological and technical issues regarding delta smelt and to develop recommendations for consideration by USFWS. The working group generally acts when Reclamation and DWR seek consultation with USFWS on delta smelt or when unusual salvage of delta smelt occurs. It also has assisted in developing strategies to improve habitat conditions for delta smelt.

The Delta Smelt Working Group employs a delta smelt decision tree when forming recommendations to send to the WOMT. The working group does not decide what actions will be taken and does not supplant the Data Assessment Team, but merely provides additional advice to the WOMT. The group may propose operations modifications that it believes will protect delta smelt, either by reducing take at the export facilities or by preserving smelt habitat. The decision tree is adapted by the working group as new knowledge becomes available.

American River Operations Work Group In 1996, Reclamation established an operational working group for the lower American River, known as the American River Operations Work Group. Although open to anyone, the working group's meetings generally include representatives from several agencies and organizations with ongoing concerns about management of the lower American River: Reclamation, USFWS, NMFS, CDFW, the Sacramento Area Flood Control Agency, the Water Forum, the City of Sacramento, Sacramento County, the Western Area Power Administration, and the Save the American River Association. The American River Operations Work Group convenes at least monthly to provide fishery updates and reports to enable Reclamation to better manage Folsom Reservoir for fish resources in the lower American River.

National Forest Management Act

The National Forest Management Act requires the USFS to prepare a Land and Resource Management Plan (LRMP) for each National Forest. The LRMPs provide the direction to manage the lands and resources that are associated with National Forest System lands managed by the USFS. In addition to the requirement for LRMPs, the National Forest Management Act also has a specific requirement to "provide for a diversity of plant and animal communities" (16 U.S Code 1604(g)(3)(B)) as part of their multiple use mandate. The USFS must maintain "viable populations of existing native and desired nonnative species in the planning area" (36 Code of Federal Regulations 219.19). In its decision making process, the USFS must also consider impacts to management indicator species (assemblages). These are defined as any species or assemblage of plants or animals that has been identified as representative of a larger group of species with special habitat requirements. The Shasta-Trinity and Mendocino National Forest LRMPs are directly applicable to efforts related to the SLWRI.

U.S. Forest Service Sensitive Species

The Sensitive Species program is designed to meet the National Forest Management Act requirement to demonstrate the USFS's commitment to maintaining biodiversity on National Forest System lands. The program is a proactive approach to conserving species to prevent a trend toward listing under the ESA, and to ensure the continued existence of viable, well-distributed populations. A "Sensitive Species" is any species of plant or animal that has been recognized by the Regional Forester to need special management to prevent it from becoming threatened or endangered.

Shasta-Trinity and Mendocino National Forest Land and Resource Management Plans

Both the STNF and Mendocino LRMPs incorporate the applicable elements of what is commonly referred to as the Northwest Forest Plan, a plan for the management of habitat for late-successional and old-growth forest-related species within the range of the northern spotted owl. These LRMPs encompasses all the goals, standards, and guidelines established in the 1994

ROD for the Northwest Forest Plan, as a well as the goals, standards, and guidelines designed to guide the management of these National Forests. As part of the STNF LRMP, the USFS is required to implement any recovery plans established under the ESA Section 7(a)(1). As signed in 1995, the STNF LRMP incorporates the following goals, standards, and guidelines related to aquatic and fisheries resource issues associated with the project site, which were excerpted from the STNF LRMP (USFS 2003).

Biological Diversity

Goals (LRMP, p. 4-4)

- Integrate multiple resource management on a landscape level to provide and maintain diversity and quality of habitats that support viable populations of plants, fish, and wildlife.

Threatened, Endangered, and Sensitive Species (Plants and Animals)

Goals (LRMP, p. 4-5)

- Monitor and protect habitat for Federally listed threatened and endangered and candidate species. Assist in recovery efforts for threatened and endangered species. Cooperate with the State to meet objectives for state listed species.

- Manage habitat for sensitive plants and animals in a manner that will prevent any species from becoming a candidate for threatened and endangered status.

Wildlife

Goals (LRMP, p. 4-6)

- Meet habitat or population objectives established for management indicator species or assemblages.

- Cooperate with Federal, State, and local agencies to maintain or improve wildlife habitat.

- Maintain natural wildlife species diversity by continuing to provide special habitat elements within Forest ecosystems.

Standards and Guidelines (LRMP, pp. 4-29 through 4-30)

- Consider transplants, introductions, or reintroductions of wildlife species only after ecosystem analysis and coordination with other agencies and the public.

- Develop interpretation/view sites for wildlife viewing, photography, and study. Provide pamphlets, slide shows, and other educational material that enhance the watchable wildlife and other interpretive programs.

- Maintain and/or enhance habitat for Federally listed threatened and endangered or USFS sensitive species consistent with individual species recovery plans.

U.S. Forest Service Survey and Manage Species

In 1994, the U.S. Bureau of Land Management and USFS adopted standards and guidelines. The Northwest Forest Plan was designed to address human and environmental needs served by the Federal forests of the western part of the Pacific Northwest and Northern California. The development of the Northwest Forest Plan was triggered in the early 1990s by the listing of the northern spotted owl and marbled murrelet as threatened under the ESA.

To mitigate potential impacts to plant and wildlife species that have the potential to occur within the range of the northern spotted owl, surveys are required for species thought to be rare or whose status is unknown due to a lack of information. These species became known as the Survey and Manage species. The Northwest Forest Plan has gone through several revisions since its implementation in 1994, including the elimination of the Survey and Manage Mitigation Measure Standards and Guidelines in 2004. RODs to modify the Survey and Manage rule were published in 2004 and 2007; however, both of these RODs were set aside by the courts. As a result of a court-mandated settlement agreement in litigation on the 2007 ROD (Conservation Northwest v. Sherman Case No. C08-1067-JCC (W.D. Wash. July 5, 2011)), modifications to the Survey and Manage Standards and Guidelines were again made; however, the 2011 Settlement Agreement was set aside by the Ninth Circuit Court of Appeals in 2013, and the 2001 ROD was reinstated.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area contains management strategies intended to achieve or maintain a desired condition. These strategies take into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. The following strategies related to biological resource issues associated with the project were excerpted from the Management Guide (USFS 2003).

Wildlife (Management Guide, pp. IV-19 through IV-20)

- Management activities will assure population viability for all native and non-native desirable species. Management to insure viability will occur within occupied habitat for bald eagle, peregrine falcon, northern spotted owl, northern goshawk, willow flycatcher, northwestern pond turtle, Pacific fisher, Shasta salamander, and candidate species in accordance with species and/or territory management plans, Forest Orders, and appropriate laws and policy.

- Surveys will continue within potential suitable habitats to determine occupancy status for threatened, endangered, sensitive, and candidate species.

- Cooperation will continue with CDFW and the USFWS regarding habitat management of wildlife species inhabiting the National Recreation Area. Consultation with USFWS will continue regarding habitat management for threatened and endangered species.

11.2.2 State

California Endangered Species Act

Pursuant to the California Endangered Species Act (CESA), a permit from CDFW is required for projects that could result in take of a State-listed threatened or endangered species. Under CESA, "take" is defined as an activity that would directly or indirectly kill an individual of a species, but the definition does not include "harming" or "harassing," as the ESA does. As a result, the threshold for take under CESA is higher than under the ESA (e.g., habitat modification is not necessarily considered take under CESA; proposed activities must meet a no-net-loss standard for CESA listed species). Authorization for take of State-listed species can be obtained through a California Fish and Game Code, Section 2080.1, Consistency Determination or Section 2081 Incidental Take Permit.

"Fully Protected" Fish Species

California law (Fish and Game Code, Section 5515) also identifies 10 "fully protected fish" that cannot lawfully be "taken," even with an incidental take permit. None of these species are present in the primary study area.

California Fish and Game Codes

Additional sections of the California Fish and Game Code that are subject to regulation by CDFW include Section 1505 covering spawning areas on state-owned lands; Sections 5930 through 5948 covering dams and obstructions; and Section 7261 recognizing native trout.

Section 1602 handles streambed alteration agreements. All diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by CDFW under Section 1602 of the California Fish and Game Code. Under Section 1602, it is unlawful for any person, governmental agency, or public utility to do the following without first notifying CDFW: substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake. A stream is defined as a body of water that flows at least periodically or intermittently through a bed or channel that has banks and supports fish or other aquatic life. This definition includes watercourses with a surface or subsurface flow that supports or has supported riparian vegetation. CDFW's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife. A CDFW streambed alteration agreement must be obtained for any project that would result in an impact on a river, stream, or lake.

California Public Resources Code, Sections 5093.50-5093.70

The California Public Resources Code (PRC) Sections 5093.50 – 5093.70 were established through 1972 enactment of the Wild and Scenic Rivers Act, which was subsequently amended on several occasions. The essential policy of the State in regard to the matters addressed by the PRC is expressed in Section 5093.50:

> *5093.50 It is the policy of the State of California that certain rivers which possess extraordinary scenic, recreational, fishery, or wildlife values will be preserved in their free-flowing state, together with their immediate environments, for the benefit and enjoyment of the people of the state. The Legislature declares that such use of these rivers is the highest and most beneficial use and is a reasonable and beneficial use of water within the meaning of Section 2 of Article X of the California Constitution.*

The PRC identifies, classifies, and provides protection for specific rivers or river segments, as approved by the Legislature (much of the text of the PRC is devoted to detailed descriptions of river segment locations). Rivers or river segments that are specifically identified and classified in the PRC comprise the California Wild and Scenic Rivers System. As described in Section 5093.50 of the PRC, rivers or river segments included in the California Wild and Scenic Rivers System must possess "extraordinary scenic, recreational, fishery, or wildlife values"; however, the PRC does not define these "extraordinary values."

Various amendments to the California Wild and Scenic Rivers Act have been passed, modifying the PRC. Rivers or river segments are added to (or, as in a few past cases, removed from) the System by Legislative action. In 1986, Assembly Bill 3101 (Statutes of 1986, Chapter 894) established a study process to help determine eligibility for potential additions to the California Wild and Scenic Rivers System (Section 5093.547 and Section 5093.548). In 1982, the original mandate in the PRC requiring management plans for designated rivers was eliminated; however, the California Resources Agency is required to coordinate activities affecting the California Wild and Scenic Rivers System with other Federal, State, and local agencies (Section 5093.69).

The PRC has also been modified to protect river segments without formally identifying them as part of the California Wild and Scenic Rivers System. Such protective language for the McCloud River was added to the PRC in Section

5093.542, emphasizing protection of the wild trout fishery in the McCloud River.

California Wild Trout Program

The California Wild Trout Program was established by the California Fish and Game Commission in 1971 to protect and enhance high-quality fisheries sustained by wild strains of trout. The primary purpose of the wild trout program is to identify, enhance, and perpetuate natural and attractive trout fisheries where wild strains of trout are given major emphasis, in contrast to the majority of the State's accessible waters that are managed by planting domesticated catchable-sized trout on a "put and take" basis (Rode 1989; Rode and Dean 2004). The Commission adopted a wild trout policy that provides for the designation of "aesthetically pleasing and environmentally productive" streams and lakes to be managed exclusively for wild trout, where the trout populations are managed with appropriate regulations to be "largely unaffected by the angling process."

All designated waters must meet the following policy criteria (Rode 1989, Rode and Dean 2004):

- Be open to public angling
- Be of sufficient size to accommodate a significant number of anglers without overcrowding
- Be able to support, with appropriate angling regulations, wild trout populations of sufficient magnitude to provide satisfactory trout catches in terms of number or size of fish

Designated wild trout waters are required to have a management plan and must be subject to angling restrictions that "emphasize unique values and diversity of opportunity in the geographic area" (Rode 1989, Rode and Dean 2004). Wild trout waters are required to be managed in accordance with the following stipulations:

- Domestic strains of catchable-sized trout will not be planted in designated wild trout waters.
- Hatchery-produced trout of suitable wild and semi-wild strains may be planted in designated waters, but only if necessary to supplement natural trout reproduction.
- Habitat protection is of utmost importance for maintenance of wild trout populations. All necessary actions, consistent with State law, will be taken to prevent adverse impacts by land or water development projects affecting designated wild trout waters.

The California Fish and Game Commission in 1976 designated a 10.5-mile river segment immediately below McCloud Dam for special management and habitat protection under the Commission's wild trout program (Rode 1988).

11.2.3 Regional and Local

County and City Policies and Ordinances

Shasta, Tehama, Glenn, Sutter, Sacramento, and Yolo counties and the cities of Redding, Colusa, and Sacramento have established codes and policies that address protection of natural resources, including fisheries, sensitive species, and aquatic resources, and are applicable to the project.

Shasta County's general plan emphasizes that the maintenance and enhancement of quality fish and wildlife habitat is critical to the recreation and tourism industry, and acknowledges that any adverse and prolonged decline of these resources could result in negative impacts on an otherwise vibrant industry. The general plan identifies efforts to protect and restore these habitats to sustain the long-term viability of the tourism and recreation industry (Shasta County 2004).

The City of Redding's general plan strives to strike a balance between development and conservation by implementing several measures such as creek-corridor protection and habitat protection (City of Redding 2000).

Tehama County's general plan update provides an overarching guide to future development and establishes goals, policies, and implementation measures designed to address potential changes in county land use and development.

Glenn County's general plan provides a comprehensive plan for growth and development in Glenn County through 2027. This plan recognizes that public lands purchased for wildlife preservation generate economic activity as scientists and members of the public come to view and study remnant ecosystems (Glenn County 1993).

The City of Colusa's general plan seeks to promote its natural resources through increased awareness and improved public access (City of Colusa 2007).

Sutter County's general plan contains policies that generally address preservation of aquatic resources.

Sacramento County's general plan contains policies that promote protection of marsh and riparian areas, including specification of setbacks and "no net loss" of riparian woodland or marsh acreage (Sacramento County 1993).

Yolo County's general plan aims to provide an active and productive buffer of farmland and open space separating the San Francisco Bay Area from

Sacramento, and integrating green spaces into its communities (Yolo County 2009).

11.2.4 Federal, State, and Local Programs and Projects

Watershed Conservancies

Several watershed conservancy groups exist within the study area. These include but may not be limited to the Butte Creek, Mill Creek, Deer Creek, and Cottonwood Creek watershed conservancies. Watershed conservancies tend to focus on developing and implementing conservation efforts on watershed lands.

California Bay-Delta Authority

The California Bay-Delta Authority (CBDA) was established as a State agency in 2003 to oversee implementation of CALFED for the 25 Federal and State agencies working cooperatively to improve the quality and reliability of California's water supplies while restoring the Bay-Delta ecosystem. The July 2000 CALFED *Final Programmatic EIS/EIR* (CALFED 2000b) identified and analyzed a range of alternatives to address these needs and included a Multi-Species Conservation Strategy (MSCS) to provide a framework for compliance with ESA, CESA, and Natural Community Conservation Planning Act. The August 2000 CALFED Programmatic ROD identified 12 action plans, including Ecosystem Restoration, Watersheds, and Water Supply Reliability, among others (CALFED 2000c). The CALFED ERP has provided a funding source for projects that include those involving acquisition of lands within the Sacramento River Conservation Area (SRCA), initial baseline monitoring and preliminary restoration planning, and preparation of long-term habitat restoration management and monitoring plans. In 2009, the California Legislature passed sweeping water reform legislation, including the establishment of the Delta Stewardship Council (DSC). The DSC was transferred all the responsibilities, programs, staff and most of the funding from the CBDA, and the CBDA was dissolved. The DSC was also given additional mandates, including the development of a Delta Plan to guide activities and programs of State and local programs in the legal Delta through a consistency determination process. The Delta Plan is currently undergoing the final public review.

Cantara Trustee Council

The Cantara Trustee Council administers a grant program that has provided funding for numerous environmental restoration projects in the primary study area, including programs in the Fall River watershed, Sulphur Creek, the upper Sacramento River, Middle Creek, lower Clear Creek, Battle Creek, Salt Creek, and Olney Creek. The Cantara Trustee Council is a potential local sponsor for future restoration actions in the primary study area. The Cantara Trustee Council includes representatives from CDFW, USFWS, the CVRWQCB, California Sportfishing Protection Alliance, and Shasta Cascade Wonderland Association.

Resource Conservation Districts

There are numerous resource conservation districts (RCD) within the study area. Once known as soil conservation districts, RCDs were established under California law with a primary purpose to implement local conservation measures. Although RCDs are locally governed agencies with locally appointed, independent boards of directors, they often have close ties to county agencies and the U.S. Natural Resources Conservation Service. RCDs are empowered to conserve resources within their districts by implementing projects on public and private lands and to educate landowners and the public about resource conservation. They are often involved in the formation and coordination of watershed working groups and other conservation alliances. Districts in the vicinity of Shasta Lake and the Sacramento River upstream from Shasta Lake include the Western Shasta County RCD and the Tehama County RCD. To the east are the Fall River and Pit River RCDs, and to the west and north are the Trinity County and Shasta Valley RCDs.

Riparian Habitat Joint Venture

The Riparian Habitat Joint Venture (RHJV) was initiated in 1994 and includes signatories from 18 Federal, State, and private agencies. The RHJV promotes conservation and the restoration of riparian habitat to support native bird population through three goals:

- Promote an understanding of the issues affecting riparian habitat through data collection and analysis.
- Double riparian habitat in California by funding and promoting on-the-ground conservation projects.
- Guide land managers and organizations to prioritize conservation actions.

RHJV conservation and action plans are documented in the *Riparian Bird Conservation Plan* (RHJV 2004). The conservation plan targets 14 “indicator” species of riparian-associated birds and provides recommendations for habitat protection, restoration, management, monitoring, and policy. The report notes habitat loss and degradation as one of the most important factors causing the decline of riparian birds in California. The RHJV has participated in monitoring efforts within the Sacramento National Wildlife Refuge Complex and other conservation areas. The RHJV’s conservation plan identifies lower Clear Creek as a prime breeding area for yellow warblers and song sparrows, advocating a continuous riparian corridor along lower Clear Creek. Other recommendations of the conservation plan apply to the North Delta Offstream Storage Investigation study area.

Sacramento River Advisory Council

In 1986, the California Legislature passed Senate Bill 1086, which called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance fisheries and riparian habitat in an area stretching from the confluence of the Sacramento River with the Feather River and continuing northward to Keswick Dam. The law established an advisory council that included representatives of Federal and State agencies, county supervisors, and representatives of landowners, water contractors, commercial and sport fisheries, and general wildlife and conservation interests. Responsibilities of the advisory council included development of the *Sacramento River Conservation Area Forum Handbook* to guide management of riparian habitat and agricultural uses along the river (Resources Agency 2003). This action also resulted in formation in May 2000 of the SRCA Forum, a nonprofit public-benefit corporation with a board of directors that includes private landowners and public-interest representatives from a seven-county area, an appointee of the California Resources Agency, and ex-officio members from six Federal and State resource agencies. The work of the organization is generally focused on planning actions and river management within the SRCA planning area.

Sacramento River Conservation Area Forum

Senate Bill 1086 called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance both fisheries and riparian habitat. The SRCA Program has an overall goal of preserving remaining riparian habitat and reestablishing a continuous riparian ecosystem along the Sacramento River between Redding and Chico, and reestablishing riparian vegetation along the river from Chico to Verona. The program is to be accomplished through an incentive-based, voluntary river management plan. The *Upper Sacramento River Fisheries and Riparian Habitat Management Plan* (Resources Agency 1989) identifies specific actions to help restore the Sacramento River fishery and riparian habitat between the Feather River and Keswick Dam. The *Sacramento River Conservation Area Forum Handbook* (Resources Agency 2003) is a guide to implementing the program. The Keswick Dam–Red Bluff portion of the conservation area includes areas within the 100-year floodplain, existing riparian bottomlands, and areas of contiguous valley oak woodland, totaling approximately 22,000 acres. The 1989 fisheries restoration plan recommended several actions specific to the study area:

- Fish passage improvements at the Red Bluff Diversion Dam (completed)
- Modification of the Spring Creek Tunnel intake for temperature control (completed)
- Spawning gravel replacement program (ongoing)
- Development of side-channel spawning areas, such as those at Turtle Bay in Redding (ongoing)
- Structural modifications to the Anderson-Cottonwood Irrigation District Dam to eliminate short-term flow fluctuations (completed)

- Maintaining instream flows through coordinated operation of water facilities (ongoing)
- Improvements at the Coleman National Fish Hatchery (partially completed)
- Measures to reduce acute toxicity caused by acid mine drainage and heavy metals (ongoing)
- Various fisheries improvements on Clear Creek (partially completed)
- Flow increases, fish screens, and revised gravel removal practices on Battle Creek (ongoing)
- Control of gravel mining, improvement of spawning areas, improvement of land management practices in the watershed, and protection and restoration of riparian vegetation along Cottonwood Creek (ongoing)

The Nature Conservancy

The Nature Conservancy (TNC) is a private nonprofit organization involved in environmental restoration and conservation throughout the United States and the world. TNC approaches environmental restoration primarily by strategically acquiring land from willing sellers and obtaining conservation easements. Some of the lands are retained by TNC for active restoration, research, or monitoring activities, while others are turned over to government agencies such as USFWS or CDFW for long-term management. Lower in the Sacramento River basin, TNC has been instrumental in acquiring and restoring lands for the Sacramento River National Wildlife Refuge and managing several properties along the Sacramento River. It also has pursued conservation easements on various properties at tributary confluences, including Cottonwood and Battle creeks.

11.3 Environmental Consequences and Mitigation Measures

11.3.1 Methods and Assumptions

The following sections describe the methods, processes, procedures, and/or assumptions used to formulate and conduct the environmental impact analysis.

This analysis of impacts on fisheries and aquatic ecosystems resulting from implementation of the project alternatives under consideration is based on extensive review of existing documentation that addresses aquatic habitats and fishery resources in the primary and extended study areas, and on water resources modeling analysis.

Summary of Water Resources Modeling

Extensive modeling of hydrologic conditions, water temperature, and salmon production and mortality was performed to provide a quantitative basis from which to assess potential operational effects of the project alternatives on fisheries resources and aquatic habitats within the primary and extended study areas. Model selection and use for each of the variables were as follows:

- **Hydrologic modeling –** CalSim-II (primary and extended study areas)
- **Water temperature modeling –** Sacramento River water temperature model (primary study area)
- **Salmon production and mortality –** SALMOD, Version 3.8 (SALMOD) (primary study area)

Modeling output provided monthly values for each year of the 82-year period of record modeled for river flows, reservoir storage and elevation. These monthly values are then converted to daily values for use in water temperature modeling, which gives 6-hour interval river water temperatures. The period of record is based on records from 1921 through 2003. Outputs on river flow and water temperature were put into weekly form for use in SALMOD to characterize flow- and water temperature–induced production and mortality of salmon under each simulated condition.

The models used in the fisheries analyses (i.e., CalSim-II, Sacramento River water temperature model, and SALMOD) are tools that have been developed for comparative planning purposes, rather than to predict actual river conditions at specific locations and times. The 82-year period of record for CalSim-II and water temperature modeling provides an index of the kinds of changes that would be expected to occur with implementation of a specified set of operational conditions. Output on reservoir storage, river flows, water temperature, and salmon survival for the period modeled should not be interpreted or used as definitive absolutes depicting actual river conditions that would occur in the future. Rather, output for the project alternatives was compared to that for the simulation of the Existing Condition (2005) and No-Action Alternative (future 2030) to determine the following:

- Whether reservoir storage or river flows and water temperatures would be expected to change with implementation of the SLWRI alternatives
- The months in which changes to reservoir storage and river flow and water temperatures could occur
- The relative magnitude of change that could occur during specific months of particular water year types, and whether the relative magnitude anticipated would be expected to result in effects on fisheries resources and aquatic habitats within the region

The models used, though mathematically precise, should be viewed as having reasonable detection limits. Establishing reasonable detection limits is useful when interpreting modeling output for an impact assessment; establishing such limits prevents the user from making inferences beyond the capabilities of the models and beyond the ability to actually measure changes.

The Modeling Appendix provides a more detailed discussion of the modeling process and its application to the project analysis. The appendix describes (1) the primary assumptions and model inputs used to represent hydrologic, regulatory, structural, and operational conditions; and (2) the simulations performed from which effects were estimated. SALMOD is discussed in more detail below.

Modeling Uncertainties and Real-Time Decision-Making As described in Section 11.2, "Regulatory Fraemwork," a process exists to make decisions about CVP and SWP operations in real time. This process allows for fishery management that involves flexible decision-making and adjustments for uncertainties as the outcomes of management actions and other events become better understood.

The modeling simulations conducted to support the analysis of the project alternatives are based on operational assumptions that are generally accepted. However, they do not always capture operational changes that may be associated with the human element of real-time decision-making. Therefore, there may be isolated inaccuracies regarding human decisions made in real time to ensure operational compliance with existing objectives, standards, and/or agreements.

For example, both the NMFS BO for the CVP/SWP long-term operations and various State Water Board orders require that CVP and SWP operations for the Sacramento River meet specific water temperature criteria. In 1997, construction was completed on the TCD at Shasta Dam. The TCD was designed to selectively withdraw water from elevations within Shasta Lake to better manage water temperatures in the upper river, while allowing power generation. The SRTTG is an interagency team that identifies water management alternatives and TCD operations in real time, interprets the availability of cold-water resources in Shasta Lake, and designs an annual/seasonal river temperature compliance strategy, following the guidelines provided in State Water Board Water Right Order 90-5 and multiple BOs.

Reservoir Fisheries Analysis

Monthly values for WSEL, surface area, and cold-water storage in Shasta Lake were calculated for the period from 1921 to 2003 using data outputs from CalSim-II. Values were produced for six alternative dam raise scenarios (project alternatives) using a 2005 water supply demand, and a projected 2030 water supply demand for a total of 12 scenarios. Each year of the hydrologic record was categorized as one of five water year categories (wet, above-normal, below-normal, dry, critical) based on the Sacramento River Inflow Index. Model outputs for the last day of each month from February to July (e.g., February 29, March 31) were used for analysis of potential changes in surface area and WSEL. End-of-month values for April, June, August, and October were used to analyze the potential changes in Shasta Lake's cold-water storage. Potential impacts of the enlargement of Shasta Dam and Shasta Lake on the fisheries resources of Shasta Lake were investigated using several habitat-based metrics that are associated with factors known to limit or otherwise regulate warm-water and cold-water reservoir fish populations. The following metrics were computed and used:

- **Surface Area –** Surface area is the metric used to investigate changes in the amount of available littoral (i.e., shoreline) and limnetic (i.e., open water) habitat, which could impact warm-water and cold-water fisheries, under each of the project alternatives. Variations in surface area influence biological productivity (including fish production) because the upper, lighted layer of the pelagic zone is the principal plankton-producing region of the reservoir. Reservoir enlargement may initially produce a "trophic upsurge" phenomenon that occurs in response to terrestrial habitat inundation, nutrient loading, and increases in labile detritus (Kimmel and Groeger 1986). The initial trophic enrichment will decline and stabilize over time as the reservoir ecosystem approaches its natural trophic equilibrium (Kimmel and Groeger 1986). Trophic depression is a response to decreased nutrient loading and decreased labile detritus. Fisheries production experiences a depression in response to the same factors as well as decreases in available terrestrial organic detritus and loss of cover as inundated vegetation deteriorates (Stables et al. 1990).

- **Cold-Water Storage to Surface Area Ratio –** Cold-water storage to surface area ratio (a dimensionless value) is a useful metric for assessing the potential impact of project alternatives on Shasta Lake's cold-water fishery. Because this ratio relates cold-water volume to the surface area of the reservoir, the metric is sensitive to disproportionate changes in surface area without concomitant changes in the cold-water pool. Stables et al. (1990) suggest that an increase in pelagic and littoral trout habitat accompanied by lake enlargement should lead to higher total fish yield. While increases in water surface area, such as those that might result from reservoir enlargement, can stimulate primary and secondary productivity (Jones and Stokes Associates 1988), access to cold-water refuge can be a limiting factor for cold-water fish production. Therefore, increases in reservoir surface area without proportional increases in cold-water storage are likely to result in little change in cold-water fish production. Conversely, a proportional increase in the cold-water storage to surface area ratio should result in increased cold-water fish productivity.

- **WSEL –** WSEL is a metric that is useful in analyzing the impact of project alternatives on the Shasta Lake warm-water fishery. The timing and duration of WSEL fluctuation can have a great impact on the reproductive success of nearshore spawning fishes (Ploskey 1986). Stable or increasing WSEL during spring months (March through June) can contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of several warm-water species, including the black basses (Lee 1999, Ploskey 1986). Inundation of shoreline vegetation and structural habitat enhancement features installed around the reservoir also leads to increased structural diversity and availability of spawning substrate and cover for juvenile fishes (Miranda, Shelton, and Bryce 1984, Ratcliff 2006). Conversely, reduced or variable WSEL due to reservoir drawdown during spring spawning months can cause reduced spawning success for warm-water fishes through nest dewatering, egg desiccation, and physical disruption of spawning or nest guarding activities (Lee 1999, Ploskey 1986). Loss of access to inundated shoreline vegetation and habitat enhancement structures during reservoir drawdown in the summer increases predation mortality of juvenile bass and other sport fish (Lee 1999, Ploskey 1986, Ratliff 2006).

WSEL values were obtained from CalSim-II outputs, as described above, and were graphed for each comparison set. Monthly change in surface elevation (monthly change in elevation) was calculated by subtracting the previous month's surface elevation from each month. For example, change in elevation for March was calculated by subtracting the February 29 WSEL from the March 31 WSEL. The relative difference in monthly change in elevation from the basis-of-comparison and the relative percent difference in monthly change in elevation were graphed for each comparison set, with the basis-of-comparison as the Existing Condition in sets one and three, and the No-Action Alternative in set two. The relative difference and relative percent difference in monthly change in elevation between CP3, CP4, and CP4A were also graphed for comparison sets one and three.

Surface area values obtained from CalSim-II outputs were graphed for each comparison set. Relative differences in monthly surface area values from the basis-of-comparison were graphed for each comparison set, as described for WSEL.

Cold-Water Storage Values obtained from CalSim-II outputs were divided by surface area outputs to generate monthly cold-water storage to surface area ratios. The cold-water storage to surface area ratios were graphed for comparison set two only. The relative difference and relative percent difference in monthly cold-water storage to surface area ratio from the basis-of-comparison were also calculated and graphed for comparison set two only.

For each metric, CalSim-II projections for monthly change under the Existing Condition were graphed against the No-Action Alternative.

Additionally, graphs were prepared depicting the expected ratio of monthly cold-water storage to surface area, monthly surface area, and expected monthly changes in elevation under 2005 and 2030 water demands (separately) for all water year types for CP1, CP2, CP3, CP4, CP4A, and CP5 for the Shasta Lake and vicinity portion of the primary study area. For example, in the discussion of potential impacts associated with implementation of CP1 is a graph comparing monthly surface area under CP1 with a 2005 water supply demand to monthly surface area under the Existing Condition, and a separate graph making this comparison for CP1 with a 2030 water supply demand versus the No-Action Alternative.

Values for the three habitat metrics were compared in graphical form to address the following issues:

- How reservoir cold-water storage, WSEL, or the cold-water storage to surface area ratio would be expected to change with implementation of the project alternatives
- Months or seasons when potential changes in the habitat metrics could occur
- Relative magnitude of change that could occur during specific months of particular water year types, and the potential impacts these changes could have on fisheries resources, aquatic resources, and habitats within the reservoir

All analyses were based on CalSim-II model outputs. CalSim-II is California's primary water operations planning model, used by both Reclamation and DWR. While model sensitivity and accuracy calibrations are still being developed for CalSim-II, the model's widespread use for water planning and management operations in Central California makes it useful and its projections easily comparable between projects. However, model outputs should be used as tools for interpretation of anticipated impacts rather than actual projections (Close et al. 2003).

Tributaries to Shasta Lake

The existing data on the aquatic resources occurring in many of the tributaries to Shasta Lake are limited. Early in the SLWRI planning process, 12 representative tributary streams to Shasta Reservoir were selected for focused examination as part of this assessment, including five tributaries to Shasta Lake: Sacramento River, McCloud River, Pit River, Squaw Creek, and Big Backbone Creek. Subsequently, to support ongoing analyses of potential impacts of the proposed enlargement of Shasta Dam and Reservoir, Reclamation, USFS, and CDFW collaboratively developed a study plan to obtain additional data on other important tributary streams. Data were collected by surveying 132 representative tributaries to Shasta Lake between November 2011 and August 2012. The primary objectives of this study were to document:

1. The composition, distribution, and relative abundance of native and nonnative fish species.
2. The condition of aquatic habitat.
3. The condition of benthic macroinvertebrate communities.
4. The occurrence of special-status species.
5. The occurrence of invasive aquatic species.

Chinook Salmon Between Keswick Dam and Red Bluff Pumping Plant

SALMOD is a computer model that simulates the dynamics of freshwater salmonid populations, but for the SLWRI, SALMOD simulates population dynamics for all four runs of Chinook salmon between Keswick Dam and RBPP. SALMOD was applied to this project because:

1. SALMOD had been previously used on the upper Sacramento River (from Keswick Dam to Battle Creek) (Kent 1999, Bartholow 2003). John Bartholow and John Heasley (contractor to the U.S. Geological Survey (USGS)) were instrumental in extending SALMOD to assess fish production and mortality between Keswick Dam and the RBPP. They also assisted in preparation of the SALMOD description included in the Modeling Appendix, Chapter 5, which contains a detailed discussion of the SALMOD model.
2. SALMOD has been updated using model parameters and techniques developed for use on the Klamath River and from Sacramento River-specific Chinook salmon information obtained from USFWS and CDFW fisheries biologists (Bartholow 2003; Modeling Appendix, Chapter 5). The USGS completed a thorough review and update of model parameters and techniques on the Klamath River that enabled a smooth transfer of relevant model parameters to the Sacramento River (Bartholow and Henriksen 2006).
3. Resource agency personnel agreed that using SALMOD was the appropriate means of evaluating potential conditions after being presented with the model's capabilities by John Bartholow (formerly with USGS) under contract by Reclamation.
4. SALMOD was peer reviewed by Lisa Thompson and Chris Mosser of University of California (UC) Davis (Thompson and Mosser 2011).

5. SALMOD was approved for use in several other Federal-level studies, including the Reclamation's 2008 Biological Assessment on the Continued Long-Term Operations of the CVP and SWP for compliance with Section 7 of the ESA (Reclamation 2008) and resulting NMFS 2009 BO (NMFS 2009).

Comprehensive Plans Evaluated SALMOD used weekly streamflow and water temperature to evaluate multiple scenarios: the Existing Condition, No-Action Alternative, CP1, CP2, CP3, CP4, CP4A, and CP5. The Existing Condition is based on a 2005 level of development. The No-Action Alternative represents the Future Conditions (2030) without completion of a project to address the objectives of the SLWRI. CP1 is based on a 6.5-foot dam raise; CP2 is based on a 12.5-foot dam raise; and CP3 is based on an 18.5-foot dam raise. CP4 and CP4A were developed based on an 18.5-foot dam raise with operations modified to create a more "fish-friendly" environment, with a portion of the reservoir storage dedicated to fish, to either improve flows or water temperatures, and adds spawning and rearing habitat restoration. CP5 is based on an 18.5-foot dam raise that adds spawning and habitat restoration.

Additional scenarios were evaluated, but not pursued further, due to inconsistencies or lack of achievement of the primary goals of the project.

In the original presentation (August 16, 2005) of the SALMOD model to resource agency personnel, interest was expressed in setting the number of spawning adults at the AFRP production goal for the Sacramento River upstream from the RBPP (Table 11-3). The AFRP defined natural production to be that portion of Chinook salmon not produced in hatcheries, and defined total production to be the sum of harvest and escapement. The production goals include adult fish removed from the system due to both sport and commercial fishing in both freshwater and marine environments.

SALMOD was also conducted using a spawning population based on the 1999 to 2006 average adult return provided by CDFW (2014), which documents spawning escapement estimates for each year in the Central Valley. Using this average was expected to result in a more realistic effect of the project operations on Chinook salmon under the Existing Condition, and on the premise that the AFRP goals should take the populations closer to a state of carrying capacity. Thus, if a population is already at or nearing carrying capacity, increases in the populations are unlikely. The starting year for calculating the average number of spawners was in 1999 because the effects of the TCD began in 1999.

Populations of 500 or more spawning Chinook salmon are considered necessary for accurate results using SALMOD because it is a deterministic model that relies on the "law of large numbers." When populations are "low" (an arbitrary term), mean responses are quickly affected by environmental stochasticity and individual variability, which are factors SALMOD was not designed to address. Therefore, because the 1999 to 2006 average for spring-run Chinook salmon was 207 adult spawners, the criterion of 500 or more fish was not met. However, because of concerns expressed by CDFW and USFWS, the spawning population was left at 207 fish for purposes of the model.

While steelhead are not evaluated directly in SALMOD, effects for late fall-run Chinook salmon are considered representative for steelhead since NMFS, in their 2009 BO, assumed late fall-run Chinook salmon could be used as a surrogate for steelhead because they have similar life history stages, including spawning at the same time of the year (NMFS 2009).

Production numbers generated by SALMOD are not intended to be used as actual population estimates, but as a basis of comparison between alternatives. There are multiple reasons why the juvenile production results should not be used as strict population estimates, including the fact that each year, the same spawning population is used. That is, any increase or decrease in production at the end of a cohort year is not carried forward into another set of spawners. In other words, SALMOD is not a life-cycle model, and only takes into account the environmental and biological factors that affect survival of Chinook salmon between Keswick Dam and RBPP. Because each alternative starts with the same number of spawners each year, the differences between the effects of alternatives on each run of Chinook salmon become clear and easy to evaluate. Additionally, the use of SALMOD allows the focus of impacts to be where the greatest direct effects of the project occur – that is, the Sacramento River upstream from RBPP.

Table 11-3. Number of Spawning Fish Incorporated into SALMOD Model

Reach	Fall-Run	Late Fall-Run	Winter-Run	Spring-Run
California Department of Fish and Game (Grand Tab, 1999 through 2006 average)				
Keswick to ACID	6,658	4,725	3,591	9
ACID to Highway 44 Bridge	4,011	2,096	1,761	39
Highway 44 Bridge to Airport Road Bridge	7,175	3,123	3,041	66
Airport Road Bridge to Balls Ferry Bridge	12,405	2,507	163	36
Balls Ferry Bridge to Battle Creek	8,337	767	9	22
Battle Creek to Jellys Ferry Bridge	12,146	282	9	31
Jellys Ferry Bridge to Bend Bridge	8,789	130	17	3
Bend Bridge to RBPP Inundation Zone	5,044	67	0	0
Total Adult Spawners	**64,565**	**13,697**	**8,591**	**207**
Potential Eggs	**154,956,000**	**32,872,800**	**12,371,040**	**496,800**

Table 11-3. Number of Spawning Fish Incorporated into SALMOD Model (contd.)

Reach	Fall-Run	Late Fall-Run	Winter-Run	Spring-Run
U.S. Fish and Wildlife Service (AFRP goals)				
Keswick to ACID	10,218	9,761	19,320	1,003
ACID to Highway 44 Bridge	6,174	4,328	9,455	4,235
Highway 44 Bridge to Airport Road Bridge	10,925	6,447	16,358	7,021
Airport Road Bridge to Balls Ferry Bridge	19,022	6,169	886	3,901
Balls Ferry Bridge to Battle Creek	12,731	1,591	66	2,340
Battle Creek to Jellys Ferry Bridge	18,629	597	26	3,343
Jellys Ferry Bridge to Bend Bridge	13,427	278	106	334
Bend Bridge to RBPP Inundation Zone	7,705	146	0	0
Total Adult Spawners	**98,830**	**28,318**	**46,218**	**22,178**
Potential Eggs	**237,200,000**	**67,960,000**	**66,552,000**	**53,220,000**

Notes:

Spawners include 52 percent males and 48 percent females.

Number of eggs for late fall-, fall- and spring-run equals 5,000 eggs per female. Winter-run Chinook salmon were assumed to have a lower fecundity of 3,000 eggs per female.

Key:
ACID = Anderson-Cottonwood Irrigation District
AFRP = Anadromous Fish Restoration Program
RBPP = Red Bluff Pumping Plant

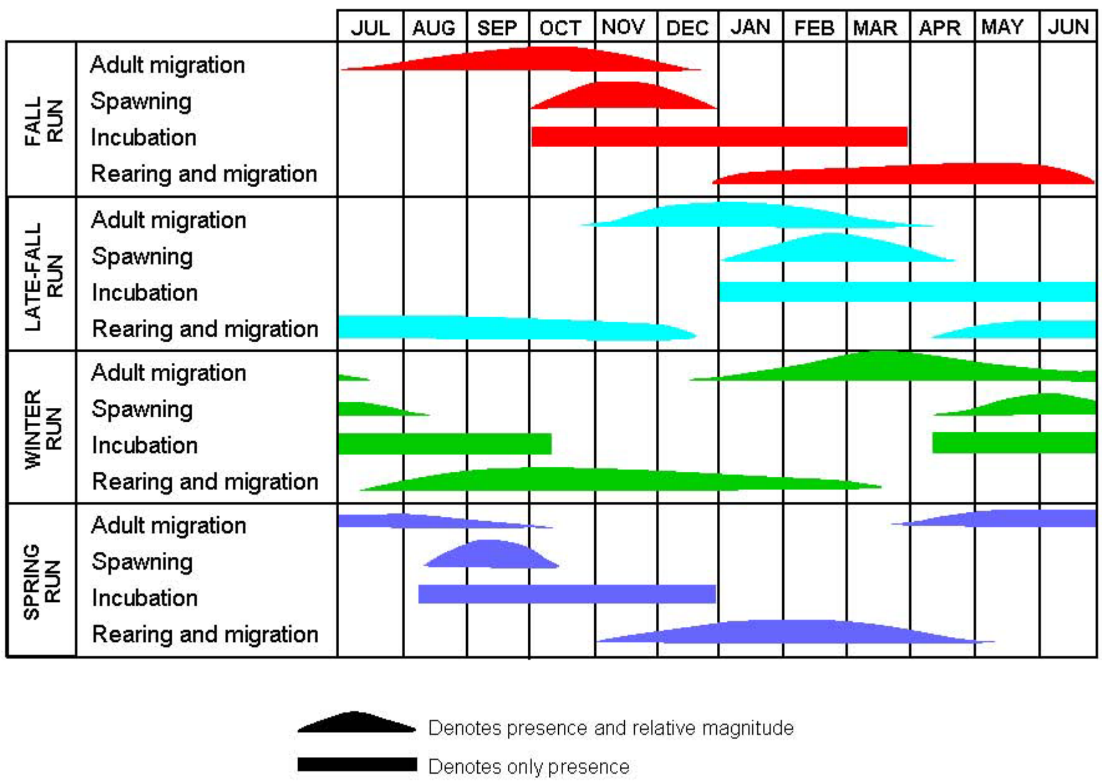
For purposes of evaluating the potential effect of changes in Sacramento River flow and temperature on Chinook Salmon populations between Keswick Dam and Red Bluff Pumping Plant, it was assumed that simulated changes in average annual production that were less than 5 percent (plus or minus) relative to the basis-of-comparison (No-Action Alternative and Existing Conditions) would not be expected to result in a significant (detectable) effect on long term Chinook Salmon production potential. The 5 percent significance threshold was selected to account for the inherent limitations and uncertainties associated with SALMOD, as well as the limitations and uncertainties in the hydrologic model (CalSim-II) and temperature model (Sacramento River water temperature model) used to develop inputs to SALMOD.

SALMOD Output SALMOD produces many forms of output files, but two basic output files – production and mortality (both weekly and annual) – were used in this assessment.

Production derived with SALMOD is the number of immature smolts that survive to pass the RBPP. Because of the uncertainties and limitations inherent in SALMOD, the simulated production should be interpreted as an index which can be used to make relative comparisons between alternatives, and should not be treated as a prediction of absolute numbers of fish production under any alternative.

Two types of mortality were calculated – those caused by the operations (triggered by changes in flow and water temperature) and those that are nonoperations-related (mortalities caused by factors that would still occur without the project in effect, such as disease, predation, and entrainment). Mortality was calculated for each life stage, from migrating/holding adult to the emigrating juvenile.

SALMOD evaluated five separate life stages of Chinook salmon – adult, egg, fry, presmolt, and immature smolt. Figure 11-1 shows the timing for each life stage. Mortality of adults in SALMOD was calculated during the adult migration and spawning time periods. Mortality of eggs (both eggs and in-gravel alevins) was calculated during the adult migration, spawning, and incubation stages, while fry, presmolts, and immature smolts were calculated during the rearing and migration time period.



Source: Vogel and Marine 1991

Figure 11-1. Approximate Timing of the Four Runs of Chinook Salmon in the Sacramento River

Production SALMOD defines production as follows:

Production = (Potential eggs + entrants) – (prespawn egg mortality + other mortality + residuals)

Where:

- Production is the number of young fish surviving to migrate downstream from the RBPP
- Potential eggs are the number of eggs that could be spawned, providing there is no prespawn mortality of either adult females or eggs *in vivo*
- Entrants are the number of young fish entering the project reach (Keswick Dam to RBPP) from the tributaries
- Mortality is the number of eggs and/or fish that die before leaving the project reach
- Residuals are the number of young fish under 60 mm that, after 52 weeks, have not left the project reach

Mortality The mortality process computed all mortality not explicitly included with one of the other processes. This includes mortality from unsuitable water temperature, population density, superimposition, and eggs while *in vivo* and incubating. In addition, a base mortality for all causes not related to any other process (e.g., entrainment, predation) was also computed.

Categories of mortality calculated in SALMOD include the following and are further described in Chapter 5 of the Modeling Appendix:

- **Flow- and Water Temperature-Related Mortality**
  - **Habitat** – Operations-related mortality resulting from forced movement of fry, presmolts, or immature smolts due to habitat constraints.
  - **Temperature** – Operations-related mortality to adults, eggs, fry, presmolts, and/or immature smolts caused by unsuitable water temperatures.
  - **Pre-Spawn** – Includes both lost egg mortality and *in vivo* mortality.
  - **Lost Egg** – Number of eggs lost due to the lack of spawning habitat (a single adult Chinook salmon female cannot spawn because all redds are guarded). It was assumed that these eggs are shed, but as they are alive when leaving the female spawners, they were tallied in the mass balance table. The lack of spawning habitat could be

due to lack of spawning gravel, or lower flows precluding access to suitable spawning habitat.

  - ***In Vivo*** – Number of eggs lost because of operations-related water temperature mortality within the female either before spawning, or prespawning, thermal mortality in which exposure kills the egg or malformed young fish after spawning.
  - **Incubation** – Number of eggs lost if redds (or portions of redds) are affected by changing egg incubation habitat through the duration of the incubation season due to flushing flows scouring out the redds (occurs at a minimum of 60,000 cfs) or redd dewatering from a drop in streamflows resulting from operations-related actions.
  - **Superimposition** – Number of eggs lost due to new spawning on top of a currently incubating redd resulting from operations-related activities.

- **Nonoperations Mortality**
  - **Base** – An accounting of mortality of adults, eggs, fry, presmolts, and immature smolts for everything other than what is in the model, or background mortality (mortality that would occur regardless of the project operations) from factors, such as predation and disease. While these factors may be exacerbated by project operations, they cannot be directly quantified.
  - **Seasonal** – Extra outmigration mortality of presmolts or immature smolts, including diversion-related mortality.

Analysis To evaluate the effects of the project, productions and mortalities were calculated and the differences between the project alternatives and the No-Action Alternative and the Existing Condition were then compared. Most of the years for each run showed minimal differences from the No-Action Alternative, creating an overall average production approaching zero. Each model has its own inherent level of error. In addition, flow data derived from CalSim-II had to be disaggregated from monthly data to weekly, resulting in potential additional error. Because water year type affects Chinook salmon populations, separate production trends based on water year type were evaluated for each run.

Starting populations used in SALMOD were derived from an average population for the years 1999 through 2006, based on the CDFW Grandtab table (CDFW 2014), which lists population estimates on a yearly basis. The AFRP populations were based on the goals identified for the Sacramento River for each run of Chinook salmon.

SALMOD computes mortality by lifestage from various sources, including water temperature and habitat availability. For this evaluation, the lifestage-specific mortalities were converted to smolt equivalent mortality by using annual survival rates for the lifestages later than those at which the mortality occurred. This was an attempt to provide information on the relative effect of water temperature versus habitat availability (as affected by flow volume) on juvenile production. Smolt equivalents were calculated as follows:

Prespawn/Egg Mortality to Immature Smolt Equivalent Prespawn/ Egg Mortality

$$Immature\ Smolt\ Equivalent\ Mortality_i = Mortality_i \times \%\ Survival_{Eggs\ to\ Fry} \times \%\ Survival_{Fry\ to\ Presmolt} \times \%\ Survival_{Preolt\ to\ Immature\ Smolt}$$

Where: $i =$ *Prespawn Base, Prespawn Temperature, Incubation, Superimposition, Eggs-Base, or Eggs-Temperature Mortality*

Fry Mortality to Immature Smolt Equivalent Fry Mortality

$$Immature\ Smolt\ Equivalent\ Mortality_i = Mortality_i \times \%\ Survival_{Fry\ to\ Presmolt} \times \%\ Survival_{Presmolt\ to\ Immature\ Smolt}$$

Where: $i =$ *Base, Temperature, or Habitat Mortality*

Presmolt Mortality to Immature Smolt Presmolt Mortality

$$Immature\ Smolt\ Equivalent\ Mortality_i = Mortality_i \times \%\ Survival_{Pre-Smolt\ to\ Immature\ Smolt}$$

Where: $i =$ *Base, Temperature, Habitat, or Seasonal Mortality*

Although water year classifications are somewhat arbitrary, and the biological year for each run of Chinook salmon encompasses portions of two separate water years, mortalities caused by operations were separated by water year types to identify trends, such as changes in mortality in critical water years due to unsuitable water temperatures. Once the years were separated by water year type, the mortality categories were ranked to determine which mortality category under each alternative was the primary factor affecting production for each run.

The SLWRI has the greatest variations in project operations from the Existing Condition, No-Action Alternative, and the Comprehensive Plans during critical and dry water years (for further detail, refer to the *Hydrology, Hydraulics and Water Management Technical Report*). Besides providing a more reliable water source for delivery, CP1 through CP5 are able to provide more suitable flows and water temperatures during critical and dry water years. This is shown in increased production and/or decreased operations-related mortalities.

The action alternatives are meant to provide the greatest benefits to anadromous fish in critical and dry water years, when anadromous fish are generally at highest risk of flow- and temperature-related mortality. According to NMFS (2009b), Chinook salmon populations, especially winter-run Chinook, are highly vulnerable to global and localized climate changes, including prolonged drought conditions. This is caused by reduced volumes of cold water that can be released from reservoirs, including Shasta Lake, thus affecting spawning and rearing habitat conditions.

Moreover, an evolutionarily significant unit (ESU) that is represented by a single population is vulnerable to the limitation in life history and genetic diversity that would otherwise increase the ability of individuals in the population to withstand environmental variation. Although the status of winter-run Chinook salmon is improving, there is only one population, and it depends on cold water releases from Shasta Dam, which would be vulnerable to a prolonged drought.

The 2009 NMFS BO RPA Action Suite I.2 indicate that the Shasta cold water pool must be managed to maintain suitable water temperatures and habitat for winter-run Chinook salmon downstream from Shasta Dam, particularly in critical water years, extended drought years, and under future conditions, which will be affected by increased downstream water demands and climate change (NMFS 2009). Therefore, critical and dry water years are the most important water year types for the survival of the anadromous fishes, particularly when there is a series of critical and dry water years in succession, because the low storage levels caused by multiple dry years result in warmer waters available for release. These warmer waters increase mortality and reduce production.

Increasing storage, particularly in the cold water pool, and targeting the release of the cold water for critical and dry water years, is expected to improve survival and production of Chinook salmon and steelhead during those periods when they are most vulnerable to temperature- and flow-related mortality. The SLWRI is not intended or expected to significantly increase production during wet, above normal or below normal water year types, because the existing cold water pool is generally sufficient to provide adequate flows and temperatures for Chinook and Steelhead during those years. As a result, the analysis of project impacts on anadromous fish focuses on the impacts in critical and dry years, in addition to considering the average impact for all years combined. In the simulated 81 years modeled in CalSim-II, 13 years were identified as critical water years, and 17 were identified as dry water years.

Riverine Fisheries

Riverine fish, including steelhead and green sturgeon, were evaluated based on differences between monthly mean flows at various modeling locations on the lower Sacramento River and tributaries under each Comprehensive Plan and the monthly mean flows simulated for Existing Conditions and No-Action Alternative conditions. Modeling for the lower American River occurred at Verona and Freeport; for the lower Feather River, modeling occurred below Thermalito Afterbay; and American River modeling occurred near the H Street Bridge in Sacramento. Modeling also occurred on the Trinity River. Additionally, flow changes were used to evaluate the potential change in ecologically important geomorphic processes such as channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Changes in river flow for each alternative, relative to the basis-of-comparison, were used to reflect and evaluate potential impacts to juvenile salmonid rearing habitat that could result from altered flow regimes. For purposes of evaluating the potential effects of changes in flows on fish habitat, and considering the accuracy and inherent noise within the hydrologic model, it was assumed that changes in the average monthly flows less than 5 percent (plus or minus) relative to the basis-of-comparison would not be expected to result in a significant (i.e., detectable) effect on habitat quality or availability.

Delta Fisheries

Delta Outflow Water development has changed the volume and timing of freshwater flows through the Bay-Delta. Over the past several decades, the volume of the Bay-Delta's freshwater supply has been reduced by upstream diversions, in-Delta use, and Delta exports. As a result, the proportion of Delta outflow depleted by upstream and Delta diversions has grown substantially. In wet years, diversions reduce outflow by 10 percent to 30 percent. In dry years, diversions may reduce outflow by more than 50 percent.

Water development has also altered the seasonal timing of flows passing into and through the Bay-Delta. Flows have decreased in April, May, and June and have increased slightly during the summer and fall (State Water Board 2012). Seasonal flows influence the transport of eggs and young organisms (e.g., zooplankton, fish eggs, larvae) through the Delta and into San Francisco Bay. Flows during the months of February through June play an especially important role in determining the reproductive success and survival of many estuarine species, including salmon, striped bass, American shad, delta smelt, longfin smelt, splittail, and others (Stevens and Miller 1983, Stevens et al. 1985, Herbold 1994, Meng and Moyle 1995, Rosenfield 2010, Rosenfield and Baxter 2007).

For purposes of evaluating the potential effect of changes in outflow on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the hydrologic model, it was assumed that changes in the average monthly flows that were less than 5 percent (plus or minus) relative to the basis-of-comparison would not be expected to result in a significant (detectable) effect on habitat quality or availability. It would also not be expected to result in a significant effect on the transport mechanisms provided by Delta outflow, on resident or migratory fish or the zooplankton and phytoplankton on which they rely for a food resource.

Delta Inflow Changes in upstream reservoir storage have the potential to affect Delta inflow (water entering the Delta). Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly or indirectly affects fish and other aquatic resources.

The comparison includes the estimated average monthly inflow under the basis-of-comparison conditions (Existing Condition and No-Active Alternative), the average monthly flow under each of the project alternatives evaluated, and the percentage change between base flows and operations. For purposes of evaluating the potential effect of changes in Delta inflow on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the hydrologic model, it was assumed that changes in the average monthly flows that were less than 5 percent (plus or minus) relative to the basis-of-comparison would not be expected to result in a significant (detectable) effect on habitat quality or availability, or the transport mechanisms provided by Delta inflow, on resident or migratory fish or the zooplankton and phytoplankton that they rely on for a food resource.

Sacramento River Inflow Flow within the Sacramento River has been identified as an important factor affecting the survival of emigrating juvenile Chinook salmon, important to the downstream transport of planktonic fish eggs and larvae such as delta smelt and longfin smelt, striped bass, and shad, and important for seasonal floodplain inundation that has been identified as important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon and steelhead. Sacramento River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. A reduction in Sacramento River flow as a result of SLWRI alternative operations, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

For purposes of evaluating the potential effect of changes in Sacramento River inflow on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the hydrologic model, it was assumed that changes in the average monthly flows less than 5 percent (plus or minus) relative to the basis-of-comparison would not be expected to result in a significant (detectable) effect on habitat quality or availability, or the transport mechanisms provided by Sacramento River inflow, on resident or migratory fish or the zooplankton and phytoplankton that they rely on for a food resource.

San Joaquin River Flow at Vernalis Flow within the San Joaquin River has been identified as an important factor affecting the survival of juvenile Chinook salmon migrating downstream from the tributaries through the mainstem San Joaquin River and Delta, important to the downstream transport of planktonic fish eggs and larvae such as striped bass, and important for seasonal floodplain inundation that is considered to be important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon. San Joaquin River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. A reduction in San Joaquin River flow as a result of SLWRI alternative operations, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

For purposes of evaluating the potential effect of changes in San Joaquin River flow at Vernalis on fish habitat within the Bay-Delta, and considering the accuracy and inherent noise within the hydrologic model, less than a 5-percent change (plus or minus) relative to the basis-of-comparison, would not be expected to result in a significant (detectable) effect on habitat quality or availability, or the transport mechanisms provided by San Joaquin River flow at Vernalis, on resident or migratory fish or the zooplankton and phytoplankton that they rely on for a food resource.

Low Salinity Zone and X2 In many segments of the Bay-Delta, but particularly in Suisun Bay and the Delta, salinity is controlled by the balance of saltwater intrusion from San Francisco Bay and freshwater flow from the tributaries to the Delta. By altering the timing and volume of flows, water development has affected salinity patterns in the Delta and in parts of San Francisco Bay (Kimmerer 2002, Kimmerer 2004, State Water Board 2012). Under natural conditions, the Carquinez Strait/Suisun Bay region marked the approximate boundary between saltwater and freshwater in the Bay-Delta during much of the year. In the late summer and fall of drier years, when Delta outflow was minimal, seawater moved into the Delta from San Francisco Bay. Beginning in the 1920s, following several dry years and because of increased upstream storage and diversions, salinity intrusions became more frequent and extensive.

Since the 1940s, releases of freshwater from upstream storage facilities have increased Delta outflows during summer and fall. These flows have correspondingly limited the extent of salinity intrusion into the Delta. Reservoir releases have helped to ensure that the salinity of water diverted from the Delta is acceptable during the summer and late fall for farming, municipal, and industrial uses (State Water Board 2012).

Salinity is an important habitat factor in the Bay-Delta (Baxter et al. 1999). All estuarine species are assumed to have optimal salinity ranges, and their survival may be affected by the amount of habitat available within the species' optimal salinity range. Because the salinity field in the Bay-Delta is largely controlled by freshwater outflows, the level of outflow may determine the surface area of optimal salinity habitat that is available to the species (Unger 1994, Kimmerer 2002).

The transition area between saline waters within the Bay and freshwater within the rivers, frequently referred to as the LSZ, is located within Suisun Bay and the western Delta. The LSZ has also been associated with the region of the Bay-Delta characterized by higher levels of particulates, higher abundances of several types of organisms, and a turbidity maximum. It is commonly associated with the position of the 2 parts per thousand salinity isohaline (X2), but actually occurs over a broader range of salinities (Kimmerer 1992, Kimmerer 2004). Originally, the primary mechanism responsible for this region was thought to be gravitational circulation, a circulation pattern formed when freshwater flows seaward over a dense, landward-flowing marine tidal current. However, studies have shown that gravitational circulation does not occur in the LSZ in all years, nor is it always associated with X2 (Burau et al. 1998). Lateral circulation within the Bay-Delta or chemical flocculation may play a role in the formation of turbidity maximum within the estuary.

As a consequence of higher levels of particulates, the LSZ may be biologically significant to some species. Mixing and circulation in this zone concentrates plankton and other organic material, thus increasing food biomass and production. Larval fish such as striped bass, delta smelt, and longfin smelt may benefit from enhanced food resources. Since about 1987, however, introduced species have cropped much of the primary production in the Bay-Delta and there has been virtually no enhancement of phytoplankton production or biomass in the LSZ (CUWA 1994, Lund et al. 2012).

This region continues to have relatively high levels of invertebrates and larval fish, even though the base of the food chain may not have been enhanced in the LSZ during the past decade. Vertical migration of these organisms through the water column at different parts of the tidal cycle has been proposed as a possible mechanism to maintain high abundance in this region, but evidence suggests that vertical migration does not provide a complete explanation (Kimmerer et al. 2002).

Although evidence indicates that X2 and the LSZ are not as closely related as previously believed (Burau et al. 1998), X2 continues to be used as an index of the location of the LSZ and area/or of increased biological productivity. Historically, X2 has varied between San Pablo Bay (River Kilometer 50) during high Delta outflow and Rio Vista (River Kilometer 100) during low Delta outflow. X2 has typically been located between approximately Honker Bay and Sherman Island (River Kilometer 70 to 85). X2 is controlled directly by the volume of Delta outflow, although changes in X2 lag behind changes in outflow. Minor modifications in outflow do not greatly alter X2.

Operations of upstream storage reservoirs have the potential to affect the location of X2 as a result of changes in freshwater flows from the upstream tributaries through the Delta. For purposes of evaluating changes in habitat quantity and quality for estuarine species, a significance criterion of an upstream change in X2 location within 1 kilometer (km) of the basis-of-comparison condition was considered to be less than significant. The criterion was applied to a comparison of hydrologic model results for basis-of-comparison conditions and project alternatives, by month and water year, for the months from February through May and September through November.

Old and Middle River Reverse Flows Reverse flows occur when Delta exports and agricultural demands exceed San Joaquin River inflow plus Sacramento River inflow through the DCC, Georgiana Slough, and Threemile Slough. The capacities of the DCC, Georgiana Slough, and Threemile Slough are fixed; therefore, if pumping rates exceed that total capacity, plus flows in Old River and Eastside streams, the pumping causes Sacramento River water to flow around the west end of Sherman Island and then eastward up the San Joaquin River. This condition occurs frequently during dry years with low Delta inflows and high levels of export at the CVP and SWP pumps. The reverse flow condition within the lower San Joaquin River is typically referred to as Qwest. As second reverse flow condition occurs within Old and Middle rivers as the rate of water diverted at the CVP and SWP export facilities exceeds tidal and downstream flows within the central region of the Delta.

Reverse flows in Old and Middle rivers, resulting from low San Joaquin River inflows and increased exports to the CVP and SWP, have been identified as a potential cause of increased delta smelt and salmonid mortality at the CVP and SWP fish facilities within recent years (Simi and Ruhl 2005, USFWS 2008, NMFS 2009, Wanger 2007). Results of analyses of the relationship between the magnitude of reverse flows in Old and Middle rivers and salvage of adult delta smelt in the late winter shows a substantial increase in salvage as reverse flows exceed approximately -5,000 cfs. Concerns regarding reverse flows in Old and Middle rivers have also focused on planktonic egg and larval stages of delta and longfin smelt, striped bass, splittail, and on Chinook salmon smolts, and while these species do not spawn to a significant extent in the south Delta, eggs and larvae may be transported into the area by reverse flows in Old and Middle rivers. As discussed previously, these early life stages are generally entrained, since they are too small to be effectively screened from export waters.

Old and Middle river reverse flows have been calculated for project alternatives that equate San Joaquin River flow at Vernalis and exports to Old and Middle river flows. Summaries of Old and Middle river reverse flows are included for the Existing Condition, No-Action and action alternatives, by month and water year type. The most biologically sensitive period when the potential effects of reverse flows could affect delta smelt, Chinook salmon, and many other species extends from the late winter through early summer. For purposes of these analyses, a comparison of reverse flows within Old and Middle rivers under the basis-of-comparison and proposed alternative project operations was prepared for the seasonal period extending from January through June. Per the RPAs in the USFWS 2008 and NMFS 2009 BOs, any reduction in Old and Middle River reverse flows (i.e., flows that are more negative) that result in flows greater than (i.e., flows that are more negative) -5,000 cfs are considered to be a significant impact. Additionally, a 5 percent reduction in Old and Middle River flows making them more negative is also considered a significant impact.

CVP and SWP Export Operations Increased exports could increase the risk of entrainment and salvage of resident and migratory fish present in the south Delta, which may include delta smelt, longfin smelt, juvenile Chinook salmon, steelhead, striped bass, and other species of fish as well as macroinvertebrates and nutrients. Increased exports during drier water years in the summer could result in an increased risk of entrainment and salvage for juvenile delta smelt and salmon (April to June) and resident warm-water fish such as striped bass, threadfin shad, catfish, and others during the warmer summer months (July through August). Increased exports could also increase the entrainment and removal of phytoplankton, zooplankton, macroinvertebrates, organic material, and nutrients from the Delta.

Estimated Fish Entrainment/Losses Changes in the volume of water exported at the CVP and SWP facilities is assumed to result in a direct proportional increase or decrease in the risk of fish being entrained and salvaged at the facilities. Using information from the hydrodynamic operations model, in combination with information on the densities of various fish species observed at the salvage facilities, an index in the form of a change in the numbers of a fish species theoretically affected by a change in export operations can be developed. Fish lost to entrainment/salvage at the CVP and SWP were estimated based on monthly estimated combined exports. The project alternatives were modeled in CalSim and assume, for each alternative, that the project would be implemented under the Existing Condition, and under the Future Condition. Both the Existing Condition, or “existing base” conditions, and future base conditions, or “future No-Action Alternative” conditions – which assumes no project was implemented, were assessed.

Data sources used to calculate fish losses at the CVP and SWP consisted of 1995 through 2005 monthly average density data, collected by DWR (2006) at the Skinner Fish Facility and by Reclamation at the Jones Fish Facility located at each export facility, respectively. These density data were calculated for delta smelt, longfin smelt, Chinook salmon, steelhead, striped bass, and splittail. Green sturgeon were considered for this analysis; however, they are seldom collected at the fish facilities, and thus, have not been modeled in the entrainment loss estimates. Fish density data was combined with CalSim results export flows modeled.

From CalSim modeling results, average monthly exports, and average exports each year from 1922 to 2003 in cfs were converted to acre-feet per each month (January through December), and were then multiplied by monthly average densities (number of fish per acre-foot), for each of the selected fish species. Average monthly fish losses calculated for each year were then averaged by water year type (e.g., wet, above-normal, normal, below-normal, dry, and critical) for each month, as well as an average across all years (all water year types), for each month. Fish losses, for each species, were totaled across months to show the total fish loss index for a given species for an average year (all water year types), wet, above-normal, normal, below-normal, dry, and critical years.

Fish losses resulting from entrainment were calculated two ways, which both produced identical entrainment indices to represent the change in entrainment based on changes in CVP and SWP exports as a result of the SLWRI alternatives:

- Fish losses were estimated by calculating losses under the base conditions, and then by calculating losses under the project alternative, from CalSim modeling. The total number of fish lost under the base case was subtracted from the number lost under the project alternative, indicating whether a net benefit (negative number) or a net loss (positive number) would result from the project alternatives.

- Fish losses were estimated by calculating losses directly from the "Alt minus Base" modeling results in CalSim.

The general calculation of the change in entrainment/salvage risk is shown below:

A = Density of fish per acre-foot for a given fish species (e.g., delta smelt, longfin smelt, salmon, striped bass, steelhead, splittail)

B = Monthly export rate (cfs), by year

C = [*B* x 1.983 x (number of days/month)] = average monthly exports (for CVP+SWP) for a given year, 1922 to 2003, in acre-feet

D = [A] [C] = Average monthly fish loss, per species, in a given year

D_A = $\sum$ ($C_{1922,}$ C_{1923} … C_{2003}) = Average monthly fish losses at the CVP + SWP

D_W = $\sum$ (*wet water years*) = Fish losses, by month, at the CVP + SWP, based on wet water years, 1922 to 2003

D_{AN} = $\sum$ (*above-normal water years*) = Fish losses, by month, at the CVP + SWP, based on above-normal water years, 1922 to 2003

D_N = $\sum$ (*normal water years*) = Fish losses, by month, at the CVP + SWP, based on normal water years, 1922 to 2003

D_{BN} = $\sum$ (*below-normal water years*)) = Fish losses, by month, at the CVP + SWP, based on below-normal water years, 1922 to 2003

D_D = $\sum$ (*dry water years*) = Fish losses, by month, at the CVP + SWP, based on dry water years, 1922 to 2003

D_C = $\sum$ (*critical water years*) = Fish losses, by month, at the CVP + SWP, based on critical water years, 1922 to 2003

E_A = ($D_{A\text{-}JANUARY}$ +$D_{A\text{-}FEBRUARY...}$+ $D_{A\text{-}DECEMBER}$) = Total yearly average fish losses, based on monthly average 1922 to 2003 fish losses

E_W = ($D_{W\text{-}JANUARY}$ +$D_{W\text{-}FEBRUARY...}$+ $D_{W\text{-}DECEMBER}$) = Total yearly fish losses in a wet year, based on monthly average 1922 to 2003 fish losses

E_{AN} = ($D_{AN\text{-}JANUARY}$ +$D_{AN\text{-}FEBRUARY...}$+ $D_{AN\text{-}DECEMBER}$) = Total yearly fish losses in an above-normal year, based on monthly average 1922 to 2003 fish losses

E_N = ($D_{N\text{-}JANUARY}$ +$D_{N\text{-}FEBRUARY...}$+ $D_{N\text{-}DECEMBER}$) = Total yearly fish losses in a normal year, based on monthly average 1922 to 2003 fish losses

E_{BN} = ($D_{BN\text{-}JANUARY}$ +$D_{BN\text{-}FEBRUARY...}$+ $D_{BN\text{-}DECEMBER}$) = Total yearly fish losses in a below-normal year, based on monthly average 1922 to 2003 fish losses

E_D = ($D_{D\text{-}JANUARY}$ +$D_{D\text{-}FEBRUARY...}$+ $D_{D\text{-}DECEMBER}$) = Total yearly fish losses in a dry year, based on monthly average 1922 to 2003 fish losses

$E_C = (D_{C\text{-}JANUARY} + D_{C\text{-}FEBRUARY} \ldots + D_{C\text{-}DECEMBER})$ = Total yearly fish losses in a critical year, based on monthly average 1922 to 2003 fish losses

Impact Mechanisms

The project could potentially affect fisheries and aquatic ecosystems through the following impact mechanisms:

- Construction-related impacts:
  - Temporary construction-related loss or degradation of aquatic habitat
- Operations-related impacts, including the following:
  - Flow- and/or water temperature–related impacts on species of primary management concern
  - Geomorphic impacts resulting from reduced frequency, duration, and/or magnitude of ecologically important intermediate and peak flows
- Delta flow-related effects, including the following:
  - Delta outflow and inflow related effects on species of primary management concern
  - Effects related to changes in Sacramento River inflow to the Delta
  - San Joaquin River flow-related effects
  - Effects on species of primary management concern resulting from changes in the location of the LSZ and X2
  - Effects resulting from reverse flows in Old and Middle rivers
  - Effects of changes in CVP and SWP exports to fish entrainment and salvage

The analysis assessed potential effects on fish species of primary management concern and important aquatic ecological processes from construction activities and/or operations occurring in the primary study area or the extended study area. Species of primary management concern are special-status, ecologically important, and recreationally or commercially important fish species. For the upper Sacramento River (Shasta Dam to Red Bluff) portion of the primary study area, fish species of primary management concern consist of the following:

- Four runs of Chinook salmon (winter-, spring-, fall-, and late fall-run)

- Steelhead
- Green sturgeon
- Sacramento splittail
- American shad
- Striped bass

For the lower Sacramento River to the Delta portion of the extended study area, fish species of primary management concern include the same fish identified above, as well as delta smelt and longfin smelt, and exclude American shad.

For the Trinity River portion of the extended study area, fish species of primary management concern consist of the following:

- Chinook salmon
- Steelhead
- Coho salmon
- Green sturgeon
- White sturgeon

The analysis of potential impacts on primary fish species of management concern considered species' life history stages (adult migration, spawning, egg incubation, and juvenile rearing and emigration) and biological requirements. For all fish species of primary management concern in the Sacramento River, evaluation of potential impacts on individual life stages was based on life history descriptions provided in the *Fisheries and Aquatic Ecosystems Technical Report*.

Increased water supplies or increased supply reliability also could reduce a limitation on population growth, changes in local land use, or on other activities that could affect aquatic habitats and fishery resources in the primary and extended study areas, resulting in potentially significant impacts. The impacts of this growth would be analyzed in general plan EIRs and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these impacts would be the responsibility of these local jurisdictions, and not of Reclamation. The expected increase in water supply deliveries relative to the entire CVP and SWP service areas would be small, however. Assuming increased deliveries could be provided to any number of geographic areas within the CVP and SWP service areas, the project's impact on growth that could affect aquatic habitats would be minor.

Similarly, projects potentially affecting most aquatic habitats and listed species would require permits from CDFW, USACE, USFWS, and NMFS. It is anticipated that effects on aquatic habitats and listed species would be avoided, minimized, and/or mitigated during those agency consultations.

The extent, location, and timing of induced growth are currently highly uncertain; the effects of this growth would be analyzed and mitigated during future land use planning and environmental review for specific projects. Therefore, growth-inducing effects on aquatic habitats and fisheries resources are not discussed further in this chapter.

11.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect of the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (CEQA Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (CEQA Section 15126.4(a)).

Significance criteria (sometimes called "thresholds of significance") used in this analysis are based on the checklist presented in Appendix G of CEQA; factual or scientific information and data; and regulatory standards of Federal, State, and local agencies. These thresholds also encompass the factors taken into account under NEPA to determine the significance of an action in terms of the context and the intensity of its effects.

For the assessment of impacts on fisheries and aquatic ecosystems, habitat indicators for project operations such as water temperature, flows, and important ecological processes have been used to evaluate whether the project alternatives would have an adverse effect on the species and/or species' habitat. For example, exceedence of monthly mean water temperatures identified by NMFS for certain species (e.g., 56ºF at Bend Bridge from April 15 through September 30 for winter-run Chinook salmon) is one such impact on a habitat indicator. Reduction of reservoir WSELs can reduce the availability of nearshore littoral habitat used by warm-water fish for spawning and rearing, thereby reducing spawning and rearing success and subsequent year class strength; therefore, reservoir WSEL is another habitat indicator used. Changes in river flows and water temperatures during certain periods of the year have the potential to affect spawning, fry emergence, and juvenile emigration. Therefore, changes in monthly mean river flows and water temperatures during certain times of the year (during spawning, incubation, and initial rearing) have also been used as habitat impact indicators for species of primary management concern.

The following significance criteria were developed based on guidance provided by CEQA, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on fisheries and aquatic ecosystems would be significant if project implementation would do any of the following:

- Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by CDFW, USFWS, or NMFS.
- Conflict with the provisions of an adopted HCP, natural community conservation plan, or other approved local, regional, or State HCP or policies or ordinances protecting biological resources.
- Interfere substantially with the movement of any native resident or migratory fish species or with established habitat, or impede the use of native fish nursery/rearing sites.
- Conflict with a local policy or ordinance that protects aquatic and fishery resources.
- Substantially reduce the habitat of a fish species, cause a fish species to drop below self-sustaining levels, threaten to eliminate a fish or macroinvertebrate community, or substantially reduce the number or restrict the range of an endangered, rare, or threatened fish species.

Significance statements are relative to both the Existing Condition (2005) and Future Conditions (2030), unless stated otherwise.

11.3.3 Direct and Indirect Effects

This section identifies how aquatic habitats and fish communities could be affected by the project. The project could affect fisheries and aquatic ecosystems through the following:

- Causing construction-related loss or degradation of aquatic habitat in the vicinity of and downstream from Shasta Dam.
- Altering flow regimes and water temperatures downstream from Shasta Dam and downstream from other reservoirs with altered releases.

- Causing a reduction in ecologically important geomorphic processes resulting from reduced frequency and magnitude of intermediate to high flows.

By altering reservoir storage and releases, the project would change flow regimes in downstream waterways. In turn, these alterations to the flow regime could affect fishery resources and important ecological processes on which the fish community depends, particularly their instream and seasonal floodplain habitats along waterways immediately downstream from reservoirs.

No-Action Alternative

Under the No-Action Alternative, the Federal Government would take reasonably foreseeable actions, including actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete. However, the Federal Government would not take additional actions toward implementing a plan to raise Shasta Dam to help increase anadromous fish survival in the Sacramento River between Shasta Dam and Red Bluff, nor help address the growing water reliability issues in California. Shasta Dam would not be modified, and the CVP would continue operating similar to the Existing Condition. Changes in regulatory conditions and water supply demands would result in differences in flows on the Sacramento River and at the Delta between existing and future conditions. Possible changes include the following:

- Firm Level 2 Federal refuge deliveries
- SWP deliveries based on full Table A amounts
- Full implementation of the Grassland Bypass Project
- Implementation of salinity management actions similar to the Vernalis Adaptive Management Plan
- Implementation of the South Bay Aqueduct Improvement and Enlargement Project
- Increased San Joaquin River diversions for water users in the Stockton metropolitan area associated with the Delta Water Supply Project
- Increased Sacramento River diversions by Freeport Regional Water Project agencies
- San Joaquin River Restoration Program Full Restoration Flows

This alternative is used as a basis of comparison for future condition comparisons.

Shasta Lake and Vicinity

Impact Aqua-1 (No-Action): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under the No-Action Alternative, dam enlargement activities would not be implemented. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could be affected, however, by changing water supply demand and regulatory conditions, which could in turn affect the amount of nearshore, warm-water habitat in Shasta Lake. Such fluctuations could have an adverse effect on the quality and quantity of nearshore, warm-water habitat in the lake.

Under the No-Action Alternative with a 2030 water supply demand, the mean surface area of Shasta Lake in all months and all water year types, except critical years, would be slightly less than under the Existing Condition. The greatest potential decreases would be experienced from September through November in above-normal water years (Figure 11-2). Fluctuations in WSELs are similar for the No-Action Alternative and the Existing Condition and differ by no more than ± 1-foot in any month under all hydrologic conditions (Figure 11-3). Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Seasonal fluctuations in the surface area and WSEL of Shasta Lake could be affected by changing water supply demand and regulatory conditions. Such fluctuations could have an adverse effect on the quality and quantity of nearshore, warm-water habitat in the lake. Therefore, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-2 (No-Action): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Under the No-Action Alternative, dam enlargement activities would not be implemented and no new facilities would be constructed within the vicinity of Shasta Lake. There would be no impact. Mitigation is not required for the No-Action Alternative.

Figure 11-3. Average Monthly Change in WSEL (in feet) for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, the Existing Condition Versus No-Action Alternative

Impact Aqua-3 (No-Action): Effects on Cold-Water Habitat in Shasta Lake
Under the No-Action Alternative, dam enlargement activities would not be implemented. Under this alternative, seasonal fluctuations in the ratio of the volume of cold-water storage in Shasta Lake to the surface area of the lake could be affected by changing water supply demand and regulatory conditions, which could affect the amount of cold-water habitat, including habitat for cold-water fishes, such as resident trout and stocked salmon. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-4 (No-Action): Effects on Special-Status Aquatic Mollusks Under the No-Action Alternative, dam enlargement activities would not be implemented. Seasonal fluctuations in the surface area and WSEL of Shasta Lake in response to water demand and regulatory conditions could affect special-status aquatic mollusks that may occupy habitat in or near Shasta Lake and its tributaries. These impacts would continue to occur under this alternative. This impact would be less than significant.

One special-status mollusk, the California floater, is known to have historically occurred in tributaries near the head of Shasta Lake. However, surveys of historically occupied sites around Shasta Lake failed to find this species (Howard 2010), and it was not detected during reconnaissance-level surveys of the smaller perennial and intermittent tributaries to Shasta Lake in 2012 (Reclamation 2014). Nine other special-status mollusks could occupy seeps, springs, or tributaries surrounding the reservoir. However, evidence from field surveys of the lower reaches of representative tributaries to the lake did not detect any special-status mollusks (see the *Fisheries and Aquatic Ecosystems Technical Report* for details).

Except for the California floater, the probability of occurrence of other special-status mollusks in Shasta Lake and the lower reaches of its tributaries is low. The California floater is a bivalve that resides in soft sediment on stream and lake beds and, therefore, could be adversely affected by seasonal fluctuations in the WSEL of the lake that currently exists. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-5 (No-Action): Effects on Special-Status Fish Species Under the No-Action Alternative, dam enlargement activities would not be implemented. However, one fish species occurring within the primary study area and designated as sensitive by the USFS, the hardhead minnow, could be affected by seasonal fluctuations in the surface area and WSEL of Shasta Lake in response to changing water demand and regulatory conditions; however, this impact would be less than significant.

Two other USFS sensitive species, rough sculpin (in the Pit River) and redband trout (*Oncorhynchus mykiss stonei*) (in the upper McCloud River), are known to occur upstream from Shasta Lake, but their presence have not been documented in Shasta Lake or in their respective tributaries within the primary study area. The analysis of the No-Action Alternative therefore excludes consideration of these two special-status species.

Fluctuations in the surface area and WSEL of Shasta Lake under the No-Action Alternative could interfere with the connectivity to riverine habitat preferred by hardhead in tributaries that drain into Shasta Lake. However, access to riverine habitat among all the main tributaries to the reservoir would not likely become any more limiting than under current conditions. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-6 (No-Action): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under the No-Action Alternative, dam enlargement activities would not be implemented, and tributaries to Shasta Lake would continue to respond to fluctuations in reservoir levels. New barriers would not be created or removed that could impede or facilitate the movement of native and nonnative fish species between Shasta Lake and its tributaries. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Aqua-7 (No-Action): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake Under the No-Action Alternative, dam enlargement activities would not be implemented, and there would be no change to spawning and rearing habitat for adfluvial salmonids in low-gradient tributaries to Shasta Lake. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Aqua-8 (No-Action): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake Under the No-Action Alternative, dam enlargement activities would not be implemented. Therefore, aquatic connectivity in non-fish-bearing streams would not be affected. There would be no impact. Mitigation is not required for the No-Action Alternative.

Impact Aqua-9 (No-Action): Effects on Water Quality at Livingston Stone Hatchery Under the No-Action Alternative, dam enlargement activities would not be implemented. Therefore, there would be no changes to the water system that supplies high-quality water to the Livingston Stone Hatchery. There would be no impact. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Aqua-10 (No-Action): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Under the No-Action Alternative, there would be no construction-related loss or degradation of aquatic habitat. No project-generated variation in the storage levels of CVP and SWP reservoirs along the upper Sacramento River or tributaries would occur. If none of the project alternatives were implemented, actions to protect fisheries and aquatic resources would likely continue under existing regulatory requirements. Such actions would include other restoration/management actions intended to protect and enhance fisheries resources. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Aqua-11 (No-Action): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Under the No-Action Alternative, no project construction–related contaminant exposure in the upper

Sacramento River or tributaries would occur. If none of the project alternatives were implemented, actions to protect fisheries and aquatic resources would likely continue under existing regulatory requirements. Such actions would include other restoration/management actions intended to protect and enhance fisheries resources. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Aqua-12 (No-Action): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon and Steelhead Flow releases would continue to be operated in compliance with existing BOs and regulatory and contractual requirements, which represent the regulatory baseline. However, it is anticipated that climate change would result in an increase in water temperatures in the upper Sacramento River (NMFS 2009, 2014), which could make it more difficult, especially in critical water years, to meet the water temperature requirements needs for all runs of Chinook salmon, particularly winter-run and spring-run Chinook salmon, as well as steelhead. As a result, the impact to Chinook salmon and steelhead in the upper Sacramento River would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-13 (No-Action): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass Flow releases would continue to be operated in compliance with existing BOs and other regulatory and contractual requirements, which represent the regulatory baseline. However, climate change would likely result in an increase in water temperatures (NMFS 2009, 2014). This could make it much more difficult, especially in critical water years, to meet the water temperature requirements for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. As a result, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Aqua-14 (No-Action): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Under the No-Action Alternative, no change to the ongoing geomorphic processes in the upper Sacramento River would occur. No impact would occur. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River, Tributaries, Delta and Trinity River Under the No-Action Alternative, no project-related alteration of CVP and SWP reservoir storage levels, river flows, or water temperatures would occur in the lower Sacramento River, tributaries, and Delta. If none of the project alternatives were implemented, actions to protect fisheries and benefit aquatic environments would likely continue under existing regulatory requirements. Such actions would include other restoration/management actions intended to protect and enhance fisheries resources. Compliance with existing BOs would result in continued pumping curtailments, particularly in dry years. Reclamation and DWR would continue to attempt to reoperate the CVP and SWP, respectively, to avoid decreased deliveries to export users. Therefore, no change in impacts on fisheries and aquatic ecosystems in the lower Sacramento River, tributaries, and Delta would occur under the No-Action Alternative.

Under the No-Action Alternative, no project-related alteration of CVP and SWP reservoir storage levels, river flows, or water temperatures would occur in the Trinity River. Therefore, no change in impacts on aquatic resources in the Trinity River would occur under the No-Action Alternative.

CVP/SWP Service Areas Under the No-Action Alternative, there would be no project-related change in CVP and SWP operations or deliveries to the CVP and SWP service areas. It is anticipated that if the project alternatives were not implemented, actions to protect fisheries and benefit aquatic environments would continue under existing regulatory requirements, including other restoration/management actions and existing BOs intended to protect and enhance fisheries resources.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability and increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 6.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 8.5 feet and enlarge the total storage capacity in the reservoir by 256,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing municipal and industrial (M&I) deliveries. CP1 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact Aqua-1 (CP1): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP1, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. Project operations would also result in reduced monthly fluctuations in the WSEL, which would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. The increase in the WSEL will influence riparian vegetation, including willow species planted to enhance lacustrine habitat, likely resulting in some amount of willow mortality. The increase in the WSEL will also influence the effectiveness of the brush structures that have been installed by the STNF at various locations within the current drawdown zone of Shasta Lake. While the value of these structural improvements will be influenced by an overall increase in the maximum WSEL, these structures will continue to function to varying degrees under the operational conditions established for CP1. The environmental commitments described in Chapter 2, "Alternatives," include maintaining and enhancing brush structures and placing large woody debris and rock/boulder clusters within the CP1 innundation zone. These impacts to structural habitat improvements are expected to be localized and will vary as the brush structures age and riparian vegetation readjusts to a new average reservoir pool elevation. The retention of vegetation along more than 40 percent of the increased shoreline area that would be subject to inundation as a result of CP1 is expected to offset reductions in effective structural habitat improvements for a period of time. The benefits of inundated vegetation will decrease over time (e.g., 10-20 years) as the vegetation decays and the shoreline erosion processes expand into the new drawdown zone. This impact would be less than significant.

Biological productivity is greatest in the upper, lighted layer of the reservoir, where most plankton production occurs. An increase in the surface area of the reservoir could affect warm-water habitat by increasing the area of littoral (nearshore) habitat, which could result in increased biological productivity. Increased inundation of terrestrial habitat, leading to increased nutrient loading from vegetative debris along the shore for some period of time, could increase plankton production, causing an upsurge in nutritional sources for warm-water species (Kimmel and Groeger 1986).

CalSim-II modeling indicated that the surface area of Shasta Lake would be larger under CP1 with a 2005 water supply demand than under the Existing Condition for all five water year types (Figure 11-4). The Shasta Lake surface area would be larger under CP1 with a 2030 water supply demand than under the No-Action Alternative in all five water years (Figure 11-5).

An increase in the WSEL could benefit fish by increasing the amount and quality of available warm-water habitat in Shasta Lake. According to Ozen and Noble (2002), inundation of a reservoir creates an area that is sparsely populated by fish (i.e., decreases fish density per unit of habitat); the low population numbers stimulate the natural reproductive and growth processes of the fish. The newly inundated vegetation creates temporary cover for shoreline-dwelling fishes. As the vegetation decomposes, it releases nutrients for phytoplankton and periphyton, which are in turn consumed by the fish.

According to CalSim-II modeling, the Shasta Lake WSEL would be higher under CP1 with a 2005 water supply demand than under the Existing Condition for all five water year types. The Shasta Lake WSEL would also be higher under CP1 with a 2030 water supply demand than under the No-Action Alternative in all five water years.

Figure 11-5. Average Monthly Surface Area for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP1 (2030) Versus No-Action Alternative

Rapid rates of increase in WSEL during the critical spring nesting period can lead to such adverse effects as decreased spawning success through nest abandonment or decreased egg survival (Mitchell 1982; Lee 1999). Jones & Stokes (1998) reported that mortality approaches 10 percent for eggs in nests submerged under more than 15 feet of water during periods of rapid increase in reservoir elevations.

Rapidly decreasing WSELs can also have an adverse effect on aquatic organisms. According to Lee (1999), the maximum rate of drawdown that would allow a nesting success rate of 10 percent varied between species, with receding water level rates of less than 0.07, less than 0.03, and less than 0.02 feet per day for largemouth, smallmouth, and spotted bass nests, respectively. Lee found that daily drawdown rates of 0.36, 0.36, and 0.72 feet per day for largemouth, smallmouth, and spotted bass, respectively, resulted in 20-percent nest survival. Under CP1, none of the changes in monthly WSEL fluctuation were substantially different from the Existing Condition.

Monthly WSEL fluctuations were compared with projections for water supply demand. For CP1 with a 2005 water supply demand, 24 percent of monthly changes in projected WSELs (i.e., 6 of the 25 total projections made for the 5 months from March through July for all five water year types) showed decreased monthly WSEL fluctuations relative to the Existing Condition and 4 percent showed a slight increase in monthly WSEL fluctuations (Figure 11-6). For CP1 with a projected 2030 water supply demand, 36 percent of monthly changes in projected WSELs showed decreased WSEL fluctuations relative to the No-Action Alternative and 4 percent showed a slight increase in monthly WSEL fluctuations (Figure 11-7).

Increases in the overall surface area and WSEL under CP1 would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake, although the value of structural and vegetative improvements that currently provide effective structural habitat at specific locations will be decreased to some extent. This effect will be offset by (1) using brush and trees cleared for other project purposes and placing them in the new inundation varial zone to provide structural fish habitat; (2) identifying locations for planting and monitoring of structural plants such as willows, buttonbrush and cottonwoods (See Chapter 2, "Alternatives," for additional detailed descriptions of the environmental commitments); and (3) retaining newly inundated vegetation along more than 40 percent of the increased shoreline area. Overall, CP1 would result in reductions in the magnitude of monthly WSEL fluctuations and would contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water species, and provide for an increase in structural habitat (inundated vegetation) for some period of time. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-7. Average Monthly Change in WSEL for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP1 Versus No-Action Alternative

Impact Aqua-2 (CP1): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Localized increases in soil erosion and resulting runoff sedimentation, and turbidity resulting from project construction in the vicinity of Shasta Dam and at utility, road, and other facility relocation areas could affect nearshore warm-water habitat. However, the environmental commitments described in Chapter 2, "Alternatives," for all action alternatives include the development and implementation of a Construction Management Plan, Erosion and Sediment Control Plan, Stormwater Pollution Prevention Plan (SWPPP), and Revegetation Plan as well as water quality and fisheries conservation measures (e.g., stockpiling of materials for future use as fish habitat structure or installation concurrent with construction activity) and compliance with all required permit terms and conditions. These environmental commitments would result in less-than-significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-3 (CP1): Effects on Cold-Water Habitat in Shasta Lake Under CP1, operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout. This impact would be beneficial.

CalSim-II modeling showed that under CP1 with a 2030 water supply demand[3], the ratio of the volume of cold-water storage to surface area was slightly higher than under the No-Action Alternative in all water years and during all months modeled. The greatest projected increases over the No-Action Alternative occurred between June 30 and August 31, which is a critical rearing and oversummering period for cold-water fishes in reservoirs; the increases were highest in wet water years (Figure 11-8). The proportional increase in the cold-water storage to surface area ratio would result in increased cold-water fish productivity (Stables et al. 1990, Jones and Stokes Associates 1988).

CP1 would increase the availability of suitable habitat for cold-water fish in Shasta Lake and would increase cold-water fish production. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-4 (CP1): Effects on Special-Status Aquatic Mollusks Under CP1, habitat for special-status mollusks may become inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could also adversely affect special-status aquatic mollusks that may occupy habitat in or near Shasta Lake and its tributaries. This impact would be potentially significant.

[3] Only the 2030 water demand scenario is shown for this reservoir fishery metric because it illustrates the worst case benefit to cold-water fisheries of the water demand scenarios analyzed.

Figure 11-8. Average Monthly Cold-water Storage to Surface Area Ratio for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP1 Versus No-Action Alternative

The occurrence of special-status mollusks in Shasta Lake and the lower reaches of its tributaries is unlikely. California floaters historically occurred in the tributaries, but have not been observed in recent surveys (Howard 2010, Reclamation 2014). Modification or loss of suitable habitat for the California floater would occur through increased WSEL and seasonal fluctuations in the surface area under CP1. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-5 (CP1): Effects on Special-Status Fish Species The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP1 could affect one species designated as sensitive by USFS known to occur there, the hardhead. This impact would be less than significant.

Two other USFS sensitive species, rough sculpin (in the Pit River) and redband trout (in the upper McCloud River), are known to occur upstream from Shasta Lake, but their presence have not been documented in Shasta Lake or in their respective tributaries within the primary study area. The analysis of the CP1 therefore excludes consideration of these special-status fish species.

Expansion of the surface area of Shasta Lake could be modestly beneficial to hardhead because it could expand the amount of habitat available to this species in the lake, although high annual fluctuations in surface level and the abundance of warm-water predators, primarily sunfishes and basses, in the lake already likely limits the hardhead population there (Moyle 2002, J. Zustak 2007). Hardhead prefer low-gradient, clear and deep (greater than 2.5 feet) flatwater-stream habitat with sand-gravel-boulder substrates, which can be created by the backwater effect of the reservoir within the transition reaches of the main tributaries at their confluence; however, this would not be expected to be much greater than under existing conditions, since reservoir enlargement would simply shift the transition reaches farther upstream in the tributaries.

No hardhead were detected in tributary stream fish surveys in 2011 or 2012 (see *Fisheries and Aquatic Ecosystems Technical Report* for details). Hardhead were not observed in surveys conducted in the Sacramento and McCloud rivers in the vicinity of Shasta Lake (Nevares and Liebig 2007, Weaver and Mehalik 2008), suggesting that this species may not occur in these tributaries or is very uncommon. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP1): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP1, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to approximately the 1,080-foot contour, the maximum inundation level under this alternative. This impact would be less than significant.

Potential impacts of reservoir enlargement may occur in areas where fish communities are currently impeded or isolated by passage barriers. Fifty-four percent of the intermittent and 30 percent of the perennial tributaries surveyed in 2012 contained partial or complete barriers to fish migration between the 1,070-foot and 1,090-foot elevation contours. Twenty-two percent of the perennial tributaries (34 total perennial tributaries) and 24 percent (259 total intermittent tributaries) of the intermittent tributaries (of which only 18 percent are potentially fish bearing and only 2 percent of those were fish-bearing in 2012) to Shasta Lake have partial or complete fish passage barriers between the 1,070 and 1,076-foot contours subject to full or partial inundation under CP1. Sixty-one percent of the streams with passage impediments between the 1,070-foot and 1,090-foot contours also had impediments upstream from 1,090-foot contour (i.e., even if downstream barriers were periodically inundated, the length of additional stream habitat that would be accessible to fish from Shasta Lake is limited, particularly in intermittent tributaries).

The likelihood of potential impacts is greater in perennial tributaries as the proportion of these streams bearing fish (87 percent) is much greater than intermittent streams (2 percent) and in tributaries where inundation may create fish passage conditions at existing complete passage barriers. However, the estimated number of streams with complete passage barriers between the 1,070-foot and 1,090-foot contours is only 15 of the 154 perennial tributaries to Shasta Lake (see *Fisheries and Aquatic Ecosystems Technical Report* for details). Five streams with fish passage impediments near the existing full reservoir elevation, including two unnamed intermittent tributaries and three perennial tributaries, Little Squaw Creek, Squaw Creek and Indian Creek. The CP1 reservoir enlargement scenario would at least partially inundate these barriers at a new full pool, potentially allowing fish from the reservoir to immigrate into these streams. This could have a small and localized beneficial effect for adfluvial cold-water fishes in Shasta Lake by increasing the amount of suitable spawning and rearing habitat available for these species.

Inundation of fish passage impediments in tributaries to Shasta Lake would not adversely affect hardhead because: (1) hardhead are uncommon; and (2) it would not facilitate fish passage of predatory warm-water fish species into streams where these species do not already both occur. Under CP1, inundation may create passage opportunities for warm-water fish species into some currently inaccessible portions of these tributaries, which could alter existing resident fish communities in those areas. However, the upstream extent of any colonization by warm-water species is expected to be limited primarily to the newly inundated reaches based on current distribution patterns. With the exception of the main river tributaries (i.e., Sacramento, Pit, and McCloud rivers, and Squaw Creek), less than 10 percent of the lake's currently accessible tributaries have been found to be colonized by warm-water fish upstream from the existing inundation zone.

CP1 would not result in the widespread c*reation or elimination of fish passage barriers in tributaries to Shasta Lake that would affect existing fish communities. However, inundation of a barrier near the mouth of Squaw Creek could potentially allow warm-water fish to move upstream and colonize previously inaccessible habitat with consequent effects on the native fish community and some mollusks, such as California floater, a USFS sensitive* *species. Environmental commitments to monitor fish communities in Squaw Creek and adaptively manage to prevent warm-water fish invasions in Squaw Creek, as described in Chapter 2, "Alternatives," would reduce this impact to a less than significant level.* Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP1): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake CP1 would result in additional periodic inundation of riverine habitat potentially suitable for spawning and rearing habitat for adfluvial salmonids (trout and land-locked salmon that spawn in streams and rear in lakes) in tributaries to Shasta Lake. In addition to modification of the hydraulic regimes of these affected reaches, changes in the WSEL as a result of CP1 will affect the character and location of substrate (e.g., spawning gravel) at some locations, thereby influencing the suitability and availability of spawning and rearing habitat for adfluvial salmonids.

CP1 would inundate perennial stream reaches with gradients of less than 7 percent that could provide suitable spawning and rearing habitat for adfluvial salmonids. Chapter 4, "Geology, Geomorphology, Minerals, and Soils," discusses the periodic inundation of low-gradient stream reaches. The lengths of low-gradient tributaries to each arm of Shasta Lake and estimated suitable spawning habitat areas (both intermittent and perennial) that would be periodically affected are as follows:

- Sacramento Arm – 2.2 miles (7,040 square feet, excludes mainstem river)
- McCloud Arm – 1.1 miles (9,768 square feet)
- Pit Arm – 1.0 mile (355 square feet, excludes mainstem river)
- Big Backbone Arm – 0.5 miles (106 square feet)
- Squaw Arm – 0.6 miles (1,300 square feet)

Only 5.4 miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids (based on channel slope, and confirmed by surveys of representative stream reaches) would be affected by CP1, which is only about 1.4 percent of the low-gradient habitat upstream from Shasta Lake. Although a small proportion of total stream mileage would be affected by CP1, most of the suitable spawning habitat between the 1,070-foot and 1,090-foot contours was estimated to occur in this reach.

Only 7 percent of intermittent streams surveyed contained suitable salmonid spawning habitat between the 1,070-foot and 1,080-foot contours, while 71 percent of perennial streams contained suitable salmonid spawning habitat (see

Fisheries and Aquatic Ecosystems Technical Report for details). The cumulative estimated area of suitable cold-water spawning habitat in all intermittent tributaries to Shasta Lake between the 1,070-foot and 1,080-foot contours was only 205 square feet. Thus, the contribution of intermittent streams, of which only 2 percent are considered to be fish bearing, to spawning and rearing habitat for adfluvial salmonids in Shasta Lake is, collectively, very small. Conversely, approximately 23,253 square feet of suitable cold-water spawning habitat, exclusive of mainstem habitat in the Sacramento and Pit rivers, was estimated to occur within the projected varial zone of perennial tributaries under CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Impact Aqua-8 (CP1): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP1 would result in periodic inundation of varying amounts of non-fish-bearing intermittent tributaries to Shasta Lake. About 12.6 miles of non-fish-bearing tributary habitat would be affected by CP1, which is a length of only about 0.4 percent of non-fish-bearing tributary habitat upstream from Shasta Lake.

As described in Chapter 4, “Geology, Geomorphology, Minerals, and Soils,” CP1 would inundate intermittent tributary segments with channel slopes in excess of 7 percent. Although these segments do not typically support salmonid populations, they do provide riparian and aquatic habitat for a variety of organisms and serve as corridors that connect habitat types. The lengths of non-fish-bearing tributaries based on channel slope (greater than 7 percent) and confirmed by surveys of representative stream reaches for each arm of Shasta Lake that would be periodically inundated are as follows:

- Sacramento Arm – 2.9 miles
- McCloud Arm – 2.1 miles
- Pit Arm – 1.8 miles
- Big Backbone Arm – 1.3 miles
- Squaw Arm – 0.9 miles
- Main Body – 3.6 miles

Surveys of representative tributaries determined that 52 percent of perennial tributaries to Shasta Lake were inhabited by special-status vertebrate species[4], but none occurred in the intermittent tributaries surveyed. No special-status invertebrates (e.g., aquatic mollusks) were detected by casual surveys and benthic sampling of the smaller perennial and intermittent tributaries to Shasta Lake in 2011 or 2012 (see *Fisheries and Aquatic Ecosystems Technical Report*

[4] Hardhead minnow, a USFS sensitive species and foothill yellow-legged frog, a USFS and CDFW sensitive species

for details). Field surveys indicate that few, if any of the non-fish-bearing streams, particularly intermittent ones, contain special-status invertebrate or vertebrate species that would be affected by increased connectivity to Shasta Lake.

Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP1): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP1. There would be no impact.

This impact is the same as Impact Aqua-9 (No-Action), and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Aqua-10 (CP1): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Temporary construction-related increases in sediments and turbidity levels would adversely affect aquatic habitats and fish populations immediately downstream in the upper Sacramento River. However, environmental commitments would be in place to reduce the effects. This impact would be less than significant.

Increasing the height of Shasta Dam, constructing haul roads, using staging areas, and placing excavated material could disturb sediments and soils within and adjacent to waterways. Any construction-related erosion or disturbance of sediments and soils would temporarily increase downstream turbidity and sedimentation throughout the primary study area if soils were transported in river flows, stormwater runoff, or reservoir water. Such sedimentation and increased turbidity, or other contamination, would be most pronounced in the segment of river from Shasta Dam to Keswick Dam because of the backwater effect that Keswick Reservoir has on flow conditions in the Sacramento River. It is also important to note that Keswick Dam acts as a barrier to upstream fish migration; therefore, all anadromous fish species are downstream from this facility. (See Chapter 7, “Water Quality,” for additional discussion of this issue.)

The abundance, distribution, and survival of fish populations have been linked to levels of turbidity and silt deposition. Prolonged exposure to high levels of suspended sediment would create a loss of visual capability in fish in aquatic habitats within the study area, leading to reduced feeding and growth rates. Such exposure would also result in a thickening of the gills, potentially causing the loss of respiratory function; in clogging and abrasion of gills; and in increased stress levels, which in turn could reduce tolerance to disease and toxicants (Waters 1995, Clark and Wilber 2000, Newcombe and Jensen 1996, Wilber and Clark 2001). Turbidity also could result in increased water temperature and decreased DO levels, especially in low-velocity pools, which can cause stressed respiration.

High levels of suspended sediments could also cause redistribution and movement of fish populations in the upper Sacramento River, and could diminish the character and quality of the physical habitat important to fish survival. Deposited sediments can reduce water depths in stream pools and can contribute to a reduction in carrying capacity for juvenile and adult fish (Waters 1995). Increased sediment loading downstream from construction areas would degrade food-producing habitat, by interfering with photosynthesis of aquatic flora, and could displace aquatic fauna.

Many fish, including salmonids, are sight feeders; turbid waters reduce the ability of these fish to locate and feed on prey. Some fish, particularly juveniles, likely would become disoriented and leave the areas where their main food sources are located, ultimately reducing growth rates.

Prey of fish populations, such as macroinvertebrates, could be adversely affected by declines in habitat quality (water quality and substrate conditions) caused by increased turbidity, decreased DO content, an increased level of pollutants (Coull and Chandler 1992), and (although unlikely) an extreme change in pH or water temperatures (Rundle and Hildrew 1990). Decreases in the diversity and abundance of smaller organisms living on or in the sediments have been associated with smaller sediment grain sizes (Coull 1988) and associated DO decreases in those sediments (Boulton et al. 1991).

Avoidance of adverse habitat conditions by fish is the most common result of increases in turbidity and sedimentation. Fish will not occupy areas unsuitable for survival unless they have no other option. Some fish, such as bluegill and bass species, will not spawn in excessively turbid water (Bell 1990), and salmonids require gravels that are relatively clean and free of excess amounts of fine sediments. Therefore, increased turbidity attributed to construction activities could preclude fish from occupying habitat required for specific life stages. In some locations, few opportunities for escape from turbid waters may be available, particularly during low-flow conditions.

Construction-related sedimentation and increased turbidity or other contamination could temporarily degrade water quality and reduce or adversely affect fish habitat and fish populations in localized areas. However, the environmental commitments for all action alternatives include the development and implementation of best management practices (BMP), including a Construction Management Plan, Erosion and Sediment Control Plan, Storm Water Pollution Prevention Plan (SWPPP), and revegetation plan. Water quality and fisheries conservation measures would also be implemented and project activities would be in compliance with all required permit terms and conditions. With implementation of these environmental commitments, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-11 (CP1): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants. Such exposure could adversely affect aquatic habitats, the aquatic food web, and fish populations, including special-status species, downstream in the primary study area. However, environmental commitments would be in place to reduce the effects. Therefore, this impact would be less than significant.

Contaminants such as fuels, oils, other petroleum products, cement, and various chemicals used during construction could be introduced into the water system directly through accidental spills or incrementally through surface runoff from haul routes and construction sites. In sufficient concentrations, contaminants would be toxic to fish and prey organisms (e.g., benthic macroinvertebrates) occupying habitats in the study area. They also may alter oxygen diffusion rates and cause acute and chronic toxicity to aquatic organisms, thereby reducing growth and survival and/or leading to mortality.

A potential release of hazardous materials into the upper Sacramento River could reduce aquatic habitats and fish populations if proper procedures were not implemented to contain the discharge. However, the environmental commitments for all action alternatives include the development and implementation of a Construction Management Plan, Emergency Response Plan, Erosion and Sediment Control Plan, SWPPP, and revegetation plan. They also include implementation of water quality and fisheries conservation measures and compliance with all required permit terms and conditions. With implementation of these environmental commitments, this impact would be less than significant. Mitigation for this impact is not needed, and thus is not proposed.

Impact Aqua-12 (CP1): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon and Steelhead CP1 operation would result in generally improved flow and water temperature conditions in the upper Sacramento River for Chinook salmon and steelhead relative to both the No-Action Alternative and the Existing Condition, but not all runs show a significant (greater than 5 percent) increase in production. This impact would be less than significant.

Winter-Run Chinook Salmon

Production

CP1 would have a less-than-significant (less than 5 percent) average decrease in winter-run Chinook salmon production relative to the Existing Condition and the No-Action Alternative. The maximum increase in simulated production relative to the No-Action Alternative for CP1 was nearly 23 percent (critical water year). The largest decrease in production relative to the No-Action

Alternative was less than 5 percent (Table 11-5, Figure 11-9, and Attachment 3 of the Modeling Appendix). The largest increase in production relative to the Existing Condition for CP1 was 54 percent, while the largest decrease was -27 percent (Table 11-4 and Attachment 4 of the Modeling Appendix).

Figure 11-9 shows the change in production relative to the No-Action Alternative for all water years and all comprehensive plans. Separating production by water year type to focus on critical water years (when water storage is more reliable) showed an average 0.6-percent increase over the No-Action Alternative, but 2 out of 10 critical water years resulted in a significant (greater than 5 percent) increase in winter-run production relative to the No-Action Alternative, ranging from 0.1 percent to almost 23 percent (Table 11-4).

Table 11-4. Change in Production by Water Year Type Under CP1 for Winter-Run Chinook Salmon

Year Type	No. of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease

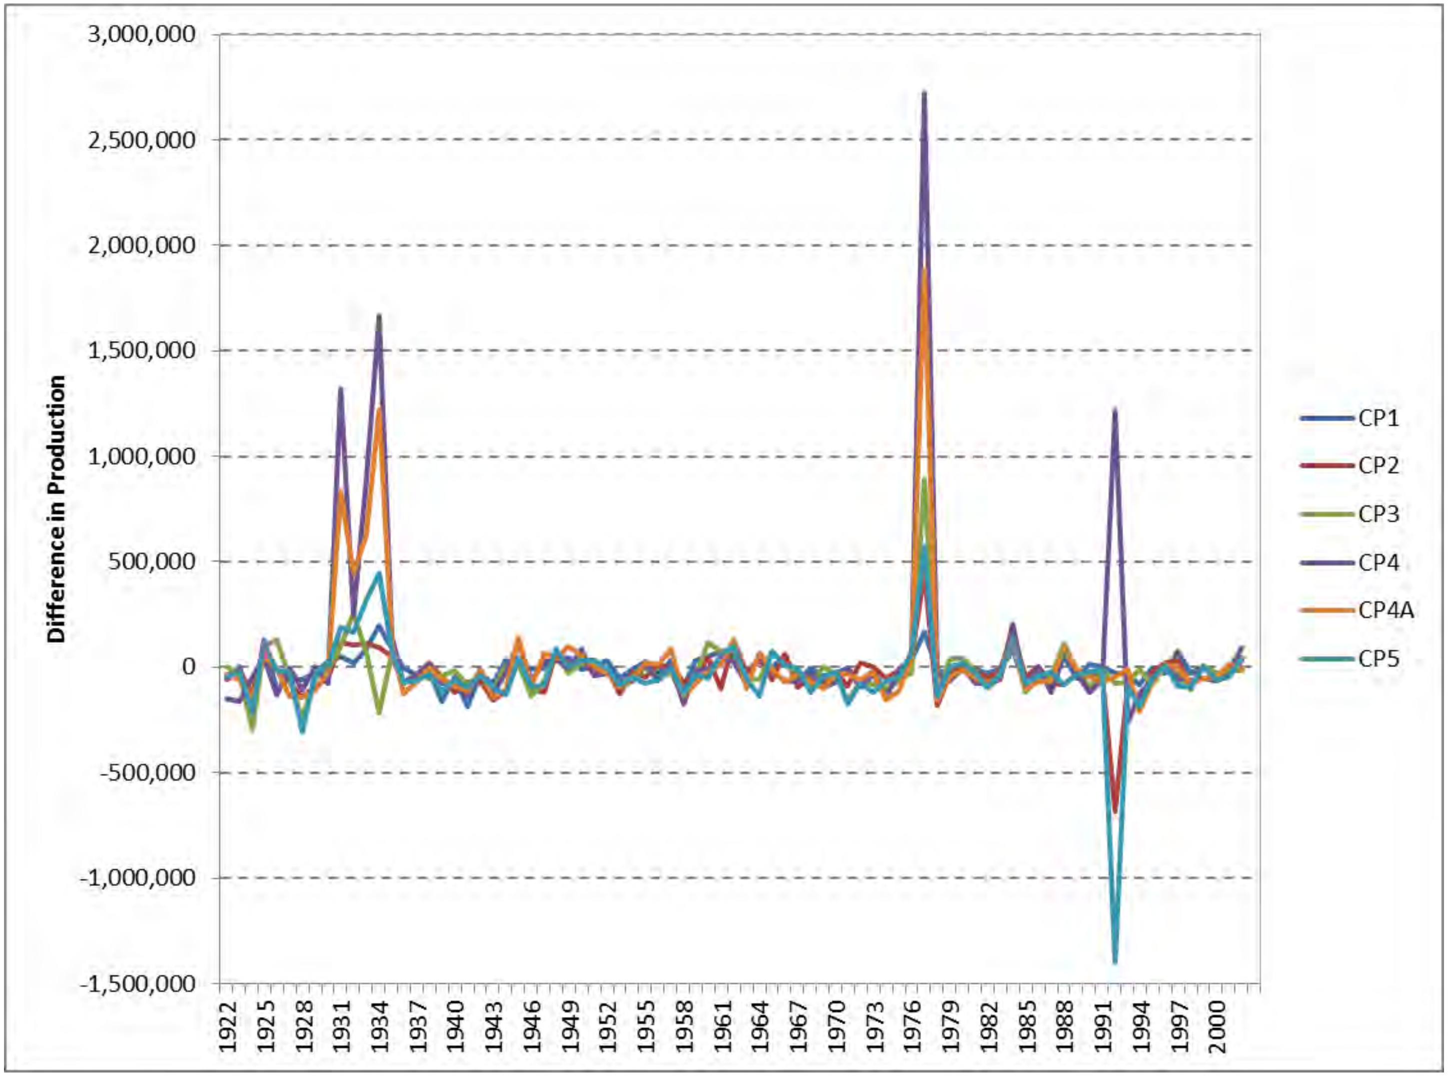
Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Key:

CP = Comprehensive Plan

No. = number



Key: CP = Comprehensive Plan

Figure 11-9. Change in Production of Winter-Run Chinook Salmon Compared to the No-Action Alternative

CP1 production under 2005 conditions was similar to the Existing Condition. The maximum increase in production was 54 percent for CP1, and the largest decrease in production was less than 5 percent for CP1 (Table 11-4 and Attachment 4 of the Modeling Appendix). Under CP1, 2 out of 10 critical water years resulted in a significant increase in winter-run production relative to the Existing Condition with a maximum of 54 percent; however, water year 1992 resulted in a -27-percent decrease in production. In all other water years, there was an insignificant change in production except for wet water year 1928, which decreased production by -5.3 percent.

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on winter-run Chinook salmon caused by the actions of the project (Attachments 3 and 4 of the Modeling Appendix). Nonoperations-related mortality are the base and seasonal mortality that would occur even without the effects of Shasta operations (such as disease, predation, and entrainment). Flow- and water temperature-related mortality is that caused by altering flow and water temperatures. In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)− around 86 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 3 and 4 of the Modeling Appendix). The greatest average mortality to winter-run Chinook salmon under CP1 in all water year types based on smolt equivalents would occur to the fry life stage, followed by eggs, then presmolts, and lastly to immature smolts. Table 11-5 displays the overall mortalities for each Comprehensive Plan that were caused by changes in operations (i.e., water temperature and flow) (Attachments 3 and 4 of the Modeling Appendix).

Years with the highest simulated flow- and water temperature-related mortality were the same for the No-Action Alternative, the Existing Condition, and CP1. Each of these years was a critical water year, and was preceded by either a critical (1976, 1991), or dry (1930, 1932). Years in which the project had the greatest effect, both as an increase and decrease in production were the years in which the lowest production occurs (Attachments 3 and 4 of the Modeling Appendix).

Table 11-5. Average Annual Winter-Run Chinook Salmon Smolt Equivalent Mortality Under Each Base Condition and the Difference in Mortality Under Each Comprehensive Plan Caused by Changes in Flow and Water Temperature

Plan	Egg Count Based on Smolt Equivalent[1,2]	Difference in Mortality Factor from Baseline Condition (in Smolt Equivalents)										Total (in Smolt Equivalents)	Percent Mortality[2]

Notes:

[1] The potential number of smolt equivalent is based on the spawning population of 8,591 adults, using the formula:
Immature Smolt Equivalent Mortality = Mortality * % Survival $_{(eggs\ to\ fry)}$ * % Survival $_{(fry\ to\ presmolts)}$ * % Survival $_{(presmolts\ to\ immature\ smolts)}$

[2] Values in these two columns do not constitute a difference from the baseline condition.

Key:

CP = Comprehensive Plan

Because winter-run Chinook salmon would have an insignificant change (1 percent or less) in flow- and water temperature-related mortality under CP1, and an insignificant change in production (less than 5 percent overall), a less-than-significant impact to winter-run Chinook salmon would occur from actions taken in CP1. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Spring-run Chinook salmon production for the 81-year period does not change significantly between CP1 and the No-Action Alternative and the Existing Condition (Attachments 6 and 7 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was around 71 percent for CP1, while the largest decrease in production relative to the No-Action Alternative was -66 percent, both in critical water years (Table 11-6, Figure 11-10, and Attachment 6 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 256 percent for CP1, while the largest decrease in production relative to the Existing Condition was -41 percent, also both in critical water years (Table 11-6, Figure 11-10, and Attachment 7 of the Modeling Appendix).

Figure 11-10 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans. Separating production by water year type to focus on critical years in which production was the lowest under the No-Action Alternative typically had the largest increase under CP1 conditions, except for 1977 and 1992, which had 12 percent and 52 percent reductions, respectively (Attachment 6 of the Modeling Appendix).

Compared to the No-Action Alternative, six critical, one dry, and one below-normal water years had significant increases in production, while three critical water years have a significant decrease in production (Table 11-6 and Attachment 6 of the Modeling Appendix). Compared to the Existing Condition, nine critical and two dry water years had significant increases in production, while one critical water years resulted in significant decreases in production (Table 11-6 and Attachment 7 of the Modeling Appendix).

Table 11-6. Change in Production Under CP1 for Spring-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease

Figure 11-10. Change in Production of Spring-Run Chinook Salmon Compared to the No-Action Alternative

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on spring-run Chinook salmon caused by the actions of the project (Attachments 6 and 7). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)‒around 83 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 6 and 7 of the Modeling Appendix). Under both the 2030 and 2005 conditions, the greatest mortality to spring-run occurred to eggs, with minimal mortality to the other life stages. Table 11-7 displays the smolt-equivalent mortalities for each Comprehensive Plan that are caused by flow- and water-related factors (also see Attachments 6 and 7 of the Modeling Appendix). In both 2030 and 2005 conditions, only eggs and fry would be affected by operation of the Comprehensive Plans (Table 11-7 and Attachments 6 and 7 of the Modeling Appendix). In all but wet water years, mortality to eggs due to unsuitable water temperatures would be the primary cause of operations-related mortalities (Attachments 6 and 7 of the Modeling Appendix).

Years with the highest flow- and water temperature-related mortality were the same for all the Comprehensive Plans. Except in 1932 (a dry water year), each of these years was a critical water year type and was preceded by either a below, dry, or (predominantly) critical water year. However, years with the lowest mortality varied between all but critical water year types (Attachments 6 and 7 of the Modeling Appendix).

Spring-run Chinook salmon would have, overall, an insignificant change flow- and water temperature-related mortality, and an insignificant increase in production for all 82 years. However, spring-run Chinook salmon would have a significant increase in production in critical water years. Therefore, spring-run Chinook salmon would benefit from actions taken in CP1. Mitigation for this impact is not needed, and thus not proposed.

Table 11-7. Average Annual Spring-Run Chinook Salmon Smolt Equivalent Mortality Under Each Base Condition and the Difference in Mortality Under Each Comprehensive Plan Caused by Changes in Flow and Water Temperature

CP = Comprehensive Plan

Fall-Run Chinook Salmon

Production

The overall average fall-run Chinook salmon production for the 81-year period was similar for CP1 relative to the No-Action Alternative and the Existing Condition (Attachments 9 and 10 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 17 percent for CP1. The largest decrease in production relative to the No-Action Alternative was 51 percent for CP1 (Table 11-8 and Attachment 9 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 61 percent for CP1. The largest decrease in production relative to the Existing Condition was 5 percent for CP1 (Table 11-8 and Attachment 10 of the Modeling Appendix).

Figure 11-11 shows the annual change in production relative to the No-Action Alternative for all Comprehensive Plans.

Under CP1, three critical water years, two dry water years, and one below-normal water year resulted in increases in production relative to the No-Action Alternative greater than 5 percent. Only critical water year resulted in a significant decrease (more than 5 percent) in production relative to the No-Action (Attachment 9 of the Modeling Appendix).

Under CP1, one critical and one dry water year resulted in significant increases in production relative to the Existing Condition greater than 5 percent. Critical water years 1977 and 1992 and wet water years 1929 and 1992 resulted in significant decreases in production relative to the Existing Condition greater than 5 percent.

Figure 11-11. Change in Production of Fall-Run Chinook Salmon Compared to the No-Action Alternative

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on fall-run Chinook salmon caused by the actions of the project (Attachments 9 and 10). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 64 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 9 and 10 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality based on the smolt equivalents to fall-run Chinook salmon under CP1 occurred to fry, followed by eggs, prespawn adults, presmolts, and lastly to immature smolts. Flow-related effects triggered a higher percentage of the operations-related mortality (Table 11-9). In all water year types, the greatest portion of mortality under CP1 occurred to fry caused by forced movement to downstream habitats. Other non-flow- and water temperature-related conditions were the primary causes of mortality for all life stages except fry (Attachments 9 and 10 in the Modeling Appendix).

Most differences in production and mortality are insignificant for fall-run Chinook salmon. Therefore, there would be a less-than-significant impact to fall-run Chinook salmon. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon and Steelhead

Late fall-run Chinook salmon were evaluated directly using SALMOD and were considered to be a surrogate for steelhead; therefore, the following discussion regarding SALMOD results for late fall-run Chinook salmon are applicable to steelhead.

Production

Overall average late fall-run Chinook salmon production for the 80-year period was similar for CP1 relative to the No-Action Alternative. The maximum increase in production relative to the No-Action Alternative was almost 9 percent for CP1, while the largest decrease in production relative to the No-Action Alternative was less than 5 percent for CP1 (Table 11-10 and Attachment 12 of the Modeling Appendix).

Overall average late fall-run Chinook salmon production for the 80-year period was similar for CP1 relative to Existing Conditions. There were two critical water years with a significant increase (greater than 5 percent) in production, and no years with significant decreases in production relative to Existing Conditions (Table 11-10 and Attachment 13 of the Modeling Appendix).

Figure 11-12 and Table 11-10 display the annual differences in production for late fall-run Chinook salmon for all Comprehensive Plans.

Table 11-10. Change in Production Under CP1 for Late Fall-Run Chinook Salmon

Figure 11-12. Change in Production of Late Fall-Run Chinook Salmon Compared to the No-Action Alternative

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on late fall-run Chinook salmon caused by the actions of the project (Attachments 12 and 13 of the Modeling Appendix). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 78 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 12 and 13 of the Modeling Appendix). Under both 2030 and 2005 conditions, the largest mortality to late fall-run Chinook salmon under CP1 occurred to fry, followed by eggs, presmolts, immature smolts, and prespawn adults. Table 11-11 displays the overall mortalities for each Comprehensive Plan that are caused by changes in water temperature and flow (see also Attachments 12 and 13 of the Modeling Appendix).

When comparing mortality for flow- and water temperature-related activities only, fry are most affected, followed by eggs, presmolts, and immature smolts. Most mortality occurred as a result of flow conditions rather than water temperature (Table 11-11).

Years with the highest mortality under CP1 occurred in all water year types under both 2030 and 2005 conditions. Three years were preceded by a wet water year, one was preceded by an above-normal water year, and one was preceded by a dry water year (see also Attachments 12 and 13 of the Modeling Appendix).

Because SALMOD indicates an insignificant change in mortality and production index for late fall-run Chinook salmon, late fall-run Chinook salmon and steelhead (as represented by their surrogate late fall-run Chinook salmon) would experience a less-than-significant impact from actions taken in CP1. Mitigation for this impact is not needed, and thus not proposed.

Table 11-11. Average Annual Late Fall-Run Chinook Salmon Smolt Equivalent Mortality Under Each Base Condition and the Difference in Mortality Under Each Comprehensive Plan Caused by Changes in Flow and Water Temperature

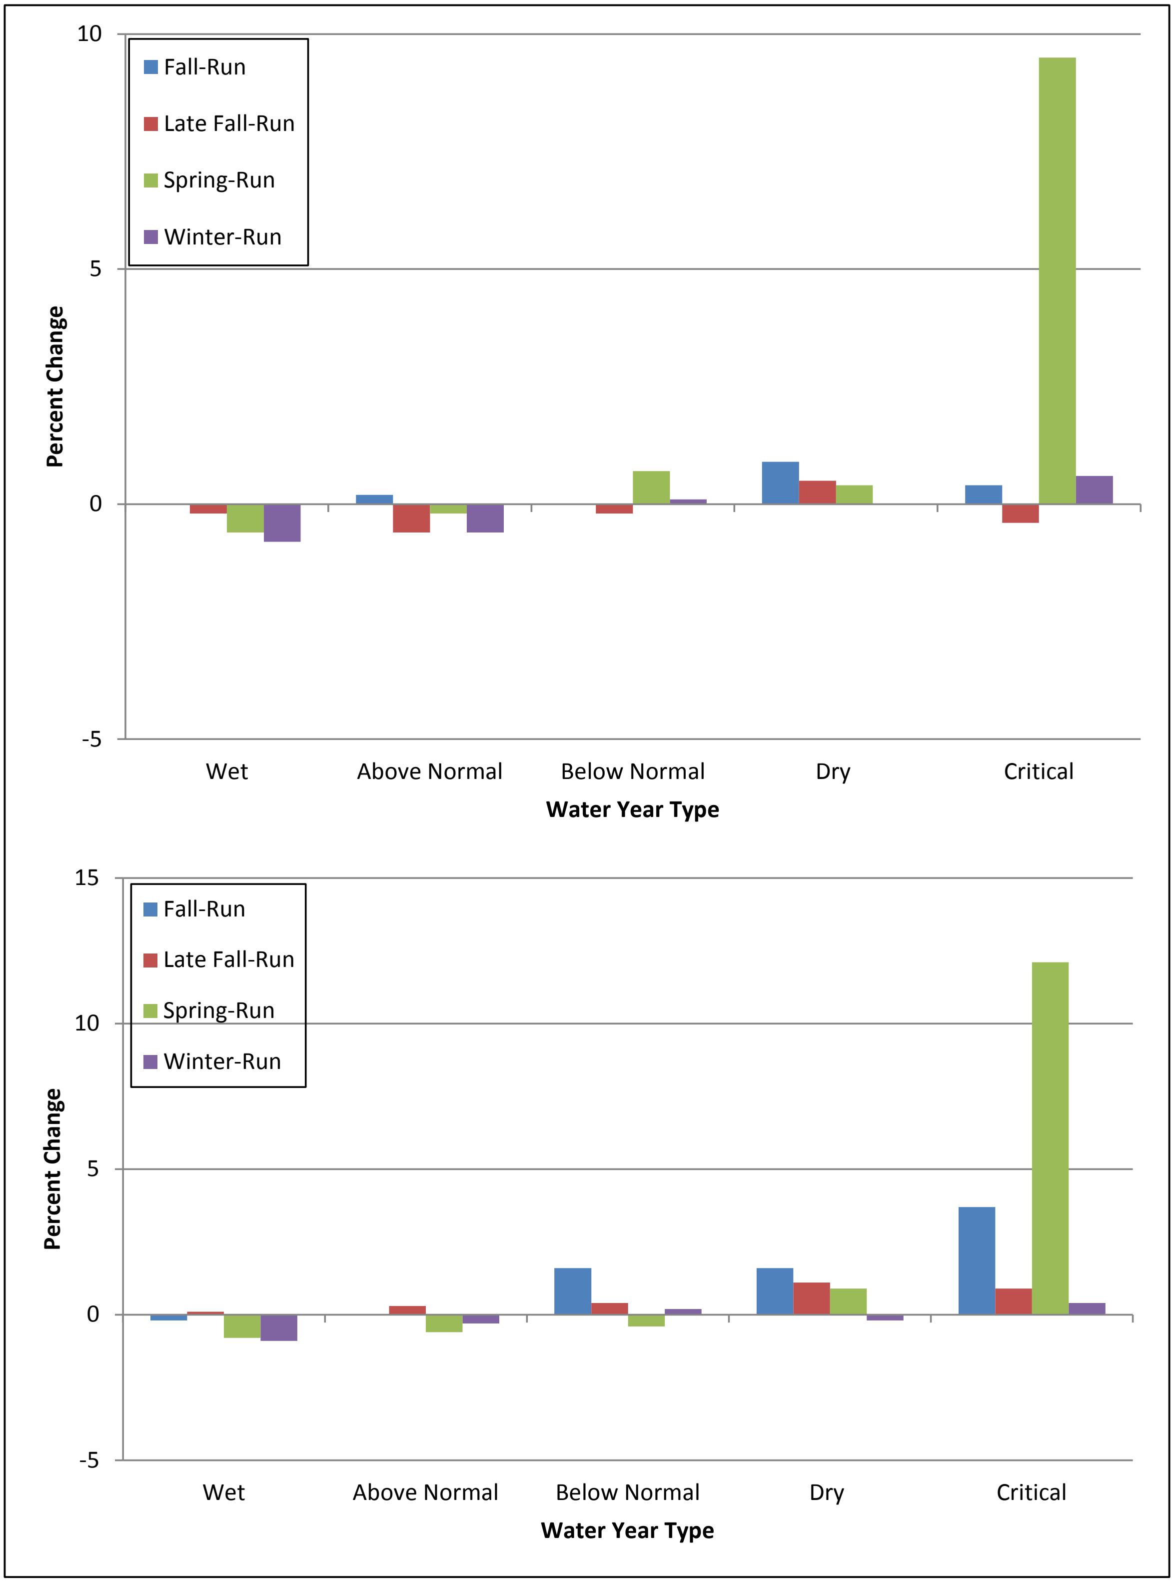
CP = Comprehsensive Plan

All Chinook Runs Combined

Raising Shasta Dam by 6.5 feet under CP1, in conjunction with spillway modifications, would result in an increase in full pool depth of 8.5 feet and an additional 256,000 acre-feet of storage capacity in Shasta Reservoir. The additional storage created by the dam raise would be used to improve the ability to meet water temperature objectives and habitat requirements for anadromous fish during drought years (see Figure 11-13). Under the 2030 conditions, overall production for all four runs of Chinook salmon combined would increase by over 61,000 immature smolts migrating below RDPP. Under the 2005 conditions, overall production for all four runs of Chinook salmon combined would increase by almost 344,000 immature smolts migrating below RDPP.



Note: Changes in outmigrating Chinook salmon simulated using SALMOD; Water Year Types based on the Sacramento Valley Water Year Hydrologic Classification

Figure 11-13. Percent Change in Production of Chinook Salmon for CP1 Compared to the No-Action Alternative (top) and Existing Conditions (bottom)

Impact Aqua-13 (CP1): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass Project operation generally would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

Flow-Related Effects Under CP1, monthly mean flows at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBPP) would be essentially equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for all months. (See the Modeling Appendix for complete modeling results.)

Potential flow-related effects of CP1 on fish species of management concern in the upper Sacramento River would be minimal. During most years, releases from Shasta Lake would be unchanged. During average and wet years, river flows would decrease slightly from December through February in some years because of the use of increased capacity within Shasta Lake, usually after an extended dry period. Also, flows (and stages) would increase slightly from June through October in most years. Although small, increased flow would be most pronounced during dry periods as a result of increased releases from Shasta Dam for water supply reliability purposes. However, few to no changes would occur in water flows during dry years in winter and spring.

The average changes in monthly mean flow would be reductions or increases of several percent, although the changes in monthly mean flow would be greater in some years. Nonetheless, differences generally would be small (less than 2 percent). Potential changes in flows and stages would diminish downstream from RBPP because of increased effects from tributary inflows, diversions, and flood bypasses.

Changes in monthly mean flows under CP1 relative to the Existing Condition and No-Action Alternative would have no discernible effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for these species would be unchanged. Therefore, flow-related impacts on these species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Water Temperature–Related Effects Under CP1, monthly mean water temperatures at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, Balls Ferry, above Bend Bridge, and above RBPP) would be the same as, or fractionally less than, water temperatures under the Existing Condition and No-Action Alternative conditions simulated for all months (Figures 11-14 and 11-15). See the Modeling Appendix for complete modeling results.

As discussed above, the modeling simulations may not fully account for real-time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature (i.e., small benefits) are likely conservative and understated to some degree. Potential water temperature–related effects of CP1 on fish species of management concern in the upper Sacramento River would be minimal.

The slightly cooler monthly mean water temperatures under CP1 relative to the Existing Condition and the No-Action Alternative would have very small effects on steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass in the upper Sacramento River. Mean monthly water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River. Therefore, water temperature–related impacts on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-15. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (CP1 Versus No-Action Alternative)

Impact Aqua-14 (CP1): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operations could cause a reduction in the magnitude, duration, and frequency of intermediate to large flows both in the upper Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel formation and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and shaded riverine aquatic (SRA) habitat. These processes are regulated by the magnitude, duration, and frequency of flows. Relatively large floods provide the energy required to mobilize sediment from the riverbed, produce meander migration, and create seasonally inundated floodplains. Project operations could cause a reduction in the intermediate to large flows necessary for channel formation and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Channel Forming and Maintenance In undisturbed alluvial rivers, channels and bedforms develop in response to flow and sediment loading conditions that may vary by orders of magnitude within a few hours. In many cases, the frequency distribution of flow and sediment supply are such that rivers convey the greatest fraction of their sediment load at an intermediate dominant discharge, which is often close to the bankfull flow (Leopold, Wolman, and Miller 1964). Although the recurrence interval of bankfull flow varies from river to river, it is often close to 1.5 to 2 years (Leopold, Wolman, and Miller 1964). This provides a rational basis for assuming that coarse sediment is routed as bedload during the 1.5-year flood (i.e., Q1.5). Flow regulation of the Sacramento River has reduced the river's Q1.5 by 30 percent from 86,000 cfs to 61,000 cfs (Kondolf et al. 2000).

Bankfull flow may provide a good first approximation for assessing the threshold for bed mobilization; however, it does not necessarily indicate the flow levels required to maintain the health of habitats in the alluvial system. For example, it has been estimated that a naturally occurring flood with a 5- to 10-year recurrence interval may often be required for maintenance of a mobile alternating bar-pool sequence (Trush, McBain, and Leopold 2000), which is an ecologically desired condition. In the regulated flow regime of the Sacramento River, the 10-year flood has been reduced by 38 percent from 218,000 cfs to 134,000 cfs (Kondolf et al. 2000).

At many locations between Keswick Dam and RBPP, the channel is characterized by bedrock control of its base level and its banks. This implies that, compared to alluvial reaches downstream, the channel in this area has been less able to adjust hydraulic geometry (channel width and depth) in response to dam-related changes in flow. Thus, it is possible that the channel is not in balance with the current flow regime, so that typical recurrence intervals of mobilization and bedform alteration are much longer than they were before the dams reduced the magnitude of the 1.5-year and 10-year floods (i.e., Q1.5 and Q10). This implies that the bed and point bars may have become static in the post-dam era, and that only remnants of gravel from once-abundant spawning habitat in this reach remain.

The flow required for mobilization and scour of a channel bed depends in part on the grain-size distribution of the bed sediment. On the Sacramento River, the grain-size distributions of deposits between Keswick Dam and Cottonwood Creek may have increased since construction of Shasta Dam because of winnowing associated with dam-related reductions in sediment supply (Stillwater Sciences 2006). This would tend to increase the threshold for mobilization and scour of the channel bed, even as the frequency of high flows was reduced by operations of Shasta Dam. The hypothesized coarsening of the bed would thus tend to make mobilization of sediment and bedforms even less likely under the regulated flow regime in the upper Sacramento River.

Changes (reductions) in intermediate to large flows in the Sacramento River also have the potential to affect the lower reaches (confluence areas) of tributaries by reducing the mainstem river’s backwater effect on the lower reaches of the tributaries. A decrease in the frequency, duration, and intensity of intermediate to large flows on the Sacramento River, and an associated decrease in the stage elevation of the river surface, could increase the amount of downcutting in the lower reaches of the tributaries. Downcutting of the lower tributaries could result in bank erosion, channel widening, and disconnection of the channel from its floodplain, which in turn could affect riparian recruitment and succession processes.

Meander Migration Suitable spawning habitat on the mainstem Sacramento River currently extends from Keswick Dam to Princeton. Since 1945, Shasta (and later Keswick) Dam has altered mainstem flow and sediment supply, and has thus affected the quantity and grain-size distributions of gravel in the channel bed. This in turn has affected the extent and quality of salmonid spawning habitat. The expected evolution of spawning gravel in the Sacramento River can be summarized in the following three working hypotheses (Stillwater Sciences 2006):

1. Bed coarsening in the upper Sacramento River has occurred and is continuing. As a result, spawning habitat has been progressively reduced in the reach between Keswick Dam and Anderson Bridge, despite the effects of regular gravel augmentation.

2. Bed coarsening has progressed downstream since 1980 and has now reduced the area of spawning habitat between Anderson Bridge and Cottonwood Creek.

3. The concentration of fine sediment below the surface has appeared to remain suitably low between Keswick Dam and Cottonwood Creek. It may have become higher in downstream reaches, however, because of a combination of factors: dam-related reductions in large flows, high sediment supply from Cottonwood Creek, and local hydraulic conditions (i.e., a break in slope) that promote local deposition. Thus, successful spawning of Chinook salmon in reaches below Cottonwood Creek may have been compromised.

The success of anadromous salmonids depends strongly on gravel dynamics in the mainstem river. However, other fish species of primary management concern rely much more heavily on the dynamics of meander migration, which affects the quality and availability of near- and off-channel habitat such as SRA.

SRA habitat is defined as the nearshore aquatic habitat occurring at the interface between a river and adjacent woody riparian habitat. SRA habitat is composed of vegetation and instream tree and shrub debris that provides important fish habitat. The principal attributes of this cover type are (1) an adjacent bank composed of natural, eroding substrates supporting riparian vegetation that either overhang or protrude into the water; and (2) water that contains variable amounts of woody debris, such as leaves, logs, branches, and roots, and has variable depths, velocities, and currents.

Riparian habitat provides structure (through SRA habitat) and food for fish species. Shade decreases water temperatures, while low overhanging branches can provide sources of food by attracting terrestrial insects. As riparian areas mature and banks erode, the vegetation sloughs off into the rivers, creating structurally complex habitat consisting of instream woody material that furnishes refugia from predators, alters water velocities, and provides habitat for aquatic invertebrates. For these reasons, many fish species are attracted to SRA habitat.

On the upper Sacramento River, actively migrating reaches alternate with stable reaches, which migrate slowly or not at all because they are confined by erosion-resistant geologic deposits or revetment placed to protect adjacent land uses. Meander migration and bank erosion occur by progressive channel migration and episodic meander-bend cutoff. Over decadal timescales, cutoffs generally affect less than 10 percent of the actively migrating length of the Sacramento River. Even so, cutoffs can account for well over 20 percent of the integrated lateral channel change, because they affect relatively large areas when they do occur (Stillwater Sciences 2006).

Chute cutoff and progressive migration interact to produce a characteristic pattern of planform development over time. Individual bends evolve greater sinuosity and curvature via progressive channel migration. Cutoffs reduce sinuosity when it exceeds a local threshold for the initiation of cutoff processes. This should produce measurable changes in local geomorphology over time. Averaged over larger timescales, however, changes in morphology in one reach should be balanced by changes in morphology in others. Thus, in the absence of human modifications, the overall pattern of planform geometry for migrating portions of rivers should approach a state of dynamic equilibrium. Studies indicate that the sinuosity of cutoff bends on the Sacramento River is decreasing over time (Stillwater Sciences 2006). This suggests that the Sacramento River is not in a state of dynamic equilibrium. The fact that cutoff migration has increased in frequency and is increasingly dominated by partial cutoffs (which affect smaller areas than complete cutoffs) provides further evidence that nonequilibrium conditions may prevail.

Process-based interpretations suggest that potential project-related changes in flow (i.e., reductions in peak flow and overbank discharge) could tend to reduce the frequency of these important geomorphic processes. This would generally be accompanied by a reduction in average sinuosity; however, observations from the Sacramento River indicate that the overall number of channel cutoffs has nevertheless increased. This supports the hypothesis that the erodibility of banks and floodplains has increased (thus enhancing the likelihood of cutoff) because of the effects of agricultural clearing of riparian forests on floodplains (Micheli, Kirchner, and Larsen 2004).

Floodplain Inundation Inundation of floodplains reduces the magnitude (i.e., peak volume) of flood flows and promotes exchange of nutrients, organisms, sediment, and energy between the terrestrial and aquatic systems. Flood pulses contribute to high rates of primary productivity in functioning floodplain systems (Junk, Bayley, and Sparks 1989). On the Sacramento River, floodplains provide important winter and spring spawning and rearing habitats for native fish, such as Sacramento splittail and Chinook salmon (Moyle et al. 2004, Sommer et al. 2001).

Typically, the floodplain immediately adjacent to the river is maintained at an elevation equal to the bankfull stage of the channel, such that discharge magnitudes greater than the bankfull flow inundate the adjacent floodplains (Leopold, Wolman, and Miller 1964). Because bankfull flow typically has a recurrence interval of 1.5 to 2 years (Q1.5–2) on alluvial rivers, flow magnitudes greater than the 1.5-year (Q1.5) flow event are often assumed to initiate floodplain inundation.

These effects would likely occur throughout the upper Sacramento River portion of the primary study area. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Lower Sacramento River and Tributaries, Delta, and Trinity River

Impact Aqua-15 (CP1): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern Project operation would result in no discernible change in monthly mean flows or water temperature conditions in the lower Sacramento River. However, predicted changes in flows in the Feather, American, and Trinity rivers could result in adverse effects on Chinook salmon, steelhead, Coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be potentially significant.

As described below, monthly mean flows at various modeling locations on the lower Sacramento River and tributaries under CP1 were compared with monthly mean flows simulated for the Existing Condition and No-Action Alternative conditions. Modeling for the lower American River occurred at Verona and Freeport; for the lower Feather River, modeling occurred below Thermalito Afterbay, and American River modeling occurred near the H Street Bridge in Sacramento. Modeling also occurred on the Trinity River. See the Modeling Appendix for complete CalSim-II modeling results.

Lower Sacramento River Under CP1, monthly mean flows at the lower Sacramento River modeling locations would be comparable to flows under the Existing Condition and No-Action Alternative conditions simulated for all months. Differences in modeled monthly mean flow were generally small (less than 2 percent) and within the existing range of variability. Potential changes in flows would diminish rapidly downstream from RBPP because of increased effects from tributary inflows, diversions, and flood bypasses. Thus, potential flow-related effects of CP1 on fish species of management concern in the lower Sacramento River would be minimal.

Mean monthly mean flows at all modeling locations on the lower Feather River and American River under CP1 would be essentially equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative conditions simulated for all months. Potential changes in flows are diminished in these areas because of operation of upstream CVP and SWP reservoirs (i.e., Lake Oroville and Folsom Lake) and increasing effects from tributary inflows, diversions, and flood bypasses. Potential flow-related effects of CP1 on fish species of management concern in the Feather River and American River would be minimal and within the existing range of variability. Potential changes in water temperatures in the lower Sacramento River caused by small changes in releases would diminish rapidly downstream because of the increasing effects of inflows, atmospheric influences, and groundwater. Therefore, flow- and water temperature–related impacts on fish species in the lower Sacramento River would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

The effects of altered flow regimes resulting from implementation of CP1 are unlikely to extend into the lower Sacramento River downstream from Verona and into the Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The operational requirements, including the 2008 USFWS BO and the 2009 NMFS BO, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with these ESA BOs. Thus, implementation of CP1 would likely not alter flow to the Delta or water temperatures in the lower Sacramento River and its primary tributaries to a degree sufficient to affect Chinook salmon, steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and water temperature–related effects on these fish species in the lower Sacramento River and tributaries would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Feather River and American River Under CP1, monthly mean flows at modeling locations on the lower Feather River and American River would be essentially equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative conditions simulated for most months. However, simulations for several months within the modeling record show substantial changes to flows in tributaries. Potential changes in flows in these areas could be reduced by real-time operations to meet existing rules and operation of upstream CVP and SWP reservoirs (Lake Oroville and Folsom Lake). Nevertheless, based on predicted changes in flow and associated flow-habitat relationships (including water temperature) for fish, potential flow-related impacts on species of management concern in the American and Feather rivers would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Trinity River As with the lower Feather River and American River, monthly mean flows at all modeling locations within the Trinity River under CP1 would be essentially equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for most months. Based on predicted changes in flow and associated flow-habitat relationships for fish, potential flow-related impacts on species of management concern in the Trinity River would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-16 (CP1): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could cause a reduction in intermediate to large flows both in the lower Sacramento River and in the lowermost (confluence) areas of its tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

As discussed under Impact Aqua-14 (CP1), sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. These processes are regulated by the magnitude, duration, and frequency of flows. Relatively large flows provide the energy required to mobilize sediment from the riverbed, produce meander migration, and create seasonally inundated floodplains. Project operations could cause a reduction in the intermediate to large flows necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains (including floodplain bypasses) along the lower Sacramento River.

There is substantially less bedrock control in the middle reach of the Sacramento River (between RBPP and Colusa) than along the Sacramento River between Keswick Dam and the RBPP. Consequently, sediment transport and meander migration processes are more pronounced in this more alluvial reach. This is supported by widespread evidence of frequent lateral migration in the middle reach of the Sacramento River (e.g., Micheli, Kirchner, and Larsen 2004). This implies that the middle reach of the Sacramento River experience much more frequent bed and bar mobilization than the Sacramento River between Keswick Dam and RBPP.

As discussed under Impact Aqua-14 (CP1), changes (reductions) in intermediate to large flows in the Sacramento River have the potential to affect the lower reaches (confluence areas) of tributaries by reducing the mainstem river's backwater effect on the lower reaches of the tributaries. A decrease in the frequency, duration, and intensity of intermediate to large flows on the Sacramento River, and an associated decrease in the stage elevation of the river surface, could increase the amount of downcutting in the lower reaches of the tributaries. Downcutting of the lower tributaries could result in bank erosion, channel widening, and disconnection of the channel from its floodplain, which in turn could affect riparian recruitment and succession processes.

Reaches of the Sacramento River differ in the extent of floodplain inundation. Most of the upper Sacramento River between Keswick Dam and RBPP is also bounded by high banks and terraces, limiting the opportunity for floodplain inundation in this reach. Also along the upper reaches of the lower Sacramento River, between Chico Landing and Colusa, the river is bounded by levees that provide flood protection for cities and agricultural areas. However, the levees of this reach of the Sacramento River are mostly set back from the mainstem channel, so that substantial flooding can occur within the river corridor. In the lower Sacramento River between RBPP and Chico Landing, the mainstem channel is flanked by broad floodplains. Evidence of ongoing sediment deposition of these areas testifies to continued inundation in floodplains in this reach (Buer 1994).

An important attribute of the middle and lower reaches of the Sacramento River is the presence of floodplain bypasses (e.g., Butte Basin, Sutter Bypass, and Yolo Bypass). In winter and spring, agricultural fields and wetland habitats throughout the floodplain bypasses often flood during high flows and are used by Sacramento splittail for spawning and rearing, and by Chinook salmon and steelhead for rearing (Sommer et al. 2001, 2003). Numerous studies have shown that shallow water and dense vegetation in these areas provide highly productive rearing areas for numerous species, including Chinook salmon and splittail. Seasonally flooded habitat provides rearing habitat for Chinook salmon and spawning, rearing, and foraging habitat for splittail (Sommer et al. 1997, 2001, 2002; Baxter et al. 1996; USACE 1999). Floodplain habitat offers protection from large piscivorous fish such as striped bass. The temporary nature of the flooded habitat and the protection offered by shallow water and dense vegetative cover serve to exclude predatory fish.

The productivity of floodplains is generally related to the frequency, timing, water depths, velocities, vegetation, water quality, and duration of inundation relative to the life history and habitat requirements of fish species. Physical conditions (e.g., type and extent of vegetation, soil conditions, and drainage patterns) may also contribute to habitat quality. Flooded vegetation provides an abundant source of food, consisting of detrital material, insect larvae, crustaceans, and other invertebrates. Juvenile Chinook salmon and splittail apparently forage among a variety of vegetation types, such as trees, brush, and herbaceous vegetation; however, the relative importance of these vegetation types, alone or in combination, is unknown.

Juvenile Chinook salmon that rear in seasonally flooded habitat have higher survival and growth rates than juveniles that remain in the main river channel to rear (USACE 1999, Sommer et al. 2001). The increased growth rate may be related to the higher water temperatures in the shallow water in this habitat. It also may be related to the higher associated rate of production of invertebrates, which are a substantial source of food for rearing juveniles, and of the grasses that support the invertebrates. Increases in the area available to juveniles could also reduce competition for food and space, and could reduce the likelihood of encounters with predators (Sommer et al. 2001). In addition, juvenile Chinook salmon that grow faster are likely to migrate downstream sooner, which helps to reduce the risks of predation and competition in freshwater systems.

In summary, implementation of CP1 could cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing effects on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along the upper reaches of the lower Sacramento River. Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-17 (CP1): Effects to Delta Fisheries Resulting from Changes to Delta Outflow Based on the results of hydrologic modeling comparing Delta outflow under the No-Action Alternative, Existing Condition, and CP1, CP1 would result in changes to average monthly Delta outflow of less than 5 percent in all year types (with the exception of November of above-normal water years under 2005 conditions). Delta outflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources.

This impact on Delta fisheries and hydrologic transport processed within the Bay-Delta would be less than significant.

Results of the comparison of Delta outflows are summarized by month and water year type in Table 11-12. Delta outflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources.

The comparison includes the estimated average monthly outflow under the Existing Condition, No-Action Alternative, and CP1, and the percentage change between base flows and CP1 operations. Results of the analysis (Table 11-12) show that Delta outflows would be slightly lower under many of the CP1 operations, and slightly higher than basis-of-comparison conditions depending on month and water year type. However, only one of the simulated changes was greater than 5 percent (November of above-normal water years under 2005 conditions). Based on results of this analysis, CP1 would result in a less-than-significant impact on Delta fisheries as a consequence of changes in Delta outflow. Mitigation for this impact is not needed, and thus not proposed.

Table 11-12. Delta Outflow Under the Existing Condition, No-Action Alternative, and CP1

Impact Aqua-18 (CP1): Effects to Delta Fisheries Resulting from Changes to Delta Inflow Based on the results of hydrologic modeling comparing Delta inflow under CP1 to the Existing Condition and No-Action Alternative, CP1 would result in changes to average monthly Delta inflow of less than 5 percent in all year types. This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant.

Changes in upstream reservoir storage have the potential to affect Delta inflow. Delta inflow may affect hydrologic conditions within Delta channels, hydraulic residence times, salinity gradients, and the transport and movement of various life stages of fish, invertebrates, phytoplankton, and nutrients into and through the Delta. Delta inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources.

Results of the comparison of Delta inflows between the Existing Condition, No-Action Alternative, and CP1 are summarized by month and water year type in Table 11-13. The comparison includes the estimated average monthly inflow under the 2005 and 2030 conditions, the average monthly Delta inflow under CP1, and the percent change in flows between the Existing Condition or No-Action Alternative and CP1. Delta inflows would be slightly lower under many of the CP1 operations and slightly higher than basis-of-comparison conditions, depending on month and water year type. The difference in simulated average monthly Delta inflow between CP1 and the Existing Condition and the No-Action Alternative did not exceed 5 percent. Based on the results of this analysis, CP1 would have a less-than-significant effect on Delta fisheries and hydrologic transport processes within the Bay-Delta as a consequence of changes in Delta inflow. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP1): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow CP1 operation would result in a variable response in Sacramento River inflow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water year. Decreases in Sacramento River inflow would not equal or exceed 5 percent. This impact would be less than significant.

Flow within the Sacramento River has been identified as an important factor affecting the survival of emigrating juvenile Chinook salmon; important to the downstream transport of planktonic fish eggs and larvae such as delta and longfin smelt, striped bass and shad; and important for seasonal floodplain inundation that has been identified as important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon and steelhead. Sacramento River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. Sacramento River inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. A reduction in Sacramento River flow as a result of CP1, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

Results of hydrologic modeling, by month and year type, for the Existing Condition, No-Action Alternative, and CP1 for Sacramento River inflow are presented in Table 11-14. Results of these analyses show a variable response in Sacramento River inflow with CP1 operations resulting in both increases and decreases in river inflow above the Existing Condition and the No-Action Alternative, depending on month and water year type. Under CP1, Sacramento River flow would not decrease by 5 percent or more. Based on these results the impact of CP1 on fish habitat and transport mechanisms within the lower Sacramento River and Delta would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP1): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP1 operation would result in no discernible change in San Joaquin River flows at Vernalis, and, therefore, no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta from CP1 relative to No-Action Alternative and the Existing Condition. There would be no impact.

Flow within the San Joaquin River has been identified as an important factor affecting the survival of juvenile Chinook salmon migrating downstream from the tributaries through the mainstem San Joaquin River and Delta; important to the downstream transport of planktonic fish eggs and larvae such as striped bass; and important for seasonal floodplain inundation that is considered to be important habitat for successful spawning and larval rearing by species such as Sacramento splittail and as seasonal foraging habitat for juvenile Chinook salmon. San Joaquin River flows are also important in the transport of organic material and nutrients from the upper regions of the watershed downstream into the Delta. San Joaquin River inflow serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. A reduction in San Joaquin River flow as a result of

CP1 operations, depending on the season and magnitude of change, could adversely affect habitat conditions for both resident and migratory fish species. An increase in river flow is generally considered to be beneficial for aquatic resources within the normal range of typical project operations and flood control. Very large changes in river flow could also affect sediment erosion, scour, deposition, suspended and bedload transport, and other geomorphic processes within the river and watershed.

Results of hydrologic modeling, by month and year type, for the Existing Condition, No-Action Alternative, and CP1 for San Joaquin River flow are summarized in Table 11-15. Results of these analyses show that CP1 would have no effect on seasonal San Joaquin River flows compared with the Existing Condition and No-Action Alternative. Based on these results CP1 would have no impact on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta under CP1. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP1): Reduction in Low-Salinity Habitat Conditions Resulting from an Upstream Shift in X2 Location CP1 operation would result in a less than 0.5 km movement upstream or downstream from the X2 location from its location during February through May or September through November under the Existing Condition or No-Action Alternative, and thus cause minimal reduction in low-salinity habitats. This impact would be less than significant.

Operations of upstream storage reservoirs have the potential to affect the location of X2 as a result of changes in freshwater flows from the upstream tributaries through the Delta. X2 serves as a surrogate metric for a variety of habitat conditions within the Delta that directly, or indirectly, affects fish and other aquatic resources. For purposes of evaluating changes in habitat quantity and quality for estuarine species, a significance criterion of an upstream change in X2 location less than 1 km of the location under either the Existing Condition or the No-Action Alternative was considered to be less than significant. The criterion was applied to a comparison of hydrologic model results for basis-of-comparison conditions and CP1, by month and water year, for February through May and September through November.

Results of the comparison of X2 position under the Existing Condition, No-Action Alternative, and CP1 are summarized in Table 11-16. The results showed that changes in X2 location under CP1 as compared with the Existing Condition would be less than 1 km (all were less than 0.5 km) with both variable upstream and downstream movement of the X2 location, depending on month and water year. Changes in X2 location between the No-Action Alternative and CP1 assuming future operating conditions would also be small (less than 0.2 km). These results are consistent with model results for Delta outflow that showed a less-than-significant change in flows under CP1. Based on these results, CP1 would have a less-than-significant impact on low-salinity habitat conditions within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP1): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers CP1 operation would result in minimal changes to reverse flows in Old and Middle rivers. The increases in reverse flows under CP1 do not exceed -5,000 cfs; thus, the increases in reverse flows are not expected to contribute to an increase in the vulnerability of delta smelt, longfin smelt, Chinook salmon, juvenile striped bass, or threadfin shad—but summer Old and Middle river flows could contribute to an increase in vulnerability of other resident warm-water fish to increased salvage and potential losses. This impact would be less than significant.

Results of the analysis show two occurrences relative to the Existing Condition, and one compared with the No-Action Alternative when reverse flows within Old and Middle rivers would increase by more than 5 percent; however, neither change resulted in a flow greater (more negative) than -5,000 cfs. Two of these events occurred in critical water years, which would be expected as a result of greater export operations under CP1. During January, operations under CP1 would result in an increase in reverse flow of 5 percent during critical years under future conditions (Table 11-17). Based on results of the delta smelt analysis of the relationship between reverse flows and delta smelt salvage, the increase from approximately 3,900 cfs in January under the basis-of-comparison in a critical water year to approximately 4,100 cfs under CP1would not be expected to result in a significant increase in adverse impacts to delta smelt or longfin smelt.

	C	-6,355	-6,397	1	-5,928	-6,089	3

Note:
A positive percentage change reflects more negative reverse flows under CP1 when compared to the Existing Condition or the No-Action Alternative.

Key:
AN = above-normal
BN = below-normal
C = critical
cfs = cubic feet per second
CP = Comprehensive Plan
D = dry
W = wet

Juvenile Chinook salmon and steelhead are migrating through the Delta during January, and an increase in average monthly reverse flows of around 200 cfs would be expected to increase the potential risk of increased mortality to these species. However, given the tidal volumes and hydrodynamics of the Old and Middle river region, it is not expected that the change in reverse flows in January in a critical year would result in a detectable change in fish survival. The majority of juvenile Chinook salmon emigrating from the San Joaquin River typically migrate downstream later in dry years and would not be expected to occur in high numbers within Old and Middle rivers in January.

The increase in reverse flows estimated to occur under CP1 in critical and above-normal water years in March would exceed 5 percent, but would not increase the flows beyond -5,000 cfs. The potential change in Old and Middle river flows of approximately 100 to 200 cfs may result in a small increase in vulnerability of fish, particularly delta smelt and longfin smelt, to CVP and SWP salvage, resulting in a potentially significant impact. The increased reverse flows would not result in a significant increase in risk of mortality for Chinook salmon. The potential change in Old and Middle river flows would result in a less-than-significant impact to juvenile striped bass, threadfin shad, and other resident warm-water fish inhabiting the south Delta, due mainly to larger resident populations of these species.

The potential increase in losses during January and March is considered to be less than significant for Chinook salmon, steelhead, delta smelt, longfin smelt, and Chinook salmon, but potentially significant for other resident warm-water fish. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species.

Impact Aqua-23 (CP1): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP1 operations may result in an increase in CVP and SWP exports, which is assumed to result in a direct proportional increase in the risk of fish being entrained and salvaged at the facilities. Future operations of the SWP and CVP export facilities would continue to be managed and regulated in accordance with incidental take limits established for each of the protected fish by USFWS, NMFS, and CDFW. The resulting impact to Chinook salmon, steelhead, longfin smelt, striped bass, and splittail would be less than significant; the resulting impact to delta smelt would be potentially significant. Overall, this impact would be potentially significant.

Results of entrainment loss modeling at the CVP and SWP export facilities are presented in Table 11-18 for CP1. The initial modeling was conducted using average fish densities developed from past fish salvage monitoring at the SWP and CVP export facilities. Average monthly water exports were used in the analysis based on hydrologic simulation modeling. The indices of the potential risk of entrainment for some species, such as Chinook salmon, were not estimated separately for each species (e.g., winter-run Chinook salmon) in these analyses. These indices were calculated for wet, above-normal, below-normal, dry, and critical water year types, and for an average across all years (no water year type specified). The total numbers of fish lost annually, by species, are presented in Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report.* The difference between the nonoperations-related and operations-related fish mortality is represented as the entrainment index, shown in Table 11-18, to represent the effect of project operations on each fish species for the CVP and SWP.

Table 11-18. Indices of Entrainment at the CVP and SWP facilities Under the Existing Condition, No-Action Alternative, and CP1

Note:
Negative percentage change reflects a reduction in entrainment risk while a positive percentage change reflects an increase in entrainment risk.

Key:
AN = above-normal
BN = below-normal
C = critical
CP = Comprehensive Plan
CVP = Central Valley Project
D = dry
SWP = State Water Project
W = wet

The greatest change in the risk of entrainment at the CVP and SWP export facilities would be expected to occur in dry and critical water year types when export rates would increase, especially during February and summer months. Entrainment indices under CP1 operations indicate a relatively minor increase, on average, in salvage for most species (e.g., delta smelt, steelhead, Chinook salmon, and longfin smelt). Although the risk of entrainment showed both increases and decreases depending on species and water year type, the general trend was a small incremental increase in the risk of entrainment/salvage losses at the CVP and SWP export facilities when compared to the Existing Condition. Species with relatively lower abundance at the CVP and SWP, such as longfin smelt, during months of the highest exports, would be less affected by CP1 operations, with entrainment indices typically representing a net benefit as a result of CP1 relative to the Existing Condition. Species with relatively higher abundance at the CVP and SWP fish facilities, such as splittail and striped bass, would experience increased risk of mortality due to higher exports during June and July, as these species are generally collected at their highest abundances during these months. Under CP1, the risk of entrainment of juvenile Chinook salmon, whose occurrence at the facilities is highest during February through May, would increase as a result of generally higher project export rates during these months when compared to the Existing Condition.

Results of the entrainment risk calculations for delta smelt showed a change of less than 1 percent from the Existing Condition in all water year types and up to a 2-percent increase during critical water years (Table 11-18). The risk of increased losses of delta smelt would be greatest in critical years with a net reduction in losses under CP1 relative to the No-Action Alternative. Although the incremental change in the risk of delta smelt losses resulting from CVP and SWP export operations would be small, the delta smelt population abundance is currently at such critically low levels that even a small increase in the risk of losses is considered to be potentially significant. The increase in risk would also contribute to cumulative factors affecting the survival of delta smelt.

The estimated change in the risk of losses for Chinook salmon under CP1 follows a similar pattern to that described for delta smelt (Table 11-18). Overall, CP1 would result in a small increase in the risk of losses relative to both the Existing Condition and No-Action Alternative. Given the numbers of juvenile Chinook salmon produced each year in the Central Valley, the relatively small incremental increase in the risk of entrainment/salvage at the CVP and SWP export facilities is considered to be a less-than-significant direct impact but would contribute incrementally to the overall cumulative factors affecting juvenile Chinook salmon survival within the Delta and population dynamics of the stocks.

The estimated change in the risk of longfin smelt entrainment/salvage under CP1 compared with the Existing Condition and No-Action Alternative include small positive and negative changes (less than 2 percent), depending on water year type (Table 11-18). Given the greater abundance of longfin smelt, when compared to delta smelt, their 2-year life history, and geographic distribution within the estuary, these small changes in the risk of entrainment are considered to be less than significant.

The estimated change in the risk to steelhead of entrainment/salvage at the CVP and SWP export facilities under CP1 are summarized in Table 11-18. The increase in risk of steelhead losses in wet years (as compared with the No-Action Alternative) and critical water years (as compared with the Existing Condition) would be less than significant based on the abundance of Sacramento and San Joaquin river juvenile steelhead migrating through the Delta, but would contribute directly to cumulative factors affecting the survival and population dynamics of Central Valley steelhead. The predicted increase in potential entrainment risk for steelhead under critical water years represents an initial estimate of the change (percentage) between the CP1 and the Existing Condition and No-Action Alternatives and does not allow the predicted losses to be evaluated at the population level (see Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report).*

The change in risk to juvenile striped bass for entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-18. The changes in risk in all water year types of less than 2 percent would be less than significant to striped bass but would contribute to the cumulative factors affecting striped bass survival and population dynamics in the Delta. The increased losses, particularly in drier water years when juvenile striped bass production is lower, would contribute to the cumulative effects of factors affecting juvenile striped bass survival in the Delta.

Results of the risk estimates for juvenile splittail losses relative to the Existing Condition and No-Action Alternative show a pattern similar to other species (Table 11-18). The increased risk index of less than 2 percent was considered to be a less-than-significant impact. The simulated loss index increased during dry and critical water years. Higher risk of entrainment/salvage losses in drier water years has a potentially greater effect on abundance of juvenile splittail since reproductive success and overall juvenile abundance is typically lower in the Delta in dry years. The increased risk of losses in drier years would not be potentially significant, but the increased losses would contribute to cumulative factors affecting survival of juvenile splittail within the Delta.

Impact Aqua-23 (CP1) is considered to be less than significant for all species except delta smelt which could experience potentially significant effects. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species.

CVP/SWP Service Areas

Impact Aqua-24 (CP1): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow

Regimes CP1 implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, hydrologic effects to tributaries and reservoirs with CVP and SWP dams, as well as the conveyances south of the Delta would be substantially less than impacts on the lower Sacramento River. Changes in hydrology could affect aquatic habitats that provide habitat for the fish communities. However, these changes would not result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. Therefore, this impact would be less than significant.

CP1 implementation could result in modified flow regimes that would shift the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects in tributaries (e.g., San Joaquin River, canals), reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams, and conveyances are expected to be substantially less than impacts on the lower Sacramento River. The change in hydrology and reservoir levels could affect aquatic habitats for local resident fish communities, but these changes would not result in substantial effects on the distribution or abundance of these species in the CVP and SWP service areas. The effects from CP1 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and the resulting flows downstream from those reservoirs, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As with CP1, CP2 focuses on increasing water supply reliability and increasing anadromous fish survival. CP2 primarily consists of raising Shasta Dam by 12.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 14.5 feet and enlarge the total storage capacity in the reservoir by 443,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir reserved to specifically focus on increasing M&I deliveries. CP2 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the Sacramento River between Shasta Dam and Red Bluff.

Shasta Lake and Vicinity

Impact Aqua-1 (CP2): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP2, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. CP2 operations would also result in reduced monthly fluctuations in WSEL, which would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. Similar to CP1, the value of existing structural habitat improvements (e.g., piles, willow plantings) would be diminished; however, the existing habitat-enhancement features would become functional during reservoir drawdowns later in the season and during normal and drier years; however, environmental commitments during construction, which include placing brush in the new inundation varial zone to extend and enhance existing fish habitat structures, would offset this effect (See Chapter 2, "Alternatives," for additional detailed descriptions of the environmental commitments). Additionally, large areas of the shoreline would not be cleared, and the vegetation along these sections would be inundated periodically. In the short term, this newly inundated vegetation will initially increase warm-water fish habitat, with decay expected to occur over several decades. This impact would be less than significant.

This impact would be similar to Impact Aqua-1 (CP1), but the surface area would be larger under the 12.5-foot dam raise than under the 6.5-foot dam raise. CalSim-II modeling shows that the surface area of Shasta Lake would be larger under the CP2 than the Existing Condition or No-Action Alternative in all five water year types (Figures 11-16 and 11-17).

Figure 11-17. Average Monthly Surface Area for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP2 Versus No-Action

Monthly WSEL fluctuations were compared with projections for water supply demand. For CP2, with a 2005 water supply demand, 44 percent of monthly changes in projected WSEL (i.e., 11 of the 25 total projections made for the 5 months from March through July for all five water year types) showed decreased monthly WSEL fluctuations relative to the Existing Condition and 4 percent showed increased monthly WSEL fluctuations (Figure 11-18). For CP2, with a projected 2030 water supply demand, 36 percent of monthly changes in projected WSEL showed decreased WSEL fluctuations relative to the No-Action Alternative and 16 percent showed increased monthly WSEL fluctuations (Figure 11-19). Under CP2, none of the changes in monthly WSEL fluctuation is different enough from the Existing Condition to warrant the investigation of daily WSEL fluctuation.

Increases in the overall surface area and WSEL under CP2 would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake for a period of time, possibly for several decades. Furthermore, reductions in the magnitude of monthly WSEL fluctuations, along with the environmental commitment to install and extend existing habitat brush piles and structures, could contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water fish species. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-19. Average Monthly Change in Water Surface Elevation for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP2 Compared with No-Action

Impact Aqua-2 (CP2): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Localized increases in soil erosion and resulting runoff sedimentation, and turbidity resulting from project construction in the vicinity of Shasta Dam and at utility, road, and other facility relocation areas could affect nearshore warm-water habitat. This impact would be similar to Impact Aqua-2 (CP1). However, CP2 would have a larger project footprint and would take longer to implement. However, the environmental commitments for all action would result in less-than-significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-3 (CP2): Effects on Cold-Water Habitat in Shasta Lake Under CP2, operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout. This impact would be beneficial.

This impact would be similar to Impact Aqua-3 (CP1). However, it would be of greater magnitude owing to a greater increase in the ratio of the volume of cold-water storage in the lake to the surface area of the lake. CalSim-II modeling shows that under CP2 with a 2030 water supply demand, the ratio of cold-water storage to surface area is higher than under the No-Action Alternative in all water years and during all months modeled. The greatest projected increases over the No-Action Alternative occur between June 30 and August 31, which is a critical rearing and oversummering period for cold-water fishes in reservoirs, and the increases are greatest in wet and above-normal water years (Figure 11-20).

	Apr 30	Jun 30	Aug 31	Oct 31

D = dry water years
NA = No-Action
W = wet water years

Figure 11-20. Average Monthly Cold-water Storage to Surface Area Ratio for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP2 Compared with the Existing Condition

CP2 would increase the availability of suitable habitat for cold-water fish in Shasta Lake, particularly in dry to wetter water year, with a slight improvement in critical years. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-4 (CP2): Effects on Special-Status Aquatic Mollusks Under CP2, habitat for special-status mollusks could become inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could adversely affect special-status aquatic mollusks and their habitat in or near Shasta Lake and its tributaries. This impact would be similar to Impact Aqua-4 (CP1). However, a larger area would be inundated under CP2, which could result in an increase in impacts to these species and their habitat. Except for the California floater, the occurrence of special-status mollusks in Shasta Lake and the lower reaches of its tributaries is unlikely. Modification or loss of suitable habitat for the California floater would occur through increased WSEL and seasonal fluctuations in the surface area under CP2. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-5 (CP2): Effects on Special-Status Fish Species The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP2 could affect one species designated as sensitive by USFS, the hardhead. However, available data suggest that hardhead do not currently occur or are very uncommon in the primary tributaries to Shasta Lake, other than the Pit River above the Pit 7 Afterbay.

The 14.5-foot increase in full pool elevation of Shasta Lake would inundate partial or complete fish passage barriers in approximately 68 perennial and 400 intermittent tributaries (greater than 98 percent of which are non-fish-bearing), including the 15-foot high cascade in Squaw Creek that could expand access to Squaw Creek for hardhead; expanded access could be locally beneficial to this special-status species, although the increase may also permit access by predatory warm-water fishes. Access to, and the availability of, suitable riverine habitat among all the main tributaries to the reservoir would not likely become any more limiting than under current conditions, nor would it greatly expand. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP2): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP2, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,084-foot contour, the maximum inundation level under this alternative. This impact would be less than significant.

This impact would be similar to Impact Aqua-6 (CP1) (i.e., creation and elimination of fish passage barriers in tributaries to Shasta Lake would primarily be limited to non-fish-bearing intermittent streams). However, the maximum inundation level would be higher under CP2, which would inundate (eliminate) partial or complete fish barriers in approximately 34 perennial tributaries, only 15 of which have complete barriers, and the most important of which is a 15-foot boulder cascade in Squaw Creek. Potential impacts of reservoir enlargement to fish communities above passage barriers would be greatest among perennial tributaries as the proportion of fish-bearing perennial streams (87 percent) is much greater than for intermittent streams (2 percent). This could have a small and localized beneficial effect for adfluvial cold-water fish in Shasta Lake by increasing the amount of suitable spawning and rearing habitat available to these species.

Conversely, the potential for access of warm-water fish species into some tributaries, with a potential to alter existing resident fish communities, would be extended by inundation of passage barriers under CP2. However, except for the main river tributaries (i.e., Sacramento, Pit, and McCloud rivers), less than 10 percent of the lake's other accessible tributaries have been found to be colonized by warm-water fish above the varial zone and any further access is expected to be limited primarily to the newly inundated reaches of some streams.

CP2 would not result in the widespread c*reation or elimination of fish passage barriers in tributaries to Shasta Lake. One exception is Squaw Creek, where inundation of a barrier at the current head of the reservoir would potentially allow warm-water fish to move upstream and colonize previously inaccessible habitat with consequent effects on the native fish community and sensitive invertebrates (e.g., mollusks). Environmental commitments, described in Chapter 2, "Alternatives," to monitor fish communities in Squaw Creek and adaptively manage to prevent warmwater fish invasions would reduce this impact to a less than significant level.* Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP2): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake Similar to CP1, CP2 would result in additional periodic inundation of potential spawning and rearing habitat for adfluvial salmonids in low-gradient tributaries. In addition to modification of the hydraulic regimes of these affected reaches, changes in the WSEL as a result of CP2 will affect the character and location of substrate (e.g., spawning gravel) at some locations, thereby influencing the suitability.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils," CP2 would inundate perennial reaches with gradients of less than 7 percent that could provide potentially suitable spawning and rearing habitat for adfluvial salmonids. The lengths of low-gradient tributaries to each arm of Shasta Lake and estimated suitable spawning habitat areas (both intermittent and perennial) that would be periodically affected are as follows:

- Sacramento Arm – 3.1 miles (16,430 Square feet, excludes mainstem river)
- McCloud Arm – 1.4 miles (9,990 square feet)
- Pit Arm – 1.4 miles (523 square feet, excludes mainstem river)
- Big Backbone Arm – 0.6 miles (144 square feet)
- Squaw Arm – 0.9 miles (1,300 square feet)

A total of 7.4 miles of low-gradient reaches (based on channel slope and confirmed by surveys of representative stream reaches) that could provide some spawning and rearing habitat for adfluvial salmonids (estimated as 31,500 square feet for all tributaries) would be affected by CP2, which is only about 1.8 percent of the low-gradient habitat upstream from Shasta Lake. An additional 8,285 square feet of suitable cold-water spawning habitat is estimated to be periodically inundated under CP2 compared to CP1. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-8 (CP2): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP2 would result in periodic inundation of the lower reaches of high-gradient, intermittent non-fish-bearing tributaries to Shasta Lake. About 17.3 miles of non-fish-bearing tributary habitat (based on channel slope and confirmed by surveys of representative stream reaches) would be affected by CP2, which is only about 0.7 percent of this habitat upstream from Shasta Lake.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils," CP2 would inundate tributary segments with channel slopes in excess of 7 percent. Although these segments do not typically support salmonid populations, they do provide riparian and aquatic habitat for a variety of organisms and serve as corridors that connect habitat types. The lengths of non-fish-bearing tributaries for each arm of Shasta Lake that would be periodically inundated are as follows:

- Sacramento Arm – 3.9 miles
- McCloud Arm – 2.8 miles
- Pit Arm – 2.5 miles
- Big Backbone Arm – 1.8 miles
- Squaw Arm – 1.3 miles

- Main Body – 5.0 miles

This impact would be similar to Impact Aqua-8 (CP1). However, it would periodically inundate a larger amount of habitat in low-gradient reaches to Shasta Lake, but the total amount inundated would be only 0.7 percent of the non-fish-bearing tributary habitat (based on channel slope) upstream from the lake and no special-status aquatic vertebrate or invertebrate species have been detected in these reaches. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP2): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP2. There would be no impact.

This impact is the same as Impact Aqua-9 (CP1) and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Aqua-10 (CP2): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Temporary construction-related increases in sediments and turbidity levels would adversely affect aquatic habitats and fish populations immediately downstream in the upper Sacramento River. However, environmental commitments would be in place to reduce the effects. This impact would be less than significant.

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater under CP2 than under CP1 because of the increased activity associated with a 12.5-foot raise compared to a 6.5-foot raise. However, as under CP1, environmental commitments for all actions would be in place to reduce the effects. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-11 (CP2): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants. Such exposure could adversely affect aquatic habitats, the aquatic food web, and fish populations, including special-status species, downstream in the primary study area. However, environmental commitments would be in place to reduce the effects. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater under CP2 than under CP1 because of the increased activity associated with a 12.5-foot raise compared to a 6.5-foot raise. A potential release of hazardous materials into the upper Sacramento River could cause a reduction in aquatic habitats and fish populations if proper procedures were not implemented to contain the discharge. However, as under CP1, environmental commitments for all actions would be in place to reduce the effects. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-12 (CP2): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon and Steelhead CP2 operation under CP2 would generally result in improved flow and water temperature conditions in the upper Sacramento River for Chinook salmon and steelhead, but not all runs have an increase in production. This impact would be beneficial.

Winter-Run Chinook Salmon

Production

The overall average winter-run production for the 81-year period was similar for CP2 relative to the No-Action Alternative and the Existing Condition (Attachments 3 and 4 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 61 percent in a critical water year for CP2, while the largest decrease in production relative to the No-Action Alternative was around 24 percent, also in a critical water year (Table 11-19 and Attachment 3 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 45 percent for CP2, while the largest decrease in production relative to the Existing Condition was around 27 percent under CP2 (Table 11-19 and Attachment 4 of the Modeling Appendix). Figure 11-9 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP2, only two critical water years had significant increases (greater than 5 percent) in production relative to the No-Action Alternative for winter-run Chinook salmon. No other water year type had a significant increase in production. One critical water year had a significant decrease in production.

Under CP2, four critical, one dry water, and one below-normal water years had significant increases in production relative to the Existing Condition for winter-run Chinook salmon. Three years (one each in critical, dry and above-normal water year types) had significant decreases in production greater than 5 percent.

Table 11-19. Change in Production Under CP2 for Winter-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
Future Condition (2030)								
All	81	3,772,931	-28,184	-0.7	61.1	2	-23.8	1
Critical	13	3,343,654	-34,302	-1.0	61.1	2	-23.8	1
Dry	17	3,953,711	-18,620	-0.5	2.9	0	-2.9	0
Below Normal	14	3,941,590	3,032	0.1	3.6	0	-2.6	0
Above Normal	11	3,799,691	-59,239	-1.5	0.5	0	-4.7	0
Wet	26	3,767,230	-35,048	-0.9	4.4	0	-3.9	0
Existing Condition (2005)								
All	81	3,776,950	-4,297	-0.1	44.5	6	-5.8	2
Critical	13	3,357,691	146,752	4.6	44.5	4	-5.6	1

Below Normal	14	3,941,118	968	0.0	5.2	1	-4.4	0
Above Normal	11	3,782,121	-70,562	-1.8	2.3	0	-5.8	1
Wet	26	3,772,968	-45,168	-1.2	1.5	0	-4.4	0

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on winter-run Chinook salmon caused by the actions of the project (Attachments 3 and 4). Nonoperations-related mortality are the base and seasonal mortality that would occur even without the effects of Shasta operations (such as disease, predation, and entrainment). Flow- and water temperature-related mortality is that caused by altering flow and water temperatures. In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 86 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 3 and 4 of the Modeling Appendix). The greatest average mortality to winter-run Chinook salmon under CP1 in all water year types based on smolt equivalents would occur to the fry life stage, followed by eggs, then presmolts, and lastly immature smolts. Table 11-5 displays the overall mortalities for each Comprehensive Plan that were caused by changes in water temperature and flow) (Attachments 3 and 4 of the Modeling Appendix).

Years with the highest flow- and water temperature-related mortality were the same for the No-Action Alternative, the Existing Condition, and CP2. Each of these years was a critical water year, and was preceded by either a critical (1933, 1976, 1991), or dry (1930, 1932) water year type. Years with the lowest mortality varied between all water year types. Years in which the project has the greatest effect on winter-run were also years in which the lowest production occurred (Attachments 3 and 4).

Although winter-run Chinook salmon have, under both 2030 and 2005 conditions, an insignificant change in productivity, there is a decrease in project-related mortality under 2005 conditions (4.4 percent) and an increase in project-related mortality under 2030 conditions (0.9 percent). Additionally, there would not be a significant improvement in production during critical water years. Therefore, the actions taken in CP2 would result in less-than-significant impacts to winter-run Chinook salmon under both 2030 and 2005 conditions. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

The overall 81-year average production for spring-run Chinook salmon under CP2 is insignificantly higher relative to the No-Action Alternative and insignificantly lower than the Existing Condition (Attachments 6 and 7 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 97 percent in a critical water year for CP2, while the largest decrease in production relative to the No-Action Alternative was -17 percent, also in a critical water year (Table 11-20 and Attachment 6 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 375 percent for CP2 and the largest decrease in production was less than -5 percent under CP2 in 1977 (Table 11-20 and Attachment 7 of the Modeling Appendix). Figure 11-10 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP2, five critical, two dry, and one below-normal water years had significant increases in production relative to the No-Action Alternative. Production significantly decreased in five critical water years (between -11 and -17 percent). No other water year type had a significant decrease in production.

Under CP2, nine critical, two dry, and one below-normal water years had significant increases in production relative to the Existing Condition. No water years had significant decrease in production relative to the Existing Condition.

Table 11-20. Change in Production Under CP2 for Spring-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
Future Condition (2030)								
All	81	164,655	601	0.4	97.4	8	-17.4	5
Critical	13	87,341	6,152	7.6	97.4	5	-17.4	5
Dry	17	171,229	1,777	1.0	96.7	2	-1.7	0
Below Normal	14	177,935	754	0.4	21.1	1	-3.8	0
Above Normal	11	182,449	-1,317	-0.7	4.2	0	-2.9	0
Wet	26	184,335	-2,215	-1.2	1.6	0	-3.9	0
Existing Condition (2005)								
All	81	165,357	2,149	1.3	375	12	-4.2	0
Critical	13	89,925	15,863	21.4	151	9	-4.2	0
Dry	17	171,694	2,833	1.7	375	2	-2.4	0
Below Normal	14	178,901	872	0.5	29.6	1	-2.5	0
Above Normal	11	182,404	-1,709	-0.9	3.3	0	-2.8	0
Wet	26	184,424	-2,834	-1.5	1.9	0	-4.2	0

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on spring-run Chinook salmon caused by the actions of the project (Attachments 6 and 7 of the Modeling Appendix). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 83 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 6 and 7 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality to spring-run Chinook salmon under CP2 (as with CP1) in all water year types based on smolt equivalents would occur to eggs, with minimal mortality to the other life stages. Table 11-7 displays the smolt-equivalent mortalities for each Comprehensive Plan that are caused by flow- and water-related factors (also see Attachments 6 and 7 of the Modeling Appendix).

Years with the highest flow- and water temperature-related mortality were the same for the No-Action Alternative, the Existing Condition, and CP2. Except for 1932 (a dry water year), each of these years was a critical water year type and was preceded by either a below, dry, or (predominantly) a critical water year. However, years with the lowest mortality varied between all water year types (Attachments 6 and 7 of the Modeling Appendix).

Under both 2030 and 2005 conditions, spring-run Chinook salmon would experience a significant reduction in flow- and water temperature-related mortality, but an insignificant increase in overall production. However, spring-run would experience a significant increase in production overall for critical water years, especially in years in which the spring-run Chinook salmon could be extirpated from the Sacramento River due to such a low number of fish surviving to pass RBPP. Therefore, spring-run Chinook salmon would benefit from actions taken in CP2. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Overall average fall-run Chinook salmon production for the simulation period was slightly higher for CP2 than for either the No-Action Alternative or Existing Condition (Attachments 9 and 10 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 44 percent for CP2 in a critical water year, while the largest decrease in production relative to the No-Action Alternative was -6 percent, also in a critical water year (Table 11-21 and Attachment 9 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 47 percent for CP2, and the largest decrease in production was around -27 percent under CP2 (Table 11-21 and Attachment 10 of the Modeling Appendix). Figure 11-11 shows the annual change in production relative to the No-Action Alternative for all Comprehensive Plans.

Table 11-21. Change in Production Under CP2 for Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
No-Action Alternative (2030)								
All	81	29,926,852	408,446	1.4	44.0	10	-6.0	1
Critical	13	27,955,633	1,510,805	5.7	44.0	4	-1.4	0
Dry	17	30,244,797	704,637	2.4	18.4	3	-1.7	0
Below Normal	14	31,488,759	390,848	1.3	22.1	2	-4.4	0
Above Normal	11	31,022,573	-10,437	0.0	4.9	0	-3.4	0
Wet	26	29,399,974	-149,702	-0.5	7.2	1	-6.0	1
Existing Condition (2005)								
All	81	29,770,129	341,787	1.2	47.4	10	-26.8	3
Critical	13	27,223,572	1,047,436	4.0	47.4	3	-26.8	1
Dry	17	30,168,009	707,608	2.4	27.5	5	-2.9	0
Below Normal	14	31,401,051	382,789	1.2	36.4	2	-6.0	1
Above Normal	11	30,916,415	46,018	0.1	2.7	0	-2.8	0
Wet	26	29,420,098	-147,172	-0.5	4.3	0	-6.4	1

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Except for 1977, in critical, dry, and below-normal water years, when production was lowest over the simulation period, the increase in production resulting from operations-related activities was greatest. In wet water years, however, the lowest production years typically had a slight decrease in production under CP2 conditions relative to the No-Action Alternative.

Under CP2, four critical, three dry, two below-normal, and one wet water year had significant increases in production relative to the No-Action Alternative. Only one year (1969) out of the 81 simulated years had a significant decrease in production (Table 11-21).

Under CP2, three critical, five dry, and two below-normal water years had significant increases in production relative to the Existing Condition. One critical (1977), one below-normal (1979), and one wet (1969) water years resulted in significantly decreased production relative to the Existing Condition (Table 11-21).

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on fall-run Chinook salmon caused by the actions of the project (Attachments 9 and 10). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 65 percent of the total mortality.

Under both 2030 and 2005 conditions, the greatest mortality to fall-run Chinook salmon under CP2 (as with CP1) in all water year types based on smolt equivalents would occur to fry, then to eggs, prespawn adults, presmolts and then immature smolts. Table 11-9 displays the overall mortalities for each alternative that would be caused by flow and water temperature changes (Attachments 9 and 10 of the Modeling Appendix). Mortalities caused by operations-related activities would be lower for CP2 than for the No-Action Alternative (Table 11-9).

There was no real trend with respect to water year type with the greatest mortality.

Fall-run Chinook salmon have an insignificant increase in production and an insignificant reduction in project-related mortality, but would have a significant increase in production overall during critical water years. However, the fall-run Chinook salmon would benefit from actions taken in CP2. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon

Late fall-run Chinook salmon were evaluated directly using SALMOD and were considered to be a surrogate for steelhead; therefore, the following discussion regarding SALMOD results for late fall-run Chinook salmon are applicable to steelhead.

Production

Overall average late fall-run Chinook salmon production for the 80-year period was similar (less than 5 percent change) for CP2 relative to the No-Action Alternative and the Existing Condition (Attachments 12 and 13 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was almost 9 percent for CP2 in a dry water year, while the greatest decrease in production relative to the No-Action Alternative was -5 percent in a critical water year (Table 11-22 and Attachment 12 of the Modeling Appendix).

The maximum increase in production relative to the Existing Condition was 12 percent for CP2 in 1985. The largest decrease in production relative to the Existing Condition was less than almost -7 percent under CP2 (Table 11-22 and Attachment 13 of the Modeling Appendix). Figure 11-12 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP2, production significantly (greater than 5 percent) increased for two critical and two dry water years, while two critical water years had significant decreases in production relative to the No-Action Alternative.

Table 11-22. Change in Production Under CP2 for Late Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
Future Condition (2030)								
All	80	7,416,831	-1,656	0.0	8.7	3	-5.1	1
Critical	13	7,044,042	-20,127	-0.3	5.9	2	-5.1	1
Dry	16	7,429,076	74,707	1.0	8.7	1	-3.2	0
Below Normal	14	7,588,598	-24,020	-0.3	1.6	0	-3.4	0
Above Normal	11	7,574,775	-11,309	-0.1	3.6	0	-2.6	0
Wet	26	7,436,378	-23,286	-0.3	4.3	0	-2.9	0
Existing Condition (2005)								
All	80	7,445,153	58,592	0.8	12.3	4	-6.6	1

Below Normal	14	7,657,874	46,780	0.6	3.2	0	-2.3	0
Above Normal	11	7,616,470	56,796	0.8	2.6	0	-2.3	0
Wet	26	7,418,665	-1,566	0.0	3.5	0	-6.6	1

Notes:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Late fall-run Chinook salmon are used as a surrogate for steelhead

Under CP2 compared with the Existing Condition, one critical and three dry water years had significant increases in production. One wet water year had a significant (greater than 5 percent) decreases in production.

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on late fall-run Chinook salmon caused by the actions of the project (Attachments 12 and 13). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)–around 78 percent of the total mortality.

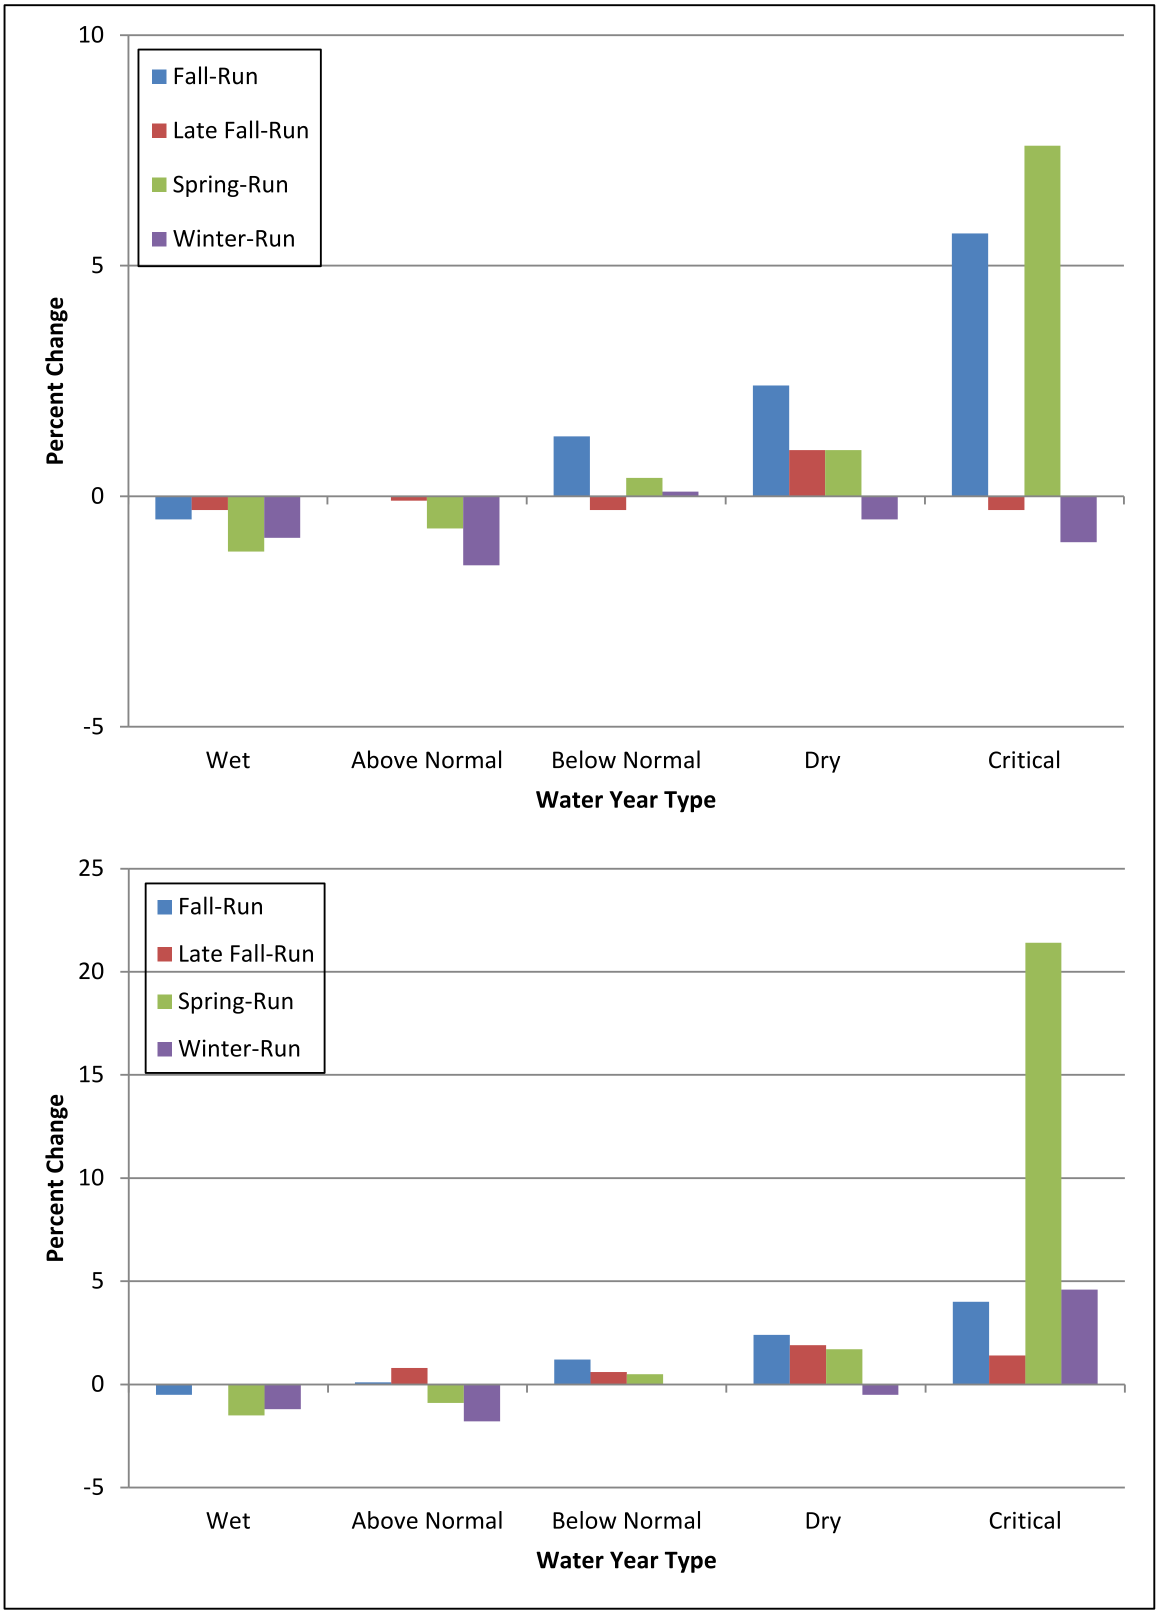
Under both 2030 and 2005 conditions, the greatest mortality to late fall-run Chinook salmon under CP2 (as with CP1) in all water year types based on smolt equivalents would occur to fry, then eggs, presmolts, immature smolts, and lastly to prespawn adults. Table 11-11 displays overall mortalities for each Comprehensive Plan that would be caused by changes in flow and water temperature (see also Attachments 12 and 13 of the Modeling Appendix).

Years with the highest operations-related mortality would be the same for CP2, the No-Action Alternative, and Existing Condition. All water year types were covered. Three years were preceded by a wet water year, and one preceded by an above-normal water year (Attachments 12 and 13 of the Modeling Appendix).

Because SALMOD indicates an insignificant change in mortality and production index for late fall-run Chinook salmon, late fall-run Chinook salmon and steelhead (as represented by late fall-run Chinook salmon as their surrogate) would experience a less-than-significant impact from actions taken in CP2. Mitigation for this impact is not needed, and thus not proposed.

All Chinook Runs Combined

Raising Shasta Dam by 12.5 feet, in conjunction with spillway modifications, would result in an increase in full pool depth of 14.5 feet and an additional 443,000 acre-feet of storage capacity in Shasta Reservoir. The additional storage created by the dam raise would be used to improve the ability to meet water temperature objectives and habitat requirements for anadromous fish during drought years (see Figure 11-21). Under the 2030 conditions, overall production for all four runs of Chinook salmon combined would increase by over 379,000 immature smolts migrating below RDPP. Under the 2005 conditions, overall production for all four runs of Chinook salmon combined would increase by over 398,000 immature smolts migrating below RDPP.



Note: Changes in outmigrating Chinook salmon simulated using SALMOD; Water Year Types based on the Sacramento Valley Water Year Hydrologic Classification

Figure 11-21. Percent Change in Production of Chinook Salmon for CP2 Compared to the No-Action Alternative (top) and Existing Conditions (bottom)

Impact Aqua-13 (CP2): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass Project operation generally would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

This impact would be similar to Impact Aqua-13 (CP1). The impact could be greater under CP2 than under CP1 because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow storage of additional water volume (and flows) behind the raised dam.

Flow-Related Effects As under CP1, monthly mean flows at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBPP) under CP2 would generally be equivalent to (less than 2-percent difference from, with more increases than decreases) flows under the Existing Condition and No-Action Alternative simulated for all months. (See the Modeling Appendix for complete modeling results.)

Potential flow-related effects of CP2 on fish species of management concern in the upper Sacramento River would be minimal. Potential changes in flows and stages would diminish rapidly downstream from RBPP because of increased effects from tributary inflows, diversions, and flood bypasses.

Changes in monthly mean flows under CP2 relative to the Existing Condition and No-Action Alternative would have no discernible effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for these species would be unchanged. Therefore, flow-related impacts on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Water Temperature–Related Effects As under CP1, monthly mean water temperatures at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, Balls Ferry, above Bend Bridge, and above RBPP) under CP2 would be the same as, or fractionally less than, water temperatures under the Existing Condition and No-Action Alternative simulated for all months (Figures 11-22 and 11-23). (See the Modeling Appendix for complete modeling results.)

As discussed above, the modeling simulations may not fully account for real-time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature (i.e., small benefits) are likely conservative and understated to some varying degree. Potential water temperature-related effects of CP2 on fish species of management concern in the upper Sacramento River would be minimal. During most years, releases from Shasta Lake would be unchanged.

The slightly cooler monthly mean water temperatures under CP2 relative to the Existing Condition and the No-Action Alternative would have very small effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Monthly mean water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River. Therefore, water temperature–related impacts on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 vs Existing Condition (2005)

Figure 11-23. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (CP2 Versus No-Action Alternative)

Impact Aqua-14 (CP2): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operations could cause a reduction in the magnitude, duration, and frequency of intermediate to large flows both in the upper Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-14 (CP1). The impact could be greater under CP2 than under CP1 because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, reducing the potential for downcutting. These processes are regulated by the magnitude and frequency of flow. Relatively large floods provide the energy required to mobilize sediment from the riverbed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. Operations under CP2 could result in a reduction in the intermediate to large flows necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains.

Implementation of CP2 would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing effects on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains. These effects would likely occur throughout the upper Sacramento River portion of the primary study area.

Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Lower Sacramento River and Delta

Impact Aqua-15 (CP2): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project

Operation – Fish Species of Primary Management Concern Project operation would result in no discernible change in monthly mean flows or water temperature conditions in the lower Sacramento River. However, predicted changes in flows in the Feather, American, and Trinity rivers could result in adverse effects on Chinook salmon, steelhead, Coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be potentially significant.

This impact would be similar to Impact Aqua-15 (CP1). The impact could be greater under CP2 than under CP1 because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and increased cold-water pool) behind the raised dam.

As described below, mean monthly flows at various modeling locations on the lower Sacramento River and tributaries under CP2 were compared with mean monthly flows simulated for the Existing Condition and No-Action Alternative conditions. See the Modeling Appendix for complete CalSim-II modeling results.

Lower Sacramento River As under CP1, monthly mean flows at the lower Sacramento River modeling locations under CP2 would be comparable to flows under the Existing Condition and No-Action Alternative conditions simulated for all months. Differences in monthly mean flow were generally small (less than 2 percent) and within the existing range of variability. Potential changes in flows would diminish rapidly downstream from RBPP because of increased effects from tributary inflows, diversions, and flood bypasses. Similarly, potential changes in water temperatures in the lower Sacramento River caused by small changes in releases would diminish rapidly downstream because of the increasing effects of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts of CP2 on fish species in the lower Sacramento River would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Also, as under CP1, the effects of altered flow regimes resulting from implementation of CP2 are unlikely to extend into the lower Sacramento River downstream from Verona and into the Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the SWP and the CVP). The operational requirements, including the 2008 USFWS BO and the 2009 NMFS BO, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with these ESA BOs. Thus, implementation of CP2 would not likely alter flow to the Delta or water temperatures in the lower Sacramento River and its primary tributaries to a degree sufficient to affect Chinook salmon, steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and water temperature–related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Feather River, American River, and Trinity River Also, as under CP1, monthly mean flows at modeling locations on the lower Feather River, the American River, and the Trinity River under CP2 would generally be equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for most months. However, simulations for several months within the modeling record show substantial changes to flows in tributaries. Potential changes in flows could be reduced by real-time operations to meet existing rules and because of operation of upstream reservoirs (Lake Oroville, Folsom Lake, and Trinity Lake) and increasing effects from tributary inflows, diversions, and flood bypasses. Potential changes in water temperatures in the Feather River and American River caused by altered releases from reservoirs could diminish downstream because of the increasing effect of inflows, and atmospheric and groundwater influences. Nevertheless, based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts on species of management concern in the American, Feather, and Trinity rivers could occur. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-16 (CP2): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could cause a reduction in intermediate to large flows both in the lower Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-16 (CP1). The impact could be greater under CP2 than under CP1 because the increased reservoir capacity associated with a 12.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flows. Relatively large floods provide the energy required to mobilize sediment from the riverbed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Operations under CP2 could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Implementation of CP2 would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along the upper reaches of the lower Sacramento River.

Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Impact Aqua-17 (CP2): Effects to Delta Fisheries Resulting from Changes to Delta Outflow Based on results of hydrologic modeling comparing Delta outflow under the No-Action Alternative, Existing Condition, and CP2, CP2 would result in changes to average monthly Delta outflow of less than 5 percent in all year types (with the exception of December of critical years under 2005 conditions). This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant.

Results of the comparison of Delta outflows between CP2 and the Existing Condition and No-Action Alternative are summarized by month and water year type in Table 11-23. Delta outflow would increase by greater than 5 percent under CP2 only in December of critical water years. Based on the results of this analysis, CP2 would have a less-than-significant effect on Delta fisheries and hydrologic transport processes within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP2): Effects to Delta Fisheries Resulting from Changes to Delta Inflow Based on the results of hydrologic modeling comparing Delta inflow under CP2 to the Existing Condition and No-Action Alternative, CP2 would not decrease average monthly Delta inflow by 5 percent or more in any year type. This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant.

Results of the comparison of Delta inflows between the No-Action Alternative, Existing Condition, and CP2 are summarized by month and water year type in Table 11-24. Under CP2, Delta inflow would not decrease by more than 5 percent during any month compared to either the Existing Condition or the No-Action Alternative. Based on the results of this comparison, CP2 would have a less-than-significant effect on Delta fisheries and hydrologic transport processes within the Bay-Delta as a consequence of changes in Delta inflow. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP2): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow CP2 operation would result in a variable response in Sacramento River inflow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water year type. Decreases in Sacramento River inflow would not equal or exceed 5 percent. This impact would be less than significant.

Results of hydrologic modeling, by month and water year type, for the Existing Condition, No-Action Alternative, and CP2 for Sacramento River inflow are presented in Table 11-25. Results of these analyses show a variable response in Sacramento River inflow with CP2 operations resulting in both increases and decreases in river inflow above the Existing Condition and the No-Action Alternative, depending on month and water year type. Under CP2, Sacramento River inflow would not decrease by 5 percent or more. Based on these results the impact of CP2 on fish habitat and transport mechanisms within the lower Sacramento River and Delta would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP2): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP2 operation would result in no discernible change in San Joaquin River flows at Vernalis, and therefore no impact to Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta would occur under CP2 relative to the No-Action Alternative or Existing Condition. There would be no impact.

Results of hydrologic modeling, by month and water year type, for the Existing Condition, No-Action Alternative, and CP2 for San Joaquin River flow are summarized in Table 11-26. Results of these analyses show that the proposed CP2 would have no effect on seasonal San Joaquin River flows compared with the Existing Condition and No-Action Alternative. Based on these results CP2 would have no impact on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP2): Reduction in Low-Salinity Habitat Conditions Resulting from an Upstream Shift in X2 Location CP2 operation would result in less than 0.5 km movement upstream or downstream from the X2 location from its location during February through May or September through November under the Existing Condition or No-Action Alternative, and thus cause minimal reduction in low-salinity habitats. This impact would be less than significant.

Results of the comparison of X2 position under the Existing Condition, No-Action Alternative, and CP2 are summarized in Table 11-27. The results showed that changes in X2 location under CP2 as compared with the Existing Condition during February through May and September through November would be less than 1 km (all were less than 0.3 km) with both variable upstream and downstream movement of the X2 location, depending on month and water year type. Changes in X2 location between the No-Action Alternative and CP2 assuming future operating conditions would also be small (less than 0.4 km). These results are consistent with model results for Delta outflow that showed a less-than-significant change in flows. Based on these results, CP2 would have a less-than-significant impact on low-salinity habitat conditions within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP2): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in the Old and Middle Rivers CP2 operation would result in minimal changes to reverse flows in Old and Middle rivers. The increases in reverse flows under CP2 would not be expected to contribute to an increase in the vulnerability of Chinook salmon, delta smelt, longfin smelt striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses because the flows do not exceed (become more negative) -5,000 cfs. This impact would be less than significant.

Results of the analysis showed two occurrences relative to the Existing Condition when reverse flows within Old and Middle rivers would increase by more than 5 percent. Based on results of the delta smelt analysis of the relationship between reverse flows and delta smelt salvage in March, the increased reverse flows from approximately -4,000 cfs to -4,200 cfs in above-normal water years, and around -2,000 to -2,100 in critical water years would not be expected to result in a significant increase in adverse effects to delta smelt (Table 11-28). Additionally, given the tidal volumes and hydrodynamics of the Old and Middle river region, it is not expected that the change in reverse flows in March would result in detectable changes in fish survival, including for Chinook salmon, striped bass, and other anadromous and resident warm-water fishes.

Note:
A positive percentage change reflects more negative reverse flows under CP2 when compared to the Existing Condition or the No-Action Alternative.
Key:
AN = above-normal
BN = below-normal
C = critical
cfs = cubic feet per second
CP = Comprehensive Plan
D = dry
W = wet

Juvenile Chinook salmon and steelhead migrate through the Delta during January, and an increase in average monthly reverse flows of 100 to 200 cfs would be expected to increase the potential risk of increased mortality to these species. However, given the tidal volumes and hydrodynamics of the Old and Middle river region, it is not expected that the change in reverse flows in January in a critical year would result in a detectable change in fish survival. The majority of juvenile Chinook salmon emigrating from the San Joaquin River typically migrate downstream later in dry years and would not be expected to occur in high numbers within Old and Middle rivers in January. Delta smelt would not be significantly affected by the slight increase in reverse flows in January because their presence in the region is minimal during this time. Longfin smelt larvae, however, are present in January, particularly in critical years, however, reverse flows do not exceed (become more negative) -5,000 cfs, and therefore, do not constitute a significant impact to longfin smelt.

Under 2030 conditions, the increase in reverse flows estimated to occur under CP2 in critical water years in May would be 5 percent, but the flows are less than 1,000 cfs. The increased reverse flows in May of critical water years occurred at a time of the year when water temperatures in the Delta were elevated and juvenile Chinook salmon or steelhead could occur in the area in high numbers. However, changes to reverse flows in March and May would not exceed the -5,000 cfs criteria established by the USFWS and NMFS BOs, and would result in less-than-significant impacts to Chinook salmon and steelhead.

Juvenile delta smelt may occur in the area in May; however a change in Old and Middle rivers flow of approximately 100 to 200 cfs may result in a small increase in their vulnerability to CVP and SWP salvage, but this increase is expected to be less than significant. As water temperatures increase in the Delta during May, the majority of delta smelt move towards Suisun Bay where temperatures are more suitable. The increase in reverse flows in May of a critical year would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses as a result of increased reverse flows. The increased reverse flows in low-flow years would be expected to result in a low, but potentially significant, increase in mortality for resident warm-water fish inhabiting the south Delta under CP2.

The potential increase in losses relative to the Existing Conditions during March and No-Action Alternative during January and May is considered to be less than significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species.

Impact Aqua-23 (CP2): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP2 operations may result in an increase in CVP and SWP exports, which is assumed to result in a direct proportional increase in the risk of fish being entrained and salvaged at the facilities. Future operations of the SWP and CVP export facilities would continue to be managed and regulated in accordance with incidental take limits established for each of the protected fish by USFWS, NMFS, and CDFW. The resulting impact to Chinook salmon, steelhead, and longfin smelt would be less than significant; the resulting impact to delta smelt, striped bass, and splittail would be potentially significant. Overall, this impact would be potentially significant.

Results of entrainment loss modeling at the CVP and SWP export facilities are presented in Table 11-29 for CP2. The estimated index of total numbers of fish lost annually, by species, are presented in Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report.* The difference between fish losses under CP2 relative to the No-Action Alternative and the Existing Condition is represented as the entrainment index, shown in Table 11-29, to represent the effect of project operations on each fish species at the CVP and SWP facilities.

Note:
Negative percentage change reflects a reduction in entrainment risk while a positive percentage change reflects an increase in entrainment risk.
Key:
AN = above-normal
BN = below-normal
C = critical
CP = Comprehensive Plan
D = dry
W = wet

Results of the entrainment risk calculations for delta smelt showed a change of less than 1 percent from the Existing Condition in all water years (Table 11-29). The greatest increase in risk (0.9 percent) was estimated for CP2 in a critical year. The entrainment risk for delta smelt relative to the No-Action Alternative would increase in critical years by almost 3 percent (Table 11-29). Although the incremental change in the risk of delta smelt losses resulting from CVP and SWP export operations would be small, the delta smelt population abundance is currently at such critically low levels that even a small increase in the risk of losses is considered to be potentially significant. The increase in risk would also contribute to cumulative factors affecting the survival of delta smelt.

The estimated change in the risk of losses for Chinook salmon under CP2 follows a similar pattern to that described for delta smelt (Table 11-29). Overall, CP2 would result in a small increase in the risk of losses relative to both the Existing Condition and No-Action Alternative. The change in risk under CP2 would not exceed 2 percent in any year type as compared with the Existing Condition and the No-Action Alternative, and is considered to be less than significant. Given the numbers of juvenile Sacramento and San Joaquin river Chinook salmon produced each year in the Central Valley, the relatively small incremental increase in the risk of entrainment/salvage at the CVP and SWP export facilities is considered to be a less-than-significant direct impact but would contribute incrementally to the overall cumulative factors affecting juvenile Chinook salmon survival within the Delta and population dynamics of the stocks.

The estimated change in the risk of longfin smelt entrainment/salvage under CP2 compared with the Existing Condition and No-Action Alternative includes small positive and negative changes depending on water year type (Table 11-29). The increased risk of losses in drier years was considered to be potentially significant. These small changes in the risk of entrainment are considered to be less than significant in most water years, but potentially significant in critically dry years when juvenile longfin smelt production is typically low. The increased losses would also contribute to cumulative factors affecting survival of juvenile longfin smelt within the Delta.

The estimated change in the risk to steelhead of entrainment/salvage at the CVP and SWP export facilities under CP2 are summarized in Table 11-29. The small positive and negative changes in risk under most year types are considered to be less than significant. The increase in risk of steelhead losses in below-normal and critical water years (as compared with the Existing Condition) and in wet water years (as compared with the No-Action Alternative) is considered to be less than significant based on the abundance of juvenile Sacramento and San Joaquin river steelhead migrating through the Delta, but would contribute directly to cumulative factors affecting the survival and population dynamics of Central Valley steelhead. The increased risk of losses in drier years was considered to be potentially significant. The predicted increase in potential entrainment risk for steelhead under wet, below-normal, and critical water years represents an initial estimate of the change (percentage) between CP2 and the Existing Condition and the No-Action Alternative, and does not allow the predicted losses to be evaluated at the population level (see Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report)*. The increased losses would also contribute to cumulative factors affecting survival of juvenile steelhead within the Delta.

The change in risk to juvenile striped bass for entrainment/salvage at the CVP and SWP export facilities is summarized in Table 11-29. The change in risk in all water years is considered to be less than significant for striped bass, but would contribute to the cumulative factors affecting striped bass survival and population dynamics in the Delta. The losses of juvenile striped bass increased substantially under dry and critical year conditions, which would be expected with an increase in exports during the summer months. The increased losses, particularly in drier water years when juvenile striped bass production is lower, would be expected to contribute to the cumulative effects of factors affecting juvenile striped bass survival in the Delta.

Results of the risk estimates for juvenile splittail losses show a pattern similar to other species (Table 11-29). The risk index would increase by less than 3 percent under CP2 compared to the Existing Condition or the No-Action Alternative. Higher risk of entrainment/salvage losses in drier water years has a potentially greater effect on abundance of juvenile splittail since reproductive success and overall juvenile abundance is typically lower within the Delta in dry years. The increased risk of losses in drier years was considered to be potentially significant. The increased losses would also contribute to cumulative factors affecting survival of juvenile splittail within the Delta.

Impact Aqua-23 (CP2) is considered to be less than significant for Chinook salmon, but potentially significant for delta smelt, steelhead, longfin smelt, striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species, and will thus benefit non-listed fishes as well.

CVP/SWP Service Areas

Impact Aqua-24 (CP2): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes CP2 implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects to tributaries and reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams, as well as the conveyances south of the Delta would be substantially less than impacts on the lower Sacramento River. The change in hydrology in the CVP and SWP service areas could affect aquatic habitats for the local resident fish community; however the changes would not result in substantial effects on their distribution or abundance. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-24 (CP1). The hydrologic effects to the CVP and SWP service areas would not result in substantial effects on the distribution or abundance of fish populations. The effects from CP2 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and the resulting flows downstream from those reservoirs would be small and well within range of variability that commonly occurs in these reservoirs and downstream, as described for Impact Aqua-24 (CP1). Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3 focuses on increasing agricultural water supply reliability while also increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 18.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Because CP3 focuses on increasing agricultural water supply reliability, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, with the additional storage retained for water supply reliability and to expand the cold-water pool for downstream anadromous fisheries.

Simulations of CP3 did not involve any changes to the modeling logic for deliveries or flow requirements; all rules for water operations were updated to include the new storage, but were not otherwise changed.

Shasta Lake and Vicinity

Impact Aqua-1 (CP3): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP3, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. CP3 operations would also result in reduced monthly fluctuations in WSEL, which would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. Similar to CP-1, the value of existing structural habitat improvements would be diminished by deeper and longer periods of inundation to varying degrees; however, the existing habitat enhancement features would become functional during reservoir drawdowns later in the season and during below-normal and drier years; however, environmental commitments during construction, which include placing brush in the new inundation varial zone to extend and enhance existing fish habitat structures, would offset this effect (See Chapter 2, "Alternatives," for additional detailed descriptions of the environmental commitments). Additionally, large areas of the shoreline would not be cleared, and the vegetation along these sections would be inundated periodically. In the short term, this newly inundated vegetation will initially increase warm-water fish habitat, with decay expected to occur over several decades. This impact would be less than significant.

This impact would be similar to Impacts Aqua-1 (CP1 and CP2), but the surface area would be larger under the 18.5-foot dam raise than under the 6.5-foot and 12.5-foot dam raises. CalSim-II modeling shows that the surface area of Shasta Lake would be larger under CP3 for both a 2005 and a 2030 water supply demand than under the Existing Condition or the No-Action Alternative in all five water year types (Figures 11-24 and 11-25).

Monthly WSEL fluctuations were compared with projections for water supply demand. For CP3, with a 2005 water supply demand, 52 percent of monthly changes in projected WSELs (i.e., 13 of the 25 total projections made for the 5 months from March through July for all five water year types) showed decreased monthly WSEL fluctuations relative to the Existing Condition and 4 percent showed increased monthly WSEL fluctuations (Figure 11-26). For CP3, with a projected 2030 water supply demand, 52 percent of monthly changes in projected WSELs showed decreased WSEL fluctuations relative to the No-Action Alternative and 4 percent showed increased monthly WSEL fluctuations (Figure 11-27). Under CP3, none of the changes in monthly WSEL fluctuation are different enough from the Existing Condition to warrant the investigation of daily WSEL fluctuation.

Increases in the overall surface area and WSEL under CP3 would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake for a period of time, possibly for several decades. Furthermore, reductions in the magnitude of monthly WSEL fluctuations, along with the environmental commitment to install and extend existing habitat brush piles and structures, could contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water fish species. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-27. Average Monthly Change in Water Surface Elevation for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP3 Versus No-Action Alternative

Impact Aqua-2 (CP3): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction Localized increases in soil erosion and resulting runoff sedimentation, and turbidity resulting from project construction in the vicinity of Shasta Dam and at utility, road, and other facility relocation areas could affect nearshore warm-water habitat. However, the environmental commitments for all action alternatives would result in less-than-significant impacts. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-3 (CP3): Effects on Cold-Water Habitat in Shasta Lake Operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout. This impact would be beneficial.

This impact would be similar to Impacts Aqua-3 (CP1 and CP2). However, it would be of greater magnitude owing to a greater increase in the ratio of the volume of cold-water storage in the lake to the surface area of the lake. CalSim-II modeling shows that under CP3 with a 2030 water supply demand, the ratio of cold-water storage to surface area is higher than under the No-Action Alternative in all water years and during all months modeled. The greatest projected increases over the No-Action Alternative occurred between June 30 and August 31, which is a critical rearing and oversummering period for cold-water fishes in reservoirs, and are greatest in wet, above-normal, and below-normal water years (Figure 11-28).

CP3 would increase the availability of suitable habitat for cold-water fish in Shasta Lake. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-4 (CP3): Effects on Special-Status Aquatic Mollusks Under CP3, habitat for special-status mollusks could be inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could also adversely affect special-status aquatic mollusks that could occupy habitat in or near Shasta Lake and its tributaries. This impact would be similar to Impacts Aqua-4 (CP1 and CP2). However, a larger area would be inundated under CP3, which could result in an increase in impacts to these species and their habitat.

Except for the California floater, the occurrence of special-status mollusks in Shasta Lake and the lower reaches of its tributaries is unlikely. Modification or loss of suitable habitat for California floater would occur through increased WSEL and seasonal fluctuations in the surface area under CP3. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Figure 11-28. Average Monthly Cold-water Storage to Surface Area Ratio for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP3 Versus No-Action Alternative

Impact Aqua-5 (CP3): Effects on Special-Status Fish Species The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat under CP3 could affect one species designated as sensitive by USFS, the hardhead.

This impact would be similar to Impacts Aqua-5 (CP1 and CP2), but its magnitude would be greater owing to an increase in surface area and WSEL and expansion of the area subject to inundation. This impact would be less than significant.

Hardhead do not currently occur or are very uncommon in the primary tributaries to Shasta Lake, except in the Pit River above the Pit 7 Afterbay. Access to and the availability of suitable riverine habitat among all the main tributaries to the reservoir would not likely become any more limiting than under current conditions, nor would it greatly expand. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP3): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP3, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,090-foot contour, the maximum inundation level under this alternative. This impact would be less than significant.

This impact would be similar to Impact Aqua-6 (CP2) (i.e., creation and elimination of fish passage barriers in tributaries to Shasta Lake would primarily be limited to non-fish-bearing intermittent streams). However, the maximum inundation level would be higher under CP3, which would inundate (eliminate) partial or complete fish barriers in approximately 13 more perennial tributaries than CP2.

Similar to CP2, implementation of CP3 could have small localized beneficial effects for adfluvial cold-water fishes and provide access to warm-water fish species, which would primarily be limited to the newly inundated reaches of the new varial zone of some streams. Impacts would not be expected to be much greater than under existing conditions. *Environmental commitments, described in Chapter 2, "Alternatives," to monitor fish communities in Squaw Creek and adaptively manage to prevent warmwater fish invasions would reduce this impact to a less than significant level.* Therefore, this impact is considered to be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP3): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake CP3 would result in additional periodic inundation of potentially suitable spawning and rearing habitat for adfluvial salmonids (trout and land-locked salmon that spawn in streams and rear in lakes) in tributaries to Shasta Lake. It would also affect the character and location of substrate (e.g., spawning gravel) at some locations, influencing the suitability and availability of spawning and rearing habitat for adfluvial salmonids.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils,"CP3 would inundate perennial reaches with gradients of less than 7 percent that could provide spawning and rearing habitat for adfluvial salmonids. The lengths of low-gradient tributaries to each arm of Shasta Lake and estimated suitable spawning habitat areas (both intermittent and perennial) that would be periodically affected are as follows:

- Sacramento Arm – 4.0 miles (19,852 square feet, excludes mainstem river)
- McCloud Arm – 2.7 miles (13,601 square feet)
- Pit Arm – 1.9 miles (615 square feet, excludes mainstem river)
- Big Backbone Arm – 1.1 miles (175 square feet)
- Squaw Arm – 1.3 miles (1,300 square feet)

Eleven miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids (only about 2.8 percent of the low-gradient habitat upstream from Shasta Lake) would be affected by CP3. Although a small proportion of the total stream length would be affected by CP3, approximately 31,093 square feet of suitable cold-water spawning habitat, exclusive of mainstem habitat in the Sacramento and Pit rivers, was estimated to occur within the projected varial zone under CP3 during 2012 stream surveys.

This impact would be similar to Impacts Aqua-7 (CP1 and CP2); however, an additional 8,565 square feet (a total of 39,763 square feet) of suitable spawning habitat in low-gradient reaches to Shasta Lake would periodically be inundated. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-8 (CP3): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP3 would result in periodic inundation of the lower reaches of high-gradient, intermittent non-fish-bearing tributaries to Shasta Lake. Twenty-four miles of non-fish-bearing tributary habitat (based on channel slope and confirmed by surveys of representative stream reaches) would be affected by CP3, which is only about 1 percent of the total length of non-fish-bearing tributaries upstream from Shasta Lake. Field surveys suggest that few, if any of the non-fish bearing streams contain special-status invertebrate or vertebrate species that would be affected by increased connectivity to Shasta Lake. This impact would be less than significant.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils," CP3 would inundate tributary segments with channel slopes in excess of 7 percent. Although these segments do not typically support salmonid populations, they do provide riparian and aquatic habitat for a variety of organisms and serve as corridors that connect habitat types. The lengths of non-fish-bearing tributaries for each arm of Shasta Lake that would be periodically inundated are as follows:

- Sacramento Arm – 5.5 miles
- McCloud Arm – 4.1 miles
- Pit Arm – 3.5 miles
- Big Backbone Arm – 2.7 miles
- Squaw Arm – 1.9 miles
- Main Body – 6.3 miles

This impact would be similar to Impacts Aqua-8 (CP1 and CP2). It would periodically inundate a larger amount of habitat than under CP1 and CP2, but the total amount inundated would be only 1 percent of the intermittent non-fish-bearing tributary habitat (based on channel slope) upstream from the lake. No special-status aquatic vertebrate or invertebrate species have been detected in these reaches. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP3): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP3. There would be no impact.

This impact is the same as Impact Aqua-9 (CP1), and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Aqua-10 (CP3): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River during Construction Activities Temporary construction-related increases in sediments and turbidity levels would adversely affect aquatic habitats and fish populations immediately downstream in the upper Sacramento River. However, environmental commitments would be in place to reduce the effects. This impact would be less than significant.

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater under CP3 than under CP1 because of the increased activity associated with an 18.5-foot dam raise compared to a 6.5-foot dam raise. However, as under CP1, environmental commitments for all actions would be in place to reduce the effects. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-11 (CP3): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants. Such exposure could adversely affect aquatic habitats, the aquatic food web, and fish populations, including special-status species, downstream in the primary study area. However, environmental commitments would be in place to reduce the effects. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater under CP3 than under CP1 because of the increased activity associated with an 18.5-foot raise compared to a 6.5-foot raise. However, as under CP1, environmental commitments for all actions would be in place to reduce the effects. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-12 (CP3): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon and Steelhead CP3 operation would result in improved overall flow and water temperature conditions in the upper Sacramento River for Chinook salmon and steelhead as well as other native fishes. This impact would be beneficial.

Winter-Run Chinook Salmon

Production

Overall average winter-run production for the 82-year period would be similar (less than 5 percent change) for CP3 relative to the No-Action Alternative and the Existing Condition (Attachments 3 and 4 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 121 percent for CP3, and the largest decrease in production relative to the No-Action Alternative was -14 percent (Table 11-30 and Attachment 3 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 191 percent for CP3, and the largest decrease in production relative to the Existing Condition was -7 percent (Table 11-30 and Attachment 4 of the Modeling Appendix). Figure 11-9 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP3, two critical and one dry water year had significant increases in production compared to the No-Action Alternative, while two critical and one above-normal water years had a significantly decreased production.

Table 11-30. Change in Production Under CP3 for Winter-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease

Key:

CP = Comprehensive Plan

Under CP3, five out of 13 critical and one out of 17 dry water years had significant increases in production, compared to the Existing Condition. One above-normal (out of 11 years) and one wet (out of 26 years) water year had significant decreases in production.

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on winter-run Chinook salmon caused by the actions of the project (Attachments 3 and 4 of the Modeling Appendix). Nonoperations-related mortality is the base and seasonal mortality that would occur even without the effects of Shasta operations (such as disease, predation, and entrainment). Flow- and water temperature-related mortality is that caused by altering flow and water temperatures. In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 87 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 3 and 4 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality to winter-run Chinook salmon under CP3 (as with CP1 and CP2) in all water year types, based on smolt equivalents, would occur to fry, then eggs, presmolts, immature smolts, and prespawn adults. Table 11-5 displays the overall mortalities for each Comprehensive Plan that would be caused by changes in water temperature and flow (see also Attachments 3 and 4 of the Modeling Appendix).

Years with the highest mortality were the same for the No-Action Alternative and CP3. Each of these years was a critical water year, and was preceded by either a critical (1933, 1976, 1991) or dry (1930 and 1932) water year type (Attachments 3 and 4).

Winter-run Chinook salmon would have, overall, an insignificant change in project-related mortality relative to No-Action Alternative, but significant compared with the Existing Condition. They would also have an insignificant change in production (including in critical water years), winter-run Chinook salmon would have a less-than-significant impact from actions taken in CP3. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Overall average spring-run Chinook salmon production for the 81-year period remained relatively similar (less than 5 percent change) to the No-Action Alternative and Existing Condition. The maximum increase in production relative to the No-Action Alternative was 123 percent for CP3 in a dry water year, while the largest decrease in production was almost 44 percent in a critical water year (Table 11-31 and Attachment 6 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 602 percent for CP3. The largest decrease in production relative to the Existing

Condition was 9 percent for CP3 (Table 11-31 and Attachment 7 of the Modeling Appendix). Figure 11-10 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP3, five critical, one dry, and one below-normal water years had significant increases in production compared to the No-Action Alternative, while two critical water years had significant decreases in production (Attachment 6 of the Modeling Appendix).

Under CP3, eight critical, one dry, and one below-normal water years had significant increases in production compared to the Existing Condition. Only one critical water year had a significant decrease in production (Attachment 7 of the Modeling Appendix).

Key:
CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on spring-run Chinook salmon caused by the actions of the project (Attachments 6 and 7). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−about 83 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 6 and 7 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality to spring-run Chinook salmon under CP3 (as with CP1 and CP2) in all water year types based on smolt equivalents, would occur to the eggs, then fry, followed by presmolts and lastly immature smolts. Nonoperational conditions would be the primary causes of mortality for all life stages under all Comprehensive Plans. Table 11-7 displays the smolt-equivalent mortalities for each Comprehensive Plan changes in water temperature and flow (Attachments 6 and 7 of the Modeling Appendix).

Years with the highest operations-related mortality were the same CP3, No-Action Alternative and the Existing Condition. These were each preceded by a critical or dry water year. However, years with the lowest mortality varied between all water year types (Attachments 6 and 7).

Because spring-run Chinook salmon have, overall, a significant reduction in project-related mortality under both 2030 and 2005 conditions, but insignificant increase in overall production. However, spring-run Chinook salmon would have a significant increase in production during critical water years–those years in which they are at greatest risk. Therefore, spring-run Chinook salmon would benefit from actions taken in CP3. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Overall average fall-run Chinook salmon production for the 81-year period was similar between CP3 and the No-Action Alternative and the Existing Condition (Attachments 9 and 10 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 41 percent (below-normal water year) for CP3, while the largest decrease in production relative to the No-Action Alternative was around -14 percent (in a critical water year) (Table 11-32 and Attachment 9 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was just around 144 percent for CP3 in a critical water year, and the largest decrease in production relative to the Existing Condition was –less than 7 percent in a wet water year (Table 11-32 and Attachment 10 of the Modeling Appendix). Figure 11-11 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Table 11-32. Change in Production Under CP3 for Fall-Run Chinook Salmon

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Key:

CP = Comprehensive Plan

In critical, dry, and below-normal water years, when production was lowest over the simulation period, the increase in production resulting from operations-related activities was greatest. In above-normal and wet water years, however, the lowest production years typically had a slight decrease in production under CP1 conditions relative to the No-Action Alternative (Attachments 9 and 10 of the Modeling Appendix).

Under CP3, five critical, five dry, and two below-normal water years had significant increases in production relative to the No-Action Alternative. Significant decreases in production occurred in one critical, one below-normal, and one wet water year (Attachment 9 of the Modeling Appendix).

Under CP3, six critical, four dry, two below-normal, and one wet water year had significant increases in production relative to the Existing Condition. Significant reductions in production occurred in one below-normal, and two wet water years (Attachment 10 of the Modeling Appendix).

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on fall-run Chinook salmon caused by the actions of the project (Attachments 9 and 10). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 65 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 9 and 10 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality based on the smolt equivalents to fall-run Chinook salmon under CP3 (as with CP1 and CP2) occurs to fry, followed by egg, prespawn adults, presmolts, and lastly to immature smolts. Table 11-9 displays the overall mortalities for each Comprehensive Plan that were caused by changes in water temperature and flow (see also Attachments 9 and 10 of the Modeling Appendix).

There was no real trend with respect to years with the greatest mortality. Years with the lowest production were in all water years except above-normal water years, and were preceded by all water year types.

Fall-run Chinook salmon have a significant reduction in project-related mortality under CP3 but an insignificant increase in average production. However, fall-run Chinook salmon would benefit from actions taken in CP3, experiencing a significant increase in 15 percent of the years. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon and Steelhead

Late fall-run Chinook salmon were evaluated directly using SALMOD and were considered to be a surrogate for steelhead; therefore, the following discussion regarding SALMOD results for late fall-run Chinook salmon are applicable to steelhead.

Production
Overall average late fall-run Chinook salmon production for the 80-year period was similar to CP3 and the No-Action Alternative and the Existing Condition (Attachments 12 and 13 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 12 percent in a dry water year for CP3, while the largest decrease in production relative to the No-Action Alternative was less than 5 percent for CP3 (Table 11-33 and Attachment 12 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was almost 13 percent for CP3 (in a dry water year), while the largest decrease in production relative to the Existing Condition was less than -5 percent (Table 11-33 and Attachment 13 of the Modeling Appendix). Figure 11-12 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP3, one critical and two dry water years had significant increases in production compared to the No-Action Alternative, and there were no significant decreases in production.

Table 11-33. Change in Production Under CP3 for Late Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
Future Condition (2030)								
All	80	7,424,900	6,413	0.1	12.1	3	-4.9	0
Critical	13	7,107,373	43,205	0.6	7.5	1	-2.9	0
Dry	16	7,390,273	35,904	0.5	12.1	2	-4.9	0
Below Normal	14	7,599,738	-12,880	-0.2	2.4	0	-3.2	0
Above Normal	11	7,583,369	-2,715	0.0	1.7	0	-3.0	0
Wet	26	7,443,783	-15,881	-0.2	4.4	0	-3.9	0
Existing Condition (2005)								
All	80	7,422,929	36,368	0.5	12.9	5	-4.7	0
Critical	13	7,054,205	90,909	1.3	12.2	2	-3.4	0

Below Normal	14	7,632,250	21,156	0.3	3.3	0	-2.6	0
Above Normal	11	7,593,708	34,035	0.5	2.6	0	-1.2	0
Wet	26	7,437,163	16,932	0.2	3.5	0	-4.0	0

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Late fall-run Chinook salmon are used as a surrogate for steelhead

Key:

CP = Comprehensive Plan

Under CP3, two critical and three dry water years had significant increases in production compared to the Existing Condition, and there were no significant decreases in production.

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on late fall-run Chinook salmon caused by the actions of the project (Attachments 12 and 13 of the Modeling Appendix). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 78 percent of the total mortality.

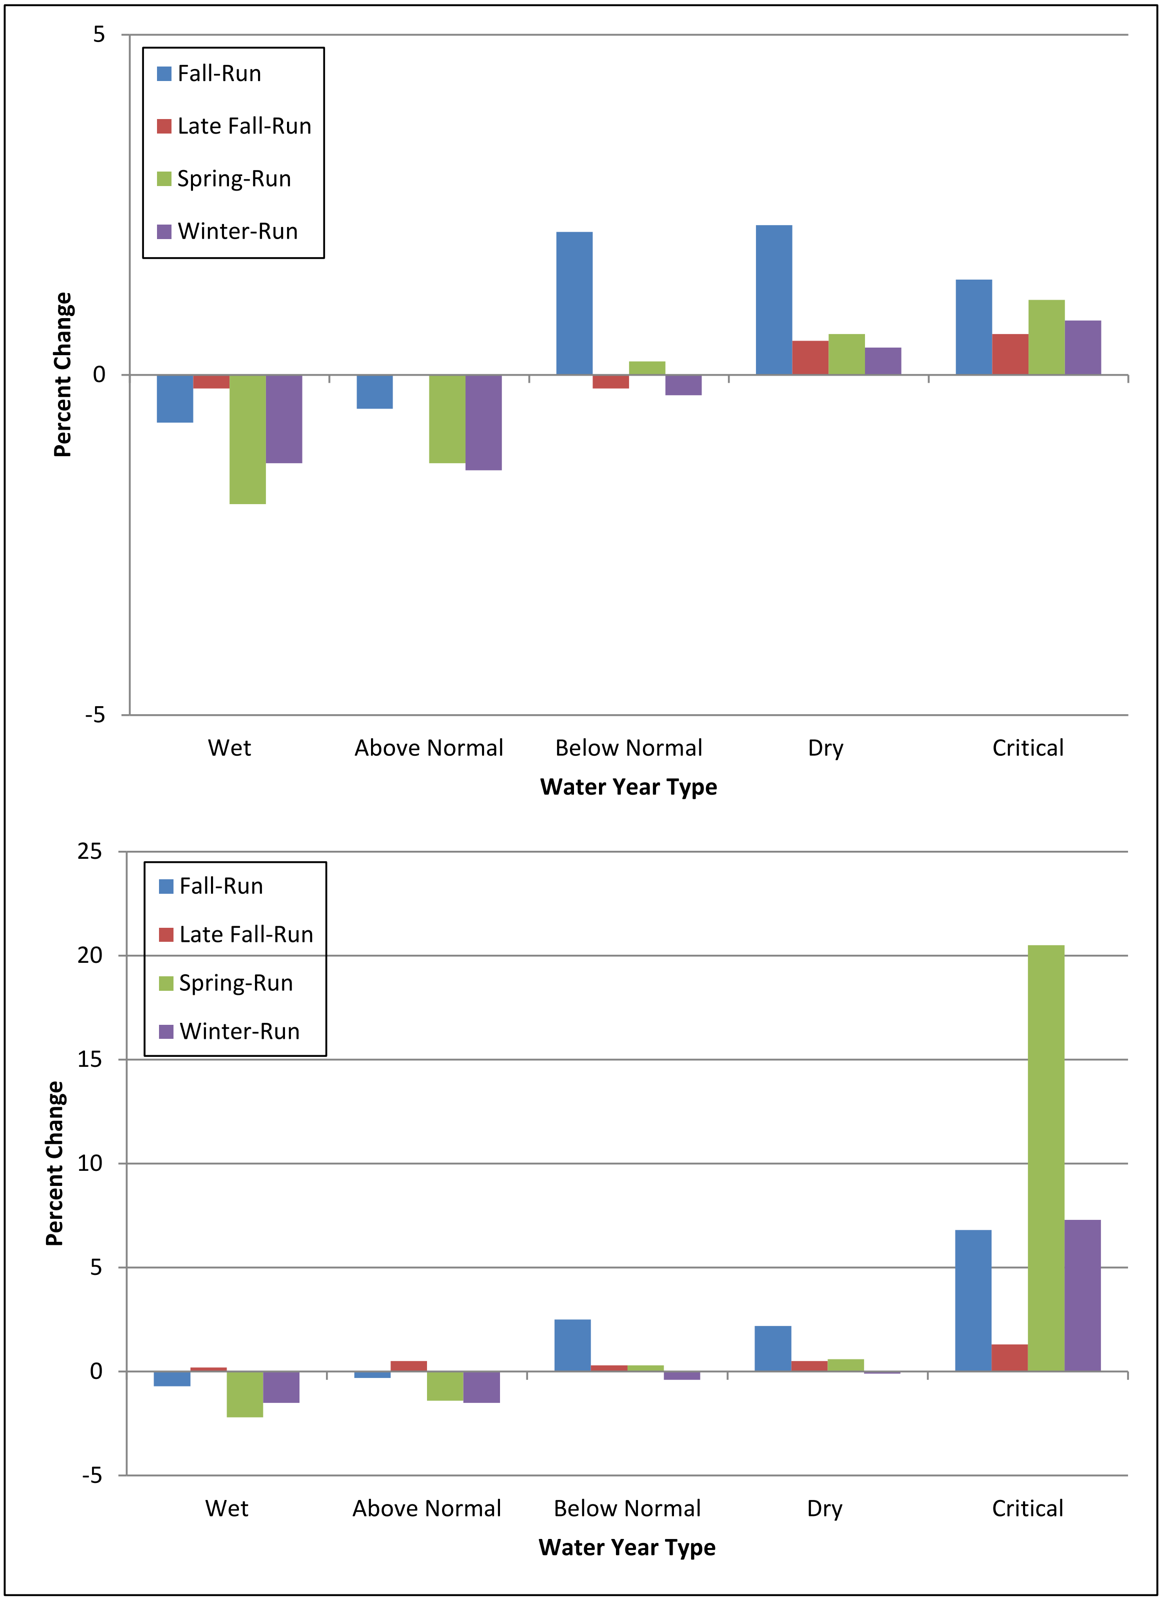
Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 12 and 13 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality to late fall-run under CP3 (as with CP1 and CP2) in all water year types based on smolt equivalents, would occur to fry, then eggs, presmolts, immature smolts, and lastly to prespawn adults. Table 11-11 displays the overall mortalities for each Comprehensive Plan that were caused by changes in water temperature and flow) (Attachments 12 and 13 of the Modeling Appendix).

Years with the highest mortality were the same for CP3, the No-Action Alternative and Existing Conditions. All water year types were covered. Two years were preceded by a wet water year, one preceded by an above-normal water year, and two by a below-normal water year (Attachments 12 and 13 of the Modeling Appendix).

Because SALMOD indicates an insignificant change in mortality and production index for late fall-run Chinook salmon, late fall-run Chinook salmon and steelhead (as represented by their surrogate, late fall-run Chinook salmon) would experience a less-than-significant impact from actions taken in CP3. Mitigation for this impact is not needed, and thus not proposed.

All Chinook Runs Combined

Raising Shasta Dam by 18.5 feet, in conjunction with spillway modifications, would result in an increase in full pool depth of 20.5 feet and an additional 634,000 acre-feet of storage capacity in Shasta Reservoir. The additional storage created by the dam raise would be used to improve the ability to meet water temperature objectives and habitat requirements for anadromous fish during drought years (see Figure 11-29). Under the 2030 conditions, overall production for all four runs of Chinook salmon combined would increase by over 207,000 immature smolts migrating below RDPP. Under the 2005 conditions, overall production for all four runs of Chinook salmon combined would increase by almost 522,000 immature smolts migrating below RDPP.



Note: Changes in outmigrating Chinook salmon simulated using SALMOD; Water Year Types based on the Sacramento Valley Water Year Hydrologic Classification

Figure 11-29. Percent Change in Production of Chinook Salmon for CP3 Compared to the No-Action Alternative (top) and Existing Conditions (bottom)

Impact Aqua-13 (CP3): Changes in Flow and Water Temperatures in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass CP3 operation generally would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

This impact would be similar to Impact Aqua-13 (CP1). The impact could be greater under CP3 than under CP1 because of the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise.

Flow-Related Effects As under CP1, monthly mean flows at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBPP) under CP3 would generally be equivalent to (less than 5-percent difference from) flows under the Existing Condition and No-Action Alternative conditions simulated for all months. (See the Modeling Appendix for complete modeling results.)

Potential flow-related effects of CP3 on fish species of management concern in the upper Sacramento River would be minimal. Potential changes in flows and stages would diminish rapidly downstream from RBPP because of increased effects from tributary inflows, diversions, and flood bypasses.

Changes in monthly mean flows under CP3 relative to the Existing Condition and No-Action Alternative would have no discernible effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for these species would be unchanged. Flow-related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Water Temperature–Related Effects As under CP1, monthly mean water temperatures at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, Balls Ferry, above Bend Bridge, and above RBPP) under CP3 would be the same as, or fractionally lower than, water temperatures under the Existing Condition and No-Action Alternative simulated for all months (Figures 11-30 and 11-31). See the Modeling Appendix for complete modeling results.

As discussed above, the modeling simulations may not fully account for real time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature (i.e., small benefits) are likely conservative and understated to some degree. Potential water temperature–related effects of CP3 on fish species of management concern in the upper Sacramento River would be minimal. During most years, annual releases from Shasta Dam would be unchanged.

Potential changes in flows and stages would diminish downstream from RBPP because of the increasing effect from tributary inflows, diversions, and flood bypasses.

The slightly cooler monthly mean water temperatures under CP3 relative to the Existing Condition and the No-Action Alternative would have very small effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Monthly mean water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River. Therefore, water temperature–related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-31. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (CP3 Versus No-Action Alternative)

Impact Aqua-14 (CP3): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operations could cause a reduction in the magnitude, duration, and frequency of intermediate to large flows both in the upper Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-14 (CP1). The impact could be greater under CP3 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, reducing the potential for downcutting. These processes are regulated by the magnitude and frequency of flow. Relatively large flows provide the energy required to mobilize sediment from the riverbed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. Operations under CP3 could result in a reduction in the intermediate to large flows necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Implementation of CP3 would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing effects on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These effects would likely occur throughout the upper Sacramento River portion of the primary study area.

Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Lower Sacramento River and Delta

Impact Aqua-15 (CP3): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern Project operation would result in no discernible change in monthly mean flows or water temperature conditions in the lower Sacramento River. However, predicted changes in flows in the Feather, American, and Trinity rivers could result in adverse effects on Chinook salmon, steelhead, Coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be potentially significant.

This impact would be similar to Impact Aqua-15 (CP1). The impact could be greater under CP3 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and increased cold-water pool) behind the raised dam.

As described below, mean monthly flows at various modeling locations on the lower Sacramento River and tributaries under CP3 were compared with mean monthly flows simulated for Existing Conditions and No-Action Alternative conditions. See the Modeling Appendix for complete CalSim-II modeling results.

Lower Sacramento River As under CP1, monthly mean flows at the lower Sacramento River modeling locations under CP3 would be comparable to flows under the Existing Condition and No-Action Alternative conditions simulated for all months. Differences in monthly mean flow were generally small (less than 2 percent) and within the existing range of variability. Potential changes in flows diminished rapidly downstream from RBPP because of the increasing effect from tributary inflows, diversions, and flood bypasses. Similarly, potential changes in water temperatures in the lower Sacramento River caused by small changes in releases would diminish rapidly downstream because of the increasing effect of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts on fish species in the lower Sacramento River would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Also, as under CP1, the effects of altered flow regimes resulting from implementation of CP3 are unlikely to extend into the lower Sacramento River and Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the SWP and the CVP). The operational requirements, including the USFWS BO and the 2009 NMFS BO, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with these ESA BOs. Thus, implementation of CP3 would not likely alter flow to the Delta or water temperatures in the lower Sacramento River and its primary tributaries to a degree sufficient to affect Chinook salmon, steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and water temperature–related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Feather River, American River, and Trinity River Also, as under CP1, monthly mean flows at modeling locations on the lower Feather River, the American River, and the Trinity River under CP3 would generally be equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for most months. However, simulations for several months within the modeling record showed substantial changes to flows in tributaries. Potential changes in flows could be reduced by real-time operations to meet existing rules and because of operation of upstream reservoirs (Lake Oroville, Folsom Lake, and Trinity Lake) and increasing effects from tributary inflows, diversions, and flood bypasses. Potential changes in water temperatures in the Feather River and American River caused by altered releases from reservoirs could diminish downstream because of the increasing effect of inflows, and atmospheric and groundwater influences. Nevertheless, based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts on species of management concern in the American, Feather, and Trinity rivers could occur. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-16 (CP3): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could cause a reduction in intermediate to large flows both in the lower Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-16 (CP1). The impact could be greater under CP3 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flows. Relatively large floods provide the energy required to mobilize sediment from the riverbed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Operations under CP3 could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains.

Implementation of CP3 would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along upper reaches of the lower Sacramento River (mostly upstream from RBPP).

Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-17 (CP3): Effects to Delta Fisheries Resulting from Changes to Delta Outflow Based on the results of hydrologic modeling comparing Delta outflow under the No-Action Alternative, Existing Condition, and CP3, CP3 would result in changes to average monthly Delta outflow of less than 5 percent in all year types (with the exception of November of above-normal water years under 2005 and 2030 conditions). This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant.

Results of the comparison of Delta outflows under CP3 compared with the Existing Condition and No-Action Alternative are summarized by month and water year type in Table 11-34. Only in November of above-normal water years (compared to the Existing Condition and No-Action Alternative) would changes in Delta outflow exceed 5 percent. Based on the results of this comparison, CP3 would have a less-than-significant impact on Delta fisheries and hydrologic transport processes within the Bay-Delta as a consequence of changes in Delta outflow under existing conditions. Mitigation for this impact is not needed, and thus not proposed.

Table 11-34. Delta Outflow Under Existing Conditions, No-Action Alternative, and CP3

Impact Aqua-18 (CP3): Effects to Delta Fisheries Resulting from Changes to Delta Inflow Based on the results of hydrologic modeling comparing Delta inflow under CP3 to the Existing Condition and No-Action Alternative, CP3 would not decrease average monthly Delta inflow by 5 percent or more in any year type. This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant.

Results of the comparison of Delta inflows between the Existing Condition, No-Action Alternative, and CP3 are summarized by month and water year type in Table 11-35. Under CP3, Delta inflow would not decrease by more than 5 percent during any month compared to either the Existing Condition or the No-Action Alternative. Based on the results of this comparison, CP3 would have a less-than-significant effect on Delta fisheries and hydrologic transport processes within the Bay-Delta as a consequence of changes in Delta inflow. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP3): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow CP3 operation would result in a variable response in Sacramento River inflow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water year type. Decreases in Sacramento River inflow would not equal or exceed 5 percent. This impact would be less than significant.

Results of hydrologic modeling, by month and year type, for the Existing Condition, No-Action Alternative, and CP3 for Sacramento River inflow are presented in Table 11-36. Results of these analyses show a variable response in Sacramento River inflow with CP3 operations resulting in both increases and decreases in river inflow above the Existing Condition and the No-Action Alternative, depending on month and water year. Under CP3, Sacramento River inflow would not decrease by 5 percent or more. Based on these results, the impact of CP3 on fish habitat and transport mechanisms within the lower Sacramento River and Delta would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 11-36. Sacramento River Inflow Under Existing Conditions, No-Action Alternative, and CP3

		Existing Condition	CP3 (2005)		No-Action Alternative	CP3 (2030)

Impact Aqua-20 (CP3): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP3 operation would result in no discernible change in San Joaquin River flows at Vernalis, and therefore no effects on fish habitat or transport mechanisms within the lower San Joaquin River and Delta compared with the Existing Condition and No-Action Alternative. There would be no impact.

Results of hydrologic modeling, by month and water year type, for the Existing Condition, No-Action Alternative, and CP3 for San Joaquin River flow are summarized in Table 11-37. Results of these analyses show that CP3 would have no effect on seasonal San Joaquin River flows compared with the Existing Condition and No-Action Alternative. Based on these results CP3 would have no impact on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP3): Reduction in Low-Salinity Habitat Conditions Resulting from an Upstream Shift in X2 Location CP3 operation would result in less than 0.5 km movement upstream or downstream from the X2 location from its location under the Existing Condition or No-Action Alternative during February through May and September through November, and thus cause minimal reduction in low-salinity habitats. This impact would be less than significant.

The 1 km X2 criterion was applied to a comparison of hydrologic model results for the Existing Condition, No-Action Alternative, and CP3, by month and water year type, for the months from February through May and September through November. Results of the comparisons are summarized in Table 11-38. These results showed that changes in X2 location under CP3 were less than 1 km (all were less than 0.2 km) with both variable upstream and downstream movement of the X2 location depending on month and water year type. These results are consistent with model results for Delta outflow that showed a less-than-significant change in flows. Based on these results, CP3 would have a less-than-significant impact on low-salinity habitat conditions within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP3): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers CP3 operation would result in minimal changes to reverse flows in Old and Middle rivers during January, March and April; however, flows do not exceed (become more negative) -5,000 cfs. Because the flows do not exceed -5,000 cfs, the increases in reverse flows are not expected to contribute to an increase in the vulnerability of delta smelt, longfin smelt, Chinook salmon, juvenile striped bass, or threadfin shad, but summer Old and Middle river flows could contribute to an increase in vulnerability of other resident warm-water fish to increased salvage and potential losses. This impact would be less than significant.

Results of the analysis showed several occurrences when reverse flows within Old and Middle rivers would be higher than under the Existing Condition or No-Action Alternative by more than 5 percent. These events would occur in critical, dry, and above-normal water years, which would be expected as a result of greater export operations under CP3.

During January (Table 11-39), operations under CP3 would result in an increase in reverse flow of greater than 5 percent during critical years compared with both Existing Conditions and the No-Action Alternative. Based on results of the delta smelt analysis of the relationship between reverse flows and delta smelt salvage, the increase of approximately 200 cfs in a critical water year would not be expected to result in a significant increase in adverse effects to delta smelt because their presence in the region is minimal during this time. Longfin smelt, however, are likely in the area during dry water years, but the flows do not exceed -5,000 cfs, so longfin smelt are not expected to experience significant impacts.

D = dry
W = wet

Juvenile Chinook salmon and steelhead are migrating through the Delta during January, and an increase in average monthly reverse flows of around 200 cfs would be expected to increase the potential risk of increased mortality to these species. However, given the tidal volumes and hydrodynamics of the Old and Middle rivers region, it is not expected that the change in reverse flows in January in a critical year would result in a detectable change in fish survival. The majority of juvenile Chinook salmon emigrating from the San Joaquin River typically migrate downstream later in dry years and would not be expected to occur in high numbers within Old and Middle rivers in January.

The increase in reverse flows estimated to occur under CP3 in above-normal water years in March (under 2005 conditions) and in dry water years in April (under 2030 conditions) would exceed 5 percent. Juvenile and larval delta smelt occur in the area in March and April. A change in Old and Middle river flows of approximately 100 to 200 cfs does not increase the flows to beyond -5,000 cfs.

The potential increase in losses during January, March and April under CP3 is considered to be less than significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species, which would thus reduce impacts to non-listed species as well.

Impact Aqua-23 (CP3): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP3 operations may result in an increase in CVP and SWP exports, which is assumed to result in a direct proportional increase in the risk of fish being entrained and salvaged at the facilities. Future operations of the SWP and CVP export facilities would continue to be managed and regulated in accordance with incidental take limits established for each of the protected fish by USFWS, NMFS, and CDFW. The resulting impact to Chinook salmon would be less than significant; the resulting impact to delta smelt, longfin smelt, steelhead, striped bass, and splittail would be potentially significant. Overall, this impact would be potentially significant.

Results of entrainment loss modeling at the CVP and SWP export facilities are presented in Table 11-40 for CP3. The total numbers of fish lost annually, by species, are presented in Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report.* The difference between the nonoperations-related and operations-related fish mortality is represented as the entrainment index, shown in Table 11-40, to represent the effect of project operations on each fish species at the CVP and SWP facilities.

Table 11-40. Indices of Entrainment at the CVP and SWP Facilities Comparing Existing Conditions, No-Action Alternative, and CP3

Note: A negative percentage change reflects a reduction in entrainment risk while a positive percentage change reflects an increase in entrainment risk.

Key:
AN = above-normal
BN = below-normal
C = critical
cfs = cubic feet per second
CP = Comprehensive Plan
CVP = Central Valley Project
D = dry
SWP = State Water Project
W = wet

Results of entrainment risk calculations for delta smelt showed a change of less than 1 percent in wet, above-normal, and below-normal water years and an increase in risk of less than 3 percent during critical water years under CP3 relative to the Existing Condition (Table 11-40). The risk of increased losses of delta smelt under CP3 compared to the No-Action Alternative (Table 11-40) would be greatest in the below-normal water years. Although the incremental change in the risk of delta smelt losses resulting from CVP and SWP export operations is small, delta smelt population abundance is currently at such critically low levels that even a small increase in the risk of losses is considered to be potentially significant. The increase in risk is also expected to contribute to cumulative factors affecting the survival of delta smelt.

The estimated change in the risk of losses for Chinook salmon increases during below-normal and critical water years under 2005 conditions, and above-normal and below-normal water years under 2030 conditions (Table 11-40). Given the numbers of juvenile Sacramento River Chinook salmon produced each year in the Central Valley, the relatively small incremental increase in the risk of entrainment/salvage at the CVP and SWP export facilities would be a less-than-significant direct impact but would contribute incrementally to the overall cumulative factors affecting juvenile Chinook salmon survival within the Delta, and population dynamics of the stocks.

The estimated change in the risk of longfin smelt entrainment/salvage under CP3 compared to the Existing Condition and the No-Action Alternative shows small positive and negative changes depending on water year type and alternative (Table 11-40). These small changes in the risk of entrainment are considered to be less than significant.

The estimated change in the risk to steelhead of entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-40. The small positive and negative changes in risk under wet, above-normal, below-normal, and dry water years are considered to be less than significant. The increase (approximately 2 percent) in risk of steelhead losses in critical water years are considered to be potentially significant based on the apparently low abundance of juvenile Sacramento and San Joaquin river steelhead migrating through the Delta, but would contribute directly to cumulative factors affecting the survival and population dynamics of Central Valley steelhead. The predicted increase in potential entrainment risk for steelhead under critical water years represents an initial estimate of the change (percentage) between CP3 and Existing Conditions and the No-Action Alternative, and does not allow the predicted losses to be evaluated at the population level (see Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report).*

The change in risk to juvenile striped bass for entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-40. The change in risk in wet, above-normal, and below-normal water years are considered to be less than significant based on the abundance of striped bass, but would contribute to the cumulative factors affecting striped bass survival and population dynamics in the Delta. The losses of juvenile striped bass increased substantially under dry and critical water years, which would be expected with an increase in exports during the summer months and is considered to be potentially significant. The increased losses under CP3, particularly in drier water years when juvenile striped bass production is lower, would be expected to contribute to the cumulative effects of factors affecting juvenile striped bass survival in the Delta.

The increased risk index for splittail was less than 1 percent under both the Existing Condition and No-Action Alternative, and was considered to be less than significant. The loss index increased during dry and critical water years, with the greatest increase for CP3. Higher risk of entrainment/salvage losses in drier water years has a potentially greater effect of abundance of juvenile splittail since reproductive success and overall juvenile abundance is typically lower within the Delta in dry years. The increased risk of losses in drier years was considered to be potentially significant. The increased losses would also contribute to cumulative factors affecting survival of juvenile splittail within the Delta.

Impact Aqua-23 (CP3) is considered to be less than significant for Chinook salmon, and longfin smelt, but potentially significant for delta smelt, steelhead, striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species, and thus, reduce impacts to non-listed fishes as well.

CVP/SWP Service Areas

Impact Aqua-24 (CP3): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes   Project implementation would result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects to tributaries and reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams, as well as the conveyances south of the Delta would be substantially less than impacts on the lower Sacramento River. The change in hydrology in the CVP and SWP service areas could affect aquatic habitats that provide habitat for the fish community; however, these changes would not result in substantial effects on their distribution or abundance. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-24 (CP1). The hydrologic effects to the CVP and SWP service areas would not result in substantial effects on the distribution or abundance of the fish species in the CVP and SWP service areas. The effects from CP3 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and resulting flows downstream from those reservoirs, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 and CP4A focus on increasing anadromous fish survival while also increasing water supply reliability. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP4 and CP4A would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. The additional storage created by the 18.5-foot dam raise would be used to improve the ability to meet temperature objectives and habitat requirements for anadromous fish during drought years and increase water supply reliability. CP4A is identical to CP4 except for the operations of Shasta Dam and reservoir. Both alternatives have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for Sacramento River anadromous fish purposes (e.g., cold water pool); however, the portion of this dedicated storage varies.

For CP4, about 378,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival. Operations for the remaining portion of increased storage for CP4A (approximately 256,000 acre-feet) would be the same as in CP1, with 70,000 acre-feet reserved in dry years and 35,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries.

For CP4A, about 191,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival. Operations for the remaining portion of increased storage for CP4A (approximately 443,000 acre-feet) would be the same as in CP2, with 120,000 acre-feet reserved in dry years and 60,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries.

CP4 and CP4A both include an adaptive management plan for the cold-water pool, and augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat at one or more sites in the upper Sacramento River.

Shasta Lake and Vicinity This section describes impacts on the Shasta Lake and vicinity portion of the primary study area for CP4 and CP4A.

Impact Aqua-1 (CP4 or CP4A): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP4 or CP4A, project operations would contribute to an increase in the surface area and WSEL of Shasta Lake, which would in turn increase the area and productivity of nearshore, warm-water habitat. CP4 or CP4A operations would also result in reduced monthly fluctuations in WSEL, which would contribute to increased reproductive success, young-of-the-year production, and the juvenile growth rate of warm-water fish species. Similar to CP3, the value of existing structural habitat improvements would be diminished to varying degrees; however, the existing habitat enhancement features would become functional during reservoir drawdowns later in the season and during below-normal and drier years, when the reservoir does not refill. Additionally, environmental commitments during construction include using brush and trees cleared for other project purposes to extend and enhance existing fish habitat structures into the new inundated varial zone. Large areas of the shoreline would not be cleared, and the vegetation along these sections will be inundated periodically, providing additional structural fish habitat. In the short term, this newly inundated vegetation will initially increase warm-water fish habitat, with decay expected to occur over several decades. This impact would be less than significant for alternatives CP4 and CP4A.

This impact would be similar to Impacts Aqua-1 (CP1, CP2, and CP3), but the surface area would be larger under the 18.5-foot dam raise than under CP1 and

CP2, where the surface area under CP4 would be slightly greater than under CP4A (Figures 11-32 and 11-33). CalSim-II modeling shows that the surface area of Shasta Lake would be larger under CP4 and CP4A for both a 2005 and 2030 water supply demand than under the Existing Condition or the No-Action Alternative in all five water year types (Figures 11-32 through 11-35).

Monthly WSEL fluctuations were compared to projections for water supply demand. For CP4 or CP4A, with a 2005 water supply demand, 76 percent and 68 percent, respectively, of monthly changes in projected WSELs (i.e., 19 and 17 of the 25 total projections made for the 5 months from March through July for all five water year types) showed decreased monthly WSEL fluctuations relative to the Existing Condition and none showed an increased monthly WSEL fluctuation (Figure 11-36 and Figure 11-37). For CP4 or CP4A, with a projected 2030 water supply demand, 72 and 64 percent, respectively, of monthly changes in projected WSELs showed decreased WSEL fluctuations relative to the No-Action Alternative and none showed an increase in monthly WSEL fluctuation (Figure 11-38 and Figure 11-39). Under CP4 or CP4A, none of the changes in monthly WSEL fluctuation are different enough from the Existing Condition to warrant the investigation of daily WSEL fluctuation.

Increases in the overall surface area and WSEL under CP4 or CP4A would increase the area of available warm-water habitat and stimulate biological productivity, including fish production, of the entire lake for a period of time, possibly for several decades. Furthermore, reductions in the magnitude of monthly WSEL fluctuations could contribute to increased reproductive success, young-of-the-year production, and juvenile growth rate of warm-water fish species. Similar to CP1, CP2, and CP3, CP4 and CP4A include environmental commitments during construction to offset the effects on existing fish habitat enhancement structures (see Chapter 2, “Alternatives,” for additional detailed descriptions of the environmental commitments).

This impact for CP4 would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-39. Average Monthly Change in Water Surface Elevation for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP4A Versus No-Action Alternative (2030)

Impact Aqua-2 (CP4 or CP4A): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction This impact would be similar to Impact Aqua-2 (CP3). Localized increases in soil erosion and resulting runoff sedimentation, and turbidity resulting from project construction in the vicinity of Shasta Dam and at utility, road, and other facility relocation areas, could affect nearshore warm-water habitat. However, the environmental commitments for all action alternatives would reduce potential impacts and result in less-than-significant impacts.

This impact for CP4 would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-3 (CP4 or CP4A): Effects on Cold-Water Habitat in Shasta Lake Operations-related changes in the ratio of cold-water storage to surface area would increase the availability of suitable cold-water habitat in Shasta Lake. This impact would be beneficial for CP4 or CP4A.

This impact would be similar to Impacts Aqua-3 (CP1, CP2, and CP3) but would be of greater benefit to the reservoir cold-water fishery than Aqua-1 (CP3) owing to its focus on increasing the volume of cold water storage available to the TCD to benefit anadromous fish downstream from Shasta Dam.

CalSim-II modeling shows that under CP4 or CP4A, with a 2030 water supply demand, the ratio of cold-water storage to surface area is higher than under the No-Action Alternative in all water years and during all months modeled (Figure 11-33 and Figures 11-34 and 11-35). The greatest projected increases over the No-Action Alternative occurred between June 30 and August 31, which is a critical rearing and oversummering period for cold-water fishes in reservoirs (Figure 11-40 and 11-41).

This impact would be beneficial for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be beneficial for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-41. Average Monthly Cold-water Storage to Surface Area Ratio for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP4A Versus the No-Action Alternative (2030)

Impact Aqua-4 (CP4 or CP4A): Effects on Special-Status Aquatic Mollusks Under CP4 or CP4A, habitat for special-status mollusks could be inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could adversely affect special-status aquatic mollusks that could occupy habitat in or near Shasta Lake and its tributaries. This impact would be similar to Aqua-4 (CP3).

Except for the California floater, the occurrence of special-status mollusks in Shasta Lake and the lower reaches of its tributaries is unlikely. Modification or loss of suitable habitat for California floater would occur through increased WSEL and seasonal fluctuations in the surface area under CP4 or CP4A. Therefore, this impact would be potentially significant for CP4 or CP4A. Mitigation for this impact would be the same for CP4 or CP4A and is included in Section 11.3.4, "Mitigation Measures."

Impact Aqua-5 (CP4 or CP4A): Effects on Special-Status Fish Species The expansion of the surface area of Shasta Lake and the inundation of additional tributary habitat (including inundation of fish passage barriers) under CP4 or CP4A would be similar to CP3 and could affect one species designated as sensitive by the USFS, the hardhead. Access to, and the availability of, suitable riverine habitat along all the main tributaries to the reservoir would not likely become any more limiting than under current conditions, nor would it greatly expand.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP4 or CP4A): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP4 or CP4A, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,090-foot contour, the maximum inundation level under this alternative. This impact would be less than significant.

Similar to CP3, implementation of CP4 or CP4A could have small localized beneficial effects for adfluvial cold-water fishes and provide access to warm-water fish species, with a potential to alter existing resident fish communities, which would primarily be limited to the newly inundated reaches of the new varial zone of some streams. Impacts would not be expected to be much greater than under existing conditions with implementation of environmental commitments to monitor and adaptively manage to prevent warm-water fish invasion of Squaw Creek (See Chapter 2, "Alternatives," for additional detailed descriptions of the environmental commitments).

This impact is considered to be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact is considered to be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed. *Impact Aqua-7 (CP4 or CP4A): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake* Similar to that described for CP3, CP4 or CP4A would result in additional periodic inundation of potentially suitable spawning and rearing habitat for adfluvial salmonids in the tributaries of the Sacramento River, McCloud River, Pit River, Big Backbone Creek, and Squaw Creek upstream from Shasta Lake. A total of 11 miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids (estimated at 40,103 square feet for all tributaries) would be affected by CP4 or CP4A.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

This impact would be potentially significant for CP4A. Mitigation for this impact would be the same as that proposed for CP4, and is included in Section 11.3.4, “Mitigation Measures.”

Impact Aqua-8 (CP4 or CP4A): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake Similar to CP3, CP4 or CP4A would result in periodic inundation of the lower reaches of intermittent high-gradient, non-fish-bearing intermittent tributaries to Shasta Lake. Twenty-four miles of non-fish-bearing tributary stream habitat (based on channel slope and confirmed by surveys of representative stream reaches) upstream from Shasta Lake could be affected by CP4 or CP4A, which is only about 1 percent of the total length of non-fish-bearing tributary habitat upstream from the lake. Field surveys suggest that few, if any, of the non-fish-bearing streams contain special-status invertebrate or vertebrate species that would be affected by increased connectivity to Shasta Lake.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP4 or CP4A): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP4 or CP4A.

There would be no impact for CP4. Mitigation for this impact is not needed, and thus not proposed.

There would be no impact for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Aqua-10 (CP4 or CP4A): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Temporary construction-related increases in sediments and turbidity levels would adversely affect aquatic habitats and fish populations immediately downstream in the upper Sacramento River. However, environmental commitments would be in place to reduce the effects. This impact would be less than significant for CP4 or CP4A.

Construction activities for CP4 and CP4A are identical. The construction activities and potential borrow sources associated with CP4 or CP4A are described in Section 2.3.8 in Chapter 2, "Alternatives."

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater under CP4 or CP4A than under CP1 because of the increased activity associated with an 18.5-foot dam raise compared to a 6.5-foot dam raise. Also, CP4 and CP4A include implementation of a 10-year gravel augmentation program as an additional environmental commitment. Placing gravel along the Sacramento River channel and bank annually would release an additional source of fine sediment and expose it to the river and aquatic communities. However, the gravel augmentation activities would occur only during previously specified in-water work windows, which would minimize the potential for impacts associated with this activity.

CP4 and CP4A also include restoration of riparian, floodplain, and side-channel habitat in the upper Sacramento River at up to six potential restoration sites. Riparian, floodplain, and side-channel restoration at these sites could result in additional disturbed surfaces, but most of this construction is expected to occur away from the wetted channel, and all disturbed areas would be revegetated.

The restoration actions and environmental commitments as proposed for either CP4 or CP4A are intended to reduce any potential negative effects.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus is not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus is not proposed.

Impact Aqua-11 (CP4 or CP4A): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants. Such exposure could adversely affect aquatic habitats, the aquatic food web, and fish populations, including special-status species, downstream in the primary study area. However, environmental commitments would be in place to reduce the effects. Therefore, this impact would be less than significant for CP4 or CP4A.

Construction activities for CP4 and CP4A are identical. The construction activities and potential borrow sources associated with CP4 or CP4A are described in Section 2.3.8 in Chapter 2, “Alternatives.”

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater under CP4 or CP4A than under CP1 because of the increased activity associated with an 18.5-foot raise compared to a 6.5-foot raise. Additionally, as discussed above, CP4 and CP4A include implementation of a 10-year gravel augmentation program and restoration of riparian, floodplain, and side-channel habitat as additional environmental commitments. Both of these construction activities could cause additional sources of equipment-related contaminants to be released and exposed to the river and aquatic communities. However, implementation of additional environmental commitments that call for in-water work windows and specific BMPs would minimize and/or avoid the potential for impacts associated with this activity. As under CP1, environmental commitments for all actions would be in place to reduce effects.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-12 (CP4 or CP4A): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon and Steelhead CP4 or CP4A operation would result in generally improved flow and water temperature conditions in the upper Sacramento River for Chinook salmon, steelhead and other native fishes. As well, the restoration actions proposed under CP4 would provide additional benefits to Chinook salmon and steelhead. This impact would be beneficial.

Winter-Run Chinook Salmon

<u>Production</u>

Overall average winter-run production for the 81-year period would be greater under CP4 conditions relative to the No-Action Alternative and Existing Condition (Attachments 3 and 4 of the Modeling Appendix). The maximum increase in simulated production relative to the No-Action Alternative was 369 percent (critical water year), while the largest decrease in production under CP4 relative to the No-Action Alternative was less than -7 percent (above-normal water year) (Table 11-41 and Attachment 3 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was around 392 percent in 1934 (critical water year) for CP4, while the largest decrease in production relative to the Existing Condition was less than -5 percent CP4 (Table 11-41 and Attachment 4 of the Modeling Appendix). Figure 11-9 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4, five critical, one dry, and one wet water year had significant increases in production compared to the No-Action Alternative, while one above-normal water year had a significant decrease in production compared with the No-Action Alternative (Table 11-41 and Attachment 3 of the Modeling Appendix).

Under CP4, six critical and one dry water years had significant increases in production compared to the Existing Condition, while no water years had a significant decrease in production (Table 11-41 and Attachment 4 of the Modeling Appendix).

Table 11-41. Change in Production Under CP4 for Winter-Run Chinook Salmon

Key:
CP = Comprehensive Plan

Under CP4A, overall average winter-run production for the 81-year period would be greater relative to the No-Action Alternative and Existing Condition (Attachments 3 and 4 of the Modeling Appendix). The maximum increase in simulated production relative to the No-Action Alternative was 255 percent (critical water year), while the largest decrease in production under CP4A relative to the No-Action Alternative was -5 percent (critical water year) (Table 11-42 and Attachment 3 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was around 258 percent (critical water year) for CP4A, while the largest decrease in production relative to the Existing Condition was less than -6 percent for CP4A (wet water year) (Table 11-42 and Attachment 4 of the Modeling Appendix). Figure 11-9 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4A, four critical and one dry water year had significant increases in production compared to the No-Action Alternative, while one critical water year had a significant decrease in production compared with the No-Action Alternative (Table 11-42 and Attachment 3 of the Modeling Appendix).

Under CP4A, six critical and one dry water years had significant increases in production compared to the Existing Condition, while one wet water year had a significant decrease in production (Table 11-42 and Attachment 4 of the Modeling Appendix).

CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on winter-run Chinook salmon caused by the actions of the project (Attachments 3 and 4 of the Modeling Appendix). Nonoperations-related mortality is the base and seasonal mortality that would occur even without the effects of Shasta operations (such as disease, predation, and entrainment). Flow- and water temperature-related mortality is that caused by altering flow and water temperatures. In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 89 percent of the total mortality under CP4 and around 88 percent of the total mortality under CP4A.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 3 and 4 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest average mortality to winter-run Chinook salmon under CP4 and CP4A (as with CP1 through CP3) in all water year types, based on smolt equivalents, would occur to fry, followed by eggs, presmolts, immature smolts, and prespawn adults. Table 11-5 displays the overall mortalities for each Comprehensive Plan that would be caused by changes in water temperature and flow (see also Attachments 3 and 4 of the Modeling Appendix). Under CP4, years with the highest mortality were different between CP4, No-Action Alternative and Existing Conditions and included critical, dry and wet water year types. These years with highest mortality were preceded by three critical, and three dry water years. Years with the lowest mortality varied between all water year types (Attachments 3 and 4).

Under CP4A, years with the highest mortality were different between CP4A, No-Action Alternative and Existing Conditions and included critical, dry and wet water year types. These years with highest mortality were preceded by three critical, and three dry water years. Years with the lowest mortality varied between all water year types (Attachments 3 and 4).

Under CP4, winter-run Chinook salmon would have, overall, a significant reduction in project-related mortality relative to the No-Action Alternative and Existing Condition. Winter-run Chinook salmon would have an overall insignificant increase in production, but a significant increase in production during critical water years–those years in which they are at greatest risk. Therefore, winter-run Chinook salmon would benefit from water temperature and flow conditions under in CP4. Additionally, winter-run Chinook salmon will likely benefit from the downstream restoration program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Under CP4A, winter-run Chinook salmon would have, overall, a significant reduction in project-related mortality relative to the No-Action Alternative (6 percent and the Existing Conditions. Winter-run Chinook salmon would have an overall insignificant increase in production, but a significant increase in production during critical water years–those years in which they are at greatest risk. Therefore, winter-run Chinook salmon would benefit from water temperature and flow conditions under in CP4A. Additionally, winter-run Chinook salmon will benefit from the downstream restoration program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Overall average spring-run Chinook salmon production increased for the 82-year period under CP4 compared to the No-Action Alternative and the Existing Condition (Attachments 6 and 7 of the Modeling Appendix). The maximum increase in simulated production relative to the No-Action Alternative was 6,006 percent for CP4 (critical water year). The largest decrease in production relative to the No-Action Alternative was -8 percent for CP4 (wet water year) (Table 11-43 and Attachment 6 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 5,516 percent for CP4 (critical water year). The largest decrease in production relative to the Existing Condition was -8.5 percent for CP4 (wet water year) (Table 11-43 and Attachment 7 of the Modeling Appendix). Figure 11-10 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4, 12 critical, two dry, one below-normal, and one above-normal water years had significant increases in production compared to the No-Action Alternative. One each dry, below-normal and wet water years had significant decreases in production (Table 11-43 and Attachment 6 of the Modeling Appendix).

Under CP4, 12 critical, one dry, and one below-normal water years had significant increases in production compared to the Existing Condition. Two wet water years had significant decreases in production (Table 11-43and Attachment 7 of the Modeling Appendix).

Table 11-43. Change in Production Under CP4 for Spring-Run Chinook Salmon

Key:

CP = Comprehensive Plan

Overall average spring-run Chinook salmon production increased for the 82-year period under CP4A compared to the No-Action Alternative and the Existing Condition (Attachments 6 and 7 of the Modeling Appendix). The maximum increase in simulated production relative to the No-Action Alternative was 1,480 percent for CP4A (critical water year), while the largest decrease in production relative to the No-Action Alternative was -5 percent for CP4A (wet water year) (Table 11-44 and Attachment 6 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 2,258 percent for CP4A (dry water year), while the largest decrease in production relative to the Existing Condition was -8.3 percent for CP4A (wet water year) (Table 11-44 and Attachment 7 of the Modeling Appendix). Figure 11-10 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4A, 12 critical, three dry, one below-normal, and one above-normal water years had significant increases in production compared to the No-Action Alternative. Two wet water years had significant decreases in production (Table 11-44 and Attachment 6 of the Modeling Appendix).

Under CP4A, 12 critical, three dry, and one below-normal water years had significant increases in production compared to the Existing Condition. Two wet water years had significant decreases in production (Table 11-44 and Attachment 7 of the Modeling Appendix).

Table 11-44. Change in Production Under CP4A for Spring-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease

CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on spring-run Chinook salmon caused by the actions of the project (Attachments 6 and 7). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)‒around 89 percent of the total mortality under CP4 and 87 percent of the total mortality under CP4A.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 6 and 7 of the Modeling Appendix). Under both the 2030 and 2005 conditions, the greatest mortality to spring-run Chinook salmon under CP4 and CP4A (as with CP1 through CP3) in all water year types based on smolt equivalents, occurred to eggs, with minimal mortality to the other life stages. Table 11-7 displays the smolt-equivalent mortalities for each Comprehensive Plan that are caused by flow- and water-related factors (also see Attachments 6 and 7 of the Modeling Appendix).

Years with the highest operations-related mortality were different for CP4 and CP4A compared with No-Action Alternative and Existing Conditions with fewer years with high mortality. All years with the highest mortality were preceded by either a critical or dry water year. Years with the lowest mortality varied between all water year types (Attachments 6 and 7 of the Modeling Appendix).

Spring-run Chinook salmon would have significantly reduced flow- and water temperature-related mortality under CP4 and CP4A, but an insignificant increase in overall production. However, they would experience a significant increase in production during almost all critical water years, and a significant increase in average production during critical years, under CP4 and CP4A. Therefore, spring-run Chinook salmon would benefit from actions taken in CP4 and CP4A. Additionally, spring-run Chinook salmon will benefit from the downstream restoration program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Overall average fall-run Chinook salmon production under CP4 increased for the 81-year period compared with the No-Action Alternative and Existing Condition (Attachments 9 and 10 of the Modeling Appendix). The maximum increase in simulated production relative to the No-Action Alternative was 617 percent (critical water year), while the largest decrease in production relative to the No-Action Alternative was -6.5 percent (wet water year) (Table 11-45 and Attachment 9 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 656 percent (critical water year). The largest decrease in production relative to the Existing Condition was -6.7 percent (wet water year) (Table 11-45 and Attachment 10 of the Modeling

Appendix). Figure 11-11 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4, five critical, three dry, and one above-normal water years had significant increases in production relative to the No-Action Alternative. Significant reductions in production occurred in two dry, one below-normal, and three wet water years (Table 11-45 and Attachment 9 of the Modeling Appendix).

Under CP4, five critical, three dry, and two below-normal water years had significant increases in production relative to the Existing Condition. One dry, one below-normal, and two wet water years resulted in significant decreases in production relative to the Existing Condition (Table 11-45 and Attachment 10 of the Modeling Appendix).

Table 11-45. Change in Production Under CP4 for Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Key:
CP = Comprehensive Plan

Overall average fall-run Chinook salmon production under CP4A increased for the 81-year period compared with the No-Action Alternative and Existing Condition (Attachments 9 and 10 of the Modeling Appendix). The maximum increase in simulated production relative to the No-Action Alternative was 75 percent (critical water year). The largest decrease in production relative to the No-Action Alternative was -6.4 percent (wet water year) (Table 11-46 and Attachment 9 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 148 percent (critical water year). The largest decrease in production relative to the Existing Condition was -6.7 percent (wet water year) (Table 11-46 and Attachment 10 of the Modeling Appendix). Figure 11-11 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4A, six critical, three dry, and two below-normal water years had significant increases in production relative to the No-Action Alternative. Significant reductions in production occurred in one below-normal and one wet water years (Table 11-46 and Attachment 9 of the Modeling Appendix).

Under CP4A, six critical, four dry, one below-normal, and one wet water years had significant increases in production relative to the Existing Condition. Significant reductions in production occurred in one wet water year (Table 11-46 and Attachment 10 of the Modeling Appendix).

Table 11-46. Change in Production Under CP4A for Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease

Key:

CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on fall-run Chinook salmon caused by the actions of the project (Attachments 9 and 10). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)‒around 66 percent of the total mortality under CP4 and around 65 percent of the total mortality under CP4A.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 9 and 10 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality based on the smolt equivalents to fall-run Chinook salmon under CP4 and CP4A (as with CP1 through CP3) in all water year types based on smolt equivalents occurred to fry, followed by eggs, prespawn adults, presmolts, and lastly to immature smolts. Flow-related effects triggered a higher percentage of the operations-related mortality (Table 11-9). In all water year types, the greatest portion of mortality under CP4 and CP4A occurred to fry caused by forced movement to downstream habitats. Other non-flow- and water temperature-related conditions were the primary causes of mortality for all life stages except fry (Attachments 9 and 10 in the Modeling Appendix).

There was no real trend with respect to years with the greatest mortality.

Fall-run Chinook salmon would have significantly reduced project-related mortality, but an insignificant increase in overall production However, fall-run Chinook salmon would experience a significant overall average increase in production during critical water years under CP4 and CP4A. Therefore, fall-run Chinook salmon would benefit from actions taken in CP4 and CP4A. Additionally, fall-run Chinook salmon will benefit from the downstream restoration program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon and Steelhead

Late fall-run Chinook salmon were evaluated directly using SALMOD and were considered to be a surrogate for steelhead; therefore, the following discussion regarding SALMOD results for late fall-run Chinook salmon are applicable to steelhead.

Production

Overall average late fall-run Chinook salmon production for the 80-year period under CP4 conditions was slightly greater than the No-Action Alternative and the Existing Condition (Attachments 12 and 13 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 23 percent (critical water year), while there were no significant decreases in production relative to the No-Action Alternative (Table 11-47 and Attachment 12 of the Modeling Appendix). The maximum increase in production relative to Existing Conditions was 27 percent (critical water year), there were no significant decreases in production relative to Existing Conditions (Table 11-47 and Attachment 13 of the Modeling Appendix). Figure 11-12 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4, six critical and five dry water years had significant increases in production compared to the No-Action Alternative. Significant reductions in production did not occur in any years (Table 11-47 and Attachment 12 of the Modeling Appendix).

Under CP4, four critical, four dry, one below-normal, and two wet water years had significant increases in production compared to the Existing Condition. Significant reductions in production did not occur in any years (Table 11-47 and Attachment 13 of the Modeling Appendix).

Table 11-47. Change in Production Under CP4 for Late Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease

Key:

CP = Comprehensive Plan

Overall average late fall-run Chinook salmon production for the 80-year period under CP4A conditions was slightly greater than the No-Action Alternative and the Existing Condition (Attachments 12 and 13 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 15 percent (dry water year), while there were no significant decreases in production relative to the No-Action Alternative (Table 11-48 and Attachment 12 of the Modeling Appendix). The maximum increase in production relative to Existing Conditions was 19 percent (dry water year), while the maximum decrease in production relative to Existing Condition was -6.3 percent (dry water year) (Table 11-48 and Attachment 12 of the Modeling Appendix). Figure 11-12 shows the change in production for CP4A relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP4A, three critical and four dry water years had significant increases in production compared to the No-Action Alternative. Significant reductions in production did not occur in any years (Table 11-48 and Attachment 12 of the Modeling Appendix).

Under CP4A, four critical, three dry, one below-normal, and two wet water years had significant increases in production compared to the Existing Condition. A significant reduction in production occurred in one dry water year (Table 11-48 and Attachment 13 of the Modeling Appendix).

Table 11-48. Change in Production Under CP4A for Late Fall-Run Chinook Salmon

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Late fall-run Chinook salmon are used as a surrogate for steelhead

Key:

CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on late fall-run Chinook salmon caused by the actions of the project (Attachments 12 and 13). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 79 percent of the total mortality under both CP4 and CP4A.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 12 and 13 of the Modeling Appendix). Under both 2030 and 2005 conditions, the largest mortality to late fall-run Chinook salmon under CP4 and CP4A (as with CP1 through CP3) in all water year types based on smolt equivalents, occurred to the egg life stage, followed by fry, then presmolts, and lastly to immature smolts. Most mortality occurred as a result of flow conditions rather than water temperature (Table 11-11).

Years with the highest mortality were the same for CP4 and CP4A and the No-Action Alternative and the Existing Condition, and occurred in all water year types. Four of these years were preceded by a wet water year, and the rest were each preceded by an above-normal, below-normal or dry water year (Attachments 12 and 13 of the Modeling Appendix).

Because SALMOD indicates an insignificant change in mortality and production index for late fall-run Chinook salmon, late fall-run Chinook salmon and steelhead (as represented by their surrogate late fall-run Chinook salmon) would experience less-than-significant impacts from actions taken in CP4 and CP4A. Additionally, late fall-run Chinook salmon and steelhead would benefit from the downstream restoration program, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

All Chinook Runs Combined

As with CP3, the raise for both CP4 and CP4A would increase the full pool depth by 20.5 feet and enlarge total reservoir storage capacity by 634,000 acre-feet. The additional storage created by the dam raise would be used to improve the ability to meet water temperature objectives and habitat requirements for anadromous fish during drought years (Figures 11-42 and 11-43) and increase water supply reliability. Of the increased reservoir storage space, about 378,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival in CP4; 191,000 acre-feet would be dedicated in CP4A.

Under CP4 for the 2030 conditions, overall production for all four runs of Chinook salmon combined would increase by nearly 813,000 immature smolts migrating below RDPP. Under the CP4 2005 conditions, overall production for all four runs of Chinook salmon combined would increase by almost 1,129,000 immature smolts migrating below RDPP.

Under CP4A for the 2030 conditions, overall production for all four runs of Chinook salmon combined would increase by over 710,000 immature smolts migrating below RDPP. Under the CP4A 2005 conditions, overall production for all four runs of Chinook salmon combined would increase by almost 815,000 immature smolts migrating below RDPP.

Figure 11-43. Percent Change in Production of Chinook Salmon for CP4A Compared to the No-Action Alternative and Existing Conditions

Impact Aqua-13 (CP4 or CP4A): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass CP4 and CP4A operations generally would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. Overall, potential flow changes resulting from the implementation of CP4 or CP4A would not be of sufficient frequency or magnitude to beneficially or adversely affect these species. However, potential water temperature changes (reductions) resulting from the implementation of CP4 or CP4A would result in beneficial effects on steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass in the river, especially during critical water years. Flow- and water temperature–related effects on these fish species would be less than significant (flow) and beneficial (water temperature) relative to the Existing Condition and No-Action Alternative for both CP4 and CP4A. The benefits of the water temperature decrease outweigh the minimal effects of flow changes. Therefore, this impact would be beneficial for both CP4 and CP4A.

For CP4, this impact would be similar to Impact Aqua-13 (CP1). However, during certain years, the impact could be greater (beneficial) under CP4 than under CP1 because of the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise, and because of the additional volume of cold water that would be available for anadromous fish.

For CP4A, this impact would be similar to Impact Aqua-13 (CP2). However, during certain years, the impact could be greater (beneficial) under CP4A than under CP2 because of the increased reservoir capacity associated with an 18.5-foot raise compared to a 12.5-foot raise, and because of the additional volume of cold water that would be available for anadromous fish.

Flow-Related Effects As under CP1, monthly mean flows at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBPP) under CP4 would be similar to (generally less than 4-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for all months. (See the Modeling Appendix for complete modeling results.)

As under CP2, monthly mean flows at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, above Bend Bridge, and above RBPP) under CP4A would be similar to (generally less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for all months. (See the Modeling Appendix for complete modeling results.)

Potential flow-related effects of CP4 or CP4A on fish species of management concern in the upper Sacramento River would be minimal. Potential changes in flows and stages would diminish rapidly downstream from RBPP because of increased effects from tributary inflows, diversions, and flood bypasses.

Changes in monthly mean flows under CP4 or CP4A relative to the Existing Condition and No-Action Alternative would have no discernible effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for these species would be unchanged. Therefore, flow-related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Water Temperature–Related Effects Changes in monthly mean water temperatures at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, Balls Ferry, above Bend Bridge, and above RBPP) under CP4 would change fractionally when compared to water temperatures under the Existing Condition and No-Action Alternative for all months simulated (Figures 11-44 and 11-45; see the Modeling Appendix for complete modeling results).

Monthly mean water temperatures at all modeling locations along the upper Sacramento River (below Shasta Dam, below Keswick Dam, Balls Ferry, above Bend Bridge, and above RBPP) under CP4A would change fractionally when compared to water temperatures under the Existing Condition and No-Action Alternative for all months simulated (Figures 11-46 and 11-47; see the Modeling Appendix for complete modeling results).

Figure 11-47. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (CP4A Versus No-Action Alternative)

As discussed above, the modeling simulations may not fully account for real-time management of the cold-water pool and TCD (through the SRTTG) to achieve maximum cold-water benefits. Therefore, the modeled changes in water temperature are likely conservative and understated to some varying degree. Potential changes in flows and stages would diminish rapidly downstream from RBPP because of the increasing effect of tributary inflows, diversions, and flood bypasses.

The slight changes in monthly mean water temperatures under CP4 and CP4A relative to the Existing Condition and the No-Action Alternative would have very small effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Monthly mean water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River. Therefore, water temperature–related effects on these fish species would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-14 (CP4 or CP4A): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operations could cause a reduction in the magnitude, duration, or frequency of intermediate to large flows both in the upper Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-14 (CP1) for CP4. The impact could be greater under CP4 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

This impact would be similar to Impact Aqua-14 (CP2) for CP4A. The impact could be greater under CP4A than under CP2 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 12.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, reducing the potential for downcutting. These processes are regulated by the magnitude and frequency of flow. Relatively large floods provide the energy required to mobilize sediment from the riverbed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. Operations under CP4 or

CP4A could result in a reduction in the intermediate to large flows necessary for channel forming and maintenance, meander migration, and creation of seasonally inundated floodplains.

Implementation of CP4 or CP4A would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing effects on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These effects would likely occur throughout the upper Sacramento River portion of the primary study area.

As discussed above, CP4 and CP4A both include a 10-year gravel augmentation program and the restoration of riparian, floodplain, and side-channel habitat at up to six potential restoration sites as additional environmental commitments. Placing gravel along the Sacramento River channel and bank annually and restoring riparian, floodplain, and side-channel habitat at up to six sites would result in benefits to ecological processes (e.g., sediment transport and deposition, floodplain inundation) that would partially offset the effects described above. Nevertheless, reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

This impact would be potentially significant for CP4A. Mitigation for this impact is identical to that proposed for CP4 in Section 11.3.4, "Mitigation Measures."

Lower Sacramento River and Delta

Impact Aqua-15 (CP4 or CP4A): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern Project operation would result in no discernible change in monthly mean flows or water temperature conditions in the lower Sacramento River. However, predicted changes in flows in the Feather, American, and Trinity rivers could result in adverse effects on Chinook salmon, steelhead, Coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be potentially significant for both CP4 and CP4A.

This impact would be similar to Impact Aqua-15 (CP1) for CP4. The impact could be greater under CP4 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and increased cold-water pool) behind the raised dam.

This impact would be similar to Impact Aqua-15 (CP2) for CP4A. The impact could be greater under CP4A than under CP2 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 12.5-foot raise would allow for storage of additional water volume (and increased cold water pool) behind the raised dam.

As described below, mean monthly flows at various modeling locations on the lower Sacramento River and tributaries under CP4 and CP4A were compared with mean monthly flows simulated for Existing Conditions and No-Action Alternative conditions. See the Modeling Appendix for complete CalSim-II modeling results.

Lower Sacramento River As under CP1, monthly mean flows at the lower Sacramento River modeling locations under CP4 or CP4A would be essentially equivalent to flows under the Existing Condition and No-Action Alternative simulated for all months. Differences in monthly mean flow were generally small (less than 2 percent) and within the existing range of variability. Potential changes in flows would diminish rapidly downstream from RBPP because of the increasing effect from tributary inflows, diversions, and flood bypasses. Similarly, potential changes in water temperatures in the lower Sacramento River caused by small changes in releases would diminish rapidly downstream because of the increasing effects of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts on fish species in the lower Sacramento River would be less than significant for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

As under CP1, the effects of altered flow regimes resulting from implementation of CP4 or CP4A are unlikely to extend into the lower Sacramento River and Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the SWP and the CVP). The operational requirements, including the 2008 USFWS BO and the 2009 NMFS BO, have been designed to maintain standards for flow to the lower Sacramento River and Delta. CVP and SWP operations must be consistent with these ESA BOs. Thus, implementation of CP4 would not likely alter flow to the Delta or water temperatures in the lower Sacramento River and primary tributaries within the extended study area to a degree sufficient to cause discernible effects on Chinook salmon, steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass relative to the Existing Condition and No-Action Alternative. Functional flows for fish migration, attraction, spawning, egg incubation, and rearing/emigration for all these fish species would be unchanged. Therefore, flow- and water temperature–related effects on these fish species would be less than significant for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

Lower Feather River, American River, and Trinity River Also, as under CP1, monthly mean flows at all modeling locations on the lower Feather River, the American River, and the Trinity River under CP4 or CP4A would be essentially equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for most months. However, simulations for several months within the modeling record show substantial changes to flows in tributaries. Potential changes in flows could be reduced by real-time operations to meet existing rules and because of operation of upstream reservoirs (Lake Oroville, Folsom Lake, and Trinity Lake) and increasing effects from tributary inflows, diversions, and flood bypasses. Potential changes in water temperatures in the Feather and American rivers caused by altered releases from reservoirs could diminish downstream because of the increasing effect of inflows, and atmospheric and groundwater influences. Nevertheless, based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts on species of management concern in the American, Feather, and Trinity rivers could occur.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

This impact would be potentially significant for CP4A. Mitigation for this impact is identical to that proposed for CP4 in Section 11.3.4, "Mitigation Measures."

Impact Aqua-16 (CP4 or CP4A): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could cause a reduction in intermediate to large flows both in the lower Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-16 (CP1) for CP4 and CP4A. The impact could be greater under CP4 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flows. Relatively large floods provide the energy required to mobilize sediment from the bed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Operations under CP4 or CP4A could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Implementation of CP4 or CP4A would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from the operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along the upper reaches of the lower Sacramento River.

Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

This impact would be potentially significant for CP4A. Mitigation for this impact is identical to that proposed for CP4 in Section 11.3.4, “Mitigation Measures.”

Impact Aqua-17 (CP4 or CP4A): Effects to Delta Fisheries Resulting from Changes to Delta Outflow Delta outflow conditions under CP4 would be the same as those under CP1, and would result in changes to average monthly Delta outflow of less than 5 percent in all water year types (with the exception of December of critical years under 2005 conditions), as shown in Table 11-12. This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta for CP4 would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Delta outflow conditions under CP4A would be the same as those under CP2, and would result in changes to average monthly Delta outflow of less than 5 percent in all water year types (with the exception of December of critical years under 2005 conditions), as shown in Table 11-23. This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta for CP4A would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP4 or CP4A): Effects to Delta Fisheries Resulting from Changes to Delta Inflow Delta inflow conditions under CP4 would be the same as those under CP1, and would not decrease average monthly Delta inflow by 5 percent or more in any year type, as shown in Table 11-13. This impact on

Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Delta inflow conditions under CP4A would be the same as those under CP2, and would not decrease average monthly Delta inflow by 5 percent or more in any year type, as shown in Table 11-24. This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP4 or CP4A): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow CP4 operations would be the same as those under CP1 and would result in a variable response in Sacramento River flow, in turn, resulting in both increases and decreases in river flow above the Existing Condition and No-Action Alternative depending on month and water year type. Decreases in Sacramento River inflow would not equal or exceed 5 percent, as shown in Table 11-14. This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

CP4A operations would be the same as those under CP2 and would result in a variable response in Sacramento River flow, in turn, resulting in both increases and decreases in river flow above the Existing Condition and No-Action Alternative depending on month and water year type. Decreases in Sacramento River inflow would not equal or exceed 5 percent, as shown in Table 11-25. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP4 or CP4A): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP4 operation would be the same as under CP1 and would result in no discernible change in San Joaquin River flows at Vernalis, as shown in Table 11-15. Therefore, CP4 would have no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta relative to either the No-Action Alternative of Existing Condition. There would be no impact for CP4. Mitigation for this impact is not needed, and thus not proposed.

CP4A operation would be the same as under CP2 and would result in no discernible change in San Joaquin River flows at Vernalis, as shown in Table 11-26. Therefore, CP4A would have no effect on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta relative to either the No-Action Alternative of Existing Condition. There would be no impact for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP4 or CP4A): Reduction in Low-Salinity Habitat Conditions Resulting from an Upstream Shift in X2 Location CP4 operations would be the same as CP1 operations, and would result in a less than 0.5 km movement upstream or downstream from the X2 location from its location under the Existing Condition or No-Action Alternative, and thus cause minimal reduction in low-salinity habitats, as shown in Table 11-16. This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

CP4A operations would be the same as CP2 operations, and would result in a less than 0.5 km movement upstream or downstream from the X2 location from its location under the Existing Condition or No-Action Alternative, and thus cause minimal reduction in low-salinity habitats, as shown in Table 11-27. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP4 or CP4A): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers CP4 operations would be the same as CP1 operations, and would result in minimal changes to reverse flows in Old and Middle rivers, as shown in Table 11-17. The increases in reverse flows would be expected to contribute to a small increase in the vulnerability of Chinook salmon, delta smelt, striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses.

CP4A operations would be the same as CP2 operations, and would result in minimal changes to reverse flows in Old and Middle rivers, as shown in Table 11-28. The increases in reverse flows would be expected to contribute to a small increase in the vulnerability of Chinook salmon, delta smelt, striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses.

This impact would be less than significant for CP4 or CP4A for striped bass, threadfin shad, and other resident warm-water fish, and potentially significant for delta smelt and Chinook salmon. Overall, the impact for CP4 and CP4A would be potentially significant. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species, thus reducing effects to non-listed fish species as well.

Impact Aqua-23 (CP4 or CP4A): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP4 operations would be the same as CP1 operations, and may result in an increase of CVP and SWP exports, which is assumed to result in a direct proportional increase or decrease in the risk of fish being entrained and salvaged at the facilities, as shown in Table 11-18.

CP4A operations would be the same as CP2 operations, and may result in an increase of CVP and SWP exports, which is assumed to result in a direct proportional increase or decrease in the risk of fish being entrained and salvaged at the facilities, as shown in Table 11-29.

Therefore, the resulting impact of CP4 to Chinook salmon, steelhead, longfin smelt, striped bass, and splittail would be less than significant; the resulting impact to delta smelt would be potentially significant.

Under CP4A, however, the resulting impact would be less than significant for Chinook salmon, but potentially significant for delta smelt, steelhead, longfin smelt, striped bass, and splittail. Overall, this impact would be potentially significant for CP4 or CP4A. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species.

CVP/SWP Service Areas

Impact Aqua-24 (CP4 or CP4A): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes The implementation of CP4 or CP4A could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects to tributaries and reservoirs (e.g., New Melones and San Luis) with CVP and SWP dams, as well as the conveyances south of the Delta would be substantially less than impacts on the lower Sacramento River. The change in hydrology in the CVP and SWP service areas could affect aquatic habitats that provide habitat for the fish community; however, the changes would not result in substantial effects on their distribution or abundance. Therefore, this impact of CP4 or CP4A would be less than significant.

The impact of CP4 would be similar to Impact Aqua-24 (CP1). The impact of CP4A would be similar to Impact Aqua-24 (CP2).

The hydrologic effects to the CVP and SWP service areas would not result in substantial effects on the distribution or abundance of the fish species in the CVP and SWP service areas. The effects from CP4 or CP4A on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and resulting downstream flows, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream flows.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily focuses on increasing water supply reliability, anadromous fish survival, Shasta Lake area environmental resources, and recreation opportunities. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP5 would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 150,000 acre-feet and 75,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP5 also includes constructing additional fish habitat in and along the shoreline of Shasta Lake and along the lower reaches of its tributaries; augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River; and increasing recreation opportunities at Shasta Lake.

CP5 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact Aqua-1 (CP5): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Operations Under CP5, this impact would be similar to CP3, with slightly less of an increase in warm-water fish habitat than CP3 because of differences in operations, but inclusion of nearshore fish habitat enhancement would result in a similar or greater increase than CP3. Warm-water fish habitat would be increased compared to the Existing Condition and the No-Action Alternative as measured by increased lake surface area and reductions in lake level fluctuations (Figures 11-48 through 11-51). Its impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-2 (CP5): Effects on Nearshore, Warm-Water Habitat in Shasta Lake from Project Construction This impact would be similar to Impact Aqua-2 (CP3). This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-3 (CP5): Effects on Cold-Water Habitat in Shasta Lake Under CP5, operations-related changes in the ratio of the volume of cold-water storage to surface area would increase the availability of suitable habitat for cold-water fish in Shasta Lake, including rainbow trout (Figure 11-52). This impact would be beneficial.

This impact would be beneficial, but slightly less than that provided under CP3. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-52. Average Monthly Cold-water Storage to Surface Area Ratio for Each Water Year Type Within the Shasta Lake Vicinity of the Primary Study Area, CP5 Versus the No-Action Alternative

Impact Aqua-4 (CP5): Effects on Special-Status Aquatic Mollusks Under CP5, habitat for special-status mollusks could be inundated. Seasonal fluctuations in the surface area and WSEL of Shasta Lake could adversely affect special-status aquatic mollusks that could occupy habitat in or near Shasta Lake and its tributaries. This impact would be similar to Impact Aqua-4 (CP3, CP4, and CP4A).

Except for the California floater, the occurrence of special-status mollusks in Shasta Lake and the lower reaches of its tributaries is unlikely. Modification or loss of suitable habitat for California floater would occur through increased WSEL and seasonal fluctuations in the surface area under CP5.

Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-5 (CP5): Effects on Special-Status Fish Species Similar to CP3, CP4, and CP4A, the expansion of the surface area of Shasta Lake and inundation of additional tributary habitat, including inundation of fish passage barriers, under CP5 could affect one species designated as sensitive by the USFS, the hardhead. Access to and the availability of suitable riverine habitat among all the main tributaries to the reservoir would not likely become any more limiting than under current conditions, nor would it greatly expand.

This impact would be similar to Impact Aqua-5 (CP3, CP4, or CP4A) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-6 (CP5): Creation or Removal of Barriers to Fish Between Tributaries and Shasta Lake Under CP5, project implementation would result in the periodic inundation of steep and low-gradient tributaries to Shasta Lake up to the 1,090-foot contour, the maximum inundation level under this alternative. Similar to CP3, CP5 would have small localized beneficial effects for adfluvial cold-water fishes and provide access to warm-water fish species, which would primarily be limited to the newly inundated reaches of the new varial zone of some streams. Impacts would not be expected to be much greater than under existing conditions. *Environmental commitments, described in Chapter 2, "Alternatives," to monitor fish communities in Squaw Creek and adaptively manage to prevent warmwater fish invasions would reduce this impact to a less than significant level.*

This impact would be similar to Impact Aqua-6 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-7 (CP5): Effects on Spawning and Rearing Habitat of Adfluvial Salmonids in Low-Gradient Tributaries to Shasta Lake Similar to that described for CP3, CP5 would result in additional periodic inundation of potentially suitable spawning and rearing habitat for adfluvial salmonids in the tributaries of the Sacramento River, McCloud River, Pit River, Big Backbone Creek, and Squaw Creek upstream from Shasta Lake. A total of 11 miles of low-gradient reaches that could potentially provide some spawning and rearing habitat for adfluvial salmonids (estimated as 40,103 square feet for all tributaries) would be affected by CP5.

This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-8 (CP5): Effects on Aquatic Connectivity in Non-Fish-Bearing Tributaries to Shasta Lake CP5 would result in periodic inundation of the lower reaches of intermittent high-gradient, non-fish-bearing tributaries to Shasta Lake. About 24 miles of non-fish-bearing tributary habitat would be affected by CP5, which is only about 1 percent of the total length of non-fish-bearing tributaries upstream from Shasta Lake. Field surveys suggest that few, if any of the non-fish-bearing streams contain special-status invertebrate or vertebrate species that would be affected by increased connectivity to Shasta Lake. This impact would be less than significant.

This impact would be similar to Impact Aqua-8 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-9 (CP5): Effects on Water Quality at Livingston Stone Hatchery Reclamation provides the water supply to the Livingston Stone Hatchery from a pipeline emanating from Shasta Dam. This supply would not be interrupted by any activity associated with CP5. There would be no impact.

This impact would be similar to Impact Aqua-9 (CP1), and there would be no impact. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Aqua-10 (CP5): Loss or Degradation of Aquatic Habitat in the Upper Sacramento River During Construction Activities Temporary construction-related increases in sediments and turbidity levels would adversely affect aquatic habitats and fish populations immediately downstream in the upper Sacramento River. However, environmental commitments would be in place to reduce the effects. This impact would be less than significant.

This impact would be similar to Impact Aqua-10 (CP1). The impact could be greater under CP5 than under CP1 because of the increased activity associated with an 18.5-foot dam raise compared to a 6.5-foot dam raise.

Like CP4 and CP4A, CP5 includes a 10-year gravel augmentation program as an additional environmental commitment. Placing gravel along the Sacramento River channel and bank annually would release an additional source of fine sediment and expose it to the river and aquatic communities. However, the gravel augmentation activities would occur only during previously specified in-water work windows, which would minimize the potential for impacts associated with this activity.

Also, like CP4 and CP4A, CP5 includes restoration of riparian, floodplain, and side-channel habitat in the upper Sacramento River at up to six potential restoration sites. Riparian, floodplain, and side-channel restoration at these sites could result in additional disturbed surfaces, but most of this construction is expected to occur away from the wetted channel, and all disturbed areas would be revegetated.

As under CP1, CP4, and CP4A, environmental commitments for all actions would be in place to reduce effects under CP5. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-11 (CP5): Release and Exposure of Contaminants in the Upper Sacramento River During Construction Activities Construction-related activities could result in the release and exposure of contaminants. Such exposure could adversely affect aquatic habitats, the aquatic food web, and fish populations, including special-status species, downstream in the primary study area. However, environmental commitments would be in place to reduce the effects. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-11 (CP1). The impact could be greater under CP5 than under CP1 because of the increased activity associated with an 18.5-foot raise compared to a 6.5-foot raise. Like CP4 and CP4A, CP5 includes implementation of a gravel augmentation program and restoration of riparian, floodplain, and side-channel habitat at up to six potential restoration sites. Both of these construction activities could cause additional sources of equipment-related contaminants to be released and exposed to the river and aquatic communities. However, environmental commitments for all actions would be in place to reduce effects. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-12 (CP5): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Chinook Salmon and Steelhead Project operation under CP5 would generally result in improved flow and water temperature conditions in the upper Sacramento River for Chinook salmon and steelhead, but not all runs have an increase in production. As well, restoration actions that are proposed under CP5 would additional benefit Chinook salmon and steelhead. This impact would be beneficial.

Winter-Run Chinook Salmon

<u>Production</u>

The overall average winter-run production for the 1-year period was similar for CP5 relative to the No-Action Alternative and the Existing Condition (Attachments 3 and 4 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 78 percent for CP5 (critical water year), while the largest decrease in production relative to the No-Action Alternative was around 49 percent (also a critical water year) (Table 11-49 and Attachment 3 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 144 percent (critical water year) for CP5, while the largest decrease in production relative to the Existing Condition was around 26 percent (critical water year) (Table 11-49 and Attachment 4 of the Modeling Appendix). Figure 11-9 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP5, four critical water years had significant increases in production relative to the No-Action Alternative for winter-run Chinook salmon. No other water year type had a significant increase in production. Two critical and one above-normal water year had a significant decrease in production.

Under CP5, four critical, one dry, and one below-normal water years had significant increases in production relative to the Existing Condition, while four years (one each in critical, dry, above-normal and wet water year types) had significant decreases in production greater than 5 percent.

Table 11-49. Change in Production Under CP5 for Winter-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
Future Condition (2030)

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Key:

CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on winter-run Chinook salmon caused by the actions of the project (Attachments 3 and 4 of the Modeling Appendix). Nonoperations-related mortality are the base and seasonal mortality that would occur even without the effects of Shasta operations (such as disease, predation, and entrainment). Flow- and water temperature-related mortality is that caused by altering flow and water temperatures. In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 86 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 3 and 4 of the Modeling Appendix). The greatest average mortality to winter-run Chinook salmon under CP5 (as with CP1 through CP4) in all water year types based on smolt equivalents would occur to the fry life stage, followed by eggs, then presmolts, and lastly to immature smolts. Table 11-5 displays the overall mortalities for each Comprehensive Plan that were caused by changes in operations (i.e., water temperature and flow) (Attachments 3 and 4 of the Modeling Appendix).

Years with the highest mortality were the same for the No-Action Alternative and the Existing Condition and CP5. Each of these years was a critical water year, and was preceded by either a critical (1933, 1976, 1991), or dry (1930, 1932) water year type. Years with the lowest mortality varied between all water year types. Years in which the project has the greatest effect on winter-run were also years in which the lowest production occurred (Attachments 3 and 4).

Winter-run Chinook salmon have a less-than-significant change to production and project-related mortality under CP5. Therefore, the actions taken in CP5 would result in less-than-significant impacts to winter-run Chinook salmon under both 2030 and 2005 conditions. Winter-run Chinook salmon will, however, benefit from the downstream restoration efforts, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Spring-Run Chinook Salmon

Production

Overall average spring-run Chinook salmon simulated production for CP5 is slightly higher relative to the No-Action Alternative and slightly lower than Existing Condition (Attachments 6 and 7 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was 143 percent for CP5 (critical water year), and the largest decrease in production relative to the No-Action Alternative was -37 percent (also a critical water year) (Table 11-50 and Attachment 6 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 712 percent for CP5 and largest decrease in production was less than -27 percent (both in critical water years) (Table 11-50 and Attachment 7 of the Modeling Appendix).

Figure 11-10 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP5, seven critical, two dry and one below-normal water years had significant increases in production relative to the No-Action Alternative. Production significantly decreased in four critical water years and one wet year.

Under CP5, 10 critical, 2 dry, and 1 below-normal water years had significant increases in production relative to the Existing Condition, and two critical and one wet water years had significant decreases in production relative to Existing Conditions.

Table 11-50. Change in Production Under CP5 for Spring-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
Future Condition (2030)								
All	81	162,956	-1,098	-0.7	143	10	-37.3	4
Critical	13	81,451	262	0.3	143	7	-37.3	4
Dry	17	171,004	1,552	0.9	110	2	-1.8	0
Below Normal	14	176,922	-258	-0.1	20	1	-3.4	0

Wet	26	183,107	-4,151	-2.2	2.1	0	-5.1	1

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Key:

CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on spring-run Chinook salmon caused by the actions of the project (Attachments 6 and 7). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 83 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 6 and 7 of the Modeling Appendix). Under both the 2030 and 2005 conditions, the greatest mortality to spring-run under CP5 (as with CP1 through CP4) in all water year types based on smolt equivalents, occurred to eggs, with minimal mortality to the other life stages. Table 11-7 displays the smolt-equivalent mortalities for each Comprehensive Plan that are caused by flow- and water-related factors (also see Attachments 6 and 7 of the Modeling Appendix).

Years with the highest operations-related mortality were the same for the No-Action Alternative, Existing Conditions, and CP5. Except for 1932 (a dry water year), each of these years was a critical water year type and was preceded by either a below, dry, or (predominantly) a critical water year. However, years with the lowest mortality varied between all water year types (Attachments 6 and 7 of the Modeling Appendix).

Under both 2030 and 2005 conditions, spring-run Chinook salmon would experience a significant reduction in project-related mortality and significant increase in production during critical water years. Therefore, spring-run Chinook salmon would benefit from actions taken in CP5. Additionally, spring-run Chinook salmon will benefit from the downstream restoration efforts, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Fall-Run Chinook Salmon

Production

Overall average fall-run Chinook salmon simulated production for the simulation period was slightly higher for CP5 than for either the No-Action Alternative or Existing Condition (Attachments 9 and 10 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was almost 42 percent (in a below-normal water year) for CP5, and the largest decrease in was 36 percent (critical water year) (Table 11-47 and Attachment 9 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was around 162 percent (critical water year), and the largest decrease in production was 6.5 percent (wet water year) (Table 11-51 and Attachment 10 of the Modeling Appendix). Figure 11-11 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Table 11-51. Change in Production Under CP5 for Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
No-Action Alternative								
All	81	29,917,761	399,355	1.4	41.7	13	-36.0	4
Critical	13	27,603,770	1,158,942	4.4	34.9	4	-36.0	1
Dry	17	30,477,780	937,620	3.2	25.0	5	-2.4	0
Below Normal	14	31,664,669	566,758	1.8	41.7	2	-6.3	1
Above Normal	11	30,957,316	-75,694	-0.2	5.8	1	-1.8	0
Wet	26	29,328,136	-221,539	-0.7	5.0	1	-6.6	2
Existing Conditions								
All	81	30,073,307	644,966	2.2	162	13	-6.5	2
Critical	13	28,683,817	2,507,681	9.6	162	5	-1.5	0

Below Normal	14	31,576,655	558,393	1.8	53.2	2	-5.8	1
Above Normal	11	30,739,508	-130,889	-0.4	3.0	0	-3.0	0
Wet	26	29,414,471	-152,799	-0.5	5.3	1	-6.5	1

Note:

Production is the number of immature smolts surviving to pass the Red Bluff Pumping Plant

Key:

CP = Comprehensive Plan

Under CP5, four critical, five dry, two below-normal, one above-normal, and one wet water year had significant increases in production relative to the No-Action Alternative. Significant decreases in production occurred in one critical, one below-normal, and two wet water years.

Compared with Existing Conditions, five critical, five dry, two below-normal, and one wet water year had significant increases in production. One below-normal and one wet water year resulted in significantly decreased production relative to the Existing Condition.

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on fall-run Chinook salmon caused by the actions of the project (Attachments 9 and 10). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)‒around 65 percent of the total mortality.

Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 9 and 10 of the Modeling Appendix). Under both 2030 and 2005 conditions, the greatest mortality based on the smolt equivalents to fall-run Chinook salmon under CP5 (as with CP1 through CP4) in all water year types based on smolt equivalents occurred to fry, followed by eggs, prespawn adults, presmolts, and lastly immature smolts. Flow-related effects triggered a higher percentage of the operations-related mortality (Table 11-9). In all water year types, the greatest portion of mortality under CP1 occurred to fry caused by forced movement to downstream habitats. Other non-flow- and water temperature-related conditions were the primary causes of mortality for all life stages except fry (Attachments 9 and 10 in the Modeling Appendix).

There was no real trend with respect to years with the greatest mortality. Years with the lowest production were in all water years except above-normal water years, and were preceded by all water year types.

Because fall-run Chinook salmon would have a significant reduction in mortality, but an insignificant change in average production, fall-run Chinook salmon would experience a less-than-significant impact from actions taken in CP5. Additionally, fall-run Chinook salmon would benefit from the downstream restoration efforts, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

Late Fall-Run Chinook Salmon and Steelhead

Late fall-run Chinook salmon were evaluated directly using SALMOD and were considered to be a surrogate for steelhead; therefore, the following discussion regarding SALMOD results for late fall-run Chinook salmon are applicable to steelhead.

Production

Overall average late fall-run Chinook salmon simulated production for the 80-year period was similar to CP5 and the No-Action Alternative and the Existing Condition (Attachments 12 and 13 of the Modeling Appendix). The maximum increase in production relative to the No-Action Alternative was around 14 percent for CP5, while the largest decrease in production relative to the No-Action Alternative was just over 8 percent for CP5 (Table 11-52 and Attachment 12 of the Modeling Appendix). The maximum increase in production relative to the Existing Condition was 15 percent for CP5, while the largest decrease in production relative to the Existing Condition was less than 5 percent for CP5 (Table 11-52 and Attachment 13 of the Modeling Appendix). Figure 11-12 shows the change in production relative to the No-Action Alternative for all water years and all Comprehensive Plans.

Under CP5, one critical and three dry water years had significant increases in production compared to the No-Action Alternative. One critical water year had a significant decrease in production.

Under CP5, three critical and two dry water years had greater significant increases in production compared to the Existing Condition. There were no water years in which there was a significant decrease in production.

Table 11-52. Change in Production Under CP5 for Late Fall-Run Chinook Salmon

Year Type	Number of Years	Average Production	Change in Production from Baseline	Percent Change in Average Production	Maximum Percent Increase in Production	Number of Years with Significant Increase	Maximum Percent Decrease in Production	Number of Years with Significant Decrease
Future Condition (2030)

Late fall-run Chinook salmon are used as a surrogate for steelhead

Key:

CP = Comprehensive Plan

Mortality

Mortality was separated by flow- and water temperature-related mortality to assess the level of impacts on late fall-run Chinook salmon caused by the actions of the project (Attachments 12 and 13). In all cases, most mortality is caused by nonoperations-related factors (e.g., disease, predation, entrainment)−around 78 percent of the total mortality.

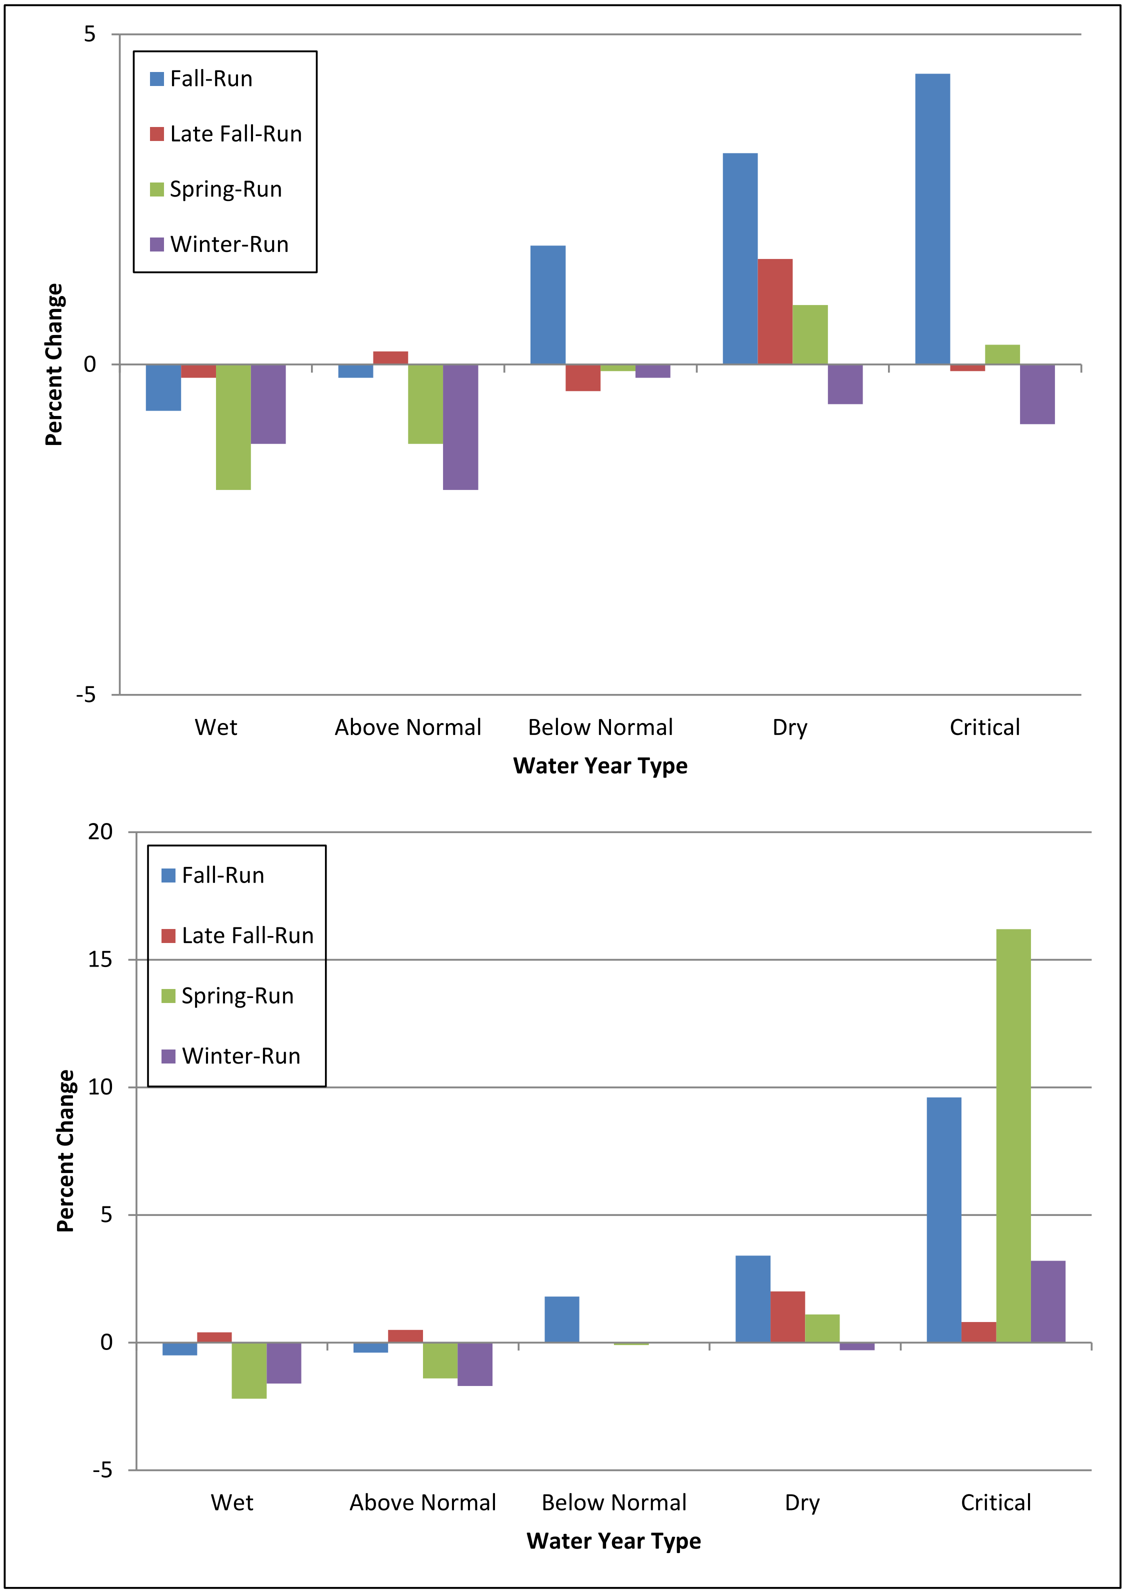
Mortality is presented in two manners–total mortality and smolt equivalent mortality (Attachments 12 and 13 of the Modeling Appendix). Under both 2030 and 2005 conditions, the largest mortality to late fall-run Chinook salmon under CP1 (as with CP1 and CP2) in all water year types based on smolt equivalents, occurred to the egg life stage, followed by fry, then presmolts, and lastly to immature smolts.

Years with the highest mortality were the same for CP5 and the No-Action Alternative and the Existing Condition, and occurred in all water year types. Four of these years were preceded by a wet water year, and the rest were each preceded by an above-normal, a below-normal, or a dry water year (Attachments 12 and 13 of the Modeling Appendix).

Because SALMOD indicates an insignificant change in mortality and production index for late fall-run Chinook salmon under CP5, late fall-run Chinook salmon and steelhead (as represented by their surrogate late fall-run Chinook salmon) would experience a less-than-significant impact from actions taken in CP5. Additionally, late fall-run Chinook salmon and steelhead will benefit from the downstream restoration efforts, although this was not modeled with SALMOD. Mitigation for this impact is not needed, and thus not proposed.

All Chinook Runs Combined

Raising Shasta Dam by 18.5 feet, in conjunction with spillway modifications, would result in an increase in full pool depth of 20.5 feet and an additional 634,000 acre-feet of storage capacity in Shasta Reservoir. The additional storage created by the dam raise would be used to improve the ability to meet water temperature objectives and habitat requirements for anadromous fish during drought years (see Figure 11-53). Under the 2030 conditions, overall production for all four runs of Chinook salmon combined would increase by nearly 378,000 immature smolts migrating below RDPP. Under the 2005 conditions, overall production for all four runs of Chinook salmon combined would increase by almost 685,000 immature smolts migrating below RDPP.



Note: Changes in outmigrating Chinook salmon simulated using SALMOD; Water Year Types based on the Sacramento Valley Water Year Hydrologic Classification

Figure 11-53. Percent Change in Production of Chinook Salmon for CP5 Compared to the No-Action Alternative (top) and Existing Conditions (bottom)

Impact Aqua-13 (CP5): Changes in Flow and Water Temperature in the Upper Sacramento River Resulting from Project Operation – Steelhead, Green Sturgeon, Sacramento Splittail, American Shad, and Striped Bass CP5 operations generally would result in slightly improved flow and water temperature conditions in the upper Sacramento River for steelhead, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be less than significant.

This impact would be the same as Impact Aqua-13 (CP3). As under CP3, monthly mean flows at all modeling locations along the upper Sacramento River under CP5 would generally be equivalent to (less than 5-percent difference from) flows under the Existing Condition and No-Action Alternative conditions simulated for all months. Changes in monthly mean flows under CP5 would have no discernible effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass in the upper Sacramento River. Functional flows for migration, attraction, spawning, egg incubation, and rearing/emigration for these species would be unchanged.

Also, as under CP3, monthly mean water temperatures at all modeling locations along the upper Sacramento River under CP5 would be the same as or fractionally lower than those under the Existing Condition and No-Action Alternative simulated for all months (Figures 11-54 and 11-55). The slightly cooler monthly mean water temperatures under CP5 relative to the Existing Condition and the No-Action Alternative would have very small effects on steelhead, green sturgeon, Sacramento splittail, American shad, or striped bass. Monthly mean water temperatures would not rise above important thermal tolerances for the species life stages relevant to the upper Sacramento River.

Therefore, with respect to both flow- and water temperature-related effects on fish species, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Figure 11-55. Changes in Mean Monthly Water Temperature at Modeled Locations in the Sacramento River Within the Primary Study Area (CP5 Versus No-Action Alternative)

Impact Aqua-14 (CP5): Reduction in Ecologically Important Geomorphic Processes in the Upper Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operations could cause a reduction in the magnitude, duration, and frequency of intermediate to large flows both in the upper Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-14 (CP1). The impact could be greater under CP5 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, reducing the potential for downcutting. These processes are regulated by the magnitude and frequency of flow. Relatively large floods provide the energy required to mobilize sediment from the riverbed, produce meander migration, increase stage elevation, and create seasonally inundated floodplains. Operations under CP5 could result in a reduction in the intermediate to large flows necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Implementation of CP5 would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows, relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing effects on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These effects would likely occur throughout the upper Sacramento River portion of the primary study area.

As discussed above, CP5 also includes a 10-year gravel augmentation program and the restoration of riparian, floodplain, and side-channel habitat at up to six potential restoration sites as additional environmental commitments. Placing gravel along the Sacramento River channel and bank annually and restoring riparian, floodplain, and side-channel habitat at up to six sites would result in benefits to ecological processes (e.g., sediment transport and deposition, floodplain inundation) that would partially offset the effects described above. Nevertheless, reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Lower Sacramento River and Tributaries, Delta, and Trinity River

Impact Aqua-15 (CP5): Changes in Flow and Water Temperatures in the Lower Sacramento River and Tributaries and Trinity River Resulting from Project Operation – Fish Species of Primary Management Concern   Project operation would result in no discernible change in monthly mean flows or water temperature conditions in the lower Sacramento River. However, predicted changes in flow in the Feather, American, and Trinity rivers could result in adverse effects on Chinook salmon, steelhead, Coho salmon, green sturgeon, Sacramento splittail, American shad, and striped bass. This impact would be potentially significant.

This impact would be similar to Impact Aqua-15 (CP1). The impact could be greater under CP5 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and increased cold-water pool) behind the raised dam.

As described below, mean monthly flows at various modeling locations on the lower Sacramento River and tributaries under CP5 were compared with mean monthly flows simulated for Existing Conditions and No-Action Alternative conditions. See the Modeling Appendix for complete CalSim-II modeling results.

Lower Sacramento River As under CP3, monthly mean flows at the lower Sacramento River modeling locations under CP5 would be essentially equivalent to flows under the Existing Condition and No-Action Alternative conditions simulated for all months. Differences in monthly mean flow were generally small (less than 2 percent) and within the existing range of variability. Potential changes in flows would diminish rapidly downstream from RBPP because of the increasing effects of tributary inflows, diversions, and flood bypasses. Potential flow-related effects of CP5 on fish species of management concern in the lower Sacramento River would be minimal. Potential changes in water temperatures in the lower Sacramento River caused by small changes in releases would diminish rapidly downstream because of the increasing effects of inflows, atmospheric influences, and groundwater. Therefore, flow- and temperature-related impacts on fish species in the lower Sacramento River would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Feather River, American River, and Trinity River Also, as under CP3, monthly mean flows at all modeling locations on the lower Feather River, the American River, and the Trinity River under CP5 would be essentially equivalent to (less than 2-percent difference from) flows under the Existing Condition and No-Action Alternative simulated for most months. However, simulations for several months within the modeling record show substantial changes to flows in tributaries. Potential changes in flows could be reduced by real-time operations to meet existing rules, and because of operation of upstream reservoirs (Lake Oroville, Folsom Lake, and Trinity Lake) and increasing effects from tributary inflows, diversions, and flood bypasses. Based on predicted changes in flow and associated flow-habitat relationships, potential flow-related impacts on species of management concern in the American, Feather, and Trinity rivers could occur. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, "Mitigation Measures."

Impact Aqua-16 (CP5): Reduction in Ecologically Important Geomorphic Processes in the Lower Sacramento River Resulting from Reduced Frequency and Magnitude of Intermediate to High Flows Project operation could cause a reduction in intermediate to large flows both in the lower Sacramento River and in the lowermost (confluence) areas of tributaries. Such flows are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains. These geomorphic processes are ecologically important because they are needed to maintain important aquatic habitat functions and values for fish and macroinvertebrate communities. This impact would be potentially significant.

This impact would be similar to Impact Aqua-16 (CP1). The impact could be greater under CP5 than under CP1 because the increased reservoir capacity associated with an 18.5-foot raise compared to a 6.5-foot raise would allow for storage of additional water volume (and flows) behind the raised dam.

Sediment transport, deposition, and scour regulate the formation of key habitat features such as point bars, gravel deposits, and SRA habitat. Intermediate to high flows and the associated stage elevation of the river surface also provide a backwater effect on the lowermost segment of tributaries, which reduces the potential for downcutting. These processes are regulated by the magnitude and frequency of flows. Relatively large floods provide the energy required to mobilize sediment from the bed, produce meander migration, increase stage elevation, create seasonally inundated floodplains, and inundate floodplain bypasses. Operations under CP5 could result in reduced intermediate to large flows that are necessary for channel forming and maintenance, meander migration, and the creation of seasonally inundated floodplains.

Implementation of CP5 would cause a further reduction in the magnitude, duration, and frequency of intermediate to large flows relative to the Existing Condition and No-Action Alternative. Overall, the project would increase the existing, ongoing impacts on geomorphic processes resulting from operation of Shasta Dam that are necessary for channel forming and maintenance, meander migration, the creation of seasonally inundated floodplains, and the inundation of floodplain bypasses. These effects would likely occur along the upper reaches of the lower Sacramento River.

Reductions in the magnitude of high flows would likely be sufficient to reduce ecologically important processes along the upper Sacramento River and its floodplain bypasses. This impact would be potentially significant. Mitigation for this impact is proposed in Section 11.3.4, “Mitigation Measures.”

Impact Aqua-17 (CP5): Effects to Delta Fisheries Resulting from Changes to Delta Outflow Based on the results of hydrologic modeling comparing Delta outflow under the No-Action Alternative, Existing Condition, and CP5, CP5 would result in changes to average monthly Delta outflow of less than 5 percent in all water year types (with the exception of September in dry years, November in above-normal years, and December of critical years). This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant.

Results of the comparison of Delta outflows under CP5 compared with the Existing Condition and No-Action Alternative are summarized by month and water year type in Table 11-53. Under 2030 and 2005 conditions, Delta outflows would decrease by greater than 5 percent only in November of above-normal water years, but would not result in an overall significant impact to Delta fisheries. Under 2030 conditions, Delta outflows would increase by 5 percent in September and December. An increase in Delta outflow by 200 to 300 cfs during dry and critical water years would not result in significant impacts to Delta fisheries, particularly at flows between 3,500 and 6,000, while a decrease in Delta outflow by around 700 cfs when outflows are higher in November would also not result in significant impacts to Delta fisheries. Based on the results of this comparison, it was concluded that CP5 would have a less-than-significant impact on Delta fisheries and hydrologic transport processed within the Bay-Delta as a consequence of changes in Delta outflow under existing conditions. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-18 (CP5): Effects to Delta Fisheries Resulting from Changes to Delta Inflow Based on the results of hydrologic modeling comparing Delta inflow under CP5 to the Existing Condition and No-Action Alternative, CP5 would not decrease average monthly Delta inflow by 5 percent or more in any year type (except in September of dry and critical years). This impact on Delta fisheries and hydrologic transport processes within the Bay-Delta would be less than significant.

Results of the comparison of Delta inflows are summarized by month and water year type in Table 11-54. Delta inflows were observed to be slightly lower under many of the CP5 operations and slightly higher than either the Existing Condition or the No-Action Alternative depending on month and water year type. Average monthly Delta inflow would increase by more than 5 percent during September of critical years compared to the Existing Condition, and during September of dry and critical years compared to the No-Action Alternative. Average monthly Delta inflow would not decrease by more than 5 percent in any water year type. Based on the results of this comparison, it was concluded that CP5 would have a less-than-significant effect on Delta fisheries and hydrologic transport processes within the Bay-Delta as a consequence of changes in Delta inflow. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-19 (CP5): Effects to Delta Fisheries Resulting from Changes in Sacramento River Inflow Project operation would result in a variable response in Sacramento River inflow, resulting in both increases and decreases in river flow above basis-of-comparison conditions depending on month and water year type. Decreases in Sacramento River inflow would not equal or exceed 5 percent. This impact would be less than significant.

Results of hydrologic modeling, by month and year type, for the Existing Condition, No-Action Alternative, and CP5 for Sacramento River inflow, are presented in Table 11-55. Results of these analyses show a variable response in Sacramento River inflow with CP5 operations resulting in both increases and decreases in river inflow above the Existing Condition and the No-Action Alternative, depending on month and water year. Under CP5, Sacramento River inflow would not decrease by 5 percent or more. Based on these results, the impact of CP5 on fish habitat and transport mechanisms within the lower Sacramento River and Delta would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-20 (CP5): Effects to Delta Fisheries Resulting from Changes in San Joaquin River Flow at Vernalis CP5 operation would result in no discernible change in San Joaquin River flows at Vernalis, and therefore no effects on fish habitat or transport mechanisms within the lower San Joaquin River and Delta compared with the Existing Condition and No-Action Alternative. There would be no impact.

Results of hydrologic modeling, by month and water year type, for the Existing Condition, No-Action Alternative, and CP5 for San Joaquin River flow are summarized in Table 11-56. Results of these analyses show that CP5 would have no effect on seasonal San Joaquin River flows compared with the Existing Condition and No-Action Alternative. Based on these results CP5 would have no impact on Delta fisheries or transport mechanisms within the lower San Joaquin River and Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-21 (CP5): Reduction in Low-Salinity Habitat Conditions Resulting from an Upstream Shift in X2 Location CP5 operation would result in less than 0.5 km movement upstream or downstream from the X2 location from its location under the Existing Condition or No-Action Alternative during February through May and September through November, and thus cause minimal reduction in low-salinity habitats. This impact would be less than significant.

The 1 km X2 criterion was applied to a comparison of hydrologic model results for the Existing Condition, No-Action Alternative, and CP5, by month and water year type, for the months from February through May and September through November. Results of the comparisons are summarized in Table 11-57. These results showed that changes in X2 location under CP5 were less than 1 km (all were less than 0.4 km) with both variable upstream and downstream movement of the X2 location depending on month and water year type. These results are consistent with model results for Delta outflow that showed a less-than-significant change in flows. Based on these results, CP5 would have a less-than-significant impact on low-salinity habitat conditions within the Bay-Delta. Mitigation for this impact is not needed, and thus not proposed.

Impact Aqua-22 (CP5): Increase in Mortality of Species of Primary Management Concern as a Result of Increased Reverse Flows in Old and Middle Rivers CP5 operation would result in minimal increases in reverse flows in Old and Middle rivers during January, March and April; however, flows do not exceed (become more negative) -5,000 cfs. Because the flows do not exceed -5,000 cfs, the increases in reverse flows are not expected to contribute to an increase in the vulnerability of delta smelt, longfin smelt, Chinook salmon, juvenile striped bass, or threadfin shad, but summer Old and Middle river flows could contribute to an increase in vulnerability of other resident warm-water fish to increased salvage and potential losses. This impact would be less than significant.

Results of the analysis showed several occurrences when reverse flows within Old and Middle rivers would be higher than either 2005 or 2030 conditions by more than 5 percent. These events would mainly occur in critical water years, which would be expected as a result of greater export operations under CP5. An increase in average monthly reverse flows of 5 percent also would occur in March of above-normal years.

During January (Table 11-58), operations under CP5 resulted in an increase in reverse flow of 5 percent during critical years compared with the No-Action Alternative. Based on results of the delta smelt analysis of the relationship between reverse flows and delta smelt salvage, the increase of approximately 200 cfs in a critical water year would not be expected to result in a significant increase in adverse effects to delta smelt or longfin smelt.

Note:
A positive percentage change reflects more negative reverse flows under CP5 when compared to the Existing Condition or the No-Action Alternative.
Key:
AN = above-normal
BN = below-normal
C = critical
cfs = cubic feet per second
CP = Comprehensive Plan
D = dry
W = wet

Juvenile Chinook salmon and steelhead are migrating through the Delta during January, and an increase in average monthly reverse flows of around 200 cfs would be expected to increase the potential risk of increased mortality to these species. However, given the tidal volumes and hydrodynamics of the Old and Middle rivers region, it is not expected that the change in reverse flows in January in a critical year would result in a detectable change in fish survival. The majority of juvenile Chinook salmon emigrating from the San Joaquin River typically migrate downstream later in dry years and would not be expected to occur in high numbers within Old and Middle rivers in January.

The increase in average monthly reverse flows estimated to occur under CP5 in critical and above-normal water years in March (under 2005 conditions), in critical years in May (under 2030 conditions), and in critical years in July (under both 2005 and 2030 conditions) would exceed 5 percent. This increase could negatively affect resident warm water fish species.

Juvenile and larval delta smelt occur in the area in March through May, and juvenile and larval longfin smelt are present in March. A change in Old and Middle river flows of approximately 100 to 200 cfs may result in an increase in their vulnerability to CVP and SWP salvage, but this increase is expected to be less than significant. The increased reverse flows in May of critical water years would occur at a time of year when water temperatures in the Delta are typically increasing and juvenile Chinook salmon or steelhead may be more abundant in the area. However, changes to reverse flows in March and May would not exceed the -5,000 cfs criteria established by the USFWS and NMFS BOs, and would result in less-than-significant impacts to Chinook salmon and steelhead.

The increased average monthly reverse flows in July of critical years would occur at a time of year when water temperatures in the Delta are elevated and juvenile Chinook salmon or steelhead would not be expected to be present in the area. Longfin smelt would not be expected in the area, and low numbers of juvenile delta smelt may occur in the area in July. However, as water temperatures increase in the Delta during June and July, the majority of delta smelt are located farther downstream in Suisun Bay where temperatures are more suitable. Therefore, changes in reverse flows in July would result in less-than-significant impacts to Chinook salmon, steelhead delta smelt and longfin smelt.

The increase in reverse flows estimated from the modeling in July of a critical water year would be expected to contribute to a small increase in the vulnerability of juvenile striped bass, threadfin shad, and other resident warm-water fish to increased salvage and potential losses as a result of increased reverse flows. The increased reverse flows in low-flow years would be expected to result in a small but less-than-significant increase in mortality for resident warm-water fish inhabiting the south Delta.

The potential increase in losses during January, March and May under CP5 is considered to be less than significant for Chinook salmon, steelhead, delta smelt and longfin smelt. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species, and thus reduce effects to non-listed fish species as well.

Impact Aqua-23 (CP5): Increase in the Risk of Entrainment or Salvage of Species of Primary Management Concern at CVP and SWP Export Facilities Due to Changes in CVP and SWP Exports CP5 operations may result in an increase in CVP and SWP exports, which is assumed to result in a direct proportional increase in the risk of fish being entrained and salvaged at the facilities. Future operations of the SWP and CVP export facilities would continue to be managed and regulated in accordance with incidental take limits established for each of the protected fish by USFWS, NMFS, and CDFW. The resulting impact to Chinook salmon and steelhead would be less than significant; the resulting impact to delta smelt, longfin smelt striped bass, and splittail would be potentially significant. Overall, this impact would be potentially significant.

Results of the entrainment loss modeling at the CVP and SWP export facilities are presented in Table 11-59 for CP5. The estimated index of total numbers of fish lost annually, by species, is presented in Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report.* The difference between the nonoperations related and operations related fish mortality is represented as the entrainment index, shown in Table 11-55, to represent the effect of project operations on each selected fish species at the CVP and SWP facilities.

Table 11-59. Entrainment at the CVP and SWP Facilities Comparing Existing Conditions, No-Action Alternative, and CP5

	D	588	0.3	2,498	1.2
	C	2,976	2.9	4,432	4.6

Note:
Negative percentage change reflects a reduction in entrainment risk while a positive percentage change reflects an increase in entrainment risk.
Key:
AN = above-normal
BN = below-normal
C = critical
CP = Comprehensive Plan
D = dry
W = wet

Results of the entrainment risk calculations for delta smelt showed a change of less than 1 percent in wet, above-normal, and below-normal water years and an increase in risk of less than 3 percent during critical water years under CP5 relative to the Existing Condition (Table 11-59). The risk of increased losses of delta smelt under CP5 compared to the No-Action Alternative (Table 11-59) would be greatest in the below-normal water years. Although the incremental change in the risk of delta smelt losses resulting from CVP and SWP export operations is small, delta smelt population abundance is currently at such critically low levels that even a small increase in the risk of losses is considered to be potentially significant. The increase in risk would also contribute to cumulative factors affecting the survival of delta smelt.

The estimated change in the risk of losses for salmon increases during below-normal and critical water years under 2005 conditions, and above-normal and below-normal water years under 2030 conditions (Table 11-59). Given the numbers of juvenile Chinook salmon produced each year in the Central Valley, the relatively small incremental increase in the risk of entrainment/salvage at the CVP and SWP export facilities would be a less-than-significant direct impact but would contribute incrementally to the overall cumulative factors affecting juvenile Chinook salmon survival within the Delta, and population dynamics of the stocks.

The change in the risk of longfin smelt entrainment/salvage under CP5 compared to the No-Action Alternative and to the Existing Condition shows small positive and negative changes depending on water year type and alternative (Table 11-59). These small changes in the risk of entrainment would be less than significant in most water years. The estimated 3 percent increase in entrainment risk in critically dry years is potentially significant given the trend of low longfin smelt juvenile production in dry years.

The change in the risk to steelhead of entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-59. The small positive and negative changes in risk under wet, above-normal, below-normal, and dry water years are considered to be less than significant. The increase in risk of steelhead losses in critical water years are considered to be less than significant (less than 2 percent), but would contribute directly to cumulative factors affecting the survival and population dynamics of Central Valley steelhead. The predicted increase in potential entrainment risk for steelhead under critical water years represents an initial estimate of the change (percentage) between CP5 and Existing Conditions and the No-Action Alternative, and does not allow the predicted losses to be evaluated at the population level (see Attachment 1 of the *Fisheries and Aquatic Ecosystems Technical Report)*.

The estimated changes in risk to juvenile striped bass from entrainment/salvage at the CVP and SWP export facilities are summarized in Table 11-55. The change in risk in wet, above-normal, and below-normal water years are considered to be less than significant for striped bass, but would contribute to the cumulative factors affecting striped bass survival and population dynamics in the Delta. The losses of juvenile striped bass increased substantially under dry and critical water years, which would be expected with an increase in exports during the summer months and is considered to be a potentially significant impact. The increased losses under CP5, particularly in drier water years when juvenile striped bass production is lower, would be expected to contribute to the cumulative effects of factors affecting juvenile striped bass survival in the Delta.

The overall average increased risk index for splittail was less than 1 percent under both 2005 and 2030 conditions, and was considered to be less than significant. The loss index is, however, higher during dry and critical water years. Higher risk of entrainment/salvage losses in drier water years has a potentially greater effect of abundance of juvenile splittail since reproductive success and overall juvenile abundance is typically lower within the Delta in dry years. The increased risk of losses in drier years was considered to be potentially significant. The increased losses would also contribute to cumulative factors affecting survival of juvenile splittail within the Delta.

Impact Aqua-23 (CP5) is considered to be less than significant for Chinook salmon and steelhead, but potentially significant for delta smelt, longfin smelt, striped bass, and splittail. Mitigation for this impact is not proposed because operations will be guided by RPAs established by NMFS and USFWS BOs to reduce any impacts to listed fish species, thus reducing the impacts to non-listed fish species.

CVP/SWP Service Areas

Impact Aqua-24 (CP5): Impacts on Aquatic Habitats and Fish Populations in the CVP and SWP Service Areas Resulting from Modifications to Existing Flow Regimes Project implementation could result in modified flow regimes that would reduce the frequency and magnitude of high winter flows along the Sacramento River; however, the hydrologic effects to tributaries and reservoirs (e.g., New Melones and San Luis) from CVP and SWP dams, as well as the conveyances south of the Delta would be substantially less than impacts on the lower Sacramento River. The change in hydrology to the CVP and SWP service areas could affect aquatic habitats that provide habitat for the fish community; however these changes would not result in substantial effects on their distribution or abundance. Therefore, this impact would be less than significant.

This impact would be similar to Impact Aqua-24 (CP1). The hydrologic effects to the CVP and SWP service areas would not result in substantial effects on the distribution or abundance of the fish species. The effects from CP5 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and the resulting downstream flows, would be small and well within the range of variability that commonly occurs in these reservoirs and downstream flows. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

11.3.4 Mitigation Measures

Table 11-60 presents a summary of mitigation measures for fisheries and aquatic ecosystems.

No-Action Alternative

No mitigation measures are required for this alternative.

Table 11-60. Summary of Mitigation Measures for Fisheries and Aquatic Ecosystems

Key:
B = beneficial
BO = Biological Opinion
CP = Comprehensive Plan
CVP = Central Valley Project
LOS = level of significance
LTS = less than significant
NI = No Impact
NMFS = National Marine Fisheries Service
PS = potentially significant
RPA = Reasonable and Prudent Alternative
S = significant
SWP = State Water Project
USFWS = U.S. Fish and Wildlife Service

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts Aqua-1 (CP1) through Aqua-3 (CP1), Impacts Aqua-5 (CP1) and Aqua-6 (CP1), Impacts Aqua-8 (CP1) through Aqua-13 (CP1), or Impacts Aqua-17 through Aqua-21 (CP1). No mitigation is proposed for Impact Aqua-22 (CP1) or Impact Aqua-23 (CP1) because operations will be guided by RPAs established by NMFS and USFWS BOs, which should reduce impacts to listed and non-listed fish species. Mitigation measures are provided below for other impacts of CP1 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP1): Implement Mitigation Measure Geo-2 (CP1): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habits in the Vicinity of the Impact The loss of 18.5 miles of intermittent and perennial streams (including 6.2 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. As described in Preliminary Environmental Commitments and Mitigation Plan Appendix, Reclamation convened an interagency working group to enhance mitigation measures presented in the DEIS. The environmental commitments described in Chapter 2, "Alternatives," of the EIS and the Preliminary Environmental Commitments and Mitigation Plan Appendix are intended to address impacts to channels within the existing drawdown zone (1070 msl).

An outcome of the interagency work group discussions was the agreement that this mitigation measure would encompass efforts within the channels actually affected by the comprehensive plan, but would also be expanded to restore degraded aquatic habitat in channels upstream from Shasta Lake. In general, this mitigation measure would follow the approach to characterize, prioritize, and identify specific restoration actions described in the *California Salmonid Stream Habitat Restoration Manual – Fourth Edition* (DFG 2010).

For CP1, this mitigation measure would result in result in restoration of up to 18.5 miles of channel, with an emphasis on low-gradient perennial channels to be identified by an interagency work group to be convened by Reclamation. This mitigation focuses on restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near reaches within the proposed inundation zone and upstream reaches.

The interagency working group would focus on identification of specific tributaries to Shasta Lake that may benefit from various mitigation techniques using available information. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing the alternative. Implementation of this mitigation measure would reduce Impact Aqua-4 (CP1) to a less-than-significant level.

Mitigation Measure Aqua-7 (CP1): Implement Mitigation Measure Aqua-4 (CP1): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habits in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Aqua-4 (CP1). Implementation of this mitigation measure would reduce Impact Aqua-7 (CP1) to a less-than-significant level.

Mitigation Measure Aqua-14 (CP1): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP1), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP1) to a less-than-significant level.

Mitigation Measure Aqua-15 (CP1): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP1) to a less-than-significant level.

Mitigation Measure Aqua-16 (CP1): Implement Mitigation Measure Bot-7(CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP1), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-16 (CP1) to a less-than-significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts Aqua-1 (CP2) through Aqua-3 (CP2), Impacts Aqua-5 (CP2) and Aqua-6 (CP2), Impacts Aqua-8 (CP2) through Aqua-13 (CP2), or Impacts Aqua-17 (CP2) through Aqua-21 (CP2). No mitigation is proposed for Impact Aqua-22 (CP2) or Impact Aqua-23 (CP2) because operations will be guided by RPAs established by NMFS and USFWS BOs, which should reduce impacts to listed and non-listed fish species. Mitigation measures are provided below for other impacts of CP2 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP2): Implement Mitigation Measure Geo-2 (CP2): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP2) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of 25.5 miles of intermittent and perennial streams (including 8.2 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Aqua-4 (CP2) to a less-than-significant level.

Mitigation Measure Aqua-7 (CP2): Implement Mitigation Measure Aqua-4 (CP2): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Aqua-4 (CP2). Implementation of this mitigation measure would reduce Impact Aqua-7 (CP2) to a less-than-significant level.

Mitigation Measure Aqua-14 (CP2): Implement Mitigation Measure Bot-7(CP2): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP2) to a less-than-significant level.

Mitigation Measure Aqua-15 (CP2): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP2) to a less-than-significant level.

Mitigation Measure Aqua-16 (CP2): Implement Mitigation Measure Bot-7(CP2): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter 12, "Botanical Resources and Wetlands." The riverine ecosystem mitigation and adaptive management plan will include mitigation measures from Shasta Dam downstream to Colusa (RM 144). The plan will be developed and implemented before project construction, and will be consistent with and will support implementation of the Senate Bill 1086 program. The plan will also be developed in coordination with USFWS, NMFS, CDFW, and the SRCA Forum. One of the goals of the plan will be to ensure that project implementation results in no net reduction in the amount (i.e., frequency and magnitude) of overbank inundation; this includes inundation of floodplains and bypasses. Therefore, implementation of this mitigation measure would reduce Impact Aqua-16 (CP2) to a less-than-significant level.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation is required for Impacts Aqua-1 (CP3) through Aqua-3 (CP3), Impacts Aqua-5 (CP3) and Aqua-6 (CP3), Impacts Aqua-8 (CP3) through Aqua-13 (CP3), or Impacts Aqua-17 (CP3) through Aqua-21 (CP3). No mitigation is proposed for Impact Aqua-22 (CP3) or Impact Aqua-23 (CP3) because operations will be guided by RPAs established by NMFS and USFWS BOs, which should reduce impacts to listed and non-listed fish species. Mitigation measures are provided below for other impacts of CP3 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP3): Implement Mitigation Measure Geo-2 (CP3): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP3) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of 36.5 miles of intermittent and perennial streams (including 12.1 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Aqua-4 (CP3) to a less-than-significant level.

Mitigation Measure Aqua-7 (CP3): Implement Mitigation Measure Aqua-4 (CP3): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Aqua-4 (CP3).

Implementation of this mitigation measure would reduce Impact Aqua-7 (CP3) to a less-than-significant level.

Mitigation Measure Aqua-14 (CP3): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Aqua-14 (CP3) to a less-than-significant level.

Mitigation Measure Aqua-15 (CP3): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP3) to a less-than-significant level.

Mitigation Measure Aqua-16 (CP3): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this measure would reduce Impact Aqua-16 (CP3) to a less-than-significant level.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for Impacts Aqua-1 (CP4/CP4A) through Aqua-3 (CP4/CP4A), Impacts Aqua-5 (CP4/CP4A) and Aqua-6 (CP4/CP4A), Impacts Aqua-8 (CP4) through Aqua-13 (CP4), or Impacts Aqua-17 (CP4/CP4A) through Aqua-21 (CP4/CP4A). No mitigation is proposed for Impact Aqua-22 (CP4/CP4A) or Impact Aqua-23 (CP4/CP4A) because operations will be guided by RPAs established by NMFS and USFWS BOs, which should reduce impacts to listed and non-listed fish species. Mitigation measures are provided below for other impacts of CP4 or CP4A on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP4 or CP4A): Implement Mitigation Measure Geo-2 (CP4 or CP4A): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP3) described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The loss of 36.5 miles of intermittent and perennial streams (including 12.1 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact AQUA-4 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Aqua-7 (CP4 or CP4A): Implement Mitigation Measure Aqua-4 (CP4 or CP4A): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Aqua-4. Implementation of this mitigation measure would reduce Impact Aqua-7 (CP4 or CP4A) to a less-than-significant level.

Mitigation Measure Aqua-14 (CP4 or CP4A): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP4 or CP4A), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Aqua-14 (CP4 or CP4A) to a less-than-significant level.

Mitigation Measure Aqua-15 (CP4 or CP4A): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP4 or CP4A) to a less-than-significant level.

Mitigation Measure Aqua-16 (CP4 or CP4A): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP1), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this measure would reduce Impact Aqua-16 (CP4 or CP4A) to a less-than-significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impacts Aqua-1 (CP5) through Aqua-3 (CP5), Impacts Aqua-5 (CP5) through Aqua-13 (CP5), or Impacts Aqua-17 (CP5) through Aqua-21 (CP5). No mitigation is proposed for Impact Aqua-22 (CP5) or Impact Aqua-23 (CP5) because operations will be guided by RPAs established by NMFS and USFWS BOs, which should reduce impacts to listed and non-listed fish species. Mitigation measures are provided below for the other impacts of CP5 on fisheries and aquatic ecosystems.

Mitigation Measure Aqua-4 (CP5): Implement Mitigation Measure Geo-2 (CP5): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Geo-2 (CP3) described in Chapter 4, “Geology, Geomorphology, Minerals, and Soils.” The loss of 36.5 miles of intermittent and perennial streams (including 12.1 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. Compensation will be accomplished by restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Aqua-4 (CP5) to a less-than-significant level.

Mitigation Measure Aqua-7 (CP5): Implement Mitigation Measure Aqua-4 (CP5): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is the same as Mitigation Measure Aqua-4. Implementation of this mitigation measure would reduce Impact Aqua-7 (CP5) to a less-than-significant level.

Mitigation Measure Aqua-14 (CP5): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Aqua-14 (CP5) to a less-than-significant level.

Mitigation Measure Aqua-15 (CP5): Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements Flows in the Feather, American, and Trinity rivers will be maintained pursuant to existing operational agreements, BOs, criteria, and standards that are protective of fisheries resources. Implementation of this measure would reduce Impact Aqua-15 (CP5) to a less-than-significant level.

Mitigation Measure Aqua-16 (CP5): Implement Mitigation Measure Bot-7 (CP3): Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this measure would reduce Impact Aqua-16 (CP5) to a less-than-significant level.

11.3.5 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," in Chapter 3, lists the projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level.

As described in Section 11.1, "Affected Environment," aquatic habitats within the primary and extended study areas historically contained large populations of anadromous and other native fish species. Water supply projects, urban development, pollution, and flood control modifications have resulted in altered and degraded habitat conditions and reduced this historical fishery throughout the primary and extended study areas. The combined effects of past and present projects have resulted in a significant adverse cumulative impact on fisheries and aquatic ecosystems of the Sacramento River and its watershed.

Many of the reasonably foreseeable future projects identified in Chapter 3 (see Table 3-1) under the Quantitative Analysis would involve changes to SWP and CVP water operations downstream from Shasta Dam. Also, projects listed in Table 3-1 under Qualitative Analysis would result in potential changes such as changes to operations of hydroelectric projects upstream from Shasta Dam, which would in turn be anticipated to affect fisheries and aquatic ecosystems. Example projects from Table 3-1 that may contribute to cumulative impacts include, but are not limited to, the CVPIA; Clear Creek Actions of the AFRP; CALFED ERP; BDCP; Fish Passage Programs at Shasta, Folsom, and Yuba Rivers; and the San Joaquin River Restoration Program. While some of these changes could result in beneficial effects compared to current conditions, aquatic habitat and fisheries resources would remain limited due to continuing effects from blockage of upstream fish habitat, blockage of spawning gravels, mortality due to water diversions, habitat alterations caused by large-scale modifications to hydrology (hydromodification), and high water temperatures due to lack of riparian vegetation and hydromodification.

The effects of climate change during this century on operations at Shasta Lake and downstream and upstream from the dam, could result in changes to water temperature, flow, and ultimately, fish populations under the No-Action Alternative. As described in the Climate Change Modeling Appendix, climate change could result in increased inflows to Shasta Lake and higher reservoir releases in the future due to an increase in winter and early spring inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage flood events resulting from these potentially larger storms. Climate change could also result in reduced-end-of September carryover storage volumes, resulting in lower lake levels for a portion of the year, and a smaller cold-water pool resulting in warmer water temperature and reduced water quality within Shasta Reservoir. Most importantly, it is expected that climate change will result in increased water temperatures downstream from Shasta Dam, particularly in summer months, and more frequent wet and drought (particularly extended drought) years. The increased water temperatures, and greater inter-annual precipitation variability will compound the threats to fish (especially anadromous fish) in the Sacramento River. Winter-run Chinook salmon are particularly vulnerable to climate warming, prolonged droughts, and other catastrophic environmental events because they have only one remaining population that spawns during the summer months, when water temperature increases are expected to be the largest (NMFS 2009, 2014). Additionally, ocean productivity is expected to decline from altered upwelling cycles. This could reduce the available food resources for ocean-rearing salmonids and sturgeon, impacting fish survival.

Climate change is also expected to result in sea-level rise during this century, which will have effects on Delta salinity levels due to greater tidal excursion. This in turn will affect the location of X2 (2 parts per thousand salinity concentration) position from February through June, moving X2 upstream, which will have adverse effects to native species in the Delta under the No-Action Alternative.

The following analysis evaluates the potential cumulative impacts on fisheries and aquatic ecosystems when considering the project alternatives in combination with other past, present, and reasonably foreseeable future projects.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As described in Section 11.3.3, “Direct and Indirect Effects,” without mitigation, CP1 could cause potentially significant effects on vegetation and habitats and special-status species in the primary and extended study areas. These effects would be caused by the loss or degradation of aquatic habitats in the primary study area, or by alteration of the flow regime of the Sacramento

River downstream from Keswick Dam and associated geomorphic processes in the primary and extended study areas.

Given the scale and duration of the project construction activities associated with CP1, the contribution of CP1 to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP1 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the CVRWQCB. The SWPPP would require implementation of extensive BMPs during project construction, as well as postconstruction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the project's contribution to cumulative construction-related impacts to a less-than-significant level.

Given major past alterations to the Sacramento River's aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP1 would be cumulatively considerable; specifically, (1) additional inundation of potential riverine habitat for special-status mollusk species above Shasta Lake, (2) additional inundation of cold-water riverine spawning and rearing habitat above Shasta Lake, and (3) reduction of the magnitude and frequency of flows for ecologically important geomorphic processes in the upper and lower Sacramento River below Shasta Dam. With implementation of Mitigation Measure Aqua-4 (CP1) (focused on Shasta Lake and vicinity) and Mitigation Measures Aqua-14 (CP1) through Aqua-16 (CP1) (focused on the Sacramento River downstream from Shasta Lake), adverse effects from CP1 would be reduced and would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP1 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for Chinook spawning. Additionally, habitat for both warm- and cold-water reservoir fisheries would be increased with an enlarged reservoir area. Under CP1, potential impacts to Sacramento River fish downstream from Shasta Dam would be beneficial.

Modeling conducted for the Climate Change Modeling Appendix was inconclusive about the effects of this alternative on Delta salinity. If exports are increased under this alternative, it could have an adverse effect on the location of X2, when considered along with other potential projects. However, if the location of X2 remains a water quality and regulatory requirement, then additional exports would not occur when X2 compliance would be violated. Therefore, no cumulative impact on X2 will occur under this alternative.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

The cumulative effects of CP2 on special-status mollusks above Shasta Dam, cold-water fish spawning and rearing habitat above Shasta Dam, and ecologically important geomorphic processes below Shasta Dam would be associated with mechanisms similar to those of CP1. However, the magnitude of these impacts would be greater, in many cases, because of the greater inundation area and greater effects increased storage volume on the timing, magnitude, and duration of flows downstream than would occur under CP1.

Given the scale and duration of the project construction activities associated with CP2, the contribution of CP2 to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP2 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the CVRWQCB. The SWPPP would require implementation of extensive BMPs during project construction, as well as post construction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the project’s contribution to cumulative construction-related impacts to a less-than-significant level.

Given major past alterations to the Sacramento River’s aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP2 would be cumulatively considerable; specifically, (1) additional inundation of potential riverine habitat for special-status mollusk species above Shasta Dam, (2) additional inundation of cold-water riverine fish spawning and rearing habitat above Shasta Dam, and (3) reduction of the magnitude and frequency of flows for ecologically important geomorphic processes in the upper and lower Sacramento River below Shasta Dam. With implementation of Mitigation Measure Aqua-4 (CP2) (focused on Shasta Lake and vicinity) and Mitigation Measures Aqua-14 through Aqua-16 (CP2) (focused on the Sacramento River downstream from Shasta Lake), adverse effects from CP2 would be further reduced, in combination with the downstream geomorphic restoration program elements, and would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP2 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for Chinook spawning. Additionally, habitat for both warm- and cold-water reservoir fisheries would be increased with an enlarged reservoir area. Under CP2, potential impacts to Sacramento River fish below Shasta Dam would be beneficial.

Modeling conducted for the Climate Change Modeling Appendix was inconclusive about the effects of this alternative on Delta salinity. If exports are increased under this alternative, it could have an adverse effect on the location of X2, when considered along with other potential projects. However, if the location of X2 remains a water quality and regulatory requirement, then additional exports would not occur when X2 compliance would be violated. Therefore, no cumulative impact on X2 will occur under this alternative.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

The cumulative effects of CP3 on special-status mollusks above Shasta Dam, cold-water fish spawning and rearing habitat above Shasta Dam, and ecologically important geomorphic processes below Shasta Dam would be associated with mechanisms similar to those of CP1 and CP2. However, the magnitude of these impacts would be greater, in many cases, because of the greater inundation area and greater effects increased storage volume on the timing, magnitude, and duration of flows downstream than would occur under CP1 and CP2.

Given the scale and duration of the project construction activities associated with CP3, the contribution of CP3 to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP3 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the CVRWQCB. The SWPPP would require implementation of extensive BMPs during project construction, as well as postconstruction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the project's contribution to cumulative construction-related impacts to a less-than-significant level.

Given major past alterations to the Sacramento River's aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP3 would be cumulatively considerable; specifically, (1) additional inundation of potential riverine habitat for special-status mollusk species above Shasta Dam, (2) additional inundation of cold-water riverine fish spawning and rearing habitat above Shasta Dam, and (3) reduction of the magnitude and frequency of flows for ecologically important geomorphic processes in the upper and lower Sacramento River below Shasta Dam. With implementation of Mitigation Measure Aqua-4 (CP3) (focused on Shasta Lake and vicinity) and Mitigation Measures Aqua-14 (CP3) through Aqua-16 (CP3) (focused on the Sacramento River downstream from Shasta Lake), adverse effects from CP3 would be further reduced, in combination with the downstream geomorphic restoration program elements, and would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP3 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for Chinook salmon. Additionally, habitat for both warm- and cold-water reservoir fisheries would be increased with an enlarged reservoir area. Under CP3, potential impacts to Sacramento River fish below Shasta Dam would be beneficial.

Modeling conducted for the Climate Change Modeling Appendix was inconclusive about the effects of this alternative on Delta salinity. If exports are increased under this alternative, it could have an adverse effect on the location of X2, when considered along with other potential projects. However, if the location of X2 remains a water quality and regulatory requirement, then additional exports would not occur when X2 compliance would be violated. Therefore, no cumulative impact on X2 will occur under this alternative.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The cumulative effects of CP4 or CP4A on special-status mollusks above Shasta Dam, cold-water fish spawning and rearing habitat above Shasta Dam, and ecologically important geomorphic processes below Shasta Dam would be associated with mechanisms similar to those of CP1, CP2, and CP3. However, the magnitude of these impacts would be greater, in many cases, because of the greater inundation area and greater effects increased storage volume on the timing, magnitude, and duration of flows downstream than would occur under CP1 and CP2, but similar to CP3. Some of these impacts would be partially offset with the implementation of the gravel augmentation program, floodplain and riparian restoration at six potential sites along the Sacramento River between Keswick Dam and Red Bluff, and cold-water supply for anadromous fish management.

Given the scale and duration of the project construction activities associated with CP4 or CP4A, the contribution of CP4 or CP4A to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP4 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the CVRWQCB. The SWPPP would require implementation of extensive BMPs during project construction, as well as postconstruction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the project's contribution to cumulative construction-related impacts to a less-than-significant level.

Given major past alterations to the Sacramento River's aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP4 or CP4A would be cumulatively considerable; specifically, (1) additional inundation of potential riverine habitat for special-status mollusk species above Shasta Dam, (2) additional inundation of cold-water riverine fish spawning and rearing habitat above Shasta Dam, and (3) reduction of the magnitude and frequency of flows for ecologically important geomorphic processes in the upper and lower Sacramento River below Shasta Dam. With implementation of Mitigation Measure Aqua-4 (CP4/CP4A) (focused on Shasta Lake and vicinity) and Mitigation Measures Aqua-14 (CP4/CP4A) through Aqua-16 (CP4/CP4A) (focused on the Sacramento River downstream from Shasta Lake), adverse effects from CP4 or CP4A would be further reduced, in combination with the downstream geomorphic restoration program elements, and would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP4 or CP4A would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for Chinook salmon. Additionally, habitat for both warm- and cold-water reservoir fisheries would be increased with an enlarged reservoir area. Under CP4 or CP4A, potential impacts to Sacramento River fish below Shasta Dam would be beneficial.

Modeling conducted for the Climate Change Modeling Appendix was inconclusive about the effects of this alternative on Delta salinity. If exports are increased under this alternative, it could have an adverse effect on the location of X2, when considered along with other potential projects. However, if the location of X2 remains a water quality and regulatory requirement, then additional exports would not occur when X2 compliance would be violated. Therefore, no cumulative impact on X2 will occur under this alternative.

CP5 – 18.5-Foot Dam Raise, Combination Plan

The cumulative effects of CP5 on special-status mollusks above Shasta Dam, cold-water fish spawning and rearing habitat above Shasta Dam, and ecologically important geomorphic processes below Shasta Dam would be associated with mechanisms similar to those of CP1, CP2, CP3, CP4, and CP4A. However, the magnitude of these impacts would be greater, in many cases, because of the greater inundation area and greater effects increased storage volume on the timing, magnitude, and duration of flows downstream than would occur under CP1 and CP2, but similar to CP3 and CP4/CP4A. Some of these impacts would be partially offset with the implementation of the gravel augmentation program, and floodplain and riparian restoration at six potential sites along the Sacramento River between Keswick Dam and Red Bluff.

Given the scale and duration of the project construction activities associated with CP5, the contribution of CP5 to construction-related cumulative impacts on fisheries and aquatic ecosystems would be cumulatively considerable. CP5 would be undertaken in accordance with a project-specific SWPPP as reviewed and approved by the CVRWQCB. The SWPPP would require implementation of extensive BMPs during project construction, as well as postconstruction site restoration and stabilization to control erosion and sedimentation and to prevent the discharge of pollutants into the Sacramento River and other waterways. Implementation of these measures would reduce the project's contribution to cumulative construction-related impacts to a less-than-significant level.

Given major past alterations to the Sacramento River's aquatic ecosystem and associated aquatic habitats, the contributing adverse effects from CP5 would be cumulatively considerable; specifically, (1) additional inundation of potential riverine habitat for special-status mollusk species above Shasta Dam, (2) additional inundation of cold-water riverine fish spawning and rearing habitat above Shasta Dam, and (3) reduction of the magnitude and frequency of flows for ecologically important geomorphic processes in the upper and lower Sacramento River below Shasta Dam. With implementation of Mitigation Measure Aqua-4 (CP5) (focused on Shasta Lake and vicinity) and Mitigation Measures Aqua-14 (CP5) through Aqua-16 (CP5) (focused on the Sacramento River downstream from Shasta Lake), adverse effects from CP5 would be reduced, in combination with the downstream geomorphic restoration program elements, and would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP5 would potentially reduce these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. More importantly, an increased cold-water pool volume will allow Shasta Lake to be managed to provide cooler water releases downstream during critical life stages, particularly for Chinook salmon. Additionally, habitat for both warm- and cold-water reservoir fisheries would be increased with an enlarged reservoir area. Under CP5, potential impacts to Sacramento River fish below Shasta Dam would be beneficial.

Modeling conducted to evaluate project effects on Delta salinity for the Climate Change Modeling Appendix was focused on CP5. Under this alternative Delta outflows are reduced by 15,000 to 100,000 acre-feet/year compared to the Baseline due to greater diversions. The changes are largest with the drier climate scenarios. If exports are increased under this alternative, it could have an adverse effect on the location of X2, when considered along with other potential projects. However, if the location of X2 remains a water quality and regulatory requirement, then additional exports would not occur when X2 compliance would be violated. Therefore, no cumulative impact on X2 will occur under this alternative.

Chapter 12
Botanical Resources and Wetlands

12.1 Affected Environment

This section describes the affected environment related to botanical resources and wetlands for the dam and reservoir modifications that are proposed under SLWRI action alternatives. For a more in-depth description, see the *Botanical Resources and Wetlands Technical Report*.

The botanical resources and wetlands setting for the Shasta Lake and vicinity portion of the primary study area consists of the impoundment area (five arms and the Main Body of Shasta Lake, as described below) and the relocation areas (Figure 12-1).

Reclamation established project boundaries for focused surveys in the areas that would be subject to inundation under the various enlargement scenarios. The lower boundary corresponds to the current full pool elevation defined by Reclamation (1,070-foot mean sea level contour line). The upper boundary was established using the 1,090-foot mean sea level contour line around the entire lake. This area is referred to as the “impoundment area” (Figure 12-1).

Areas subject to physical disturbance as an indirect result of the proposed project (i.e., areas proposed as relocation sites for roadways, bridges, utilities, and campgrounds that would be inundated after the enlargement of Shasta Dam as well as proposed dike locations) were incorporated into the Shasta Lake and vicinity portion of the primary study area. These locations are hereafter referred to as “relocation areas” (Figure 12-1).

To examine the biological resources along riverine reaches that would be subject to inundation if Shasta Dam were enlarged, reaches of 11 streams and rivers that are tributary to Shasta Lake were also incorporated into the Shasta Lake and vicinity portion of the primary study area. These streams were selected by Reclamation in conjunction with the USFS as an initial sampling of streams representative of riverine and riparian habitats. Subsequently, botany studies have been expanded into select areas of the impoundment area and within all of the relocation areas.

As a component of the SLWRI, Reclamation proposes to restore and/or enhance riparian and riverine habitats at six locations along the lower Sacramento River below Shasta Dam. These six locations occur generally between the city of Redding and Reading Island, Shasta County, California. The purpose of the restoration effort is to improve spawning and rearing habitat for anadromous fish occurring in the Sacramento River. These six locations are referred to as the potential Sacramento River downstream habitat restoration areas (Figure 12-2).

For the purposes of this investigation, approximate acreages for vegetation types and waters of the United States are reported by arm of the lake. For a relocation area that falls between two arms, the area is included with the arm that has the most acreage of the vegetation type or water of the United States. Habitats and waters of the United States are also reported for the potential Sacramento River downstream habitat restoration areas.

Vegetation communities and special-status plant species in the extended study area are discussed in less detail. The extended study area includes the Sacramento River basin from Red Bluff Pumping Plant (RBPP) south to the Delta. It also includes the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) area and portions of the American River basin, San Joaquin River basin, and the water service areas of the CVP and the SWP.

Descriptions of biological resources were derived primarily from the following sources:

- SLWRI Mission Statement Milestone Report (Reclamation 2003)
- SLWRI Initial Alternatives Information Report (Reclamation 2004)
- Chapter 3, "Biological Environment," in the Draft SLWRI Plan Formulation Report (Reclamation 2007)
- USFWS Endangered Species Lists
- The California Natural Diversity Database (CNDDB)
- The California Native Plant Society (CNPS) online inventory
- Numerous technical studies of botanical and wetland resources conducted by Reclamation in the Shasta Lake and vicinity portion of the primary study area since 2002.

Several attachments to the *Botanical Resources and Wetlands Technical Report* provide detailed lists and descriptions of special-status species present in the primary and extended study areas:

- Attachment 1, "Lists of All Special-Status Plant Species Known from or Potentially Present in the Primary and Extended Study Areas"
- Attachment 2, "List of Plant Species Observed in the Shasta Lake and Vicinity Portion of the Primary Study Area"
- Attachment 3, "Special-Status Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area"
- Attachment 4, "List of All Sensitive Plant Species in the Extended Study Area Reported to the CNDDB"
- Attachment 5, "Known Weed Source Locations, Potential Mode of Spread, and Risk of Spread"
- Attachment 6, "Botanical Survey Report 2002-2014"

12.1.1 Vegetation Communities

Shasta Lake and Vicinity

Reclamation conducted extensive mapping to characterize the plant communities in the Shasta Lake and vicinity portion of the primary study area. The study area for botanical resources and wetlands in the Shasta Lake and vicinity portion of the primary study area corresponds to the area that would be subject to inundation under all action alternatives and areas where infrastructure would be removed, modified, or relocated (Figure 12-1). The vegetation mapping followed the technical approach described in *A Manual of California Vegetation* (MCV) (Sawyer and Keeler-Wolf 1995), using the vegetation alliance classification system described in *A Manual of California Vegetation, Second Edition* (Sawyer et al, 2009).

The MCV represents the most recent effort to provide a common and accepted vegetation classification system for use throughout California. It classifies vegetation into a set of plant alliances, provisional alliances, special stands, or semi-natural stands. In this system, the plant species dominance or importance in the layer (i.e., tree, shrub, and ground) with the greatest amount of cover determines the vegetation alliance classification. The same approach used to describe and classify MCV types was applied when other vegetation types not described in the current MCV were encountered and determined to be significant vegetative components.

Vegetation mapping was conducted using recent 1:2,400-scale rectified color aerial photography. All vegetation mapping was performed in the field by ground truthing the primary study area from boat, vehicle, and/or on foot. MCV plant alliances were identified and delineated onto the aerial photographs. The delineated boundaries were digitized and generated in ArcGIS/ArcInfo software for display and data query purposes.

The Shasta Lake and vicinity area is characterized by a variety of vegetation types typical of transitional mixed woodland and low-elevation forest habitats. MCV plant series types in this portion of the primary study area are birch-leaf mountain mahogany chaparral, black willow thicket, blue oak woodland, Brewer's oak scrub, buck brush chaparral, California annual grassland, California black oak forest, California ash chaparral, California buckeye groves, California yerba santa scrub, canyon live oak forest, deer brush chaparral, Fremont cottonwood forest, ghost pine woodland, Himalayan blackberry brambles, interior live oak chaparral, interior live oak woodland, knobcone pine forest, mixed willow, Oregon ash groves, Oregon white oak woodland, pale spike rush marshes, ponderosa pine–Douglas fir forest, ponderosa pine forest, red osier thickets, sandbar willow thickets, spicebush thickets, valley oak woodland, white alder groves, and white leaf manzanita chaparral. Vegetation in each of these series varies, with dramatic changes often occurring in relation to aspect, slope, geologic substrate, or juxtaposition with other habitats.

Summaries of MCV types found in the impoundment area along the Main Body and the five arms of Shasta Lake are shown in Table 12-1, and the acreage of MCV types found in the relocation areas along the Main Body and the five arms of Shasta Lake is shown in Table 12-2. The locations of each type are depicted on Figures 12-3a through 12-3f. General descriptions of each type are provided below. Plant taxonomy follows Baldwin et al. (2012).

Barren Barren habitat consists mainly of nonvegetated human-made features. Barren habitat is scattered throughout the Shasta Lake and vicinity portion of the primary study area, including boat ramps, parking lots, and roads. Other barren habitats are a large gravel plain feature at the confluence of Butcher Creek and Shasta Lake (Main Body) and a sealed riprap feature adjacent to Interstate 5 near the upper Sacramento Arm and Shasta Lake confluence. Vegetation is usually not present, although sparse opportunistic grasses/forbs or weedy species may occur.

Birch-Leaf Mountain-Mahogany Chaparral Birch-leaf mountain-mahogany chaparral is a relatively common associate species in many chaparral and woodland plant series types. As a plant series, birch-leaf mountain-mahogany occurs in the Shasta Lake and vicinity portion of the primary study area along the upper McCloud and Sacramento arms. These sites are located on floodplain terraces and are characterized as moderate to dense chaparral stands dominated by birch-leaf mountain-mahogany (*Cercocarpus betuloides*), with occasional buck brush (*Ceanothus cuneatus*), poison oak (*Toxicodendron diversilobum*), western redbud (*Cercis occidentalis*), yerba santa (*Eriodictyon californicum*), and Brewer oak (*Q. garryana* var. b*reweri*).

Black Willow Thicket Although commonly associated with willow and other riparian plant series types, black willow thicket is uncommon in the Shasta Lake and vicinity portion of the primary study area. This plant series is dominated by black willow (*Salix gooddingii*), with spicebush (*Calycanthus occidentalis*), rushes (*Juncus* spp.), and California grape (*Vitis californica*). It occurs at only two locations in the Shasta Lake and vicinity portion of the primary study area, one along the Sacramento Arm and the other in the Jones Valley area (Pit Arm).

Blue Oak Woodland The blue oak plant series occurs mainly as small inclusions within other more prevalent plant series types; however, moderate-sized stands also occur. This plant series occurs at scattered locations along the Main Body, McCloud Arm, and Pit Arm and is characterized by open to moderate woodlands dominated by blue oak (*Quercus douglasii*). Associated tree species include occasional interior live oak (*Q. wislizenii* var. *wislizenii*) and gray pine (*Pinus sabiniana*). The shrub layer is open or absent, and a moderate to dense forb layer dominates the understory.

Brewer Oak Scrub The Brewer oak plant series consists of moderate to very dense stands of Brewer oak, the shrub form of Oregon white oak (*Q. garryana* var. *garryana*). This plant series type is widespread throughout the Shasta Lake and vicinity portion of the primary study area. Brewer oak stands are often nearly pure; occasionally, however, shrub species such as poison oak, white leaf manzanita, yerba santa, buck brush, bush poppy (*Dendromecon rigida*), Fremont's silktassel (*Garrya fremontii*), deer brush (*Ceanothus integerrimus*), skunkbrush (*Rhus trilobata*), and snowdrop bush (*Styrax officinalis*) occur in association with Brewer oak.

Buck Brush Chaparral Buck brush chaparral occurs at scattered locations throughout the Shasta Lake and vicinity portion of the primary study area. This plant series is dominated by moderate to dense stands of buck brush. Associated species include white leaf manzanita, poison oak, western redbud, yerba santa, Brewer oak, birch-leaf mountain-mahogany, and coffeeberry (*Frangula* sp.).

California Annual Grassland California annual grassland is uncommon in the Shasta Lake and vicinity portion of the primary study area, occurring only as small inclusions in other more prevalent plant series types or in areas subjected to previous disturbance. Dominant species include wild oat (*Avena fatua*), downy brome (*Bromus tectorum*), ripgut (*B. diandrus*), yellow star-thistle (*Centaurea solstitialis*), squirreltail (*Elymus elymoides*), and European hairgrass (*Aira caryophyllea*).

California Ash Chaparral California ash (*Fraxinus dipetala*) is a relatively common associate species in many chaparral and woodland plant series types. As a plant series, California ash chaparral occurs in the Shasta Lake and vicinity portion of the primary study area at several locations along the McCloud Arm. This plant series is characterized as a moderate to dense chaparral stand dominated by California ash, with occasional birch-leaf mountain-mahogany, buck brush, poison oak, western redbud, yerba santa, and Brewer oak.

California Black Oak The black oak series is characterized by moderate to dense stands of California black oak (*Quercus kelloggii*). This plant series is relatively common throughout the Shasta Lake and vicinity portion of the primary study area. Understory associates include white leaf manzanita (*Arctostaphylos viscida*), poison oak, snowdrop bush (*Styrax officinalis*), and buck brush. The ground layer is open to dense and is dominated by various grasses and forbs.

California Buckeye Groves Although a common associate in many plant series types in the Shasta Lake and vicinity portion of the primary study area, California buckeye groves are uncommon as a plant series type. This plant series is dominated by California buckeye (*Aesculus californica*). Associated species include poison oak, Brewer oak, buck brush, and various grasses and forbs. It occurs at only several scattered locations in the Sacramento Arm, McCloud Arm, and Pit Arm.

California Yerba Santa Scrub California yerba santa scrub is a relatively common associate species in many chaparral and woodland plant series types. California yerba santa is a pioneer species that readily responds to various disturbances and wildfire. As a plant series, California yerba santa scrub occurs in the Shasta Lake and vicinity portion of the primary study area at two general locations subject to wildfires in 2004 and 2008: the Dry Creek area (Main Body) and the Jones Valley area (Pit Arm). This plant series is characterized as moderate to dense chaparral stands dominated by California yerba santa, with occasional shrub interior live oak, shrub canyon live oak, buck brush, poison oak, western redbud, and Brewer oak.

Canyon Live Oak Forest The canyon live oak plant series is characterized by moderate to dense stands of canyon live oak (*Quercus chrysolepis*). This plant series is relatively common throughout the Shasta Lake and vicinity portion of the primary study area. Associated tree species include occasional California black oak. Understory associates include white leaf manzanita and poison oak. The ground layer is open to moderate and is dominated by various grasses and forbs.

Deer Brush Chaparral Deer brush chaparral is a relatively common associate in chaparral and forest plant series types in the Shasta Lake and vicinity portion of the primary study area; however, deer brush is uncommon in the study area as a plant series type. This plant series is dominated by deer brush. It occurs at several scattered locations along the Main Body, McCloud Arm, and Pit Arm.

Fremont Cottonwood Forest In the Shasta Lake and vicinity portion of the primary study area, Fremont cottonwood forest is an uncommon plant series type that occurs as single stands of trees along small portions of the upper Sacramento Arm and the Pit Arm. The dominant species is Fremont cottonwood (*Populus fremontii*).

Ghost (Gray) Pine The ghost pine plant series occurs in all parts of the Shasta Lake and vicinity portion of the primary study area except along the Big Backbone Arm. This plant series type is characterized by open to moderate stands of gray pine. Associated species include blue oak, canyon live oak, interior live oak, and California black oak. Shrub species are moderate to dense and include white leaf manzanita, western redbud, buck brush, Brewer oak, poison oak, and yerba santa.

Himalayan Blackberry Brambles Himalayan blackberry (*Rubus armeniacus*) is a common associate in many riparian plant series and in various other plant series with mesic microhabitats and/or previous disturbance. As a plant series, Himalayan blackberry brambles occur in portions of the Dry Creek (Main Body) and Jones Valley (Pit Arm) areas recently disturbed by wildfire. This plant series occurs in and along drainage and stream features and is characterized as dense thickets of Himalayan blackberry. Associated species include spicebush, willow, and rushes.

Interior Live Oak Chaparral In the Shasta Lake and vicinity portion of the primary study area, the interior live oak chaparral plant series is relatively uncommon, occurring mainly along the Sacramento Arm. However, this plant series also occurs at scattered locations along the Main Body, the McCloud Arm, and the Pit Arm. This plant series is dominated by moderate to dense stands of the shrub form of interior live oak. Associated species include Brewer oak, white leaf manzanita, poison oak, and buck brush.

Interior Live Oak Woodland The interior live oak woodland plant series is uncommon in the Shasta Lake and vicinity portion of the primary study area. It occurs in several small areas along the Sacramento Arm, the Pit Arm, the McCloud Arm, and the Main Body.

Knobcone Pine Forest The knobcone pine forest plant series consists of open to dense knobcone pine (*Pinus attenuata*) stands. This plant series is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. Knobcone pine forest often occurs at locations characterized by disturbances, including historic mining activities and past or recent wildfires. Dominant species include knobcone pine, with occasional canyon live oak, California black oak, ponderosa pine (*Pinus ponderosa*), and gray pine. The shrub layer is moderate to dense and is dominated by white leaf manzanita and poison oak. The ground layer varies and is dominated by various grasses and forbs.

Lacustrine Lacustrine habitat consists of the area regularly inundated by Shasta Lake (i.e., areas at and below the 1,070-foot elevation). Most of this area is barren of vegetation and is characterized as exposed soil and/or rock. Portions of the lacustrine habitat do support vegetation, including woody riparian species such as black willow, button willow (*Cephalanthus occidentalis*), Fremont cottonwood, and various grasses and forbs, during draw-down periods.

Mixed Willow Mixed willow is the most common willow plant series type in the Shasta Lake and vicinity portion of the primary study area and occurs throughout the entire area. Dominant species include red willow (*Salix laevigata*), black willow, shining willow (*S. lasiandra*), arroyo willow (*S. lasiolepis*), and narrowleaf willow (*S. exigua*).

Oregon Ash Groves Oregon ash groves are an uncommon plant series type in the Shasta Lake and vicinity portion of the primary study area. This type occurs along the upper McCloud Arm and is dominated by open to moderate stands of Oregon ash (*Fraxinus latifolia*) with willow, California grape, mock orange, brickellbush (*Brickellia* sp.), and poison oak.

Oregon White Oak Woodland The Oregon white oak woodland plant series is uncommon in the Shasta Lake and vicinity portion of the primary study area and occurs as small inclusions in other more prevalent plant series types. This plant series is characterized by open to moderate woodlands dominated by Oregon white oak. Associated tree species include occasional canyon live oak, blue oak, and California black oak. The shrub layer is open or absent, and a moderate to dense forb layer dominates the understory.

Pale Spike Rush Marshes Pale spike rush is an uncommon plant series in the Shasta Lake and vicinity portion of the primary study area; it is known to occur only in a portion of one relocation area near Lakehead (Sacramento Arm). This plant series is characterized as a seasonal wetland dominated by a complex of annual and perennial upland and wetland plant species. Dominant species include pale spike rush (*Eleocharis macrostachya*), jointed coyote-thistle (*Eryngium articulatum*), pennyroyal (*Mentha pulegium*), panic grass (*Panicum acuminatum*), iris-leaf rush (*Juncus xiphioides*), sedges (*Carex* spp.), rushes, poison oak, white leaf manzanita, western choke-cherry (*Prunus virginiana*), interior rose (*Rosa woodsii*), and Himalayan blackberry.

Ponderosa Pine–Douglas-Fir Ponderosa pine-Douglas-fir is the second-most-common conifer plant series type in the Shasta Lake and vicinity portion of the primary study area, occurring everywhere except along the Big Backbone Arm. This plant series is characterized by open to dense conifer stands dominated by Douglas-fir (*Pseudotsuga menziesii*) and ponderosa pine. Associated species include occasional sugar pine (*P. lambertiana*), incense cedar (*Calocedrus decurrens*), canyon live oak, and California black oak. Associated understory species vary and include Pacific dogwood (*Cornus nuttallii*), mock orange (*Philadelphus lewisii*), poison oak, snowdrop bush, and white leaf manzanita. The ground layer is open to moderate and is dominated by various grasses and forbs.

Ponderosa Pine Ponderosa pine is the most common conifer plant series type in the Shasta Lake and vicinity portion of the primary study area and is scattered throughout all portions of the area. This plant series is characterized by open to dense conifer stands dominated by ponderosa pine. Associated species include occasional Douglas-fir, sugar pine, incense cedar, canyon live oak, and California black oak. Associated understory species vary and include redbud, buck brush, mock orange, poison oak, snowdrop bush, and white leaf manzanita. The ground layer is open to moderate and is dominated by various grasses and forbs.

Red Osier Thickets Red osier is a common associate in many riparian plant series types in the Shasta Lake and vicinity portion of the primary study area. As a plant series, red osier thickets are an uncommon plant series type. In the vicinity of Shasta Lake, red osier thickets are found along the upper McCloud Arm. Dominant species include red osier (*Cornus stolonifera*), brown dogwood (*C. glabrata*), mock orange, spicebush, and California grape.

Riverine Riverine habitat includes the free-flowing portions of the larger Shasta Lake tributaries occurring in the Shasta Lake and vicinity portion of the primary study area. The riverine habitat is highly variable and ranges from moderate, low-gradient to steep, well-confined stream reaches.

Sandbar Willow Thickets Sandbar willow thicket is an uncommon plant series that occurs at one location each along the McCloud Arm and the Squaw Creek Arm. Dominant species include narrowleaf willow, with occasional red willow, black willow, shining willow, and arroyo willow.

Spicebush Thickets Spicebush is a common associate in many riparian plant series types in the Shasta Lake and vicinity portion of the primary study area. As a plant series, spicebush thickets are an uncommon plant series type. This plant series occurs at several locations along the McCloud Arm. Dominant species include spicebush, red osier, mock orange, and California grape.

Urban Urban habitat consists of various man-made features scattered throughout the Shasta Lake and vicinity portion of the primary study area, including resorts and a portion of the visitor center complex at Shasta Dam. These features are typically a combination of various buildings, pavement areas with manicured landscaping, and lawns.

Valley Oak Woodland Valley oak woodland is an uncommon plant series and occurs at two small locations in the Lakehead area (Sacramento Arm). Dominant species include valley oak (*Quercus lobata*) with white leaf manzanita, redbud, poison oak, and various grasses and forbs.

White Alder Groves The white alder plant series occurs in the riparian vegetation found in drainages throughout the Shasta Lake and vicinity portion of the primary study area. This plant series is characterized as narrow bands of vegetation occurring in and along the margins of rivers, streams, or other drainages. Dominant species include white alder (*Alnus rhombifolia*) with occasional Oregon ash, red osier, big-leaf maple (*Acer macrophyllum*), narrowleaf willow, red willow, shining willow, and arroyo willow. Associated shrubs include spicebush, mock orange, California blackberry (*Rubus ursinus*), mugwort (*Artemisia douglasiana*), ninebark (*Physocarpus capitatus*), and western azalea (*Rhododendron occidentale*). Common lianas include California grape, pipevine (*Aristolochia californica*), greenbriar (*Smilax californica*), and virgin's bower (*Clematis ligusticifolia*). The ground layer is open to dense and is dominated by sedges with various grasses and forbs.

White Leaf Manzanita Chaparral White leaf manzanita is the most common chaparral plant series type in the Shasta Lake and vicinity portion of the primary study area and is scattered throughout all portions of the area. The dominant species is white leaf manzanita. Associated species include occasional common manzanita (A. manzanita), western redbud, buck brush, deer brush, poison oak, birch-leaf mountain-mahogany, interior live oak (shrub form), Fremont's silktassel, bush poppy, yerba santa, and Brewer's oak.

Upper Sacramento River (Shasta Dam to Red Bluff)

The following section provides a description of the wildlife habitats that exist throughout the primary study area, and a detailed discussion of potential Sacramento River downstream habitat restorations areas.

Plant Communities in the Primary Study Area (Shasta Dam to RBPP) The plant communities present in the primary study area between Shasta Dam and RBPP include common and sensitive communities as described below, and the relevant aspects of their ecology are discussed in detail in the *Botanical Resources and Wetlands Technical Report*, and summarized below for sensitive communities. These descriptions are generally applicable to the extended study area as well. (Plant community names and descriptions used in this section are based primarily on the Preliminary Descriptions of the *Terrestrial Natural Communities of California* (Holland 1986).)

Common plant communities present within the primary study area include annual grassland, chaparral, and agricultural lands. The upper banks along steep-sided, bedrock-constrained segments of the Sacramento River and its tributaries are characterized primarily by upland communities, including blue oak woodland, foothill pine-oak woodland, and chaparral. These segments occur primarily between Shasta Dam and Redding.

Sensitive plant communities include those that are of special concern to resource agencies or are afforded specific consideration through CEQA, Section 1602 of the California Fish and Game Code, Section 404 of the Federal Clean Water Act (CWA), and the State of California's (State) Porter-Cologne Water Quality Control Act, as discussed in Section 12.2, "Regulatory Framework."

Oak Woodlands Oak woodlands present in the primary study area include blue oak woodland, blue oak savanna, foothill pine-oak woodland, and valley oak woodland. The oaks that dominate the tree layer of oak savannas and woodlands are long-lived trees that are resilient to damage; their stems often survive fire, and when their stems are killed by fire or are cut down, basal sprouts often grow into new stems. (Valley oak also tolerates inundation during winter before it has leafed out.) Nonetheless, there are concerns regarding the status and ongoing trends of tree mortality and recruitment in tree canopies of blue oak- and valley oak-dominated savannas and woodlands (Tyler, Kuhn, and Davis 2006).

Riparian Communities California's riparian communities have experienced the most extensive reductions in their acreage, and in the Sacramento Valley more than 90 percent of riparian vegetation has been converted to agriculture or development, and the remainder substantially altered by dams, diversions, gravel mining, grazing practices, and invasive species (Hunter et al. 1999).

In the primary study area, much of the Sacramento River from Shasta Dam to Redding is deeply entrenched in bedrock, which precludes development of extensive areas of riparian vegetation. The river corridor between Redding and Red Bluff, however, still maintains extensive areas of riparian vegetation.

Riparian communities present within the floodplain of the Sacramento River, within the primary study area, include blackberry scrub, Great Valley willow scrub, Great Valley cottonwood riparian forest, Great Valley mixed riparian forest, and Great Valley valley oak riparian forest. Willow and blackberry scrub and cottonwood- and willow-dominated riparian communities are present along active channels and on the lower flood terraces whereas valley oak-dominated communities occur on higher flood terraces.

More than 15 native species of deciduous trees and shrubs occur in the riparian forests, woodlands, and scrubs of the Central Valley and the Delta (Conard, MacDonald, and Holland 1977; Vaghti and Greco 2007). Flow regime, disturbance, and species attributes determine the species composition and physical structure of this woody vegetation. Although flow regime influences the dispersal, establishment, growth, and survival of all the woody riparian species, Fremont's cottonwood (*Populus fremontii*) and the willow species (*Salix* sp.) particularly depend on specific hydrologic events for their recruitment. During seed release, flows must be high enough to disperse seed to surfaces where scouring by subsequent flows does not occur, yet not so high that seedlings desiccate after flows recede, and flows must recede gradually to enable germination and seedling establishment while the substrate is still moist (Mahoney and Rood 1998).

Fremont's cottonwood and willow species are rapidly growing, shade intolerant and relatively short-lived (Burns and Honkala 1990, Vaghti and Greco 2007). Within 10 to 20 years, initially shrubby thickets may reach 10–40 feet in height. Other species, such as Oregon ash (*Fraxinus latifolia*) and valley oak (*Quercus lobata*), establish concurrently or subsequent to the willows and cottonwood, grow more slowly but are more tolerant of shade, and are longer-lived (Burns and Honkala 1990, Tu 2000). In the absence of frequent disturbance, these species enter the canopy, particularly after 50 years, as mortality of willows and cottonwood frees space. Conversely, frequent disturbance prevents the transition to mature mixed riparian or valley oak forests.

The operation of Shasta Dam has limited the frequency, magnitude, and duration of intermediate and larger flows during fall and winter since the dam's construction, and flow volumes have been greater during the growing season. The operation of Shasta Dam also produces increasing flow volumes during the period of cottonwood seed dispersal (rather than flow volume decreasing during this period), largely precluding establishment of cottonwoods (and to a lesser extent willows) throughout much of the riparian zone (Roberts et al. 2002). The combined effect of these changes in flow regime has been a decrease in early- and mid-successional communities along the Sacramento River that is still ongoing (Fremier 2003).

Wetland Communities Similar to riparian communities, much of the wetland habitat that once occurred in the Sacramento River Valley has been eliminated as a consequence of land use conversion to agriculture and urbanization. It is estimated that nearly 1.5 million acres of wetlands once occurred in the Central Valley. Today, approximately 123,000 acres remain. Wetland communities that are likely to occur in the primary study area between Shasta Dam and RBPP include freshwater marsh, freshwater seep, northern hardpan vernal pools, northern volcanic mudflow vernal pools, and other seasonal wetlands.

Freshwater marshes are herbaceous wetland plant communities that occur along rivers and lakes and are characterized by dense cover of perennial, emergent plant species. Marshes are typically perennial wetlands, but may dry out for short periods of time. In marsh vegetation, vegetation structure and species richness are strongly influenced by disturbance, changes in water levels, and the range of elevations present at a site (Keddy 2000). Disturbances, and water level drawdowns that expose previously submerged surfaces, provide opportunities for species to establish, which creates diversity in species composition and vegetation structure. With increasing depth of water, the growth of marsh plants is reduced, and thus this vegetation type is typically restricted to shallow water.

Freshwater seep is a wetland plant community characterized by dense cover of perennial herb species usually dominated by rushes, sedges, and grasses. Freshwater seep communities occur on sites with permanently moist or wet soils resulting from daylighting groundwater.

Vernal pools are seasonal wetlands that fill during winter rains and dry up in spring. They occur in undulating or mima mound (i.e., mound-intermound) topography where the soil or underlying rock has layers that are relatively impermeable to water. Vernal pools may be isolated from one another, but more often they are interconnected by swales or ephemeral drainages in vernal pool complexes that may extend for hundreds of acres. Vernal pool complexes generally include water features. The two predominant types of vernal pool communities in the primary study area are northern hardpan vernal pools and northern volcanic mudflow vernal pools.

Pool size and the depth, duration, and seasonal timing of ponding are important factors that influence the composition and diversity of plant and animal species in vernal pools (Solomeshch, Barbour, and Holland 2007). Consequently, the vegetation of vernal pools can vary substantially from year to year in response to interannual fluctuations in climate.

Management activities such as grazing and burning also influence species composition and diversity. In fact, research indicates that the abundance of nonnative grasses, grazing practices, and hydrology are strongly interrelated and can substantially affect the plant communities of vernal pools (Robins and Vollmar 2002, Pyke 2004, Marty 2005).

Seasonal wetlands are ephemeral wetlands that pond or remain flooded for long periods during a portion of the year, generally the rainy winter season, then dry up, typically in spring. They often occur in shallow depressions on flood terraces that are occasionally to infrequently flooded. Seasonal wetlands are herbaceous communities typically characterized by species adapted for growth in both wet and dry conditions, and may contain considerable cover of upland species as well. Seasonal wetlands differ from vernal pools in that they do not have a restrictive hardpan layer and are usually dominated by nonnative plant species, especially nonnative grasses.

Potential Sacramento River Downstream Habitat Restoration Areas Many of the same plant community classifications found in the Shasta Lake and vicinity portion of the primary study area also occur in the potential Sacramento River habitat restoration areas. However, the species composition, structure, and overall function of these areas are significantly different, as these areas are situated in a separate geographic setting and region. Plant communities occurring in the potential Sacramento River habitat restoration areas include broom patches, black locust groves, California yerba santa scrub, cattail marshes, Fremont cottonwood forest, ghost pine woodlands, Hind's walnut stands, Oregon ash groves, sandbar willow thickets, shining willow groves, soft rush marshes, valley oak woodland, Wright's buckwheat patches, water primrose wetlands, white alder groves, and white-root beds. Other plant or habitat communities include California annual grassland, mixed riparian forest, parrot's feather mats, reed canarygrass swards, silver wattle thickets, barren, orchard, and riverine.

The potential Sacramento River downstream habitat restoration areas are characterized by habitats typical of riparian and riverine areas found in the Sacramento River below Shasta Dam. These habitats were also mapped and classified using the MCV. Habitats present in the potential Sacramento River downstream habitat restoration areas are summarized in Table 12-3 and depicted in Figures 12-4a through 12-4f. General habitat descriptions for these locations are also described below.

Table 12-3. Summary of Plant Communities in the Potential Sacramento River Downstream Restoration Areas

Broom Patches Broom patches mainly occur on open gravel bars and are characterized by sparse to dense patches of Spanish broom (*Spartium junceum*). Associated species include Bermuda grass (*Cynodon dactylon*), Oregon golden aster (*Heterotheca oregona*), gumweed (*Grindelia* sp.), and common ragweed (*Ambrosia artemisiifolia*).

Black Locust Groves Black locust groves are an uncommon plant community in the potential restoration sites and occur as small stands at the Shea Island Complex site. This community is characterized by a moderate to dense canopy of black locust with occasional valley oak. The dominant understory vegetation is Himalayan blackberry.

California Yerba Santa Scrub California yerba santa scrub occurs on open rocky areas and is characterized by sparse to moderate cover of California yerba santa. Sparse annual grasses and forb cover also occurs in these areas including Oregon golden aster, wright's buckwheat (*Eriogonum wrightii*), naked buckwheat (*Eriogonum nudum*), slender wild oat (*Avena barbata*), mousetail (*Myosurus* sp.), ripgut grass (*Bromus diandrus*), soft chess (*Bromus hordeaceus*), and red brome (*Bromus madritensis* ssp. *rubens*).

Cattail Marshes Cattail marshes occur along the margins of backwater sloughs, pond margins, and as small inclusions in riparian forests. This plant community is characterized by dense stands of broadleaf cattail (*Typha latifolia*). Within the shallow fringes of these cattail marshes are small patches of reed canarygrass (*Phalaris arundinacea*), horsetail (*Equisetum* sp.), rush (*Juncus* sp.), and dallisgrass (*Paspalum dilatatum*). Parrot's feather (*Myriophyllum aquaticum*), smartweed (*Persicaria* sp.) and water primrose (*Ludwigia peploides*) grow in the deep water areas of the marshes.

Fremont Cottonwood Forest Fremont cottonwood forest occurs as multi-layered riparian forest stands characterized by a moderate to dense canopy of predominantly Fremont cottonwood. Associated species including valley oak, Oregon ash, white alder, narrowleaf willow, shining willow, Goodding's black willow, black locust (*Robinia pseudoacacia*), and silver wattle (*Acacia dealbata*) are also present in the canopy layer. Dominant understory vegetation includes Himalayan blackberry, California grape, Santa Barbara sedge (*Carex barbarae*), giant reed (*Arundo donax*), mugwort (*Artemisia douglasiana*), horsetail, Bermuda grass (*Cynodon dactylon*), and Johnson grass (*Sorghum halepense*).

Ghost Pine Woodland Ghost pine woodlands occur in upland areas above the active floodplain and are characterized by a moderately dense canopy of foothill pine with occasional valley oak and Fremont cottonwood. Dominant understory species include Himalayan blackberry and Spanish broom.

Hind's Walnut Stands Hind's walnut and related stands occur as a small stand of riparian trees in the southeast portion of the Henderson Open Space potential restoration site. This semi-natural stand is dominated by an overstory of black walnut (*Juglans nigra*) with occasional valley oak and narrowleaf willow. Understory vegetation is moderately dense and includes Himalayan blackberry, California grape, Johnson grass, and Bermuda grass.

Oregon Ash Groves Oregon ash groves are an uncommon plant community in the potential restoration sites and are characterized by a moderately dense canopy of Oregon ash. Associated tree species include Fremont cottonwood, shining willow, and narrowleaf willow. Dominant shrub species include French broom (*Genista monspessulana*), giant reed, and Himalayan blackberry. The herbaceous layer is dominated by Bermuda grass.

Sandbar Willow Thickets Sandbar willow thickets occur in riparian habitats throughout the study area. This plant community is characterized by a moderate to dense canopy of narrowleaf willow. Associated trees and shrubs include shining willow, Fremont cottonwood, Goodding's black willow, Oregon ash, black walnut, black locust, and Himalayan blackberry. The herbaceous layer consists of primarily broomsedge bluestem (*Andropogon virginicus*), horsetail, rushes, nut sedges (*Cyperus* spp.), dallisgrass, and Johnson grass.

Shining Willow Groves Shining willow groves are an uncommon plant community in the potential restoration sites and are characterized by dense stands of shining willow with occasional narrowleaf willow, Himalayan blackberry, and California grape.

Soft Rush Marshes Soft rush marshes are an uncommon wetland plant community in the potential restoration sites and occur in patches along the shallow margins of the Sacramento River. This plant community is characterized by dense cover of soft rush (*Juncus effusus*) with occasional Santa Barbara sedge, reed canarygrass, nut sedge (*Cyperus eragrostis*), and spikerush (*Eleocharis* sp.).

Valley Oak Woodland Valley oak woodland occurs in portions of the potential restoration sites above the active floodplain of the Sacramento River. This plant community is characterized by a moderately dense canopy of valley oak with some interior live oak, foothill pine, narrowleaf willow, shining willow, black locust, Fremont cottonwood, black willow, Oregon ash, and tree of heaven (*Ailanthus altissima*) scattered throughout. Dominant understory vegetation includes western redbud, California coffee berry (*Frangula californica*), mugwort, winter vetch (*Vicia villosa*), Santa Barbara sedge, ripgut grass, common ragweed, California grape, California pipevine, and Bermuda grass.

Wright's Buckwheat Patches Wright's buckwheat patches occur in open rocky areas and are characterized by sparse to moderate cover of Wright's buckwheat. Sparse cover of annual grasses and forbs also occur in these areas including Oregon golden aster, naked buckwheat, slender wild oat, mousetail, ripgut grass, soft chess, and red brome.

Water Primrose Wetlands Water primrose wetlands occur in sloughs, backwater marshes, and along pond margins. These wetlands are characterized by dense mats of water primrose (*Ludwigia peploides*) with parrot's feather, smartweed (*Persicaria* sp.), and broadleaf cattail.

White Alder Groves White alder groves occur as multi-layered stands along the river margins characterized by a moderate to dense canopy of white alder. Associated species include Fremont cottonwood, shining willow, narrowleaf willow, black locust, valley oak, Oregon ash, and box elder. Dominant understory vegetation includes Himalayan blackberry, Santa Barbara sedge, mugwort, horsetail, verbena, water iris, and rush.

White-Root Beds White-root beds occur as small inclusions in riparian forest habitats. This plant community is characterized by dense patches of Santa Barbara sedge with occasional Himalayan blackberry, verbena, horsetail, and goose grass (*Galium aparine*).

California Annual Grasslands California annual grasslands are uncommon in the study area and occur as open ruderal areas and vegetated gravel bars. This plant community is characterized by moderate to dense cover of annual grasses and forbs including black mustard (*Brassica nigra*), California poppy (*Eschscholzia californica*), ripgut grass, soft chess, wild oat, rose clover (*Trifolium hirtum*), long beaked storks bill (*Erodium botrys*), turkey mullein (*Croton setigeris*), Oregon golden aster, and tall sock-destroyer (*Torilis arvensis*).

Mixed Riparian Forest Mixed riparian forest occurs at the Reading Island potential restoration site and consists of moderate to dense stands of riparian trees and shrubs. A diverse assemblage of tree species occur including valley oak, narrowleaf willow, Goodding's black willow, shining willow, white alder, black walnut, tree of heaven, box elder, black locust, California buckeye, and blue elderberry (*Sambucus nigra* ssp. *caerulea*). Dominant understory species include buttonbush, Himalayan blackberry, California grape, California pipevine, mugwort, Santa Barbara sedge, and California man-root (*Marah fabacea*).

Parrot's Feather Mats Parrot's feather mats occur in sloughs and backwater marshes. This vegetation type is characterized by dense patches of parrot's feather with small inclusions of water primrose, smartweed, and broadleaf cattail.

Reed Canarygrass Swards Reed canarygrass swards occur in sloughs and backwater areas in the study area. This semi-natural stand is characterized by moderate to dense cover of reed canarygrass. Associated species include narrowleaf willow, broadleaf cattail, smartweed, sedges, and rushes.

Silver Wattle Thickets Silver wattle thickets are an uncommon plant community in the potential restoration sites and occur as small riparian stands in the northern portion of Tobiasson Island. This plant community is characterized by a moderate to dense canopy of silver wattle. Associated species include Oregon ash, Fremont cottonwood, black locust, giant reed, horsetail, and Bermuda grass.

Barren Barren habitat occurs on gravel bars and is characterized by open areas of gravel and cobble substrates. Vegetation is typically absent, although in some barren areas sparse opportunistic grasses/forbs or weedy species may occur.

Orchard Orchard habitat is uncommon in the potential Sacramento River habitat restoration areas and only occurs at the Reading Island site. This habitat consists of a small portion of a walnut orchard extending into a portion of the northern site boundary. The walnut orchard is mature and well maintained. Vegetation includes an overstory of walnut trees and ground cover of various grasses and forbs.

Riverine Riverine habitat occurs at each potential Sacramento River habitat restoration area and consists of portions of active Sacramento River channel within and/or around each site. The riverbed is dominated by primarily gravel, cobble, and boulder substrates.

Lower Sacramento River and Delta

A large number of natural plant communities occur in the extended study area, and some are described in this section and the “CVP/SWP Service Areas” section, or in the *Botanical Resources and Wetlands Technical Report*. The other natural plant communities are described in the following sections, and in Mayer and Laudenslayer (1988), Sawyer and Keeler-Wolf (1995), and CALFED (2000a). In addition to natural plant communities, plant communities of agricultural and urban areas occupy extensive portions of the extended study area.

The lower Sacramento River can be subdivided into distinct reaches that differ in topography, hydrology, and geomorphology; and thus, in vegetation and associated habitat functions.

Red Bluff Pumping Plant to Colusa

In this reach, the Sacramento River is classified as a meandering river, where relatively stable, straight sections alternate with more sinuous, dynamic sections (Resources Agency 2003). The channel remains active and has the potential to migrate in times of high water. Point bars, islands, high and low terraces, instream woody cover, early-successional riparian plant growth, and other evidence of river meander and erosion are common in this reach. Major physiographic features include floodplains, basins, terraces, active and remnant channels, and oxbow sloughs. These features sustain a diverse array of riparian plant communities.

Colusa to the Delta

The general character of the Sacramento River changes quite drastically downstream from Colusa from a dynamic and active meandering channel to a confined, narrow channel restricted from migration. Surrounding agricultural lands encroach directly adjacent to the levees, which have cut the river off from most of its riparian corridor, especially on the eastern side of the river. Most of the levees in this reach are lined with riprap, allowing the river no erodible substrate and limiting the extent of riparian vegetation.

Primary Tributaries to the Lower Sacramento River

The primary tributaries of the lower Sacramento River are the Feather River, American River, and Sacramento River floodplain bypasses. The aquatic ecosystem in the lower Feather River, down to the confluence with the Sacramento River at Verona, is influenced by DWR's Oroville Facilities. The upper extent is fairly confined by levees as the river flows through the city of Oroville. Downstream from Oroville, the Feather River is fairly active and meanders its way south to Marysville. However, this stretch is bordered by active farmland, which confines the river into an incised channel in certain stretches and limits the width of riparian woodland. Some of this adjacent farmland is in the process of being restored to floodplain habitat with the relocation of levees to become setback levees.

The lower American River (below Folsom and Nimbus dams) is fairly low gradient. Most of the lower American River is surrounded by the American River Parkway, which preserves the surrounding riparian zone. The river channel does not migrate to a large degree because it has become deeply incised, leaving tall cliffs and bluffs adjacent to the river.

Multiple water diversion structures in the lower Sacramento River move floodwaters into floodplain bypass areas during high-flow events. These floodplain bypass areas – the Butte basin, Sutter Bypass, and Yolo Bypass – provide broad, inundated floodplain habitat during wet years. Unlike other Sacramento River and Delta habitats, floodplains and floodplain bypasses are seasonally dewatered (as high flows recede). Their predominant communities include grassland, seasonal wetlands, and agricultural vegetation.

Sacramento-San Joaquin River Delta

The Delta comprises an area of approximately 750,000 acres divided into a number of islands by hundreds of miles of waterways. Before reclamation, the Delta was inundated each year by winter and spring runoff, which changed channel geometry in response to flood conditions and tidal influence. Consequently, there were extensive areas of marsh in the Delta.

Nearly all of the Delta's marshland has since been reclaimed by agriculture, peat production, and urban and industrial uses. More than 1,000 miles of levees protect this reclaimed land (CALFED 2000b). However, some small islands remain in a quasinatural state, as do some other areas with aquatic and wetland communities (e.g., "flooded islands" that were once reclaimed land, but have been abandoned after levee failures). The species composition and ecology of these riparian, marsh, and aquatic plant communities differ from the composition and ecology of communities in the upper and lower Sacramento River portions of the combined primary and extended study areas and are described below.

Along the lower Sacramento River and in the Delta, riparian vegetation is characterized by narrow linear strips of trees and shrubs, in single- to multiple-story canopies. Tree canopies may be continuous or discontinuous, or absent altogether (as in riparian scrubs). These patches of riparian vegetation may be on or at the toe of levees (particularly in the Delta). Riparian communities in this region include cottonwood-willow woodland, Valley oak riparian woodland, riparian scrub, and willow scrub. These communities are described below.

The dynamics of riparian communities along the lower Sacramento River and in the Delta are similar to those described for riparian communities along the upper Sacramento River. However, along the Sacramento River south of Colusa, in the flood bypasses, and in the Delta, the disturbances that remove riparian vegetation, or create newly exposed surfaces where riparian vegetation can establish, differ somewhat from those along the upper Sacramento River. In these downstream areas, disturbances related to meander migration are more limited, and anthropogenic (human-caused) disturbances, such as levee maintenance and trampling, are greater than those upstream. This is because of the close proximity to levees, extensive placement of bank protection, and greater human population.

In addition to the wetland communities described for the upper Sacramento River, the Delta has tidal freshwater and brackish-water emergent marshes that, like nontidal marshes, are dominated by clonal perennial plants. This community occurs on instream islands and along tidally influenced waterways. In addition to the environmental factors affecting nontidal marshes, the species composition of tidal marshes in the Delta is also affected by regional salinity gradients.

The Delta also supports extensive areas of aquatic vegetation. These communities consists of submerged plants generally rooted in the substrate, whose stems may partially extend above the water surface (e.g., during flowering) and floating plants that are generally not rooted in the substrate. The availability of light (which decreases with depth), turbidity, and shade cast by overtopping vegetation can restrict submerged plants to relatively shallow areas. In the Delta (which has turbid waters), most submerged vegetation appears to be restricted to areas less than 5–10 feet deep. The velocity of flows may contribute to this depth restriction.

CVP/SWP Service Areas

Although agricultural and urban land uses have substantially reduced the area and connectivity of natural vegetation, the service areas still contain a large diversity of both lowland and upland plant communities, including many sensitive plant communities (see the *Botanical Resources and Wetlands Technical Report*). The most dramatic difference between historical and existing conditions is the fragmentation of what were once large contiguous blocks of habitat. Significant changes to the natural landscape in the region occurred in the late 1800s and early 1900s with land conversions to agriculture. However, in Southern California, that pattern shifted dramatically compared to the pattern in the Central Valley, as urban growth in the region that started in the 1900s began to convert large areas of agricultural lands and of remaining natural vegetation to developed land uses.

12.1.2 Special-Status Species

Special-status species addressed in this section include plants that are legally protected or are otherwise considered sensitive by Federal, State, or local resource conservation agencies and organizations. These include species that are State listed and/or Federally listed as rare, threatened, or endangered; those considered as candidates or proposed for listing as threatened or endangered; species identified by CDFW as Species of Special Concern or USFS as sensitive, endemic, or needing additional survey or management actions; and plants considered jointly by CDFW and CNPS to be rare, threatened, or endangered; and species afforded protection under local planning documents, including the CALFED Bay-Delta Program’s (CALFED) Multi-Species Conservation Strategy (MSCS).

Shasta Lake and Vicinity

Within the Shasta Lake and vicinity portion of the primary study area are a wide variety of vegetative communities and habitat components that support a large diversity of plant species. To aid in determining the potential impacts of the project, a list of potential plant species of concern was developed.

For the purposes of this evaluation, botanical species of concern are plants, lichen, and fungi that fall into any of the following categories:

- Designated as rare or listed as threatened or endangered by the State or Federal government
- Proposed for designation as rare or listing as threatened or endangered by the State or Federal government
- Candidate species for State or Federal listing as threatened or endangered
- Ranked as California Rare Plant Rank (CRPR) 1A, 1B, 2, 3, or 4 (formerly CNPS List 1A, 1B, 2, 3, or 4)

- Considered sensitive or Forest Plan Endemic by the USFS
- Considered a Northwest Forest Plan Survey and Manage (S&M) species by the USFS or U.S. Department of the Interior, Bureau of Land Management (BLM)
- Designated as an MSCS covered species by CALFED (see California Bay-Delta Authority, Section 12.2.4).

Potentially occurring plant species of concern were determined by performing several database searches, reviewing USFWS and CDFW special-status species lists for Shasta County, reviewing other appropriate literature, discussions with resource agency personnel, and professional experience in the region. Additionally, results from the various vegetation habitat mapping efforts, botanical surveys, and wildlife surveys conducted in the area by Reclamation since 2002 were used in developing the list of species of concern.

Table 12-4 summarizes special-status plant species identified as having a potential to occur in the Shasta Lake and vicinity portion of the primary study area. Potentially occurring special-status plant species in the potential Sacramento River downstream restoration sites are summarized in Table 12-5.

Table 12-4. Plant Species of Concern with Potential to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area

Common Name	Scientific Name	Status[1]
Shasta ageratina	*Ageratina shastensis*	CRPR 1B.2, FPE
Sanborn's onion	*Allium sanbornii* var. *sanbornii*	CRPR 4.2
Bent-flowered fiddleneck	*Amsinckia lunaris*	CRPR 1B.2, BLMS
Mallory's manzanita	*Arctostaphylos malloryi*	CRPR 4.3
Shasta County arnica	*Arnica venosa*	CRPR 4.2, FPE
Marbled ginger	*Asarum marmoratum*	CRPR 2B.3
Depauperate milk-vetch	*Astragalus pauperculus*	CRPR 4.3
Moonwort, grape-fern	*Botrychium subgenus Botrychium*	USFS S, S&M
Yellow-twist horsehair	*Bryoria tortuosa*	BLMS
Green bug moss	*Buxbaumia viridis*	USFS S, BLMS, S&M
Callahan's mariposa lily	*Calochortus syntrophus*	CRPR 1B.1
Butte County morning-glory	*Calystegia atriplicifolia ssp. buttensis*	CRPR 4.2
Castle Crags harebell	*Campanula shetleri*	CRPR 1B.3, USFS S, BLM S
Buxbaum's sedge	*Carex buxbaumii*	CRPR 4.2
Bristly sedge	*Carex comosa*	CRPR 2B.1, MSCS r
Shasta clarkia	*Clarkia borealis ssp. arida*	CRPR 1B.1, MSCS m, BLM S
Northern clarkia	*Clarkia borealis ssp. borealis*	CRPR 1B.3, BLM S
Silky cryptantha	*Cryptantha crinita*	CRPR 1B.2, MSCS m, BLM S
California lady's-slipper	*Cypripedium californicum*	CRPR 4.2

Table 12-4. Plant Species of Concern with Potential to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Status[1]
Clustered lady's-slipper	*Cypripedium fasciculatum*	CRPR 4.2, USFS S, BLM S, S&M
Mountain lady's-slipper	*Cypripedium montanum*	CRPR 4.2, USFS S, BLM S, S&M
Four-angled spike rush	*Eleocharis quadrangulata*	MSCS m
Shasta limestone monkeyflower	*Erythranthe taylori*	CRPR 1B.1
	Erythronium sp. *nov*.	New species of fawn lilly endemic to Shasta Lake region; occurs in shady, northerly aspect forest habitats and below limestone outcrops; taxonomic treatment in preparation. Considered a special-status species for the purposes of this evaluation.
Butte County fritillary	*Fritillaria eastwoodiae*	CRPR 3.2, USFS S
Dubious pea	*Lathyrus sulphureus* var. *argillaceus*	CRPR 3
Broad-lobed linanthus	*Leptosiphon latisectus*	CRPR 4.3
Cantelow's lewisia	*Lewisia cantelovii*	CRPR 1B.2, USFS S, BLM S
Howell's lewisia	*Lewisia cotyledon* var. *howellii*	CRPR 3.2
Bellinger's meadowfoam	*Limnanthes floccosa* ssp. *bellingeriana*	CRPR 1B.2, MSCS m, BLM S
Awl-leaved navarretia	*Navarretia subuligera*	CRPR 4.3
Shasta snow-wreath	*Neviusia cliftonii*	CRPR 1B.2, USFS S, MSCS m, BLM S
Thread-leaved beardtongue	*Penstemon filiformis*	CRPR 1B.3, MSCS m, BLM S
Narrow-petaled rein orchid	*Piperia leptopetala*	CRPR 4.3
Bidwell's knotweed	*Polygonum bidwelliae*	CRPR 4.3
Eel-grass pondweed	*Potamogeton zosteriformis*	CRPR 2B.2, MSCS m
Pacific fuzzwort	*Ptilidium californicum*	BLM S, S&M
Hoary gooseberry	*Ribes roezlii* var. *amictum*	CRPR 4.3
Bug on a stick	*Schistostega pennata*	S&M
Brownish beaked-rush	*Rhynchospora capitellata*	CRPR 2B.2
Sanford's arrowhead	*Sagittaria sanfordii*	CRPR 1B.2, MSCS m, BLM S
Marsh skullcap	*Scutellaria galericulata*	CRPR 2B.2, MSCS m
Canyon Creek stonecrop	*Sedum obtusatum* ssp. *paradisum*	CRPR 1B.3, USFS S, BLM S
English Peak greenbriar	*Smilax jamesii*	CRPR 1B.3, MSCS m, BLM S

Table 12-4. Plant Species of Concern with Potential to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

[1] NoteS:
Status Codes
S&M = Survey and Manage Species
CRPR 2 = Plants rare, threatened, or endangered in California but more common elsewhere (includes rare plant ranks 2B.1, 2B.2, and 2B.3)
CRPR 3 = Plants for which more information is need – a review list
CRPR 4 = Plants of limited distribution – a watch list
CRPR Threat Ranks
0.1 = Seriously threatened in California
0.2 = Fairly threatened in California
0.3 = Not very threatened in California

MSCS (Multi Species Conservation Strategy) covered species
R = Recovery. Recover species' populations within the MSCS focus area to levels that ensure the species' long-term survival in nature.
r = Contribute to recovery. Implement some of the actions deemed necessary to recover species' populations within the MSCS focus area.
m = Maintain. Ensure that any adverse effects on the species that could be associated with implementation of CALFED actions will be fully offset through implementation of actions beneficial to the species (CALFED 2000c).

The CNDDB was reviewed for records of special-status plant species in or near the Shasta Lake and vicinity portion of the primary study area. The CNDDB is a database consisting of historical observations of special-status plant species, wildlife species, and natural communities. The CNDDB is limited to reported sightings and is not a comprehensive list of special-status species that may occur in a particular area.

A search of the CNPS Electronic Inventory was also conducted. The Electronic Inventory allows users to query the database using a set of variable search criteria. The result of the search is a list of potentially occurring special-status plant species. The criteria used for the query included all CRPR 1A, 1B, 2A, 2B, 3, and 4 plants occurring in Shasta County in closed-cone coniferous forest, chaparral, cismontane woodland, lower montane coniferous forest, marshes and swamps, pebble plain, valley and foothill grasslands, riparian forest, riparian woodland, and riparian scrub habitats between the elevations of approximately 900 feet and 2,500 feet.

Botanical Surveys Reclamation conducted several botanical surveys for special-status plant species in the Shasta Lake and vicinity portion of the primary study area. Botanical surveys were conducted in between 2002 and 2014. A list of species observed during the surveys is provided as Attachment 2 to the Botanical Resources and Wetlands Technical Report in the Biological Resources Appendix. Detailed survey information is provided as Attachment 6 to the Botanical Resources and Wetlands Technical Report in the Biological Resources Appendix. Baldwin et al. (2012) is used as the standard reference for taxonomic nomenclature and identification.

Botanical surveys were performed during 2002 along the Big Backbone and Squaw Creek arms. In 2003, botanical surveys were conducted along 11 selected riverine reaches: Little Backbone Creek, Sugarloaf Creek, upper Sacramento River, middle Salt Creek, Salt Creek, Nosoni Creek, Dekkas Creek, Campbell Creek, Flat Creek, Ripgut Creek, and Potem Creek. The surveys were conducted in general accordance with the technical methods prescribed in *California Department of Fish and Wildlife Protocols for Surveying and Evaluating Impacts to Special Status Plant Populations and Natural Plant Communities* (California Department of Fish and Game 2009), except that only portions of the project area have been surveyed . In 2004, botanical surveys were conducted at a series of randomly and nonrandomly selected locations. Nonrandomly selected sites were located throughout the Shasta Lake and vicinity portion of the primary study area (not including relocation areas) based on 2002 and 2003 survey results. Sites were selected based on the presence of unique habitat and ecological attributes, such as recently burned areas, unique geologic substrates, late-seral forests, and uncommon plant series. Nonrandomly selected sites varied in size and often included several plant series types. Randomly selected sites were selected throughout the area using plant series polygons developed from previously completed vegetation mapping. Using the geographic information system (GIS), individual vegetation polygons were assigned a unique number, and 100 numbers (i.e., vegetation polygons) were then randomly selected.

Based on previous surveys resulting in discoveries of Shasta snow-wreath (*Neviusia cliftonii*) and Shasta huckleberry (*Vaccinium* sp. *nov*), specific surveys for these species have been conducted since 2009. These surveys were designed to identify potential habitat for and locate populations of these species outside of the proposed project area. Pedestrian surveys were conducted to search the focus areas identified. Using methods described in Lindstrand and Nelson (2006), potential survey areas were identified using soil and geologic information at known sites and choosing areas with those same characteristics. In addition, survey sites were identified using intuitive techniques, such as selecting areas with vegetative cover types similar to those of known populations and areas near known populations (regardless of vegetative cover).

A genetic study of the Shasta snow-wreath was conducted in 2009 and 2010 to help determine potential project impacts and evaluate potential mitigation measures. The goal of the genetic study was to (1) determine whether all Shasta snow-wreath populations are genetically identical, (2) determine whether there are several homogeneous population clusters, or (3) determine whether some other pattern is present. Twenty-one of the 23 Shasta snow-wreath occurrences known at the time were included in the study. The genetic study determined that the species is characterized by low genetic diversity and high levels of genetic differentiation (National Forest Genetics Laboratory 2010, DeWoody et al. 2012). No strong patterns were found between the Shasta snow-wreath populations and several physical and geographic variables, including soil, geology, population size, and geographic location. Although high levels of genetic differentiation and no strong population patterns are present, the genetic study found three general population clusters, providing insight and basic species information for potential mitigation planning.

A separate genetic study was conducted in 2009, 2010, and 2013 to describe the genetics of Shasta *Vaccinium* (huckleberry). The goal of the study was to determine if the Shasta *Vaccinium* was different genetically from coastal and Sierra Nevada *Vaccinium* populations and, if so, to determine if it warrants recognition as a new taxon. The genetic study determined that the species is genetically distinct from the other *Vaccinium* populations (National Forest Genetics Laboratory 2010, DeWoody et al. 2012b, National Forest Genetics Laboratory 2014). Based on the results of the genetic study combined with distinct morphologic and ecologic characteristics, the Shasta huckleberry appears to be an uncommon and geographically restricted species and warrants recognition as a new taxon. The taxonomic treatment is in preparation.

Between 2010 and 2014, botanical surveys were conducted in all relocation areas, including the dam footprint. The surveys were conducted in general accordance with the *California Department of Fish and Wildlife Protocols for Surveying and Evaluating Impacts to Special Status Plant Populations and Natural Plant Communities* (California Department of Fish and Game 2009).

Eight special-status plant species were found during the survey efforts and/or incidentally during other technical studies: Shasta County arnica (*Arnica venosa*), Northern clarkia (*Clarkia borealis* ssp. *borealis*), Cantelow's lewisia (*Lewisia cantelovii*), Shasta snow-wreath, slender false lupine (*Thermopsis gracilis* var. *gracilis*), Shasta huckleberry, and oval-leaved viburnum (*Viburnum ellipticum*), and Shasta limestone monkeyflower (*Erythranthe taylorii*).

One population of Shasta County arnica was found in ponderosa pine habitat south of Bridge Bay Resort along the Main Body and another near the privately owned cabins on USFS lands in the Salt Creek inlet on the Sacramento Arm.

Additionally, USFS has located a population along the Sacramento Arm north of Slaughterhouse Island during surveys conducted in 2010 (Figure 12-5a and 12-3c).

One population of northern clarkia was found in hardwood-conifer/chaparral habitat near Bailey Cove on the McCloud Arm, and another population was found in hardwood-conifer/chaparral habitat in Sugarloaf Cove west of Beehive Point on the Sacramento Arm. The northern clarkia locations are shown in Figures 12-5c through 12-5d.

One population of Cantelow's lewisia was discovered on a rock outcrop on the right bank of the upper Sacramento River near the Shasta Lake/upper Sacramento River transition zone. Additionally, three populations were found along the Sacramento Arm near Elmore Mountain during surveys conducted in 2010 (Figure 12-5c).

Shasta snow-wreath is currently known from 24 locations, most of which occur at or near the periphery of Shasta Lake. Ten Shasta snow-wreath populations occur in habitats associated with limestone formations, and 13 occur in other habitat types. Most populations are associated with stream drainages or the lower portions of upland slopes. Of these, 13 Shasta snow-wreath populations were discovered during the botanical surveys along the McCloud Arm (south of Shasta Caverns and Keluche Creek), Pit Arm (Brock Creek, Ripgut Creek, Flat Creek, Stein Creek, and west of Stein Creek), and the Main Body (Blue Ridge east, Blue Ridge west, Blue Ridge middle, Cove Creek, south of Cove Creek, and Jones Valley). Locations of Shasta snow-wreath found incidentally and during the surveys are shown in Figures 12-5a through 12-3f.

Slender false lupine populations were discovered in all portions of the primary study area, generally on low-gradient slopes. Locations of slender false lupine found during the surveys and incidentally are shown in Figures 12-5a through 12-5f.

Shasta huckleberry is currently known from 23 occurrences at 13 general locations. Shasta huckleberry occurs at four locations in the project area: (little) Squaw Creek, Shoemaker Gulch, Little Backbone Creek, and Horse Creek near Bully Hill. The Shasta huckleberry populations at these locations represent the lower portions of larger populations of hundreds to over a thousand shrubs that extend further upstream in and around each stream. All locations occur in an area historically known as the Copper Belt of Shasta County and occur in the vicinity of historic copper mining activities. Locations of Shasta huckleberry in the project area found during the surveys are shown in Figures 12-5a through 12-5f. Two oval-leaved viburnum populations were found during the surveys. One population was found in a forested upland slope west of Pine Point Campground along the McCloud Arm and a second in chaparral habitat in Jones Valley along the Pit Arm near the Clikapudi Trail. Locations of oval-leaved viburnum found during the surveys are shown in Figures 12-5d and 12-5f.

Three Shasta limestone monkeyflower occurrences were found in the impoundment area. These occurrences are in the McCloud Arm and include populations downslope from Samwell Cave, at Dekkas Rock, and in the Campbell Creek inlet. The Samwell Cave and Dekkas Rock populations extend upslope and above the impoundment areas, while the population at Campbell Creek occurs entirely within the impoundment area. Nineteen additional Shasta limestone monkeyflower occurrences were found in locations outside the project area. Locations of Shasta limestone monkeyflower found during the surveys are shown in Figures 12-5d and 12-5f.

Reclamation conducted biological resource assessments at each of the six potential Sacramento River downstream habitat restoration areas during 2013. The assessments include botanical surveys for special-status plants and noxious weeds. No special-status plants were found during these surveys. The biological resource assessment results are included as Attachments 12 through 23 to the Botanical Resources and Wetlands Technical Report.

Upper Sacramento River (Shasta Dam to Red Bluff)

Based on review of CNDDB and CNPS database searches, a USFWS list of species that could be potentially affected in this portion of the primary study area, and previously prepared biological reports for the area, 25 special-status plant species were identified as possibly occurring in the primary study area between Shasta Dam and RBPP, and thus their potential to occur in this portion of the study area was evaluated further. These special-status plant species, along with the legal status, habitat, and potential for occurrence of each species, are provided in Table 12-6.

Sixteen of the special-status plant species listed in Table 12-6 have the potential to occur within habitat present along the Sacramento River between Shasta Dam and RBPP. Many of these species, such as Bogg's Lake hedge hyssop (*Gratiola heterosepala*; State endangered, MSCS m, CRPR 1B.2), Ahart's dwarf rush (*Juncus leiospermus* var. *ahartii*; MSCS m, CRPR 1B.2), Ahart's paronychia (*Paronychia ahartii*; MSCS m, CRPR 1B.1), dwarf downingia (*Downingia pusilla*; CRPR 2B.2), Greene's legenere (*Legenere limosa*; MSCS m, CRPR 1B.1), Henderson's bent grass (*Agrostis hendersonii*; MSCS m, CRPR 3.2), Red Bluff dwarf rush (*Juncus leiospermus* var. *leiospermus*; CRPR 1B.2), and slender Orcutt grass (*Orcuttia tenuis*; Federal endangered, state endangered, MSCS m, CRPR 1B.1), typically occur in vernal pools, which are generally not present within the active floodplain of regulated rivers in the extended study area. Other special-status plants, however, could occur in the extended study area in the freshwater marshes, swamps, and riparian woodlands that are found along the river corridor. These species include rose mallow (*Hibiscus lasiocarpus* var. *occidentalis*; MSCS m, CRPR 2B.2) and silky cryptantha (*Cryptantha crinita*; USFS SM, CRPR 1B.2). The remaining five species may occur in annual grassland, chaparral, cismontane woodland, and lower montane coniferous forest vegetation communities along the river corridor, including adobe-lily (*Fritillaria pluriflora*; MSCS m, CRPR 1B.2), Butte County fritillary (*Fritillaria eastwoodiae*; USFS S, CRPR 3.2), dubious pea (*Lathyrus sulphureus* var. *agillaceous*; CRPR 3), mountain lady's slipper (*Cypripedium fasciculatum*; USFS SM, CRPR 4.2), and oval-leaved viburnum (*Viburnum ellipticum*; CRPR 2B.3).

Of the special-status species that could occur along the upper Sacramento River, four are known to occur along the edge of the Sacramento River channel, or along a Sacramento River tributary within 0.2 mile of the river proper, and their establishment and reproduction could potentially be affected by changes in flow regime: silky cryptantha, rose mallow, and Ahart's paronychia (CNDDB 2007, University of California 2011).

Table 12-6. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Pumping Plant

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	CDFW	MSCS	USFS	CRPR		
Shasta ageratina *Ageratina shastensis*		–		E	1B.2	Rocky carbonate outcrops in chaparral and lower montane coniferous forest; 1,300–5,900 feet elevation. Blooms June–October.	Could occur near Shasta Dam if suitable outcrops are present. Potential is low because most of the primary study area is below species' known elevation range.
Henderson's bent grass *Agrostis hendersonii*	–	–	m	–	3.2	Mesic sites in valley and foothill grassland, vernal pools; 230–1,000 feet elevation. Blooms April–May.	Could occur along the Sacramento River if suitable vernally mesic habitat is present.
Shasta County arnica *Arnica venosa*	–	–	–	E	4.2	Cismontane woodlands and lower montane coniferous forests, often in disturbed areas and roadcuts; 1,300–4,900 feet elevation. Blooms May–July.	Could occur along the Sacramento River and tributaries within the primary study area. Potential is low because most of the study area is below species' known elevation range.
Sulphur Creek Brodiaea *Brodiaea matsonii*	–	–	–	–	1B.1	Rocky, metamorphic amphibolite schist. Cismontane woodland (streambanks), meadows, and seeps; 640-700 feet elevation. Blooms May–June.	Could occur along the Sacramento River and tributaries within the primary study area.
Silky cryptantha *Cryptantha crinita*	–	–	m	–	1B.2	Gravelly streambeds within cismontane woodland, lower montane coniferous forest, riparian forest, riparian woodland, valley and foothill grassland; 275–4,000 feet elevation. Blooms April–May.	Could occur along the Sacramento River and tributaries within the primary study area.
Clustered lady's slipper *Cypripedium fasciculatum*	–	–	–	SM	4.2	Lower montane coniferous forest, North Coast coniferous forest; often in serpentinite seeps or on streambanks; 300–8,000 feet elevation. Blooms March–July.	Unlikely; no coniferous forest known in the primary study area.

Table 12-6. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Pumping Plant (contd.)

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	CDFW	MSCS	USFS	CRPR		
Mountain lady's slipper *Cypripedium montanum*	–	–	–	SM	4.2	Broadleaved upland forest, cismontane woodland, lower montane coniferous forest, North Coast coniferous forest; 500–7,000 feet elevation. Blooms March–July.	Could occur at Shasta Dam or along the Sacramento River and tributaries.
Dwarf downingia *Downingia pusilla*	–	–	–	–	2.2	Mesic sites in valley and foothill grassland, vernal pools. Blooms March–May.	Could occur along the Sacramento River if suitable vernally mesic habitat is present.
Butte County fritillary *Fritillaria eastwoodiae*	–	–	–	S	3.2	Openings and sometime serpentine areas in chaparral, cismontane woodland, and lower montane coniferous forest; 160–4,900 feet elevation. Blooms March–June.	Could occur along the Sacramento River and tributaries within the primary study area.
Adobe-lily *Fritillaria pluriflora*	–	–	m	–	1B.2	Chaparral, cismontane woodland, valley and foothill grassland; often in adobe soils; 200–2,300 feet elevation. Blooms February–April.	Could occur at Shasta Dam and along the Sacramento River.
Bogg's Lake hedge hyssop *Gratiola heterosepala*	–	E	m	–	1B.2	Marshes and swamps, vernal pools; 30–8,000 feet elevation. Blooms April–August.	Could occur along the Sacramento River and tributaries.
Rose mallow *Hibiscus lasiocarpus* var. *occidentalis*	–	–	m	–	1B.2	Freshwater marshes and swamps.	Could occur along the Sacramento River and tributaries.
Ahart's dwarf rush *Juncus leiospermus* var. *ahartii*	–	–	m	–	1B.2	Mesic sites in valley and foothill grassland; 100–300 feet elevation. Blooms March–May.	Could occur along the Sacramento River if suitable vernally mesic habitat is present. Shasta Dam is higher than species' known elevation range.
Red Bluff dwarf rush *Juncus leiospermus* var. *leiospermus*	–	–	–	–	1B.1	Vernally mesic sites in chaparral, cismontane woodland, meadows and seeps, valley and foothill grassland, vernal pools; 100–3,350 feet elevation. Blooms March–May.	Could occur at Shasta Dam or along the Sacramento River if suitable vernally mesic habitat is present.

Table 12-6. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Pumping Plant (contd.)

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	CDFW	MSCS	USFS	CRPR		
Dubious pea *Lathyrus sulphureus* var. *argillaceous*	–	–	–	–	3	Cismontane woodland, lower montane coniferous forest, upper montane coniferous forest; 500–1,000 feet elevation. Blooms in April.	Could occur at Shasta Dam and along the Sacramento River.
Greene's legenere *Legenere limosa*	–	–	m	–	1B.1	Vernal pools; 1–3,000 feet elevation. Blooms April–June.	Could occur along Sacramento River if suitable vernal pool habitat is present.
Cantelow's lewisia *Lewisia cantelovii*	–	–	–	S	1B.2	Mesic granitic sites within broadleaved upland forest, chaparral, cismontane woodland, and lower montane coniferous forest; 1,250–4,500 feet. Sometimes in serpentinite seeps. Blooms May–October.	Could occur in the Shasta Dam area. The remainder of the primary study area is below species' known elevation range.
Bellinger's meadowfoam *Limnanthes floccosa* ssp. *bellingeriana*	–	–	m	–	1B.2	Mesic sites in cismontane woodland, meadows and seeps; 950–3,600 feet elevation. Blooms April–June.	Could occur at Shasta Dam. Potential along Sacramento River is low because majority of the primary study area is below species known elevation range.
Shasta snow-wreath *Neviusia cliftonii*	–	–	m	S	1B.2	Carbonate substrates in lower montane coniferous forest and riparian woodland; 1,000–1,600 feet elevation. Blooms May–June.	Could occur in Shasta Dam area. Unlikely to occur along Sacramento River because the primary study area is lower than species known elevation range.
Slender orcutt grass *Orcuttia tenuis*	E	E	m	–	1B.1	Vernal pools; 100–6,000 feet elevation. Blooms May–October.	Could occur along the Sacramento River if suitable vernal pool habitat is present. Federally designated critical habitat for this species occurs east of the Sacramento River, east of Cottonwood (Units 3A and 3B) and northeast of Anderson (Units 2C and 2D).

Table 12-6. Special-Status Plant Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Pumping Plant (contd.)

Species	Legal Status[1]					Habitat and Blooming Period	Potential for Occurrence
	USFWS	CDFW	MSCS	USFS	CRPR		
Ahart's paronychia *Paronychia ahartii*	–	–	m	–	1B.1	Cismontane woodland, valley and foothill grassland, vernal pools; 100–1,700 feet elevation. Blooms March–June.	Could occur at Shasta Dam and along the Sacramento River.
Pacific fuzzwort *Ptilidium californicum*	–	–	–	SM	4.3	An epiphytic on bark at the base of standing mature to old-growth trees or recently fallen logs; rarely on other organic substrates such as decaying logs and stumps, or humus covering boulders; 1,275–5,725 feet elevation.	Could occur along the Sacramento River and tributaries within the primary study area. Potential is low because most of the study area is below species' known elevation range.
Canyon Creek stonecrop *Sedum obtusatum* ssp. *paradisum*	–	–	–	S	1B.3	Granitic, rocky areas in broadleafed upland forest, chaparral, lower montane coniferous forest, subalpine coniferous forest; 980–6,100 feet elevation. Blooms May–June.	Could occur along the Sacramento River and tributaries within the primary study area. Potential is low because most of the study area is below species' known elevation range.
English Peak greenbriar *Smilax jamesii*	–	–	m	-	1B.3	Found along streambanks and lake margins in broadleafed upland forest, lower montane, upper montane, and north coast coniferous forests, and marshes and swamps; 1,600–8,200 feet elevation. Blooms May–July, rarely through August.	Could occur along the Sacramento River and tributaries within the primary study area. Potential is low because most of the study area is below species' known elevation range.
Oval-leaved viburnum *Viburnum ellipticum*	–	–	–	–	2.3	Chaparral, cismontane woodland, lower montane coniferous forest; 800–4,600 feet elevation. Blooms May–June.	Could occur at Shasta Dam and along the Sacramento River.

Lower Sacramento River and Delta

Most of the special-status plant species listed in Table 12-6 have the potential to occur within the extended study area (lower Sacramento River and Delta and CVP/SWP service areas). Numerous additional special-status plant species could occur in the extended study area. Attachment 4 of the *Botanical Resources and Wetlands Technical Report* contains comprehensive lists of all sensitive plant species in the extended study area that have been reported to the CNDDB, or that otherwise have the potential to occur in the extended study area.

A number of special-status plant species could be affected in the lower Sacramento River and Delta by changes in hydrology (CALFED 2000c). These include species associated with vernal pool, riparian, marsh, and aquatic plant communities; and several other species with restricted distributions on or near channel banks, active floodplains, flood bypasses, and Delta waterways. These assemblages of special-status species are described below.

Species of Vernal Pool Communities In addition to species that are potentially present in the primary study area (Table 12-6), special-status plant species that may be associated with vernal pools along the lower Sacramento River and in the Delta region include alkali milk-vetch (*Astragalus tener* var. *tener*; MSCS r, CRPR 1B.2), brittlescale (*Atriplex depressa*; MSCS m, CRPR 1B.2), Hoover's spurge (*Euphorbia hooveri*; Federal threatened, MSCS m, CRPR 1B.2), Contra Costa goldfields (*Lasthenia conjugens*; Federal endangered, MSCS m, CRPR 1B.1), hairy orcutt grass (*Orcuttia pilosa*; Federal endangered, MSCS m, CRPR 1B.1), slender Orcutt grass (*Orcuttia tenuis*; Federal threatened, MSCS m, CRPR 1B.1), bearded popcornflower (*Plagiobothrys hystriculus*; CRPR 1B.1), Delta woolly-marbles (*Psilocarphus brevissimus* var. *multiflorus*; CRPR 4.2), Crampton's tuctoria (*Tuctoria mucronata*; Federal and State endangered, MSCS r, CRPR 1B.1), and Greene's tuctoria (*Tuctoria greenei*; Federal endangered, MSCS m, CRPR 1B.1). The primary threats affecting most of these species at multiple locations are habitat loss because of development, nonnative species, and incompatible grazing practices. Additional threats affecting some of these species at one or more location include game management practices (e.g., inundation of land for waterfowl during the growing season), off-road vehicle use and trampling, incompatible agricultural practices, and hydrological alterations.

Species of Riparian and Marsh Communities In addition to species considered potentially present in the primary study area (Table 12-6), special-status plant species associated with riparian and marsh communities along the lower Sacramento River or in the Delta region include bristly sedge (*Carex comosa*; MSCS r, CRPR 2B.1), Suisun thistle (*Cirsium hydrophilum* var. *hydrophilum*; Federal endangered, MSCS R, CRPR 1B.1), Soft bird's-beak (*Chloropyron molle* ssp. *molle*; Federal endangered, State rare, MSCS R, CRPR 1B.2), Delta button-celery (*Eryngium racemosum*; MSCS r, CRPR 1B.1), Northern California black walnut (*Juglans hindsii*; MSCS r, CRPR 1B.1), Delta tule pea (*Lathyrus jepsonii* var. *jepsonii*; MSCS r, CRPR 1B.2), Mason's lilaeopsis (*Lilaeopsis masonii*; MSCS R, CRPR 1B.1), Delta mudwort (*Limosella australis*; MSCS r, CRPR 2B.1), Sanford's arrowhead (*Sagittaria sanfordii*; MSCS m, CRPR 1B.2), Marsh skullcap (*Scutellaria galericulata*; MSCS m, CRPR 2B.2), blue skullcap (*Scutellaria lateriflora*; MSCS m, CRPR 2B.2), and Suisun Marsh aster (*Symphyotrichum lentum*; CRPR 1B.2) (CNDDB 2007, CRPR 2011). The primary threats affecting these species are habitat loss, competition from nonnative species, and alterations to hydrology (including trenching and diking). Additional threats include grazing and trampling, installation of riprap, and anthropogenic disturbances (e.g., off-road vehicles; road, utility, and levee maintenance).

Species of Aquatic Communities Eel-grass pondweed (*Potamogeton zosteriformis*; MSCS m, CRPR 2B.2), a submerged aquatic plant of assorted freshwater habitats, is rare in California but more common elsewhere (CNPS 2011). Overall, the distribution, abundance, and threats affecting this species in California are not well known.

CVP/SWP Service Areas

Special-status plants are not likely to occur in a substantial portion of the CVP and SWP service areas because the agricultural and urban land uses tend to preclude suitable habitat for most native species. Although agricultural and developed land uses account for most of the CVP and SWP service areas, a portion of these areas still remains in natural vegetation, Because of the large size of the CVP and SWP service areas, this natural vegetation is distributed over a wide range of climate and soils, and is varied in structure and species composition. Consequently, a large number of special-status plant species has the potential to occur in the natural vegetation that remains within the CVP and SWP service areas (see the *Botanical Resources and Wetlands Technical Report*).

12.1.3 Invasive Species

Shasta Lake and Vicinity and Potential Sacramento River Downstream Restoration Sites

Nonnative plant species introduced to the region are of concern in the Shasta Lake and vicinity portion of the primary study area. When plants that evolved in one region of the globe are moved by humans to another region, a few flourish, crowding out native vegetation and wildlife that feed on the native species. Some invasive plants can even change ecosystem processes such as hydrology, fire regimes, and soil chemistry. These invasive plants have a competitive advantage because they are no longer controlled by their natural predators and can quickly spread. In California, approximately 3 percent of the plant species growing in the wild are considered invasive, but they inhabit a much greater proportion of the landscape (Cal-IPC 2007).

Plant pests are defined by law, regulation, policy, and technical organizations, and are regulated by many different bodies, including the California Department of Food and Agriculture (CDFA), U.S. Department of Agriculture, and the California Invasive Plant Council (Cal-IPC). The CDFA uses an action-oriented pest-rating system. The low rating assigned to a pest by CDFA does not necessarily mean that the pest is not a problem; rather, the rating system is meant to prioritize response by CDFA and county agricultural commissioners. Plants on CDFA's highest priority "A" list are defined as plants "of known economic importance subject to state-county enforced action involving eradication, quarantine regulation, containment, rejection or other holding action." Cal-IPC has developed a list of plant pests specific to California wildlands. The Cal-IPC list is based on information submitted by land managers, botanists, and researchers throughout the state and on published sources. To determine plant pests potentially occurring in the Shasta Lake and vicinity portion of the primary study area, this list was reviewed and local agencies (BLM, USFS, California Department of Transportation, and Shasta County Department of Agriculture) were contacted to gather information about known weed locations (Table 12-7). Additional information about noxious weeds has been compiled by Reclamation from observations made during botanical and other technical studies. Attachment 5 describes each weed source location, the potential mode of spread, and the risk of spread at each of the known sites.

Management actions have been required to prevent the loss of habitat caused by some of the more invasive exotic species that out-compete native vegetation. However, these management actions have been limited and have been confined primarily to areas adjacent to campgrounds and USFS facilities.

Table 12-7. Nonnative Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area

Common Name	Scientific Name	Cal-IPC Rating[1]	CDFA Rating[2]	Habitat
Silver wattle	*Acacia dealbata*	Moderate	None	Mixed woodlands, riparian
Barbed goatgrass	*Aegilops triuncialis*	High	B	Grassland, rangeland, oak woodland
Tree of heaven	*Ailanthus altissima*	Moderate	None	Grassland, oak woodland, riparian
Broomsedge	*Andropogon virginicus*	None	None	Riparian, disturbed areas
Giant reed	*Arundo donax*	High	None	Riparian
Slender wild oats	*Avena barbata*	Moderate	None	Coastal scrub, grassland, oak woodland, forest
Common wild oats	*Avena fatua*	Moderate	None	Coastal scrub, grassland, oak woodland, forest
Black mustard	*Brassica nigra*	Moderate	None	Disturbed areas, fields

Table 12-7. Nonnative Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Cal-IPC Rating[1]	CDFA Rating[2]	Habitat
Rattlesnake grass	*Briza maxima*	Limited	None	Grassland
Ripgut brome	*Bromus diandrus*	Moderate	None	Dunes, scrub, grassland, woodland, forest
Soft brome	*Bromus hordeaceus*	Limited	None	Grassland, sage brush, serpentine soils
Red brome	*Bromus madritensis* ssp. *rubens*	High	None	Interior scrub, woodlands, grassland
Cheatgrass	*Bromus tectorum*	High	None	Interior scrub, woodlands, grassland
Lenspod whitetip	*Cardaria chalapensis*	Moderate-ALERT	B	Central Valley wetlands
Italian thistle	*Carduus pycnocephalus*	Moderate	None	Forest, scrub, grasslands, woodlands.
White knapweed	*Centaurea diffusa*	Moderate	A	Great basin scrub, coastal prairie
Spotted knapweed	*Centaurea maculosa*	High	A	Riparian, grassland, wet meadows, forests
Maltese star-thistle	*Centaurea melitensis*	Moderate	None	Disturbed areas, fields
Yellow star-thistle	*Centaurea solstitialis*	High	C	Grassland, woodlands, occasionally riparian
Squarrose knapweed	*Centaurea virgata* var. *squarrosa*	Moderate	A	Scrub, grassland, pinyon-juniper woodland
Rush skeleton weed	*Chondrilla juncea*	Moderate	A	Grassland
Canada thistle	*Cirsium arvense*	Moderate	B	Grassland, riparian areas, forests
Bull thistle	*Cirsium vulgare*	Moderate	None	Riparian areas, marshes, meadows
Poison hemlock	*Conium maculatum*	Moderate	None	Riparian areas
Field bindweed	*Convolvulus arvensis*	Evaluated, not listed	C	Agricultural weed
Pampas grass	*Cortaderia selloana*	High	None	Coastal, riparian
Bermuda grass	*Cynodon dactylon*	Moderate	C	Riparian scrub, common landscape weed
Gypsyflower	*Cynoglossum officinale*	Moderate	None	Disturbed areas
Hedgehog dogtailgrass	*Cynosurus echinatus*	Moderate	None	Grassland, oak woodland, disturbed areas
Scotch broom	*Cystis scoparius*	High	C	Coastal scrub, oak woodland
Orchardgrass	*Dactylis glomerata*	Limited	None	Grassland, disturbed areas

Burclover	*Medicago polymorpha*	Limited	None	Grassland, disturbed areas
Parrotfeather	*Myriophyllum aquaticum*	High	None	Ponds, lakes
Oleander	*Nerium oleander*	Evaluated, not listed	None	Riparian areas
Pokeweed	*Phytolacca americana*	None	None	Riparian forest, riparian woodland
Annual rabbitsfoot grass	*Polypogon monspeliensis*	Limited	None	Riparian areas
Wild radish	*Raphanus sativus*	Limited	None	Fields, disturbed areas
Black locust	*Robinia pseudoacacia*	Limited	None	Riparian areas, canyons
Himalayan blackberry	*Rubus armeniacus*	High	None	Riparian areas, marshes, oak woodlands
Cutleaf blackberry	*Rubus laciniatus*	None	None	Riparian areas, marshes, oak woodlands
Common sheep sorrel	*Rumex acetosella*	Moderate	None	Grassland, disturbed areas
Curly dock	*Rumex crispus*	Limited	None	Grassland, vernal pools, meadows, riparian
Bouncingbet	*Saponaria officinalis*	Limited	None	Oak woodland, streambed
Tansy ragwort	*Senecio jacobaea*	Limited	B	Grassland, riparian
Rattlebox	*Sesbania punicea*	High	None	Riparian
Johnsongrass	*Sorghum halepense*	None	C	Disturbed sites, moist places
Spanish broom	*Spartium junceum*	High	None	Coastal scrub, grassland, wetlands, oak woodland, forests
Medusa-head	*Taeniatherum caput-medusae*	High	C	Grassland, scrub, woodland
Spreading hedgeparsley	*Torilis arvensis*	Moderate	None	Grassland, woodland, disturbed areas
Puncturevine	*Tribulus terrestris*	None	C	Dry, disturbed areas
Rose clover	*Trifolium hirtum*	Limited	None	Grassland, woodland
Common mullein	*Verbascum thapsus*	Limited	None	Meadows, riparian, sagebrush, pinyon-juniper woodland
Periwinkle	*Vinca major*	Moderate	None	Riparian, oak woodlands, coastal scrub
Rat-tail fescue	*Vulpia myuros*	Moderate	None	Coastal sage scrub, chaparral

Table 12-7. Nonnative Plant Species Known to Occur in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Notes:
[1] Cal-IPC Inventory Categories:

High	Severe ecological impacts on physical processes, plant and animal communities, and vegetation structure. Reproductive biology and other attributes are conducive to moderate to high rates of dispersal and establishment. Widely distributed ecologically.
Moderate	Substantial and apparent ecological impacts on physical processes, plant and animal communities, and vegetation structure. Reproductive biology and other attributes are conducive to moderate to high rates of dispersal, although generally dependent on ecological disturbance. Ecological amplitude and distribution may range from limited to widespread.
Limited	These species are invasive but their ecological impacts are minor on a statewide level or there was not enough information to justify a higher score. Their reproductive biology and other attributes result in low to moderate rates of invasiveness. Ecological amplitude and distribution are generally limited, but these species may be locally persistent and problematic (Cal-IPC 2012).

[2] CDFA Pest Ratings of Noxious Weed Species and Noxious Weed Seed

A – Eradication, containment, rejection, or other holding action at the state-county level.
B – Intensive control or eradication, where feasible, at the county level.
C – Control or eradication as local conditions warrant, at the county level.
Q – Rating as "A" is pending at the state or county level.

Key:
Cal-IPC = California Invasive Plant Council
CDFA = California Department of Food and Agriculture

Upper Sacramento River (Shasta Dam to Red Bluff) and Lower Sacramento River and Delta

A number of nonnative species have been introduced and become abundant in the riparian areas and marshes (fresh emergent wetlands) of the Sacramento Valley and Delta (Hunter et al. 2003). Several of these invasive nonnatives, including red sesbania (*Sesbania punicea*), Himalayan blackberry (*Rubus discolor*), giant reed (*Arundo donax*), and perennial pepperweed (*Lepidium latifolium*), form dense, monotypic stands that preclude the establishment of native species (Bossard, Randall, and Hoshovsky 2000). In general, these species displace native plants, reduce biodiversity, alter river flows, and reduce wildlife habitat values. Table 12-8 lists the most problematic of those species in Sacramento Valley and Delta riparian areas and marshes—invasive species rated by Cal-IPC; many of these species have severe ecological impacts on physical processes, plant and animal communities, and vegetation structure (Cal-IPC 2006).

Table 12-8. Cal-IPC High-Rated Invasive Plants of Sacramento Valley and Delta Riparian and Marsh Habitats

Scientific Name Common Name	Cal-IPC Rating[1]	CDFA Rating[2]	Primary Riparian/ Marsh Habitat(s)	Plant Type
Ailanthus altissima Tree-of-heaven, Chinese sumac	M	C	Marsh, riparian forest/woodland/scrub	Tree
Arundo donax Giant reed	H	B	Riparian forest/scrub	Perennial grass
Bromus diandrus Ripgut brome, great brome	M	–	Riparian scrub	Annual grass
Bromus madritensis ssp. *rubens* Red brome, foxtail chess	H	–	Riparian woodland/scrub	Annual grass
Centaurea melitensis Malta starthistle, tocalote	M	C	Riparian scrub	Annual herb
Centaurea solstitialis Yellow starthistle	H	C	Riparian scrub	Annual herb
Cirsium vulgare Bull thistle	M	C	Marsh	Perennial herb
Conium maculatum Poison hemlock	M	–	Riparian forest	Perennial herb
Cortaderia selloana, Cortaderia jubata Pampasgrass, white pampasgrass, jubatagrass	H	B	Riparian scrub	Perennial grass
Delairea odorata Cape-ivy, German ivy	H	–	Riparian forest	Perennial vine
Dipsacus fullonum Common teasel, wild teasel	M	–	Bog and fen, riparian scrub, marsh	Perennial herb
Egeria densa Brazilian waterweed, egeria	H	C	Lakes, ponds, reservoirs	Perennial aquatic herb
Eucalyptus globules Bluegum, Tasmanian bluegum	M	–	Marsh, riparian forest/woodland	Tree
Ficus carica Edible fig	M	–	Riparian forest, marsh	Shrub/tree
Foeniculum vulgare fennel	H	–	Riparian scrub/woodland	Perennial herb
Geranium dissectum Cutleaf geranium	L	–	Riparian woodland	Annual herb

Notes:

[1] Cal-IPC Inventory Ratings:

A = Alert – Plant species with the potential to spread explosively; infestations currently small and localized

H = High – species that have severe ecological impacts on physical processes, plant and animal communities, and vegetation structure

M = Moderate –species that have substantial and apparent, but generally not severe, ecological impacts on physical processes, plant and animal communities, and vegetation structure

L = Limited –species that are invasive but their impacts are minor on a statewide level or there was not enough information to justify a higher score

[2] CDFA Weed Ratings:

B = known to be of economic or environmental detriment, and of limited distribution, if present in California

C = known to be of economic or environmental detriment, and usually widespread, if present in California

Key:

Cal-IPC = California Invasive Plant Council

CDFA = California Department of Food and Agriculture

12.1.4 Waters of the United States, Including Wetlands, in Shasta Lake and Vicinity

Reclamation delineated wetlands and other waters of the United States under Federal jurisdiction (jurisdictional waters) in the impoundment area between 2004 and 2010. Jurisdictional waters on public lands in the relocation areas were delineated between 2009 and 2013, and on private lands where access was granted. Supplemental fieldwork is planned for additional private lands in the relocation areas where access has recently been granted. These data will be provided in a wetland delineation report prepared for submittal to the USACE. The wetland delineation report is in preparation and has not been verified by the USACE. All information regarding jurisdictional waters is preliminary.

Jurisdictional waters occur in the impoundment and relocation areas as wetlands and other waters. For wetlands, the impoundment area is defined as the area between 1,070 and 1,090 msl surrounding Shasta Lake. For other waters, the impoundment area includes the lacustrine waters associated with Shasta Lake below 1,070 msl. Wetlands include fresh emergent/riparian wetland, intermittent swale, riparian wetland, seasonal wetland, seep/spring wetland, and vegetated ditch. Other waters include ephemeral, intermittent, and perennial streams, roadside ditches, seep/spring waters, and lacustrine. Because some construction activities associated with the impoundment and relocation areas extend into Shasta Lake below the existing full pool elevation, the surface area of the lake is included in the delineation results. Approximately 46 acres of wetlands and 30,092 acres of other waters occur in the impoundment and relocation areas. Total jurisdictional waters in the impoundment and relocation areas, excluding Shasta Lake at full pool, include approximately 51 acres of wetlands and 103 acres of other waters.

Jurisdictional waters occur in the potential Sacramento River downstream restoration areas as wetlands and other waters. Wetlands include fresh emergent wetlands, pond, riparian wetlands, and riparian/fresh emergent wetland complex. Other waters include ephemeral, intermittent, and perennial streams. Approximately 67 acres of wetlands and 100 acres of other waters occur in the potential Sacramento River downstream restoration areas.

Main Body

The wetland delineation of the impoundment area along the Main Body was conducted from January to April 2010. Jurisdictional waters include seep/spring, riparian, and vegetated ditch wetlands and ephemeral stream, intermittent stream, and perennial stream, seep/spring, and roadside ditch waters. Total acres of jurisdictional waters occurring in the Main Body are summarized in Table 12-9.

Big Backbone Arm

The wetland delineation along the Big Backbone Arm was conducted during November 2006. Jurisdictional waters included seep/spring and riparian wetlands, and ephemeral stream, intermittent stream, and perennial stream waters. Total acres of jurisdictional waters occurring in the Big Backbone Arm are summarized in Table 12-9.

Sacramento Arm

The wetland delineation along the Sacramento Arm was conducted from September through early December 2010 and during March, April, and June 2010. Jurisdictional waters include seep/spring, riparian, seasonal, and riparian/fresh emergent wetlands, and ephemeral stream, intermittent stream, and perennial stream, seep/spring, and roadside ditch waters. Total acres of jurisdictional waters occurring in the Sacramento Arm are summarized in Table 12-9.

McCloud Arm

The wetland delineation along the McCloud Arm was conducted during December 2009 and in April, June, and November 2010. Jurisdictional waters include seep/spring, riparian, and vegetated ditch wetlands and ephemeral stream, intermittent stream, perennial stream, and seep/spring waters. Total acres of jurisdictional waters occurring in the McCloud Arm are summarized in Table 12-9.

Squaw Creek Arm

The wetland delineation along the Squaw Creek Arm was conducted from late August through September 2004. Jurisdictional waters include seep/spring, riparian, and seasonal wet meadow wetlands, and ephemeral stream, intermittent stream, perennial stream, and seep/spring other waters. Total acres of jurisdictional waters occurring in the Squaw Creek Arm are summarized in Table 12-9.

Pit Arm

The wetland delineation along the Pit Arm was conducted from late November 2006 through April 2007. Jurisdictional waters include riparian, seep/spring, seasonal and intermittent swale wetlands, and ephemeral stream, intermittent stream, and perennial stream waters. Total acres of jurisdictional waters occurring in the Pit Arm are summarized in Table 12-9.

Notes:
[1] Acreage values are approximate
[2] Lacustrine acreage includes area below 1070 msl

Relocation Areas

Wetland delineations at the relocation areas were conducted between January 2010 and September March 2013. Jurisdictional waters include wetlands and other waters. Wetlands include fresh emergent, intermittent swale, riparian, seep/spring, and seasonal wetlands, and vegetated ditches. Other waters present include ephemeral, intermittent, and perennial streams, seep/spring, and roadside ditches. Total acres of jurisdictional waters occurring in the Relocation Areas are summarized in Table 12-10.

Potential Sacramento River Downstream Restoration Areas

Wetland delineations at the potential Sacramento River downstream restoration areas were conducted between March and November 2013. Jurisdictional waters occur in the potential Sacramento River downstream restoration areas as wetlands and other waters. Wetlands include fresh emergent wetlands, pond, riparian wetlands, and riparian/fresh emergent wetland complex. Other waters include ephemeral, intermittent, and perennial streams. Approximately 67 acres of wetlands and 100 acres of other waters occur in the potential Sacramento River downstream restoration areas. Total acres of jurisdictional waters occurring in the relocation areas are summarized in Table 12-11.

Characterization of Wetland Features

Jurisdictional wetlands occurring in the Shasta Lake and vicinity portion of the primary study area include fresh emergent/riparian wetland, intermittent swale, riparian wetland, seasonal wetland, seep/spring wetland, and vegetated ditch.

Fresh emergent/riparian wetlands are uncommon in the Shasta Lake and vicinity portion of the primary study area, occurring only at one location along the Sacramento Arm. This location consists of a former USFS recreation site developed at the confluence of Salt Creek and Shasta Lake, immediately east of I-5. This former recreation site coupled with an undercrossing at I-5 has partially impounded the flows of Salt Creek, resulting in the development of an area characterized by a complex of fresh emergent and riparian wetland vegetation. Dominant overstory species include Goodding's black willow (OBL[1]), arroyo willow (FACW), red willow (assume FACW), and shining willow (OBL). Fresh emergent species include pennyroyal (*Mentha pulegium*–OBL), willow dock (*Rumex salicifolius*–OBL), and broadleaf cattail (*Typha latifolia*). Wetland hydrology and soils criteria are met through evidence of frequent flooding, including sediment deposits, watermarks, drift lines, and drainage patterns.

Intermittent swales occur along the Big Backbone and Pit arms. These features are characterized as linear, or somewhat linear, drainages that lack evidence of scour and are dominated by wetland plant species resulting from seasonally saturated soils. Typical species occurring in these features include seep monkey flower (*Mimulus guttatus*–OBL), spiny fruit buttercup (*Ranunculus muricatus*–FACW), slender rush (*Juncus tenuis*–FACW), and centaury (*Centaurium venustum*–Not Listed (NL)). Wetland hydrology and soils criteria are met through evidence of long-duration saturation, including saturation in the upper 12 inches, aquic moisture regime, and drainage patterns.

Riparian wetlands are common throughout the Shasta Lake and vicinity portion of the primary study area and generally occur as "stringers," or narrow features found immediately adjacent to intermittent or perennial streams. Typical species found in riparian wetlands include arroyo willow (FACW), Goodding's black willow (OBL), white alder (FACW), Oregon ash (FACW), Indian rhubarb (*Darmera peltata*-NL), mugwort (*Artemisia douglasiana*-FACW), California wild grape (FACW), and Himalayan blackberry (FACW). Wetland hydrology and soils criteria are met through evidence of frequent flooding, including sediment deposits, watermarks, drift lines, and drainage patterns.

Seasonal wetlands occur along the Sacramento, Squaw Creek, and Pit arms. These features are dominated by herbaceous vegetation and are typically adjacent to other wetland features or are depressions that frequently pond. Typical plant species found in these features include slender rush (FACW), sword leaf rush (*Juncus ensifolius*–FACW), seep monkey flower (OBL), yampah (*Perideridia californica*–FACW), annual checker bloom (*Sidalcea calycosa*–OBL), little quaking grass (*Briza minor*–FACW), California oatgrass (*Danthonia californica*–FACW), and spiny fruit buttercup (FACW). Wetland hydrology and soils criteria are met through evidence of long-duration saturation, including saturation in the upper 12 inches, an aquic moisture regime, and drainage patterns.

[1] OBL = Obligate Wetland Plants—Estimated probability of occurring in wetland >99 percent.
FACW = Facultative Wetland Plants—Estimated probability of occurring in wetland >67 percent to 99 percent.
FAC = Facultative Plants—Estimated probability of occurring in wetland 33 percent to 67 percent.
FACU = Facultative Upland Plants—Estimated probability of occurring in wetland 1 percent to <33 percent.
UPL = Obligate Upland Plants—Estimated probability of occurring in wetland <1 percent.
NI = No Indicator—Plants for which insufficient information was available to determine an indicator status.
NL = Not listed—Plants not listed in Reed 1988.

Seep/spring wetlands are found throughout the Shasta Lake and vicinity portion of the primary study area. These features form at locations where groundwater flows meet the ground surface. Hydrophytic vegetation typically colonizes the area where water is provided by the seep/spring. Typical species include white alder (FACW), chain fern (*Woodwardia fimbriata*–FACW), goat's beard (*Aruncus dioicus*–FACW), Indian rhubarb (NL), seep monkey flower (OBL), horsetail (*Equisetum arvense*–FAC), red stem dogwood (*Cornus stolonifera*–FACW), spicebush (NL), and western azalea (FAC). The wetland hydrology and soils criteria are met through evidence of long-duration saturation, including inundation, saturation in the upper 12 inches, watermarks, and drainage patterns.

Vegetated ditches are uncommon in the Shasta Lake and vicinity portion of the primary study area and occur along the Main Body, the McCloud Arm, and in several relocation areas. These features consist of ditches that have been excavated to drain adjacent uplands, parking areas, roads, or railways. These features are generally low gradient and provide hydrologic conditions suitable for colonization by hydrophytic vegetation. Dominant plant species include nutsedge (*Cyperus eragrostis*–FACW), seep monkey flower (OBL), broadleaf cattail, and rush (*Juncus* sp.–assume FACW). Wetland hydrology and soil criteria were met by long-duration inundation and long-duration saturation.

Jurisdictional waters (i.e., other waters) occurring in the Shasta Lake and vicinity portion of the primary study area include ephemeral, intermittent, and perennial streams, roadside ditches, and seep/spring waters.

Ephemeral streams are common throughout the Shasta Lake and vicinity portion of the primary study area. These features are linear drainages characterized by indicators of scour and deposition, minor drift lines, and sediment deposits, but lack a groundwater component that contributes to their flow. The wetland hydrology is provided by sheet flow and these features typically cease flowing soon after storm or runoff events. Ephemeral streams are characterized by poorly defined wetland hydrology indicators, and are typically found in headwater areas with relatively small drainage areas.

Intermittent streams are the most common jurisdictional feature in the Shasta Lake and vicinity portion of the primary study area. Intermittent streams range from small, poorly defined tributaries to larger, well-defined streams that flow into the summer. Like ephemeral streams, intermittent streams flow seasonally, but, in addition to precipitation and sheet flow from adjacent slopes, these features have a groundwater component to their flow regime. Intermittent streams are characterized by the presence of a defined bed and bank, and scour and deposition. Other characteristics, such as algae growth or hydrophytic vegetation in or adjacent to the stream, indicate longer inundation periods. Wetland hydrology and hydric soil criteria are met through evidence of frequent flooding, including water marks, algal matting, drift lines, and sediment deposits.

Perennial streams occur throughout the Shasta Lake and vicinity portion of the primary study area. These features are characterized by perennial flow and often bounded by riparian wetlands. Dominant substrates consist of boulders, bedrock, cobble, sand, and gravel. Wetland hydrology and hydric soil criteria are met through evidence of frequent flooding, including water marks, algal matting, drift lines, and sediment deposits.

Roadside ditches are uncommon in the Shasta Lake and vicinity portion of the primary study area but some are found along the Sacramento Arm. These ditch features occur near roadways and railroad tracks and have been excavated solely to drain uplands. Wetland vegetation is sparse or absent. The wetland boundaries were indicated by sediment and drift deposits.

Seep/spring other waters are uncommon in the Shasta Lake and vicinity portion of the primary study area but some are found along the Main Body, the Sacramento Arm, the McCloud Arm, and the Squaw Creek Arm. These features form at locations where groundwater flows meet the ground surface; however, the features are not dominated by hydrophytic vegetation. The wetland hydrology and soils criteria are met through evidence of long-duration saturation, including inundation, saturation in the upper 12 inches, watermarks, and drainage patterns.

12.2 Regulatory Framework

Biological resources in California are protected and/or regulated by a variety of Federal and State laws and policies. In addition, in many parts of California, there are local or regional habitat and species conservation planning efforts in which a project applicant may participate. Key regulatory and conservation planning issues applicable to the project and alternatives under consideration are discussed below.

12.2.1 Federal

Endangered Species Act

Pursuant to the Federal Endangered Species Act (ESA), USFWS and NMFS have authority over projects that may result in "take" of a Federally listed species. In general, ESA Section 7 prohibits persons (including private parties) from "taking" listed endangered or threatened fish and wildlife species on private property, and from "taking" listed endangered or threatened plant species in areas under Federal jurisdiction or in violation of State law (16 United States Code (USC) 1532, 50 Code of Federal Regulations (CFR) 17.3). Under the ESA, the definition of "take" is to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct" as part of an intentional or negligent act or omission. The term "harm" includes acts that result in death or injury to wildlife. Such acts may include significant habitat modification or degradation if it results in death or injury to wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering. Section 7(a) of the ESA, as amended, requires Federal agencies to evaluate their actions with respect to any species that is proposed for listing or is listed as endangered or threatened. Section 7(a)(2) requires Federal agencies to ensure that activities they authorize, fund, or carry out are not likely to jeopardize the continued existence of a listed species or to destroy or adversely modify its critical habitat. If a Federal action may affect a listed species or its critical habitat, the responsible Federal agency must enter into formal consultation with USFWS.

As defined in the ESA, critical habitat is a specific geographic area that is essential for the conservation of a threatened or endangered species and that may require special management and protection. It may include an area that is not currently occupied by the species but that will be needed for its recovery. Critical habitats are designated to ensure that actions authorized by Federal agencies will not destroy or adversely modify critical habitat, thereby protecting areas necessary for the conservation of the species.

Clean Water Act

The CWA is the major Federal legislation governing the water quality aspects of the SLWRI. The objective of the act is “to restore and maintain the chemical, physical, and biological integrity of the nation’s waters.” The CWA establishes the basic structure for regulating discharge of pollutants into the waters of the United States and gives EPA the authority to implement pollution control programs, such as setting wastewater standards for industries. In certain states, such as California, EPA has delegated authority to State agencies.

Section 303 of the CWA requires states to adopt water quality standards for all surface waters of the United States. The three major components of water quality standards are designated users, water quality criteria, and antidegradation policy. Section 303(d) of the CWA requires states and authorized Native American tribes to develop a list of water-quality-impaired segments of waterways. The list includes waters that do not meet water quality standards necessary to support the beneficial uses of a waterway, even after point sources of pollution have had minimum required levels of pollution control technology installed. Only waters impaired by “pollutants” (e.g., clean sediments, nutrients such as nitrogen and phosphorus, pathogens, acids/bases, temperature, metals, cyanide, and synthetic organic chemicals (EPA 2002)), not those impaired by other types of “pollution” (e.g., altered flow, channel modification), are to be included on the list.

Section 303(d) of the CWA also requires states to maintain a list of impaired water bodies so that a total maximum daily load (TMDL) can be established A TMDL is a plan to restore the beneficial uses of a stream or to otherwise correct an impairment. It establishes the allowable pollutant loadings or other quantifiable parameters (e.g., pH, temperature) for a water body and thereby provides the basis for establishing water-quality-based controls. The calculation for establishing TMDLs for each water body must include a margin of safety to ensure that the water body can be used for the purposes of state designation. Additionally, the calculation also must account for seasonal variation in water quality (EPA 2002). The Central Valley Regional Water Quality Control Board (RWQCB) develops TMDLs for Shasta Lake and its tributaries.

Section 401 of the CWA requires entities to obtain certification from the state or Native American tribes when applying for a Federal license or permit that may result in increased pollutant loads to a water body. The certification is issued only if such increased loads would not cause or contribute to exceedences of water quality standards.

Section 402 created the National Pollutant Discharge Elimination System (NPDES) permit program. This program covers point sources of pollution discharging into a surface water body.

A permit must be obtained from USACE under Section 404 for the discharge of dredged or fill material into “waters of the United States, including wetlands.” Waters of the United States include wetlands and lakes, rivers, streams, and their tributaries. Wetlands are defined for regulatory purposes as areas inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support and, under normal circumstances do support, vegetation typically adapted for life in saturated soil conditions.

Rivers and Harbors Act

USACE regulates the construction of structures in, over, or under; excavation of material from; or deposition of material into “navigable waters of the United States” under Section 10 of the Federal Rivers and Harbors Act (33 USC 401 et seq.). Navigable waters of the United States are defined as those waters subject to the ebb and flow of the tide shoreward to the mean high-water mark or those that are currently used, have been used in the past, or may be susceptible to use to transport interstate or foreign commerce.

U.S. Forest Service Sensitive Species

The National Forest Management Act requires USFS to “provide for a diversity of plant and animal communities” (16 USC 1604(g)(3)(B)) as part of its multiple-use mandate. USFS must maintain “viable populations of existing native and desired nonnative species in the planning area” (36 CFR 219.19). The Sensitive Species program is designed to meet this mandate and to demonstrate USFS’s commitment to maintaining biodiversity on National Forest System lands. The program is a proactive approach to conserving species to prevent a trend toward listing under the ESA and to ensure the continued existence of viable, well-distributed populations. A “Sensitive Species” is any species of plant or animal that has been recognized by the Regional Forester to need special management to prevent the species from becoming threatened or endangered.

Shasta-Trinity National Forest Land and Resource Management Plan

The Shasta-Trinity National Forest (STNF) Land and Resource Management Plan (LRMP) contains forest goals, standards, and guidelines designed to guide the management of STNF. The following goals, standards, and guidelines related to botanical resource issues associated with the primary study area were excerpted from the STNF LRMP (USFS 1995).

Biological Diversity

Goals (LRMP, p. 4-4) Integrate multiple resource management on a landscape level to provide and maintain diversity and quality of habitats that support viable populations of plants, fish, and wildlife.

Standards and Guidelines (LRMP, p. 4-14)

- **Natural Openings –** Management of natural openings will be determined at the project level consistent with desired future conditions.

- **Snags –** Over time, provide the necessary number of replacement snags to meet density requirements as prescribed for each land allocation and/or management prescription. Live, green culls and trees exhibiting decadence and/or active wildlife use are preferred.

- **Hardwood –** Apply the following standards in existing hardwood types:

  – Manage hardwood types for sustainability.

  – Conversion to conifers will only take place to meet desired future ecosystem conditions.

  – Where hardwoods occur naturally within existing conifer types on suitable timber lands, manage for a desired future condition for hardwoods as identified during ecosystem analysis consistent with management prescription standards and guidelines. Retain groups of hardwoods over single trees.

Threatened, Endangered, and Sensitive Species (Plants and Animals)

Goals (LRMP, p. 4-5)

- Monitor and protect habitat for Federally listed threatened and endangered and candidate species. Assist in recovery efforts for threatened and endangered species. Cooperate with the State to meet objectives for state listed species.

- Manage habitat for sensitive plants and animals in a manner that will prevent any species from becoming a candidate for threatened and endangered status.

Botany (Sensitive and Endemic Plants)

Standards and Guidelines (LRMP, pp. 4-14 through 4-16)

- Map, record, and protect essential habitat for known and newly discovered sensitive and endemic plant species until conservation strategies are developed.
- Analyze the potential effects of all ground-disturbing projects on sensitive and endemic plants and their habitat. Mitigate project effects to avoid a decline in species viability at the Forest level.
- Monitor the effects of management activities on sensitive and endemic plants. If monitoring results show a decline in species viability, alter management strategy.
- Provide reports of sensitive plant populations to the CDFW annually.
- Coordinate sensitive plant inventory and protection efforts with CDFW, USFWS, The Nature Conservancy (TNC), the CNPS, and other concerned agencies, organizations, and adjacent landowners.
- Protect type localities of sensitive and endemic plants for their scientific value.

U.S. Forest Service Survey and Manage

Standards and Guidelines The 1994 Record of Decision (ROD) for Amendments to USFS and Bureau of Land Management Planning Documents Within the Range of the Northern Spotted Owl and Standards and Guidelines for Management for Late-Successional and Old-Growth Related Species in the Range of the Northern Spotted Owl (Northwest Forest Plan (NWFP) ROD amended or was incorporated into BLM and USFS land management plans to require certain actions for rare amphibians, mammals, bryophytes, mollusks, vascular plants, fungi, lichens, and arthropods that occupy late-successional and old-growth forests (USFS and BLM 1994). These rare species were identified in Appendix C of the NWFP ROD collectively as S&M Species. The NWFP ROD also established protection buffers on matrix lands for certain species (i.e., protection buffer species) that were not on the 1994 S&M list and required that those buffers be managed as part of the Late Successional Reserve network. Four survey strategies were developed to guide management of S&M species: (1) manage known sites; (2) survey before ground-disturbing activities; (3) conduct extensive surveys; and (4) conduct general regional surveys.

The NWFP ROD also established overall objectives for managing S&M species populations that were referred to as “persistence objectives.” These objectives were based on the USFS viability provision in the 1982 National Forest System Land and Resource Management Planning Regulation for the National Forest Management Act of 1976. This provision is targeted toward vertebrate species, but was also applied to nonvertebrate species to the extent practicable, as described in the NWFP ROD. The provision generally states that the USFS shall manage habitat “to maintain viable populations of existing native and desired non-native vertebrate species in the planning area” (36 CFR 219.19). Although the viability standard is part of the USFS planning regulations, the protections for S&M species were also applied to BLM lands in the NWFP ROD with a goal of protecting the long-term health and sustainability of all Federal forests within the range of the northern spotted owl and the species that inhabit them. Because of the uncertainty associated with the continued persistence of species due to natural factors, the NWFP ROD noted that compliance with the planning regulations is not subject to precise numerical interpretations and cannot be fixed at any single threshold; rather, “as in any administrative field, common sense and agency expertise must be applied” (NWFP ROD, p. 44).

In 2001, the *Record of Decision and Standards and Guidelines for Amendments to the Survey and Manage, Protection Buffer, and other Mitigation Measures Standards and Guidelines* (2001 S&M ROD) (USFS and BLM 2001) modified the management direction provided in the NWFP ROD for S&M and protection buffer species and amended BLM and USFS land management plans in the range of the northern spotted owl accordingly. The list of S&M species was also modified to remove 72 species in all or part of their range because new information indicated they were secure or otherwise did not meet the basic criteria for S&M. Species remaining on the list were assigned to one of six categories using the following criteria: their relative rarity, the ability to reasonably and consistently locate occupied sites during surveys before habitat-disturbing activities, and the level of information known about the species or group of species. The 2001 S&M ROD also removed the direction specific to protection buffer species, excluding these species from S&M Standards and Guidelines requirements. As part of the 2001 Standards and Guidelines, objectives, criteria, and management direction were defined for each category. Specific criteria were also established to add, remove, or change species categories based on new information and as part of the annual species review processes.

In 2004 and again in 2007, the BLM and USFS issued a ROD to eliminate the S&M requirements of the 2001 S&M ROD and to provide protection for species on the S&M lists by managing them under the agencies’ special-status species programs. As a result of litigation, the requirements of the 2001 S&M ROD were reinstated. In a subsequent court-mandated settlement agreement (USFS and BLM 2011), the list of S&M species was modified. The settlement agreement also made the following modifications: (1) acknowledged existing exemption categories (2006 Pechman Exemptions), (2) updated the 2001 S&M species list, (3) established a transition period for application of the species list, and (4) established new exemption categories (2011 Exemptions). Agency decisions made after September 30, 2012, are required to use the 2011 S&M list. Some species considered in the S&M program also occur on non-Federal lands. The requirements of the 1994 NWFP ROD and 2001 S&M ROD as modified under the 2011 Settlement Agreement apply only to lands managed by the BLM and USFS within the range of the northern spotted owl. The 2011 Settlement Agreement was later struck down by the court, and the S&M program has reverted to the 2001 S&M ROD with the 2006 Pechman Exemptions still intact.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

A portion of the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area is included in the Shasta Lake and vicinity portion of the primary study area. The 2014 NRA Management Guide for the Shasta and Trinity Units of the NRA contains management guidance intended to achieve or maintain a desired condition. This guidance takes into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. The following guidance related to strategies for botanical and wetland resource issues associated with the Shasta Lake and vicinity portion of the primary study area were excerpted from the NRA Management Guide (USFS 2014).

- Protect known populations of threatened, endangered and sensitive plant, lichen, and fungi species and their habitats, and implement mitigation measures if necessary to maintain or enhance their continued viability. Conservation strategies for these species will be used as they are developed. Survey for special-status plants, lichens and fungi before ground-disturbing projects.

- Follow the national direction for the use of native plant materials in the revegetation, restoration, and rehabilitation of NFS lands. This includes making native plant materials the first choice in revegetation for restoration and rehabilitation of native ecosystems where timely natural regeneration of the native plant community will not occur.

- Do not authorize, fund, or carry out actions that are likely to cause or promote the introduction or spread of invasive species unless, pursuant to guidelines that it has prescribed, the USFS has determined and made public its determination that the benefits of such actions clearly outweigh the potential harm caused by invasive species; and that all feasible and prudent measures to minimize risk of harm will be taken in conjunction with the actions. An integrated approach for addressing invasive plant problems will be explored since it offers the most thoroughly effective treatment of invasive plants by using a variety of treatment options to eradicate, control, or contain invasive plants where they occur. The combination of treatment methods, including manual, mechanical, biological, controlled grazing, prescribed burning, cultural, and herbicidal methods, will be tailored to fit each site-specific situation and each type of invasive plant. By proposing several methods for invasive plant control, this approach recognizes that using only one management method is unlikely to be effective in all situations.

- Dead, dying and live defective trees are an important part of a healthy, functioning forest ecosystem. They play many ecological roles in forests such as altering plant succession and providing wildlife habitat. Retention of these types of trees is necessary to meet the needs of snag dependent species and ecosystem health.

U.S. Forest Service Noxious Weed Management Policy 20900

USFS Manual Policy 20900, Noxious Weed Management (USFS 2011), includes the following policy for the management of aquatic and terrestrial invasive species (including vertebrates, invertebrates, plants, and pathogens), based on an integrated pest management approach, throughout the National Forest System:

1. Initiate, coordinate, and sustain actions to prevent, control, and eliminate priority infestations of invasive species in aquatic and terrestrial areas of the National Forest System using an integrated pest management approach, and collaborate with stakeholders to implement cooperative invasive species management activities in accordance with law and policy.

2. When applicable, invasive species management actions and standards should be incorporated into resource management plans at the forest level, and in programmatic environmental planning and assessment documents at the regional or national levels.

3. Determine the vectors, environmental factors, and pathways that favor the establishment and spread of invasive species in aquatic and terrestrial areas of the National Forest System, and design management practices to reduce or mitigate the risk for introduction or spread of invasive species in those areas.

4. Determine the risk of introducing, establishing, or spreading invasive species associated with any proposed action, as an integral component of project planning and analysis, and where necessary provide for alternatives or mitigation measures to reduce or eliminate that risk before project approval.

5. Ensure that all USFS management activities are designed to minimize or eliminate the possibility of establishment or spread of invasive species on the National Forest System, or to adjacent areas. Integrate visitor use strategies with invasive species management activities on aquatic and terrestrial areas of the National Forest System. At no time are invasive species to be promoted or used in site restoration or re-vegetation work, watershed rehabilitation projects, planted for bio-fuels

production, or other management activities on national forests and grasslands.

6. Use contract and permit clauses to require that the activities of contractors and permittees are conducted to prevent and control the introduction, establishment, and spread of aquatic and terrestrial invasive species. For example, where determined to be appropriate, use agreement clauses to require contractors or permittees to meet USFS-approved vehicle and equipment cleaning requirements/standards before using the vehicle or equipment in the National Forest System.

7. Make every effort to prevent the accidental spread of invasive species carried by contaminated vehicles, equipment, personnel, or materials (including plants, wood, plant/wood products, water, soil, rock, sand, gravel, mulch, seeds, grain, hay, straw, or other materials).

    a. Establish and implement standards and requirements for vehicle and equipment cleaning to prevent the accidental spread of aquatic and terrestrial invasive species on the National Forest System or to adjacent areas.

    b. Make every effort to ensure that all materials used on the National Forest System are free of invasive species and/or noxious weeds (including free of reproductive/propagative material such as seeds, roots, stems, flowers, leaves, larva, eggs, veligers, and so forth).

8. Where States have legislative authority to certify materials as weed-free (or invasive-free) and have an active State program to make those State-certified materials available to the public, forest officers shall develop rules restricting the possession, use, and transport of those materials unless proof exists that they have been State-certified as weed-free (or invasive-free), as provided in 36 CFR 261 and Departmental Regulation 1512-1.

9. Monitor all management activities for potential spread or establishment of invasive species in aquatic and terrestrial areas of the National Forest System.

10. Manage invasive species in aquatic and terrestrial areas of the National Forest System using an integrated pest management approach to achieve the goals and objectives identified in Forest LRMPs, and other USFS planning documents, and other plans developed in cooperation with external partners for the management of natural or cultural resources.

11. Integrate invasive species management funding broadly across a variety of National Forest System programs, while associating the funding with the specific aquatic or terrestrial invasive species that is being

prioritized for management, as well as the purpose and need of the project or program objective.

12. Develop and use site-based and species-based risk assessments to prioritize the management of invasive species infestations in aquatic and terrestrial areas of the National Forest System. Where appropriate, use a structured decision making process and adaptive management or similar strategies to help identify and prioritize invasive species management approaches and actions.

13. Comply with the USFS performance accountability system requirements for invasive species management to ensure efficient use of limited resources at all levels of the Agency and to provide information for adapting management actions to meet changing program needs and priorities. When appropriate, use a structured decision-making process to address invasive species management problems in changing conditions, uncertainty, or when information is limited.

14. Establish and maintain a national record keeping database system for the collection and reporting of information related to invasive species infestations and management activities, including invasive species management performance, associated with the National Forest System. Require all information associated with the National Forest System invasive species management (including inventories, surveys, and treatments) to be collected, recorded, and reported consistent with national program protocols, rules, and standards.

15. Where appropriate, integrate invasive species management activities, such as inventory, survey, treatment, prevention, monitoring, and so forth, into the National Forest System management programs. Use inventory and treatment information to help set priorities and select integrated management actions to address new or expanding invasive species infestations in aquatic and terrestrial areas of the National Forest System.

16. Assist and promote cooperative efforts with internal and external partners, including private, State, tribal, and local entities, research organizations, and international groups to collaboratively address priority invasive species issues affecting the National Forest System.

17. Coordinate as needed with USFS Research and Development and State and Private Forestry programs, other agencies included under the National Invasive Species Council, and external partners to identify priority/high-risk invasive species that threaten aquatic and terrestrial areas of the National Forest System. Encourage applied research to

develop techniques and technology to reduce invasive species impacts to the National Forest System.

18. As appropriate, collaborate and coordinate with adjacent landowners and other stakeholders to improve invasive species management effectiveness across the landscape. Encourage cooperative partnerships to address invasive species threats within a broad geographical area.

U.S. Bureau of Land Management Resource Management Plan

BLM manages a number of public lands within the primary study area, including the Chappie-Shasta Off-Highway Vehicle Area west of Shasta Dam. These areas fall under the Northern California BLM district and the resource management plan of the Redding BLM field office. The purpose of BLM's resource management plan is to provide an overall direction for managing and allocating public resources in the planning area. BLM is responsible for administering the following strategies related to resource issues common to the portion of the Redding District lands located in the primary study area (BLM 1992, 1993).

- Provide a regional opportunity for motorized recreation with a focus within the Chappie-Shasta Off-Highway Vehicle Area.
- Enhance non-motorized recreation opportunities within the area via a greenway connecting Redding to Shasta Dam along the Sacramento River.
- Maintain or improve the long-term sustained yield of forest products available from commercial forest lands.
- Improve the long-term condition and protection of deer winter range habitat.
- Maintain special-status species habitat.
- Maintain the existing scenic quality of the areas.
- Maintain opportunities to explore and develop freely available minerals on public lands.

Executive Order 11990: Protection of Wetlands

Executive Order 11990 established the protection of wetlands and riparian systems as the official policy of the Federal government. It requires all Federal agencies to consider wetland protection as an important part of their policies and take action to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands.

Executive Order 11312: Invasive Species

Executive Order 11312 directs all Federal agencies to prevent and control introductions of invasive nonnative species in a cost-effective and environmentally sound manner to minimize their economic, ecological, and human health impacts. Executive Order 11312 established a national Invasive Species Council made up of Federal agencies and departments and a supporting Invasive Species Advisory Committee composed of State, local, and private entities. The Invasive Species Council and Advisory Committee oversee and facilitate implementation of the Executive Order, including preparation of a National Invasive Species Management Plan.

12.2.2 State

California Endangered Species Act

Under the California Endangered Species Act (CESA), CDFW has the responsibility for maintaining a list of endangered and threatened species (California Fish and Game Code, Section 2070). CDFW also maintains a list of "candidate species," which are species for which CDFW has issued a formal notice that they are under review for addition to the list of endangered or threatened species. Pursuant to the requirements of CESA, an agency reviewing a proposed project within its jurisdiction must determine whether any State-listed endangered or threatened species may be present in the project study area and, if so, whether the proposed project would have a potentially significant impact on any of these species. In addition, CDFW encourages informal consultation on any proposed project that may affect a species that is a candidate for state listing.

Project-related impacts on species listed as endangered or threatened under the CESA would be considered significant. "Take" of protected species incidental to otherwise lawful management activities may be authorized under Section 2081 of the California Fish and Game Code. Under the CESA, "take" is defined as an activity that would directly or indirectly kill an individual of a species, but the definition does not include "harm" or "harass," as the Federal act does. Therefore, the threshold for take may be higher under CESA than under ESA because habitat modification is not necessarily considered take under CESA.

Authorization from CDFW would be in the form of an incidental take permit or as a consistency determination (Section 2080.1(a) of the Fish and Game Code). Section 2080.1(a) of the Fish and Game Code authorizes CDFW to accept a Federal biological opinion as the take authorization for a state-listed species when a species is listed under both the ESA and the CESA.

California Native Plant Protection Act

The Native Plant Protection Act (California Fish and Game Code, Sections 1900–1913) prohibits the taking, possessing, or sale within the state of any plants with a State designation of rare, threatened, or endangered, as defined by

CDFW. The Act's definition of "endangered" and "rare" closely parallel the CESA definitions of "endangered" and "threatened" plant species.

Section 1602 of the California Fish and Game Code—Streambed Alteration

Diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by CDFW, pursuant to Section 1602 of the California Fish and Game Code. The regulatory definition of stream is a body of water that flows at least periodically or intermittently through a bed or channel that has banks and supports wildlife, fish, or other aquatic life. This includes watercourses that have a surface or subsurface flow that supports or has supported riparian vegetation. CDFW's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife. A CDFW streambed alteration agreement must be obtained for a project that would result in an impact on a river, stream, or lake.

Porter-Cologne Water Quality Control Act

The Porter-Cologne Water Quality Control Act requires that each of the nine RWQCBs prepare and periodically update basin plans for water quality control. Each basin plan sets forth water quality standards for surface water and groundwater and actions to control nonpoint and point sources of pollution to achieve and maintain these standards. Basin plans offer an opportunity to protect wetlands through the establishment of water quality objectives. The RWQCB's jurisdiction includes Federally protected waters as well as areas that meet the definition of "waters of the state." Waters of the state is defined as any surface water or groundwater, including saline waters, within the boundaries of the state. The RWQCB has the discretion to take jurisdiction over areas not Federally protected under Section 401 provided they meet the definition of waters of the state. Mitigation requiring no net loss of wetlands functions and values of waters of the state is typically required by the RWQCB.

California Department of Fish and Wildlife Species Designations

CDFW maintains an informal list of species called "species of special concern." These are broadly defined as wildlife species that are of concern to CDFW because of population declines and restricted distributions, and/or because they are associated with habitats that are declining in California. These species are inventoried in the CNDDB regardless of their legal status. Impacts on species of special concern may be considered significant.

California Department of Fish and Wildlife/California Native Plant Society Plant California Rare Plant Ranking System

CNPS is a statewide nonprofit organization that seeks to increase understanding of California's native flora and to preserve this rich resource for future generations. CDFW and CNPS assign rare plant ranks through the collaborative efforts of the Rare Plant Status Review Group composed of over 300 botanical experts from government, academia, non-government organizations, and the private sector and managed jointly by CDFW and CNPS. California native plants meeting the rarity or endangerment criteria are assigned a CRPR. These plants were formerly referred to as CNPS listed species; however, in March 2010, CDFW adopted the name CRPR for the rarity and endangerment categories to eliminate the false impression that these assignments are the exclusive work of CNPS and that CNPS has had undue influence over the regulatory process. CRPR 1 and 2 species generally qualify as endangered, rare, or threatened within the definition of State CEQA Guidelines CCR Section 15380. In general, CRPR 3 and 4 species do not meet the definition of endangered, rare, or threatened pursuant to CEQA Section 15380; however, these species may be evaluated by the lead agency on a case-by-case basis to determine significance criteria under CEQA.

California Department of Fish and Wildlife Special-Status Natural Communities Designations

CDFW maintains a list of plant communities that are native to California. On that list, CDFW identifies special-status natural communities (e.g., sensitive natural communities), which it defines as communities that are of limited distribution statewide or within a county or region, and are often vulnerable to the environmental effects of projects. Occurrences of special-status natural communities are included in the CNDDB; however, no new occurrences have been added to the CNDDB since the mid-1990s, when funding for tracking natural communities was eliminated. These correspond to communities with State rarity ranks of S1–S3: S1 = critically imperiled, S2 = imperiled, and S3 = vulnerable. These communities may or may not contain special-status species or their habitat. Because of their limited distribution in California, most types of wetlands and riparian communities are considered special-status natural communities. Impacts on special-status natural communities may be considered significant.

12.2.3 Local

Shasta, Tehama, Glenn, Sutter, Sacramento, and Yolo counties and the cities of Redding, Colusa, and Sacramento have established codes and policies that address protection of natural resources, including vegetation, sensitive species, and trees, and are applicable to the project.

Shasta County’s general plan emphasizes that the maintenance and enhancement of quality fish and wildlife habitat is critical to the recreation and tourism industry, and acknowledges that any adverse and prolonged decline of these resources could result in negative impacts on an otherwise vibrant industry. The general plan identifies efforts to protect and restore these habitats to sustain the long-term viability of the tourism and recreation industry (Shasta County 2004).

The City of Redding’s general plan strives to strike a balance between development and conservation by implementing several measures such as creek-corridor protection, sensitive hillside development, habitat protection, and protection of prominent ridge lines that provide a backdrop to the city (City of Redding 2000).

Tehama County's general plan (Tehama County 2009) update provides an overarching guide to future development and establishes goals, policies, and implementation measures designed to address potential changes in county land use and development. The general plan identifies the importance of retaining agriculture as one of the primary uses of land in Tehama County.

Glenn County's general plan provides a comprehensive plan for growth and development in Glenn County for the next 20 years (2007 to 2027). This plan recognizes that public lands purchased for wildlife preservation generate economic activity as scientists and members of the public come to view and study remnant ecosystems (Glenn County 1993).

The City of Colusa's general plan seeks to promote its natural resources through increased awareness and improved public access (City of Colusa 2007).

Sutter County's general plan contains policies that generally address preservation of natural vegetation, including wetlands. It requires that new development mitigate the loss of Federally protected wetlands to achieve "no net loss," but it does not include any other specific requirements.

Sacramento County's general plan contains policies that promote protection of marsh and riparian areas, including specification of setbacks and "no net loss" of riparian woodland or marsh acreage (Sacramento County 1993). It also addresses the need to conserve vernal pools and ephemeral wetlands to ensure no net loss of vernal pool acreage. Several policies specifically promote protection of native oak trees, and, in some areas of the county, seek to ensure that there is no net loss of canopy area. The general plan for the County of Sacramento is currently under revision.

The City of Sacramento Municipal Code addresses the protection of trees within the city boundaries, including general protection of all trees on city property and specific protection of heritage trees.

Yolo County's general plan aims to provide an active and productive buffer of farmland and open space separating the Bay Area from Sacramento, and integrating green spaces into its communities.

12.2.4 Federal, State, and Local Programs and Projects

California Bay-Delta Authority

The California Bay-Delta Authority (CBDA) was established as a State agency in 2003 to oversee implementation of CALFED for the numerous Federal and State agencies working cooperatively to improve the quality and reliability of California's water supplies while restoring the Bay-Delta ecosystem. The July 2000 CALFED *Final Programmatic EIS/EIR* (CALFED 2000b) analyzed a range of alternatives to address these needs and included a MSCS to provide a framework for compliance with ESA, CESA, and Natural Community Conservation Planning Act. The August 2000 CALFED Programmatic ROD identified 12 action plans, including Ecosystem Restoration, Watersheds, and Water Supply Reliability, among others (CALFED 2000d). The CALFED Ecosystem Restoration Program has provided a funding source for projects that include those involving acquisition of lands within the Sacramento River Conservation Area, initial baseline monitoring and preliminary restoration planning, and preparation of long-term habitat restoration management and monitoring plans. In 2009, the California Legislature passed sweeping water reform legislation, including the establishment of the Delta Stewardship Council (DSC). The DSC was transferred all the responsibilities, programs, staff and most of the funding from the CBDA, and the CBDA was dissolved. The DSC was also given additional mandates, including the development of a Delta Plan to guide activities and programs of State and local programs in the legal Delta through a consistency determination process.

Resource Conservation Districts

Numerous resource conservation districts (RCD) are within the primary study area. Once known as soil conservation districts, RCDs were established under California law with a primary purpose to implement local conservation measures. Although RCDs are locally governed agencies with locally appointed, independent boards of directors, they often have close ties to county agencies and the National Resources Conservation Service. RCDs are empowered to conserve resources within their districts by implementing projects on public and private lands and to educate landowners and the public about resource conservation. They are often involved in the formation and coordination of watershed working groups and other conservation alliances.
In the Shasta Lake and upper Sacramento River vicinity, districts include the Western Shasta County RCD and the Tehama County RCD. To the east are the Fall River and Pit River RCDs, and to the west and north are the Trinity County and Shasta Valley RCDs.

Riparian Habitat Joint Venture

The Riparian Habitat Joint Venture (RHJV) was initiated in 1994 and includes signatories from 18 Federal, State, and private agencies. The RHJV promotes conservation and the restoration of riparian habitat to support native bird populations through three goals:

- Promote an understanding of the issues affecting riparian habitat through data collection and analysis
- Double riparian habitat in California by funding and promoting on-the-ground conservation projects
- Guide land managers and organizations to prioritize conservation actions

RHJV conservation and action plans are documented in the Riparian Bird Conservation Plan (RHJV 2004). The conservation plan targets 14 "indicator" species of riparian-associated birds and provides recommendations for habitat protection, restoration, management, monitoring, and policy. The report notes habitat loss and degradation as one of the most important factors causing the decline of riparian birds in California. The RHJV has participated in monitoring efforts within the Sacramento National Wildlife Refuge Complex and other conservation areas. The RHJV's conservation plan identifies lower Clear Creek as a prime breeding area for yellow warblers and song sparrows, advocating a continuous riparian corridor along lower Clear Creek. Other recommendations of the conservation plan apply to the North Delta Offstream Storage Investigation study area in general.

Sacramento River Conservation Area Program

Senate Bill 1086 called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance both fisheries and riparian habitat. The Sacramento River Conservation Area Program has an overall goal of preserving remaining riparian habitat and reestablishing a continuous riparian ecosystem along the Sacramento River between Redding and Chico, and reestablishing riparian vegetation along the river from Chico to Verona. The program is to be accomplished through an incentive-based, voluntary river management plan. The Upper Sacramento River Fisheries and Riparian Habitat Management Plan (Resources Agency 1989) identifies specific actions to help restore the Sacramento River fishery and riparian habitat between the Feather River and Keswick Dam. The Sacramento River Conservation Area Forum Handbook (Resources Agency 2003) is a guide to implementing the program. The Keswick Dam-to-Red Bluff portion of the conservation area includes areas within the 100-year floodplain, existing riparian bottomlands, and areas of contiguous valley oak woodland, totaling approximately 22,000 acres. The 1989 fisheries restoration plan recommended several actions specific to the primary study area:

- Fish passage improvements at RBPP (under way; project final EIS/EIR released May 2008)
- Modification of the Spring Creek Tunnel intake for temperature control (completed)
- Spawning gravel replacement program (ongoing)
- Development of side-channel spawning areas, such as those at Turtle Bay in Redding (ongoing)
- Structural modifications to Anderson-Cottonwood Irrigation District Dam to eliminate short-term flow fluctuations (completed)

- Maintaining instream flows through coordinated operation of water facilities (ongoing)
- Improvements at Coleman National Fish Hatchery (partially complete)
- Measures to reduce acute toxicity caused by acid mine drainage and heavy metals (ongoing)
- Various fisheries improvements on Clear Creek (partially complete)
- Flow increases, fish screens, and revised gravel removal practices on Battle Creek (beginning summer 2006)
- Control of gravel mining, improvements of spawning areas, improvements of land management practices in the watershed, and protection and restoration of riparian vegetation along Cottonwood Creek

Sacramento River National Wildlife Refuge

The Sacramento River National Wildlife Refuge (SRNWR) is composed of many units between the cities of Red Bluff and Princeton. The SRNWR along the middle Sacramento River is part of the Sacramento National Wildlife Refuge Complex, consisting of five refuges and three wildlife management areas within the Sacramento Valley. Reaches and subreaches of the river are delineated based generally on transitions in fluvial geomorphic riverine conditions, although county boundaries were considered as well. The middle Sacramento River region between Red Bluff and Colusa includes three units within the Chico Landing Subreach that contain restoration project sites addressed in the Sacramento River–Chico Landing Subreach Habitat Restoration Draft EIR (CBDA 2005). In addition, three areas proposed for restoration in this area occur within the larger SRNWR units that were evaluated in the Environmental Assessment for Proposed Restoration Activities on the Sacramento River National Wildlife Refuge (USFWS 2001; CBDA 2005).

In June 2005, USFWS issued the Sacramento River National Wildlife Refuge Draft Comprehensive Conservation Plan and Environmental Assessment and Finding of No Significant Impact (USFWS 2005) to serve as an integrated management plan for land that it acquires and manages for inclusion in the SRNWR. The SRNWR final comprehensive conservation plan includes goals, objectives, and strategies to guide management of lands within the SRNWR. It also includes assessments of and establishes parameters for “compatible uses,” which are uses that are considered compatible with the primary purposes for which the area was established. Riparian habitat restoration projects are being implemented under cooperative agreements between USFWS and other entities such as TNC in accordance with the SRNWR final comprehensive conservation plan.

Sacramento River Preservation Trust

The Sacramento River Preservation Trust is a private, nonprofit organization active in environmental education and advocacy to preserve the natural environmental values of the Sacramento River. The trust has participated in various conservation and land acquisition projects, including securing lands for the SRNWR. The group is pursuing designation of a portion of the Sacramento River between Redding and Red Bluff as a national conservation area.

Sacramento River Watershed Program

The Sacramento River Watershed Program is an effort to bring stakeholders together to share information and work together to address water quality and other water-related issues within the Sacramento River watershed. The group is funded congressionally through the U.S. Environmental Protection Agency. The program's primary goal is "to ensure that current and potential uses of Sacramento River watershed resources are sustained, restored, and where possible, enhanced while promoting the long-term social and economic vitality of the region." The Sacramento River Watershed Program manages grants for the Sacramento River Toxic Pollutants Control Program; performs extensive water quality monitoring, data collection, and data management for the watershed; and is instrumental in the study and monitoring of toxic pollutants. Although the program does not implement restoration projects, it is a potential partner for coordinating research and monitoring through consensus-based collaborative partnerships and promoting mutual education among the stakeholders of the Sacramento River watershed.

Sacramento Watersheds Action Group

The Sacramento Watersheds Action Group is a nonprofit corporation that secures funding for, designs, and implements projects that provide watershed restoration, streambank and slope stabilization, erosion control, watershed analysis, and road removal. Sacramento Watersheds Action Group has successfully worked with local groups, agencies, and organizations to fund and complete restoration projects on the Sacramento River and tributaries downstream from Keswick Dam. Their projects include development of the Sulphur Creek Watershed Analysis and Action Plan, the Whiskeytown Lake Shoreline Erosion Control Project, the Sulphur Creek Crossing Restoration Project, and the Lower Sulphur Creek Realignment and Riparian Habitat Enhancement Project. Sacramento Watersheds Action Group is a potential local sponsor for watershed restoration actions in the study area.

Shasta Land Trust

The Shasta Land Trust is a regional, nonprofit organization dedicated to conserving open space, wildlife habitat, and agricultural land. The trust works with public agencies and private landowners and is funded primarily through membership dues and donations. It employs various voluntary programs to protect and conserve valuable lands using conservation easements, land donations, and property acquisitions. The trust is a potential local partner for restoration activities in the Shasta Dam-to-Red Bluff area.

The Nature Conservancy

TNC is a private, nonprofit organization involved in environmental restoration and conservation throughout the United States and the world. TNC approaches environmental restoration primarily through strategic land acquisition from willing sellers and obtaining conservation easements. Some of the lands are retained by TNC for active restoration, research, or monitoring activities, while others are turned over to government agencies such as USFWS or CDFW for long-term management. Lower in the Sacramento River basin, TNC has been instrumental in acquiring and restoring lands in the SRNWR and managing several properties along the Sacramento River. It also has pursued conservation easements on various properties at tributary confluences, including Cottonwood and Battle creeks.

The Trust for Public Land

The Trust for Public Land is a national, nonprofit organization involved in preserving lands with natural, historic, cultural, or recreational value, primarily through conservation real estate. The trust's Western Rivers Program has been involved in conservation efforts along the Sacramento River between Redding and Red Bluff (BLM's Sacramento River Bend Management Area), Battle Creek, Paynes Creek, Inks Creek, and Fenwood Ranch in Shasta County. The group promotes public ownership of conservation lands to ensure public access and enjoyment.

12.3 Environmental Consequences and Mitigation Measures

This section describes the methods for environmental evaluation, assumptions, and specific criteria that were used to determine significance for botanical resources and wetlands, and then discusses the effects of the project and proposes mitigation where necessary.

12.3.1 Methods and Assumptions

The following sections describe the methods, processes, procedures, and assumptions used to formulate and conduct the environmental impact analysis. Data for the following analysis were taken from modeling, existing reports on local and site-specific biology, and on-site assessments during field reviews.

CalSim Modeling

The SLWRI 2012 Version CalSim-II model, developed in 2012 for SLWRI, was used to aid in the evaluation of potential impacts of the project alternatives on water-related resources, including riparian habitats along the upper and lower Sacramento River and in the Delta. This computer modeling used historical data on California hydrology to represent the variety of weather and hydrologic patterns, including wet periods and droughts, under which water storage and conveyance facilities would be operated. Two scenarios (base cases) of demands for, and storage and conveyance of, water were used in model runs: 2005 facilities and demands ("existing conditions") and forecasted

2030 demands and reasonably foreseeable projects and facilities ("future conditions"). A model run was conducted for each of these base cases combined with each alternative, so that the effects of the No-Action Alternative and other alternatives could be evaluated relative to both existing and future conditions. CalSim-II is a useful tool for this type of comparative analysis where the model is run twice, once to represent a base condition (no action) and a second time with a specific change (action) to assess the change in the outcome due to the input change.

The hydrologic analysis conducted for this EIS used the SLWRI 2012 Version CalSim-II model to approximate system-wide changes in storage, flow, salinity, and reservoir system reoperation associated with the SLWRI alternatives. The historical flow record of October 1921 to September 2003, adjusted for the influences of land use changes and upstream flow regulation, is used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities are represented by a network of arcs and nodes. CalSim-II uses a mass balance approach to route water through this network. Simulated flows are mean flows for the month; reservoir storage volumes correspond to end-of-month storage. Monthly flow results were also used to simulate mean daily flows. A more detailed description of the SLWRI 2012 Version CalSim-II model, the modeling methodology used to evaluate this project, and key assumptions are provided in the Modeling Appendix. Summaries of the analysis and modeling results are provided in Chapter 6, "Hydrology, Hydraulics, and Water Management."

Maximum vs. Likely Area of Impact in Relocation Areas

The relocation areas identified by Reclamation in the 2013 Draft EIS were based on preliminary information, as planning and related engineering designs were incomplete at that time. Habitat impacts disclosed for the relocation areas in the June 2013 Draft EIS assumed complete impact (i.e., 100 percent loss) within all the relocation areas. Since that time, Reclamation revised the relocation area boundaries by conducting additional planning and design that in many cases reduced the size of the relocation areas. Additionally, Reclamation designed infrastructure and other activities within the revised relocation areas to avoid wetlands and other sensitive resources, and reduce habitat impacts to the extent feasible.

Since final relocation area planning and designs are incomplete, each relocation area contains a "maximum" and "likely" impact area. The maximum area of impact is defined as the maximum area potentially affected by project activities occurring within the relocation areas, while the likely impact area represents Reclamation's best estimate of the actual impact (i.e., "most likely"). For the purposes of this Final EIS, habitat impacts are based on the assumption of complete loss within the likely impact areas. Table 12-12 shows a comparison of the maximum and likely CWHR habitats in the relocation areas.

Table 12-12. Summary of "Maximum" and "Likely" Plant Communities in the Relocation Areas

Plant Communities	Area (Acres)

Max = maximum

Vegetation and Habitat Types

The impact mechanisms of construction-related activities are evaluated in the sections addressing Shasta Lake and its vicinity. Besides construction-related activities, the project could potentially affect vegetation and habitat types through any of the following impact mechanisms:

- Increased inundated width of the river during the active growing season
- Reduced frequency and/or magnitude of peak flows
- Altered geomorphic processes (e.g., meander, channel avulsion) along rivers
- Altered availability of groundwater
- Altered rates of stage decline during seed dispersal or germination establishment

For each vegetation type, environmental effects potentially resulting from each of these impact mechanisms were assessed. This assessment was based on a review of the results of CalSim simulations of mean monthly flows, aerial photographs, background information on the upper Sacramento River and adjacent uplands, and scientific literature on the ecology of each vegetation type. Results of hydraulic modeling of the project’s potential effects on peak flows and analyses of the project’s potential effects on geomorphic processes along the Sacramento River were not available to support this analysis.

In addition to these impact mechanisms, increased water supplies or increased supply reliability also could reduce a limitation on urban growth and development or on other activities that could affect vegetation in the primary and extended study areas, resulting in potentially significant impacts. The effects of this growth would be analyzed in general plan EIRs and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these impacts would be the responsibility of these local jurisdictions, and not Reclamation. The expected increase in water deliveries relative to the entire CVP and SWP would be small, however, and assuming increased deliveries could be provided to any number of geographic areas within the CVP and SWP service areas (and in part would substitute for ongoing groundwater pumping), the project’s impact on urban growth and development that could affect vegetation would be minor.

Similarly, projects potentially affecting streambeds, wetlands, and listed species would require permits from the CDFW, USACE, and USFWS, respectively; impacts on these resources would be avoided, minimized, and/or mitigated during those agency consultations.

Because the extent, location, and timing of induced growth are currently highly uncertain, and in the future the impacts of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects, growth-inducing effects on vegetation and habitat types are not discussed further in this section. However, additional discussion of growth-inducing effects specific to the alternative actions is provided in Chapter 26, "Other Required Disclosures," of this EIS.

For the purposes of the impact analysis for the loss of general habitats in the Shasta Lake and vicinity portion of the primary study area, California Wildlife Habitat Relationship (CWHR) types are used to describe the affected habitats. Table 12-13 provides a crosswalk between MCV and CWHR habitat types.

Special-Status Species

The project could affect special-status plant species through the same impact mechanisms potentially affecting vegetation and habitat types, and also by altering the structure and species composition of vegetative communities, particularly within river corridors.

Potential impacts resulting from these impact mechanisms were assessed for special-status plant species that may occur in the project area. This assessment was based on the potential impacts on vegetation and habitat types for each alternative and on available information about the distribution, ecology, and reproductive biology of each special-status species.

Assumptions

The following assumptions have been made for the purposes of the impact analysis:

- Activity areas (construction areas for infrastructure and relocation areas) would be completely cleared.
- Mechanized equipment would be used for discrete areas where total clearing would occur.
- All trees would be removed along other areas of the lake, including those that could be considered a hazard in coves used by houseboats for moorage; other vegetation would be left.

Trees would be removed using helicopters and barges.

12.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

Vegetation and Habitat Types

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on vegetation and habitat types would be significant if project implementation would do any of the following:

- Result in a substantial adverse effect on any riparian vegetation or habitat, oak woodlands or savannas, or other sensitive natural community identified in local or regional plans, policies, regulations, or by CDFW or USFWS
- Conflict with a local policy or ordinance that protects vegetation resources, such as a tree preservation policy or ordinance
- Conflict with or violate the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, State, or Federal habitat conservation plan relating to the protection of plant resources
- Result in the potential for spread of nonnative and invasive plant species

Special-Status Species

Impacts of an alternative on special-status species would be significant if project implementation would do any of the following:

- Result in a substantial adverse effect, either directly or through habitat modifications, on any plant species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by CDFW or USFWS

- Have the potential to substantially reduce the number or restrict the range of an endangered or threatened plant species or a plant species that is a candidate for State listing or proposed for Federal listing as endangered or threatened

- Have the potential for substantial reductions in the habitat of an endangered or threatened plant species or a plant species that is a candidate for State listing or proposed for Federal listing as endangered or threatened

- Substantially reduce the number or restrict the range of an endangered, rare, or threatened species, cause a native plant population to drop below self-sustaining levels, or threaten to eliminate a plant community

- Have the potential to cause a native plant population to drop below self-sustaining levels

Wetlands

Impacts of an alternative on wetlands would be significant if project implementation would do any of the following:

- Have a substantial adverse effect on Federally protected wetlands as defined by Section 404 of the CWA (including, but not limited to, marsh, vernal pool, etc.) through direct removal, filling, hydrological interruption, flooding, or other means

- Conflict with any State or local policies or ordinances protecting wetland and/or riparian resources

- Conflict with or violate the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, State, or Federal habitat conservation plan relating to the protection of wetland resources

Shasta-Trinity National Forest Land and Resource Management Plan

In addition to the above significance criteria, the STNF LRMP (USFS 1995) contains forest goals, standards, and guidelines designed to guide the management of the biological resources within the STNF, located in the Shasta Lake and vicinity portion of the primary study area. To comply with NEPA, this assessment of impacts evaluates the project's compliance with the STNF LRMP forest goals, standards, and guidelines listed in the "Regulatory Framework" section listed above. Mitigation measures are provided (as needed) to move project actions toward compliance with the STNF LRMP.

12.3.3 Topics Eliminated from Further Consideration

No topics related to botanical resources and wetlands that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

12.3.4 Direct and Indirect Effects

This section identifies how specific vegetation types could be affected by the project. The project could affect vegetation by doing any of the following:

- Causing construction-related effects at Shasta Dam and around Shasta Lake
- Altering flow regimes downstream from Shasta Lake and downstream from other reservoirs with altered operations
- Increasing water supply reliability that, in turn, could contribute to growth or changes in agricultural land uses in the CVP and SWP service areas

By altering storage and reservoir operations, the project would change flow regimes in downstream waterways. In turn, these alterations to the flow regime could affect vegetation, particularly riparian and wetland vegetation along several waterways.

No-Action Alternative

Under the No-Action Alternative, the Federal Government would take reasonably foreseeable actions, as defined in Chapter 2, “Alternatives,” but would take no additional action toward implementing a specific plan to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water reliability issues in California. Shasta Dam would not be modified, and the CVP would continue operating similar to the existing condition. Changes in regulatory conditions and water supply demands would result in differences in flows on the Sacramento River and at the Delta between existing and future conditions. Possible changes include the following:

- Firm Level 2 Federal refuge deliveries
- SWP deliveries based on full Table A amounts
- Full implementation of the Grassland Bypass Project
- Implementation of salinity management actions similar to the Vernalis Adaptive Management Plan
- Implementation of the South Bay Aqueduct Improvement and Enlargement Project

- Increased San Joaquin River diversions for water users in the Stockton Metropolitan Area after completion of the Delta Water Supply Project
- Increased Sacramento River diversions by Freeport Regional Water Project agencies
- Operation of RBPP with gates out year round
- San Joaquin River Restoration Program Full Restoration Flows

This alternative is used as a basis of comparison for future condition comparisons.

Shasta Lake and Vicinity

Impact Bot-1 (No-Action): Loss of Federally or State Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-2 (No-Action): Loss of MSCS Covered Species Species covered by the MSCS would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-3 (No-Action): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species USFS sensitive, BLM sensitive, or CRPR listed species would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-4 (No-Action): Loss of Jurisdictional Waters Waters of the United States would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-5 (No-Action): Loss of General Vegetation Habitats General vegetation habitats would not be lost as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-6 (No-Action): Spread of Noxious and Invasive Weeds Noxious and invasive weeds would not be spread as a result of inundation, vegetation removal, or construction activities. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (No-Action): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from

Altered Flow Regimes Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities along the upper Sacramento River, and habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants would be small, and beneficial effects are also anticipated to result from other management and restoration actions. Thus, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. As a consequence of these actions, the flow regime of the upper Sacramento River would change between 2005 and 2030. The CalSim-II modeling results that simulate these changes are provided in the *Hydrology, Hydraulics, and Water Management Technical Report*. CalSim-II mean monthly results used to simulate mean daily values also indicate the relative magnitude of changes to the flow regime.

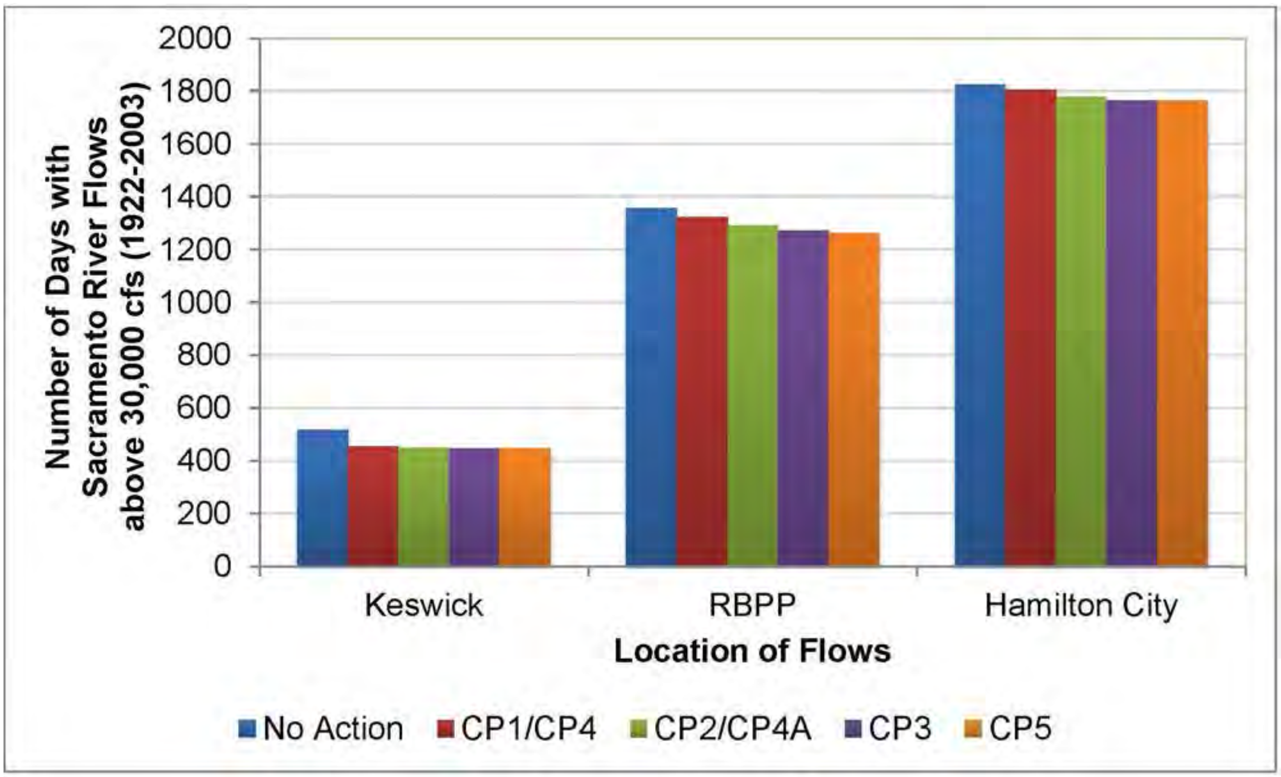
The rates of geomorphic processes strongly affect the extent of different riparian communities, and these rates are strongly related to flow regime. For example, bank erosion and the average rate of meander migration are closely related to the cumulative portion of flow above a threshold volume. On portions of the Sacramento River, this threshold may be around 30,000 cfs (Larsen, Fremier, and Greco 2006; Stillwater Sciences 2007), which is well below the bankfull discharge but well above flows during spring and summer. However, other important thresholds for bank erosion and channel avulsion along the Sacramento River have been estimated within the range from 10,000 to 80,000 cfs (Stillwater Sciences 2007). (For additional discussion of the relationship of geomorphic processes to flow along the Sacramento River, see the *Fisheries and Aquatic Ecosystem Technical Report*.)

The number of days with Sacramento River flows above 30,000 cfs (1922-2013) are summarized on Figure 12-6. Overall, these modeling results suggest there would be only very small changes in flows greater than 30,000 cfs. Flows of this magnitude strongly affect bank erosion and meander migration, and are related to other geomorphic processes affecting the extent of different riparian communities. These relationships are described in greater detail under CP1.

This change might not be sufficient to cause significant effects on riparian and wetland communities, or on associated special-status species.

In addition to causing small changes in flow regime, the No-Action Alternative would continue to alter the structure and species composition of riparian and wetland vegetation resulting from continued operation of Shasta Dam. Before the construction of Shasta Dam, river flow and stage would decrease gradually during the period of cottonwood and willow seed dispersal. In many years, this flow pattern would facilitate establishment of these early-successional species along the Sacramento River throughout the primary study area.

Operation of Shasta Dam has increased flow volumes from mid-spring to early summer. Consequently, in most years, operation of the dam precludes or substantially reduces opportunities for establishment of cottonwoods and opportunities for willow establishment. As a result of this (and other alterations to the flow regime of the Sacramento River), the structure and species composition of riparian vegetation has been changing within the primary study area (Fremier 2003, Roberts et al. 2002). The extent of early-successional riparian communities (e.g., cottonwood forest) has been decreasing while the extent of mid-successional communities (e.g., mixed riparian forest) has been increasing. Such changes would continue under the No-Action Alternative for several decades, but would diminish with time.



Key:
cfs = cubic feet per second
RBPP = Red Bluff Pumping Plant

Figure 12-6. Number of Days with Sacramento River Flows above 30,000 cfs (1922-2013)

However, under the No-Action Alternative a number of management and restoration plans and programs would be implemented. These actions are described in Section 12.2, "Regulatory Framework," of this EIS. These actions would cause beneficial effects that would likely be of similar magnitude to the anticipated adverse effects of small changes in flow regime and of continued effects from past actions, and thus would largely offset those adverse effects.

For the reasons described above, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-8 (No-Action): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Numerous local and regional plans promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Expected future effects of the No-Action Alternative on riparian communities have largely been considered in the existing plans. The No-Action Alternative would not conflict with approved local or regional plans. This impact would be less than significant.

Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River in the primary study area. These plans, which are discussed in more detail in the "Regulatory Setting" section of this EIS, include the Sacramento River Conservation Area Program, which promotes the conservation and the restoration of riparian habitat. Under the No-Action Alternative, adverse effects would result from the continued consequences of past actions (e.g., construction of Shasta Dam and the introduction of nonnative species) and from the effects of reasonably foreseeable actions. Most adverse effects that are the continued consequences of past actions have been considered in the development of existing local and regional plans. In addition, foreseeable water resources and levee actions are expected to be consistent with local and regional plans, and anticipated adverse effects are likely to be fully mitigated and not conflict with a local or regional plan. Therefore, the No-Action Alternative would not conflict with approved local or regional plans with objectives of riparian habitat protection or watershed management. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-9 (No-Action): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for vernal pool species in the upper Sacramento River area is not expected to be adversely affected. This impact would be less than significant.

Designated critical habitat for four vernal pool special-status plant species exists in the upper Sacramento River portion of the primary study area: slender orcutt grass, Hoover's spurge, hairy orcutt grass, and Greene's tuctoria. Critical habitat for these species in the primary study area is confined to vernal pool communities (USFWS 2006). Vernal pools are generally not present within the active floodplain. However, if vernal pool habitats for these special-status species are present in the active floodplain of the upper Sacramento River, they could be affected by the small reduction in the frequency and magnitude of overbank flows. It is not known if this would be an adverse or beneficial effect. Because this effect of the No-Action Alternative is somewhat speculative and not necessarily adverse, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-10 (No-Action): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Although Shasta Dam would not be altered, water storage, conveyance, and deliveries to water districts would likely increase because of reasonably foreseeable projects. However, environmental regulations would continue to provide protection for botanical resources and wetlands, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable projects that would occur with or without enlarging Shasta Dam. Consequently, deliveries to water districts along the upper Sacramento River in the primary study area would likely increase between now and 2030, and this could reduce any limitation on urban growth and development. However, environmental regulations would continue to protect wetlands, riparian habitats, other sensitive botanical communities, and special-status plant species, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Furthermore, CVP water delivered in this area would primarily be for agricultural purposes, and agricultural acreages are not expected to expand. For the reasons described above, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta

Impact Bot-11 (No-Action): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under the No-Action Alternative. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-12 (No-Action): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under the No-Action Alternative. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-13 (No-Action): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, *Floodplain, and Side Channel Habitats* The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under the No-Action Alternative. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Bot-14 (No-Action): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities along the lower Sacramento River and in the Delta, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants would be small, and beneficial effects are also anticipated to result from management and restoration actions. Thus, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would change because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. As a consequence of these actions, the flow regime of the lower Sacramento River could change between 2005 and 2030. The CalSim-II modeling results that simulate these changes are provided in the *Hydrology, Hydraulics, and Water Management Technical Report*. CalSim-II results temporally downscaled to mean daily values also indicate the relative magnitude of changes to the flow regime. The simulated change in mean daily discharges greater than 30,000 cfs below RBPP and Hamilton City are summarized on Figure 12-6. (These locations are shown on Figure 12-7.) Flows of this magnitude strongly affect bank erosion and meander migration, and are related to other geomorphic processes affecting the extent of different riparian communities. (These relationships are described in greater detail under CP1.) Overall, these modeling results suggest only a very small change in flows greater than 30,000 cfs along the uppermost portion of the lower Sacramento River. This change might not be sufficient to cause significant effects on riparian and wetland communities, or on associated special-status species.

However, besides causing additional, very small changes in flow regime, the No-Action Alternative would continue to alter the structure and species composition of riparian and wetland vegetation along the lower Sacramento River resulting from the continued operation of Shasta Dam. Before the construction of Shasta Dam, flow volume would decrease gradually during the period of cottonwood and willow seed dispersal. In many years, this flow pattern would facilitate establishment of these early- successional species along the Sacramento River throughout the extended study area. As described for the upper Sacramento River above, along the lower Sacramento River, the extent of early-successional riparian communities would continue decreasing while the extent of mid-successional communities would continue increasing under the No-Action Alternative.

However, under the No-Action Alternative, a number of management and restoration plans and programs carried out by a large number of agencies would be implemented. These actions are described in the "Regulatory Setting" section of this EIS. These actions would cause beneficial effects that would likely be of similar magnitude as the anticipated adverse effects of small changes in flow regime and of continued effects from past actions, and thus would largely offset those adverse effects.

For the reasons described above, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

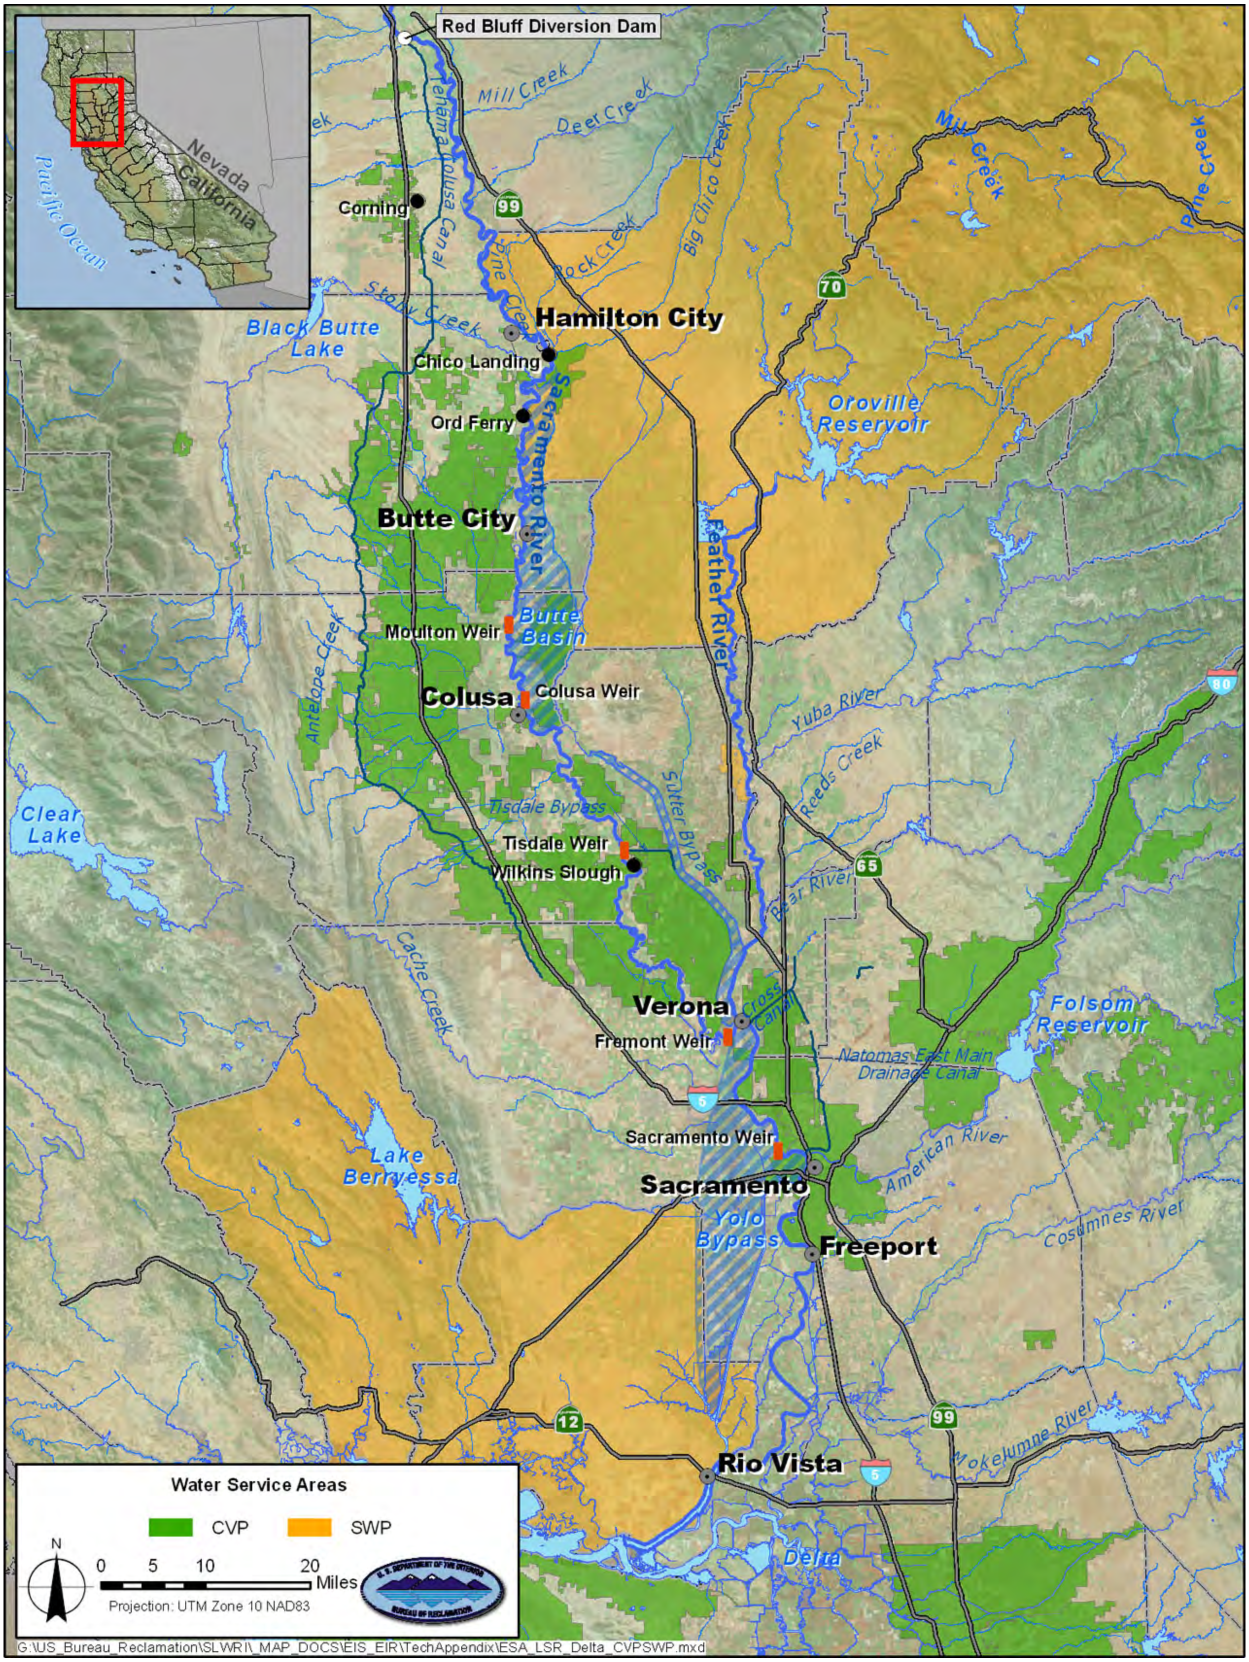


Figure 12-7. Locations Along the Lower Sacramento River

Impact Bot-15 (No-Action): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. In the development of regional and local plans, most ongoing adverse effects of past actions were considered, but not all effects of reasonably foreseeable actions. Unmitigated effects from these actions could be sufficient to conflict with these plans. Therefore, the No-Action Alternative could conflict with approved local or regional plans. This impact would be potentially significant.

Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River and in the Delta in the extended study area. These plans, which are discussed in more detail in the "Regulatory Framework" section of this EIS, include the Sacramento River Conservation Area Program and the CALFED Ecosystem Restoration Program, both of which promote the conservation and the restoration of riparian habitat. Under the No-Action Alternative, adverse effects would result from the continued consequences of past actions (e.g., construction of Shasta Dam and the introduction of nonnative species) and from the effects of foreseeable actions. Most adverse effects that are the continued consequences of past actions have been considered in the development of existing local and regional plans. However, the adverse effects of all foreseeable water resource and levee actions were not considered in the development of local and regional plans, and these adverse effects are not likely to be completely avoided or fully mitigated. The unmitigated effects of these actions could be sufficient overall to conflict with a local or regional plan. Therefore, the No-Action Alternative could conflict with approved local or regional plans with objectives of riparian habitat protection or watershed management. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-16 (No-Action): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth along the Lower Sacramento River and in the Delta Although Shasta Dam would not be altered, water storage, conveyance, and deliveries to water districts would likely increase because of reasonably foreseeable actions. However, environmental regulations would continue to provide protection for botanical resources and wetlands, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for site-specific projects. Therefore, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries would likely increase because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. Thus, deliveries to water districts in the extended study area along the lower Sacramento River and in the Delta would likely increase between now and 2030, and this could reduce a limitation on urban growth and development. However, environmental regulations would continue to protect wetlands, riparian habitats, other sensitive botanical communities, and special-status plant species, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for site-specific projects. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas

Impact Bot-17 (No-Action): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities in the CVP and SWP service areas, and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs would be less than below Shasta Dam along the Sacramento River, and may not be sufficient to alter the distribution of plant communities, or the extent or quality of associated special-status species habitat. Therefore, this impact would be less than significant.

Altered flow regimes associated with the No-Action Alternative could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected by the altered flow regime. Effects on oak communities and upland habitats for special-status plants would be somewhat speculative and may not all be adverse; thus, on oak communities and special-status plants of upland habitats, this impact would be less than significant. Although riparian and wetland communities could be affected, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. Below CVP and SWP reservoirs, these alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities, or the extent or quality of associated special-status species habitat. Therefore, this impact would be less than significant below CVP and SWP reservoirs in the extended study area. Mitigation is not required for the No-Action Alternative.

Impact Bot-18 (No-Action): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas The No-Action Alternative would not have substantial effects on riparian vegetation and habitats, and thus, would not conflict with existing local and regional plans in the CVP and SWP service areas. This impact would be less than significant.

Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of the No-Action

Alternative would not have substantial effects on riparian vegetation and habitats. Therefore, implementation of this alternative would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact in the CVP and SWP service areas would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Bot-19 (No-Action): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Although Shasta Dam would not be altered, water storage, conveyance, and deliveries to the CVP and SWP service areas would likely increase because of reasonably foreseeable actions. However, environmental regulations would continue to protect botanical resources and wetlands, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant.

Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries to the CVP and SWP service areas would likely increase because of several reasonably foreseeable actions that would occur with or without enlarging Shasta Dam. Thus, CVP and SWP deliveries would likely increase between now and 2030, and this could reduce any limitation on growth. However, environmental regulations would continue to protect wetlands, riparian habitats, other sensitive botanical communities, and special-status plant species, and the effects of future growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability and increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 6.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 8.5 feet and enlarge the total storage capacity in the reservoir by 256,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years[2] and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP1 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to

[2] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact Bot-1 (CP1): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No such species are known or expected to occur. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP1): Loss of MSCS Covered Species Implementation of the project would result in the loss of MSCS-covered species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant. The only MSCS species known to occur in the project area is Shasta snow-wreath.

Reclamation conducted detailed surveys of all Shasta snow-wreath populations in the vicinity of the project area between March and May 2014 to determine the overall extent of these populations. Surveys were conducted using a total station and survey-grade GPS instruments to obtain accurate population boundaries at each Shasta snow-wreath population. Using the survey information, Reclamation verified whether flooding impacts would occur at each population, and if so, estimates of the amount of loss to each population were calculated using existing topographic information for each dam raise alternative.

Inundation caused by a 6.5-foot dam raise would affect all or portions of nine Shasta snow-wreath populations. These nine populations represent 38 percent of all known Shasta snow-wreath populations and encompass approximately 79 acres. Flooding impacts under CP1 would result in the loss of approximately 1.5 acres, or approximately 2 percent of these nine Shasta snow-wreath populations. The greatest proportional impacts to these populations occur at the Blue Ridge West, Brock Creek, Cove Creek, Keluche Creek, and Shasta Caverns populations. Table 12-14 provides a detailed summary of impacts to Shasta snow-wreath under CP1. Mitigation measures for impacts to Shasta snow-wreath populations are presented in Section 12.3.5, “Mitigation Measures.”

Because complete surveys have not been conducted in the entire impoundment area, other MSCS plant species may be present. In these areas, all or portions of MSCS plant populations could be inundated. This loss of MSCS-covered species and their habitat would be substantial; the impact would be significant. Potential mitigation lands containing comparable habitat and conceptual habitat enhancement projects have been identified adjacent to the project and in the vicinity. Additional discussion of how these lands may be applied as mitigation and at what ratios is provided in Section 12.3.5, “Mitigation Measures.”

Table 12-14. Summary of Impacts to Shasta Snow-wreath Populations Adjacent to Shasta Lake Under CP1

Population	Location	Size (Acres)	CP1 Impact (Acres)	Percent Total Impact to Population	Comments
Blue Ridge (west)	Main Body	1.11	0.470	42%	Lower portion of population would be flooded.
Blue Ridge (east)	Main Body	0.03	0	0%	No impact under CP1.
Brock Creek	Pit River Arm	1.38	0.487	35%	Lower portion of population would be flooded.
Campbell Creek	McCloud River Arm	1.90	0.002	<1%	Small area at the downstream portion of the population would be flooded.
Cove Creek	Main Body	1.87	0.264	14%	Lower portion of population would be flooded.
Ellery Creek	McCloud River Arm	28.65	0.031	<1%	The entire very small disjunct sub-population located near Ellery Creek Campground would be flooded.
Jones Valley	Main Body	0.33	0	0%	No Impact under CP1.
Keluche Creek	McCloud River Arm	0.15	0.085	56%	More than half of the population would be flooded.
Shasta Caverns	McCloud River Arm	0.08	0.018	21%	Lower portion of population would be flooded.
South of Cove Creek	Main Body	1.39	0.143	10%	Lower portion of population would be flooded.
Stein Creek	Pit River Arm	42.15	0.023	<1%	Lower portion of population would be flooded.

CP = Comprehensive Plan

Impact Bot-3 (CP1): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species
Implementation of the project would result in the loss of USFS sensitive, BLM sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

For areas where botanical surveys have been conducted, direct impacts have been determined using GIS to ascertain the populations within the impoundment area, relocation areas, and construction footprints.

Based on results of surveys to date, special-status plant species known to occur in the primary study area include Shasta County arnica, northern clarkia, Cantelow's lewisia, Shasta snow-wreath, slender false lupine, Shasta huckleberry, and Shasta limestone monkeyflower.

Direct impacts to Shasta snow-wreath under CP1 are addressed in Impact Bot-2 (CP1). As a USFS sensitive species, the Shasta snow-wreath is recognized by the USFS to require special management to prevent the species from becoming threatened or endangered. Because the snow-wreath is a Shasta County endemic species, the impacts will result in a decline in populations and habitat and may result in a trend towards listing.

Inundation caused by a 6.5-foot dam raise and activities in the relocation areas could impact all or portions of Shasta County arnica, northern clarkia, Cantelow's lewisia, slender false lupine, Shasta huckleberry, and Shasta limestone monkeyflower populations occurring in the impoundment and relocation areas. Potential populations occurring in the unsurveyed portions of the impoundment area could be flooded and result in a potentially significant impact. Impacts on known populations are provided below.

Inundation of the impoundment area would impact all or portions of the Shasta arnica population south of Bridge Bay Resort on the Main Body of the lake.

Vegetation removal and/or construction activities in the relocation areas would impact all or portions of the northern clarkia populations in Bailey Cove (McCloud Arm).

Inundation of the impoundment area would impact all or portions of the Cantelow's lewisia population on a rock outcrop on the right bank of the Upper Sacramento River riverine reach near the Shasta Lake/upper Sacramento River transition zone. Inundation will also impact populations found along the Sacramento Arm near Elmore Mountain.

Inundation of the impoundment area and vegetation removal in the relocation areas would impact all or portions of 82 slender false lupine populations at scattered locations throughout these areas.

Inundation caused by a 6.5-foot dam raise would impact small portions (approximately 14 shrubs) of four Shasta huckleberry populations located on the Main Body ((little) Squaw Creek, Shoemaker Gulch, Little Backbone Creek) and the Squaw Creek Arm (Horse Creek). These populations extend beyond the project boundary at each location and consist of hundreds to over a thousand shrubs. No Shasta huckleberry population will be completely lost as a result of CP1.Because complete surveys have not been conducted in the entire impoundment area, other USFS sensitive, BLM sensitive, and CRPR species plant species may be present. In these areas, all or portions of USFS sensitive, BLM sensitive, and CRPR species plant populations could be inundated. This would be a potentially significant impact.

Collectively, the loss of USFS sensitive, BLM sensitive, and CRPR species and their habitat would therefore be potentially significant. Mitigation for this impact is described in Section 12.3.5, "Mitigation Measures."

Impact Bot-4 (CP1): Loss of Jurisdictional Waters Implementation of the project will result in the loss of jurisdictional waters caused by flooding the impoundment area and discharge of fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine habitat). Therefore, this impact would be significant.

Direct impacts would occur by conversion of jurisdictional waters (e.g., wetlands and streams) to lacustrine habitat with implementation of CP1. All features within the impoundment area would be converted to lacustrine habitat. Under CP1, approximately 14 acres of wetlands and 19 acres of other waters would be converted to lacustrine habitat (Table 12-15). This will result in a net loss of approximately 14 acres of wetlands. No net loss of other waters will occur under CP1, as lacustrine waters will replace riverine waters; however, lacustrine and riverine waters provide many different functions and values and are separate aquatic resources. The loss of wetlands and the conversion of approximately 19 acres of riverine waters to lacustrine waters would be a significant impact.

Direct impacts on wetlands and other waters that will be filled as a result of relocation of facilities or dam construction are summarized in Table 12-16.

The impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-5 (CP1): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Under CP1, 1,227 acres of general vegetation habitat will be directly impacted by the inundation of the impoundment area and 698 acres of general vegetation habitat will be impacted by vegetation removal in the construction footprints of the relocation areas (Table 12-17 and Table 12-18).

This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-6 (CP1): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds as a result of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). Therefore, this impact would be potentially significant.

Noxious and invasive weeds are abundant around Shasta Lake, specifically in the relocation areas. Vectors that would increase as a result of project implementation include weed seed and seed parts brought in on tools, vehicles, and workers' clothing and boots. The extent of the risk would depend on the construction methods used and site-specific actions implemented to complete the project. As access into specific project areas is improved, road construction, temporary roads, and road maintenance would increase the number of vectors in an area. As traffic along new and existing corridors increases, the risk for weed dispersal would increase. Seed mixtures and mulches may be used during erosion control efforts and revegetation of areas. These mixtures and mulches are potential vectors for noxious weed and invasive plant dispersal.

Construction of the dam would result in inundation of shoreline habitat. Depending on the extent of colonization, many populations of noxious weeds could be inundated. However, there would be no increase in vector traffic and no soil disturbance due to inundation. Therefore, the risk of weed spread from the inundation of habitat is low.

However, vegetation removal in areas to be inundated may increase risk of weed spread. Habitat vulnerability and project-associated vectors in inundation zones would be variable, based on the extent of the vegetation removal and the location of the proposed activity. All habitats are vulnerable when canopies are opened and soil is disturbed. Increased traffic and soil disturbance coupled with an adjacent, high-ranking noxious weed may result in a moderate to high risk of weed spread.

Because of the dam expansion, other ground-disturbing projects would be implemented to relocate displaced roads, railways, utilities, homes, and recreation facilities. The potential for disturbance of noxious weeds is highly variable, based on the proposed activity and the abundance of weeds present. Depending on the location of high-ranking noxious weeds, the extent of ground-disturbing activities, and the amount of traffic entering a project site, the risk of noxious weed infestation would vary.

This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (CP1): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP1 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

Potential impacts on structure and species composition and loss of sensitive plant communities and special-status plant species resulting from altered flow regimes were determined using the best available information and tools as described in Chapter 2 “CalSim-II” and Chapter 3 “Temporal Downsizing of CalSim-II Flows for Use in Temperature Modeling” of the Engineering Appendix. See Chapter 4 “Geology, Geomorphology, Minerals, and Soils,” for additional information on fluvial geomorphology and hydrology, and channel erosion and meander migration.

Potential impacts on flow and stages of the upper Sacramento River from CP1 would be small. On average, in each month, changes in mean monthly flow would be reductions or increases of several percent. Generally, these effects diminish with distance downstream because of the influence of inflows from tributaries and of diversions and flood bypasses.

In average and wet years, river flows would decrease during the November through February period of some years. This would be because of the increased storage space that could be filled in some years, usually following dry or critical water years.

During March through May, changes in mean monthly flows would be small reductions or increases (generally less than 2 percent) typically transitional between small reductions in winter flows and small increases in summer flows. During the June through August period of some years, flow and stage would increase. This increase would be most pronounced during some dry years as more water is released from Shasta Dam for water supply reliability purposes. During March, September, and October, mean monthly flows would generally be increased 1 to 6 percent.

Northern hardpan vernal pools and northern volcanic mudflow vernal pools are not present at Shasta Dam and are generally not present within the active floodplain immediately adjacent to the channel of the upper Sacramento River or its tributaries in the primary study area. Therefore, northern hardpan vernal pools and associated special-status plant species would likely not be affected by the altered flows in the primary study area downstream from Shasta Dam.

The altered flow regime of the upper Sacramento River associated with implementation of CP1 could affect oak communities and upland habitat for special-status plant species by prolonging inundation and changing the availability of soil moisture. Prolonged inundation during the growing season kills most upland plants. This effect would occur during years when mean monthly stage during March – October is greater than in preceding years. Interannual fluctuations in stage during the growing season already cause upland vegetation to become removed from (or prevent its establishment within) a zone along rivers downstream from Shasta Dam. CP1 could increase the average elevation of this zone slightly (by, on average, increasing stage during the growing season of most years), but it would not increase the zone's elevation range. For some upland vegetation, greater summer flows in some years also could increase summer soil moisture, and reduced intermediate and large flows during winter in some years could reduce spring soil moisture. Because of the important influence of water availability on plant growth and survival, these changes in the availability of moisture could change the structure and species composition of oak communities or affect special-status plants of upland habitats.

These effects, however, are speculative, and may not all prove to be adverse with project implementation and operation. For example, greater summer flows in some years could increase summer soil moisture; in dry years, increased soil moisture could sustain plants that otherwise would be damaged or die. Therefore, the impact on oak communities and on upland habitat for special-status plants resulting from altered flow regimes on the upper Sacramento River within the primary study area would be less than significant.

The flow regime of a river or stream strongly influences the structure and species composition of the riparian and wetland communities associated with it. For this reason, the altered flow regimes resulting from project implementation would affect riparian and wetland vegetation. These effects are described below.

River flows strongly affect the growth and survival of riparian plants. Riparian plants are strongly affected by the timing and duration of inundation; abrasion and burial by water-borne sediment; and by water table fluctuations (Toner and Keddy 1997; Friedman and Auble 1999; Karrenberg, Edwards, and Kollmann 2002; Bagstad, Stromberg, and Lite 2005; Lite and Stromberg 2005; Williams and Cooper 2005). As a result, riparian communities often differ in structure and species composition along gradients of elevation or flooding frequency and intensity (Conard, MacDonald, and Holland 1977; Harris 1987; Toner and Keddy 1997; Bagstad, Stromberg, and Lite 2005; Vaghti and Greco 2007).

River flows not only affect the survival and growth of established riparian vegetation, but also create sites for establishment of early-successional vegetation. The geomorphic processes of channel meander migration, avulsion, and deposition of sediment on floodplains, which result primarily from intermediate and large flows, bury and uproot herbaceous vegetation and uproot or undercut trees and shrubs. These disturbances also create opportunities for early-successional vegetation to establish, including willow and cottonwood seedlings that grow to form willow scrub and Great Valley cottonwood riparian forest.

Early successional riparian communities change rapidly in structure and species composition (Tu 2000, Fremier 2003, Vaghti and Greco 2007). Over several decades, early-successional vegetation develops into mid- and late-successional vegetation with less willow and cottonwood and a greater abundance of other trees, including box-elder, Oregon ash, black walnut, and valley oak (e.g., Great Valley mixed riparian forest) (Fremier 2003).

Thus, for riparian vegetation, the rates of geomorphic processes strongly affect the extent of different riparian communities, and these rates are strongly related to flow regime. For example, bank erosion and the average rate of meander migration are closely related to the cumulative portion of flow above a threshold volume. On portions of the Sacramento River, this threshold may be around 30,000 cfs (Larsen, Fremier, and Greco 2006; Stillwater Sciences 2007), which is well below the bankfull discharge but well above flows during spring and summer. However, other important thresholds for bank erosion and channel avulsion along the Sacramento River have been estimated within the range from 10,000 to 80,000 cfs (Stillwater Sciences 2007). (For additional discussion of the relationship of geomorphic processes to flow along the Sacramento River, see the *Fisheries and Aquatic Ecosystem Technical Report*.)

Flow regimes during the period of seed dispersal also strongly influence establishment of seedlings of riparian trees and shrubs, particularly willows and cottonwoods. In general, seeds of riparian plants can only successfully germinate and establish on exposed surfaces; prolonged inundation of a surface during the growing season prevents establishment. Willows and cottonwoods have very small, short-lived seed and are shade-intolerant plants; thus, their seeds must disperse to exposed, moist surfaces that are largely free of vegetation. Such surfaces are often created by channel migration, avulsion, and sediment deposition during larger winter and spring flows. They are then exposed by declining flows during the seed dispersal period of willow and cottonwood species. These seed dispersal periods are staggered across spring and summer; for example, March through April for arroyo willow, April through June for cottonwood, and May through August for black willow. Once willow and cottonwood seeds germinate, slowly declining flows are necessary to maintain their roots in contact with saturated soils, which in turn is necessary for establishment. Rapidly declining flows (i.e., those greater than 1 to 1.5 inches per day) result in desiccation and mortality of seedlings (Mahoney and Rood 1998, Stillwater Sciences 2007). Conversely, flows that increase during the growing season kill many seedlings (e.g., by burial, uprooting, or scouring).

Consequently, reductions in the magnitude, duration, and frequency of intermediate and large flows could reduce opportunities for cottonwood and willow species to establish and thus limit the extent of early and mid-successional riparian communities. The absence of slowly declining spring flows also would reduce cottonwood establishment.

Since its construction, the operation of Shasta Dam has limited the frequency, magnitude, and duration of intermediate and larger flows during fall and winter, and flow volumes have been greater during the growing season. The operation of Shasta Dam also produces increasing flow volumes during the period of cottonwood seed dispersal (rather than flow volume decreasing during this period), largely precluding establishment of cottonwoods (and to a lesser extent willows) throughout much of the riparian zone (Roberts et al. 2002). The combined effect of these changes in flow regime has been a decrease in early- and mid-successional communities along the Sacramento River that is ongoing (Fremier 2003).

CP1 would lead to a further reduction in the magnitude, duration, and frequency of intermediate and large flows, but it would not alter the general annual pattern of flows increasing during the cottonwood seed dispersal period. However, CP1's effects on larger flows could further reduce the frequency or extent of suitable conditions for cottonwoods to establish from seed. Overall, the project would increase the existing, ongoing impacts on riparian vegetation resulting from the operation of Shasta Dam. This could reduce the area of riparian vegetation slightly, and reduce the proportion of riparian vegetation that is in early- and mid-successional stages (e.g., willow- and cottonwood-dominated communities) while increasing the extent of mid-successional communities (e.g., mixed riparian forest). This would be an exacerbation of an ongoing transition (which is described under Impact Bot-7 (No-Action)). These effects would not substantially alter the establishment and spread of invasive plant species. There would, however, be some reduction in the magnitude, duration, and frequency of overbank flows that facilitate the dispersal and establishment of invasive plants, and some reduction in the amount of early successional vegetation that provides suitable habitat for many invasive plant species.

These effects would likely occur along the upper Sacramento River throughout the primary study area. Reductions in the magnitude of intermediate and large flows would likely be sufficient to alter the dynamics and structure of the riparian corridor along the upper Sacramento River, downstream from Shasta Dam, throughout the primary study area. These effects on flows greater than 30,000 cfs downstream from Keswick Dam, RBPP, and Hamilton City are shown on Figure 12-6. As described previously, flows of this magnitude strongly affect bank erosion and meander migration, and are related to other geomorphic processes affecting the extent of different riparian communities. In the primary study area, there would be a small reduction in the number of mean daily flows greater than 30,000 cfs. Downstream from Keswick and the RBPP the number of days with mean flows greater than 30,000 cfs would be reduced by approximately 9 and 2 percent, respectively.

Although the establishment of most wetland plants is less strongly influenced by specific attributes of the flow regime than willows and cottonwoods, flow regime still plays an important role in wetland communities. In general, wetland communities on floodplains are strongly influenced by timing and duration of inundation, scour and deposition of sediment, and fluctuations in water table elevations within and among years (Keddy 2000, Leyer 2005, van Eck et al. 2006). Changes in flow during some years would change the extent of some wetland communities (e.g., seeps, seasonal wetlands) during that year and/or subsequent years, and thus the average extent of those communities. Overall, wetland communities could experience effects similar to those described for riparian communities.

For the reasons outlined above, and because riparian and wetland communities are sensitive natural communities, this impact would be significant.

Ten special-status plant species could occur in riparian or wetland habitats in the primary study area (including mesic upland-associated species; Table 12-6). Of these, within the primary study area and nearby counties (Butte and Glenn), three are known to occur along the edge of the Sacramento River channel, or along a Sacramento River tributary within 0.2 mile of the river proper, and their establishment and reproduction could potentially be affected by changes in flow regime: silky cryptantha (CRPR 1B), rose mallow (CRPR 2B.2), and Ahart's paronychia (CRPR 1B) (CNDDB 2007, University of California 2011). Because altered flow regimes associated with the project could modify habitat for these special-status species, this impact would be significant.

Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-8 (CP1): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management
Numerous local and regional plans promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP1 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

Local and regional plans addressing riparian habitats in the primary study area are discussed in more detail in the "Regulatory Setting" section of this EIS and include the RHJV and the Sacramento River Conservation Area Program, both of which promote the conservation and the restoration of riparian habitat. As described for Impact Bot-7 (CP1), implementation of this alternative could cause substantial adverse effects on riparian and wetland communities by altering the flow regime of the upper Sacramento River and could, therefore, conflict with existing local and regional plans that aim to conserve riparian habitats. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-9 (CP1): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP1. This impact would be less than significant.

Critical habitat for four special-status species — slender orcutt grass, Hoover's spurge, hairy orcutt grass, and Greene's tuctoria — exists within the primary study area. Critical habitat for these species in the primary study area is confined to vernal pool communities (USFWS 2006). Vernal pools are generally not present within the active floodplain. However, if vernal pool habitats for these special-status species are present in the active floodplain of the upper Sacramento River, they could be affected by the small reduction in the frequency and magnitude of overbank flows. It is not known if this would be an adverse or beneficial effect. Because this effect of CP1 is somewhat speculative and not necessarily adverse, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP1): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementing CP1 could increase water supplies for deliveries to water districts in the primary study area along the upper Sacramento River. This increase in water deliveries could reduce any limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

Along the upper Sacramento River, the CVP and SWP service areas contain wetland, riparian, oak, and other sensitive plant communities, and a large number of special-status plant species (Attachment 4). Increased water supplies or increased supply reliability could reduce a limitation on urban growth and development or on other activities that could affect sensitive plant communities or special-status plants in the primary and extended study areas.

The expected increase in water deliveries relative to the entire CVP and SWP service areas would be small (i.e., less than 1 percent), however, and increased deliveries would be provided to a number of geographic areas within the CVP and SWP service areas. Also, a substantial portion of this water would substitute for groundwater pumping, allow for changes in crop type or agricultural irrigation practices, or return idle cropland to production. Consequently, this alternative's effect on growth that could affect vegetation would be minor.

Furthermore, the effects of this growth would be analyzed in general plan EIRs and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these effects would be the responsibility of these local jurisdictions, and not of Reclamation. Similarly, projects potentially affecting riparian and wetland habitats and listed species would require permits from CDFW, USACE, and USFWS; it is anticipated that effects on these resources would be avoided, minimized, and/or mitigated during those agency consultations.

The extent of induced growth that could affect botanical resources and wetlands would likely be minor, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP1): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-12 (CP1): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-13 (CP1): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Bot-14 (CP1): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP1 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and loss of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be similar to Impact Bot-7 (CP1) for the upper Sacramento River, but alteration of the Sacramento River's flow regime would be attenuated in the lower river by the effects of inflows from tributaries and of diversions and flood bypasses. Measurable effects on riparian and wetland plant communities are unlikely to extend as far downstream as the Delta, in part because releases from Shasta Dam account for a smaller fraction of total flow with increasing distance downstream as tributaries cumulatively add to the Sacramento River's flow.

Nonetheless, significant impacts on riparian and wetland communities, and associated special-status plants, would be caused on the lower Sacramento River, particularly near the upper Sacramento River. South of RBPP, the portion of the Sacramento River's total annual flow that is accounted for by flows greater than 30,000 cfs would still be reduced, and also the frequency of flows greater than 60,000 to 80,000 cfs (i.e., roughly the size of the current 1.5- to 2-year events) would be reduced. Changes in the number of days with mean daily flows greater than 30,000 cfs downstream from RBPP and Hamilton City are summarized on Figure 12-6. (These two locations are shown on Figure 12-7.) As described for Impact Bot-7 (CP1) (and in the *Fisheries and Aquatic Ecosystem Technical Report*), flows above about 30,000 cfs and 1.5- to 2-year events cause substantial changes in riparian ecosystems. These changes indicate that although they would be small, the alterations to the lower Sacramento River's flow regime could be sufficient to cause significant impacts in the Red Bluff-to-Chico Landing reach. This reach is immediately downstream from the primary study area but upstream from the flood bypasses and the Feather and American rivers, which substantially attenuate the effects of flows released from Shasta Dam. This reach is mostly unleveed and has few other constraints to channel movement, river meander, and flooding; consequently, it has an extensive acreage of early-, mid-, and late-successional riparian communities (Resources Agency 2003).

Effects are unlikely to extend to the Delta because the flood bypasses and the Feather and American rivers attenuate the effects of flows released from Shasta Dam. In addition, much of the Sacramento River's length south of Colusa, and almost all Delta sloughs, are leveed (often close to the channel) with extensive reinforcement of channel banks with revetment, restricting channel movement, river meander and flooding. Further; the acreage of early-, mid-, and late-successional riparian communities is much less extensive along the Sacramento River south of Colusa and in the Delta.

Effects of flow alterations are also unlikely to extend to the Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The guidelines for this management, which are described in the CVP Operations Criteria and Plan, have been designed to maintain standards for Delta inflow. CVP and SWP operations must be consistent with the Operations Criteria and Plan to allow coverage by the Operations Criteria and Plan biological opinion. Thus, implementation of CP1 is not anticipated to alter Sacramento River flows to the Delta sufficiently to alter the dynamics or structure of vegetation in the Delta. Thus, impacts on the Delta portion of the extended study area would be less than significant.

This impact would be significant along the lower Sacramento River and less than significant in the Delta. Mitigation for this impact along the lower Sacramento River is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-15 (CP1): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP1 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River and in the Delta. These plans, which are discussed in more detail in the “Regulatory Framework” of this EIS, include the RHJV and the Sacramento River Conservation Area Program, both of which promote the conservation and restoration of riparian habitat. As described for Impact Bot-14 (CP1), implementation of this alternative could cause substantial adverse effects on riparian and wetland communities along a portion of the lower Sacramento River by altering its flow regime, but such effects would not occur in the Delta. Because the project has the potential to result in substantial adverse effects on riparian communities, it could conflict with existing local and regional plans. Therefore, on the lower Sacramento River, this impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-16 (CP1): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Along the Lower Sacramento River and in the Delta Implementation of CP1 could increase water supplies for deliveries to water districts in the extended study area along the lower Sacramento River. This increase in water deliveries could reduce a limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1) for the upper Sacramento River, but the increased water supplies available along the lower Sacramento River would differ from that along the upper Sacramento River. However, for the same reasons as Impact Bot-10 (CP1), this impact would also be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP1): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP1 could alter the structure and species composition or cause the loss of sensitive plant communities and habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early successional riparian and wetland communities or of associated habitat for special-status species. Therefore, below CVP and SWP reservoirs in the extended study area, this impact would be less than significant.

Because CVP and SWP reservoirs and diversions are managed as a single integrated system, changing releases from Shasta Dam can result in offsetting releases from other reservoirs (e.g., to meet Delta inflow standards). The effects from CP1 on CVP and SWP reservoir elevations, filling, spilling, and planned releases, and the resulting flows downstream from those reservoirs, would be small and within the range of variability that commonly occurs in these reservoirs and downstream. These alterations may not be sufficient to alter the extent of early successional riparian and wetland communities or of associated habitat for special-status species. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP1): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementing CP1 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP1 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, in the CVP and SWP service areas, this impact would be less than significant.

Local and regional plans address and promote the conservation of riparian vegetation and associated habitats in the CVP and SWP service areas. (These plans are discussed in more detail in Section 12.2, “Regulatory Framework.”) However, as described for Impact Bot-17 (CP1), implementation of CP1 would not cause significant impacts on riparian and wetland communities in the CVP and SWP service areas. Therefore, CP1 would not conflict with existing local and regional plans. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP1): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP1 could increase water supplies for deliveries to water districts in the CVP and SWP service areas. This increase in water deliveries could reduce a limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1) for the upper Sacramento River, but the increased water supplies available in the CVP and SWP service areas would differ from that along the upper Sacramento River. However, for the same reasons as Impact Bot-10 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As with CP1, CP2 focuses on increasing water supply reliability and increasing anadromous fish survival. CP2 primarily consists of raising Shasta Dam by 12.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir’s full pool by 14.5 feet and enlarge the total storage capacity in the reservoir by 443,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP2 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact Bot-1 (CP2): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP2): Loss of MSCS Covered Species Implementation of the project would result in the loss of MSCS covered species because of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant. Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to but greater than CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would affect all or portions of ten Shasta snow-wreath populations. These ten populations represent 42 percent of all known Shasta snow-wreath populations and encompass approximately 79 acres. Flooding impacts under CP2 would result in the loss of approximately 1.8 acres, or approximately 2 percent of these ten Shasta snow-wreath populations. The greatest proportional impacts to these populations occur at the Blue Ridge West, Brock Creek, Cove Creek, Keluche Creek, and Shasta Caverns populations. Table 12-19 provides a detailed summary of impacts to Shasta snow-wreath under CP2. Mitigation measures for impacts to Shasta snow-wreath populations are presented in Section 12.3.5, “Mitigation Measures.”

The impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Table 12-19. Summary of Impacts to Shasta Snow-Wreath Populations Adjacent to Shasta Lake Under CP2

Population	Location	Size (Acres)	CP2 Impact (Acres)	Percent Total Impact to Population	Comments
Blue Ridge (west)	Main Body	1.11	0.594	53%	More than half of the population would be flooded.
Blue Ridge (east)	Main Body	0.03	0	0%	No impact under CP2.
Brock Creek	Pit River Arm	1.38	0.545	39%	Lower portion of population would be flooded.
Campbell Creek	McCloud River Arm	1.90	0.002	<1%	Small area at the downstream portion of the population would be flooded.
Cove Creek	Main Body	1.87	0.337	18%	Lower portion of population would be flooded.
Ellery Creek	McCloud River Arm	28.65	0.038	<1%	The entire very small disjunct sub-population located near Ellery Creek Campground would be flooded.
Jones Valley	Main Body	0.33	0.003	1%	Small area at lower portion or population would be flooded.
Keluche Creek	McCloud River Arm	0.15	0.112	73%	Nearly ¾ of the population would be flooded.
Shasta Caverns	McCloud River Arm	0.08	0.026	31%	Lower portion of population would be flooded.
South of Cove Creek	Main Body	1.39	0.149	11%	Lower portion of population would be flooded.
Stein Creek	Pit River Arm	42.15	0.028	<1%	Lower portion of population would be flooded.

Key:
% = percent
< = less than
CP = Comprehensive Plan

Impact Bot-3 (CP2): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species Implementation of the project would result in the loss of USFS sensitive, BLM sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to but greater than CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam could result in the loss of more individual plants or plant populations and their habitat.

Impacts to Shasta County arnica, northern clarkia, Cantelow's lewisia, and Shasta limestone monkeyflower populations resulting from CP2 are similar to those described for CP1; however, CP2 would impact 85 slender false lupine populations. Impacts to Shasta huckleberry resulting from CP2 are the same as those described for CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-4 (CP2): Loss of Jurisdictional Waters Implementation of the project will result in the loss of jurisdictional waters caused by flooding the impoundment area and discharge of fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine habitat). Therefore, this impact would be significant.

Direct impacts would incur by conversion of jurisdictional waters (e.g., wetlands and streams) to lacustrine habitat with implementation of CP2. All features within the impoundment area would be converted to lacustrine habitat. Under CP2, approximately 19 acres of wetlands and 26 acres of other waters would be converted to lacustrine habitat (Table 12-20). This will result in a net loss of approximately 19 acres of wetlands and loss of approximately 26 acres of riverine waters by conversion to lacustrine waters. The impacts associated with relocation are the same as Impact Bot-4, CP1 as shown on Table 12-16. The impacts to wetlands from relocations would result in the loss of approximately 2.3 acres of wetlands and 1.6 acres of other waters.

Table 12-20. Impacts to Jurisdictional Waters (Acres[1]) in the Impoundment Area (12.5-Foot Dam Raise)

Total Waters of the U.S.	3.77	2.33	21.35	11.40	3.12	3.75	45.72

Note:
[1] Acreage values are approximate.

The impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-5 (CP2): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Under CP2, a total of 1,725 acres of general vegetation habitats will be directly impacted by the inundation of the impoundment area (Table 12-21).

Table 12-21. Impacts to CWHR Habitats (Acres*) in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total

Riverine	0.00	0.42	4.02	4.51	0.84	0.00	9.80
Urban	16.65	0.00	1.63	6.42	0.00	1.24	25.94
Total	327.28	61.20	498.30	303.14	171.18	364.75	1725.85

Note:
[1] Acreage values are approximate.

The impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-6 (CP2): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds as a result of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). Therefore, this impact would be potentially significant.

Impacts resulting from the spread of noxious weeds under CP2 are anticipated to be similar to, but greater than, those described for CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Bot-7 (CP2): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP2 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. For example, greater summer flows in some years could increase summer soil moisture, especially during some dry and critical years as more water is released

from Shasta Dam for water supply reliability purposes. (Shasta Dam operations historically have increased flow volumes from mid-spring to early summer.) This increased soil moisture in dry years could reduce losses of upland vegetation during drought years. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

This impact would be similar to Impact Bot-7 (CP1). The extent of the impact under CP2 would be greater than that under CP1. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below Keswick Dam and RBPP are summarized on Figure 12-6.) This impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-8 (CP2): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Numerous local and regional plans promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP2 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Bot-8 (CP1), and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-9 (CP2): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, critical habitat for vernal pool species is not expected to be adversely affected by CP2 because vernal pools are generally not present within the active floodplain. For this reason, this impact would be less than significant.

This impact would be similar to Impact Bot-9 (CP1). The extent of the impact under CP2 would be greater than that under CP1, CP4, and CP4A, but less than that under CP3 and CP5, which would entail greater alterations of flow regimes. For the same reasons as Impact Bot-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP2): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP2 could increase water supplies for deliveries to water districts in the primary study area along the upper Sacramento River. This increase in water deliveries could reduce any limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1). The extent of the impact under CP2 would be greater than that under CP1, CP4, and CP4A, but less than that under CP3 and CP5, which would result in a greater increase in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP2): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-12 (CP2): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-13 (CP2): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Bot-14 (CP2): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP2 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, for riparian and wetland communities and special-status plants, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be similar to Impact Bot-14 (CP1). The extent of the impact under CP2 would be greater than that under CP1, CP4, and CP4A, but less than that under CP3 and CP5, which would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below RBPP and Hamilton City are summarized on Figure 12-6.) Therefore, for riparian and wetland plant communities and associated special-status plant species on the lower Sacramento River, the impact would be significant, but in the Delta, the impact would be less than significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-15 (CP2): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP2 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-16 (CP2): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth along the Lower Sacramento River and in the Delta Implementation of CP2 could increase water supplies for deliveries to water districts in the extended study area along the lower Sacramento River. This increase in water deliveries could reduce any limitation on urban growth and development that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-16 (CP1). The extent of the impact under CP2 would be greater than that under CP1, CP4, and CP4A, but less than that under CP3 and CP5, which would result in greater increases in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP2): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP2 could alter the structure and species composition or cause the loss of sensitive plant communities and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to affect the extent of early-successional riparian and wetland communities or of associated habitats for special-status plant species. Therefore, below CVP and SWP reservoirs in the extended study area, this impact would be less than significant.

This impact would be similar to Impact Bot-17 (CP1). The extent of the impact under CP2 would be greater than that under CP1, CP4, and CP4A, but less than that under CP3 and CP5, which would entail more substantial alterations of flow regimes. Nonetheless, for the same reasons as Impact Bot-17 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP2): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP2 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP2 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, in the CVP and SWP service areas, this impact would be less than significant.

This impact would be to the same as Impact Bot-18 (CP1); the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP2): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP2 could increase water supplies for deliveries to water districts in the CVP and SWP service areas. This increase in water deliveries could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-19 (CP1). The extent of the impact under CP2 would be greater than that under CP1, CP4, and CP4A, but less than that under CP3 and CP5, which would result in greater increases in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3 focuses on increasing agricultural water supply reliability while also increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 18.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Because CP3 focuses on increasing agricultural water supply reliability, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, with the additional storage retained for water supply reliability and to expand the cold-water pool for downstream anadromous fisheries.

Simulations of CP3 did not involve any changes to the modeling logic for deliveries or flow requirements; all rules for water operations were updated to include the new storage, but were not otherwise changed.

The botany and wetland impact analysis previously presented for CP1 assumes maximum vegetation clearing within the relocation areas. Vegetation clearing impacts within the relocation areas under CP3 would be greater than under CP1 and CP2, but would not exceed those acreages of impacts presented under CP1.

Shasta Lake and Vicinity

Impact Bot-1 (CP3): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP3): Loss of MSCS Covered Species Implementation of the project would result in the loss of MSCS covered species because of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant. Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to but greater than CP2. However, inundation caused by an 18.5-foot raise of Shasta Dam would affect all or portions of eleven Shasta snow-wreath populations. These eleven populations represent 46 percent of all known Shasta snow-wreath populations and encompass approximately 79 acres. Flooding impacts under CP2 would result in the loss of approximately 2.6 acres, or approximately 3 percent of these eleven Shasta snow-wreath populations. The greatest proportional impacts to these populations occur at the Blue Ridge West, Brock Creek, Cove Creek, Keluche Creek, and Shasta Caverns populations. Table 12-22 provides a detailed summary of impacts to Shasta snow-wreath under CP3. Mitigation measures for impacts to Shasta snow-wreath populations are presented in Section 12.3.5, "Mitigation Measures."

Table 12-22. Summary of Impacts to Shasta Snow-Wreath Populations Adjacent to Shasta Lake Under CP3

Population	Location	Size (Acres)	CP3 Impact (Acres)	Percent Total Impact to Population	Comments
Blue Ridge (west)	Main Body	1.11	0.750	68%	Lower portion of population would be flooded.
Blue Ridge (east)	Main Body	0.03	0.002	7%	Lower portion of population would be flooded.
Brock Creek	Pit River Arm	1.38	0.634	46%	Nearly half of the population would be flooded.
Campbell Creek	McCloud River Arm	1.90	0.036	2%	Small area at the downstream portion of the population would be flooded.
Cove Creek	Main Body	1.87	0.401	21%	Lower portion of population would be flooded.
Ellery Creek	McCloud River Arm	28.65	0.047	<1%	The entire very small disjunct sub-population located near Ellery Creek Campground would be flooded.
Jones Valley	Main Body	0.33	0.015	4%	Nearly all of both small disjunct sub-populations at the lower portion of the population would be flooded.
Keluche Creek	McCloud River Arm	0.15	0.146	95%	Nearly all of the population would be flooded.
Shasta Caverns	McCloud River Arm	0.08	0.018	21%	Lower portion of population would be flooded.
South of Cove Creek	Main Body	1.39	0.149	11%	Lower portion of population would be flooded.
Stein Creek	Pit River Arm	42.15	0.469	1%	Lower portion of population would be flooded.

Key:
% = percent
< = less than
CP = Comprehensive Plan

Impacts related to dam construction and vegetation clearing or other construction activities within the relocation areas would be similar to but greater than CP2. However, inundation caused by an 18.5-foot raise of Shasta Dam could result in the loss of more individual plants or plant populations, and their habitat.

This impact would be significant. Mitigation for this impact is described in Section 12.3.5, "Mitigation Measures."

Impact Bot-3 (CP3): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species
Implementation of the project would result in the loss of USFS sensitive, BLM sensitive, or CRPR species because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Impacts related to dam construction and vegetation clearing within the relocation areas would be similar to but greater than CP2. However, inundation caused by an 18.5-foot raise of Shasta Dam could result in the loss of more individual plants.

Impacts to Shasta County arnica and Shasta limestone monkeyflower populations resulting from CP3 are similar to those described for CP2; however, CP3 would impact four Cantelow's lewisia populations, two northern clarkia populations, and 99 slender false lupine populations. Impacts to Shasta huckleberry resulting from CP3 are the same as those described for CP1.This impact would be significant. Mitigation for this impact is described in Section 12.3.5, "Mitigation Measures."

Impact Bot-4 (CP3): Loss of Jurisdictional Waters Implementation of the project will result in the loss of jurisdictional waters caused by flooding the impoundment area and discharge of fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine habitat). Therefore, this impact would be significant.

Direct impacts would incur by conversion of jurisdictional waters (e.g., wetlands and streams) to lacustrine habitat with implementation of CP3. All features within the impoundment area would be converted to lacustrine habitat. Under CP3, approximately 31 acres of wetlands and 49 acres of other waters would be converted to lacustrine habitat (Table 12-23). This will result in a net loss of approximately 31 acres of wetlands and loss of approximately 49 acres of riverine waters by conversion to lacustrine waters. The impacts associated with relocation are the same as Impact Bot-4, CP1 as shown on Table 12-16. The relocation impacts to wetlands would result in the loss of approximately 2.3 acres of wetlands and 1.6 acres of other waters.

The impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Note:
[1] Acreage values are approximate

Impact Bot-5 (CP3): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

Under CP3, 2,492 acres of general vegetation habitats will be directly impacted by the inundation of the impoundment area (Table 12-24).

The impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Table 12-24. Impacts to CWHR Habitats (Acres[1]) in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total

CWHR = California Wildlife Habitat Relationship

Impact Bot-6 (CP3): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds because of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). Therefore, this impact would be potentially significant.

Impacts resulting from the spread of noxious weeds under CP3 are anticipated to be similar to, but greater than, those described for CP1. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (CP3): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP3 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

This impact would be similar to Impact Bot-7 (CP1). The extent of the impact would be greater under CP3 than under CP2. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below Keswick Dam and RBPP are summarized on Figure 12-6.) This impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-8 (CP3): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP3 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Bot-8 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-9 (CP3): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP3. For this reason, this impact would be less than significant.

This impact would be similar to Impact Bot-9 (CP1). The extent of the impact would be greater than under CP1, CP2, CP4, and CP4A, but less than under CP5, which would entail a greater alteration of flow regimes. However, for the same reasons as Impact Bot-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP3): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP3 could increase water supplies for deliveries to water districts in the primary study area along the upper Sacramento River. This increase in water deliveries could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1). The extent of the impact would be greater under CP3 than under CP1, CP2, CP4, and CP4A, but less than under CP5, which would result in a greater increase in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP3): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-12 (CP3): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-13 (CP3): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The proposed gravel augmentation program and riparian, floodplain, and side channel restoration activities would not be implemented under CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Bot-14 (CP3): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP3 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and of habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River, but these effects are unlikely to extend to the Delta; thus, for riparian and wetland communities and special-status plants, this impact would be significant on the lower Sacramento River, and less than significant in the Delta.

This impact would be similar to Impact Bot-14 (CP1). The extent of the impact would be greater under CP3 than under CP1, CP2, CP4, and CP4A, but would be less than under CP5, which would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below RBPP and Hamilton City are summarized on Figure 12-6.) This impact would be significant on the lower Sacramento River and less than significant in the Delta. Mitigation for this impact on the lower Sacramento River is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-15 (CP3): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River in the extended study area. Because CP3 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-16 (CP3): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth along the Lower Sacramento River and in the Delta Implementation of CP3 could increase water supplies for deliveries to water districts in the extended study area along the lower Sacramento River. This increase in water deliveries could reduce any limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-16 (CP1). The extent of the impact under CP3 would be greater than under CP1, CP2, CP4, and CP4A, but less than that under CP5, which would result in a greater increase in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP3): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP3 could alter the structure and species composition or cause the loss of sensitive plant communities and of habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities or associated habitats for special-status plant species. Therefore, this impact would be less than significant.

This impact would be similar to Impact Bot-17 (CP1). The extent of the impact would be greater under CP3 than under CP1, CP2, CP4, and CP4A, but less than that under CP5, which would entail more substantial alterations of flow regimes. Nonetheless, for the same reasons as Impact Bot-17 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP3): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP3 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP3 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact would be less than significant.

This impact would be the same as Impact Bot-18 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP3): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP3 could increase water supplies for deliveries to water districts in the extended study area in the CVP and SWP service areas. This increase in water deliveries could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-19 (CP1). The extent of the impact under CP3 would be greater than that under CP1, CP2, CP4, and CP4A, but less than that under CP5, which would result in a greater increase in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 and CP4A focus on increasing anadromous fish survival while also increasing water supply reliability. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP4 or CP4A would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. The additional storage created by the 18.5-foot dam raise would be used to improve the ability to meet temperature objectives and habitat requirements for anadromous fish during drought years and increase water supply reliability. CP4A is identical to CP4 with the exception of Shasta Dam and reservoir operations. CP4 and CP4A have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for fisheries purposes; however, the portion of this dedicated storage varies.

For CP4, about 378,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1, with 70,000 acre-feet and 35,000 acre-feet reserved to specifically focus on increasing M&I deliveries during dry and critical years, respectively.

For CP4A, about 191,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. For CP4A, operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2, with 120,000 acre-feet reserved in dry years and 60,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries.

CP4 and CP4A also include augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River. Gravel placement would occur at one or more sites per year over a 10-year period and would be accomplished by one of three methods: lateral berms, talus cone, or direct placement in river, as appropriate, depending on specific conditions, including geomorphology, of the augmentation site. To the extent available, existing river access points would be used to deliver gravel to the river; however, temporary new access roads would be needed in some cases, mostly adjacent to the river. In addition, riparian, floodplain, and side channel habitat restoration would be constructed at up to six sites identified along the upper Sacramento River: Henderson Open Space, Tobiasson Island, Shea Island Complex, Kapusta Island, Anderson River Park, and Reading Island. These restoration projects could involve some vegetation clearing.

Impacts under CP4 or CP4A associated with vegetation clearing within the relocation areas would be the same under CP3. However, additional vegetation clearing would result under CP4 or CP4A as a result of clearing to access gravel augmentation sites and to construct the identified riparian, floodplain, and side channel restoration projects.

Shasta Lake and Vicinity

Impact Bot-1 (CP4 and CP4A): Loss of Federally or State-Listed Plant Species

Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact would occur for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP4 and CP4A): Loss of MSCS Covered Species

Implementation of the project would result in the loss of MSCS covered species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be significant for CP4 or CP4A.

This impact would be similar to Impact Bot-2 (CP3). This impact would be significant for CP4 or CP4A. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-3 (CP4 and CP4A): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species Implementation of the project would result in the loss of USFS sensitive, BLM sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Bot-3 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

This impact would be similar to Impact Bot-3 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-4 (CP4 and CP4A): Loss of Jurisdictional Waters Implementation of the project would result in the loss of jurisdictional waters because of flooding of the impoundment area and fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine habitat). Therefore, this impact would be significant for CP4 or CP4A.

This impact would be similar to Impact Bot-4 (CP3) and would be significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

This impact would be similar to Impact Bot-4 (CP3) and would be significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-5 (CP4 and CP4A): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities.

This impact would be similar to Impact Bot-5 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

This impact would be similar to Impact Bot-5 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-6 (CP4 and CP4A): Spread of Noxious and Invasive Weeds
Implementation of the project could result in the spread of noxious and invasive weeds as a result of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). This impact would be potentially significant for CP4 or CP4A.

Impacts resulting from the spread of noxious weeds under CP4 are anticipated to be similar to those described for CP3. This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impacts resulting from the spread of noxious weeds under CP4A are anticipated to be similar to those described for CP3. This impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Bot-7 (CP4 and CP4A): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP4 or CP4A, could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities, and habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, for riparian and wetland communities and special-status plants, this impact would be significant.

This impact would be the same as Impact Bot-7 (CP1) and would be significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

This impact would be similar to Impact Bot-7 (CP1), but greater as in Impact Bot-7 (CP2) due to more substantial alterations of flow regimes for CP4A. This impact would be significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-8 (CP4 and CP4A): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP4 or CP4A would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant for CP4 or CP4A.

This impact would be the same as Impact Bot-8 (CP1) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

This impact would be the same as Impact Bot-8 (CP1) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-9 (CP4 and CP4A): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP4 or CP4A. This impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Bot-9 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact Bot-9 (CP1), but greater, as in Impact Bot-9 (CP2) for CP4A. The extent of the impact under CP4A would be greater than that under CP1 and CP4, but less than that under CP3 and CP5, which would entail greater alterations of flow regimes. For the same reasons as Impact Bot-9 (CP2), this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP4 and CP4A): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP4 or CP4A could increase water supplies for deliveries to water districts in the primary study area along the upper Sacramento River. This increase in water deliveries could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Bot-10 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact Bot-10 (CP1), but greater, as in Impact Bot-10 (CP2). The extent of the impact under CP4A would be greater than that under CP1 and CP4, but less than that under CP3 and CP5, which would result in a greater increase in water deliveries. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP4 and CP4A): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or

Restoring Riparian, Floodplain, and Side Channel Habitats Implementation of the gravel augmentation program could result in the removal of riparian and wetland vegetation or the degradation of riparian and wetland habitats, including wetlands qualifying as waters of the United States. In addition, actions to restore riparian, floodplain, and side channel habitats would remove riparian vegetation, and could result in discharge of fill material into waters of the United States. This impact would be potentially significant for CP4 or CP4A.

A gravel augmentation program would be implemented under CP4 or CP4A, as described in Chapter 2, “Alternatives.” Gravel placement falls under Nationwide Permit (NWP) 27, “Aquatic Habitat Restoration, Establishment, and Enhancement.” Activities qualifying for NWPs have been determined by USACE to have no more than minimal adverse effects on the aquatic environment (72 Federal Register 11092). Therefore, the direct placement of gravel into the Sacramento River would not be considered a significant impact on waters of the United States. No vernal pools or other seasonal wetlands are present at any of the proposed augmentation sites. However, gravel augmentation could result in removal of riparian vegetation during construction of access routes to the gravel placement sites. To the extent feasible, existing access roads would be used, but access to some of the proposed placement sites does not currently exist. Clearing and grubbing would be needed to create access to these gravel placement sites, and in some areas, vegetation clearing along banks would be used to allow gravel to fall easily from the banks into the river. These activities could result in removal of riparian vegetation.

In addition, actions would be implemented to restore riparian, floodplain, and side channel habitats by increasing connectivity between the Sacramento River and one or more side channels at the potential downstream Sacramento River restoration sites. As described in Chapter 2, “Alternatives,” these actions would involve excavation and grading to modify side channel and adjacent floodplain topography, and subsequent revegetating of disturbed floodplain with native riparian vegetation. This is expected to provide a beneficial effect on floodplain and riparian habitat along these side channels. However, some construction activities associated with restoring river connectivity or removing or rehabilitating existing facilities could result in the long-term removal of riparian vegetation. See Table 12-25 for a summary of the potential impacts to plant communities and see Table 12-26 for potential impacts to jurisdictional waters.

Table 12-25. Summary of Potential Impacts to Plant Communities in the Potential Sacramento River Downstream Restoration Areas

Modification of side channels and the side-channel openings connecting them to the Sacramento River would fall under NWP 27, "Aquatic Habitat Restoration, Establishment, and Enhancement." The potential relocation or rehabilitation of the existing power line and poles at the Henderson Open Space and of the existing boat ramp at Reading Island would also qualify for an NWP. Activities qualifying for NWPs have been determined by USACE to have no more than minimal adverse effects on the aquatic environment (72 Federal Register 11092). Although the activities described above would not have a significant impact on waters of the United States, implementation of the gravel augmentation program and riparian, floodplain, and side channel habitat restoration at up to six sites, would have a potentially significant impact on sensitive natural communities for CP4. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Although the activities described above would not have a significant impact on waters of the United States, implementation of the gravel augmentation program and riparian, floodplain, and side channel habitat restoration at up to six sites, would have a potentially significant impact on sensitive natural communities for CP4A. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-12 (CP4 and CP4A): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The gravel augmentation program would involve vegetation removal and gravel placement that could result in the loss of special-status plants if they are present at the gravel placement sites. Similarly, restoring riparian, floodplain, and side channel habitats would involve excavation, grading, and vegetation clearing that could result in the loss of special-status plants if they are present at the restoration sites. This impact would be potentially significant for CP4 or CP4A.

Special-status plant species could be killed during vegetation clearing and grubbing or gravel placement if they are present at the gravel placement sites or areas that would be cleared for access. Similarly, special-status plants could be killed during vegetation clearing, excavation, and grading if they are present at the riparian, floodplain, and side channel restoration sites or areas disturbed for access.

The impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

The impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-13 (CP4 and CP4A): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats Implementation of the gravel augmentation program could result in the spread of noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. Similarly, actions to restore riparian, floodplain, and side channel habitats could also spread noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. This impact would be potentially significant for CP4 or CP4A.

Vegetation removal and grubbing at gravel placement sites and access routes could result in increased risk of introduction and spread of noxious and invasive weeds. Riparian, floodplain, and side channel restoration projects also could result in increased risk of introduction and spread of noxious and invasive weeds.

The risk of introducing or spreading noxious weeds would vary depending on the proximity of existing noxious weed infestations, extent of ground-disturbing activities, and the amount of traffic entering a project site. Vectors that would increase as a result of project implementation include weed seed and seed parts brought in on tools, vehicles, and workers' clothing and boots. The number of weed vectors in an area would be increased by vegetation clearing and construction of temporary access routes for gravel placement and would be associated with modifying side channels and adjacent floodplain. As traffic along new and existing corridors increases, the risk for weed dispersal would increase. Seed mixtures and mulches may be used during erosion control efforts and revegetation of disturbed areas. These mixtures and mulches are potential vectors for noxious weed and invasive plant dispersal.

This impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

This impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Lower Sacramento River and Delta

Impact Bot-14 (CP4 and CP4A): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River The alteration of flow regimes associated with project implementation under CP4 or CP4A could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities and habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. However, adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River. For riparian and wetland plant communities and associated special-status plant species on the lower Sacramento River, the impact would be significant for CP4 or CP4A, but in the Delta, the impact would be less than significant. This impact would be significant for CP4 or CP4A.

This impact would be the same as Impact Bot-14 (CP1) and would be significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

This impact would be similar to Impact Bot-14 (CP1), but greater, as in Impact Bot-14 (CP2). The extent of the impact under CP4A would be greater than that under CP1 and CP4, but less than that under CP3 and CP5, which would entail more substantial alterations of flow regimes. The relative magnitude of changes to larger flows, which are most important for riparian and wetland vegetation, have been simulated for each alternative below RBPP and Hamilton City and are summarized on Figure 12-6. Therefore, for riparian and wetland plant communities and associated special-status plant species on the lower Sacramento River, the impact would be significant for CP4A, but in the Delta, the impact would be less than significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-15 (CP4 and CP4A): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP4 or CP4A would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant for CP4 or CP4A.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-16 (CP4 and CP4A): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth along the Lower Sacramento River and in the Delta Implementation of CP4 or CP4A could increase water supplies for deliveries to water districts in the extended study area along the lower Sacramento River. This increase in water deliveries could reduce any limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supply for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Bot-16 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact Bot-16 (CP1), but greater as in Impact Bot-16 (CP2). The extent of the impact under CP4A would be greater than that under CP1 and CP4 but less than that under CP3 and CP5, which would result in greater increases in water deliveries. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP4 and CP4A): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with implementation of CP4 or CP4A could alter the structure and species composition or cause the loss of sensitive plant communities and habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities or associated habitats for special-status plant species. Therefore, this impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Bot-17 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact Bot-17 (CP1), but greater, as in Impact Bot-17 (CP2). The extent of the impact under CP4A would be greater than that under CP1 and CP4, but less than that under CP3 and CP5, which would entail more substantial alterations of flow regimes. Nonetheless, for the same reasons as Impact Bot-17 (CP1), this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP4 and CP4A): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP4 or CP4A would not cause a significant impact on riparian vegetation and habitats. Therefore, CP4 or CP4A would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Bot-18 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact Bot-18 (CP1) and would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP4 and CP4A): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas The implementation of CP4 or CP4A could increase water supplies for deliveries to water districts in the extended study area along the lower Sacramento River. This increase in water deliveries could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Bot-19 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact Bot-19 (CP1), but greater, as in Impact Bot-19 (CP2) for CP4A. The extent of the impact under CP4A would be greater than that under CP1 and CP4 but less than that under CP3 and CP5, which would result in greater increases in water deliveries. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily focuses on increasing water supply reliability, anadromous fish survival, Shasta Lake area environmental resources, and recreation opportunities. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP5 would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 150,000 acre-feet and 75,000 acre-feet , respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries.

CP5 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

At Shasta Lake, CP5 would also include (1) implementing environmental restoration features along the lower reaches of major tributaries, (2) constructing shoreline fish habitat, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. Formulation of specific environmental restoration features and increased recreation components is included in the Plan Formulation Appendix.

Along the upper Sacramento River, CP5 would also include implementing the same gravel augmentation program and the same riparian, floodplain, and side channel habitat restoration as described for CP4 and CP4A.

Shasta Lake and Vicinity

Impact Bot-1 (CP5): Loss of Federally or State-Listed Plant Species Habitat for Federally or State-listed plant species does not occur at Shasta Lake or in the vicinity. No species are known or expected to occur. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-2 (CP5): Loss of MSCS Covered Species Implementation of the project would result in the loss of MSCS covered species as a result of ground-disturbing construction activities or inundation. Therefore, this impact would be significant.

This impact would be similar to Impact Bot-2 (CP4 and CP4A) and would be significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-3 (CP5): Loss of USFS Sensitive, BLM Sensitive, or CRPR Species Implementation of the project would result in the loss of USFS Sensitive, BLM

Sensitive, or CRPR species as a result of inundation, vegetation removal, or construction activities. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Bot-3 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-4 (CP5): Loss of Jurisdictional Waters Implementation of the project would result in the loss of jurisdictional waters because of flooding of the impoundment area and fill associated with the relocation of facilities and dam construction. Flooding caused by implementation of the project would result in the conversion of jurisdictional water types (e.g., wetlands and streams to lacustrine habitat). This impact would be significant.

This impact would be similar to Impact Bot-4 (CP3) and would be significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-5 (CP5): Loss of General Vegetation Habitats Implementation of the project would result in a loss of general vegetation habitats because of inundation, vegetation removal, or construction activities. This impact would be potentially significant.

This impact would be similar to Impact Bot-5 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-6 (CP5): Spread of Noxious and Invasive Weeds Implementation of the project could result in the spread of noxious and invasive weeds because of ground-disturbing activities during construction and an increased number of vectors (means of dispersal). This impact would be potentially significant.

Impacts resulting from the spread of noxious weeds under CP5 are anticipated to be similar to those described for CP3.

This impact would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Bot-7 (CP5): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes Altered flow regimes associated with project implementation under CP5 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities and habitat for special-status plant species. Vernal pool plant communities and associated special-status species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial; thus, this impact would be significant.

This impact would be similar to Impact Bot-7 (CP1). The extent of the impact would be greater than under CP1 because CP5 would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below Keswick Dam and RBPP are summarized on Figure 12-6). This impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-8 (CP5): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Numerous local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the upper Sacramento River. Because CP5 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Bot-8 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-9 (CP5): Disturbance or Removal of Designated Critical Habitat for Special-Status Species Designated critical habitat for four vernal pool special-status plant species exists within the primary study area. However, such critical habitat is not expected to be adversely affected by CP5. This impact would be less than significant.

This impact would be similar to Impact Bot-9 (CP1). The extent of the impact would be greater than under CP1 through CP4, because CP5 would entail a greater alteration of flow regimes. However, for the same reasons as Impact Bot-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-10 (CP5): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth Implementation of CP5 could increase water supplies for deliveries to water districts in the primary study area along the upper Sacramento River. This increase in water deliveries could reduce any limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-10 (CP1). The extent of the impact under CP5 would be greater than that under CP1 through CP4 because it would result in a greater increase in water deliveries. However, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-11 (CP5): Loss of Sensitive Natural Communities or Habitats Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats Implementation of the gravel augmentation program could result in the removal of riparian and wetland vegetation or the degradation of riparian and wetland habitats, including wetlands qualifying as waters of the United States. In addition, actions to restore riparian, floodplain, and side channel habitats at the potential downstream Sacramento River restoration sites would remove riparian vegetation, and could result in discharge of fill material into waters of the United States. This impact would be potentially significant.

This impact would be the same as Impact Bot-11 (CP4 and CP4A) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-12 (CP5): Loss of Special-Status Plants Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats The gravel augmentation program would involve vegetation removal and gravel placement that could result in the loss of special-status plants if they are present at the gravel placement sites. Similarly, restoring riparian, floodplain, and side channel habitats would involve excavation, grading, and vegetation clearing that could result in the loss of special-status plants if they are present at the restoration sites. This impact would be potentially significant.

This impact would be the same as Impact Bot-12 (CP4 and CP4A) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Impact Bot-13 (CP5): Spread of Noxious and Invasive Weeds Resulting from Implementing the Gravel Augmentation Program or Restoring Riparian, Floodplain, and Side Channel Habitats Implementation of the gravel augmentation program could result in the spread of noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. Similarly, actions to restore riparian, floodplain, and side channel habitats could also spread noxious and invasive weeds as a result of vegetation clearing and grubbing and an increased number of vectors. This impact would be potentially significant.

This impact would be the same as Impact Bot-13 (CP4 and CP4A) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, “Mitigation Measures.”

Lower Sacramento River and Delta

Impact Bot-14 (CP5): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes on the Lower Sacramento River Altered flow regimes associated with project implementation under CP5 could alter the structure and species composition or cause the loss of riparian, wetland, and oak communities and habitat for special-status plant species. Vernal pool plant communities and associated special-status plant species likely would not be affected. Effects on oak communities and upland habitats for special-status plants may not all be adverse. Adverse effects on riparian and wetland communities and associated special-status plants could be substantial on the lower Sacramento River. Thus, this impact would be significant.

This impact would be similar to Impact Bot-14 (CP1). The extent of the impact would be greater under CP5 than under CP1 through CP4, because CP5 would entail more substantial alterations of flow regimes. (The relative magnitude of changes to larger flows (which are most important for riparian and wetland vegetation) simulated for each alternative below RBPP and Hamilton City are summarized on Figure 12-6). This impact would be significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-15 (CP5): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management along the Lower Sacramento River Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along the lower Sacramento River. Because CP5 would adversely affect riparian communities, this alternative could conflict with existing local and regional plans focused on preserving riparian habitats. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Bot-15 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 12.3.5, "Mitigation Measures."

Impact Bot-16 (CP5): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth along the Lower Sacramento River and in the Delta Implementation of CP5 could increase water supplies for deliveries to water districts in the extended study area along the lower Sacramento River. This increase in water deliveries could reduce any limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-16 (CP1). The extent of the impact under CP5 would be greater than that under CP1 through CP4 because it would result in a greater increase in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Bot-17 (CP5): Altered Structure and Species Composition and Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Altered Flow Regimes in the CVP/SWP Service Areas Altered flow regimes associated with project implementation under CP5 could alter the structure and species composition or cause the loss of sensitive plant communities and habitat for special-status plant species. However, alteration of flow regimes below CVP and SWP reservoirs in the extended study area would be less than below Shasta Dam along the upper and lower Sacramento River. These alterations may not be sufficient to alter the extent of early-successional riparian and wetland communities or associated habitats for special-status plant species. Therefore, this impact would be less than significant.

This impact would be similar to Impact Bot-17 (CP1). The extent of the impact under CP5 would be greater than that under CP1 through CP4, because it would entail more substantial alterations of flow regimes. Nonetheless, for the same reasons as Impact Bot-17 (CP2), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-18 (CP5): Conflict with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management in the CVP/SWP Service Areas Adopted local and regional plans address and promote the conservation of riparian vegetation and associated habitats along rivers below reservoirs in the CVP and SWP service areas. However, implementation of CP5 would not cause a significant impact on riparian vegetation and habitats. Therefore, CP5 would not conflict with existing local and regional plans focused on preserving riparian habitats. Thus, this impact would be less than significant.

This impact would be the same as Impact Bot-18 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Bot-19 (CP5): Loss of Sensitive Plant Communities and Special-Status Plant Species Resulting from Induced Growth in the CVP/SWP Service Areas Implementation of CP5 could increase water supplies for water districts in the CVP and SWP service areas. This increase in water deliveries could reduce a limitation on growth that could affect sensitive plant communities and special-status plant species. However, this increase in water supplies for growth that could affect these resources would be small, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects. For these reasons, this impact would be less than significant.

This impact would be similar to Impact Bot-19 (CP1). The extent of the impact under CP5 would be greater than that under CP1 through CP4, because it would result in a greater increase in water deliveries. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

12.3.5 Mitigation Measures

Table 12-27 presents a summary of mitigation measures for botanical resources and wetlands.

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Bot-1 (CP1), Bot-9 (CP1) through Bot-13 (CP1), and Bot-16 (CP1) through Bot-19 (CP1). Mitigation is provided below for the remaining impacts of CP1 on botanical resources and wetlands.

Mitigation Measure Bot-2 (CP1): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas
As described in the Preliminary Environmental Commitments and Mitigation Plan Appendix, Reclamation convened an interagency working group to enhance mitigation measures presented in the DEIS. This working group had the benefit of additional information acquired during investigations of nearby private lands available for mitigation and refined analyses of potential project impacts. Using this updated information, the working group developed and refined mitigation measures for botanical and wetland resources, including Shasta snow-wreath. This mitigation measure includes the following components.

Reclamation will facilitate and implement actions necessary to acquire and/or propose land exchanges for Shasta snow-wreath populations on private land for transfer into federal ownership, including roads or other access to those lands. Alternatively, if acquisition and/or land exchange efforts are deemed insufficient, Reclamation will work with cooperating and responsible agencies to establish conservation easements at Shasta snow-wreath populations located on private land, including access to the conservation easements by State and Federal resource agencies to monitor the populations.

Reclamation will select and/or acquire test plot locations for establishment of experimental Shasta snow-wreath populations. At least four currently unoccupied sites with potential Shasta snow-wreath habitat within the STNF boundary will be selected.

Reclamation will develop a program for conservation of genetic material from Shasta snow-wreath sites subject to inundation. This program will include collection of genetic material, including seeds and scions, at all existing Shasta snow-wreath populations within the inundation area. Appropriate endowment funding for long-term maintenance and storage of at least two public botanical conservatories, one of which will be a California institution affiliated with the Center for Plant Conservation, will be provided.

	Mitigation Measure	None required.					
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS

Key:
CP = Comprehensive Plan
CVP = Central Valley Project
LOS = level of significance
LTS = less than significant
NA = not applicable
NI = no impact
PS = potentially significant
S = significant
SU = significant and unavoidable
SWP = State Water Project

Reclamation will investigate the feasibility of protecting Shasta snow-wreath populations to be inundated with dikes/berms. Two existing Shasta snow-wreath sites will be chosen for their genetic diversity and and/or extent. Reclamation will then investigate the feasibility of building dike or berm structures designed to eliminate the flooding that would otherwise occur at the new inundation level at these Shasta snow-wreath sites.

Reclamation will develop an active management program for existing Shasta snow-wreath populations. The program, which will be led by Reclamation and include appropriate stakeholders, will provide active management of known Shasta snow-wreath populations outside of the project area on USFS lands to enhance and protect these existing populations. Management activities will include measures to increase fire suppression capacity, use of prescribed fire under rigorous experimental conditions, fencing, integrated weeds management including weed inventory, control (mechanical, chemical, cultural, and biological), abatement, monitoring, and public education. This mitigation measure applies to known and any newly established experimental populations.

Additional studies to determine the biology of Shasta snow-wreath will be conducted by Reclamation. Studies will be undertaken to understand the pollination biology of Shasta snow-wreath and the genetic compatibility of different genotypes and to understand the conditions under which sexual reproduction occurs in this species. Seed germination and scion rooting techniques will be explored to find reliable means of producing material for establishment of experimental populations.

Reclamation will establish an outreach communication program to local land owners and determine if additional Shasta snow-wreath populations occur on private land. Following development, Reclamation will implement the communications program, including applicable subsequent outreach and monitoring.

Reclamation will develop a Shasta Snow-wreath Conservation Agreement. This Conservation Agreement will serve as the overall management document for Shasta snow-wreath and include all responsible State and Federal resource management agencies and appropriate private landowners. At a minimum, the Conservation Agreement will include the following sections:

- Introduction
- Geographic area and entities included in the agreement
- Authority, purpose, objective, and management goal(s) of the Conservation Agreement
- Description, status, distribution, ecology, and population biology of the species

- Known and potential threats to the species
- Current threats of destruction, modification, or curtailment of its habitat or range
- Issues related to overutilization for commercial, recreational, scientific, or educational purposes
- Disease or predation
- Efficacy of existing regulatory mechanisms
- Other natural or manmade factors affecting the species' continued existence
- Conservation or management actions that will be implemented
- Funding of conservation or management actions
- Duration of agreement
- Signatures
- References

The STNF has established monitoring transects in eight Shasta snow-wreath populations, with three years of data for seven populations and two years of data for the eighth population. Reclamation will continue the monitoring efforts at the established populations and expand the effort to additional populations, based on criteria developed by Conservation Agreement participants.

The following mitigation measures will reduce impacts on other MSCS plants, if applicable:

- When feasible in relocation areas, avoid or minimize actions that can result in harm or mortality to individuals or to the viability of populations.
- When feasible, Reclamation will relocate populations of MSCS plants that will be directly affected to suitable habitat within undisturbed portions of the Shasta Lake and vicinity portion of the primary study area.
- When feasible, Reclamation will use seed banking and other *ex situ* (off site) conservation methods for MSCS populations that will be directly affected.

- When feasible, Reclamation will restore/enhance populations of other MSCS plants in the project vicinity.

- A mitigation and monitoring plan will be developed to monitor success of MSCS plant populations that have been relocated or revegetated. The plan will identify suitable sites for mitigation, species to be planted, and numbers and sizes of plantings. It will describe planting techniques, prescribe methods to remove existing noxious weeds, and establish reasonable performance standards and contingency measures. Furthermore, it will establish conservation easements as appropriate. The vegetation restoration plan will be developed in consultation with coordinating and responsible agencies (e.g., USACE, USFWS, and USFS).

- Where appropriate, MSCS covered plant species will be used for revegetation.

Implementation of this mitigation measure would reduce impacts on MSCS plant species; however, because successful relocation, transplanting, and artificial propagation of Shasta snow-wreath are unproven, impacts would remain significant and unavoidable.

Mitigation Measure Bot-3 (CP1): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive, and CRPR Plants and Revegetate Affected Areas As described in the Preliminary Environmental Commitments and Mitigation Plan Appendix, Reclamation convened an interagency working group to enhance mitigation measures presented in the DEIS. This working group had the benefit of additional information from recent investigations of nearby private lands available for mitigation and refined analyses of potential project impacts. Using this updated information, the working group developed and refined mitigation measures for botanical and wetland resources, including include land acquisition, habitat management and enhancement, and other measures.

Mitigation measure Bot-3 consists of a program to acquire nearby private lands with similar habitat attributes and species composition as those impacted by the SLWRI project. Reclamation has identified several willing private landowners and specific parcels for purchase in the project area vicinity. Preliminary investigations of these lands have shown they contain similar and/or additional habitats and special-status species as those impacted by SLWRI. Special-status plant species known to occur on the lands subject to these preliminary investigations include Shasta huckleberry, Shasta arnica, Shasta limestone monkeyflower, Canyon Creek stonecrop, Howell’s lewisa, and Shasta eupatory. Additionally, the interagency working group identified other private parcels with similar biological resources in the vicinity of the project area, some of which have owners willing to discuss purchase agreements.

As discussed during the interagency working group meetings, mitigation measure Bot-3 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. The interagency working group also agreed that additional considerations will be made for other replacement ratios (more or less) depending on habitat quality at a particular site. Emphasis will be placed on lands containing high value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

This mitigation measure includes the following components intended to reduce impacts on USFS sensitive, BLM sensitive, and CRPR plants:

- When feasible in relocation areas, avoid or minimize actions that can result in harm or mortality to individuals or to the viability of populations.

- When feasible, Reclamation will relocate populations of USFS sensitive, BLM sensitive, and CRPR plants that will be directly affected to suitable habitat within undisturbed portions of the Shasta Lake and vicinity portion of the primary study area.

- When feasible, Reclamation will use seed banking and other *ex situ* (off site) conservation methods for USFS sensitive, BLM sensitive, and CRPR plant populations that will be directly affected.

- When feasible, Reclamation will restore/enhance populations of other USFS sensitive, BLM sensitive, and CRPR plants in the project vicinity.

- Reclamation will develop a mitigation and monitoring plan to monitor success of USFS sensitive, BLM sensitive, and CRPR plant populations that have been relocated or revegetated. The plan will identify suitable sites for mitigation, species to be planted, and numbers and sizes of plantings. It will describe planting techniques, prescribe methods to remove existing noxious weeds, and establish reasonable performance standards and contingency measures. Furthermore, it will establish conservation easements as appropriate. The vegetation restoration plan will be developed in consultation with cooperating and responsible agencies (e.g., USACE, USFWS, USFS).

- To the extent feasible, USFS sensitive, BLM sensitive, and CRPR plant species will be used for revegetation.

Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive, and CRPR plant species; however, because successful relocation and transplantation of these species are unproven, impacts would remain potentially significant and unavoidable.

Mitigation Measure Bot-4 (CP1): Mitigate Loss of Jurisdictional Waters Reclamation will prepare a conceptual wetland mitigation plan following current USACE guidance and requirements. The mitigation plan will incorporate wetland habitats within lands acquired under Bot-3 as appropriate, and may include additional mitigation lands. The wetland mitigation plan will also include measures for wetland habitat creation, restoration, and/or enhancement.

Under CP1, Bot-4 will mitigate for the loss of approximately 14 acres of wetlands and 19 acres of other waters of the U.S. in the inundation area, and approximately 2 acres of wetlands and 2 acres of other waters of the U.S. in the relocation areas. Collectively Bot-4 (CP1) will mitigate for the loss of approximately 16 acres of wetlands and approximately 21 acres of other waters of the U.S.

Until the details of this mitigation measure are developed through the ongoing planning process, Impact Bot-4 (CP1) would remain significant and unavoidable.

Mitigation Measure Bot-5 (CP1): Acquire, Preserve, and Restore Mitigation Lands for Loss of General Vegetation Habitats As described in Bot-3, mitigation lands will be acquired to mitigate for the loss of vegetation habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Bot-5 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied to each specific habitat type. Additional considerations will be made for other replacement ratios (more or less) depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Bot-5 will mitigate for the loss of 1,227 acres of habitats in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 5,775 acres of mitigation lands containing comparable habitats.

Until the details of this mitigation measure are developed, Impact Bot-5 (CP1) would remain significant and unavoidable.

Mitigation Measure Bot-6 (CP1): Develop and Implement a Weed Management Plan in Conjunction with Stakeholders Reclamation will develop and implement a weed management plan in conjunction with stakeholders to avoid or minimize the potential for project-related impacts from noxious and invasive plants. This plan will incorporate a combination of inventory, adaptive measures for treatment of existing populations, and measures for controlling spread. The plan will have long-term consideration and be designed as an ongoing program. At a minimum, the plan will include:

- Identification of key established weed populations for removal/treatment.
- Measures to treat source populations, prevent introduction of new infestations during project construction, and ongoing maintenance.
- Provide a mechanism for monitoring and addressing weed populations as the new shoreline develops over time.
- Include objective statements which are achievable and can be readily implemented (e.g., to protect potentially impacted sensitive species, to minimize project impacts, to avoid and control weed spread that affects rare and otherwise desirable species, recreation, fuels/fire implications).
- Consideration for construction-related species, which may be distinctly different from species likely to invade new inundation areas.

Environmental commitments outlined in Chapter 2, “Alternatives,” include measures to use native species for revegetation and erosion control in construction areas, including establishment of local source populations for seed/propagule collection; include standard equipment cleaning provisions in all construction contracts; and use only weed-free road fill, gravel, mulches, and erosion control devices.

Implementation of these measures would reduce Impact Bot-6 (CP1) to a less-than-significant level.

Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities Reclamation will implement a riverine ecosystem mitigation and adaptive management plan to mitigate to the extent feasible the identified effects of an altered Sacramento River flow regime on existing riparian and wetland communities, and associated instream, riparian, and wetland habitat values for aquatic and terrestrial special-status species along the Sacramento River from Shasta Dam to Colusa (River Mile 144). The plan is consistent with and will support implementation of the Senate Bill 1086 program, and will be implemented in coordination with USFWS, NMFS, CDFW, and the Sacramento River Conservation Area Forum. The plan will be implemented before or during project construction. The plan is limited to the Sacramento River from Shasta Dam to Colusa (River Mile 144). The plan mitigates to the existing conditions as of 2010 which are considered the baseline conditions.

The goals of the plan, which also serve as performance standards, are to have no net reduction in the average amount of any of the following caused by the project along the Sacramento River from Shasta Dam to Colusa:

- Channel migration in selected areas of natural vegetation dominated by native species
- Overbank inundation of natural vegetation dominated by native species in selected areas
- Regeneration of early-successional riparian vegetation (e.g., cottonwood regeneration) in selected areas

The riverine ecosystem mitigation plan includes a menu of potentially feasible elements:

- Modeling or monitoring at representative locations to quantify direct and indirect impacts resulting from adaptive management of project implementation. A method of quantifying impacts will be used that ensures repeatability. This would include at least one of the following approaches:
  - Conducting aerial surveys to evaluate changes in riparian habitat communities
  - Development and monitoring of up to 15 riparian habitat transects along the Sacramento River at potentially sensitive locations (e.g., downstream from the confluence of tributaries, downstream from diversion structures)

  Monitoring would be conducted for an initial 10-year period, after which the need for continued monitoring would be re-evaluated.
- An evaluation of modifications to the procedures for operating Shasta Dam (e.g., ramping rates) to accomplish any of the following:
  - Reduce or eliminate adverse impacts on ecologically important bankfull and overbank flows (as feasible within existing flood reduction constraints)
  - Reduce or eliminate adverse impacts (e.g., reduction) on meander migration rates
  - Facilitate establishment of cottonwoods and early-successional vegetation at intervals sufficient to sustain cottonwoods and early-successional riparian vegetation along the Sacramento River riparian corridor and floodplain (e.g., at 5- to 15-year intervals)

  - Avoid any increase in flood risk from implementing this mitigation measure. Feasible modifications to operational procedures are those not in conflict with applicable laws, agreements, and regulations, or with the purpose of the project.

- A specific combination of mitigation actions will be implemented to attain the plan's goals. Mitigation actions consist of modifications to dam operation procedures and/or funding of appropriate restoration actions that have been developed by Reclamation, other Federal agencies, State or local governments, or private nonprofits and received applicable Federal and State permits. Appropriate restoration actions include the following:

  - Enhance connectivity of river side channels (e.g., by modifying the elevation of secondary channels, remnant oxbows, or meander scars)

  - Expand the river meander zone at selected locations (e.g., by assisting in funding projects that meet this objective)

  - Increase floodplain connectivity (e.g., by assisting in funding projects that meet this objective)

  - Control and remove nonnative, invasive plant species from riparian areas to shift dominance to native species

  - Create riparian and wetland communities (e.g., through plantings)

  - Increase shaded riverine aquatic habitat (e.g., through plantings)

The following will be considered in implementation of the riverine ecosystem mitigation plan:

- The adaptive management process will evaluate the performance of the restoration actions towards meeting the performance standards and goals.

- The location of restoration actions will be on preserved sites and with funding for management in perpetuity. (Preserved sites will include sites previously preserved by other entities.) A specific restoration plan will be developed for each restoration location and coordinated with resource agencies and local stakeholders.

- Mechanisms by which Reclamation will fund implementation will be determined after project approval for implementation.

At a minimum, mitigation that will be implemented under this plan will include the following:

- Feasible modifications to dam operation procedures identified as reducing adverse impacts on meander migration or ecologically important bankfull and overbank flows, or as facilitating cottonwood establishment, and

- Either of the following elements:

  – Provide actions or funding to increase meander migration, side-channel connectivity, or floodplain connectivity along the Sacramento River, and creation (or conversion of nonnative-dominated to native-dominated) of riparian or wetland communities

or

  – Provide mitigation that has been determined by USFWS, NMFS, and CDFW to be of comparable or greater value and is included in the terms and conditions of permits for impacts on species listed as threatened or endangered by the State or Federal governments

Implementation of this mitigation measure would mitigate the impact of altered flow regimes on instream, riparian, and wetland communities, and thus would reduce Impact Bot-7 (CP1) to a less-than-significant level.

Mitigation Measure Bot-8 (CP1): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP1) as described above.

As described under Mitigation Measure Bot-7 (CP1), implementing a riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the upper Sacramento River in the primary study area. Consequently, implementation of the previous mitigation measure would reduce Impact Bot-8 (CP1) to a less-than-significant level.

Mitigation Measure Bot-14 (CP1): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This measure is identical to Mitigation Measure Bot-7 (CP1) as described above. Reclamation will implement a riverine ecosystem mitigation plan.

Implementation of this mitigation measure would reduce Impact Bot-14 (CP1) to a less-than-significant level.

Mitigation Measure Bot-15 (CP1): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP1) as described above.

As described under Mitigation Measure Bot-7 (CP1), implementing a riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the lower Sacramento River in the extended study area. Consequently, implementing the previous mitigation measure would reduce Impact Bot-15 (CP1) to a less-than-significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Bot-1 (CP2), Bot-9 (CP2) through Bot-13 (CP2), and Bot-16 (CP2) through Bot-19 (CP2). Mitigation is provided below for the remaining impacts of CP2 on botanical resources and wetlands.

Mitigation Measure Bot-2 (CP2): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on Shasta snow-wreath; however, because many of the proposed mitigation measures relocation of this species are unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-3 (CP2): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive and CRPR plant species; however, because relocation of these species is unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-4 (CP2): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1).

Under CP2, Bot-4 will mitigate for the loss of approximately 19 acres of wetlands and 26 acres of other waters of the U.S. in the inundation area, and approximately 2 acres of wetlands and 2 acres of Other Waters of the U.S. in the relocation areas. Collectively Bot-4 (CP2) will mitigate for the loss of approximately 21 acres of wetlands and approximately 28 acres of other waters of the U.S.

Until the details of this mitigation measure are developed, Impact Bot-4 (CP2) would remain significant and unavoidable.

Mitigation Measure Bot-5 (CP2): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical to Mitigation Measure Bot-3 (CP1).

Under CP2, Bot-5 will mitigate for the loss of 1,725 acres of habitats in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 7,269 acres of mitigation lands containing comparable habitats.

Until the details of this mitigation measure are developed, Impact Bot-5 (CP2) would remain significant and unavoidable.

Mitigation Measure Bot-6 (CP2): Develop and Implement a Weed Management Plan in Conjunction with Stakeholders This mitigation measure is identical to Mitigation Measure Bot-6 (CP1). Implementation of this mitigation measure would reduce Impact Bot-6 (CP2) to a less-than-significant level.

Mitigation Measure Bot-7 (CP2): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1), except that mitigation in the riverine ecosystem mitigation plan will include either of the following elements:

- Increased meander migration, side-channel connectivity, or floodplain connectivity along the Sacramento River, and creation (or conversion from nonnative-dominated to native-dominated) of riparian or wetland communities

or

- Mitigation that has been determined by USFWS, NMFS, and CDFW to be of comparable or greater value and is included in the terms and conditions of permits for impacts on species listed as threatened or endangered by the State or Federal government

Implementation of this mitigation measure would reduce Impact Bot-7 (CP2) to a less-than-significant level.

Mitigation Measure Bot-8 (CP2): Implement Mitigation Measure Bot-7 (CP2): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional

Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP2) as described above.

Implementing this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the upper Sacramento River in the primary study area. Implementation of this mitigation measure would reduce Impact Bot-8 (CP2) to a less-than-significant level.

Mitigation Measure Bot-14 (CP2): Implement Mitigation Measure Bot-7 (CP2): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP2). Reclamation will implement a riverine ecosystem mitigation plan.

Implementation of this mitigation measure would reduce Impact Bot-14 (CP2) to a less-than-significant level.

Mitigation Measure Bot-15 (CP2): Implement Mitigation Measure Bot-7 (CP2): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP2) as described above.

Implementing this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the lower Sacramento River in the extended study area. Implementation of this mitigation measure would reduce Impact Bot-15 (CP2) to a less-than-significant level.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation is needed for Impacts Bot-1 (CP3), Bot-9 (CP3) through Bot-13 (CP3), and Bot-16 (CP3) through Bot-19 (CP3). Mitigation is provided below for the remaining impacts of CP3 on botanical resources and wetlands.

Mitigation Measure Bot-2 (CP3): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on Shasta snow-wreath; however, because many of the proposed mitigation measures for relocation of this species are unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-3 (CP3): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive and CRPR plant species; however, because relocation of these species is unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-4 (CP3): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1).

Under CP3, Bot-4 will mitigate for the loss of approximately 29 acres of wetlands and 48 acres of other waters of the U.S. in the inundation area, and approximately 2 acres of wetlands and 2 acres of Other Waters of the U.S. in the relocation areas. Collectively Bot-4 (CP3) will mitigate for the loss of approximately 31 acres of wetlands and approximately 50 acres of Other Waters of the U.S.

Until the details of this mitigation measure are developed, Impact Bot-4 (CP3) would remain significant and unavoidable.

Mitigation Measure Bot-5 (CP3): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical to Mitigation Measure Bot-3 (CP1).

Under CP3, Bot-5 will mitigate for the loss of 2,492 acres of habitats in the inundation area and 698 acres in the relocation areas by acquiring a minimum 9,570 acres of mitigation lands containing comparable habitats.

Until the details of this mitigation measure are developed, Impact Bot-5 (CP3) would remain significant and unavoidable.

Mitigation Measure Bot-6 (CP3): Develop and Implement a Weed Management Plan in Conjunction with Stakeholders This mitigation measure is identical to Mitigation Measure Bot-6 (CP1). Implementation of this mitigation measure would reduce Impact Bot-6 (CP3) to a less-than-significant level.

Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1), except that mitigation in the riverine ecosystem mitigation plan will include either of the following elements:

- Increased meander migration, side-channel connectivity, or floodplain connectivity along the Sacramento River, and creation (or conversion from nonnative-dominated to native-dominated) of riparian or wetland communities

or

- Mitigation that has been determined by USFWS, NMFS, and CDFW to be of comparable or greater value and is included in the terms and conditions of permits for impacts on species listed as threatened or endangered by the State or Federal government.

Implementation of this mitigation measure would reduce Impact Bot-7 (CP3) to a less-than-significant level.

Mitigation Measure Bot-8 (CP3): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP3) as described above.

The implementation of this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the upper Sacramento River in the primary study area. Implementation of this mitigation measure would reduce Impact Bot-8 (CP3) to a less-than-significant level.

Mitigation Measure Bot-14 (CP3): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Reclamation will implement a riverine ecosystem mitigation plan.

Implementation of this mitigation measure would reduce Impact Bot-14 (CP3) to a less-than-significant level.

Mitigation Measure Bot-15 (CP3): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management Reclamation will implement Mitigation Measure Bot-7 (CP3) as described above.

The implementation of this riverine ecosystem mitigation plan would reduce conflicts with approved local and regional plans that address and promote the conservation of riparian vegetation communities along the lower Sacramento River in the extended study area. Implementation of this mitigation measure would reduce Impact Bot-15 (CP3) to a less-than-significant level.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Bot-1 (CP4 and CP4A), Bot-9 (CP4 and CP4A), Bot-10 (CP4 and CP4A), and Bot-16 (CP4 and CP4A) through Bot-19 (CP4 and CP4A). Mitigation is provided below for the remaining impacts of CP4 or CP4A on botanical resources and wetlands.

Mitigation Measure Bot-2 (CP4 and CP4A): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on Shasta snow-wreath; however, because many of the proposed mitigation measures for relocation of this species are unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-3 (CP4 and CP4A): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1).

Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive, and CRPR plant species; however, because relocation of these species is unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-4 (CP4 and CP4A): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1).

Until the details of this mitigation measure are developed, Impact Bot-4 (CP4 and CP4A) would remain significant and unavoidable.

Mitigation Measure Bot-5 (CP4 and CP4A): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical to Mitigation Measure Bot-3 (CP1).

Until the details of this mitigation measure are developed, Impact Bot-5 (CP4 and CP4A) would remain significant and unavoidable.

Mitigation Measure Bot-6 (CP4 and CP4A): Develop and Implement a Weed Management Plan in Conjunction with Stakeholders This mitigation measure is identical to Mitigation Measure Bot-6 (CP1).

Implementation of this mitigation measure would reduce Impact Bot-6 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Bot-7 (CP4 and CP4A): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and

Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1).

Implementation of this mitigation measure would reduce Impact Bot-7 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Bot-8 (CP4 and CP4A): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP1).

Implementation of this mitigation measure would reduce Impact Bot-8 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Bot-11 (CP4 and CP4A): Revegetate Disturbed Areas, Consult with CDFW, and Mitigate Loss of Jurisdictional Waters Reclamation will implement the following measures to reduce and compensate for loss of sensitive natural communities:

- Before removing any vegetation at the augmentation sites and access areas, a survey will be conducted to map and classify the natural communities present in these areas, including wetland communities.
- Augmentation access will be designed to avoid disturbing wetland plant communities to the extent feasible. Removal of mature riparian vegetation and other sensitive vegetation will be minimized to the extent possible while still allowing access to gravel augmentation sites.
- CDFW will be consulted with to determine if a Section 1602 streambed alteration agreement will be required for the gravel augmentation activities affecting the bed and bank of the Sacramento River and side channels.
- Staging and gravel and equipment storage will be confined to developed or disturbed areas to the extent feasible.
- A revegetation plan will be prepared to restore native vegetation in all areas cleared to implement the gravel augmentation program immediately following completion of the gravel augmentation activities at each augmentation site. The revegetation plan will include performance standards and success criteria to ensure that mitigation habitat would be successfully maintained and result in no net loss of sensitive natural communities, including riparian vegetation.

- All conditions of the streambed alteration agreement will be implemented to the satisfaction of CDFW, subject to limitations on its authority set forth in Fish and Game Code Section 1600 et seq.

In addition, Reclamation will implement the following measures to reduce and compensate for potential loss of sensitive natural communities from the riparian, floodplain, and side channel restoration actions:

- A survey will be conducted before removing any vegetation at the augmentation sites and access areas to map and classify the natural communities present in restoration and potential construction areas at restoration sites.

- CDFW will be consulted with to determine if a Section 1602 streambed alteration agreement will be required for the restoration and construction activities at each restoration site affecting the bed and bank of the Sacramento River and side channel.

- Relocated and/or rehabilitated facilities (e.g., power poles) will be designed to avoid disturbing sensitive plant communities to the extent feasible.

- A 100-foot no disturbance buffer will be established around sensitive plant communities that are to be avoided during construction. Removal of mature riparian vegetation and other sensitive vegetation will be minimized to the extent possible.

- Staging, equipment storage, and construction access will be designed to avoid disturbing vegetation to the extent feasible.

- Native riparian and other sensitive vegetation, if any, removed from restoration sites will be replaced on a no-net-loss basis. Riparian vegetation will be replaced through planting and establishment of comparable native riparian vegetation on-site. Other sensitive plant communities may be replaced through restoration of comparable native vegetation at other sites if necessary.

- Planting mix, composition, and density will be determined by a more detailed site analysis, but could include native cottonwood, willow, box elder, valley oak, western sycamore, elderberry, and a variety of understory brush species. Temporary irrigation will be provided on an as-needed basis, where feasible.

- All conditions of the streambed alteration agreement will be implemented to the satisfaction of CDFW, subject to limitations on its authority set forth in Fish and Game Code Section 1600 et seq.

Reclamation will prepare and implement a wetland mitigation plan following current USACE guidance and requirements. The wetland mitigation plan will include measures for wetland habitat creation, restoration, and/or enhancement.

Implementation of this mitigation measure would reduce Impact Bot-11 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Bot-12 (CP4 and CP4A): Conduct Preconstruction Surveys for Special-Status Plants and Avoid Special-Status Plant Populations during Construction Reclamation will implement the following measures to avoid impacts on special-status plants resulting from the gravel augmentation program:

- Botanists will be hired to conduct protocol-level special-status plant surveys before commencing any construction activities that could disturb vegetation.
- All special-status plants identified within 250 feet of the proposed augmentation sites will be mapped and identified for avoidance. Access routes and gravel placement will be designed to avoid impacts on special-status plants.
- Fencing will be installed a minimum of 100 feet from special-status plants, and no project activity will be permitted within the area occupied by special-status plants or the 100-foot buffer area around these plants.
- Insecticides, herbicides, fertilizers, or other chemicals that might harm special-status plants will not be used within 100 feet of the plants. Roadways and disturbed areas within 100 feet of special-status plants will be watered at least twice a day and as needed to minimize dust emissions.

In addition, Reclamation will implement the following measures to avoid impacts on special-status plants resulting from the riparian, floodplain, and side channel restoration actions:

- Qualified botanists will be hired to conduct protocol-level special-status plant surveys before commencing any construction activities that could disturb vegetation.
- All special-status plants identified within 250 feet of the proposed augmentation sites will be mapped and avoided to the extent feasible. Protective fencing will be installed around special-status plant locations and a 100-foot buffer zone during construction activities.

- Insecticides, herbicides, fertilizers, or other chemicals that might harm special-status plants will not be used within 100 feet of special-status plants. Roadways and disturbed areas within 100 feet of special-status plants will be watered at least twice a day and as needed to minimize dust emissions.

Implementation of this mitigation measure would reduce Impact Bot-12 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Bot-13 (CP4 and CP4A): Implement Weed Management Measures and Revegetation Reclamation will implement the following measures to reduce the risk of introducing and spreading noxious weeds or invasive plant species during gravel augmentation and riparian, floodplain, and side channel restoration:

- Before conducting gravel augmentation activities, invasive plant and noxious weed infestations will be identified and mapped within the augmentation sites, including vegetation clearing sites.

- Noxious weeds will be removed at the onset of construction and disposed of properly. If noxious weeds are not removed at the onset of construction, they will be fenced and avoided during construction.

- Any clothing, footwear, and equipment used during construction will be ensured free of soil, seeds, vegetative matter or other debris or potential seed-bearing material before entering the project sites or before moving from infested sites to uninfested sites.

- Mitigation Measure Bot-11 (CP4 and CP4A) will be implemented to restore native vegetation in all areas disturbed by gravel placement and construction of access routes immediately following completion of the gravel augmentation activities at each augmentation site.

- Only weed-free gravel, fill soil, mulch, seed mixes, and straw materials will be used during construction; best management practices will be implemented; and postconstruction revegetation will be conducted. Certified weed-free material will be used if available.

Implementation of this mitigation measure would reduce Impact Bot-13 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Bot-14 (CP4 and CP4A): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP1).

Implementation of this mitigation measure would reduce Impact Bot-14 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Bot-15 (CP4 and CP4A): Implement Mitigation Measure Bot-7 (CP1): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP1). Implementation of this mitigation measure would reduce Impact Bot-15 (CP4 and CP4A) to a less-than-significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Bot-1 (CP5), Bot-9 (CP5), Bot-10 (CP5), and Bot-16 (CP5) through Bot-19 (CP5). Mitigation is provided below for the remaining impacts of CP5 on botanical resources and wetlands.

Mitigation Measure Bot-2 (CP5): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate MSCS Plants; and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-2 (CP1). Implementation of this mitigation measure would reduce impacts on Shasta snow-wreath; however, because many of the proposed mitigation measures for relocation of this species are unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-3 (CP5): Acquire and Preserve Mitigation Lands; Avoid Populations; Relocate USFS Sensitive, BLM Sensitive and CRPR Plants and Revegetate Affected Areas This mitigation measure is identical to Mitigation Measure Bot-3 (CP1). Implementation of this mitigation measure would reduce impacts on USFS sensitive, BLM sensitive, and CRPR plant species; however, because relocation of these species is unproven, the impact would remain significant and unavoidable.

Mitigation Measure Bot-4 (CP5): Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-4 (CP1).

Until the details of this mitigation measure are developed, Impact Bot-4 (CP5) is considered significant and unavoidable.

Mitigation Measure Bot-5 (CP5): Acquire and Preserve Mitigation Lands for Loss of General Vegetation Habitats This mitigation measure is identical to Mitigation Measure Bot-3 (CP1).

Until the details of this mitigation measure are developed, Impact Bot-5 (CP5) would remain significant and unavoidable.

Mitigation Measure Bot-6 (CP5): Develop and Implement a Weed Management Plan in Conjunction with Stakeholders This mitigation measure is identical to Mitigation Measure Bot-6 (CP1). Implementation of this mitigation measure would reduce Impact Bot-6 (CP5) to a less-than-significant level.

Mitigation Measure Bot-7 (CP5): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-7 (CP5) to a less-than-significant level.

Mitigation Measure Bot-8 (CP5): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-8 (CP5) to a less-than-significant level.

Mitigation Measure Bot-11 (CP5): Revegetate Disturbed Areas, Consult with CDFW, and Mitigate Loss of Jurisdictional Waters This mitigation measure is identical to Mitigation Measure Bot-11 (CP4 and CP4A). Implementation of this mitigation measure would reduce Impact Bot-11 (CP5) to a less-than-significant level.

Mitigation Measure Bot-12 (CP5): Conduct Preconstruction Surveys for Special-Status Plants and Avoid Special-Status Plant Populations during Construction This mitigation measure is identical to Mitigation Measure Bot-12 (CP4 and CP4A). Implementation of this mitigation measure would reduce Impact Bot-12 (CP5) to a less-than-significant level.

Mitigation Measure Bot-13 (CP5): Implement Weed Management Measures and Revegetation This mitigation measure is identical to Mitigation Measure Bot-13 (CP4 and CP4A). Implementation of this mitigation measure would reduce Impact Bot-13 (CP5) to a less-than-significant level.

Mitigation Measure Bot-14 (CP5): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-14 (CP5) to a less-than-significant level.

Mitigation Measure Bot-15 (CP5): Implement Mitigation Measure Bot-7 (CP3): Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Reduce Conflicts with Approved Local or Regional Plans with Objectives of Riparian Habitat Protection or Watershed

Management This mitigation measure is identical to Mitigation Measure Bot-7 (CP3). Implementation of this mitigation measure would reduce Impact Bot-15 (CP5) to a less-than-significant level.

12.3.6 Cumulative Effects

Chapter 3, “Considerations for Describing the Affected Environment and Environmental Consequences,” discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, “Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area,” in Chapter 3, lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level.

The action alternatives would not combine with any of the quantitatively assessed projects listed in Table 3-1 to have a cumulatively considerable impact on botanical resources in the primary study area. Impacts on botanical resources in the extended study area from these projects would not combine with the impacts from any of the action alternatives as the geographic scope of the impacts do not overlap.

The following analysis relates to the cumulative impacts of the qualitatively assessed projects listed in Table 3-1 when considered with the impacts of the action alternatives. Projects listed in Table 3-1 that could contribute to a cumulative impact on botanical resources in the primary and extended study area include, but are not limited to, Sacramento River Basin Salmonid Rearing Habitat Improvements, Bay-Delta Conservation Plan, Sacramento River Conservation Area Forum Program, Butte Regional Conservation Plan, Fremont Landing Conservation Bank, Antlers Bridge Replacement, Moody Flats Quarry, and Mountain Gate at Shasta Mixed-Use Plan.

A large number of past actions have occurred in the primary and extended study areas. These past actions have substantially degraded botanical resources and wetlands within the study areas. This degradation is indicated by the number of species that have been listed as threatened or endangered under the CESA and Federal ESA, and by the large portion of all native plant species that are now assigned a CRPR, listed by CDFW and CNPS. Consequently, there is an existing significant cumulative impact on botanical resources.

Past actions have caused these effects by converting habitat to developed or agricultural land uses, altering biotic interactions or physical processes, and damaging or causing mortality from human activities (e.g., vegetation removal during road, levee, or utility maintenance).

Most botanical resources and wetlands in the study areas have been adversely affected by most of the mechanisms described above (i.e., conversion of habitat to developed or agricultural land uses, the spread of invasive species, alteration of physical processes, and human disturbance). Overall, these botanical resources and wetlands have been substantially degraded by past actions, and past actions are continuing to affect them. In particular, the geographic range and abundance (and thus the effects) of many nonnative, invasive plant species that were introduced into the study areas in the past are still rapidly increasing.

The construction of Shasta Dam and the subsequent flooding of the area now known as Shasta Lake affected botanical and wildlife resources endemic to the region. For example, based on existing population locations, Shasta snow-wreath populations may have connected at the confluence of the Pit, Squaw, McCloud, and Sacramento rivers before inundation. The creation of Shasta Lake fragmented the habitat and populations of this species. As a result, these populations are more vulnerable to extirpation.

The effects of climate change on operations at Shasta Lake could potentially affect botanical resources both at the lake and downstream. As described in the Climate Change Modeling Appendix, climate change could result in higher reservoir releases in the future because of an increase in winter and early-spring inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in flooding frequency and acreages and distribution of vegetation.

Shasta Lake and Vicinity

As described in Section 12.3, without mitigation, CP1 through CP5 could cause potentially significant effects on botanical and wetland resources in the primary and extended study areas. These effects could be caused by project construction activities; increased elevations of the water surface of Shasta Lake; and alteration of the flow regime of the Sacramento River and associated geomorphic processes, and thus of riparian vegetation. Although causing similar effects, CP1 through CP5 differ in the magnitude of their effects. At Shasta Lake and its vicinity, these potential adverse effects would be similar for all alternatives, but differ with the height of the dam raise: the effects of CP2 and CP4A would be greater than CP1, but less than CP3 through CP5 (which would be identical). Along the upper Sacramento River and in the extended study area, potential adverse effects would be the result of altered flow regimes and would differ with both the height of the dam raise and operation of the dam: the effects of CP2 and CP4A would be greater than CP1 and CP4 (which would be identical), but less than CP3 and CP5 (which also would have identical effects).

At Shasta Lake and vicinity, CP1 through CP5 would cause the loss of MSCS Covered Species, USFS sensitive, BLM sensitive, or CRPR Species, Jurisdictional Waters, and general habitats, and could cause the spread of noxious and invasive weeds. The mitigation measures described in Section 12.3.6 would reduce impacts on botanical and wetland resources. However, the adverse effects of CP1 through CP5 caused by construction activities and inundation would not be eliminated, with the exception of noxious and invasive weed impacts (Impact Bot-6). Because the overall effect of past actions on botanical resources and wetlands has been cumulatively significant, and the likely additional effects of reasonably foreseeable future actions on these at Shasta Lake and in its vicinity, the adverse effects under CP1 through CP5 (except Impact Bot-6) would potentially be cumulatively considerable and these effects would be potentially cumulatively significant. Because mitigation measures to control the spread of weeds would effectively address the project's impact from that mechanism, however, CP1 through CP5 would not make a cumulatively considerable incremental contribution to an overall significant cumulative impact on plants and wetlands from noxious and invasive weeds.

Upper Sacramento River and Extended Study Area

Along the Sacramento River and other rivers downstream from CVP and SWP reservoirs, substantial past alterations to geomorphic processes, vegetation, and associated habitats have resulted in an overall significant and substantial effect on these resources. For example, as a result of past actions, wetland and riparian vegetation occupies less than 10 percent of its historical extent in the Central Valley (DWR 2012). Therefore, additional adverse effects that are considered to have cumulatively considerable incremental contributions would increase the existing significant cumulative impact. This adverse effect would be the result of the continued consequences of past actions (e.g., construction of Shasta Dam and introduction of nonnative species), and of present and foreseeable water resource and levee actions whose adverse effects may not be fully mitigated.

Most adverse effects that are the continued consequences of past actions have been considered in the development of existing local and regional plans. Consequently, with respect to local and regional plans, an overall significant cumulative effect does not already exist. However, the adverse effects of all present and reasonably foreseeable water resources and levee actions are not likely to be avoided or fully mitigated. The unmitigated impact of these actions could be sufficiently considerable to result in a significant cumulative impact overall.

Habitat loss along the upper Sacramento River and in the extended study area already has resulted in an overall effect on sensitive communities and special-status plants that is significant and substantial. (This is the primary reason that a large number of plant species along the upper Sacramento River and in the extended study area have been listed as threatened or endangered by the State or Federal governments, or have been assigned a CRPR by CDFW and CNPS.)

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability As described in Chapter 2, “Alternatives,” without mitigation, by altering the flow regime and associated geomorphic processes on the Sacramento River, CP1 could affect sensitive plant communities and special-status species (Impact Bot-7 (CP1) and Bot-14 (CP1)) and could potentially affect regional or local plans with objectives of riparian habitat protection or watershed management (Impact Bot-8 (CP1) and Bot-15 (CP1)). These effects could occur on the upper Sacramento River and portions of the lower Sacramento River. Because substantial past alterations to geomorphic processes, vegetation, and associated habitats along the Sacramento River have resulted in an overall significant cumulative effect on these resources, additional incremental adverse effects would likely be cumulatively considerable. However, with the implementation of Mitigation Measure Bot-7 (CP1), adverse effects from CP1 on botanical resources and wetlands along the Sacramento River would be fully mitigated. Thus, CP1 would not result in a cumulatively considerable incremental impact on these resources, and the potential to affect regional or local plans would also be eliminated. Therefore, the impacts of CP1 would not make a cumulatively considerable incremental contribution to a significant cumulative impact.

By altering the flow regimes below CVP and SWP reservoirs in the extended study area, CP1 could possibly cause similar effects on these rivers as along the Sacramento River. (These effects were identified as Impacts Bot-17 (CP1) and Bot-18 (CP1).) However, the alteration of these flow regimes would be less extensive than along the Sacramento River. Even without mitigation, the effects of CP1 on these rivers might not be sufficient to alter the extent or species composition of sensitive communities or to alter the habitats of special-status plant species. In addition, Mitigation Measure Aqua-15 (CP1), “Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements,” would reduce these effects to a level that is unlikely to alter the extent or species composition of sensitive communities or to alter the extent or quality of habitat for special-status plant species. Therefore, the impacts of CP1 would not make a cumulatively considerable incremental contribution to a significant cumulative impact.

By altering flow regimes on the upper Sacramento River, CP1 also could affect designated critical habitat for special-status species of vernal pool habitats (Impact Bot-9 (CP1)). However, vernal pool plant communities and associated special-status species likely would not be affected by any of the alternatives. Therefore, the project would not make a cumulatively considerable incremental contribution to a significant cumulative impact on critical habitat for special-status species of vernal pool habitats.

Along the upper Sacramento River and in the extended study area, CP1 could induce growth that results in the loss of sensitive plant communities and special-status plant species (Impacts Bot-10 (CP1), Bot-16 (CP1), and Bot-19

(CP1)). Habitat loss has resulted in an overall significant cumulative effect on sensitive communities and special-status plants that is substantial. (It is the primary reason that a large number of plant species along the upper Sacramento River and in the extended study area have been listed as threatened or endangered by the State or Federal governments, or have been assigned a CRPR by CDFW and CNPS.) CP1 could induce growth-related effects because it would increase water supplies for deliveries to water districts, and this could reduce a limitation on growth. For example, most CVP water supports agricultural purposes, and agricultural acreages are not expected to increase substantially over time.

However, some increment of the CVP water could be used for municipal and industrial contractors, such as Contra Costa Water District or Santa Clara Valley Water District, as would SWP water. In this case, some growth-related effects could occur from development and have an incremental effect on botanical resources and wetlands. Present and foreseeable future projects are also likely to add to this habitat loss. Although the future effects of any growth-related effects induced by CP1 would be analyzed and mitigated during land use planning and environmental review for site-specific development projects, it is unlikely that all effects would be avoided or fully mitigated. Therefore, CP1 would make a small incremental, but cumulatively considerable, contribution to an existing significant cumulative impact. This would be a cumulatively significant and unavoidable impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP1 could contribute to potentially significant impacts of climate change on habitat acreages and distribution. Although the mitigation measures listed above would be implemented to reduce project-related impacts of CP1, CP1 would still make a cumulatively considerable incremental contribution to a significant cumulative impact on botanical resources and wetlands. This would be a cumulatively significant and unavoidable impact.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability The cumulative effects of CP2 would be similar to those of CP1, but greater in magnitude (because CP2 would entail more substantial alterations of flow regimes). Although greater in magnitude than the effects of CP1, the effects of CP2 on sensitive plant communities and special-status species along the upper Sacramento River and in the extended study area (Impacts Bot-7 (CP2), Bot-14 (CP2), and Bot-17 (CP2)), and potential effects on regional or local plans with objectives of riparian habitat protection or watershed management (Impacts Bot-8 (CP2), Bot-15 (CP2), and Bot-18 (CP2)) would not make a cumulatively considerable incremental contribution to a significant cumulative impact, for the same reasons given for CP1.

Similarly, although greater in magnitude than the effects of CP1, the impact of CP2 on designated critical habitat for special-status species of vernal pool habitats (Impact Bot-9 (CP2)) would not be a cumulatively considerable incremental contribution to a significant cumulative impact for the same reasons given for CP1.

Also similar to CP1, along the upper Sacramento River and in the extended study area, CP2 could cause growth-related effects that result in the loss of sensitive plant communities and special-status plant species (Impacts Bot-10 (CP2), Bot-16 (CP2), and Bot-19 (CP2)). However, the potential for CP2 to cause growth-related effects would be greater than for CP1. For the same reasons given for CP1, CP2 would make a small incremental, but cumulatively considerable, contribution to an existing significant cumulative impact. This would be a cumulatively significant and unavoidable impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP2 could contribute to potentially significant impacts of climate change on habitat acreages and distribution. Although mitigation measures listed above would be implemented to reduce project-related impacts of CP2, CP2 would still make a cumulatively considerable incremental contribution to a significant cumulative impact on botanical resources and wetlands. This would be a cumulatively significant and unavoidable impact.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply
The cumulative effects of CP3 would be similar to those of CP1 and CP2, but greater in magnitude. Although greater in magnitude than the effects of CP1 or CP2 (because CP3 would entail more substantial alterations of flow regimes), the effects of CP3 on sensitive plant communities and special-status species along the upper Sacramento River and in the extended study area (Impacts Bot-7 (CP3), Bot-14 (CP3), and Bot-17 (CP3)), and potential effects on regional or local plans with objectives of riparian habitat protection or watershed management (Impacts Bot-8 (CP3), Bot-15 (CP3), and Bot-18 (CP3)) would not make a cumulatively considerable incremental contribution to a significant cumulative impact, for the same reasons given for CP1.

Similarly, although greater in magnitude than the effects of CP1 or CP2, the effects of CP3 on designated critical habitat for special-status species of vernal pool habitats (Impact Bot-9 (CP3)) would not make a cumulatively considerable incremental contribution to a significant cumulative impact, for the same reasons given for CP1.

Also similar to CP1 and CP2, along the upper Sacramento River and in the extended study area, CP3 could cause growth-related effects that result in the loss of sensitive plant communities and special-status plant species (Impacts

Bot-10 (CP3), Bot-16 (CP3), and Bot-19 (CP3)). However, because CP3 would not reserve any storage capacity to specifically focus on increasing M&I deliveries, the potential for CP3 to cause growth-related effects would be less than for CP1 or CP2. For the same reasons given for CP1, CP3 would make a small incremental, but cumulatively considerable, contribution to an existing significant cumulative impact. This would be a cumulatively significant and unavoidable impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP3 could contribute to potentially significant impacts of climate change on habitat acreages and distribution. Although mitigation measures listed above would be implemented to reduce project-related impacts of CP3, CP3 would still make a cumulatively considerable incremental contribution to a significant cumulative impact on botanical resources and wetlands. This would be a cumulatively significant and unavoidable impact.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability The cumulative effects of CP4 would be the same as CP1, and the effects of CP4A would be the same as CP2, except that CP4 and CP4A would also result in effects from the gravel augmentation program, and riparian, floodplain, and side channel restoration in the primary study area.

However, the gravel augmentation program, and riparian, floodplain, and side channel restoration actions would not make a cumulatively considerable incremental contribution to a significant cumulative impact on botanical resources and wetlands. These additional actions would not cause growth-related effects or effects on vernal pool habitats, but could affect sensitive plant communities, special-status species, and invasive plants. To sensitive communities, the overall, long-term effect of the gravel augmentation program and riparian, floodplain, and side channel restoration actions would be beneficial, and Mitigation Measure Bot-11 (CP4 and CP4A), Revegetate Disturbed Areas; Consult with CDFW, would substantially reduce the effects of any localized, short-term vegetation removal during their implementation. Without additional mitigation, however, these actions could adversely affect special-status species and facilitate the spread of invasive plants. Implementing mitigation measures Bot-12 (CP4 and CP4A), Conduct Preconstruction Surveys for Special-Status Plants and Avoid Special-Status Plant Populations during Construction, and Bot-13 (CP4 and CP4A), Implement Weed Management Measures and Revegetation, would avoid effects on special-status plants and effectively prevent facilitation of the spread of invasive plants.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP4 or CP4A could contribute to potentially significant impacts of climate change on habitat acreages and distribution. However, the gravel augmentation program and the riparian, floodplain, and side channel restoration actions would not make a cumulatively considerable incremental contribution to a significant cumulative impact on botanical resources and wetlands. The overall, long-term effect of the gravel augmentation program and riparian, floodplain, and side channel restoration actions would be beneficial. Further, the mitigation measures described immediately above would be implemented and avoid effects on special-status plants and effectively prevent facilitation of the spread of invasive plants, including during climate change and an expected increase in high-flow events.

Consequently, the gravel augmentation and riparian, floodplain, and side channel restoration actions would not make a cumulatively considerable incremental contribution to a potentially significant cumulative impact on botanical resources and wetlands.

CP5 – 18.5-Foot Dam Raise, Combination Plan The cumulative effects of CP5 would be similar to those of CP1, CP2, CP3, CP4, and CP4A, but greater in magnitude. Although greater in magnitude than the effects of CP1 through CP4 (because CP5 would entail more substantial alterations of flow regimes), the effects of CP5 on sensitive plant communities and special-status species along the upper Sacramento River and in the extended study area (Impacts Bot-7 (CP5), Bot-14 (CP5), and Bot-17 (CP5)), and potential effects on regional or local plans with objectives of riparian habitat protection or watershed management (Impacts Bot-8 (CP5), Bot-15 (CP5), and Bot-18 (CP5)) would not make a cumulatively considerable incremental contribution to a significant cumulative impact, for the same reasons given for CP1.

Similarly, although greater in magnitude than the effects of CP1 through CP4, the effects of CP5 on designated critical habitat for special-status species of vernal pool habitats (Impact Bot-9 (CP5)) would not make a cumulatively considerable incremental contribution to a significant cumulative impact, for the same reasons given for CP1.

CP5 includes the same gravel augmentation program and riparian, floodplain, and side channel restoration actions included in CP4 and CP4A. For the same reasons given for CP4 and CP4A, the effects of the gravel augmentation program and the restoration actions on sensitive communities, special-status species, and spread of invasive plants would not make a cumulatively considerable incremental contribution to a significant cumulative impact.

Similar to CP1 through CP4, along the upper Sacramento River and in the extended study area, CP5 could cause growth-related effects that result in the loss of sensitive plant communities and special-status plant species (Impacts Bot-10 (CP5), Bot-16 (CP5), and Bot-19 (CP5)). However, the potential for

CP5 to cause growth-related effects would be greater than for CP1 through CP4, because it would result in a greater increase in average annual water deliveries. For the same reasons given for CP1, CP5 would make a small incremental, but cumulatively considerable, contribution to an existing significant cumulative impact. This would be a cumulatively significant and unavoidable impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high flow events, potentially resulting in changes to downstream vegetation. Potentially significant effects on vegetation and special-status species that would occur with implementation of CP5 could contribute to potentially significant impacts of climate change on habitat acreages and distribution. Although mitigation measures listed above would be implemented to reduce project-related impacts of CP5, CP5 would still make a cumulatively considerable incremental contribution to a significant cumulative impact on botanical resources and wetlands.

Chapter 13
Wildlife Resources

13.1 Affected Environment

This section describes the affected environment related to wildlife resources, including special-status species, for the dam and reservoir modifications proposed under SLWRI action alternatives. For a more in-depth description, see the *Wildlife Resources Technical Report.*

Shasta Dam and Shasta Lake are located on the upper Sacramento River in Northern California. Shasta Dam is located approximately 9 miles northwest of Redding, and the dam and entire reservoir are located in Shasta County. Elevations in the Shasta Lake vicinity portion of the primary study area range between approximately 1,070 and 1,200 feet, and the terrain is moderate to steep.

The wildlife resources setting for the Shasta Lake and vicinity portion of the primary study area consists of the impoundment area (five arms and the main body of Shasta Lake) and the relocation areas (Figure 13-1). The Shasta Lake and vicinity portion of the primary study area is composed of Shasta Dam and Shasta Lake and the lower reaches of the tributaries draining into Shasta Lake.

Reclamation established project boundaries for focused surveys in the area that would be subject to inundation under various enlargement scenarios. The lower boundary corresponds to the current full-pool elevation defined by Reclamation (1,070-foot mean sea level (msl) contour line). The upper boundary was established using the 1,090-foot msl contour line around the entire lake. This area is hereafter referred to as the “impoundment area” (Figure 13-1).

To examine the physical and biological resources along riverine habitats that would be subject to inundation if Shasta Dam were enlarged, reaches of 11 streams and rivers that are tributary to Shasta Lake were also incorporated into the Shasta Lake and vicinity portion of the primary study area. These streams were selected by Reclamation in conjunction with USFS as an initial sampling of streams representative of riverine and riparian habitats.

Areas subject to physical disturbance as an indirect result of the proposed project (i.e., areas proposed as relocation sites for roadways, bridges, utilities, and campgrounds that would be inundated subsequent to the enlargement of Shasta Dam as well as proposed dike locations) were incorporated into the

Shasta Lake and vicinity portion of the primary study area. These locations are hereafter referred to as “relocation areas” (Figure 13-1).

In addition to the areas subject to inundation and/or relocation, Reclamation has identified six locations considered for river restoration. These six locations are referred to as the potential Sacramento River downstream habitat restoration areas (Figure 13-2).

For the purposes of this investigation, approximate acreages for habitat types are reported by arm of the lake. For a relocation area that falls between two arms, the area is included with the arm that has the most acreage of the vegetation type or water of the United States.

Descriptions of biological resources were derived primarily from the following sources:

- SLWRI Mission Statement Milestone Report (Reclamation 2003)
- SLWRI Initial Alternatives Information Report (Reclamation 2004)
- Chapter 3, “Biological Environment,” in the Draft SLWRI Plan Formulation Report (Reclamation 2007)
- USFWS Endangered Species Lists
- California Natural Diversity Database (CNDDB)
- Numerous technical studies of botanical, wetland, and wildlife resources conducted by Reclamation in the Shasta Lake and vicinity portion of the primary study area since 2002.

Several attachments to the *Wildlife Resources Technical Report* provide detailed lists and descriptions of special-status wildlife species present in the primary and extended study areas:

- Attachment 1, Special-Status Wildlife Species Potentially Occurring in the Shasta Lake and Vicinity Portion of the Primary Study Area
- Attachment 2, Species Accounts for Special-Status Wildlife in the Shasta Lake and Vicinity Portion of the Primary Study Area
- Attachment 3, Breeding Bird Surveys 2007-2013
- Attachment 4, Species Accounts for Special-Status Wildlife in the Primary Study Area Downstream from Shasta Dam
- Attachment 5, Federal Lists of Special-Status Wildlife Species in the Vicinity of the Primary Study Area

- Attachment 6, Special-Status Wildlife Species with Potential to Occur in the Primary and Extended Study Areas by Area
- Attachment 7, List of All Sensitive Wildlife Species in the Extended Study Area Reported to the CNDDB
- Attachment 8, Forest Carnivore Survey Report
- Attachment 9, Shasta Salamander Survey Report
- Attachment 10, Terrestrial Mollusk Survey Report

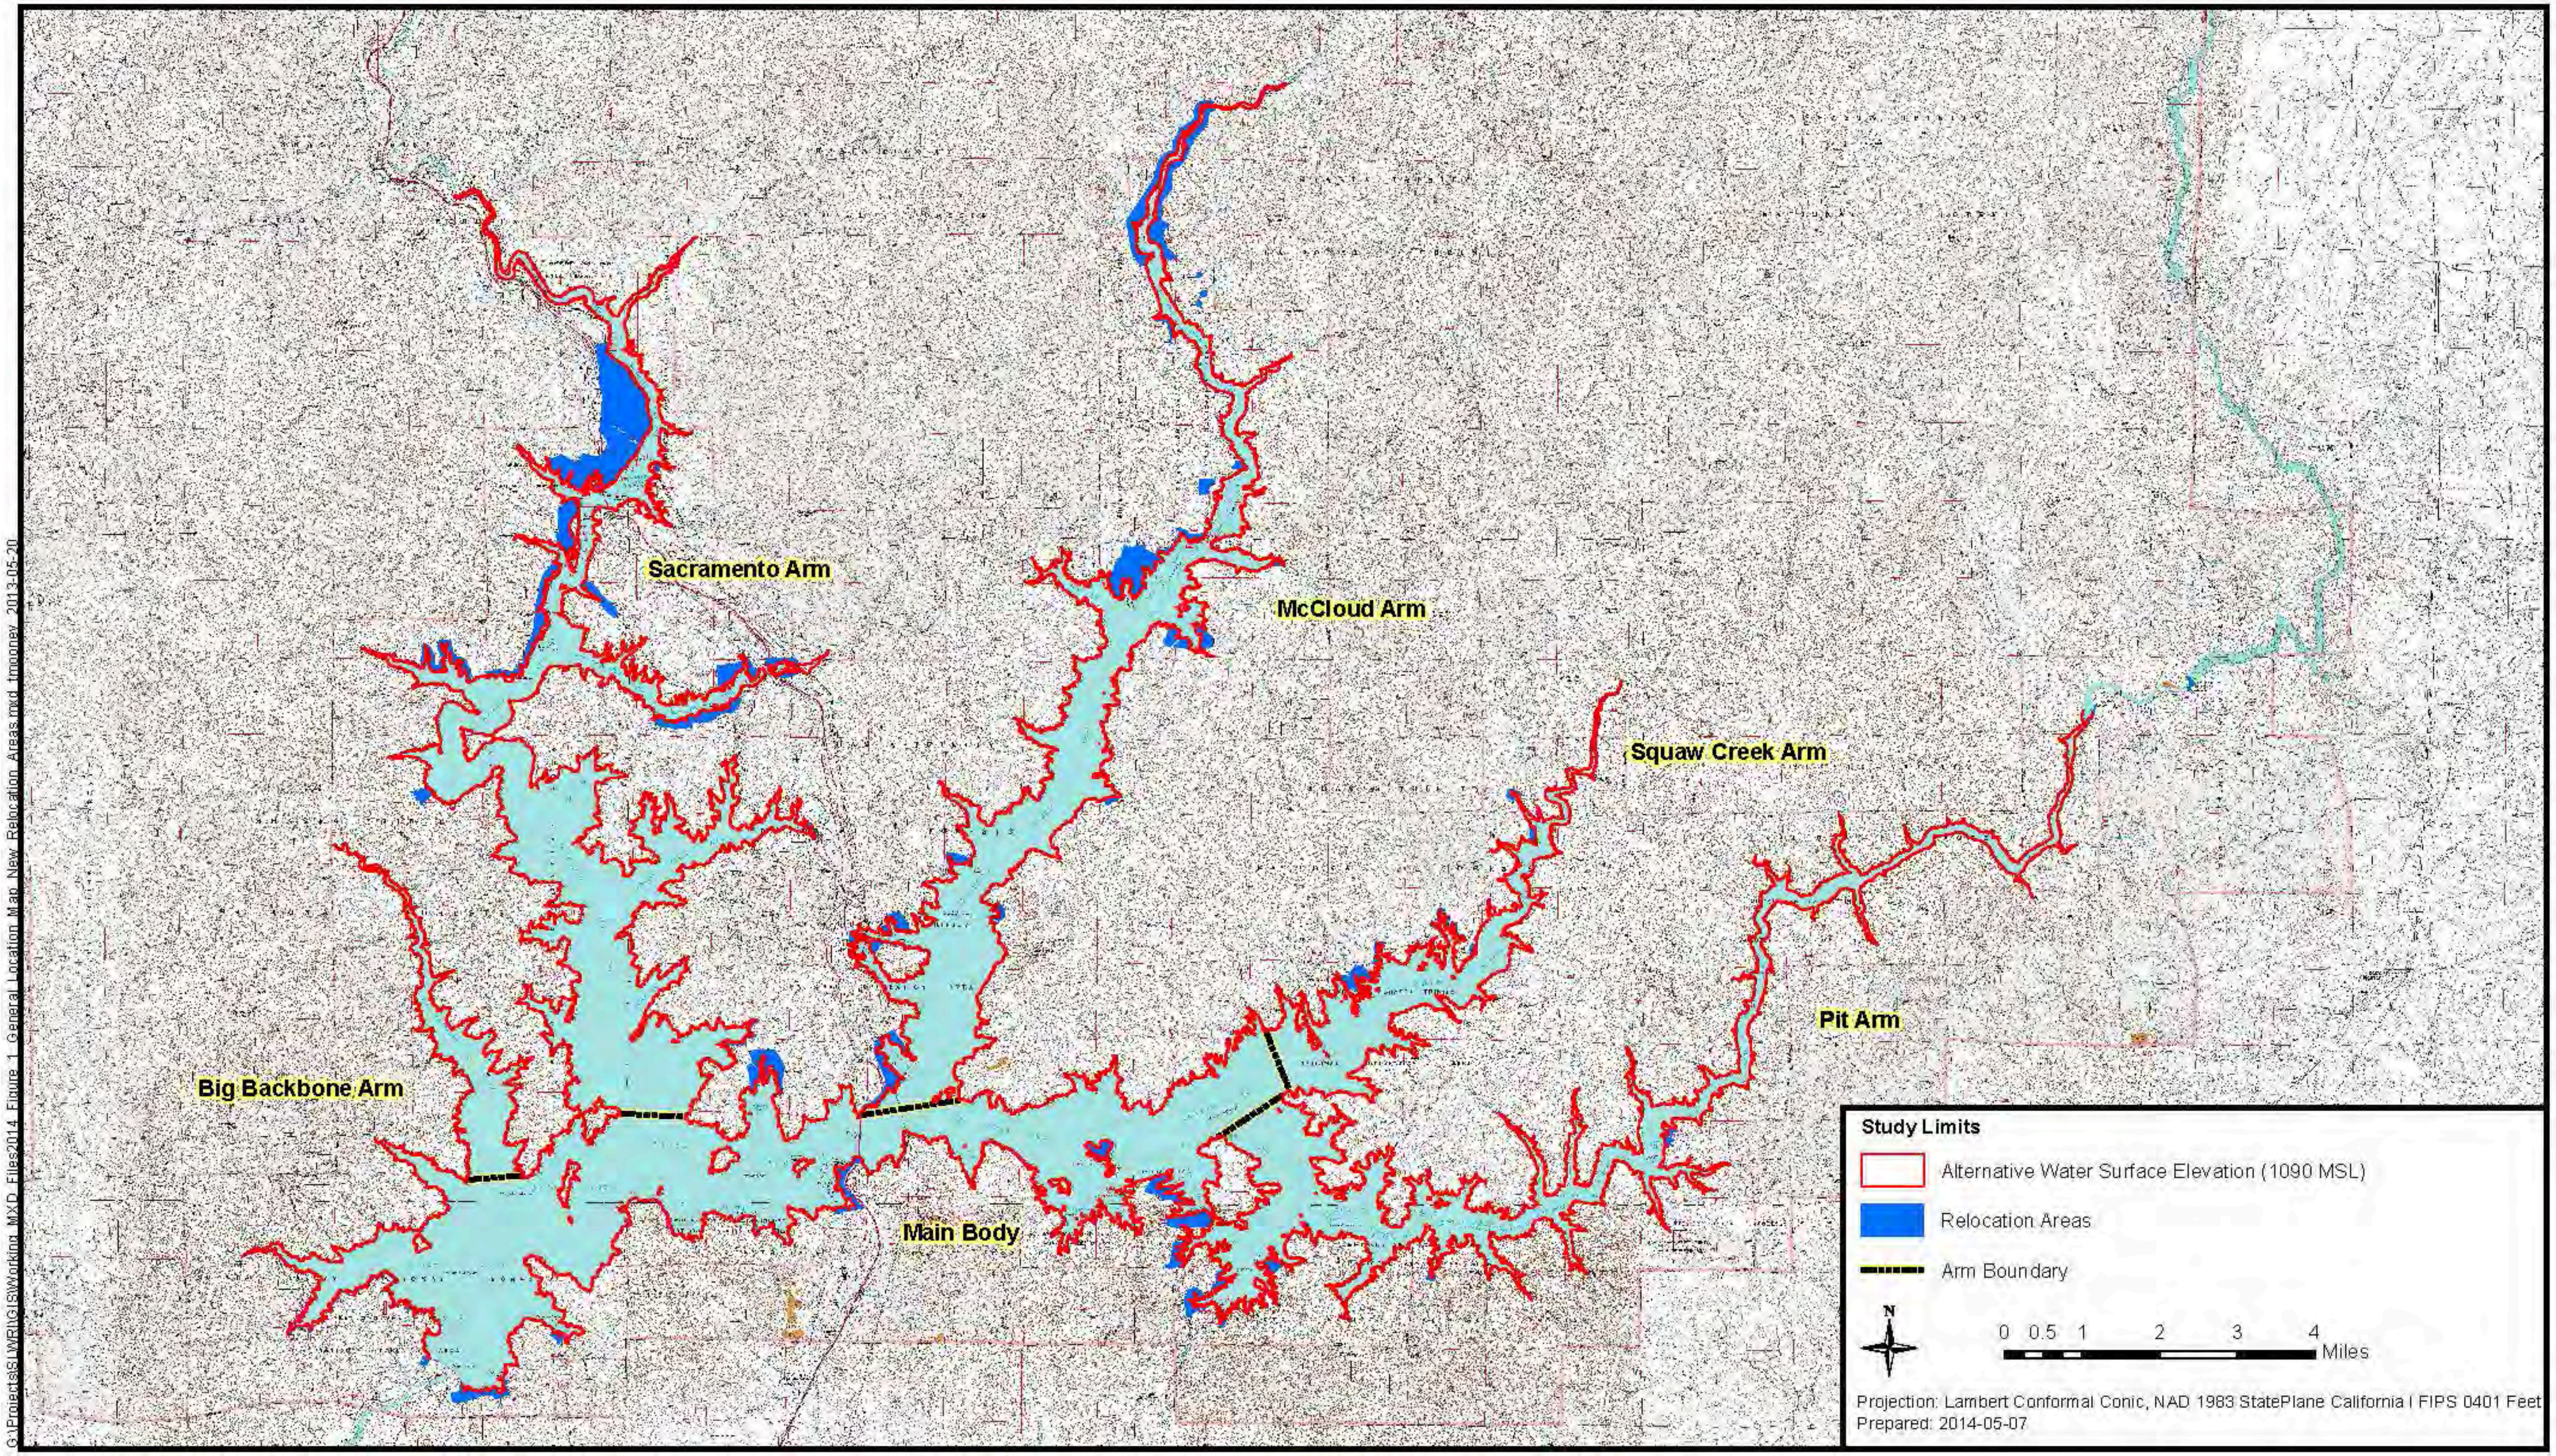
13.1.1 Wildlife

Shasta Lake and Vicinity

Wildlife resources described in this chapter result from the wealth and diversity of climatic and vegetative associations in and adjacent to the Shasta Lake and vicinity portion of the primary study area. Influences from the southeastern Klamath Mountains, Coast Ranges, the southern Cascade Range, the northern Sierra Nevada, the Great Basin, and the Central Valley provide for a unique mix of biota. Much of this region, especially in the Central Valley, has been modified by past and present land uses.

Wildlife Habitats The Shasta Lake and vicinity portion of the primary study area is characterized by a variety of habitats typical of mixed woodlands and low-elevation forests found in the southeastern Klamath Mountains. These habitats were mapped and classified using the *Guide to Wildlife Habitats of California* (Mayer and Laudenslayer 1988). Habitats present in the Shasta Lake and vicinity portion of the primary study area are summarized in Tables 13-1 and 13-2, and depicted in Figures 13-3a through 13-3f. General habitat descriptions, including typically occurring wildlife species, are described below. Plant taxonomy follows Baldwin et al. (2012).



Key: MSL = feet above mean sea level

Annual Grassland Annual grassland is uncommon in the Shasta Lake and vicinity portion of the primary study area and occurs as small inclusions in other more prevalent plant series types or in areas subjected to previous disturbance. Dominant species include wild oat (*Avena fatua*), cheatgrass (*Bromus tectorum*), ripgut (*B. diandrus*), yellow star-thistle (*Centaurea solstitialis*), squirreltail (*Elymus elymoides*), and European hairgrass (*Aira caryophyllea*). Grassland bird species, such as the mourning dove (*Zenaida macroura*), savannah sparrow (*Passerculus sandwichensis*), and white-crowned sparrow (*Zonotrichia leucophrys*), as well as rodents, such as the California ground squirrel (*Spermophilus beecheyi*), Botta's pocket gopher (*Thomomys bottae*), and deer mouse (*Peromyscus maniculatus*), may forage on the seed crop this community provides. These species, in turn, attract predators, such as the gopher snake (*Pituophis melanoleucus*), American kestrel (*Falco sparverius*), red-tailed hawk (*Buteo jamaicensis*), and coyote. Reptile species expected to inhabit this area include the western fence lizard (*Sceloporus occidentalis*), western skink (*Eumeces skiltonianus*), western rattlesnake (*Crotalus viridis*), and yellow-bellied racer (*Coluber constrictor*).

Barren Barren habitat consists mainly of human-made features without vegetation scattered throughout the Shasta Lake and vicinity portion of the primary study area, including boat ramps, parking lots, and roads. Other barren habitats include a large gravel plain feature at the confluence of Butcher Creek and Shasta Lake (Main Body) and a sealed riprap feature adjacent to Interstate 5 near the upper Sacramento Arm and Shasta Lake confluence. Vegetation is usually not present, although a sparse cover of grasses/forbs or weedy species may be present. Barren habitat has limited value for wildlife; however, many species in adjacent habitats may use these areas occasionally as opportunities arise, such as for feeding. Also, open nesting species, such as killdeer (*Charadrius vociferus*), may use some barren surfaces for nesting.

Blue Oak Woodland Blue oak woodland occurs mainly as small inclusions within other more prevalent habitats; however, moderate-sized stands also occur. This habitat occurs at scattered locations along the Main Body, McCloud Arm, and Pit Arm. Blue oak woodland is characterized by a moderate overstory of blue oak *(Quercus douglasii)* with a dense herbaceous understory. Oak woodlands produce acorns used as forage by a variety of species, including acorn woodpeckers (*Melanerpes formicivorus*), western scrub-jays (*Aphelocoma californica*), turkey (*Meleagris gallopavo*), western gray squirrels (*Sciurus griseus*), and black-tailed deer (*Odocoileus hemionus columbianus*). Snags and live trees containing cavities provide nesting habitat for species such as the western bluebird (*Sialia mexicana*), tree swallow (*Tachycineta bicolor*), American kestrel, and northern flicker (*Colaptes auratus*), as well as roost sites for bats and denning sites for mammals, such as the raccoon, Virginia opossum (*Didelphis virginiana*), and gray fox (*Urocyon cinereoargenteus*). Raptors, including the red-tailed hawk and great horned owl, also nest in these woodlands. Amphibian and reptile species found here include the Pacific chorus frog (*Pseudacris regilla*), bullfrog (*Rana catesbeiana*), western fence lizard, southern alligator lizard (*Elgaria multicarinata*), western terrestrial garter snake (*Thamnophis elegans*), common garter snake (*Thamnophis sirtalis*), and western rattlesnake.

Blue Oak–Foothill Pine Blue oak–foothill pine habitat also occurs mainly as small inclusions within other more prevalent habitats in the Shasta Lake and vicinity portion of the primary study area; however, moderate-sized stands also occur. This habitat is found in the Main Body, Squaw Creek Arm, and Pit Arm. Species composition is similar to the blue oak woodland habitat; however, gray pine and a shrub component are more common. Dominant overstory species include blue oak, California black oak *(Quercus kelloggii),* valley oak *(Quercus lobata),* interior live oak *(Quercus wislizenii),* and gray pine *(Pinus sabiniana).* Common shrubs observed in this habitat include white leaf manzanita *(Arctostaphylos viscida),* buck brush *(Ceanothus cuneatus),* poison oak *(Toxicodendron diversilobum),* coffee berry *(Frangula californica),* snowdrop bush *(Styrax officinalis),* wild mock orange *(Philadelphus lewisii),* deer brush *(Ceanothus integerrimus),* and California buckeye *(Aesculus californica).* Common grasses and forbs observed in this vegetation habitat include pussy ears *(Calochortus tolmiei),* Pacific hounds tongue *(Cynoglossum grande),* slender wild oat, and soaproot *(Chlorogalum pomeridianum).* Lianas of Dutchman's pipe *(Aristolochia californica)* and chaparral clematis *(Clematis lasiantha)* shroud shrubs and often grow into the tree canopy.

The blue oak–foothill pine community provides breeding habitat for a large variety of wildlife species, although no species is completely dependent on it for breeding, feeding, or cover. Many of the species found in blue oak habitat are also found here. Acorns and gray pine seeds are an important resource for many of the species using this habitat, such as the acorn woodpecker, western scrub-jay, and western gray squirrel. The newly emerged leaves of oaks in the spring support an abundance of insects that attract migrating and nesting warblers, vireos, flycatchers, and other insectivorous birds. In addition, the shrubs provide habitat for birds, such as the spotted towhee (*Pipilo maculatus*), California towhee (*Pipilo crissalis*), wrentit (*Chamaea fasciata*), and blue-gray gnatcatcher (*Polioptila caerulea*). Characteristic reptiles and amphibians include western toads (*Bufo boreas*), a wide variety of snakes (common garter snakes, California whipsnakes (*Masticophis lateralis*), gopher snakes, and western rattlesnakes), western skinks, southern alligator lizards, and western fence lizards.

Closed-Cone Pine–Cypress Closed-cone pine–cypress consists of open to dense knobcone pine (*Pinus contorta*) stands. This habitat is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area and often occurs in disturbed areas, including areas subject to wildfires and historic mining activities. Dominant species include knobcone pine, with occasional canyon live oak (*Quercus chrysolepis*), California black oak, ponderosa pine, and gray pine. The shrub layer is moderate to dense and is dominated by white leaf manzanita and poison oak. The ground cover varies and is dominated by various grasses and forbs. Numerous game and nongame species make use of this habitat for feeding and cover. Steller's jays (*Cyanocitta stelleri*) and western scrub-jays, downy woodpeckers (*Picoides pubescens*), and western gray squirrels extract seeds from partially opened cones. The great horned owl and red-tailed hawk are among the few species known to use this habitat for breeding.

Douglas-Fir As a habitat type, Douglas-fir is uncommon in the Shasta Lake and vicinity portion of the primary study area. This habitat type occurs in the upper portion of the McCloud Arm. Douglas-fir is characterized by moderate to dense conifer stands dominated by Douglas-fir (*Pseudotsuga menziesii*), with occasional ponderosa pine (*Pinus ponderosa*), sugar pine (*Pinus lambertiana*), incense cedar (*Calocedrus decurrens*), canyon live oak, and California black oak. Associated understory species vary and include Pacific dogwood (*Cornus nuttallii*), mock orange (*Philadelphus lewisii*), poison oak, snowdrop bush, and white leaf manzanita. The ground layer ranges from open to moderate and is dominated by various grasses and forbs. The multilayered vegetation in the Douglas-fir community supports a variety of wildlife species. A significant feature of the community is the presence of cavity-bearing trees. Mature, fire-damaged, and wind-damaged forests typically contain snags (dead trees that are still standing), which are a valuable resource for birds and mammals that prefer nest and den sites in cavities, such as the flammulated owl (*Otus flammeolus*) and northern pygmy owl (*Glaucidium gnoma*). Snags also support wood-boring insects that provide food for bark-gleaning insectivorous birds, such as the brown creeper (*Certhia americana*). Other birds foraging and/or breeding in this habitat include the sharp-shinned hawk (*Accipiter striatus*), American peregrine falcon, mountain quail, western wood-pewee (*Contopus sordidulus*), and western tanager (*Piranga ludoviciana*). Mammals found in this habitat include the long-eared myotis (*Myotis evotis*), western red bat (*Lasiurus blossevillii*), northern flying squirrel (*Glaucomys sabrinus*), and bobcat (*Lynx rufus*).

Klamath Mixed Conifer Klamath mixed conifer is an uncommon habitat type in the Shasta Lake and vicinity portion of the primary study area. This habitat type occurs in the upper portion of the Pit Arm, and in scattered locations in the watershed above the Shasta Lake and vicinity portion of the primary study area. Klamath mixed conifer is characterized by conifer stands dominated by Douglas-fir, ponderosa pine, sugar pine, with occasional incense cedar. Dominant hardwoods include canyon live oak, California black oak, and Pacific madrone (*Arbutus menziesii*). Associated understory species vary and include Pacific dogwood, mock orange, poison oak, and snowberry (*Symphoricarpos* sp.). The ground layer ranges from open to moderate and is dominated by various grasses and forbs. These forest stands are generally complex structurally, tend to grow on cooler northerly aspect slopes, and support similar wildlife species as the Douglas-fir habitat.

Lacustrine Lacustrine habitat consists of the area regularly inundated by Shasta Lake (i.e., areas up to and below the 1,070-foot elevation). Most of this area is barren of vegetation and is characterized as exposed soil and/or rock. Portions of the lacustrine habitat do support vegetation during draw-down periods, including woody riparian species, such as black willow, button willow, Fremont cottonwood, and various grasses and forbs.

Mixed Chaparral Mixed chaparral is a common habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. This habitat often occurs on exposed slopes and/or in disturbed areas, including areas subject to wildfires and historic mining activities. Mixed chaparral is typically characterized by dense shrub stands dominated by white leaf manzanita, buck brush, toyon *(Heteromeles arbutifolia),* California buckeye, Brewer's oak *(Quercus garryana* var. *breweri),* California bay *(Umbellularia californica),* interior live oak, Lemmon's ceanothus *(Ceanothus lemmonii),* birch-leaf mountain mahogany *(Cercocarpus betuloides),* holly-leaf redberry *(Rhamnus ilicifolia),* yerba santa *(Eriodictyon californicum),* and poison oak. Few herbaceous plants occur in this habitat. Mixed chaparral provides habitat for a wide variety of wildlife species. It provides seeds, fruit, and protection from predators and harsh weather. In addition, it provides singing, roosting, and nesting sites for many species of birds, including the California quail (*Callipepla californica*), wrentit, and Bewick's wren (*Thryomanes bewickii*). Mammals common in this habitat include the black-tailed hare (*Lepus californicus*), gray fox, coyote, and deer mouse. Reptiles that make use of this habitat include the western fence lizard and southern alligator lizard.

Montane Hardwood Montane hardwood is a common tree habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. The montane hardwood stands are typically characterized by moderate to dense stands of California black oak, canyon live oak, and occasional interior live oak. The understory is variable, although often sparse in the evergreen (live oak) stands because of a typically dense overstory canopy. Mast crops provided by montane hardwood forests are an important food resource for many species, including the acorn woodpecker, Steller's jay, mountain quail (*Oreortyx pictus*), western gray squirrel, and black-tailed deer. In addition, cavities in mature trees provide nesting and denning habitat for species such as the northern flicker, western screech owl (*Otus kennicottii*), American kestrel, and Virginia opossum. In moist areas, many amphibians and reptiles are found in the duff layer, including ensatina (salamander) (*Ensatina eschscholtzii*) and western skink.

Montane Hardwood–Conifer Montane hardwood–conifer is a common tree habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. Montane hardwood–conifer is a complex forest type generally characterized by a complex of hardwood and conifer tree species. Stand composition varies, depending on numerous physical and geographic factors, and can include California black oak, canyon live oak, interior live oak, Oregon white oak (*Quercus garryana*), gray pine, ponderosa pine, Douglas-fir, sugar pine, and knobcone pine. Understory species are generally moderate to dense and include white leaf manzanita, buck brush, California buckeye, western redbud *(Cercis occidentalis)*, California bay, poison oak, birch-leaf mountain mahogany, Brewer's oak, and snowdrop bush. The ground layer varies and is dominated by various grasses and forbs, including pussy ears, soaproot, Pacific hound's tongue, and slender wild oat.

The variability of the canopy cover and understory vegetation makes montane hardwood–conifer habitat suitable for numerous species of wildlife. Hollow trees and logs provide denning sites for mammals, such as the coyote and gray fox, and cavities in mature trees are used by cavity-dwelling species, such as the acorn woodpecker, violet-green swallow (*Tachycineta thalassina*), northern flicker, great horned owl, raccoon, and California myotis (*Myotis californicus*). In addition, raptors, such as the red-tailed hawk, construct nests in the upper canopy of mature trees. Moreover, mast crops and conifer seeds are an important food source for many birds and mammals, including the Steller's jay, acorn woodpecker, California quail, black-tailed deer, and western gray squirrel. In moist areas, many amphibians and reptiles, including ensatina and western fence lizards, inhabit the duff layer. Snakes, including the western rattlesnake and sharp-tailed snake (*Contia tenuis*), also are found in this habitat.

Montane Riparian Montane riparian is the dominant riparian habitat type and is scattered throughout all portions of the Shasta Lake and vicinity portion of the primary study area. Montane riparian habitat occurs as thin stringers and large patches along most stream corridors and is characterized as a sparse overstory of white alder (*Alnus rhombifolia*), Fremont cottonwood (*Populus fremontii*), or big leaf maple (*Acer macrophyllum*), along with a fairly dense mid-story and herbaceous layer. The mid-story is dominated by red osier dogwood (*Cornus sericea*), arroyo willow (*Salix lasiolepis*), narrow-leafed willow (*S. exigua*), red willow *(S. laevigata*), spicebush (*Calycanthus occidentalis*), mock orange, button willow (*Cephalanthus occidentalis*), American dogwood (*Cornus cericea*), California ash (*Fraxinus dipetala*), and mugwort (*Artemesia douglasiana*). Brambles of Himalayan blackberry (*Rubus armeniacus*) and California blackberry (*R. ursinus*) often engulf broader, low-gradient riparian areas. Lianas, including California grape and greenbriar (*Smilax californica*), grow into the canopy.

Riparian habitats are among the most important wildlife habitats because of their high floristic and structural diversity, high biomass (and therefore high food abundance), and high water availability. In addition to providing breeding, foraging, and roosting habitat for a diverse array of animals, riparian habitats also provide movement corridors for some species, connecting a variety of habitats throughout the region.

The leaf litter, fallen tree branches, and logs associated with the riparian community in the study area provide cover for the western toad and Pacific chorus frog. The western fence lizard, western skink, and southern alligator lizard are also expected to occur here. Common species nesting and foraging primarily in the riparian tree canopy include the bushtit (*Psaltriparus minimus*), white-breasted nuthatch (*Sitta carolinensis*), and Nuttall's woodpecker (*Picoides nuttallii*). Other resident species, such as the spotted towhee and song sparrow (*Melospiza melodia*), nest and forage on or very close to the ground, usually in dense vegetation. A variety of mammals also inhabit riparian communities, including the deer mouse, raccoon, Virginia opossum, and several bat species.

Ponderosa Pine Ponderosa pine is the most common conifer habitat type in the Shasta Lake and vicinity portion of the primary study area and is scattered throughout all portions of the area. This habitat is characterized by open to dense conifer stands dominated by ponderosa pine. Associated species include occasional Douglas-fir, sugar pine, incense cedar, canyon live oak, and California black oak. Associated understory species vary and include redbud, buck brush, mock orange, poison oak, snowdrop bush, and white leaf manzanita. The ground layer ranges from open to moderate and is dominated by various grasses and forbs.

Ponderosa pine needles, cones, buds, pollen, twigs, seeds, and associated fungi and insects provide food for many species of birds and mammals, including the mountain quail, western gray squirrel, black-tailed deer, Allen's chipmunk (*Tamias senex*), and black bear (*Ursus americanus*). Mature trees provide nesting habitat for raptors, such as the bald eagle (*Haliaeetus leucocephalus*), osprey (*Pandion haliaetus*), sharp-shinned hawk, and red-tailed hawk, and snags and hollow logs provide shelter for species such as the Virginia opossum, western spotted skunk (*Spilogale gracilis*), and several bat species.

Riverine Riverine habitat includes the free-flowing portions of the rivers and larger streams tributary to Shasta Lake. The riverine habitat is highly variable and ranges from moderately to well-confined stream reaches with low to steep gradient. Most riverine habitat is dominated by run-and-riffle habitats, with bedrock, boulder, cobble, gravel, and sand substrates. The vegetation in the active stream channel is sparse, with occasional clumps of torrent sedge (*Carex nudata*) and Indian rhubarb (*Darmera peltata*).

Riverine areas provide habitat for numerous fish, including rainbow trout (*Oncorhynchus mykiss*), brown trout (*Salmo trutta*), smallmouth bass (*Micropterus dolomieu*), and riffle sculpin (*Cottus gulosus*). Aquatic wildlife species include the foothill yellow-legged frog (*Rana boylii*), aquatic garter snake (*Thamnophis atratus*), and the aquatic phase of the rough-skinned newt (*Taricha granulosa granulosa*). Birds present include the American dipper (*Cinclus mexicanus*), common merganser (*Mergus merganser*), and belted kingfisher (*Ceryle alcyon*). Many mammals in the surrounding upland habitats use the riverine areas, including raccoon, gray fox, black-tailed deer, and many bat species.

Urban Urban habitat consists of various human-made features scattered throughout the Shasta Lake and vicinity portion of the primary study area, including resorts and a portion of the visitor center complex at Shasta Dam. These features are typically a combination of buildings, pavement areas with manicured landscaping, and lawns. The wildlife species most often associated with urban areas are those that are most tolerant of periodic human disturbances, including several introduced species, such as European starling (*Sturnus vulgaris*), rock dove (*Columba livia*), and house mouse (*Mus musculus*). Native species that are able to use these habitats include the western fence lizard, American robin (*Turdus migratorius*), Brewer's blackbird (*Euphagus cyanocephalus*), northern mockingbird (*Mimus polyglottos*), mourning dove, house finch (*Carpodacus mexicanus*), California ground squirrel, black-tailed hare, and striped skunk (*Mephitis mephitis*). In addition, bats that forage in nearby habitats may make use of small cavities around the eaves of structures.

Upper Sacramento River (Shasta Dam to Red Bluff)

The following section provides a description of the wildlife habitats that exist along the Sacramento River throughout the primary study area, and a detailed discussion of potential Sacramento River downstream habitat restorations areas.

Important wildlife habitat is found throughout the upper Sacramento River portion of the primary study area, and large contiguous blocks that contain multiple habitat types have the potential to support the highest wildlife diversity and abundance. Overall, the quantity and variety of wildlife species now inhabiting the area have been reduced since agricultural and residential development permanently removed much of the native and natural habitat. Most affected have been wildlife species associated with riparian habitats, which have declined substantially and been highly altered by land use, water resources development, and land management practices. Wildlife species associated with grassland and oak woodland habitats have also been affected by habitat loss resulting from habitat conversions to residential, commercial, and agricultural uses; cattle grazing; and other compounding factors, such as lack of oak regeneration, spread of Sudden Oak Death Syndrome, and competition from invasive species. The region also supports a variety of nonnative plant and animal species, some of which are detrimental to survival of native species.

Habitats present in this portion of the primary study area are riparian woodland, riparian scrub, oak woodland, chaparral, annual grassland, agriculture, and urban. (See the *Wildlife Resources Technical Report* for a description of the plant and wildlife species typical of these habitats.) Riparian habitat has been designated by the CDFW as a sensitive habitat in California because of its limited abundance and high value to wildlife.

Potential Sacramento River Downstream Habitat Restoration Areas As a component of the SLWRI, Reclamation proposes to restore and/or enhance riparian and riverine habitats at six locations along the lower Sacramento River below Shasta Dam. These six locations occur generally between the city of Redding and Reading Island, Shasta County, California. The purpose of the restoration effort is to improve spawning and rearing habitat for anadromous fish occurring in the Sacramento River. These six locations are referred to as the potential Sacramento River downstream habitat restoration areas (Figure 13-2).

The potential Sacramento River downstream habitat restoration areas are characterized by habitats typical of riparian and riverine areas along the Sacramento River below Shasta Dam. These habitats were also mapped and classified using the Guide to Wildlife Habitats of California (Mayer and Laudenslayer 1988). Habitats present in the potential Sacramento River downstream habitat restoration areas are summarized in Table 13-3, and shown in Figures 13-4a through 13-4f. General habitat descriptions for these locations are also described below.

Table 13-3. Summary of Wildlife Habitats in the Potential Sacramento River Downstream Habitat Restoration Areas

Habitat	Area (Acres[1])						
	Henderson	Tobiasson Island	Shea Island Complex	Kapusta Island	Anderson River Park	Reading Island	Total
Annual grassland	2.50	13.73	2.61	18.15	7.83	0.00	44.82
Barren	0.31	1.10	0.00	0.00	0.55	0.00	1.96

Many of the same wildlife habitats found in the Shasta Lake and vicinity portion of the primary study area also occur in the potential Sacramento River habitat restoration areas. However, the species composition, structure, and overall function of these areas are significantly different, as these areas are situated in a separate geographic setting and region. Habitats occurring in the potential Sacramento River habitat restoration areas include annual grassland, barren, freshwater emergent wetland, mixed chaparral, orchard, riverine, valley-foothill riparian, and valley oak woodland.

Annual Grassland Annual grasslands are uncommon in the potential Sacramento River habitat restoration areas and occur as open ruderal areas and vegetated gravel bars. This plant community is characterized by moderate to dense cover of annual grasses and forbs including black mustard (*Brassica nigra*), California poppy (*Eschscholzia californica*), ripgut grass (*Bromus diandrus*), soft chess (*Bromus hordeaceus*), wild oat (*Avena barbata*), rose clover (*Trifolium hirtum*), long beaked storks bill (*Erodium botrys*), turkey mullein (*Croton setigeris*), Oregon golden aster (*Heterotheca oregona*), and tall sock-destroyer (*Torilis arvensis*).

Barren Barren habitat occurs on gravel bars and is characterized by open areas of gravel and cobble substrates. Vegetation is typically absent, although in some barren areas sparse opportunistic grasses/forbs or weedy species may occur.

Freshwater Emergent Wetland Freshwater emergent wetlands occur along the margins of backwater sloughs and other wetland features, and as small inclusions in valley-foothill riparian habitats. These wetlands are characterized by dense stands of broadleaf cattail (*Typha latifolia*), with reed canarygrass (*Phalaris arundinacea*), horsetail (*Equisetum* sp.), smartweed (*Persicaria* sp.), sedges (*Carex* spp.), rushes (*Juncus* spp.), and dallisgrass (*Paspalum dilatatum*). Submergent vegetation dominated by parrot's feather (*Myriophyllum aquaticum*) and water primrose (*Ludwigia peploides*) grow in the deep water portions of the wetlands.

Mixed Chaparral Mixed chaparral is uncommon in the potential Sacramento River habitat restoration areas and only occurs at the Anderson River Park site. This habitat consists of shrub patches in open rocky areas in the central portion of the study area dominated by California yerba santa (*Eriodictyon californicum*) and wright's buckwheat (*Eriogonum wrightii*). Other associated species include Oregon golden aster, naked buckwheat (*Eriogonum nudum*), slender wild oat, mousetail, ripgut grass, soft chess, and red brome (*Bromus madritensis* ssp. *rubens*).

Orchard Orchard habitat is uncommon in the potential Sacramento River habitat restoration areas and only occurs at the Reading Island site. This habitat consists of a small portion of a walnut orchard extending into a portion of the northern site boundary. The walnut orchard is mature and well maintained.

Vegetation includes an overstory of walnut trees and ground cover of various grasses and forbs.

Riverine Riverine habitat occurs at each potential Sacramento River habitat restoration area and consists of portions of active Sacramento River channel within and/or around each site. The riverbed is dominated by primarily gravel, cobble, and boulder substrates.

Valley-foothill Riparian Valley-foothill riparian is the dominant habitat in the potential Sacramento River habitat restoration areas and occurs as moderate to dense stands of mainly riparian trees and shrubs. Many tree and shrub species occur including Fremont cottonwood (*Populus fremontii*), valley oak (*Quercus lobata*), Oregon ash (*Fraxinus latifolia*), white alder (*Alnus rhombifolia*), narrowleaf willow (*Salix exigua*), shining willow (*Salix lasiandra*), Goodding's black willow (*Salix gooddingii*), black locust (*Robinia pseudoacacia*), and silver wattle (*Acacia dealbata*). Understory vegetation is moderate to dense and includes Himalayan blackberry (*Rubus armeniacus*), California grape (*Vitis californica*), Santa Barbara sedge (*Carex barbarae*), giant reed (*Arundo donax*), mugwort (*Artemisia douglasii*), horsetail, and Johnson grass (*Sorghum halepense*).

Valley Oak Woodland Valley oak woodland is uncommon in the potential Sacramento River habitat restoration areas and only occurs at the Anderson River Park site and a small portion of the Tobiasson Island site. This habitat occurs above the active floodplain of the Sacramento River and is characterized by a moderate overstory of valley oak (*Quercus lobata*) with occasional interior live oak (*Quercus wislizenii*), foothill pine (*Pinus sabiniana*), narrowleaf willow, shining willow, Fremont cottonwood, Oregon ash, and tree of heaven (*Ailanthus altissima*). Dominant understory vegetation includes western redbud (*Cercis occidentalis*), California coffee berry (*Frangula californica*), mugwort, winter vetch (*Vicia villosa*), Santa Barbara sedge, ripgut grass, common ragweed (*Ambrosia artemisiifolia*), and Bermuda grass (*Cynodon dactylon*).

Lower Sacramento River and Delta

The roughly 300 miles of the Sacramento River can be subdivided into distinct reaches. The reaches in the lower Sacramento River and Delta portion of the extended study area are discussed separately below because of differences in morphology, riparian vegetation, and habitat functions.

Sacramento River from Red Bluff Pumping Plant to the Delta Most habitat types and many of the wildlife species found in the upper Sacramento River portion of the primary study area have the potential to occur in the Central Valley portion of the extended study area, with additional species occurring in upland and foothill areas. The segment of the extended study area between Red Bluff Pumping Plant and the Delta includes a diverse array of wildlife habitats – floodplains, basins, terraces, active and remnant channels, and oxbow sloughs. The variety and availability of habitats along the middle Sacramento River support a wide range of wildlife species: a variety of resident and migratory waterfowl, raptors, and songbirds, plus a variety of mammals, amphibians, and reptiles that inhabit both aquatic and upland habitats.

Sacramento–San Joaquin River Delta Delta wetlands are considered to be among the most productive wildlife habitats in California. These wetlands consist of permanent saline, brackish, and freshwater marshes; seasonal freshwater wetlands; open water; tidal and nontidal marshes, and emergent wetlands; and seasonally flooded agricultural cropland, such as rice fields (CALFED 2000a). (See the *Wildlife Resources Technical Report* for a discussion of the plant and wildlife species typical of Delta wetlands.)

San Joaquin River Basin to the Delta Most habitat types and many of the wildlife species described above for the Sacramento River corridor have the potential to occur in the Central Valley portion of the extended study area, with additional species occurring in upland and foothill areas. The current wildlife habitat value of this area is somewhat limited by the predominance of agricultural lands, which support a relatively low diversity of wildlife species. However, the orchards, row and field crops, and fallow fields can be used by a number of common species, and fallow fields and some crops (e.g., wheat and barley) can support a variety of small mammals and provide high-quality foraging habitat for many species of raptors. More importantly, remnant native vegetation patches are likely to support a high diversity of wildlife species.

CVP/SWP Service Areas

The CVP and SWP service areas contain a large diversity of both lowland and upland habitats and species, although agricultural and urban growth has reduced the area and connectivity of important habitats that are critical to sustaining a wide variety of unique plants and animals (CALFED 2000a). The agricultural land and urban development that dominate the CVP and SWP service areas, respectively, can support many wildlife species, most of which are highly adapted to these disturbed environments.

13.1.2 Special-Status Species

Special-status species addressed in this section include animals that are legally protected or are otherwise considered sensitive by Federal, State, or local resource conservation agencies and organizations. Specifically, these include species that are Federally listed and/or State-listed as rare, threatened, or endangered; those considered as candidates or proposed for listing as threatened or endangered; species identified by CDFW as fully protected or species of special concern; species identified by USFS as sensitive, or endemic; species identified by the U.S. Department of the Interior, Bureau of Land Management (BLM) as sensitive; species designated by the *Northwest Forest Plan* (NWFP) as survey and manage (S&M); other animals protected by the California Fish and Game Code; and those designated as Multi-Species Conservation Strategy (MSCS) covered species by the CALFED Bay-Delta Program (CALFED).

Shasta Lake and Vicinity

For the purposes of this evaluation, wildlife species of concern include species that are any of the following:

- Designated as threatened or endangered by the State or Federal government
- Proposed or petitioned for Federal listing as threatened or endangered
- State or Federal candidates for listing as threatened or endangered
- Identified by CDFW as a species of special concern
- Considered sensitive or endemic by USFS
- Considered sensitive by BLM
- Considered S&M species by NWFP
- Designated as MSCS-covered species by CALFED

Special-status wildlife species with the potential to occur in the Shasta Lake and vicinity portion of the primary study area were determined using several database searches; review of USFWS and CDFW special-status species lists for Shasta County; review of the CALFED MSCS list; review of other appropriate literature; discussions with BLM, CDFW, DWR, USFS, and USFWS personnel; and professional experience in the area. All special-status wildlife species potentially occurring in the Shasta Lake and vicinity portion of the primary study area are discussed in Attachment 1 of the *Wildlife Resources Technical Report*, which provides a general comparison of habitat requirements for each species and the general habitats in the primary study area above Shasta Dam. For those special-status species for which generally suitable habitat was determined to be present, results from the various vegetation habitat mapping and wildlife surveys conducted in the area by Reclamation since 2002 were used to determine the likelihood of their presence in the primary study area above Shasta Dam (Table 13-4).

The S&M species include all species included in the January 2001 *Record of Decision and Standards and Guidelines for Amendments to the Survey and Manage, Protection Buffer, and Other Mitigation Measures Standards and Guidelines* (U.S. Department of Agriculture and U.S. Department of the Interior 2001) (2001 S&M Record of Decision [ROD]) The current S&M species list is from the 2001 S&M ROD and includes species listed in the 2001 S&M ROD *Survey and Manage Standards and Guidelines and Category Assignment* (BLM December 2013). For the purposes of this evaluation, S&M species of concern include taxa that are designated as Category A and C by the current category assignment. These categories include taxa that require what are known as pre-disturbance (i.e., pre-project) surveys.

The CNDDB was reviewed for records of special-status plant species in or near the Shasta Lake and vicinity portion of the primary study area. The CNDDB is a database consisting of historical observations of special-status plant species, wildlife species, and natural communities. The CNDDB is limited to reported sightings and is not a comprehensive list of special-status species that could occur in a particular area.

Table 13-4. Wildlife Species of Concern in the Shasta Lake and Vicinity Portion of the Primary Study Area

Common Name	Scientific Name	Status[1]	Potential for Occurrence
Western bumble bee	*Bombus occidentalis*	USFS S	Various habitats with abundant flowering vegetation from spring through fall.
Church's sideband	*Monadenis churchi*	S&M	Potentially occurring in mixed conifer and conifer/woodland habitats. Many known occurrences in the Shasta Lake and vicinity portion of the study area.
Shasta sideband	*Monadenia troglodytes troglodytes*	FP, USFS S, S&M, MSCS m	Endemic to Shasta County. Potentially occurring in mixed conifer and woodland habitats, especially near limestone. Species occurs in limestone on the McCloud Arm.
Wintu sideband	*Monadenia troglodytes wintu*	FP, USFS S, S&M	Endemic to Shasta County. Potentially occurring in mixed conifer and woodland habitats, especially near limestone. Known to occur between the Pit and Squaw Creek arms and at Mountain Gate.
Oregon shoulderband	*Helminthoglypta hertlenii*	S&M	Potentially occurring in mixed conifer and conifer/woodland habitats. Many known occurrences in the Shasta Lake and vicinity portion of the study area.
Shasta chaparral	*Trilobopsis roperi*	FP, USFS S, S&M	Endemic to Shasta County. Potentially occurring in mixed conifer and conifer/woodland habitats. Known occurrences in the Shasta Lake and vicinity portion of the study area.
Shasta hesperian	*Vespericola shasta*	FP, USFS S, S&M	Endemic to the southeastern Klamath Mountains. Potentially occurring in mixed conifer and conifer/woodland habitats (riparian and/or riverine habitats). Known occurrences in the Shasta Lake and vicinity portion of the study area.
Shasta salamander	*Hydromantes shastae*	CT, USFS S, S&M, MSCS m, BLMS	Only known from the southeastern Klamath Mountains. Potentially occurring in mixed conifer, woodland, and chaparral habitats, especially near limestone. Known occurrences in the Shasta Lake and vicinity portion of the study area.
Tailed frog	*Ascaphus truei*	CSC	Potentially occurring in stream habitats in the Shasta Lake and vicinity portion of the study area. Known occurrences in the McCloud Arm and the upper Sacramento Arm tributaries outside the study area boundaries (CDFG 2003).

Table 13-4. Wildlife Species of Concern in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Status[1]	Potential for Occurrence
California red-legged frog	*Rana draytonii*	FT, CSC, MSCS m	Requires aquatic habitat for breeding; also uses a variety of other habitat types, including riparian and upland areas. The Shasta Lake and vicinity portion of the study area is outside the current species range. A USFWS habitat assessment is in preparation to determine habitat suitability.
Foothill yellow-legged frog	*Rana boylii*	CSC, USFS S, MSCS m, BLMS	Potentially occurring in stream habitats. Known occurrences scattered throughout the Shasta Lake and vicinity portion of the primary study area.
Northwestern pond turtle	*Actinemys marmorata*	CSC, USFS S, MSCS m	Potentially occurring in stream or other wetland habitats. Adjacent upland habitats are potential nesting areas. Known occurrences scattered throughout the Shasta Lake and vicinity portion of the primary study area.
Great blue heron	*Ardea herodias*	MSCS m	Known to breed in nearshore wooded habitat in the Turntable Bay area of Shasta Lake.
Cooper's hawk	*Accipiter cooperi*	MSCS m	Potentially occurring in mixed conifer and conifer/woodland habitats.
Northern goshawk	*Accipiter gentilis*	CSC, USFS S, BLMS	Potentially occurring in mixed conifer habitats. Known to occur in the upper McCloud Arm.
Bald eagle	*Haliaeetus leucocephalus*	FD, FB, CE, CP, USFS S, MSCS m, BLMS	Occur in riverine and lacustrine habitats. Common at Shasta Lake, and a substantial number of nests occur in the Shasta Lake and vicinity portion of the primary study area and vicinity. Shasta Lake has the highest density of breeding bald eagles in the continental United States.
Osprey	*Pandion haliaetus*	MSCS m	Occur in riverine and lacustrine habitats. Common at Shasta Lake, and many known nests occur in the Shasta Lake and vicinity portion of the primary study area and vicinity.
American peregrine falcon	*Falco peregrinus anatum*	FD, CD, CP, MSCS m	Potentially occurring in mixed conifer and conifer/woodland habitats. Nesting sites in the study area unlikely due to lack of suitable eyrie sites; however, potential eyrie sites occur adjacent to the Shasta Lake and vicinity portion of the primary study area. A historical nest site occurs in the cliffs near Shasta Caverns and a "new" nest site is believed to occur in cliffs along the Sacramento Arm of Shasta Lake. Another nest site is located south of Shasta Lake at Gray Rocks, near Mountain Gate.
Long-eared owl	*Asio otus*	CSC, MSCS m	Potentially occurring in coniferous forest habitats.

Table 13-4. Wildlife Species of Concern in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Status[1]	Potential for Occurrence
Northern spotted owl	*Strix occidentalis caurina*	FT, MSCS m	Potentially occurring in coniferous forest habitats. The species has been recorded within 0.5 mile of the study area along the Squaw Creek Arm. Potential dispersal habitat occurs in the Shasta Lake and vicinity portion of the primary study area. No designated critical habitat occurs in the Shasta Lake and vicinity portion of the primary study area.
Vaux's swift	*Chaetura vauxi*	CSC	Potentially occurring in coniferous forest and conifer/woodland habitats. Known to occur in the Shasta Lake and vicinity portion of the study area.
Willow flycatcher	*Empidonax traillii*	CE, USFS S, MSCS r	Uncommon migrant in riparian habitat; unlikely to nest in the Shasta Lake and vicinity portion of the primary study area.
Purple martin	*Progne subis*	CSC	Potentially occurring in conifer, woodland, and riparian habitats. Foraging habitat occurs throughout Shasta Lake and vicinity portion of the primary study area. Nests along the Pit River Arm. Shasta Lake is one of the few known breeding sites in interior northern California.
Yellow warbler	*Dendroica petechia brewsteri*	CSC, MSCS r	Potentially occurring in riparian habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.
Yellow-breasted chat	*Icteria virens*	CSC, MSCS m	Potentially occurring in riparian habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.
Pallid bat	*Antrozous pallidus*	CSC, USFS S, BLMS	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the study area.
Townsend's big-eared bat	*Plecotus townsendii*	CSC, USFS S	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the study area. Known occurrence from a cave on the Backbone Arm in the Shasta Lake and vicinity portion of the primary study area.
Spotted bat	*Euderma maculatum*	CSC, BLMS	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the study area. Species has been recorded on Squaw Creek within approximately 6 miles of the Shasta Lake and vicinity portion of the primary study area.
Western red bat	*Lasiurus blossevillii*	CSC	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the Shasta Lake and vicinity portion of the primary study area.
Long-eared myotis	*Myotis evotis*	BLMS	Potentially occurring in a wide variety of forest habitats throughout the study area.
Yuma myotis	*Myotis yumanensis*	BLMS	Potentially occurring in a wide variety of forest habitats throughout the study area.

Table 13-4. Wildlife Species of Concern in the Shasta Lake and Vicinity Portion of the Primary Study Area (contd.)

Common Name	Scientific Name	Status[1]	Potential for Occurrence
Fringed myotis	*Myotis thysanodes*	USFS S	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the Shasta Lake and vicinity portion of the primary study area.
Western mastiff bat	*Eumops perotis*	CSC, MSCS m (*californicus* subspecies only), BLMS	Potentially occurring in mixed conifer and conifer/woodland habitat throughout the Shasta Lake and vicinity portion of the primary study area.
Ringtail	*Bassariscus astutus*	CP, MSCS m	Potentially occurring in mixed conifer and conifer/woodland habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.
American marten	*Martes americana*	USFS S	Potentially occurring in mixed conifer habitats.
Pacific fisher	*Martes pennanti*	FC, CSC, USFS S, BLMS	Potentially occurring in mixed conifer and conifer/woodland habitats. Known occurrences in and near the Shasta Lake and vicinity portion of the primary study area.

Note:
[1]Status Definitions

Key:
BLMS = U.S. Department of the Interior, Bureau of Land Management sensitive
CD= California delisted
CE = California endangered
CP = California fully protected
CSC = California species of special concern
CT = California (State) listed as threatened
FB = Federal Bald and Golden Eagle Protection Act
FC = Federal candidate for listing
FD = Federally delisted
FP = Federally petitioned for listing
FPD = Proposed for Federal delisting
FT = Federally listed as threatened
m = Maintain. Ensure that any adverse effects on the species that could be associated with implementation of CALFED Bay-Delta Program actions will be fully offset through implementation of actions beneficial to the species.
MSCS = Multi-Species Conservation Strategy covered species
r = Contribute to recovery. Implement some of the actions deemed necessary to recover species' populations in the Multi-Species Conservation Strategy focus area.
USFS M = U.S. Forest Service survey and manage species
USFS S = U.S. Forest Service sensitive

Species accounts for special-status wildlife in the Shasta Lake and vicinity portion of the primary study area are described in detail in Attachment 2 of the *Wildlife Resources Technical Report*. Figures 13-5a through 13-5f depict the known locations of special-status wildlife species in the primary study area above Shasta Dam located during various surveys conducted by Reclamation and from USFS records. Figures 13-6a through 13-6f depict the known locations of special-status terrestrial mollusks.

Summary of Wildlife Investigations

Terrestrial Mollusk Surveys (Survey and Manage) Reclamation has conducted three survey efforts for S&M terrestrial mollusk species in the Shasta Lake and vicinity portion of the primary study area. These include protocol-level efforts during 2002 to 2003 and 2005 along selected portions of the Shasta Lake shoreline, surveys conducted in 2010 at the relocation areas. Additionally, many other terrestrial mollusk locations have been found incidentally during numerous other biological survey tasks throughout the Shasta Lake and vicinity portion of the primary study area. Six S&M terrestrial mollusk species have been found to date: Church's sideband (*Monadenia churchi*), Shasta sideband (*Monadenia troglodytes troglodytes*), Wintu sideband (*Monadenia troglodytes wintu),* Oregon shoulderband (*Helminthoglypta hertlenii*), Shasta chaparral (*Trilobopsis roperi*), and Shasta hesperian (*Vespericola shasta*). Church's sideband and Oregon shoulderband were the most commonly occurring terrestrial mollusk species, as they were found at 325 and 220 locations, respectively. Shasta hesperian was found at 69 locations, while Shasta sideband and Shasta chaparral were found at 29 locations each. Wintu sideband was the least commonly occurring terrestrial mollusk species and was found at 2 locations (Figures 13-6a through 13-6f).

Shasta Salamander Surveys Reclamation has conducted three survey efforts for Shasta salamander in the Shasta Lake and vicinity portion of the primary study area. These include survey efforts during 2003 and 2006 to 2007 along selected portions of the Shasta Lake shoreline and surveys performed in 2010 and 2011 at the relocation areas. Additionally, several other Shasta salamander locations have been found incidentally during other biological survey tasks throughout the Shasta Lake and vicinity portion of the primary study area. Collectively, Shasta salamanders have been found at 39 locations during the survey efforts. These findings and other known locations show that this species occurs in all arms of Shasta Lake in both limestone and nonlimestone habitats (Figures 13-5a through 13-5f).

Bald Eagle/Osprey Surveys Reclamation mapped all known bald eagle and osprey nests in the Shasta Lake and vicinity portion of the primary study area in 2007 and 2010. Additional data, including diameter of nest trees, nest tree height, nest height, proximity to the high-water mark, surrounding vegetation, and shoreline erosion rating, were recorded for the bald eagle nests. Twenty-eight bald eagle nests and 54 osprey nests were located. Reclamation continued surveys and coordination with the USFS through 2013 to maintain current bald eagle and osprey nest site locations. Currently, 32 bald eagle and 54 osprey nest sites are known within or near the Shasta Lake and vicinity portion of the primary study area (Figures 13-5a through 13-5f).

Neotropical Migrant Bird Surveys Reclamation conducted a breeding bird survey in the Shasta Lake and vicinity portion of the primary study area in 2007. Additionally, focused surveys for purple martins and an analysis of purple martin habitat at Shasta Lake were conducted. These surveys provided information on use of the Shasta Lake and vicinity portion of the primary study area by breeding birds, including breeding neotropical migrant species. Sixty-seven bird species were detected during these surveys, including 38 neotropical migrant species.

These surveys also provided a basic understanding of purple martin ecology in the Shasta Lake and vicinity portion of the primary study area. Purple martin monitoring has continued through 2013, providing additional information on species distribution and habitat use (Figures 13-5d through 13-5f). The nesting purple martin population has totaled 18, 21, 24, 28, 42,27, and 17 pairs from 2007 through 2013, respectively. Most nest sites occur in flooded snags located in the reservoir; however, monitoring results show an increase in use of upland nest sites. Limited historical information from purple martin surveys information from 1978 to 2001 showed 14 to 19 nesting pairs at Shasta Lake. During the monitoring period, the nesting purple martin population showed small increases from 2007 through 2010, a large increase in 2011, and then generally returned to 2009 and 2010 levels in 2012. For unknown reasons a marked decrease to 17 pairs occurred in 2013, a population size similar to historic numbers. The 2007 to 2013 monitoring results initially show a stable to increasing population, followed by a decrease and return to more historic levels.

Forest Carnivore Surveys Reclamation conducted surveys for sensitive forest carnivore species (forest carnivores) in the Shasta Lake and vicinity portion of the primary study area during 2003 to 2005. The specific sensitive forest carnivore species (i.e., “target species”) surveyed included the Sierra Nevada red fox (*Vulpes vulpes necator*), American marten (*Martes americana*), Pacific fisher (*Martes pennanti*), and wolverine (*Gulo gulo*). One target forest carnivore species, the Pacific fisher, was detected. Pacific fisher was detected at 13 locations scattered in all areas of the Shasta Lake and vicinity portion of the primary study area, except the McCloud Arm (Figures 13-5a through 13-5f). Forest carnivore surveys conducted during 2007 and 2010 along the McCloud Arm for this project and another unrelated project detected Pacific fisher and found that the species occurs in all areas of the Shasta Lake and vicinity portion of the primary study area. Additionally, the ringtail, a California fully protected species, was detected in all areas of the Shasta Lake and vicinity portion of the primary study area during the forest carnivore surveys.

The Pacific fisher survey results provide additional information on habitat use and distribution of the species in Northern California. The survey findings represent the southeastern-most Pacific fisher occurrences in the Klamath region. Additionally, these findings show Pacific fishers in areas generally (previously) not considered habitat in California, including open second-growth conifer, hardwood–conifer, and hardwood habitats that have extensive chaparral components. Pacific fishers were also detected in forest habitats that were barren or semi-barren 50 to 60 years ago because of historical copper mining and smelting activities, and near commercial, rural residential, and industrial development areas.

California Red-Legged Frog Assessment Reclamation conducted a California red-legged frog habitat assessment in the Shasta Lake and vicinity portion of the primary study area in 2010 and 2012. In consultation with the USFWS, an assessment area was developed and field surveys of aquatic habitats were conducted in accordance with *Revised Guidance on Site Assessments and Field Surveys for the California Red-Legged Frog* (USFWS 2005a). The results suggest only one feature may represent potential California red-legged frog breeding habitat. A California red-legged frog habitat assessment report was submitted to the USFWS.

Upper Sacramento River (Shasta Dam to Red Bluff)

The following section provides a detailed discussion of wildlife species of concern specific to the potential Sacramento River downstream habitat restorations areas, as well as the wildlife species of concern known to occur or with potential to occur along the Sacramento River throughout the rest of the primary study area.

A list of special-status wildlife species with the potential to occur in the primary study area from Shasta Dam to the Red Bluff Pumping Plant (Table 13-5) was compiled based on habitat suitability and known occurrences within the area covered in the Shasta Dam, Redding, Enterprise, Cottonwood, Balls Ferry, Bend, and Red Bluff East U.S. Geological Survey 7.5-minute quadrangle maps (CNDDB 2012; USFWS 2011). This list also includes species that are identified by USFS as sensitive, or endemic; identified by BLM as sensitive; designated by the NWFP as S&M; or designated as MSCS covered species. See the *Wildlife Resources Technical Report* for a description of the life history of special-status wildlife species known or likely to occur in the area and figures depicting the recorded locations of special-status species.

Table 13-5. Special-Status Wildlife Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Pumping Plant

Common Name	Scientific Name	Status[1]	Potential for Occurrence
Invertebrates			
Conservancy fairy shrimp	*Branchinecta conservatio*	FE, MSCS	Unlikely to occur. No suitable habitat is present along the river corridor.
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*	FPD, FT, MSCS	Known to occur. Elderberry shrubs are present within the riparian woodland community along the Sacramento River.
Vernal pool tadpole shrimp Critical Habitat	*Lepidurus packardi*	FE, MSCS	Unlikely to occur. No suitable habitat is present along the river corridor. Critical habitat does not occur within the river corridor.
Vernal pool fairy shrimp Critical Habitat	*Branchinecta lynchi*	FT, MSCS	Unlikely to occur. No suitable habitat is present along the river corridor. Critical habitat does not occur within the river corridor.
Amphibians			
Shasta salamander	*Hydromantes shastae*	CT, BLM S, USFS S	Unlikely to occur. Suitable habitat generally is not found within the river corridor downstream from Shasta Dam.
California red-legged frog	*Rana aurora draytonii*	FT, CSC, MSCS	Could occur along the Sacramento River if suitable habitat is present
Foothill yellow-legged frog	*Rana boylii*	CSC, USFS S, MSCS	Could occur along the Sacramento River if suitable habitat is present
Western spadefoot toad	*Spea hammondii*	CSC, MSCS	Unlikely to occur. No suitable habitat is present along the Sacramento River corridor.
Reptiles			
Giant garter snake	*Thamnophis gigas*	FT, CT, MSCS	Unlikely to occur in the primary study area; however, known to occur in the extended study area.
Western pond turtle	*Actinemys (Clemmys) marmorata*	CSC, USFS S, MSCS	Known to occur. Suitable habitat is present in the primary study area.
Birds			
Cackling goose *(Aleutian Canada goose)*	*Branta hutchinsii leucopareia*	FD, MSCS	Unlikely to occur within the banks of the Sacramento River where flows could be altered.
American peregrine falcon *(nesting)*	*Falco peregrinus anatum*	CP, USFS S, MSCS	Unlikely to nest in this portion of the study area; however, may forage in areas of open water with large concentrations of waterbirds.
Bald eagle (nesting and wintering)	*Haliaeetus leucocephalus*	FD, CE, CP, USFS S, MSCS	Known to occur along the Sacramento River in the primary study area.
Bank swallow (nesting)	*Riparia riparia*	CT, MSCS	Known to occur along the Sacramento River in the primary study area.
Black-crowned night heron (rookery)	*Nycticorax nycticorax*	BLM S, MSCS	Could nest in trees adjacent to the Sacramento River.

Table 13-5. Special-Status Wildlife Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Pumping Plant (contd.)

Common Name	Scientific Name	Status[1]	Potential for Occurrence
California gull (nesting colony)	*Larus californicus*	MSCS	Not within breeding range. Could occur in the study area during winter or migration.
Cooper's hawk (nesting)	*Accipiter cooperii*	MSCS	Could occur. Suitable nesting and foraging habitat is present in the primary study area.
Double-crested cormorant (rookery)	*Phalacrocorax auritus*	MSCS	Could nest in trees adjacent to the Sacramento River.
Golden eagle	*Aquila chrysaetos*	CP, BLM S, MSCS	No suitable nesting habitat along the Sacramento River. Unlikely to forage along the river corridor.
Great blue heron (rookery)	*Ardea herodius*	MSCS	Could nest in trees adjacent to the Sacramento River.
Great egret (rookery)	*Casmerodius albus*	MSCS	Could nest in trees adjacent to the Sacramento River.
Greater sandhill crane (nesting and wintering)	*Grus canadensis tabida*	CT, CP, MSCS	Unlikely to breed in the primary study area. Unlikely to use the Sacramento River corridor during winter or migration.
Least bittern (nesting)	*Ixobrychus exilis*	CSC, MSCS	Could nest along the Sacramento River if suitable habitat is present.
Lesser sandhill crane (wintering)	*Grus canadensis canadensis*	CSC	Does not breed in California. Unlikely to use the Sacramento River corridor during winter or migration.
Little willow flycatcher (nesting)	*Empidonax traillii brewsteri*	CE, MSCS	Unlikely to breed in the primary study area because of the area's elevation, but may use riparian woodlands during migration.
Loggerhead shrike (nesting)	*Lanius ludovidianus*	CSC	Likely to nest and forage in woodlands and scrub habitats in the primary study area.
Long-billed curlew (nesting)	*Numenius americanus*	MSCS	Does not breed in the primary study area. Unlikely to use the Sacramento River corridor during winter or migration.
Long-eared owl (nesting)	*Asio otus*	CSC, MSCS	Does not nest in lowland Central Valley areas. Unlikely to forage along the Sacramento River corridor where flows would be altered.
Northern harrier (nesting)	*Circus cyaneus*	CSC, MSCS	Likely to occur. Suitable nesting and foraging habitat is present in the primary study area.
Northern spotted owl (nesting) (critical habitat)	*Strix occidentalis caurina*	FT, MSCS	Unlikely to occur along the Sacramento River corridor because of a lack of suitable habitat. Critical habitat does not occur in the primary study area.
Osprey (nesting)	*Pandion haliaetus*	MSCS	Known to nest along the Sacramento River in the primary study area.
Purple martin (nesting)	*Progne subis*	CSC	Could occur. Potentially suitable habitat is present along the Sacramento River corridor.
Short-eared owl (nesting)	*Asio flammeus*	CSC, MSCS	Could occur. Potentially suitable habitat is present in the primary study area.

Table 13-5. Special-Status Wildlife Species Known or with Potential to Occur in the Primary Study Area, Along the Sacramento River from Shasta Dam to Red Bluff Pumping Plant (contd.)

Common Name	Scientific Name	Status[1]	Potential for Occurrence
Snowy egret (rookery)	*Egretta thula*	MSCS	Could nest in trees adjacent to the Sacramento River.
Swainson's hawk (nesting)	*Buteo swainsoni*	CT, USFS S, MSCS	Could occur. Suitable nesting and foraging habitat is present in the primary study area.
Tricolored blackbird (nesting colony)	*Agelaius tricolor*	CSC, MSCS	Could occur. Potentially suitable habitat is present in the primary study area.
Western yellow-billed cuckoo (nesting)	*Coccyzus americanus occidentalis*	FT, CE, USFS S, MSCS	Likely to nest and forage in the primary study area.
Western burrowing owl (burrow sites)	*Athene cunicularia hypugea*	CSC, MSCS	Unlikely to occur along the Sacramento River corridor because of a lack of suitable nesting habitat.
White-tailed kite (nesting)	*Elanus leucurus*	CP, MSCS	Likely to occur. Suitable nesting and foraging habitat is present in the primary study area.
Yellow-breasted chat (nesting)	*Icteria virens*	CSC, MSCS	Likely to nest and forage in the primary study area
Yellow warbler (nesting)	*Setophaga (Dendroica) petechia*	CSC, MSCS	Could nest and forage in the primary study area. Likely to use riparian woodlands during migration.
Pacific fisher	*Martes pennanti*	FC, CSC, USFS S	Unlikely to occur. No suitable habitat is available along the Sacramento River corridor.
Ringtail	*Bassariscus astutus*	CP, MSCS	Could occur. Potentially suitable habitat is present along the Sacramento River corridor.
Pallid bat	*Antrozous pallidus (roosting)*	CSC, BLM S, USFS S	Could occur. Potentially suitable habitat is present in woodland in the primary study area.
Western mastiff bat (roosting)	*Eumops perotis californicus*	CSC, BLM S, MSCS	Unlikely to roost along the Sacramento River corridor because suitable roost sites are lacking.

Biological Resource Assessments for Potential Sacramento River Downstream Habitat Restoration Areas Reclamation conducted biological resource assessments at each of the six potential Sacramento River downstream habitat restoration areas during 2013. The assessments include botanical surveys for special-status plants and noxious weeds, vegetation and wildlife habitat mapping, general wildlife surveys, breeding bird surveys, California red-legged frog habitat assessments, and delineations of Waters of the U.S. The biological resource assessment results are included as Attachments 12-17 to the Wildlife Resources Technical Report in the Biological Resources Appendix. Potentially occurring special-status wildlife species at the potential Sacramento River downstream habitat restoration areas are documented in Attachments 18-23 to the Wildlife Resources Technical Report in the Biological Resources Appendix

Table 13-6. Wildlife Species of Concern in the Potential Sacramento River Downstream Habitat Restoration Areas

Common Name	Scientific Name	Status	Potential for Occurrence
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*	FT	Potentially occurring in blue elderberry shrubs.
California red-legged frog	*Rana draytonii*	FT, CSC, MSCS m	Potentially occurring at restoration sites or locations in the vicinity with potential breeding habitat present.
Western pond turtle	*Actinemys marmorata*	CSC, USFS S, MSCS m	Potentially occurring in stream or other wetland habitats. Adjacent upland habitats are potential nesting areas.
Double-crested cormorant	*Phalacrocorax auritus*	MSCS m	Commonly occurs in the general vicinity in riverine and adjacent riparian habitats. No known rookery sites at any potential Sacramento River downstream habitat restoration areas.
Great egret	*Ardea alba*	MSCS m	Commonly occurs in the general vicinity in riverine and adjacent riparian habitats. No known rookery sites at any potential Sacramento River downstream habitat restoration areas.
Great blue heron	*Ardea herodias*	MSCS m	Commonly occurs in the general vicinity in riverine and adjacent riparian habitats. No known rookery sites at any potential Sacramento River downstream habitat restoration areas.
Black-crowned night heron	*Nycticorax nycticorax*	MSCS m	Commonly occurs in the general vicinity in riverine and adjacent riparian habitats. No known rookery sites at any potential Sacramento River downstream habitat restoration areas.
Cooper's hawk	*Accipiter cooperi*	MSCS m	Potentially occurring in forested riparian and woodland habitats.
Bald eagle	*Haliaeetus leucocephalus*	FD, FB, CE, CP, USFS S, MSCS m, BLMS	Occurs year-round in the vicinity. Two known nests in the general vicinity of the potential Sacramento River downstream habitat restoration areas
Osprey	*Pandion haliaetus*	MSCS m	Commonly occurs in the general vicinity of the potential Sacramento River downstream habitat restoration areas. No known nests at any potential Sacramento River downstream habitat restoration areas.

Table 13-6. Wildlife Species of Concern in the Potential Sacramento River Downstream Habitat Restoration Areas (contd.)

Common Name	Scientific Name	Status	Potential for Occurrence
Western yellow-billed cuckoo	*Coccyzus americanus occidentalis*	FT, CE	Occurs only along the upper Sacramento Valley portion of the Sacramento River from Colusa to Red Bluff, the Feather River in Sutter Co., the South Fork Kern River in Kern Co., the Owen's River in Inyo Co., and along the Santa Ana, Amargosa, and lower Colorado Rivers. Riparian forest habitats in the potential Sacramento River downstream habitat restoration areas provide potential nesting habitat; however, these areas is located approximately 24 miles north of the northern extent of the known species geographic range.
Barrows goldeneye	*Bucephala islandica*	—/SC	Winter visitor to bays, lagoons, estuaries, freshwater lakes and large fast-moving rivers. Formerly nested in California at high mountain lakes. Regularly occurs on the Sacramento River in the Redding area during winter.
Willow flycatcher	*Empidonax traillii*	CE, USFS S, MSCS r	Uncommon migrant species in riparian habitat; may occur briefly during migration. No potentially nesting habitat present.
Yellow warbler	*Dendroica petechia brewsteri*	CSC, MSCS r	Potentially occurring in riparian habitats.
Yellow-breasted chat	*Icteria virens*	CSC, MSCS m	Potentially occurring in riparian habitats.
Pallid bat	*Antrozous pallidus*	CSC, USFS S, BLMS	Potentially occurring in riparian forest and woodland habitats.
Townsend's big-eared bat	*Plecotus townsendii*	CSC, USFS S	Potentially occurring in riparian forest and woodland habitats.
Western red bat	*Lasiurus blossevillii*	CSC	Potentially occurring in riparian forest and woodland habitats.
Ringtail	*Bassariscus astutus*	CP, MSCS m	Potentially occurring in riparian forest and woodland habitats.

Lower Sacramento River and Delta

Numerous special-status wildlife species are associated with riparian, floodplain, and side-channel wetland habitats along the Sacramento River and in the Delta (Table 13-7). However, as stated above, the roughly 300 miles of the Sacramento River can be subdivided into distinct reaches. The reaches in the extended study area are discussed separately below because of differences in morphology, riparian vegetation, and habitat functions. The sensitive species discussed in this section are representative species selected from the many species present in the extended study area and are presented as examples to illustrate the breadth of resources. The *Wildlife Resources Technical Report* contains a comprehensive list of all sensitive wildlife species in the extended study area that have been reported to the CNDDB.

Table 13-7. Representative Sensitive Wildlife Species of Riparian and Perennial Wetland Communities Along the Sacramento River and in the Delta

Common Name	Scientific Name	Status[1]	Habitat Description
Invertebrates			
Valley elderberry longhorn beetle	*Desmocerus californicus dimorphus*	FT	Elderberries in riparian woodlands or savanna communities.
Reptiles			
Western pond turtle	*Actinemys (Clemmys) marmorata*	CSC	Ponds, lakes, rivers, streams, creeks, marshes, and irrigation ditches with abundant vegetation and either rocky or muddy bottoms, in woodland, forest, and grassland.
Giant garter snake	*Thamnophis giga*	FT CT	Marshes, sloughs, drainage canals, and irrigation ditches, especially around rice fields, and occasionally in slow-moving creeks from sea level to 400 feet. Prefers locations with vegetation close to the water for basking.
Birds			
Tricolored blackbird	*Agelaius tricolor*	CSC	*Foraging:* On ground in croplands, grassy fields, flooded land, and along edges of ponds. *Nesting:* Dense cattails, tules, or thickets near fresh water.
Swainson's hawk	*Buteo swainsoni*	CT	*Foraging:* Open desert, grassland, or cropland containing scattered, large trees or small groves. *Nesting:* Open riparian habitat, in scattered trees or small groves in sparsely vegetated flatlands. Usually found near water in the Central Valley.
Northern harrier	*Circus cyaneus*	CSC	*Nesting:* Tall grasses and forbs in emergent wetland, along rivers or lakes, grasslands, grain fields, or on sagebrush flats several miles from water.
Western yellow-billed cuckoo	*Coccyzus americanus occidentalis*	FT CE	*Nesting:* Extensive deciduous riparian thickets or forests with dense, low-level or understory foliage adjacent to slow-moving watercourses, backwaters, or seeps. Willow is almost always a dominant component of the vegetation. In the Sacramento Valley, also uses adjacent walnut orchards.
Yellow warbler	*Setophaga (Dendroica) petechia*	CSC	*Nesting*: Low, open-canopy riparian deciduous woodlands with a heavy brush understory; sometimes in montane shrubbery in open conifer forests.

Table 13-7. Representative Sensitive Wildlife Species of Riparian and Perennial Wetland Communities Along the Sacramento River and in the Delta (contd.)

Common Name	Scientific Name	Status[1]	Habitat Description
White-tailed kite	*Elanus leucurus*	FP	*Foraging:* Undisturbed, open grasslands, meadows, farmlands, and emergent wetlands. *Nesting:* Large groves of dense, broad-leafed deciduous trees close to foraging areas.
Greater sandhill crane	*Grus canadensis tabida*	CT FP	*Foraging: Open grasslands, grain fields, and open wetlands.* *Roosting: In flocks standing in moist fields or in shallow water.* *Nesting: Open habitats with shallow lakes and fresh emergent wetlands.*
Bald eagle	*Haliaeetus leucocephalus*	CE FP	*Foraging: Large bodies of water or free-flowing rivers with abundant fish and adjacent snags or other perches.* *Nesting: Large, old-growth trees or snags in remote, mixed stands near water.*
Yellow-breasted chat	*Icteria virens*	CSC	*Foraging and nesting:* Riparian thickets of willow and other brushy species near streams or other watercourses.
California black rail	*Laterallus jamaicensis coturniculus*	CT FP	*Foraging and nesting:* Tidal emergent wetlands dominated by pickleweed, in the high wetland zones near upper limit of tidal flooding, or in brackish marshes supporting bulrushes and pickleweed. In freshwater, usually found in bulrushes, cattails, and saltgrass adjacent to tidal sloughs.
Suisun song sparrow	*Melospiza melodia maxillaries*	CSC	*Foraging:* The bare surface of tidally exposed mud among tules and along slough margins in brackish marshes. *Nesting:* Along edges of sloughs and bays supporting mixed stands of bulrush, cattail, and other emergent vegetation.
Bank swallow	*Riparia riparia*	CT	*Foraging:* Open riparian areas, grassland, wetlands, water, and cropland. *Nesting:* Vertical banks and cliffs with fine-textured or sandy soils near streams, rivers, ponds, and lakes.
Yellow-headed blackbird	*Xanthocephalus xanthocephalus*	CSC	*Foraging:* Fresh emergent wetland and sometimes along shorelines and in nearby open fields, preferably on moist ground. *Nesting:* Dense emergent wetland of cattails and tules, often along border of lake or pond.

Table 13-7. Representative Sensitive Wildlife Species of Riparian and Perennial Wetland Communities Along the Sacramento River and in the Delta (contd.)

Common Name	Scientific Name	Status[1]	Habitat Description
Mammals			
Pallid bat	*Antrozous pallidus*	CSC	*Foraging:* Relatively open oak woodlands, over water near riparian and upland forests and woodlands, and orchards and vineyards. *Roosting:* Rocky outcrops, cliffs, and crevices.
Western mastiff bat	*Eumops perotis*	CSC	*Foraging:* Over water in broad, open areas near riparian and upland forests and woodlands. *Roosting:* Crevices in vertical cliffs, usually granite or consolidated sandstone, and in broken terrain with exposed rock faces.
Western red bat	*Lasiurus blossevillii*	CSC	*Foraging:* Over water edges in open areas near riparian and upland forests and woodlands; orchards. *Roosting:* Trees along edges or in habitat mosaics in a variety of habitats and orchards.
Townsend's big-eared bat	*Plecotus townsendii*	CSC	*Foraging:* Water edges in open areas near riparian and upland forests and woodlands. *Roosting:* Caves, mines, tunnels, buildings, or other human-made structures in woodlands. Prefers mesic habitats.
Salt-marsh harvest mouse	*Reithrodontomys raviventris*	FE CE FP	Salt marsh dominated by pickleweed and salt grass. Generally requires nonsubmerged, salt-tolerant vegetation for escape during high tides.

Source: CNDDB 2012

Note:

[1] Status definitions:

Key:

CE = California listed as endangered
CSC = California species of special concern
CT = California listed as threatened
FC = federal candidate for listing
FE = Federally listed as endangered
FP = California fully protected
FT = Federally listed as threatened

Sacramento River from Red Bluff Pumping Plant to the Delta Many of the special-status wildlife species described above for the upper Sacramento River have the potential to occur in the middle and lower reaches of the Sacramento River. Wildlife species listed under the Federal Endangered Species Act (ESA) and/or California Endangered Species Act (CESA) that have the potential to occur in a portion of the extended study area from Red Bluff Pumping Plant to the Delta include valley elderberry longhorn beetle (*Desmocerus californicus dimorphus*), giant garter snake (*Thamnophis gigas*), bald eagle (*Haliaeetus leucocephalus*), Swainson's hawk (*Buteo swainsoni*), western yellow-billed cuckoo (*Coccyzus americanus occidentalis*), willow flycatcher (*Empidonax traillii*), and bank swallow (*Riparia riparia*).

Sacramento–San Joaquin River Delta Many special-status species are known or likely to occur in the Delta because of the presence of extensive wetland habitats. Tidal marshes and emergent wetlands support several special-status wildlife species: California black rail (*Laterallus jamaicensis coturniculus*), California clapper rail (*Rallus longirostris obsoletus*), greater sandhill crane (*Grus canadensis tabida*), salt marsh common yellowthroat (*Geothlypis trichas sinuosa*), salt marsh harvest mouse (*Reithrodontomys raviventris*), Suisun ornate shrew (*Sorex ornatus sinuosus*), Suisun song sparrow (*Melospiza melodia maxillaris*), and tricolored blackbird (*Agelaius tricolor*). The giant garter snake is known to inhabit sloughs, canals, and low-gradient streams and freshwater marshes in the Delta. Vernal pools and other freshwater seasonal wetlands support several special-status crustaceans, including vernal pool tadpole shrimp (*Lepidurus packardi*) and vernal pool fairy shrimp (*Branchinecta lynchi*). The valley elderberry longhorn beetle has been found in the Delta region on McCormack-Williamson and New Hope tracts (CNDDB 2012).

San Joaquin River Basin to the Delta The current wildlife habitat value of this area is somewhat limited by the predominance of agricultural lands, which support a relatively low diversity of wildlife species. Remnant native vegetation patches are likely to support a high diversity of wildlife species. More than 100 special-status wildlife and plant species occur in the San Joaquin River region. Most of the special-status wildlife species are associated with grasslands (which include vernal pools), freshwater emergent wetlands, lakes, and rivers that occur on the valley floor. Many of the species have been listed by Federal and State wildlife agencies because of habitat losses associated with agricultural development and water projects.

CVP/SWP Service Areas

The CVP and SWP service areas are dominated by agricultural land and urban development. These areas support many wildlife species, most of which are highly adapted to these altered environments. The conflict between urban growth and conservation of native habitat has resulted in the listing of a number of wildlife species that were threatened with extinction. The region also supports a variety of exotic species, some of which are detrimental to survival of native species.

The California condor (*Gymnogyps californianus*), lightfooted clapper rail (*Rallus longirostris levipes*), California least tern (*Sternula antillarum brownie*), least Bell’s vireo (*Vireo bellii pusillus*), Belding’s Savannah sparrow (*Passerculus sandwichensis beldingi*), southwestern willow flycatcher (*Empidonax traillii extimus*), California gnatcatcher (*Polioptila californica*), Mohave ground squirrel (*Spermophilus mohavensis*), and Morro Bay kangaroo rat (*Dipodomys heermanni morroensis*) are examples of species that have been listed as threatened or endangered under the ESA and/or CESA and that could occur within the CVP and SWP service areas.

13.1.3 Other Wildlife Resources

Shasta Lake and Vicinity

Critical Deer Range Critical black-tailed deer winter range for the McCloud Flats and Cow Creek herds is located in the Shasta Lake and vicinity portion of the primary study area in all five arms of the lake. Critical fawning range also is found along the south-facing slopes of Little Sugarloaf Creek (CDFG 1998). Critical deer winter range can include movement corridors, staging areas where deer congregate, and habitats with high-quality winter forage or other elements that help deer to survive the winter. Winter ranges are at lower elevations and are fewer in number than summer ranges, and thus are more vulnerable to human impact. Deer from different summer ranges may use common winter ranges when breeding typically occurs, which contributes to genetic diversity (CDFG 1998).

USFWS Habitat Evaluation Procedure Analysis Reclamation is working with USFWS to complete a Habitat Evaluation Procedure analysis to help quantify potential project impacts and meet Fish and Wildlife Coordination Act consultation requirements. To date, Habitat Evaluation Procedure studies and analyses have been completed for part of the Shasta Lake and vicinity portion of the primary study area. Additional planning and coordination are ongoing.

Incidental Observations Reclamation maintains a database of special-status wildlife species incidentally observed during all biological surveys performed since 2002. The incidental species observations include the foothill yellow-legged frog, western pond turtle (*Actinemys marmorata*), osprey (*Pandion haliaetus*), peregrine falcon (*Falco peregrinus anatum*), yellow-breasted chat (*Icteria virens*), yellow warbler (*Dendroica petechia brewsteri*), and Townsend's big-eared bat (*Plecotus townsendii*) (Figures 13-5a through 13-5f).

Upper and Lower Sacramento River, Delta, and CVP/SWP Service Areas

For the upper and lower Sacramento River, Delta, and CVP/SWP service areas, no other wildlife resources were evaluated in addition to wildlife habitats, wildlife, and special-status wildlife as described previously in Sections 13.1.1 and 13.1.2.

13.2 Regulatory Framework

Biological resources in California are protected and/or regulated by a variety of Federal and State laws and policies. Key regulatory and conservation planning issues applicable to the project and alternatives under consideration are discussed below.

13.2.1 Federal

Federal Endangered Species Act

Pursuant to the ESA, USFWS and NMFS have authority over projects that may result in "take" of a Federally listed species. In general, ESA Section 7 prohibits persons (including private parties) from "taking" listed endangered or threatened fish and wildlife species on private property, and from "taking" listed endangered or threatened plant species in areas under Federal jurisdiction or in violation of State law (16 U.S. Code (USC) 1532, 50 Code of Federal Regulations (CFR) 17.3).

Under the ESA, the definition of "take" is to "harass, harm, pursue, hunt, shoot, wound, kill, trap, capture, or collect, or to attempt to engage in any such conduct" as part of an intentional or negligent act or omission. The term "harm" includes acts that result in death or injury to wildlife. Such acts may include significant habitat modification or degradation if it results in death or injury to wildlife by significantly impairing essential behavioral patterns, including breeding, feeding, or sheltering.

Section 7(a) of the ESA, as amended, requires Federal agencies to evaluate their actions with respect to any species that is proposed for listing or is listed as endangered or threatened. Section 7(a)(2) requires Federal agencies to ensure that activities they authorize, fund, or carry out are not likely to jeopardize the continued existence of a listed species or to destroy or adversely modify its designated critical habitat. If a Federal action may affect a listed species or its designated critical habitat, the responsible Federal agency must enter into formal consultation with USFWS or NMFS, depending on the species.

As defined in the ESA, critical habitat is a specific geographic area that is essential for the conservation of a threatened or endangered species and that may require special management and protection. It may include an area that is not currently occupied by the species but that will be needed for its recovery. Critical habitats are designated to ensure that actions authorized by Federal agencies will not destroy or adversely modify designated critical habitat, thereby protecting areas necessary for the conservation of the species.

Fish and Wildlife Coordination Act

The Fish and Wildlife Coordination Act (16 USC 661–667e, as amended) provides the basic authority for the involvement of USFWS in evaluating impacts on fish and wildlife from proposed water resource development projects. It requires that fish and wildlife resources receive consideration equal to that of other project features. It also requires Federal agencies that construct, license, or permit water resource development projects to first consult with USFWS (and NMFS in some instances) and State fish and wildlife agencies regarding the impacts of the proposed action on fish and wildlife resources and measures to mitigate these impacts.

Bald Eagle Protection Act

The bald eagle and golden eagle are Federally protected under the Bald Eagle Protection Act (16 USC 668–668c). It is illegal to take, possess, sell, purchase, barter, offer to sell or purchase or barter, transport, export, or import a live or dead bald or golden eagle or any eagle part, nest, or egg unless authorized by the Secretary of the Interior. The Bald Eagle Protection Act defines "take" as "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest or disturb" (16 USC 668–668d). USFWS has further defined "disturb" under the act as follows (72 *Federal Register* 31132–31140 (June 5, 2007)):

> *Disturb means to agitate or bother a bald or golden eagle to a degree that causes, or is likely to cause, based on the best scientific information available, (1) injury to an eagle; (2) a decrease in its productivity, by substantially interfering with normal breeding, feeding, or sheltering behavior; or (3) nest abandonment, by substantially interfering with normal breeding, feeding, or sheltering behavior.*

Active nest sites are also protected from disturbance during the breeding season, generally January through August.

USFWS has proposed new permit regulations to authorize the take of bald and golden eagles under the Bald Eagle Protection Act, generally where the take to be authorized is associated with otherwise lawful activities (72 *Federal Register* 31141–31155 (June 5, 2007)). With the delisting of the bald eagle from the ESA in 2007, this act is the primary law protecting bald eagles and golden eagles. Violators are subject to fines and/or imprisonment for up to 1 year.

Migratory Bird Treaty Act

Migratory birds are protected under the Migratory Bird Treaty Act (MBTA) of 1918 (16 USC 703–711). The MBTA makes it unlawful to take, possess, buy, sell, purchase, or barter any migratory bird listed in 50 CFR Part 10, including feathers or other parts, nests, eggs, or products, except as allowed by implementing regulations (50 CFR 21). This prohibition includes direct and indirect acts, although harassment and habitat modifications are not included unless they result in direct loss of birds, nests, or eggs. The current list of species protected by the MBTA, which can be found in Title 50, Section 10.13 of the CFR, includes several hundred species, essentially all native birds. Loss of nonnative species, such as house sparrows (*Passer domesticus*), European starlings (*Sturnus vulgaris*), and rock pigeons (*Columba livia*), is not covered by this statute.

U.S. Forest Service Sensitive Species

The National Forest Management Act requires USFS to "provide for a diversity of plant and animal communities" (16 USC 1604(g)(3)(B)) as part of its multiple-use mandate. USFS must maintain "viable populations of existing native and desired nonnative species in the planning area" (36 CFR 219.19). The Sensitive Species program is designed to meet this mandate and to demonstrate USFS's commitment to maintaining biodiversity on National Forest System lands. The program is a proactive approach to conserving species to prevent a trend toward listing under the ESA and to ensure the continued existence of viable, well-distributed populations. A "Sensitive Species" is any species of plant or animal that has been recognized by the Regional Forester to need special management to prevent the species from becoming threatened or endangered.

Shasta-Trinity National Forest Land and Resource Management Plan

The *Shasta-Trinity National Forest Land and Resource Management Plan* (STNF LRMP) contains forest goals, standards, and guidelines designed to guide the management of the Shasta-Trinity National Forest. The following goals, standards, and guidelines related to wildlife resource issues associated with the study area were excerpted from the *Shasta-Trinity National Forest Land and Resource Management Plan* (USFS 1995).

Biological Diversity

Goals (STNP LRMP, p. 4-4) Integrate multiple resource management on a landscape level to provide and maintain diversity and quality of habitats that support viable populations of plants, fish, and wildlife.

Standards and Guidelines (STNF LRMP, p. 4-14)

- **Natural Openings –** Management of natural openings will be determined at the project level consistent with desired future conditions.

- **Snags –** Over time, provide the necessary number of replacement snags to meet density requirements as prescribed for each land allocation and/or management prescription. Live, green culls and trees exhibiting decadence and/or active wildlife use are preferred.

- **Hardwood –** Apply the following standards in existing hardwood types:

  - Manage hardwood types for sustainability.

  - Conversion to conifers will only take place to meet desired future ecosystem conditions.

  - Where hardwoods occur naturally within existing conifer types on suitable timber lands, manage for a desired future condition for hardwoods as identified during ecosystem analysis consistent with management prescription standards and guidelines. Retain groups of hardwoods over single trees.

Threatened, Endangered, and Sensitive Species (Plants and Animals)

Goals (STNF LRMP, p. 4-5)

- Monitor and protect habitat for Federally listed Threatened and Endangered and candidate species. Assist in recovery efforts for Threatened and Endangered species. Cooperate with the State to meet objectives for State-listed species.

- Manage habitat for sensitive plants and animals in a manner that will prevent any species from becoming a candidate for Threatened and Endangered status.

Goals (STNF LRMP, p. 4-6)

- Meet habitat or population objectives established for management indicators.
- Cooperate with Federal, State, and local agencies to maintain or improve wildlife habitat.
- Maintain natural wildlife species diversity by continuing to provide special habitat elements within Forest ecosystems.

Standards and Guidelines (STNF LRMP, pp. 4-29 through 4-30)

- Minimize accidental electrocution of raptors by ensuring that newly constructed overhead power lines meet safe design standards.
- Consider transplants, introductions, or reintroductions of wildlife species only after ecosystem analysis and coordination with other agencies and the public.
- Manage habitat for neotropical migrant birds to maintain viable population levels.
- Develop interpretation/view sites for wildlife viewing, photography, and study. Provide pamphlets, slide shows, and other educational material that enhance the watchable wildlife and other interpretive programs.
- Maintain and/or enhance habitat for Federally listed threatened and endangered or USFS sensitive species consistent with individual species recovery plans.

U.S. Forest Service Survey and Manage

Standards and Guidelines The 1994 ROD for Amendments to Forest Service and Bureau of Land Management Planning Documents Within the Range of the Northern Spotted Owl and Standards and Guidelines for Management for Late-Successional and Old-Growth Related Species in the Range of the Northern Spotted Owl (NWFP ROD) amended or was incorporated into BLM and USFS land management plans to require certain actions for rare amphibians, mammals, bryophytes, mollusks, vascular plants, fungi, lichens, and arthropods that occupy late-successional and old-growth forests (USFS and BLM 1994). These rare species were identified in Appendix C of the NWFP ROD collectively as S&M species. The NWFP ROD also established protection buffers on matrix lands for certain species (i.e., protection buffer species) that were not on the 1994 S&M list and required that those buffers be managed as part of the Late Successional Reserve network. Four survey strategies were developed to guide management of S&M species: (1) manage known sites, (2) survey before ground-disturbing activities, (3) conduct extensive surveys, and (4) conduct general regional surveys.

The NWFP ROD also established overall objectives for managing S&M species populations that were referred to as “persistence objectives.” These objectives were based on the USFS viability provision in the 1982 National Forest System Land and Resource Management Planning Regulation for the National Forest Management Act of 1976. This provision is targeted toward vertebrate species, but also was applied to nonvertebrate species to the greatest extent practicable, as described in the NWFP ROD. The provision generally states that the USFS will manage habitat “to maintain viable populations of existing native and desired non-native vertebrate species in the planning area” (36 CFR 219.19). Although the viability standard is part of the USFS planning regulations, the protections for S&M species were also applied to BLM lands in the NWFP ROD with a goal of protecting the long-term health and sustainability of all Federal forests within the range of the northern spotted owl and the species that inhabit them. Because of the uncertainty associated with the continued persistence of species due to natural factors, the NWFP ROD noted that compliance with the planning regulations is not subject to precise numerical interpretations and cannot be fixed at any single threshold; rather, “as in any administrative field, common sense and agency expertise must be applied” (NWFP ROD, p. 44).

The 2001 S&M ROD (USFS and BLM 2001) modified the management direction provided in the NWFP ROD for S&M and protection buffer species and amended BLM and USFS land management plans in the range of the northern spotted owl accordingly. The list of S&M species was also modified to remove 72 species in all or part of their range because new information indicated they were secure or otherwise did not meet the basic criteria for S&M. Species remaining on the list were assigned to one of six categories using the following criteria: their relative rarity, the ability to reasonably and consistently locate occupied sites during surveys before habitat- disturbing activities, and the level of information known about the species or group of species. The 2001 S&M ROD also removed the direction specific to protection buffer species, excluding these species from S&M Standards and Guidelines requirements. As part of the 2001 Standards and Guidelines, objectives, criteria, and management direction were defined for each category. Specific criteria were also established to add, remove, or change species categories based on new information and as part of the annual species review processes.

In 2004 and again in 2007, the BLM and USFS issued a ROD to eliminate the S&M requirements of the 2001 S&M ROD and to provide protection for species on the S&M lists by managing them under the agencies’ special-status species programs. As a result of litigation, the requirements of the 2001 S&M ROD were reinstated. In a subsequent court-mandated settlement agreement (USFS and BLM 2011), the list of S&M species was modified. The settlement agreement also made the following modifications: (1) acknowledged existing exemption categories (2006 Pechman Exemptions), (2) updated the 2001 S&M species list, (3) established a transition period for application of the species list, and (4) established new exemption categories (2011 Exemptions). Agency decisions made after September 30, 2012, are required to use the 2011 S&M list. Some species considered in the S&M program also occur on non-Federal lands. The requirements of the 1994 NWFP ROD and 2001 S&M ROD as modified under the 2011 Settlement Agreement apply only to lands managed by the BLM and USFS within the range of the northern spotted owl. The 2011 Settlement Agreement was later struck down by the court and the S&M program has reverted to the requirements of the 2001 S&M ROD with the 2006 Pechman Exemptions still intact.

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The *Management Guide for the Whiskeytown-Shasta-Trinity National Recreation Area*, including the Shasta Unit of the NRA, contains management guidance intended to achieve or maintain a desired condition (USFS 2014). These strategies take into account opportunities, management recommendations for specific projects, and mitigation measures needed to achieve specific goals. The following guidance relative to wildlife resource issues associated with the project site were excerpted from the management guide.

Maintaining Key Wildlife Habitat Components

- Limestone outcrops within the Shasta Unit are recognized as a unique habitat component for various wildlife species. The cool moist microclimate present within these outcrops provides the habitat to escape the hot, dry summer season. Maintaining limestone habitats is a top priority within the NRA. Actions which could negatively impact limestone habitats (road building, dozer-line construction, piling and burning) will be avoided if limestone habitats would be degraded.

- Due to the important role down woody material and snags play in the ecosystem, design projects to maintain large down logs and large snags. In general, down logs and snags will be retained unless they pose a direct risk to public safety. It is recognized that projects implementing prescribed fire will directly impact large snags and logs. These projects are encouraged, as they are essential in maintaining a healthy and diverse ecosystem. It is also recognized that the effects of prescribed fire on snags and down logs is a dynamic process, as fire will consume some snags and logs, but also some trees are killed by fire, which provides for recruitment of new snags and logs.

- Bald eagle nest territories will be inventoried and vegetation management plans will be developed to ensure that suitable nest and perch trees are maintained over time.

- Chaparral and woodland habitat management will occur to meet wildlife objectives.
- Interpretive materials will address the need to conserve rare plant communities in accordance with the NRA Interpretive Plan.
- Diversity of native species will be emphasized. Eradication program will be implemented for nonnative, introduced species in areas where healthy, botanically diverse plant communities are necessary to meet ecosystem management objectives.

Wildlife

- Management activities will assure population viability for all native and nonnative desirable species. Management to insure viability will occur within occupied habitat for bald eagle, peregrine falcon, northern spotted owl, northern goshawk, willow flycatcher, northwestern pond turtle, Pacific fisher, Shasta salamander, and other special-status species in accordance with species and/or territory management plans, Forest Orders, and appropriate laws and policy.
- Surveys will continue within potential suitable habitats to determine occupancy status for Threatened, Endangered, sensitive, and candidate species.
- Cooperation will continue with the CDFW and the USFWS regarding habitat management of wildlife species inhabiting the National Recreation Area. Consultation with USFWS will continue regarding habitat management for threatened and endangered species.

U.S. Bureau of Land Management Resource Management Plan

BLM manages a number of public land areas within the primary study area, including the Shasta/Chappie Off-Highway Vehicle Area west of Shasta Dam. These areas fall under the Northern California BLM district and the resource management plan of the Redding BLM field office. The purpose of BLM’s resource management plans is to provide overall direction for managing and allocating public resources in the planning area. BLM is responsible for administering the following strategies related to resource issues common to the portion of the Redding Resource Area lands located near the study area and vicinity (BLM 1992, 1993, 2005).

- Provide a regional opportunity for motorized recreation with a focus within the Shasta/Chappie Off-Highway Vehicle Area.
- Enhance non-motorized recreation opportunities within the area via a greenway connecting Redding to Shasta Dam along the Sacramento River.

- Maintain or improve the long-term sustained yield of forest products available from commercial forest lands.
- Improve the long-term condition and protection of deer winter range habitat.
- Maintain special-status species habitat.
- Maintain the existing scenic quality of the areas.
- Maintain opportunities to explore and develop freely available minerals on public lands.

Section 404 of the Clean Water Act

USACE regulates discharges of dredged or fill materials into waters of the United States under Section 404 of the Clean Water Act. Waters of the United States include lakes, rivers, streams, and relatively permanent tributaries and adjacent wetlands. Wetlands are defined under Section 404 as areas that are inundated or saturated by surface water or groundwater at a frequency and duration sufficient to support (and that do support under normal circumstances) a prevalence of vegetation typically adapted for life in saturated soil conditions. Activities that require a permit under Section 404 include but are not limited to placing fill or riprap, grading, mechanized land clearing, and dredging. Any activity that results in the deposit of dredged or fill material below the ordinary high-water mark of waters of the United States or within a jurisdictional wetland usually requires a Section 404 permit, even if the area is dry at the time the activity takes place.

Executive Order 11312: Invasive Species

Executive Order 11312 directs Federal agencies to use relevant programs and authorities to do all of the following:

- Prevent the introduction of invasive species
- Detect and respond rapidly to and control populations of such species in a cost-effective and environmentally sound manner
- Monitor invasive species populations accurately and reliably
- Provide for restoration of native species and habitat conditions in ecosystems that have been invaded
- Conduct research on invasive species and develop technologies to prevent introduction and provide for environmentally sound control of invasive species

- Promote public education on invasive species and the means to address them

- Refrain from authorizing, funding, or carrying out actions that it believes are likely to cause or promote the introduction or spread of invasive species in the United States or elsewhere unless, pursuant to guidelines that it has prescribed, the agency has determined and made public its determination that the benefits of such actions clearly outweigh the potential harm caused by invasive species; and that all feasible and prudent measures to minimize risk of harm will be taken in conjunction with the actions

Executive Order 11312 established a national Invasive Species Council made up of Federal agencies and departments and a supporting Invasive Species Advisory Committee composed of State, local, and private entities. The Invasive Species Council and Advisory Committee oversee and facilitate implementation of the executive order, including preparation of a national invasive species management plan.

Executive Order 11990: Protection of Wetlands

Executive Order 11990 established the protection of wetlands and riparian systems as the official policy of the Federal government. It requires all Federal agencies to consider wetland protection as an important part of their policies and take action to minimize the destruction, loss, or degradation of wetlands, and to preserve and enhance the natural and beneficial values of wetlands.

Executive Order 13186: Migratory Birds

Executive Order 13186 directs executive departments and agencies to take certain actions to further implement the MBTA. It requires that each Federal agency taking actions that have, or are likely to have, a measurable negative effect on migratory bird populations develop and implement a memorandum of understanding with USFWS that shall promote the conservation of migratory bird populations.

Executive Order 13443: Facilitation of Hunting Heritage and Wildlife Conservation

Executive Order 13443 directs Federal agencies that have programs and activities that have a measurable effect on public land management, outdoor recreation, and wildlife management, including the U.S. Department of the Interior and the U.S. Department of Agriculture, to facilitate the expansion and enhancement of hunting opportunities and the management of game species and their habitat.

13.2.2 State

California Endangered Species Act

Under the CESA, CDFW has the responsibility for maintaining a list of endangered and threatened species (California Fish and Game Code Section 2070). CDFW also maintains a list of “candidate species,” which are species for which CDFW has issued a formal notice that they are under review for addition to the list of endangered or threatened species. In addition, CDFW maintains lists of “species of special concern,” which serve as species “watch lists.” Pursuant to the requirements of CESA, an agency reviewing a proposed project within its jurisdiction must determine whether any State-listed endangered or threatened species may be present in the project study area and, if so, whether the proposed project would have a potentially significant impact on any of these species. In addition, CDFW encourages informal consultation on any proposed project that may affect a species that is a candidate for state listing.

Project-related impacts on species listed as endangered or threatened under the CESA would be considered significant. State-listed species are protected under the mandates of the CESA. “Take” of protected species incidental to otherwise lawful management activities may be authorized under Section 2081 of the California Fish and Game Code. Under the CESA, “take” is defined as an activity that would directly or indirectly kill an individual of a species, but the definition does not include “harm” or “harass,” as the Federal act does. As a result, the threshold for take under the CESA is higher than that under the ESA.

Authorization from CDFW would be in the form of an incidental take permit or as a consistency determination (Fish and Game Code Section 2080.1(a)). Fish and Game Code Section 2080.1(a) authorizes CDFW to accept a Federal biological opinion (BO) as the take authorization for a State-listed species when a species is listed under both the ESA and the CESA.

Sections 3503 and 3513 of the California Fish and Game Code – Protection of Birds of Prey

Under California Fish and Game Code Section 3503, it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird, except as otherwise provided in other sections. Section 3503.5 specifically states that it is unlawful to take, possess, or destroy any raptors (birds in the order of Falconiformes or Strigiformes (birds of prey) – i.e., eagles, hawks, owls, and falcons), including their nests or eggs. Section 3513 provides for adoption of the MBTA’s provisions. It states that it is unlawful to take or possess any migratory nongame bird as designated in the MBTA or any part of such migratory nongame bird. These State codes offer no statutory or regulatory mechanism for obtaining an incidental take permit for the loss of nongame, migratory birds. Typical violations include destruction of active raptor nests resulting from removal of vegetation in which the nests are located. Violation of Sections 3503.5 and 3513 could also include disturbance of nesting pairs that results in failure of an active raptor nest.

Fully Protected Species Under the Fish and Game Code

Protection of fully protected species is described in California Fish and Game Code Sections 3511, 4700, 5050, and 5515, which list 37 fully protected species. These statutes prohibit take or possession at any time of fully protected species. CDFW is unable to authorize incidental take of fully protected species when activities are proposed in areas inhabited by those species. CDFW has informed non-Federal agencies and private parties that they must avoid take of any fully protected species in carrying out projects.

Section 1602 of the California Fish and Game Code – Streambed Alteration

Diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by CDFW, pursuant to California Fish and Game Code Section 1602. The regulatory definition of a stream is a body of water that flows at least periodically or intermittently through a bed or channel having banks and supports wildlife, fish, or other aquatic life. This includes watercourses that have a surface or subsurface flow that supports or has supported riparian vegetation. CDFW's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife. A CDFW streambed alteration agreement must be obtained for a project that would result in an impact on a river, stream, or lake.

Section 401 Water Quality Certification/Porter-Cologne Water Quality Control Act

Under Section 401 of the Clean Water Act, an applicant for a Section 404 permit must obtain a certificate from the appropriate State agency stating that the intended dredging or filling activity is consistent with the State's water quality standards and criteria. In California, the authority to grant water quality certification is delegated by the State Water Resources Control Board to the nine regional water quality control boards (regional water boards). Each of the regional water boards must prepare and periodically update basin plans for water quality control in accordance with the Porter-Cologne Water Quality Control Act. Each basin plan sets forth water quality standards for surface water and groundwater, as well as actions to control nonpoint and point sources of pollution to achieve and maintain these standards. Basin plans offer an opportunity to protect wetlands through the establishment of water quality objectives. The regional water boards' jurisdiction includes Federally protected waters as well as areas that meet the definition of "waters of the state." A water of the State is defined as any surface water or groundwater, including saline waters, within the boundaries of California. The regional water boards have the discretion to take jurisdiction over areas not Federally protected under Section 401, provided that those areas meet the definition of waters of the State. Mitigation requiring no net loss of wetlands functions and values of waters of the State is typically required by the regional water board.

California Department of Fish and Wildlife Species Designations

CDFW maintains an informal list of species called "species of special concern." These are broadly defined as plant and wildlife species that are of concern to CDFW because of population declines and restricted distributions, and/or because they are associated with habitats that are declining in California. These species are inventoried in the CNDDB regardless of their legal status. Impacts on species of special concern may be considered significant.

13.2.3 Regional and Local

Shasta, Tehama, Glenn, Sutter, Sacramento, and Yolo counties and the cities of Redding, Colusa, and Sacramento have established codes and policies that address protection of natural resources, including vegetation, sensitive species, and trees, and are applicable to the project.

Shasta County's general plan emphasizes that the maintenance and enhancement of quality fish and wildlife habitat is critical to the recreation and tourism industry, and acknowledges that any adverse and prolonged decline of these resources could result in negative impacts on an otherwise vibrant industry. The general plan identifies efforts to protect and restore these habitats to sustain the long-term viability of the tourism and recreation industry (Shasta County 2004).

The City of Redding's general plan strives to strike a balance between development and conservation by implementing several measures, such as creek-corridor protection, sensitive hillside development, habitat protection, and protection of prominent ridge lines that provide a backdrop to the city (City of Redding 2000).

Tehama County's general plan update provides an overarching guide to future development and establishes goals, policies, and implementation measures designed to address potential changes in county land use and development. The general plan identifies the importance of retaining agriculture as one of the primary uses of land in Tehama County (Tehama County 2009).

Glenn County's general plan provides a comprehensive plan for growth and development in Glenn County for the next 20 years (2007–2027). This plan recognizes that public lands purchased for wildlife preservation generate economic activity as scientists and members of the public come to view and study remnant ecosystems (Glenn County 1993).

The City of Colusa's general plan seeks to promote its natural resources through increased awareness and improved public access (City of Colusa 2007).

Sutter County's general plan contains policies that generally address preservation of natural vegetation, including wetlands. It requires that new development mitigate the loss of Federally protected wetlands to achieve "no net loss," but it does not include any other specific requirements (Sutter County 2010).

Sacramento County's general plan contains goals and policies that promote management, protection, and restoration of natural habitats and sensitive species of plants and animals throughout the county (Sacramento County 2011). This includes policies for "no net loss" of riparian and oak woodland. The Sacramento County general plan includes specific setbacks from streams that can be 200 feet wide; development within setbacks is prohibited except for passive recreation and stormwater facilities in the outside-most 50 feet. It also addresses the need to conserve vernal pools and ephemeral wetlands to ensure no net loss of vernal pool acreage. Several policies specifically promote protection of native oak trees, and, in some areas of the county, seek to ensure that there is no net loss of canopy area.

Chapter 12.56, "Trees Generally," of the City of Sacramento Municipal Code addresses the protection of trees within the city boundaries, including general protection of all trees on city property and specific protection of heritage trees.

Yolo County's general plan aims to provide an active and productive buffer of farmland and open space separating the Bay Area from Sacramento, and integrating green spaces into its communities (Yolo County 2009).

13.2.4 Federal, State, and Local Programs and Projects

California Bay-Delta Authority

The California Bay-Delta Authority (CBDA) was established as a State agency in 2003 to oversee implementation of CALFED for the numerous Federal and State agencies working cooperatively to improve the quality and reliability of California's water supplies while restoring the Bay-Delta ecosystem. The July 2000 CALFED *Final Programmatic EIS/EIR* (CALFED 2000c) analyzed a range of alternatives to address these needs and included a MSCS to provide a framework for compliance with ESA, CESA, and Natural Community Conservation Planning Act. The August 2000 CALFED Programmatic ROD identified 12 action plans, including Ecosystem Restoration, Watersheds, and Water Supply Reliability, among others (CALFED 2000d). The Ecosystem Restoration Program has provided a funding source for projects that include those involving acquisition of lands within the Sacramento River Conservation Area, initial baseline monitoring and preliminary restoration planning, and preparation of long-term habitat restoration management and monitoring plans. In 2009, the California Legislature passed sweeping water reform legislation, including the establishment of the Delta Stewardship Council (DSC). The DSC was transferred all the responsibilities, programs, staff and most of the funding from the CBDA, and the CBDA was dissolved. The DSC was also given additional mandates, including the development of a Delta Plan to guide activities and programs of State and local programs in the legal Delta through a consistency determination process.

Cantara Trustee Council

The Cantara Trustee Council administers a grant program that has provided funding for numerous environmental restoration projects in the primary study area, including programs in the Fall River watershed, Sulphur Creek, the upper Sacramento River, Middle Creek, lower Clear Creek, Battle Creek, Salt Creek, and Olney Creek. The Cantara Trustee Council is a potential local sponsor for future restoration actions in the primary study area. The Cantara Trustee Council includes representatives from CDFW, USFWS, the Central Valley RWQCB, the California Sportfishing Protection Alliance, and the Shasta Cascade Wonderland Association.

Resource Conservation Districts

There are numerous resource conservation districts (RCD) within the study area. Once known as soil conservation districts, RCDs were established under California law with a primary purpose to implement local conservation measures. Although RCDs are locally governed agencies with locally appointed, independent boards of directors, they often have close ties to county agencies and the U.S. National Resources Conservation Service. RCDs are empowered to conserve resources within their districts by implementing projects on public and private lands and to educate landowners and the public about resource conservation. They are often involved in the formation and coordination of watershed working groups and other conservation alliances. In the Shasta Lake and upper Sacramento River vicinity, districts include the Western Shasta County RCD and the Tehama County RCD. To the east are the Fall River and Pit River RCDs, and to the west and north are the Trinity County and Shasta Valley RCDs.

Riparian Habitat Joint Venture

The Riparian Habitat Joint Venture (RHJV) was initiated in 1994 and includes signatories from 18 Federal, State, and private agencies. The RHJV promotes conservation and the restoration of riparian habitat to support native bird population through three goals:

- Promote an understanding of the issues affecting riparian habitat through data collection and analysis.
- Double riparian habitat in California by funding and promoting on-the-ground conservation projects.
- Guide land managers and organizations to prioritize conservation actions.

RHJV conservation and action plans are documented in *The Riparian Bird Conservation Plan* (RHJV 2004). The conservation plan targets 14 “indicator” species of riparian-associated birds and provides recommendations for habitat protection, restoration, management, monitoring, and policy. The report notes habitat loss and degradation as one of the most important factors causing the decline of riparian birds in California. The RHJV has participated in monitoring efforts within the Sacramento National Wildlife Refuge Complex and other conservation areas. The RHJV's conservation plan identifies lower Clear Creek as a prime breeding area for yellow warblers (*Setophaga petechia*) and song sparrows (*Melospiza melodia*), advocating a continuous riparian corridor along lower Clear Creek.

Sacramento River Advisory Council

In 1986 the California Legislature passed Senate Bill 1086, which called for a management plan for the Sacramento River and its tributaries to protect, restore, and enhance fisheries and riparian habitat in an area stretching from the confluence of the Sacramento River with the Feather River and continuing northward to Keswick Dam about 4 miles north of Redding. The law established an advisory council that included representatives of Federal and State agencies, county supervisors, and representatives of landowners, water contractors, commercial and sport fisheries, and general wildlife and conservation interests. Responsibilities of the advisory council included development of the *Sacramento River Conservation Area Forum Handbook* (Resources Agency 2003). This action also resulted in formation in May 2000 of the Sacramento River Conservation Area Forum, a nonprofit, public benefit corporation with a board of directors that includes private landowners and public interest representatives from a seven-county area, an appointee of the Resources Agency, and ex-officio members from six Federal and State resource agencies.

Sacramento River Conservation Area Program

The Sacramento River Conservation Area Program has an overall goal of preserving remaining riparian habitat and reestablishing a continuous riparian ecosystem along the Sacramento River between Redding and Chico, and reestablishing riparian vegetation along the river from Chico to Verona. The program is to be accomplished through an incentive-based, voluntary river management plan. The *Upper Sacramento River Fisheries and Riparian Habitat Management Plan* (Resources Agency 1989), identifies specific actions to help restore the Sacramento River fishery and riparian habitat between the Feather River and Keswick Dam. The *Sacramento River Conservation Area Forum Handbook* (Resources Agency 2003) is a guide to implementing the program. The Keswick Dam to Red Bluff portion of the conservation area includes areas within the 100-year floodplain, existing riparian bottomlands, and areas of contiguous valley oak woodland, totaling approximately 22,000 acres. The 1989 fisheries restoration plan recommended several actions specific to the study area:

- Fish passage improvements at Red Bluff Diversion Dam (completed)
- Modification of the Spring Creek Tunnel intake for temperature control (completed)

- Spawning gravel replacement program (ongoing)
- Development of side-channel spawning areas, such as those at Turtle Bay in Redding (ongoing)
- Structural modifications to the Anderson-Cottonwood Irrigation District Dam to eliminate short-term flow fluctuations (completed)
- Maintaining instream flows through coordinated operation of water facilities (ongoing)
- Improvements at the Coleman National Fish Hatchery (partially complete)
- Measures to reduce acute toxicity caused by acid mine drainage and heavy metals (ongoing)
- Various fisheries improvements on Clear Creek (partially complete)
- Flow increases, fish screens, and revised gravel removal practices on Battle Creek (beginning summer 2006, ongoing monitoring)
- Control of gravel mining, improvements of spawning areas, improvements of land management practices in the watershed, and protection and restoration of riparian vegetation along Cottonwood Creek (ongoing)

Sacramento River National Wildlife Refuge

The Sacramento River National Wildlife Refuge (SRNWR) is composed of many units between the cities of Red Bluff and Princeton. The SRNWR along the middle Sacramento River is part of the Sacramento National Wildlife Refuge Complex, consisting of five refuges and three wildlife management areas within the Sacramento Valley. Reaches and subreaches of the river are delineated based generally on transitions in fluvial geomorphic riverine conditions, although county boundaries were considered as well. The middle Sacramento River region between Red Bluff and Colusa includes three units within the Chico Landing Subreach that contain restoration project sites addressed in the *Sacramento River–Chico Landing Subreach Habitat Restoration Draft Environmental Impact Report* (CBDA 2005). In addition, three areas proposed for restoration in this area occur within the larger SRNWR units that were evaluated in the *Environmental Assessment for Proposed Restoration Activities on the Sacramento River National Wildlife Refuge* (USFWS 2001; CBDA 2005).

In June 2005, USFWS issued the *Sacramento River National Wildlife Refuge Final Comprehensive Conservation Plan and Environmental Assessment and Finding of No Significant Impact* (USFWS 2005b) to serve as an integrated management plan for land that it acquires and manages for inclusion in the SRNWR. The SRNWR final comprehensive conservation plan includes goals, objectives, and strategies to guide management of lands within the SRNWR. It also includes assessments of and establishes parameters for “compatible uses,” which are uses that are considered compatible with the primary purposes for which the area was established. Riparian habitat restoration projects are being implemented under cooperative agreements between USFWS and other entities, such as The Nature Conservancy (TNC), in accordance with the SRNWR final comprehensive conservation plan.

Sacramento River Wildlife Area

The Sacramento River Wildlife Area is managed by CDFW and consists of approximately 3,770 acres of important riparian habitat located along a 70-mile reach of the lower Sacramento River. These lands are managed to protect and enhance habitat for wildlife species, and to provide the public with compatible, wildlife-related recreational uses. This management is guided by the *Sacramento River Comprehensive Management Plan* prepared in 2004.

Sacramento River Preservation Trust

The Sacramento River Preservation Trust is a private, nonprofit organization active in environmental education and advocacy to preserve the natural environmental values of the Sacramento River. The trust has participated in various conservation and land acquisition projects, including securing lands for the SRNWR. The group is pursuing designation of a portion of the Sacramento River between Redding and Red Bluff as a national conservation area.

Sacramento River Watershed Program

The Sacramento River Watershed Program is an effort to bring stakeholders together to share information and work together to address water quality and other water-related issues within the Sacramento River watershed. The group is funded congressionally through the U.S. Environmental Protection Agency. The program’s primary goal is “to ensure that current and potential uses of Sacramento River watershed resources are sustained, restored, and where possible, enhanced while promoting the long-term social and economic vitality of the region.” The Sacramento River Watershed Program manages grants for the Sacramento River Toxic Pollutants Control Program; performs extensive water quality monitoring and data collection and management for the watershed; and is instrumental in the study and monitoring of toxic pollutants. Although the program does not implement restoration projects, it is a potential partner for coordinating research and monitoring through consensus-based collaborative partnerships and promoting mutual education among the stakeholders of the Sacramento River watershed.

Sacramento Watersheds Action Group

The Sacramento Watersheds Action Group is a nonprofit corporation that secures funding for, designs, and implements projects that provide watershed restoration, streambank and slope stabilization, erosion control, watershed analysis, and road removal. The Sacramento Watersheds Action Group has successfully worked with local groups, agencies, and organizations to fund and complete restoration projects on the Sacramento River and tributaries downstream from Keswick Dam. Their projects include development of the *Sulphur Creek Watershed Analysis and Action Plan*, the Whiskeytown Reservoir Shoreline Erosion Control Project, the Sulphur Creek Crossing Restoration Project, and the Lower Sulphur Creek Realignment and Riparian Habitat Enhancement Project. The Sacramento Watersheds Action Group is a potential local sponsor for watershed restoration actions in the study area.

Shasta Land Trust

The Shasta Land Trust is a regional, nonprofit organization dedicated to conserving open space, wildlife habitat, and agricultural land. This organization works with public agencies and private landowners and is funded primarily through membership dues and donations. It employs various voluntary programs to protect and conserve valuable lands using conservation easements, land donations, and property acquisitions. The trust is a potential local partner for restoration activities in the Shasta Dam to Red Bluff area.

The Nature Conservancy

TNC is a private, nonprofit organization involved in environmental restoration and conservation throughout the United States and the world. TNC approaches environmental restoration primarily through strategic land acquisition from willing sellers and obtaining conservation easements. Some of the lands are retained by TNC for active restoration, research, or monitoring activities, while others are turned over to government agencies, such as USFWS or CDFW, for long-term management. Lower in the Sacramento River basin, TNC has been instrumental in acquiring and restoring lands in the SRNWR and managing several properties along the Sacramento River. It also has pursued conservation easements on various properties at tributary confluences, including Cottonwood and Battle creeks.

The Trust for Public Land

The Trust for Public Land is a national, nonprofit organization involved in preserving lands with natural, historic, cultural, or recreational value, primarily through conservation real estate. This organization's Western Rivers Program has been involved in conservation efforts along the Sacramento River between Redding and Red Bluff (BLM's Sacramento River Bend Management Area), Battle Creek, Paynes Creek, Inks Creek, and Fenwood Ranch in Shasta County. The group promotes public ownership of conservation lands to ensure public access and enjoyment.

13.3 Environmental Consequences and Mitigation Measures

This section describes the environmental evaluation methods, assumptions, and specific criteria used to determine significance for each resource area, and discusses impacts and proposed mitigation measures. This impacts assessment evaluates the project's compliance with requirements outlined in the *Wildlife Resources Technical Report*. Mitigation measures are presented (as needed) to reduce impacts to a less-than-significant level.

13.3.1 Methods and Assumptions

The following sections describe the methods, processes, procedures, and assumptions used to formulate and conduct the environmental impact analysis.

This analysis of impacts on wildlife resources resulting from implementation of the project alternatives under consideration is based on review of existing documentation that addresses biological resources in or near the primary and extended study areas and on geographic information systems analysis.

Where specific habitat data were not available, suitable habitat data defined by California Wildlife Habitat Relationships (CWHR) were used to determine impacts.

The following assumptions about activity at Shasta Lake and vicinity have been made for the purposes of the impact analysis:

- Activity areas (construction areas for infrastructure and relocation areas) would be completely cleared.
- Cutting/clearing of vegetation would be conducted from late summer through late winter, to the extent feasible.
- Removal of cleared material could occur during the typical breeding season for birds in Shasta County.
- Removal of cleared vegetation would be done using conventional yarding systems and aerial (helicopter) systems.
- With the exception of Arbuckle Flat, no vegetation would be removed along the Pit Arm upstream from Painter Creek.
- No blasting would be required for the mining of materials within the current boundary of Shasta Lake.

For the upper Sacramento River and extended study area, the project has the potential to affect common wildlife and special-status wildlife species through the following impact mechanisms:

- Change in inundated width of the river from spring through fall
- Reduced frequency, duration, or magnitude of intermediate to large flows

- Altered geomorphic processes (e.g., meander, channel avulsion) along rivers
- Altered availability of groundwater
- Altered vegetative communities within the river corridor, including construction-related changes at the potential restoration sites
- Temporary or permanent disturbance of habitat at restoration and gravel augmentation sites
- Mortality of individuals of special-status species at restoration and gravel augmentation sites

Potential effects on the upper Sacramento River and extended study area resulting from these impact mechanisms were assessed for common wildlife and special-status wildlife species associated with riparian and wetland habitats located between Shasta Dam and the Red Bluff Pumping Plant and within the extended study area that may be affected by altered hydrologic flows. It is assumed that construction-related activities at the dam, their effects, and mitigation were considered in the "Shasta Lake and Vicinity" section.

The assessment of potential effects on resources downstream from Keswick Dam was based on review of the output from the SLWRI 2012 Version CalSim-II model. Monthly averages by water year type[1] were reviewed for substantial trends in stage or flow that could alter habitat used by sensitive species or affect species directly. Trend data generated by CalSim-II were considered representative of the potential changes resulting from the project alternatives. A change of less than 2 percent (plus or minus) was considered essentially equivalent to baseline operations and therefore not a substantial change. When monthly average values were changed more than 2 percent, the alternative was considered to result in a substantial change in a species habitat or directly affect the species. Monthly flow results were used to simulate mean daily flows. The use of monthly averages in the evaluation was considered more representative of potential long-term changes in flows than values from the individual months. Results for individual months (e.g., December 1944) were not used in this analysis because the extreme values presented there are sometimes artifacts of model operations and not indicative of how the system would actually operate. See Section 12.3, "Methods and Assumptions," in Chapter 12, "Botanical Resources and Wetlands," for a more detailed discussion of this modeling. The differences in flow regime among the alternatives are described in detail in Chapter 6, "Hydrology, Hydraulics, and Water Management." A more detailed description of the SLWRI 2012 Version CalSim-II model, the modeling

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification, unless specified otherwise.

methodology used to evaluate this project, and key assumptions are provided in the Modeling Appendix.

The CALFED Ecosystem Restoration Program's Sacramento River Ecological Flows Study (TNC et al. 2008) was also consulted during the evaluation of impacts. This report summarizes the results of a multifaceted analysis conducted to determine the effects of the proposed (18.5-foot) raise of Shasta Dam and the proposed North-of-the-Delta Offstream Storage Reservoir facilities on several focal species, including western pond turtle and bank swallow. CalSim data were also used as inputs for this study; hypothetical flow scenarios were based on historical flows recorded at three locations along the Sacramento River. An appendix to this report is the "Linkages Report" (Stillwater Sciences 2007), which focused the mainstem Sacramento River corridor between Keswick Dam and Colusa. The Linkages Report sought to define how flow characteristics (e.g., magnitude, timing, duration, and frequency) and associated management actions (e.g., gravel augmentation, changes in bank armoring) influence the creation and maintenance of habitats for several native species that occur in the Sacramento River corridor.

The SLWRI 2012 Version CalSim-II model was used to aid in the evaluation of potential impacts of the project alternatives on water-related resources, including riparian habitats along the upper and lower Sacramento River and in the Delta. This computer modeling used historical data about California hydrology to represent the variety of weather and hydrologic patterns, including wet periods and droughts, under which water storage and conveyance facilities would be operated. Two scenarios (base cases) of water demands, storage, and conveyance were used in the modeling runs: 2005 facilities and demands ("existing conditions") and forecasted 2030 demands and reasonably foreseeable projects and facilities ("future conditions"). A modeling run was conducted for each of these base cases combined with each alternative, so that the effects of the No-Action Alternative and other alternatives could be evaluated relative to both existing and future conditions. CalSim-II is a useful tool for this type of comparative analysis. The model is run twice: first to represent a base condition (no action), and second with a specific change (action) to assess the differences in results caused by the input change.

Maximum vs. Likely Area of Impact in Relocation Areas

The relocation areas identified by Reclamation in the 2013 Draft EIS were based on preliminary information, as planning and related engineering designs were incomplete at that time. Habitat impacts disclosed for the relocation areas in the June 2013 Draft EIS assumed complete impact (i.e., 100% loss) within all the relocation areas. Since that time, Reclamation revised the relocation area boundaries by conducting additional planning and design that in many cases reduced the size of the relocation areas. Additionally, Reclamation designed infrastructure and other activities within the revised relocation areas to avoid wetlands and other sensitive resources, and reduce habitat impacts to the extent feasible.

Since final relocation area planning and designs are incomplete, each relocation area contains a “maximum” and “likely” impact area. The maximum area of impact is defined as the maximum area potentially impacted by project activities occurring within the relocation areas, while the likely impact area represents Reclamation’s best estimate of the actual impact (i.e., “most likely”). For the purposes of this Administrative Final EIS, habitat impacts are based on the assumption of complete loss within the likely impact areas. Table 13-8 shows a comparison of the maximum and likely CWHR habitats in the relocation areas.

Table 13-8. Summary of "Maximum and Likely" CWHR Wildlife Habitats in the Relocation Areas

Plant Series	Area (Acres)													
	Main Body		Big Back-bone Arm		Sacramento Arm		McCloud Arm		Squaw Creek Arm		Pit Arm		Total	
	Max	Likely	Max	Likely	Max	Likely	Max	Likely	Max	Likely	Max	Likely	Max	Likely

13.3.2 Criteria for Determining Significance of Effects

Significance criteria used to analyze the potential impacts of the project on wildlife resources include factual and scientific information and regulatory standards of county, State, and Federal agencies, including the State CEQA Guidelines. These criteria have been developed to establish thresholds to determine the significance of impacts pursuant to CEQA Section 15064.7 and should not be confused with a "take" or adverse effect under the ESA. An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An EIS must identify reasonable means to "mitigate adverse environmental impacts" (40 E 1502.16(h)). An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (CEQA Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (CEQA Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on wildlife would be significant if project implementation would do any of the following:

- Result in mortality of State-listed or Federally-listed wildlife species, or species that are candidates for listing or proposed for listing

- Have the potential to substantially reduce the habitat of any wildlife species, including those that are listed as endangered or threatened or are candidates or proposed for endangered or threatened status

- Have the potential to cause a wildlife population to drop below self-sustaining levels

- Have a substantial adverse effect, either directly or through habitat modifications, on any non-special-status wildlife species

- Substantially adversely affect, either directly or through habitat modifications, any wildlife species identified as a candidate, sensitive, or special-status species in local or regional plans, policies, or regulations or by CDFW or USFWS

- Interfere substantially with the movement of any native resident or migratory wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites

- Conflict with or violate the provisions of an adopted habitat conservation plan, natural community conservation plan, or other approved local, regional, State, or Federal habitat conservation plan relating to the protection of wildlife species

- Conflict with any State or local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance

- Substantially reduce the habitat of a wildlife species, cause a wildlife species to drop below self-sustaining levels, threaten to eliminate an animal community, or substantially reduce the number or restrict the range of an endangered, rare, or threatened species

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise. Impact conclusions are made using the significance criteria described above and include consideration of the "context" of the action and the "intensity" (severity) of its effects in accordance with NEPA guidance (40 CFR 1508.27).

13.3.3 Topics Eliminated from Further Consideration

No topics related to wildlife resources that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

13.3.4 Direct and Indirect Effects

This section identifies how wildlife could be affected by the project. The project could affect wildlife by doing any of the following:

- Inundating existing habitat around Shasta Lake and causing habitat loss

- Causing construction-related effects at Shasta Dam and around Shasta Lake

- Altering flow regimes downstream from Shasta Lake and downstream from other reservoirs with altered operations

- Increasing water supply reliability, which in turn could contribute to human population growth or changes in agricultural land uses in the CVP and SWP service areas

By altering storage and reservoir operations, the project would change flow regimes in downstream waterways. In turn, these alterations to the flow regime could affect wildlife, particularly by affecting their riparian and wetland habitats along several waterways.

No-Action Alternative

Under the No-Action Alternative, Reclamation would not pursue an action to enlarge Shasta Dam. No new facilities would be constructed at Shasta Dam and no facilities around Shasta Lake would be relocated to accommodate higher lake levels; thus, there would be no construction-related impacts. In addition, releases from Shasta Dam or other CVP reservoirs would not change as a result of a Shasta Dam enlargement. Reasonably foreseeable projects identified elsewhere in this EIS, however, would occur and have effects on wildlife but those effects are unknown or largely speculative for many such projects, and therefore are not addressed in detail below.

Shasta Lake and Vicinity

Impact Wild-1 (No-Action): Impacts on Habitat for the Shasta Salamander No direct take of the Shasta salamander or loss of its habitat would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-2 (No-Action): Impacts on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat No impacts or loss of habitat for the foothill yellow-legged frog or tailed frog would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-3 (No-Action): Impacts on the Northwestern Pond Turtle and Its Habitat No direct take or decrease of habitat quality for the northwestern pond turtle would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-4 (No-Action): Impacts on the American Peregrine Falcon No impact on the American peregrine falcon would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-5 (No-Action): Impacts on Habitat for the Bald Eagle No take of loss of habitat for the bald eagle would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-6 (No-Action): Impacts on Dispersal Habitat for the Northern Spotted Owl No take or loss of nesting and foraging habitat for the northern spotted owl would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-7 (No-Action): Impacts on the Purple Martin and Its Nesting Habitat No impacts or loss of nesting habitat for the purple martin would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-8 (No-Action): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat No impacts or loss of foraging and nesting habitat for the willow flycatcher, Vaux's swift, yellow warbler, and yellow-breasted chat would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-9 (No-Action): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat No impact or loss of foraging and nesting habitat for the long-eared owl, northern goshawk, Cooper's hawk, great blue heron, and osprey would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-10 (No-Action): Impacts on Habitat for the Pacific Fisher No take or loss of habitat for the Pacific fisher would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-11 (No-Action): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, Yuma Myotis, and Fringed myotis), the American Marten, and Ringtail and Their Habitat No impact or loss of habitat for special-status bats (the pallid bat, spotted bat, western red bat, western mastiff bat, Townsend's big-eared bat, long-eared myotis, Yuma Myotis, and fringed myotis), the American marten, and ringtail would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-12 (No-Action): Impacts on Special-Status Terrestrial Mollusks (Church's Sideband, Shasta Sideband, Wintu Sideband, Oregon Shoulderband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat No impact or loss of habitat for special-status terrestrial mollusks (Church's sideband, Shasta sideband, Wintu sideband, Oregon shoulderband, Shasta chaparral, and Shasta hesperian) would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-13 (No-Action): Permanent Loss of Wildlife Habitat and Western Bumble Bee Habitat No permanent loss of habitat would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-14 (No-Action): Impacts on Other Birds of Prey (e.g., red-tailed hawk and Red-shouldered Hawk) and Migratory Bird Species (e.g., American Robin, Anna's Hummingbird) and their Foraging and Nesting Habitat No impact or loss of foraging and nesting habitat for other birds of prey and migratory bird species would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-15 (No-Action): Impacts on Critical Deer Winter and Fawning Range No loss of deer winter and fawning range would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-16 (No-Action): Impacts on California Red-Legged Frog No loss of California red-legged frog habitat would occur because the project would not be constructed. No impact would occur. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (No-Action): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Effects on riparian vegetation in the upper Sacramento River area from continuing the existing dam operation under the No-Action Alternative would not have a substantial adverse effect on special-status wildlife. This impact would be less than significant.

Implementing the No-Action Alternative would not result in changes to existing facilities or reservoir operations. The No-Action Alternative would continue to alter the structure and species composition of riparian vegetation resulting from continued operation of the existing Shasta Dam, as described in Chapter 12, “Botanical Resources and Wetlands.” Operation of the dam has decreased early successional riparian communities and increased the extent of mid-successional riparian communities. Although early and mid-successional riparian vegetation provides different habitat values and some shifts in species use may occur, implementing the No-Action Alternative would not have a substantial adverse effect on special-status wildlife associated with riparian vegetation, nor would it be likely to cause a population to be eliminated. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-18 (No-Action): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes Future conditions for bank swallows are not expected to differ substantially from existing conditions because only very small changes in flows greater than 30,000 cfs (a magnitude that strongly affects bank erosion and meander migration) would occur along the upper Sacramento River (see Section 12.3, “Environmental Consequences and Mitigation Measures” in Chapter 12, “Botanical Resources and Wetlands” [reference Impact Bot-7 (No-Action)]) and would result in no change to the ongoing geomorphic processes in the upper Sacramento River (see Section 11.3, “Environmental Consequences and Mitigation Measures ,” in Chapter 11, “Fisheries and Aquatic Ecosystems” [reference Impact Aqua-14 (No-Action)]).

Because water from high-flow events would be captured and stored and would be metered out in an even fashion, dam operations under the No-Action Alternative would continue with only very small changes in flows and no changes to the ongoing geomorphic processes along the upper Sacramento River. Therefore, future conditions for bank swallows are not expected to differ substantially from existing conditions. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-19 (No-Action): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime The No-Action Alternative would not alter vernal pool hydrology or affect vernal pool–associated wildlife in the upper Sacramento River area. Because the No-Action Alternative would not affect this resource, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-20 (No-Action): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Riparian habitat conditions along the upper Sacramento River under the No-Action Alternative would not differ from baseline conditions. The No-Action Alternative would not conflict with existing plans promoting conservation, protection, and restoration of riparian habitat. Local plans and policies that influence riparian management would remain in place and continue to be locally enforced. Because conditions would not differ from the existing baseline, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-21 (No-Action): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program Under the No-Action Alternative, the gravel augmentation program would not be implemented. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-22 (No-Action): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration Projects Under the No-Action Alternative, none of the restoration work described in Chapter 2, “Alternatives,” would be conducted downstream from Shasta Dam. Thus, special-status wildlife species found in riparian habitat would not be affected. No impact would occur. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta

Impact Wild-23 (No-Action): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Effects on riparian vegetation in the lower Sacramento River and Delta areas from continuing the existing dam operation under the No-Action Alternative would not have a substantial adverse effect on special-status wildlife. This impact would be less than significant.

This impact would be similar to Impact Wild-17 (No-Action) for the primary study area. The No-Action Alternative would continue to alter the structure and species composition of riparian habitat along the lower Sacramento River and into the Delta resulting from continued operation of Shasta Dam. Dam operation, which has led to a decrease in early successional riparian communities and an increase in the extent of mid-successional riparian communities, would continue under the No-Action Alternative. Thus, the No-Action Alternative would affect habitats used by special-status wildlife species because early- and mid-successional riparian vegetation provides different habitat values. However, this change is expected to be small and is not likely to have a substantial adverse effect on special-status species, nor would it be likely to cause a population to be eliminated. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-24 (No-Action): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes
Future conditions for bank swallows along the lower Sacramento River are not expected to differ substantially from existing conditions because only very small changes in flows greater than 30,000 cfs (a magnitude that strongly affects bank erosion and meander migration) would occur along the uppermost portion of the lower Sacramento River (see Section 12.3, “Environmental Consequences and Mitigation Measures” in Chapter 12, “Botanical Resources and Wetlands” [reference Impact Bot-14 (No-Action)]) and no project-related alteration of river flows would occur in the lower Sacramento River (see Section 11.3, “Environmental Consequences and Mitigation Measures” in Chapter 11, “Fisheries and Aquatic Ecosystems” [reference Lower Sacramento River, Tributaries, Delta, and Trinity River subsection under No-Action Alternative)]). This impact would be less than significant.

This impact would be similar to Impact Wild-18 (No-Action) for the primary study area. Dam operations under the No-Action Alternative would continue with only very small changes in flows and the ongoing geomorphic processes along the lower Sacramento River.. Although ongoing dam operations tend to result in the loss of eroding banks during winter flood flows, which could limit the formation of suitable nesting habitat for bank swallow, the future conditions for bank swallows are not expected to differ substantially from existing conditions. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact Wild-25 (No-Action): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability The No-Action Alternative would not affect the hydrology of vernal pools or have an adverse effect on vernal pool–associated wildlife species in the lower Sacramento River and Delta area. Because the No-Action Alternative would not affect this resource, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Wild-26 (No-Action): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta Riparian habitat conditions along the lower Sacramento River or in the Delta would not differ from baseline under the No-Action Alternative. The No-Action Alternative would not conflict with existing plans promoting conservation, protection, and restoration of riparian habitat along the lower Sacramento River and in the Delta. Because conditions would not differ from the existing baseline, no impact would occur. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas

Impact Wild-27 (No-Action): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes Changes to CVP and SWP water deliveries that would occur while the existing dam operation continues under the No-Action Alternative would not have a substantial adverse effect on special-status wildlife. This impact would be less than significant.

This impact would be similar to Impact Wild-17 (No-Action) for the primary study area and Impact Wild-21 (No-Action) for the lower Sacramento River and Delta. Although Shasta Dam would not be altered under the No-Action Alternative, CVP and SWP water storage, conveyance, and deliveries to the CVP and SWP service areas could change because of several reasonably foreseeable projects that could occur with or without enlarging Shasta Dam. CVP and SWP deliveries could increase or decrease based on any number of factors between now and 2030. Given environmental regulations to protect sensitive habitats and species, these changes are not likely to have a substantial adverse effect on special-status species, nor would they be likely to cause a population to be eliminated. For these reasons, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability while contributing to increased survival of anadromous fish, actions that are consistent with the 2000 CALFED Programmatic ROD. In addition to the common features above, CP1 primarily involves raising Shasta Dam 6.5 feet, an elevation change that would increase the reservoir's full pool by 8.5 feet and would enlarge the total storage space in the reservoir by 256,000 acre-feet. Under this plan, Shasta Dam operational guidelines would continue unchanged, with the additional storage retained for water supply reliability and increased anadromous fish survival.

Shasta Lake and Vicinity

Impact Wild-1 (CP1): Take and Loss of Habitat for the Shasta Salamander
Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, S&M species, MSCS-covered species, and BLM sensitive species. Additionally, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

Collectively, 38 Shasta salamander occurrences are known within the impoundment and relocation areas surveyed by Reclamation. Shasta salamanders have been found or are known to occur in nearly every CWHR habitat present along each arm. These known locations occur in CWHR habitats characterized by the presence (limestone habitat) or absence (nonlimestone habitat) of limestone substrate. Within the impoundment area, the presence of the Shasta salamander is presumed in all CHWR habitats, except “non-habitat” barren areas (e.g., paved parking lots, boat ramps). For the purposes of this impact analysis, all CWHR habitats in the impoundment and relocation areas are stratified as limestone or nonlimestone habitat.

Inundation resulting from a 6.5-foot dam raise would result in a loss of approximately 8 acres of limestone habitat and 1,187 acres of nonlimestone habitat. Impacts on limestone and nonlimestone habitats in the impoundment area are summarized in Table 13-9.

Table 13-9. Impacts on Suitable Habitat for the Shasta Salamander in the Impoundment Area (6.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Limestone	0.00	0.82	0.00	5.43	0.00	1.50	7.75
Nonlimestone	222.31	42.48	343.21	199.40	121.55	258.72	1187.67
Total	222.31	43.30	343.21	204.83	121.55	260.22	1195.42

Note:
[1] Acreage values are approximate.

Direct mortality of Shasta salamanders would occur in areas of suitable habitat where complete vegetation clearing is implemented and/or mechanized construction equipment is employed if these activities occur during the wet season when salamanders are on the surface. Construction activities in relocation areas would result in a loss of up to approximately 1 acre of limestone habitat and 424 acres of nonlimestone habitat. This impact would be significant. Impacts on limestone and nonlimestone habitat by CWHR type providing suitable habitat in the relocation areas are summarized in Table 13-10.

Mortality of individuals could occur over multiple years during project implementation if ground-disturbing activities are conducted during the wet season. This impact would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-10. Impacts on Suitable Habitat for the Shasta Salamander in Relocation Areas

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Limestone	0.00	0.00	0.00	0.96	0.00	0.00	0.96
Nonlimestone	127.48	0.00	146.88	108.34	20.86	20.45	424.03
Total	127.48	0.00	146.88	109.30	20.86	22.09	424.99

Note:
[1] Acreage values are approximate.

Impact Wild-2 (CP1): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and the tailed frog, a California species of special concern. Operation of equipment in or adjacent to riverine or riparian habitat would result in direct impacts on these species. In addition, inundation caused by the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. These impacts would be potentially significant.

Foothill yellow-legged frogs occur in many perennial streams within the impoundment area. They have been found in streams on all arms and the main body of the lake. Tailed frogs have not been found during surveys, but there are known occurrences in the McCloud and upper Sacramento arms. CWHR habitat types, montane riparian and riverine, are suitable habitat where these species might occur.

Individual foothill yellow-legged frogs and tailed frogs will not be affected by the inundation caused by the raise of the dam. These animals will be able to swim upstream to suitable habitat.

Although frogs may move out of harm’s way, direct take of foothill yellow-legged frog and tailed frog could also occur as a result of project-associated construction activities in or near suitable aquatic habitat. Potential construction impacts include mortality of individuals because of equipment use and vehicle traffic within suitable aquatic and upland habitat. The potential for direct take would be temporary, occurring only during project construction. Project implementation could result in the degradation of suitable aquatic habitat because of increased erosion, sedimentation, or accidental fuel leaks and spills. These impacts would be potentially significant.

Mortality of individuals could occur over multiple years during project implementation if construction activities are conducted in perennial streams. This impact would be potentially significant.

Implementation of a 6.5-foot dam raise would result in inundation of approximately 35 acres of habitat for the foothill yellow-legged frog and tailed frog. Approximately 0.72 acre of suitable habitat would be lost because of vegetation removal associated with dam construction and construction in the relocation areas. Summaries of suitable habitat loss by arm are presented in Table 13-11. Mitigation for this impact is proposed in Section 13.3.5.

Table 13-11. Impacts on Suitable Habitat for the Foothill Yellow-Legged and Tailed Frog in the Impoundment Area and Relocation Areas (6.5-Foot Dam Raise)

Habitat	Area (Acres[1])

Total	0.08	0.00	0.33	0.25	0.23	0.02	0.72

Note:
[1] Acreage values are approximate.

Impact Wild-3 (CP1): Impact on the Northwestern Pond Turtle and Its Habitat Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take of the northwestern pond turtle, a California species of special concern, a USFS sensitive species, and an MSCS-covered species. These impacts would be potentially significant.

Individual northwestern pond turtles will not be impacted by the inundation caused by the raise of the dam. Lacustrine and riverine are suitable habitats for the northwestern pond turtle.

The northwestern pond turtle occurs throughout the perimeter of the impoundment area. In addition to aquatic habitats, this species uses upland habitats for nesting and overwintering. Nests are generally located on south-facing slopes of less than 60 degrees averaging 200 meters (660 feet) from an aquatic site (CDFG 1994). Thus, loss of upland habitats adjacent to suitable aquatic habitat (within approximately 660 feet) could adversely affect this species.

Direct take of northwestern pond turtle eggs or juveniles could occur during the first inundation of habitat above 1,070 feet above msl. Turtles may lay eggs in suitable habitat that subsequently becomes inundated, resulting in the death of the eggs or overwintering juveniles. In addition, inundation caused by the raising of Shasta Dam would result in the conversion of suitable habitat to unsuitable lacustrine habitat. These impacts would be potentially significant.

Direct take of northwestern pond turtles could also occur as a result of project-associated construction activities in or near suitable aquatic and upland habitat. Potential construction impacts include mortality of individuals because of equipment use and vehicle traffic within suitable aquatic and upland habitat. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion, sedimentation, or accidental fuel leaks and spills. Additionally, it is assumed that all vegetation will be removed within the relocation areas.

Mortality of individuals could occur over multiple years during project implementation if construction activities are conducted in suitable aquatic and upland habitat. This impact would be potentially significant.

Implementation of a 6.5-foot raise of the dam would result in conversion of approximately 35 acres of suitable habitat for the northwestern pond turtle. Approximately 7 acres of riverine habitat would be converted to lacustrine habitat. Because there are equally valuable components lost or gained in either habitat, the quality of the habitat would not be compromised. However, maximum lake elevation is infrequent and would not benefit the species throughout the remainder of the year. Thus, the conversion of suitable habitats to lacustrine habitat remains an impact on northwestern pond turtle habitat.

Approximately 0.72 acre of suitable aquatic habitat would be lost because of vegetation removal associated with dam construction and construction of the relocation areas. Summaries of suitable habitat lost by arm are presented in Table 13-12.

Table 13-12. Impacts on Suitable Habitat for the Northwestern Pond Turtle in the Impoundment Area and Relocation Areas (6.5-Foot Dam Raise)

Habitat	Area (Acres[1])

Total	0.08	0.00	0.33	0.25	0.04	0.02	0.72

Note:
[1]Acreage values are approximate.

Impact Wild-4 (CP1): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected and MSCS-covered species. This impact would be potentially significant.

Cliffs within the Shasta Lake and vicinity portion of the primary study area provide suitable nesting habitat for the peregrine falcon. Overstory and complete vegetation removal is expected to occur within the impoundment area in suitable cliff habitat. Thus, overstory vegetation removal occurring in or near suitable cliff habitat during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests. Additionally, because of the steep terrain, trees would be yarded by helicopter. Noise generated by chainsaws and helicopter yarding could cause the abandonment of nests, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant.

No known eyries would be inundated by a 6.5-foot raise in lake elevation; however, 8.5 vertical feet (full pool) of cliff habitat would be inundated. Peregrine falcons nest on sheer cliffs ranging in height from 75 to 2,000 feet. Eyries are generally located between 40 and 80 percent of total cliff height (Pagel 1992). Based on the large area required for suitable nesting habitat for peregrine falcons, impacts on suitable cliff habitat for nesting would be less than significant. The conversion of uplands to lacustrine habitat would not adversely affect foraging habitat for the species because they frequently forage over water.

Impacts on nesting American peregrine falcons could occur over multiple years during project implementation if construction activities were conducted in or adjacent to active nests. This impact would be potentially significant. Construction or vegetation removal related to relocation areas is not anticipated to occur in suitable cliff habitat. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP1): Take and Loss of Habitat for the Bald Eagle Ground-disturbing activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed, fully protected, and USFS sensitive species, MSCS-covered species, and a BLM sensitive species. This impact would be significant.

Typically, 24 to 28 pairs nest in the vicinity of Shasta Lake. Vegetation removal within the impoundment area could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of bald eagle nests. Noise generated by vegetation removal, such as noise caused by helicopter yarding and chainsaw use, could also lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. The loss of nesting and foraging habitat would be a potentially significant impact.

Three known bald eagle nest trees would be affected by inundation with a 6.5-foot dam raise. When inundation occurs, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April or early June, nest trees would be flooded toward the end of the nesting season. If eagles were nesting in these trees, it would be likely that young would fledge before the nest tree died from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. Because bald eagles generally use the same nest for multiple years, the loss of nest trees would be a significant impact.

Inundation could also affect erosion and bank stability, which could affect nest trees that are in close proximity to the impoundment area. This would be a potentially significant impact.

The increase in lake elevation may increase access to eagle nests by recreational boaters. The increase in noise and human disturbance may lead to nest abandonment and the incidental loss of fertile eggs or young. Additionally, habitat inundated within the impoundment area would result in a loss of roosting and potential nest trees. This impact would be significant.

One eagle nest is located in the relocation area at Gregory Beach. Removal of nest trees would be a potentially significant impact. Additionally, one nest occurs near the Bailey Cove trail, which could be impacted by noise generated by vegetation removal activities. Vegetation removal and additional construction activities in the relocation areas would result in the same impacts on nesting bald eagles as described for vegetation removal activities proposed in the impoundment areas. This impact would be significant.

Impacts on nesting bald eagles could occur over multiple years during project implementation if construction activities are conducted at or adjacent to active nest sites. This impact would be significant.

Dam construction, vegetation removal, and inundation resulting from a 6.5-foot dam raise would result in a loss of approximately 979 acres of bald eagle nesting and roosting habitat in the impoundment area and 393 acres in the relocation areas. Potential nest and roost trees occur in blue oak woodland, blue oak–foothill pine, Douglas-fir, Klamath mixed conifer, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine habitats and are typically found in trees with diameters greater than 24 inches. Impacts on suitable bald eagle habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-13.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-13. Impacts on Suitable Habitat for the Bald Eagle in the Impoundment Area and Relocation Areas (6.5-Foot Dam Raise)

Impact Wild-6 (CP1): Loss of Dispersal Habitat for the Northern Spotted Owl
Construction activities and vegetation removal associated with the dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in the loss of northern spotted owl dispersal habitat, a species Federally listed as threatened and an MSCS-covered species. This impact would be potentially significant.

Reclamation conducted a habitat analysis within the Shasta Lake and vicinity portion of the primary study area to determine potential project impacts to northern spotted owl habitat. The analysis was performed using a GIS-based habitat model developed by the USFS northern California forests in coordination with the USFWS. The USFS developed this model using the Existing Vegetation data (EVEG) created by the USFS Remote Sensing Lab. The habitat model is referred to as NSO EVEG and defines potential northern spotted owl habitat by incorporating the vegetation data and specific northern spotted owl habitat attributes, including overstory canopy cover, proportion of conifer and hardwood trees, average tree diameter, vegetation alliance, elevation, geographic location, and ecologic setting. Using the vegetation data and northern spotted owl habitat attributes, the NSO EVEG model designates polygons as potential northern spotted owl dispersal, nesting/roosting, and foraging habitats, or non-habitat. Reclamation queried the NSO EVEG model within the Shasta Lake and vicinity portion of the primary study area to determine the amount and location(s) of potential northern spotted owl dispersal, nesting/roosting, and foraging habitats.

Dam construction, vegetation removal, and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of northern spotted owl dispersal habitat, including approximately 437 acres in the impoundment area and 340 acres in the relocation areas. Impacts on potential northern spotted owl dispersal habitat in the impoundment area and relocation areas are summarized in Table 13-14. No nesting/roosting or foraging habitat occurs in the Shasta Lake and vicinity portion of the primary study area; therefore, no impacts to these habitats would occur.

Mitigation for this impact is proposed in Section 13.3.5.

Note:
[1] Acreage values are approximate.

Impact Wild-7 (CP1): Impact on the Purple Martin and Its Nesting Habitat
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of available nest trees. This impact would be significant.

Shasta Lake supports the largest and one of only a few known purple martin breeding locations in interior northern California. Between 18 and 42 nesting pairs occur at Shasta Lake based on monitoring performed by Reclamation since 2007. The purple martin nest sites are found in flooded snags located in the existing reservoir and adjacent uplands, and occur from the vicinity of Jones Valley east up the Pit Arm. Overstory vegetation removal is proposed for the relocation of the Clikapudi Trail (Jones Valley area). With the exception of Arbuckle Flat, no vegetation removal is proposed on the Pit Arm east of the Painter Creek inlet.

Inundation of the impoundment area would result in the loss of nest trees in the lake and several known upland nest trees. Each nest tree contains several potential nest cavities at various heights above the water. Therefore, with an increase in inundation levels, fewer potential nest cavities could be available from year to year. Loss of nest trees may be temporary, as trees that are inundated would die, become snags, and provide potential nest sites. The temporal loss of nesting snags would be a significant impact.

Overstory vegetation removal is proposed for the relocation of the Clikapudi Trail. This could include removal of snags that are actively used for nesting or could provide nesting habitat for purple martin. Construction activities such as tree removal, site grading, and excavation and vegetation removal, including noise caused by helicopter yarding and chainsaw use during the nesting season, could result in the incidental loss of fertile eggs or nestlings or otherwise lead to nest abandonment. Loss of fertile eggs or nesting adults, or any activities resulting in nest abandonment, would be a significant impact.

Impacts on nesting purple martins could occur over multiple years during project implementation if construction activities were conducted at or adjacent to active nest sites. This impact would be significant.

Purple martins forage high in the air and above the tree canopy. Conversion of upland habitats to lacustrine habitat may have an effect on foraging habitat due to the loss of insect-producing vegetation; however, insect production also occurs in lacustrine habitats. Therefore, there would be an insignificant impact on foraging habitat.

Mitigation for all impacts to purple martin is proposed in Section 13.3.5.

Impact Wild-8 (CP1): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat
Construction activities and vegetation removal associated with dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a State-listed endangered, USFS sensitive, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

Vegetation removal within the impoundment area during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of these species. Noise generated by vegetation removal activities, including helicopter yarding and chainsaw use, could also lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant. The loss of nesting and foraging habitat would be a potentially significant impact.

A 6.5-foot dam raise would result in inundation of nesting and foraging habitat for these species. Understory vegetation in 15 percent of the impoundment area would be removed before inundation; the remainder would not survive the inundation. Therefore, inundation of the impoundment area would reduce the nesting habitat for these species. If removal were completed outside of the breeding season, nesting would not be affected. However, 63 percent of vegetation would not be removed and would be inundated. Because peak inundation generally occurs in late April through early June, active nests established before and while lake levels were rising could be flooded. The loss of nests and nesting and foraging habitat from inundation would be a potentially significant impact.

Construction activities, such as tree removal, site grading, excavation, and vegetation removal, at the dam and in relocation areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to nest abandonment. Additionally, noise generated by project construction activities and vegetation removal, including helicopter yarding and chainsaw use, could lead to nest abandonment resulting in the incidental loss of fertile eggs or nestlings. Vegetation removal in relocation areas would also result in a loss of nesting and foraging habitat. This would be a potentially significant impact.

Impacts on these species could occur over multiple years during project implementation if construction activities were conducted adjacent to active nests. This impact would be potentially significant.

Dam construction, vegetation removal, and inundation resulting from a 6.5-foot dam raise would result in a loss of approximately 954 acres in the impoundment area and 390 acres in the relocation areas of potential nesting and foraging habitat for the Vaux’s swift. These activities would also result in the loss of approximately 28 acres in the impoundment area and 0.72 acre in the relocation areas of willow flycatcher, yellow warbler, and yellow-breasted chat habitat. The loss of habitat for these species would be a potentially significant impact.

Impacts on suitable willow flycatcher, Vaux’s swifts, yellow warblers, and yellow-breasted chats habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-15. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-9 (CP1): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with the dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; and the Cooper's hawk, the great blue heron, and the osprey, which are MSCS-covered species. Higher lake levels caused by raising Shasta Dam would result in the loss of foraging and nesting habitat for the long-eared owl, northern goshawk, and Cooper's hawk. This impact would be potentially significant. Higher lake levels would also result in the loss of nesting habitat for osprey and great blue heron. This impact would be potentially significant. Foraging habitat would increase for osprey and great blue heron. No impact to foraging habitat for these species would occur.

Vegetation removal within the impoundment area during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of these species. Noise generated by vegetation removal activities, including helicopter yarding and chainsaw use, could also lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant. The loss of nesting and foraging habitat would be a potentially significant impact.

A 6.5-foot dam raise could result in inundation of nest trees and would result in the loss of nesting and foraging habitat for this species. When inundation of the impoundment area occurs, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April through early June, nest trees would be flooded toward the end of the nesting season. If these species were nesting in these trees, it is likely that young would fledge before the nest tree dies from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. However, the loss of nesting and foraging habitat would be a potentially significant impact.

The increase in lake elevation could increase access to nests by recreational boaters. The increase in noise and human disturbance could lead to nest abandonment and the incidental loss of fertile eggs or young. This would be a potentially significant impact.

Construction activities, such as tree removal, site grading, excavation, and vegetation removal, at the dam and in relocation areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to nest abandonment. Additionally, noise generated by project construction activities and vegetation removal, including helicopter yarding and chainsaw use, could lead to nest abandonment, resulting in the incidental loss of fertile eggs or nestlings. Vegetation removal in relocation areas would also result in a loss of nesting and foraging habitat. This would be a potentially significant impact.

Impacts on these species could occur over multiple years during project implementation if construction activities were conducted adjacent to active nests. This impact would be potentially significant.

Dam construction, vegetation removal, and inundation resulting from a 6.5-foot dam raise would result in a loss of approximately 699 acres in the impoundment area and 327 acres in the relocation areas of long-eared owl and northern goshawk nesting and foraging habitat. There would be a loss of approximately

1,072 acres in the impoundment area and 402 acres in the relocation areas of Cooper's hawk and great blue heron nesting and foraging habitat.

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-16.

Note:
[1] Acreage values are approximate.

Impacts on osprey are similar to those described for the bald eagle (Impact Wild-5 (CP1)) and the other raptors addressed above.

There are 54 osprey nest trees along the perimeter of Shasta Lake. Six nest trees would be affected by a 6.5-foot dam raise. Eleven osprey nests are located in relocation areas. Removal of nest trees would be a potentially significant impact. Because osprey generally use the same nest for multiple years, the loss of 17 nest trees (31 percent of the total in the Shasta Lake and vicinity) between the impoundment area and relocation areas would be a potentially significant impact.

Osprey nests also occur on towers and structures around the dam; otherwise, there is no suitable habitat for raptors near the dam. Blasting may occur in the vicinity of the dam. This would have a similar impact on nesting ospreys as noise generated by helicopter yarding or large construction equipment, which could result in nest abandonment and the loss of fertile eggs or young. This would be a potentially significant impact.

Impact Wild-10 (CP1): Take and Loss of Habitat for the Pacific Fisher
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Vegetation removal within the impoundment area while Pacific fisher kits (i.e., young) are in natal den trees could result in the incidental loss of kits. Noise generated by vegetation removal activities, including helicopter yarding and chainsaw use, may also lead to abandonment of young. However, females frequently move kits if the natal den is disturbed or threatened. Because females will move kits, it is not likely that individuals would be affected. However, the loss of denning, resting, and foraging habitat would be a potentially significant impact.

A 6.5-foot dam raise could result in inundation of natal den trees and would result in the loss of denning, resting, and foraging habitat for this species. When inundation of the impoundment area occurs, natal den trees within the impoundment area would die. Females frequently move kits if threatened or disturbed. Because females will move kits, it is not likely that individuals would be affected. However, the loss of denning, resting, and foraging habitat would be a potentially significant impact.

Construction activities, such as tree removal, site grading, excavation, and vegetation removal, at the dam and in relocation areas while kits are in natal den trees could result in the incidental loss of kits. Impacts on habitat would be the same as described for the impoundment area. This would be a potentially significant impact.

Impacts on the Pacific fisher could occur over multiple years during project implementation if construction activities were conducted adjacent to denning or resting habitat. This impact would be potentially significant.

Dam construction, vegetation removal, and inundation resulting from a 6.5-foot dam raise would result in a loss of approximately 749 acres of Pacific fisher habitat in the impoundment area. Approximately 330 acres of Pacific fisher habitat would be lost in the relocation areas. This impact would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-17.

Mitigation for this impact is proposed in Section 13.3.5.

Total Habitat	104.34	0.00	116.39	81.31	18.69	9.75	330.48

Note:
[1] Acreage values are approximate.

Impact Wild-11 (CP1): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, Yuma Myotis, and Fringed Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared myotis, a BLM sensitive species; the Yuma myotis, a BLM sensitive species; the fringed myotis, a USFS sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Vegetation removal within the impoundment area while young bats are in maternity colonies or kits are in natal den trees could result in the incidental loss of young. Noise generated by vegetation removal activities, including helicopter yarding and chainsaw use, could also lead to young abandonment. Furthermore, depending on the season, the removal of large trees with cavities could result in the loss of pallid bat and Townsend's big-eared bat colonies. Potential direct impacts include the take of a maternity colony (females and young) and the take of individuals in a hibernaculum, which could eliminate an entire colony because of the loss of pregnant females. Mortality of young and the loss of reproductive and foraging habitat would be a potentially significant impact.

Inundation of a 6.5-foot dam raise would result in a loss of roosting and foraging habitat for special-status bats (pallid bat, spotted bat, western red bat, western mastiff bat, Townsend's big-eared bat, long-eared myotis, Yuma myotis, and fringed myotis) that roost in hollow trees, snags, bridges, and caves. Loss of young could occur during the first inundation (above 1,070 feet msl) of bat maternity colony habitat because active maternity colonies could be flooded before young are volant (capable of flight). American marten and ringtails, which also use snags, hollow logs, and debris piles for reproduction and cover, could also be impacted. This impact would be potentially significant.

Two known caves, one occupied by Townsend's big-eared bats, are located on the Big Backbone Arm and would be wholly or partially inundated if the dam were raised. Inundation of cave/cliff habitat could result in the loss of Townsend's big-eared bat, western mastiff bat, and long-eared myotis colonies. Potential direct impacts include the take of a maternity colony and the take of individuals in a hibernaculum, which could eliminate an entire colony because of the loss of pregnant females.

Spotted bats and long-eared myotis could also roost in crevices and caves in the Shasta Lake and vicinity portion of the primary study area. However, inundation of cave/cliff habitat is less likely to result in a significant impact on these species because they do not roost colonially; thus, inundation of a cave would not result in the loss of an entire maternity colony.

Special-status bats may roost on bridges and could also be affected by bridge modification or removal. Direct impacts, including mortality and the loss of roosting habitat, would be significant.

Construction activities, such as tree removal, site grading, excavation, and vegetation removal, at the dam and in relocation areas while young bats are in maternity colonies or kits are in natal den trees could result in the incidental loss of young. Impacts on habitat would be the same as described for the impoundment area. This would be a potentially significant impact.

Impacts on these species could occur over multiple years during project implementation if construction activities are conducted in or adjacent to reproductive habitat. This impact would be potentially significant.

Foraging habitat for the pallid bat, spotted bat, western mastiff bat, and Townsend's big-eared bat includes Douglas-fir, fresh emergent wetland, lacustrine habitat, montane hardwood, montane hardwood–conifer, montane riparian, and ponderosa pine. These habitats are regionally abundant and therefore impacts on foraging habitat by inundation or vegetation removal in the relocation areas would be less than significant.

Dam construction, vegetation removal, and inundation resulting from a 6.5-foot dam raise would result in the loss of approximately 31 acres of reproductive and roosting habitat for the pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat, Yuma myotis, and fringed myotis in the impoundment area. Approximately 35 acres of reproductive and roosting habitat for these species would be lost in the relocation areas. Additionally, one limestone cave located on the Big Backbone Arm that is a known Townsend's big-eared bat roost would be affected by flooding. A 6.5-foot dam raise would result in the loss of approximately 1,201 acres of reproductive and roosting habitat for the western red bat and long-eared myotis. Approximately 457 acres of reproductive and roosting habitat for these species would be lost in the relocation areas. These impacts would be potentially significant.

Dam construction, vegetation removal, and inundation resulting from a 6.5-foot dam raise would result in the loss of approximately 1,201 acres of ringtail habitat. Approximately 457 acres of ringtail habitat would be lost in the relocation areas. A 6.5-foot dam raise would result in the loss of approximately 724 acres of American marten habitat in the impoundment area and 328 acres in the relocation areas. These impacts would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-18.

Mitigation for this impact is proposed in Section 13.3.5.

Note:
[1] Acreage values are approximate.

Impact Wild-12 (CP1): Impacts on Special-Status Terrestrial Mollusks (Church's Sideband, Shasta Sideband, Wintu Sideband, Oregon Shoulderband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and/or S&M species, and the Shasta sideband is also an MSCS-covered species. The Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian have also been petitioned for Federal listing. Ground-disturbing activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks.

In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of these species. This impact would be significant.

These species are found in nearly all CWHR habitats along the lake. The Shasta sideband and Wintu sideband are associated with limestone formations in the McCloud River and in the Pit and Squaw Creek arms, respectively. For the purposes of this impact analysis for Shasta sideband and Wintu sideband, all CWHR habitats in the impoundment and relocation areas are stratified as limestone or nonlimestone habitat. Shasta chaparral occurs in many CWHR habitats and Shasta hesperian is found in riparian habitats.

Vegetation removal in the impoundment areas and construction activities, such as tree removal, site grading, excavation, and vegetation removal at the dam and in relocation areas in suitable habitat, could result in direct take. In addition, these activities and the inundation caused by a 6.5-foot dam raise would result in the mortality of individuals and the permanent loss of suitable habitat.

Dam construction, vegetation removal, and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in the loss of approximately 1,195 and 425 acres of Church's sideband, Oregon shoulderband, and Shasta chaparral habitat in the impoundment area and relocation areas, respectively. Shasta hesperian habitat loss in the impoundment area and relocation areas would be approximately 28 and 0.72 acre, respectively. The 6.5-foot dam raise would also result in the loss of approximately 5 acres of Shasta sideband habitat in the impoundment area and 0.97 acre in the relocation areas. Wintu sideband habitat loss includes approximately 1.50 acres in the impoundment area. These impacts would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area and relocation areas are summarized in Table 13-19.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-13 (CP1): Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat The western bumblebee is designated USFS sensitive. Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in the permanent loss of habitat. This would be a potentially significant impact.

These general habitats also represent potential western bumble bee habitat. Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat containing flowering shrubs and forbs, which serve as potential Western bumble bee nectar sources and potential underground burrow locations. In addition, inundation caused by the raising of Shasta Dam would result in the permanent loss of habitat. This would be a potentially significant impact.

Dam construction, vegetation removal and construction in the relocation areas, and inundation resulting from a 6.5-foot dam raise would result in a loss of 1,227 acres of general wildlife and western bumble bee habitat in the impoundment area and 698 acres of general wildlife and western bumble bee habitat in the relocation areas. Impacts on general wildlife and western bumble bee habitat by CWHR type in the impoundment area and relocation areas are summarized in Tables 13-20 and 13-21.

Mitigation for this impact is proposed in Section 13.3.5.

CWHR = California Wildlife Habitat Relationships

Impact Wild-14 (CP1): Impacts on Other Birds of Prey (e.g., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species (e.g., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam could result in the loss of active nests and habitat for these species. This impact would be potentially significant.

Approximately 36 percent of the impoundment area would be subject to either complete (15 percent) or overstory (21 percent) vegetation removal. If vegetation removal were to occur before or after the breeding season, there would be no impact on migratory birds or raptors. When inundation of the impoundment area occurs, nest trees within the impoundment area would die. Because peak inundation generally occurs between late April and early June, nest trees would be flooded toward the end of the nesting season. If raptors were nesting in these trees, it is likely the young would fledge before the nest tree died from the effects of inundation. However, approximately 84 percent of understory vegetation inundated could have ground or shrub nesting birds that would be impacted by inundation. Impacts on ground or understory nesters would be potentially significant.

Maximum inundation would occur in late April through early June during the breeding season and many nests could be established before and while lake levels are rising. In the portions of the impoundment area where vegetation removal is not implemented, active bird nests would flood, resulting in mortality of young still dependent on the nest. This would be a potentially significant impact.

Additionally, removal of structures providing for raptor nests (e.g., power poles) in the relocation areas could result in mortality of young. This would be a potentially significant impact.

Vegetation in relocation areas would be completely removed. If vegetation removal occurred during the breeding season, there would a potentially significant impact on migratory birds or raptors.

Impacts on these species could occur over multiple years during project implementation if construction activities were conducted in or adjacent to reproductive habitat. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP1): Loss of Critical Deer Winter and Fawning Range Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas under a 6.5-foot raise of Shasta Dam would result in the loss of approximately 3,962 acres of critical deer winter and/or fawning range. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP1): Take and Loss of the California Red-Legged Frog Reclamation completed California red-legged frog habitat assessments in coordination with the USFWS in the applicable impoundment and relocation areas, and the potential downstream Sacramento River restoration sites. The assessment results will enable Reclamation and the USFWS to determine if habitat for the species occurs, if impacts are anticipated, and if additional surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and the California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is discussed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (CP1): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementing CP1 would increase available water storage in Shasta Reservoir and result in a modified flow regime, which would modify the flow and stages of the upper Sacramento River. Monthly flow results were used to simulate mean daily flows. On average, in each month, changes in mean monthly flow would be reductions or increases of several percent, and often less than 2 percent. Changes of 2 percent or less are considered essentially equivalent to baseline operations and therefore do not represent a substantial change. Generally, these effects diminish with distance downstream because of the influence of inflows from tributaries and of diversions and flood bypasses.

Implementing CP1 would reduce the frequency, duration, and magnitude of intermediate to large flows downstream from Shasta Dam during winter (December through February) in some water years, especially wet and above-normal years, because of the increase in storage space that could be filled in some years, usually after dry or critical water years. Conversely, CP1 would increase flow volumes in fall of most years (September through November) because more water would be available for delivery in the driest months. During spring and summer (generally March through August), changes in mean monthly flows would be small reductions or increases (generally less than 2 percent) and typically would be transitional between small reductions in winter flows and small increases in summer flows.

These changes in surface and subsurface hydrology could affect habitats adjacent to the river channel and reduce the formation of off-channel habitats in the long term, which would adversely affect the habitat of western pond turtle.

The portion of riparian vegetation in early successional stages would be reduced, although the total amount of riparian vegetation would not decline substantially. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species, particularly western yellow-billed cuckoos. Because CP1 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

The operation of Shasta Dam has substantially modified the natural flow regime in the primary study area. As discussed previously, dam construction and operation has limited the frequency and magnitude of intermediate to large flows downstream from the dam in winter and spring, and has increased flow volumes during the active growing season (primarily March through October). Implementation of CP1 would be expected to amplify these effects (Table 13-22) because CP1 would increase available storage. These changes are most noticeable in the modeling data for wet and above-normal water years. Reducing the magnitude, frequency, and duration of intermediate to large flows could alter the dynamics and structure of wetland and riparian habitats that support special-status wildlife species along the Sacramento River, downstream from Shasta Dam, throughout the primary study area. (See Chapter 12, “Botanical Resources and Wetlands,” for more information.)

The effects of modified flow regimes would be somewhat attenuated downstream because of the cumulative tributary flow adding to the Sacramento River. However, many of these tributaries are also part of the CVP and SWP and would likely be operated differently should CP1 be implemented. CP1 would increase the volume of flows in summer and fall of most years, most dramatically in September and October. This change is also a result of increased storage, which allows more water to be available for delivery in the driest months of the year. Although the relative contribution of CP1 to overall changes downstream from Keswick Dam would attenuate, it appears based on the modeling that in September of dry and critical water years, the effect of CP1 would be a substantial increase in flows all the way down to Freeport (Table 13-22).

Special-status wildlife that could be affected by these changes include special-status invertebrates, reptiles, amphibians, birds, and mammals, as discussed below.

- **Invertebrates –** Blue elderberry shrubs, the host plants for the valley elderberry longhorn beetle, are found throughout much of the Sacramento River's riparian corridor. Shrubs within the corridor are unlikely to be affected by modification of the existing flow regimes. Elderberry shrubs are not commonly found growing immediately next to the river's edge, but are often found on floodplain terraces or higher up the bank. Most of the effect of CP1 on flow regime, including inundation during the growing season, would be concentrated in a narrow strip along the river channel that is already subjected to seasonal inundation. Elderberry shrubs growing in these areas already experience periodic seasonal inundation. CP1 would alter flows substantially (beyond the ±2 percent threshold), but the change in river stage is predicted by CalSim-II to generally be less than about 4 inches. Because of this relatively small vertical change in water surface elevation, implementing CP1 is not likely to prevent establishment or substantially reduce the vigor of existing elderberry shrubs in the primary study area. Therefore, the impact of CP1 on invertebrate species would be less than significant.

- **Reptiles and Amphibians –** The presence of western pond turtle within the Sacramento River has been documented, and suitable habitat for the species is provided in the primary study area, including tributaries. Although they will use low-velocity areas of the main channels, western pond turtles also rely on habitat types (e.g., oxbow lakes) that have relatively slow rates of formation. Creation of new off-channel water bodies requires periodic intermediate to large fall and winter flow events that drive the processes of meander migration and channel cutoff. Similarly, off-channel water bodies gradually become terrestrial habitats as they fill with sediment and organic detritus and are colonized by riparian vegetation. Consequently, activities that prevent the long-term formation of off-channel water bodies (e.g., constructing levees and installing bank armor) reduce the extent of this important type of habitat for pond turtles. The increase in mean stage elevation resulting from implementation of CP1 could provide additional aquatic habitat for the species during some months of some years. A key potentially limiting factor for the western pond turtle is the relationship between water level and flow in off-channel water bodies during the summer incubation season (Stillwater Sciences 2007). The Sacramento River stage and flows would not be substantially changed during summer; however, less aquatic habitat for western pond turtle could be available during winter, spring, and drought periods. Modifying the flow regime by capturing channel-forming flows could also reduce the formation of off-channel water bodies in the long term. These changes in habitat availability could reduce the size of the western pond turtle population along the Sacramento River in the long term by reducing turtle survival and reproductive success. Therefore, the impact of CP1 on the western pond turtle and its habitat would be potentially significant.

- **Birds –** The riparian and wetland habitats along the Sacramento River floodway provide potential nesting and foraging habitat for western yellow-billed cuckoo, California yellow warbler, and yellow-breasted chat, all of which are special-status birds that nest in riparian vegetation. In addition, northern harrier and short-eared owl may nest in marshes in or adjacent to the stream channel. Other raptors (e.g., Cooper's hawk, Swainson's hawk, white-tailed kite, bald eagle, and osprey) may nest in trees in the riparian or oak woodlands in the study area. As described above, altering the flow regime could alter some existing riparian habitat. Over time, there would be less early successional (willow, cottonwood, and herbaceous dominated) and more mid-successional (mixed woodland) vegetation, and a smaller amount of acreage recently disturbed by erosion or scouring after intermediate to large flows (see Chapter 12, "Botanical Resources and Wetlands.") These long-term changes to the structure of riparian vegetation are expected to change habitat values, causing the loss of, and in some cases expanding, nesting territories or affecting the reproductive success of some riparian foraging and nesting birds. The birds most adversely affected by this alteration would be those that make the most extensive use of willow thickets and cottonwood- and willow-dominated riparian forests, such as yellow-billed cuckoo and yellow-breasted chat. This loss of nesting habitat would eventually lead to a reduction in local populations of sensitive bird species as habitat became unsuitable for nesting. Although some species, such as raptors that nest in later successional riparian habitats, could benefit from the long-term changes, the impact of CP1 on special-status bird species that nest in early successional riparian vegetation would be potentially significant.

- **Mammals –** Special-status mammals potentially occurring in the project area include pallid bat, western red bat, and ringtail. Riparian habitat can provide important foraging and roosting habitat for bats, but these species are not typically dependent on riparian habitats. The amount of potential foraging habitat would not decrease under CP1, and available roosting areas in riparian habitats–even if modified by the new flow regime downstream from Shasta Dam–would not be subject to a substantial reduction. Therefore, the impact of CP1 on special-status bats would be less than significant. Potential changes in riparian vegetation along the river channel in the primary study area would not substantially reduce habitat for ringtail because this species is known to use a variety of habitats and forage on a wide array of items that would not be substantially altered (Belluomini 1980). Therefore, the impact of CP1 on special-status mammals would be less than significant.

Implementing CP1 would result in substantial long-term effects on the habitat of western pond turtle and some riparian-nesting special-status bird species. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP1): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes Bank swallows generally benefit from bank erosion caused by high winter stream flow (which renews nesting habitat while they are in overwintering habitats to the south); high spring and summer flows, however, have the potential to adversely affect bank swallow colonies by destroying active nests (Stillwater Sciences 2007). Implementing CP1 would increase available water storage in Shasta Reservoir and result in a modified flow regime, which would modify the flow and stages of the upper Sacramento River. Monthly flow results were used to simulate mean daily flows; on average, in each month, changes in mean monthly flow would be reductions or increases of several percent, and often less than 2 percent. Changes of 2 percent or less are considered essentially equivalent to baseline operations and therefore do not represent a substantial change.

Generally, these effects diminish with distance downstream because of the influence of inflows from tributaries and of diversions and flood bypasses.

Implementing CP1 would reduce the frequency, duration, and magnitude of intermediate to large flows downstream from Shasta Dam during winter (December through February) in some water years, especially wet and above-normal years, because of the increase in storage space that could be filled in some years, usually after dry or critical water years. Conversely, CP1 would increase flow volumes in fall of most years (September through November) because more water would be available for delivery in the driest months. During spring and summer (generally March through August), changes in mean monthly flows would be small reductions or increases (generally less than 2 percent) and typically would be transitional between small reductions in winter flows and small increases in summer flows.

The rates of geomorphic processes, such as bank erosion and the average rate of meander migration, are strongly related to flow regime and the cumulative portion of flow exceeding a threshold volume. On portions of the Sacramento River, this threshold may be around 30,000 cubic feet per second (cfs) (Larsen et al. 2006; Stillwater Sciences 2007), which is well below the bankfull discharge but well above flows during spring and summer. However, other important thresholds for bank erosion and channel avulsion along the Sacramento River have been estimated within the range of 10,000–80,000 cfs (Stillwater Sciences 2007). For additional discussion of the relationship of geomorphic processes to flow along the Sacramento River, see the *Fisheries and Aquatic Ecosystem Technical Report*.

CalSim-II results temporally downscaled to mean daily values also indicate the relative magnitude of changes to the flow regime. The simulated change in mean daily discharges greater than 30,000 cfs below the Red Bluff Pumping Plant and Hamilton City is summarized in Figure 12-4 in Chapter 12, “Botanical Resources and Wetlands.” Flows of this magnitude strongly affect bank erosion and meander migration. Overall, these modeling results suggest only a very small change in flows greater than 30,000 cfs along the uppermost portion of the lower Sacramento River. This change is not likely sufficient to cause significant effects on bank swallow.

Any effects would likely occur along the upper Sacramento River throughout the primary study area. In the primary study area, changes in the number of mean daily flows within the magnitude of intermediate and large flows (i.e., greater than 30,000 cfs), which affect bank erosion and meander migration, would be small. Downstream from Keswick Dam and the Red Bluff Pumping Plant, the number of days with mean flows greater than 30,000 cfs would be reduced by approximately 9 and 2 percent, respectively.

Therefore, although there would be a slight alteration of the river’s geomorphic processes in some years and the rate of bank erosion would be reduced, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. High flows during the nesting season that may cause localized nest failure would not increase. The impact on habitat for bank swallow nesting colonies, and therefore bank swallows themselves, would be less than significant.

There are seven known colonies of bank swallow along the Sacramento River in the primary study area (CNDDB 2012). The bank swallow forms nesting colonies in steep-cut, eroding river banks. Generally installed to protect upland land uses, bank revetment has been preferentially applied to actively migrating bends that otherwise would be among the most suitable sites for bank swallow nests. The reduction in intermediate to large flows by CP1 would cause a small reduction in the rate of erosion at the cut banks that remain unprotected by revetment. This alteration would not reduce the amount of bank swallow nesting habitat in the short or long term. As modeled, spring flows at Keswick Dam and Bend Bridge would be substantially reduced under some water year conditions (e.g., February and March of above-normal years, May of above-normal and below-normal years), but generally would remain within the ±2 percent threshold that is considered essentially equivalent to existing conditions (Table 13-22). Therefore, the potential for spring flows to cause localized bank swallow nest failure would remain comparable to existing and no-action conditions.

The rate of bank failure is not expected to change substantially, and nest failure caused by spring flows may be reduced under certain conditions. Therefore, the impact of CP1 on bank swallow would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP1): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime Vernal pools are present in upland areas near the Sacramento River and its tributaries in the primary study area. These pools provide habitat for numerous special-status species, such as vernal pool tadpole shrimp, vernal pool fairy shrimp, and western spadefoot toad. Critical habitat for three special-status wildlife species (Conservancy fairy shrimp, vernal pool fairy shrimp, and vernal pool tadpole shrimp) is located within the primary study area. Critical habitat for these species in the primary study area is confined to vernal pool communities (USFWS 2006). However, vernal pools are generally not present within the active floodplain of the upper Sacramento River in the primary study area; thus, vernal pools are not anticipated to be affected by changes in flows that could result from implementation of CP1. Changes in flow regime in the primary study area likely would not affect vernal pool special-status species. Because CP1 would not affect vernal pool habitat or the species that occur within the habitat, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP1): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

Several local and regional plans have been developed and adopted to promote conservation and enhancement of riparian habitat in the primary and extended study areas. Examples of these include the RHJV, Sacramento River Advisory Council Forum, Sacramento River Conservation Area Program, and SRNWR comprehensive conservation plan and environmental assessment (See Section 13.2, “Regulatory Setting.”)

Because CP1 may have a potentially significant impact on riparian vegetation in the primary and extended study areas, the quality of riparian habitat may be reduced or distribution may be limited. This potential consequence of the project could conflict with the goals developed in local and regional conservation plans for the Sacramento River. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP1): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program Gravel augmentation is not included as part of CP1. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-22 (CP1): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration Projects CP1 would not include any specific restoration components. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta By altering storage and operations at several reservoirs, CP1 would change flow regimes in several downstream waterways. In turn, these alterations to the flow regime could particularly affect riparian and wetland habitats along these waterways. The potential effects on wildlife are similar to those discussed for the primary study area above. However, potential effects on flow and stages of the middle Sacramento River would be smaller than those for the upper Sacramento River; changes in flows and stages would diminish downstream from Red Bluff because of the effects of inflows from tributaries, and the effects of diversions and flood bypasses.

Impact Wild-23 (CP1): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementing CP1 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years. It also would increase flow volumes in fall of most years. This change in surface and subsurface hydrology would be of a smaller magnitude than in the upper Sacramento River, but could affect habitats adjacent to the river channel and the long-term formation of off-channel habitats along the lower Sacramento River, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP1 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

This impact would be similar to Impact Wild-17 (CP1) for the upper Sacramento River. However, the effect of CP1 on flow in the Sacramento River would generally attenuate downstream from Red Bluff Pumping Plant because of the inflows from tributaries, and because of other diversions and flood bypasses. CalSim-II modeling indicates that in most months and under most types of water years, changes in flows from Bend Bridge downstream would be within the ±2 percent to be considered essentially equivalent to existing conditions (Table 13-22). The exceptions to this are in September of dry and critical water years, for which the model predicts substantial flow increases. Nonetheless, along the middle Sacramento River, flow alterations could be sufficient to substantially affect habitat of western pond turtle and riparian-nesting birds as described for the upper Sacramento River (Impact Wild-17 (CP1)). This impact would be potentially significant.

Flow alterations may not be sufficient to measurably affect special-status wildlife in the bypasses, along the Sacramento River downstream from Colusa, or in the Delta, for several reasons:

- Flow alterations are more attenuated downstream by tributaries, diversions, and bypasses, and the results of CalSim-II modeling indicate little change in the frequency and duration of bypass inundation.

- Downstream from Colusa, the river is confined to a narrow channel closely bordered by levees lined with riprap; thus, geomorphic processes and riparian habitats are relatively unresponsive to small changes in river flows.

The effects of flow alterations are unlikely to extend to the Delta because the Central Valley's reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The CVP and SWP are managed to maintain standards for Delta inflow. CVP and SWP operations are constrained by USFWS's 2008 Formal ESA Consultation on the Proposed Coordinated

Operations of the CVP and SWP (2008 USFWS BO) and NMFS's 2009 BO and Conference Opinion on the Long-Term Operations of the CVP and SWP (2009 NMFS BO).

Thus, implementation of CP1 is not anticipated to cause an alteration in Sacramento River flow to the Delta sufficient to alter habitat for special-status wildlife species in the lower Sacramento River and Delta portion of the extended study area. However, because of the potential for substantial effects on western pond turtle and riparian-nesting birds in the lower Sacramento River (i.e., Red Bluff Pumping Plant to Colusa), this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP1): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes Implementing CP1 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the lower Sacramento River. This reduction also would alter the river's geomorphic processes. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. High flows during the nesting season that may cause localized bank and nest failure would not increase. The impact on habitat for bank swallow nesting colonies, and therefore bank swallows themselves, would be less than significant.

There are more than 100 presumed extant colonies of bank swallow in Butte, Glenn, Colusa, Yuba, Yolo, Sutter, and Sacramento counties (CNDDB 2012). The effect of CP1 on bank swallow along the lower Sacramento River would be similar to that described for the upper Sacramento River. There would be a small reduction in the rate of bank erosion, but not a substantial change in the amount of bank swallow nesting habitat, or increases in spring flows that may cause a substantial increase in localized nest failure. However, the effect of altered flow regimes on bank swallow nesting habitat along the lower Sacramento River would be smaller than the effect along the upper Sacramento River (described in Impact Wild-18 (CP1)). Flow alterations in the Sacramento River downstream from Red Bluff Pumping Plant would be attenuated by tributary inflow, and by other diversions and flood bypasses that would also alter instream flows. For these reasons, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP1): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Vernal pools are present in upland areas near the Sacramento River and its tributaries in the extended study area. These pools provide habitat for numerous special-status species. Critical habitat for three special-status species (vernal pool fairy shrimp, vernal pool tadpole shrimp, and Conservancy fairy shrimp) is located within the extended study area. Critical habitat for these species is confined to vernal pool communities (USFWS 2006). However, vernal pools are generally not present within the active floodplain of regulated rivers along the lower Sacramento River and in the Delta. The largest increase in water surface elevation predicted to occur under CP1 for locations in the lower river is about 4 inches at Verona in September of dry water years. This increase would not result in river inundation of vernal pool habitat. Because all of the other predicted increases in water surface elevation are less than this, vernal pool special-status species would not likely be affected by changes in flow regime in the extended study area. Because CP1 would not affect vernal pool habitat or the species that occur within the habitat, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP1): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat Along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

This impact is similar to Impact Wild-20 (CP1) for the upper Sacramento River. For the same reasons as described for the upper Sacramento River, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas Increased water supplies or increased supply reliability could reduce a limitation on growth or on other activities that could affect wildlife in the primary and extended study areas, potentially resulting in significant effects. The effects of this growth would be analyzed in general plan EIRs and in project-level CEQA compliance documents for the local jurisdictions in which the growth would occur. Mitigation of these effects would be the responsibility of these local jurisdictions, and not of Reclamation.

The expected increase in water deliveries relative to the entire CVP/SWP service areas would be small, however. Assuming that this increased deliveries could be provided to any number of geographic areas within the CVP and SWP service areas, the project's impact on growth that could affect wildlife habitat for sensitive species would be minor. Similarly, projects potentially affecting sensitive habitats and listed species would require permits from CDFW, USACE, and USFWS; it is anticipated that effects on these resources would be avoided, minimized, and/or mitigated during those agency consultations. Because the extent, location, and timing of induced growth is currently highly uncertain, and in the future the effects of this growth would be analyzed and mitigated during land use planning and environmental review for specific projects, growth-inducing effects on wildlife are not discussed further in this chapter. However, additional discussion of growth-inducing effects specific to the project alternatives is provided in Section 26.4, "Growth-Inducing Impacts," in Chapter 26, "Other Required Disclosures."

Impact Wild-27 (CP1): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP1 would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

Several riparian-associated or aquatic special-status wildlife species may be present in the CVP and SWP service areas, such as least Bell's vireo and arroyo toad. As discussed for the upper Sacramento River and the lower Sacramento River and Delta under Impact Wild-17 (CP1) and Impact Wild-21 (CP1), respectively, construction and operation of Shasta Dam has limited the frequency and magnitude of intermediate to large flows in winter and spring, and has increased flow volumes during the active growing season (primarily March–October). Implementation of CP1 would be expected to amplify these effects.

However, the effect of project-related alteration of flow regimes would attenuate somewhat in the Sacramento River downstream from Red Bluff Pumping Plant because of the inflows from tributaries, and because of other diversions and flood bypasses. Effects of flow alterations from Shasta Dam are also unlikely to extend to the CVP and SWP service areas because the reservoirs and diversions are managed as a single integrated system (consisting of the CVP and SWP). The CVP and SWP are managed to maintain standards for Delta inflow. CVP and SWP operations are constrained by the 2008 USFWS BO and NMFS's 2009 BO. Thus, this project is not anticipated to sufficiently alter flow to the CVP/SWP service areas to have a substantial effect on riparian habitat upon which special-status wildlife species depend. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Like CP1, this comprehensive plan focuses on enlarging Shasta Dam and Shasta Lake consistent with the goals of the 2000 CALFED Programmatic ROD, and was formulated for the primary purposes of increased water supply reliability and increased survival of anadromous fish. In addition to the common features above, CP2 involves raising Shasta Dam 12.5 feet, an elevation change that would raise the full pool by 14.5 feet (6 feet higher than under CP1) and would enlarge the total storage space in the reservoir by 443,000 acre-feet.

With respect to wildlife impacts, dam construction activities for CP1 through CP5 would be so similar that they are considered to be identical for purposes of this analysis. Because CP2 would result in higher lake levels than CP1, CP2 would also require more relocation of utilities, public service facilities, and recreational facilities than CP1, including a loss of up to 35 acres of limestone habitat and 2,870 acres of nonlimestone habitat. Because CP2 would result in higher lake levels than CP1, CP2 would also result in a larger (and deeper) area of inundation than CP1, in turn requiring more vegetation clearing within the inundation area than CP1.

Shasta Lake and Vicinity

Impact Wild-1 (CP2): Take and Loss of Habitat for the Shasta Salamander Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, S&M species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the Shasta salamander. This impact would be significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of approximately 10 acres of limestone habitat and 1,668 acres of nonlimestone habitat. Impacts to limestone and nonlimestone habitats in the impoundment area are summarized in Table 13-23

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-23. Impacts on Suitable Habitat for the Shasta Salamander in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Limestone	0.00	1.14	0.00	7.64	0.00	2.06	10.83
Nonlimestone	309.64	59.64	485.89	282.19	170.34	360.68	1668.38
Total	309.64	60.78	485.89	289.83	170.34	362.74	1679.21

Note:
[1] Acreage values are approximate.

Impact Wild-2 (CP2): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the foothill yellow-legged and tailed frogs. This impact would be potentially significant.

Implementation of a 12.5-foot raise of the dam would result in inundation of approximately 47 acres of habitat for the foothill yellow-legged frog and tailed frog. A summary of suitable habitat loss by arm is presented in Table 13-24.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-24. Impacts on Suitable Habitat for the Foothill Yellow-Legged and Tailed Frog in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Montane riparian	2.72	3.23	20.57	6.12	1.00	3.62	37.26
Riverine	0.00	0.42	4.02	4.51	0.84	0.00	9.80
Total	2.72	3.65	24.59	10.63	1.84	3.62	47.05

Note:
[1] Acreage values are approximate.

Impact Wild-3 (CP2): Impact on the Northwestern Pond Turtle and Its Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion and sedimentation. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the northwestern pond turtle. This impact would be potentially significant.

Implementation of a 12.5-foot raise of the dam would result in conversion of approximately 37 acres of montane riparian and approximately 10 acres of riverine habitat to lacustrine habitat. Because there are equally valuable components lost or gained in either habitat, the quality of the habitat would not be compromised. However, maximum lake inundation would be infrequent (at most 1 month per year) and would not benefit the species throughout the remainder of the year. Thus, the conversion to lacustrine remains an impact on northwestern pond turtle habitat. A summary of suitable habitat loss by arm is presented in Table 13-25.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-25. Impacts on Suitable Habitat for the Northwestern Pond Turtle in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Montane riparian	2.72	3.23	20.57	6.12	1.00	3.62	37.26
Riverine	0.00	0.42	4.02	4.51	0.84	0.00	9.80
Total	2.72	3.65	24.59	10.63	1.84	3.62	47.05

Note:
[1] Acreage values are approximate.

Impact Wild-4 (CP2): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the American peregrine falcon.

Similar to CP1, overstory and complete vegetation removal is expected to occur within the impoundment area in suitable cliff habitat. Thus, overstory vegetation removal occurring in or near suitable cliff habitat during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests. Additionally, because of the steep terrain, trees would be yarded by helicopter. Noise generated by chainsaws and helicopter yarding could cause the abandonment of nests, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant.

No known eyries would be inundated with a 12.5-foot raise in lake elevation; however, 12.5 vertical feet (full pool) of cliff habitat would be inundated. The impacts on this amount of cliff habitat suitable for nesting would be less than significant. The conversion of uplands to lacustrine habitat would not adversely affect foraging habitat for the species because they frequently forage over water. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP2): Take and Loss of Habitat for the Bald Eagle
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCS-covered species, and a BLM sensitive species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the bald eagle. This impact would be potentially significant.

Six known bald eagle nest trees would be affected by a 12.5-foot dam raise due to inundation. When inundation occurs, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April or early June, nest trees would be flooded toward the end of the nesting season. If eagles were nesting in these trees, it would be likely that young would fledge before the nest tree died from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. Because bald eagles generally use the same nest for multiple years, the loss of nest trees would be a significant impact.

Inundation could also affect erosion and bank stability, which could affect nest trees that are in close proximity to the impoundment area. This would be a potentially significant impact.

Inundation resulting from a 12.5-foot dam raise would result in a loss of approximately 1,376 acres of bald eagle nesting and roosting habitat. Impacts on suitable bald eagle habitat by CWHR type in the impoundment area are summarized in Table 13-26.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-26. Impacts on Suitable Habitat for the Bald Eagle in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Blue oak woodland	0.00	0.00	0.00	0.00	0.00	3.03	3.03

Note:
[1] Acreage values are approximate.

Impact Wild-6 (CP2): Loss of Dispersal Habitat for the Northern Spotted Owl
Construction activities and vegetation removal associated with the dam raise, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in the loss of northern spotted owl dispersal habitat, a Federally listed as threatened species, and MSCS-covered species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of dispersal habitat for the northern spotted owl. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of approximately 643 acres of dispersal habitat for the northern spotted owl. Impacts on suitable habitat for the spotted owl by CWHR type in the impoundment area are summarized in Table 13-27.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-27. Impacts on Suitable Habitat for the Northern Spotted Owl in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total

Foraging	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Nesting/roosting	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Total	96.85	10.29	155.97	157.79	77.74	144.87	643.51

Note:
[1] Acreage values are approximate.

Impact Wild-7 (CP2): Impact on the Purple Martin and Its Nesting Habitat
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. Also similar to CP1, nest trees occurring in the lake could be adversely affected by inundation and related vegetation removal. These impacts would be potentially significant.

Impact Wild-8 (CP2): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, which is State-listed as endangered, a USFS sensitive species, and an MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of approximately 1,341 acres of Vaux's swift nesting and foraging habitat in the impoundment area. Additionally, approximately 37 acres of willow flycatcher, yellow warbler, and yellow-breasted chat habitat would be lost in the impoundment area.

Impacts on suitable habitats for the willow flycatcher, Vaux's swift, yellow warbler, and yellow-breasted chat habitat by CWHR type in the impoundment area is summarized in Table 13-28.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-28. Impacts on Suitable Habitat for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat in the Impoundment Area (12.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Vaux's Swift							
Douglas-fir	0.00	0.00	0.00	0.06	0.00	0.00	0.06
Klamath mixed conifer	0.00	0.00	0.00	0.00	0.00	7.66	7.66
Montane hardwood	53.30	25.75	120.48	48.59	13.31	55.23	316.66
Montane hardwood–conifer	48.77	0.70	99.06	94.36	78.41	125.77	447.07

Impact Wild-9 (CP2): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; Cooper's hawk, an MSCS-covered species; great blue heron, an MSCS-covered species; and osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and nesting habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of approximately 987 acres of nesting and foraging habitat for long-eared owl and northern goshawk, approximately 1,505 acres of nesting and foraging habitat for the Cooper’s hawk, and approximately 1,505 acres of nesting habitat for the great blue heron. Foraging habitat would increase for osprey and great blue heron. No impact to foraging habitat for these species would occur.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-29.

Impacts to osprey would be the same as described for CP1. There are 54 osprey nests within the perimeter of Shasta Lake. Six nest trees would be affected by a 12.5-foot dam raise and 11 nests are located in relocation areas. Removal of nest trees would be a potentially significant impact. Because osprey generally use the same nest for multiple years, the loss of 17 nest trees (31 percent of the total in the Shasta Lake and vicinity) between the impoundment area and relocation areas would be a potentially significant impact.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP2): Take and Loss of Habitat for the Pacific Fisher
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of approximately 1,057 acres of Pacific fisher habitat.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-30.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-30. Impacts on Suitable Habitat for the Pacific Fisher in the Impoundment Area (12.5-Foot Dam Raise)

Total Habitat	203.53	25.47	243.34	215.23	114.49	245.68	1057.27

Note:
[1] Acreage values are approximate.

Impact Wild-11 (CP2): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, Yuma Myotis, and Fringed Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared myotis, a BLM sensitive species; the Yuma myotis, a BLM sensitive species; the fringed myotis, a USFS sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Dam construction, vegetation removal, and construction in the relocation areas, and inundation resulting from a 12.5-foot dam raise would result in the loss of approximately 45 acres of reproductive and roosting habitat for the pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat, Yuma myotis, and fringed myotis in the impoundment area. Additionally, one limestone cave located on the Big Backbone Arm that is a known Townsend's big-eared bat roost would be affected by flooding. A 12.5-foot dam raise would result in the loss of approximately 1,687 acres of reproductive and roosting habitat for the western red bat and long-eared myotis. These impacts would be potentially significant.

Dam construction, vegetation removal, and inundation resulting from a 12.5-foot dam raise would result in the loss of approximately 1,687 acres of ringtail habitat. A 12.5-foot dam raise would result in the loss of approximately 1,022 acres of American marten habitat in the impoundment area. These impacts would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-31.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP2): Impacts on Special-Status Terrestrial Mollusks (Church's sideband, Shasta Sideband, Wintu Sideband, Oregon shoulderband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and/or S&M species, and the Shasta sideband is also an MSCS-covered species. The Shasta sideband, Wintu sideband, Shasta chaparral, and Shasta hesperian are also petitioned for Federal listing. Ground-disturbing activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of these species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in the loss of approximately 1,679 acres of Church's sideband, Oregon shoulderband, and Shasta chaparral habitat; and 37 acres of Shasta hesperian habitat in the impoundment area. Approximately 7 acres of Shasta sideband habitat and 2 acres of Wintu sideband would be lost. These impacts would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-32.

Mitigation for this impact is proposed in Section 13.3.5.

Total Habitat	1.54	2.48	15.92	4.60	0.58	2.59	27.71

Note:
[1] Acres are approximate.

Impact Wild-13 (CP2): Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in the permanent loss of habitat. This would be a potentially significant impact.

These general habitats also represent potential Western bumble bee habitat. Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat containing flowering shrubs and forbs, which serve as potential Western bumble bee nectar sources, and potential underground burrow locations. In addition, inundation caused by the raising of Shasta Dam would result in the permanent loss of habitat. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in a greater loss of general wildlife habitat and Western bumble bee habitat. This impact would be potentially significant.

Inundation resulting from a 12.5-foot dam raise would result in a loss of approximately 1,725 acres of general wildlife habitat and Western bumble bee habitat in the impoundment area. Impacts on general wildlife habitat and Western bumble bee habitat by CWHR type in the impoundment area are summarized in Table 13-33.

Mitigation for this impact is proposed in Section 13.3.5.

Note:
[1]Acreage values are approximate.

Impact Wild-14 (CP2): Impacts on Other Birds of Prey (e.g., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species (e.g., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam could result in the loss of active nests and habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in greater impacts on nesting migratory birds and raptors. This impact would be potentially significant.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP2): Loss of Critical Deer Winter and Fawning Range Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by a 12.5-foot raise of Shasta Dam would result in the loss of approximately 4,446 acres of critical deer winter and/or fawning range. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP2): Take and Loss of the California Red-Legged Frog Reclamation completed California red-legged frog habitat assessments in coordination with the USFWS in the applicable impoundment and relocation areas, and the potential downstream Sacramento River restoration sites. The assessment results will enable Reclamation and the USFWS to determine if habitat for the species occurs, if impacts are anticipated, and if additional surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and the California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is discussed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (CP2): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementing CP2 would increase available water storage in Shasta Reservoir and result in a modified flow regime. This modification would reduce the frequency, duration, and magnitude of intermediate to large flows downstream from Shasta Dam from December through January in most types of water years, extending through March in above-normal water years. Conversely, CP2 would increase the volume of flows from summer through fall of most years, especially in dry and critical water years. One of the goals of CP2 is to improve water supply during the driest of years, so this increase is not unexpected. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and reduce the long-term formation of off-channel habitats, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP2 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

This impact would be similar to Impact Wild-17 (CP1). CP2 would affect habitat for sensitive species through the same pathways (alteration of off-channel habitat for western pond turtles, changes to successional patterns of vegetation) as discussed for CP1. The only difference between the two is the extent of the impact. Under CP2, the reductions in winter flows would be both more frequent and of larger magnitude than modeled to occur under CP1. In all water year types (except below-normal years and December of critical years), flows would be reduced by CP2 in December and January by on average about 2.2 and 8.0 percent. In above-normal years, this extends through February (-6.3 percent) and March (-5.2 percent) (Table 13-34). This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP2): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes Implementing CP2 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the Sacramento River in the primary study area. This reduction also would alter the river’s geomorphic processes, including the rate of bank erosion. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. High flows during the nesting season that may cause localized nest failure would not increase substantially (generally less than an average of a 3-inch increase in water surface elevation in the worst case). For these reasons, the impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be similar to Impact Wild-18 (CP1). The extent of the impact could be greater under CP2 than under CP1 because reductions in channel-forming flows could be more extensive than under CP1. Nonetheless, for the same reasons as discussed for CP1, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP2): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime As mentioned in Impact Wild-19 (CP1), vernal pools are generally not present within the active floodplain of the upper Sacramento River in the primary study area; vernal pools are found in upland locations outside of the main river channel and the floodplain. Thus, vernal pools are not anticipated to be affected by changes in flows that could result from implementation of CP2. Because CP2 would not affect vernal pool habitat or the species that occur within the habitat, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP2): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-20 (CP1). The extent of the impact could be greater under CP2 than under CP1. This impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP2): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program Gravel augmentation is not included as part of CP2. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-22 (CP2): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration Projects CP2 would not include any specific restoration components. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Wild-23 (CP2): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementing CP2 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter in some years. It also would increase the flow volumes in late summer and fall of most years. Although this change in surface and subsurface hydrology would be of a smaller magnitude than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats along the lower Sacramento River, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP2 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

This impact would be similar to Impact Wild-23 (CP1). Because CP2 could substantially reduce available habitat for special-status wildlife, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP2): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes Implementing CP2 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the lower Sacramento River. This reduction also would alter the river's geomorphic processes. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. High flows during the nesting season that may cause localized bank and nest failure would not increase substantially. The impact on habitat for bank swallow nesting colonies, and therefore bank swallows themselves, would be less than significant.

This impact would be similar to Impact Wild-24 (CP1). The effect of CP2 on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP2 on river flows would attenuate with distance downstream. Because the extent of bank erosion and flooding of nesting sites is not expected to substantially change under CP2, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP2): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Vernal pools are present in upland areas near the Sacramento River and its tributaries in the extended study area. These pools provide habitat for numerous special-status species. Critical habitat for three special-status species (vernal pool fairy shrimp, vernal pool tadpole shrimp, and Conservancy fairy shrimp) is located within the extended study area. Critical habitat for these species is confined to vernal pool communities (USFWS 2006). However, vernal pools are generally not present within the active floodplain of regulated rivers along the lower Sacramento River and in the Delta. Because the sensitive habitat and species are located outside of the area affected by the changes in flows, CP2 would not alter this habitat. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP2): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat Along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-26 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP2): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP2 would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

This impact would be similar to Impact Wild-27 (CP1). The CVP and SWP are operated as an integrated system with the same downstream management targets and goals. CVP and SWP operations are constrained by the 2008 USFWS BO and the 2009 NMFS BO. Thus, implementation of CP2 is not anticipated to sufficiently alter flow to the CVP/SWP service areas to have a substantial effect on the riparian habitat upon which special-status wildlife species depend. For these reasons, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3 is similar to CP1 and CP2. It focuses on the greatest practical enlargement of Shasta Dam and Shasta Lake consistent with the goals of the 2000 CALFED Programmatic ROD, and was formulated for the primary purposes of increased water supply reliability and increased survival of anadromous fish. In addition to the common features above, CP3 involves raising Shasta Dam 18.5 feet, an elevation change that would increase the full pool by 20.5 feet and enlarge the total storage space in the reservoir by 634,000 acre-feet to 5.19 million acre-feet.

With respect to wildlife impacts, dam construction activities for CP1 through CP5 would be so similar that they are considered to be identical for purposes of this analysis. Because CP3 would result in higher lake levels than CP2, CP3 would also require more relocation of utilities, public service facilities, and recreational facilities than CP2, including a loss of up to 35 acres of limestone habitat and 2,870 acres of nonlimestone habitat. Because CP3 would result in higher lake levels than CP2, CP3 would also result in a larger (and deeper) area of inundation than CP2, in turn requiring more vegetation clearing within the inundation area than CP2.

Shasta Lake and Vicinity

Impact Wild-1 (CP3): Take and Loss of Habitat for the Shasta Salamander Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, S&M species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the Shasta salamander. This impact would be significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of approximately 16 acres of limestone habitat and 2,399 acres of nonlimestone habitat. Impacts on limestone and nonlimestone habitats in the impoundment area are summarized in Table 13-35.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-35. Impacts on Suitable Habitat for the Shasta Salamander in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Limestone	0.00	1.63	0.00	11.09	0.00	2.85	15.57
Nonlimestone	436.74	89.15	710.35	407.76	241.51	511.00	2399.56
Total	436.74	90.78	710.35	418.85	241.51	513.85	2415.13

Note:
[1] Acreage values are approximate.

Impact Wild-2 (CP3): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the foothill yellow-legged and tailed frogs. This impact would be potentially significant.

Implementation of an 18.5-foot raise of the dam would result in inundation of approximately 80 acres of foothill yellow-legged frog and tailed frog habitat. A summary of suitable habitat loss by arm is presented in Table 13-36.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-36. Impacts on Suitable Habitat for the Foothill Yellow-Legged and Tailed Frog in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Montane riparian	4.16	6.67	26.16	13.91	1.53	5.52	57.94
Riverine	0.00	0.88	5.24	15.43	1.41	0.00	22.96
Total	4.16	7.55	31.40	29.34	2.94	5.52	80.90

Note:
[1] Acreage values are approximate.

Impact Wild-3 (CP3): Impact on the Northwestern Pond Turtle and Its Habitat
Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion and sedimentation. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the northwestern pond turtle. This impact would be potentially significant.

Implementation of an 18.5-foot raise of the dam would result in the conversion of approximately 58 acres of montane riparian and 23 acres of riverine habitat to lacustrine habitat. Because equally valuable components are lost or gained in either habitat, the quality of the habitat would not be compromised. However, maximum lake inundation would be infrequent (at most 1 month per year) and would not benefit the species throughout the remainder of the year. Thus, the conversion to lacustrine habitat would remain an impact on northwestern pond turtle habitat. A summary of suitable habitat loss by arm is presented in Table 13-37.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-37. Impacts on Suitable Habitat for the Northwestern Pond Turtle in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Montane riparian	4.16	6.67	26.16	13.91	1.53	5.52	57.94
Riverine	0.00	0.88	5.24	15.43	1.41	0.00	22.96
Total	4.16	7.55	31.40	29.34	2.94	5.52	80.90

Note:
[1] Acreage values are approximate.

Impact Wild-4 (CP3): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the American peregrine falcon.

Similar to CP1, overstory and complete vegetation removal is expected to occur within the impoundment area in suitable cliff habitat. Thus, overstory vegetation removal occurring in or near suitable cliff habitat during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests. Additionally, because of the steep terrain, trees would be yarded by helicopter. Noise generated by chainsaws and helicopter yarding could cause the abandonment of nests, resulting in the incidental loss of fertile eggs or nestlings. This impact would be potentially significant.

No known eyries would be inundated with an 18.5-foot raise in lake elevation; however, 18.5 (full pool) vertical feet of cliff habitat would be inundated. The impacts on this amount of cliff habitat suitable for nesting would be less than significant. The conversion of uplands to lacustrine habitat would not adversely affect foraging habitat for the species because they frequently forage over water. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP3): Take and Loss of Habitat for the Bald Eagle Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCS-covered species, and a BLM sensitive species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the bald eagle. This impact would be potentially significant.

Six known bald eagle nest trees would be affected by an 18.5-foot dam raise due to inundation. When inundation occurs, nest trees within the impoundment area would die. Because peak inundation generally occurs in late April or early June, nest trees would be flooded toward the end of the nesting season. If eagles were nesting in these trees, it would be likely that young would fledge before the nest tree died from the effects of inundation. Because of inundation timing, it is not likely that individuals would be affected. Because bald eagles generally use the same nest for multiple years, the loss of nest trees would be a significant impact.

Inundation could also affect erosion and bank stability, which could affect nest trees that are in close proximity to the impoundment area. This would be a potentially significant impact.

Inundation resulting from an 18.5-foot dam raise would result in a loss of approximately 1,989 acres of bald eagle nesting and roosting habitat. Impacts on suitable bald eagle habitat by CWHR type in the impoundment area are summarized in Table 13-38.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-38. Impacts on Suitable Habitat for the Bald Eagle in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total

Note:
[1] Acreage values are approximate.

Impact Wild-6 (CP3): Loss of Dispersal Habitat for the Northern Spotted Owl
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the northern spotted owl, a species that is Federally listed as threatened species and an MSCS-covered species. In addition, inundation caused by the raising of Shasta Dam would result in the loss of habitat for this species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for the northern spotted owl. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of approximately 976 acres of northern spotted owl dispersal habitat. Impacts on suitable spotted owl habitat by CWHR type in the impoundment area are summarized in Table 13-39.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-39. Impacts on Suitable Habitat for the Northern Spotted Owl in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres[1])						
	Main Body	Big Backbone Arm	Sacramento Arm	McCloud Arm	Squaw Creek Arm	Pit Arm	Total
Dispersal	145.16	17.49	243.53	239.73	114.12	216.06	976.09
Foraging	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Nesting/Roosting	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Total	145.16	17.49	243.53	239.73	114.12	216.06	976.09

Note:
[1] Acreage values are approximate.

Impact Wild-7 (CP3): Impact on the Purple Martin and Its Nesting Habitat
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. Also similar to CP1, nest trees occurring in the lake could be adversely affected by inundation and related vegetation removal. These impacts would be potentially significant.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-8 (CP3): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat
Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a species State listed as endangered, a USFS sensitive species, and an MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of approximately 1,938 acres of Vaux's swift nesting and foraging habitat in the impoundment area. Additionally, approximately 58 acres of willow flycatcher, yellow warbler, and yellow-breasted chat habitat would be lost in the impoundment area.

Impacts on suitable habitats for the willow flycatcher, Vaux's swift, yellow warbler, and yellow-breasted chat by CWHR type in the impoundment area are summarized in Table 13-40.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-40. Impacts on Suitable Habitat for the Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat in the Impoundment Area (18.5-Foot Dam Raise)

Impact Wild-9 (CP3): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of approximately 1,428 acres of nesting and foraging habitat for the long-eared owl and northern goshawk, approximately 2,167 acres of nesting and foraging habitat for the Cooper's hawk, and approximately 2,167 acres of nesting habitat for the great blue heron. Foraging habitat would increase for osprey and the great blue heron. No impact to foraging habitat for these species would occur.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-41.

Table 13-41. Impacts on Suitable Habitat for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, and Great Blue Heron in the Impoundment Area (18.5-Foot Dam Raise)

Habitat	Area (Acres[1])

Total Habitat	406.48	77.15	548.77	403.70	231.16	499.73	2167.00

Note:
[1] Acreage values are approximate.

Impacts to osprey would be similar to those described for CP1. There are 54 osprey nests within the perimeter of Shasta Lake. Seven nest trees would be affected by a 12.5-foot dam raise, and 11 nests are located in relocation areas. Removal of nest trees would be a potentially significant impact. Because osprey generally use the same nest for multiple years, the loss of 18 nest trees (33 percent of the total in the Shasta Lake and vicinity) between the impoundment area and relocation areas would be a potentially significant impact.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP3): Take and Loss of Habitat for the Pacific Fisher
Construction activities and vegetation removal associated with raising the dam,

construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of approximately 1,533 acres of Pacific fisher habitat.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-42.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-42. Impacts on Suitable Habitat for the Pacific Fisher in the Impoundment Area (18.5-Foot Dam Raise)

Note:
[1] Acreage values are approximate.

Impact Wild-11 (CP3): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, Yuma Myotis, and Fringed Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the

Townsend’s big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared myotis, a BLM sensitive species; the Yuma myotis, a BLM sensitive species; the fronged myotis, a USFS sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Dam construction, vegetation removal, and inundation resulting from an 18.5-foot dam raise would result in the loss of approximately 69 acres of reproductive and roosting habitat for the pallid bat, spotted bat, western mastiff bat, Townsend’s big-eared bat, Yuma myotis, and fringed myotis in the impoundment area. Additionally, one limestone cave located on the Big Backbone Arm that is a known Townsend’s big-eared bat roost would be affected by flooding. An 18.5-foot dam raise would result in the loss of approximately 2,431 acres of reproductive and roosting habitat for the western red bat and long-eared myotis. These impacts would be potentially significant.

Dam construction, vegetation removal, and inundation resulting from an 18.5-foot dam raise would result in the loss of approximately 2,431 acres of ringtail habitat. An 18.5-foot dam raise would result in the loss of approximately 1,482 acres of American marten habitat in the impoundment area. These impacts would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-43.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP3): Impacts on Special-Status Terrestrial Mollusks (Church's sideband, Shasta Sideband, Wintu Sideband, Oregon shoulderband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and/or S&M species, and the Shasta sideband is also an MSCS-covered species. The Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian are also petitioned for Federal listing. Ground-disturbing activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of these species. This impact would be significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of suitable habitat for these species. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in the loss of approximately 2,415 acres of Church's sideband, Oregon shoulderband, and Shasta chaparral habitat; and 58 acres of Shasta hesperian habitat in the impoundment area. Approximately 11 acres of Shasta sideband habitat and 3 acres of Wintu sideband habitat would be lost. These impacts would be potentially significant.

Impacts on suitable habitat by CWHR type in the impoundment area are summarized in Table 13-44.

Mitigation for this impact is proposed in Section 13.3.5.

Note:
[1] Acres are approximate.

Impact Wild-13 (CP3): Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in the permanent loss of habitat. This would be a potentially significant impact.

These general habitats also represent potential western bumble bee habitat. Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat containing flowering shrubs and forbs, which serve as potential western bumble bee nectar sources, and potential underground burrow locations. In addition, inundation caused by the raising of Shasta Dam would result in the permanent loss of habitat. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP2. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in a greater loss of general wildlife habitat and western bumble bee habitat. This impact would be potentially significant.

Inundation resulting from an 18.5-foot dam raise would result in a loss of approximately 2,492 acres of general wildlife habitat and western bumble bee habitat in the impoundment area. Impacts on general wildlife habitat and western bumble bee habitat by CWHR type in the impoundment area are summarized in Table 13-45.

Mitigation for this impact is proposed in Section 13.3.5.

Table 13-45. Impacts on CWHR Habitats and Western Bumble Bee Habitat in the Impoundment Area (18.5-Foot Dam Raise)

Note:
[1] Acreage values are approximate.

Impact Wild-14 (CP3): Impacts on Other Birds of Prey (e.g., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species (e.g., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam could result in the loss of active nests and habitat for these species. This impact would be potentially significant.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in greater impacts on nesting migratory birds and raptors. This impact would be potentially significant.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP3): Loss of Critical Deer Winter and Fawning Range Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of

Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact.

Impacts caused by construction and vegetation clearing for the dam and relocation areas would be similar to CP1. However, inundation caused by an 18.5-foot raise of Shasta Dam would result in the loss of approximately 5,182 acres of critical deer winter and/or fawning range. This impact would be potentially significant.

Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP3): Take and Loss of the California Red-Legged Frog Reclamation completed California red-legged frog habitat assessments in coordination with the USFWS in the applicable impoundment and relocation areas, and the potential downstream Sacramento River restoration sites. The assessment results will enable Reclamation and the USFWS to determine if habitat for the species occurs, if impacts are anticipated, and if additional surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and the California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is discussed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (CP3): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementing CP3 would increase available water storage in Shasta Reservoir and result in a modified flow regime. This modification would reduce the frequency, duration, and magnitude of intermediate to large flows downstream from Shasta Dam during winter and spring in some water years, and would increase the volume of flows from spring through fall of some water year types. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and reduce the formation of off-channel habitats, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP3 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

This impact would be similar to Impact Wild-17 (CP1). The goal of CP3 is to increase agricultural water supply reliability, as is evident in the CalSim-II modeling results. As modeled, in dry and critical water years, flows are generally higher – substantially so in several months – for the entire growing season, extending into November (Table 13-46). This additional water is available during the growing season because of the increase in reservoir storage. Similar to results for CP1 and CP2, flows are shown to be substantially lower in winter and early spring as the larger reservoir captures more runoff. As discussed in Impact Wild-17 (CP1), the increased storage capacity reduces the frequency of channel-forming flows that create habitat for sensitive species like western pond turtle. This reduction in flows would also lead to a long-term reduction in early successional stage riparian habitat used by many species of riparian-dependent sensitive species of birds. The change in flow regimes would substantially reduce habitat for sensitive species of riparian-dependent wildlife. For this reason, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP3): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes Implementing CP3 would cause a reduction in the magnitude, duration, and frequency of intermediate to large flows in the Sacramento River in the primary study area. This reduction also would alter the river's geomorphic processes, including the rate of bank erosion. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. High flows during the nesting season that may cause localized nest failure would not increase. The impact on habitat for bank swallow nesting colonies would be less than significant.

This impact would be similar to Impact Wild-18 (CP1). Generally installed to protect upland land uses, bank revetment has been preferentially applied to actively eroding and migrating bends that otherwise would be among the most suitable sites for bank swallow nests. The reduction in intermediate to large flows by CP3 would cause a small reduction in the rate of erosion at the cut banks that remain unprotected by revetment. This alteration would not reduce the amount of bank swallow nesting habitat in the short or long term. The increase in water surface elevation is modeled to average about 2 inches or less during the breeding season (April–July) in all water year types. Although the flow increase exceeds the ±2 percent threshold that is used to discriminate between conditions essentially equivalent to existing conditions, the actual increase in elevation is not likely to result in additional flooding of bank swallow colonies. Because CP3 would not result in a substantial reduction in available habitat or in nesting colonies, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 13-46. Percent Change in Average Monthly Flows at Keswick Dam and Downstream Under CP3

Impact Wild-19 (CP3): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Changes in Flow Regime As mentioned in Impact Wild-19 (CP1), vernal pools are generally not present within the active floodplain of the upper Sacramento River in the primary study area; vernal pools are found in upland locations outside of the main river channel and the floodplain. Thus, vernal pools are not anticipated to be affected by changes in flows that could result from implementation of CP3. Because CP3 would not affect vernal pool habitat or the species that occur within the habitat, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP3): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-20 (CP1). The alteration of flows resulting from CP3 would continue to adversely affect riparian habitat. This would make the achievement of restoration, preservation, and conservation goals under regional and local plans and policies more difficult to attain. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP3): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program Gravel augmentation is not included as part of CP3. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-22 (CP3): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration Projects CP3 would not include any specific restoration components. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Wild-23 (CP3): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementing CP3 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years, but generally not above the ±2 percent threshold that separates the alternative from existing conditions. Under CP3 there would be increases in lower Sacramento River flows during the growing season, especially in the drier water years, that would occur as water was delivered to agricultural diversions. Many of these increases would exceed the ±2 percent threshold and therefore are considered substantial flow changes. Although this change in surface and subsurface hydrology would be of a smaller magnitude than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution and abundance of riparian-nesting special-status bird species. Because CP3 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

This impact would be similar to Impact Wild-23 (CP1). Implementing CP3 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years, but generally not above the ±2 percent threshold that separates the alternative from existing conditions (except at Verona in December of wet water years). Because the focus of CP3 is the delivery of water for agricultural uses, under CP3 there would be increases in lower Sacramento River flows during the growing season, especially in the drier water years, that would occur as water was delivered to agricultural diversions. As modeled, many of these increases in lower Sacramento River flows exceed the ±2 percent threshold (Table 13-46) and therefore are considered substantial flow changes. Because CP3 could substantially reduce available habitat for special-status wildlife, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP3): Impacts on Bank Swallow along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes Implementing CP3 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the lower Sacramento River. This reduction also would alter the river's geomorphic processes. The rate of bank erosion could be different than the existing rate, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be decline substantially. High flows during the nesting season that may cause localized bank and nest failure would not increase substantially. The impact on habitat for bank swallow nesting colonies, and therefore bank swallows themselves, would be less than significant.

This impact would be similar to Impact Wild-24 (CP1). The factors affecting bank erosion have been discussed previously. The effect of CP3 on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP3 on river flows would attenuate somewhat with distance downstream. The different operational goals of CP3 would actually increase average flows in the lower Sacramento River during November and December. Modeling shows only minor reductions in flows (less than 2 percent) during January and February.

The changes in flows predicted by CalSim-II are not expected to substantially alter the rate or extent of bank erosion. The maximum increase in average monthly water surface elevation predicted for the lower Sacramento River is generally less than 3 inches; this is not expected to result in a substantial increase in flooding of bank swallow nesting colonies. Because CP3 would not result in substantial changes in available habitat, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP3): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Vernal pools are present in upland areas near the Sacramento River and its tributaries in the extended study area. These pools provide habitat for numerous special-status species. Critical habitat for three special-status species (vernal pool fairy shrimp, vernal pool tadpole shrimp, and Conservancy fairy shrimp) is located within the extended study area. Critical habitat for these species is confined to vernal pool communities (USFWS 2006). However, vernal pools are generally not present within the active floodplain of regulated rivers along the lower Sacramento River and in the Delta. Because the sensitive habitat and species are located outside of the area affected by the changes in flows, CP3 would not alter this habitat. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP3): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat Along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

This impact would be similar to Impact Wild-26 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP3): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP3 would change flow regimes in several downstream waterways. Most potential noticeable changes in flows and stages would diminish downstream from Red Bluff. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and

SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

This impact would be similar to Impact Wild-27 (CP1). Modified flow regimes would change the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. However, based on the CalSim-II modeling results, the hydrologic effects in tributaries with CVP and SWP dams, outside of the primary study area, are expected to be less than effects on the Sacramento River. The CVP and SWP are operated as an integrated system with the same downstream management targets and goals. CVP and SWP operations are constrained by the 2008 USFWS BO and the 2009 NMFS BO. Thus, this alternative is not anticipated to sufficiently alter flow to the CVP/SWP service areas to have a substantial effect on the riparian habitat upon which special-status wildlife species depend. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

The primary function of CP4 and CP4A is to address survival of anadromous fish, while still improving water supply reliability. CP4 and CP4A focus on increasing the volume of cold water available to the temperature control device through reservoir reoperations and on raising Shasta Dam by 18.5 feet. As with CP3 and the common features above, this raise would increase the full pool by 20.5 feet and enlarge total reservoir storage space by 634,000 acre-feet.

CP4 and CP4A have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for fisheries purposes, however, the portion of this dedicated storage varies. For CP4, about 378,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1. For CP4A, about 191,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. For CP4A, operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2.

In addition to the activities common to CP1–CP3, CP4 and CP4A include augmenting locations along the Upper Sacramento River segment of the study area with gravel to increase spawning habitat for anadromous fish. Gravel placement would occur at one or more sites per year over a 10-year period and would be accomplished by one of three methods; lateral berms, talus cone, direct placement in river; as appropriate depending on specific conditions, including geomorphology, of the augmentation site. To the extent available, existing river access points would be used to deliver gravel to the river; however, temporary new access roads would be needed in some cases, mostly adjacent to the river, and would be extended from existing dirt roads.

Furthermore, under CP4 and CP4A, riparian, floodplain, and side channel habitat restoration would be implemented at up to six potential sites on the upper Sacramento River to restore habitat for anadromous salmonids.

With respect to wildlife impacts, dam construction activities for CP1–CP5 would be so similar that they are considered to be identical for purposes of this analysis. Because CP4 or CP4A would result in lake levels identical to those under CP3, CP4 or CP4A would require the same relocation of utilities, public service facilities, and recreational facilities as CP3, including a loss of up to 35 acres of limestone habitat and 2,870 acres of nonlimestone habitat. Because CP4 or CP4A would result in identical lake levels as CP3, CP4 or CP4A would result the same area of inundation as CP3, in turn requiring identical vegetation clearing within the inundation area as CP3. CP4 or CP4A would also involve some vegetation clearing in the Upper Sacramento River portion of the study area to provide access for gravel augmentation.

Shasta Lake and Vicinity

Impact Wild-1 (CP4 and CP4A): Take and Loss of Habitat for the Shasta Salamander Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, S&M species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant for CP4 or CP4A.

This impact would be similar to Impact Wild-1 (CP3) and would be significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-1 (CP3) and would be significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-2 (CP4 and CP4A): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Wild-2 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-2 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-3 (CP4 and CP4A): Impact on the Northwestern Pond Turtle and Its Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion and sedimentation. This impact would be potentially significant.

This impact would be similar to Impact Wild-3 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-3 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-4 (CP4 and CP4A): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Wild-4 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-4 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP4 and CP4A): Take and Loss of Habitat for the Bald Eagle Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCS-covered species, and a BLM sensitive species. This impact would be significant.

This impact would be similar to Impact Wild-5 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-5 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-6 (CP4 and CP4A): Loss of Dispersal Habitat for the Northern Spotted Owl Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in the loss of northern spotted owl dispersal habitat, a species Federally listed as threatened and an MSCS-covered species. This impact would be potentially significant.

This impact would be similar to Impact Wild-6 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-6 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-7 (CP4 and CP4A): Impact on the Purple Martin and Its Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant for CP4 or CP4A.

This impact would be similar to Impact Wild-7 (CP3) and would be significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-7 (CP3) and would be significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-8 (CP4 and CP4A): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a species State listed as endangered, a USFS sensitive species, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Wild-8 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-8 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-9 (CP4 and CP4A): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging *and Nesting Habitat* Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and nesting habitat for these species. This impact would be potentially significant for CP4 and CP4A.

This impact would be similar to Impact Wild-9 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-9 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP4 and CP4A): Take and Loss of Habitat for the Pacific Fisher Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Wild-10 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-10 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-11 (CP4 and CP4A): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, Yuma Myotis, and Fringed Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared myotis, a BLM sensitive species; the Yuma myotis, a BLM sensitive species; the fringed myotis, a USFS sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant for CP4 and CP4A.

This impact would be similar to Impact Wild-11 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-11 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP4 and CP4A): Impacts on Special-Status Terrestrial Mollusks (Church's sideband, Shasta Sideband, Wintu Sideband, Oregon shoulderband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat
All of these species are designated USFS sensitive and/or S&M species, and the Shasta sideband is also an MSCS-covered species. The Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian are also petitioned for Federal listing. Ground-disturbing activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of these species. This would be a significant impact for CP4 or CP4A.

This impact would be similar to Impact Wild-12 (CP3) and would be significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-12 (CP3) and would be significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-13 (CP4 and CP4A): Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in a permanent loss of habitat. This would be a potentially significant impact for CP4 or CP4A.

This impact would be similar to Impact Wild-13 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-13 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-14 (CP4 and CP4A): Impacts on Other Birds of Prey (e.g., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species (e.g., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam could result in the loss of active nests and habitat for these species. This impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact Wild-14 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be similar to Impact Wild-14 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP4 and CP4A): Loss of Critical Deer Winter and Fawning Range Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact for CP4 or CP4A.

This impact would be identical to Impact Wild-15 (CP3) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

This impact would be identical to Impact Wild-15 (CP3) and would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP4 and CP4A): Take and Loss of the California Red-Legged Frog Reclamation completed California red-legged frog habitat assessments in coordination with the USFWS in the applicable impoundment and relocations areas, and the potential downstream Sacramento River restoration sites. The assessment results will enable Reclamation and the USFWS to determine if habitat for the species occurs, if impacts are anticipated, and if additional surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and the California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is discussed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (CP4 and CP4A): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementation of CP4 or CP4A would increase the available water storage in Shasta Reservoir and result in a modified flow regime. This modification would reduce the frequency, duration, and magnitude of intermediate to large flows downstream from Shasta Dam during winter and spring in some years, especially wet and above-normal water years. Conversely, CP4 or CP4A would increase flow volumes in summer and fall of most years, most dramatically in September and October, because more water would be available to enhance conditions for anadromous fish (the goal of both CP4 and CP4A) in the driest months. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and reduce the formation of off-channel habitats, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP4 or CP4A would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Table 13-47 shows the changes in monthly flows that would occur under CP4. Therefore, this impact would be the same as Impact Wild-17 (CP1) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

For CP4A, this impact would be similar to Impact Wild-17 (CP1). CP4A would affect habitat for sensitive species through the same pathways (alteration of off-channel habitat for western pond turtles, changes to successional patterns of vegetation) as discussed for CP1. The only difference between the two is the extent of the impact. Operation of CP4A would be identical to CP2, and the reductions in winter flows would be both more frequent and of larger magnitude than modeled to occur under CP1. In all water year types (except below-normal years and the Decembers of critical years), flows would be reduced by CP4A in December and January on average about 2.2 and 8.0 percent, respectively. In above-normal years, this would extend through February (-6.3 percent) and March (-5.2 percent) (see CP2 in Table 13-34). This impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP4 and CP4A): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes The implementation of CP4 or CP4A would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the Sacramento River in the primary study area. This reduction also would alter the river's geomorphic processes, including the rate of bank erosion. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not be substantially reduced. High flows during the nesting season that may cause localized nest failure would not be increased. The impact on habitat for bank swallow nesting colonies would be less than significant for CP4 or CP4A.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Therefore, this impact would be the same as Impact Wild-18 (CP1) and would be less than significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

For CP4A, the impact would be similar to Impact Wild-18 (CP1), but greater as in Impact Wild-18 (CP2). The extent of the impact could be greater under CP4A than under CP1 because reductions in channel-forming flows could be more extensive than under CP1. Nonetheless, for the same reasons as discussed for CP1, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP4 and CP4A): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Dam Construction and from Changes in Flow Regime   As mentioned in Impact Wild-19 (CP1), vernal pools are generally not present within the active floodplain of the upper Sacramento River in the primary study area; vernal pools are found in upland locations outside of the main river channel and the floodplain. Thus, vernal pools are not anticipated to be affected by changes in flows that could result from implementation of CP4 or CP4A.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Therefore, this impact would be the same as Impact Wild-19 (CP1). Because CP4 would not affect vernal pool habitat or the sensitive wildlife species that occur within the habitat, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

The operational rules that govern the management of reservoirs and delivery of water under CP4A are identical to those that guided the modeling for CP2. Therefore, this impact would be the same as Impact Wild-19 (CP2). Because CP4A would not affect vernal pool habitat or the sensitive wildlife species that occur within the habitat, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP4 and CP4A): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant for CP4 or CP4A.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Therefore, this impact would be the same as Impact Wild-20 (CP1) and would be potentially significant for CP4. Mitigation for this impact is proposed in Section 13.3.5.

The operational rules that govern the management of reservoirs and delivery of water under CP4A are identical to those that guided the modeling for CP2. This impact would be similar to Impact Wild-20 (CP2). This impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP4 and CP4A): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program CP4 and CP4A include a gravel augmentation program in the upper Sacramento River for fisheries benefit, as described in Chapter 2, "Alternatives." Implementing the gravel augmentation program could result in temporary and short-term disturbance of riparian vegetation that has the potential to support special-status wildlife. There are no vernal pools or other seasonal wetland habitats at the augmentation sites. However, riparian-associated special-status wildlife species could be killed during removal of riparian vegetation. This impact would be potentially significant for CP4 or CP4A.

The implementation of a gravel augmentation program in the upper Sacramento River for fisheries benefit could result in temporary disturbance of habitat or removal of riparian vegetation that has the potential to support special-status wildlife. Gravel augmentation would occur at one to three sites per year over a 10-year period, so the area of impact in a given year would be relatively small. Although a total of 15 potential augmentation sites have been identified between Keswick Dam and Shea Island, the choice of specific sites would be made annually through an agency consultation process that would minimize impacts and maximize benefits of the deposited gravel.

Gravel placement itself is not expected to result in substantial adverse effects on any wildlife species because the gravel would all be placed within the active stream channel where there are no vernal pools or other seasonal wetland habitats. The main avenue of impact for riparian-dependent species would be construction of access roads required to allow equipment to reach the river. This would be a short-term habitat loss that would not be sufficient to substantially affect any wildlife species. However, riparian-associated special-status wildlife species could be killed during riparian vegetation removal. Direct loss of riparian-associated special-status species during vegetation removal would be a potentially significant impact for CP4 or CP4A. Potential effects on special-status wildlife species are as follows:

- **Invertebrates –** Blue elderberry shrubs, the host plant for the valley elderberry longhorn beetle, are found throughout much of the Sacramento River's riparian corridor. Gravel augmentation activities have the potential to directly and indirectly affect blue elderberry shrubs, as well as valley elderberry longhorn beetles potentially present in the shrubs. Eleven individual elderberry shrubs and/or clumps are present within 100 feet of areas that would be disturbed during gravel augmentation; these shrubs are located 20 feet or more from the access trail. As currently designed, no elderberry shrub removal is required; the nearest project activity is restricted to use of the access trail. Should access routes need to be adjusted or elderberry shrubs become established in an access route between augmentation intervals, the resulting disturbance of elderberry shrubs would be a potentially significant impact.

- **Reptiles and Amphibians –** The western pond turtle has been documented within the Sacramento River and suitable habitat for the species is provided in the primary study area. Riparian vegetation that would be removed along the river corridor provides potential cover and foraging habitat for western pond turtle. Augmentation activities would take place during the western pond turtle's breeding season; thus, the potential also exists to affect nests, eggs, nesting females, or juvenile turtles during vegetation clearing, grading, and gravel placement. Therefore, loss of habitat for the western pond turtle would be a potentially significant impact.

- **Birds –** The riparian and wetland habitats along the Sacramento River floodway provide potential nesting and foraging habitat for western yellow-billed cuckoo, California yellow warbler, and yellow-breasted chat, all of which are special-status birds that nest in riparian vegetation. In addition, northern harrier and short-eared owl may nest in marshes in or adjacent to the stream channel. Other raptors (Cooper's hawk, Swainson's hawk, white-tailed kite, bald eagle, and osprey) may nest in trees in the riparian habitat in the study area. Gravel augmentation activities would be limited to a 1-month window from late August to September each year. Therefore, gravel augmentation would generally be conducted outside of the nesting season of most of these species. However, there would still be some potential for active nests to be present in gravel augmentation and vegetation removal areas until mid-September. For example, the nesting season for Swainson's hawk, white-tailed kite, and other raptors is from March 1 to September 15 and the nesting season of many other species extends through August 31. Therefore, vegetation removal or disturbance of active nests could result in direct mortality or loss or abandonment of active nests. This would be a potentially significant impact.

- **Mammals –** Special-status mammals potentially occurring in the project area include pallid bat, western red bat, and ringtail. Riparian habitat can provide important foraging and roosting habitat for bats, but while they may roost there, these species are not typically dependent on riparian habitats. The amount of potential foraging and roosting habitat would not substantially decrease, so impacts on special-status bats would be less than significant. Removal of small amounts of riparian vegetation along the river channel in the study area to create access routes for gravel augmentation would not substantially reduce habitat for ringtail. Therefore, impacts on special-status mammals would be less than significant.

Because creation and maintenance of access routes to gravel augmentation sites has the potential to affect valley elderberry longhorn beetle, western pond turtle, and riparian-associated special-status birds, the impact would be potentially significant for CP4 or CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-22 (CP4 and CP4A): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration Projects CP4 and CP4A include riparian, floodplain, and side-channel habitat restoration at one or a combination of potential locations along the upper Sacramento River for fisheries benefit. Restoration actions could require removing vegetation, site grading and excavation, and planting of riparian species. This could require the construction of access routes, the use of heavy equipment to excavate side channels and restore floodplains, and the installation of native riparian plant species when earth-moving is complete. Disturbances as a result of these restoration actions would generally be related to construction-related activities, and could potentially take years for the installed plants to recover to the degree that the new community would function as high-quality riparian habitat. Overall, restoration work could result in disturbance and short-term removal of riparian vegetation that support riparian-associated special-status wildlife species that could be killed during riparian vegetation removal. This impact would be potentially significant for CP4 or CP4A.

CP4 and CP4A include restoration actions at up to six proposed sites. Potential effects of these actions on special-status wildlife species are as follows:

- **Invertebrates –** Blue elderberry shrubs, the host plant for the valley elderberry longhorn beetle, are found throughout much of the Sacramento River's riparian corridor. Elderberry shrubs may be present at any of the six proposed sites but have been documented near the Henderson Open Space, Anderson Island, and Reading Island sites. Construction activities have the potential to directly and indirectly affect blue elderberry shrubs, as well as valley elderberry longhorn beetles potentially present in the shrubs. Disturbance of elderberry shrubs would be a potentially significant impact for CP4 or CP4A.

- **Reptiles and Amphibians –** The western pond turtle has been documented within the Sacramento River, and suitable habitat for the species is provided within the primary study area. Riparian vegetation that would be removed along the river corridor provides potential cover and foraging habitat for western pond turtle. Pond turtles may use the historic and partially or intermittently connected side channels found at most of the restoration sites. Enhancement of these channels to provide spawning habitat for Chinook salmon could alter the channels to the extent that they are unsuitable for western pond turtles. This would primarily occur through an increase in water velocities required for spawning salmon and removal of complex cover and basking sites that turtles require. Habitat restoration activities would take place during the western pond turtle's breeding season; thus, the potential also exists to affect nests, eggs, juveniles, nesting females, and non-nesting adults during vegetation clearing, grading, and gravel placement. Therefore, loss of habitat for the western pond turtle or direct impacts on turtles themselves would be a potentially significant impact for CP4 or CP4A.

- **Birds –** The riparian habitat along the Sacramento River provides potential nesting and foraging habitat for western yellow-billed cuckoo, California yellow warbler, and yellow-breasted chat, all of which are special-status birds that nest in riparian vegetation. In addition, northern harrier and short-eared owl may nest in marshes in or adjacent to the stream channel. Other raptors (e.g., Cooper's hawk, Swainson's hawk, white-tailed kite, bald eagle, and osprey) may nest in trees in the riparian habitat along these waterways. Bald eagles have been documented nesting at Reading Island and Kapusta Island. The streambanks at Tobiasson Island and Reading Island provide nesting habitat for bank swallows. The proposed restoration activities all would require removing existing riparian vegetation to allow access to the work areas, staging equipment, removing soil, and site grading. Although riparian vegetation would be replanted after site work is complete, the removal or disturbance of active nests could result in direct mortality or loss or abandonment of active nests. This would be a potentially significant impact for CP4 or CP4A.

- **Mammals** – Special-status mammals potentially occurring in the project area include pallid bat, western red bat, and ringtail. Riparian habitat can provide important foraging and roosting habitat for bats, but these species are not typically dependent on riparian habitats. The amount of potential foraging habitat would not decrease appreciably during restoration activities. Available riparian habitats would still be sufficient for roosting habitat, so impacts on special-status bats would be less than significant. Vegetation removal would occur at any of the sites proposed for restoration. Although ringtail are not reported in the CNDDB (2012) from any of these locations, this species is known to occur in riparian habitat. The amount of vegetation to be removed would not substantially reduce available habitat for ringtail in the vicinity of these sites. Removal of small amounts of riparian vegetation along the river corridor would not substantially reduce habitat for ringtail. Therefore, impacts on special-status mammals would be less than significant for CP4 or CP4A.

The majority of the impacts associated with special-status wildlife species in upper Sacramento River riparian areas would be for short durations during r construction, temporary impacts lasting for several years after restoration is complete. Eventually conditions at the restoration sites would likely be the same as, or higher quality than what currently exists at the sites. Because of the potential to affect valley elderberry longhorn beetle, western pond turtle, and riparian-associated special-status birds, this impact would be potentially significant for CP4 or CP4A. Mitigation for this impact is proposed in Section 13.3.5.

Lower Sacramento River and Delta

Impact Wild-23 (CP4 and CP4A): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta The implementation of CP4 or CP4A would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years. It also would increase the volume of flows in fall of most years. Although this change in surface and subsurface hydrology would be of a smaller magnitude than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats along the lower Sacramento River, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP4 or CP4A would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant for CP4 or CP4A.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Therefore, this impact would be the same as Impact Wild-23 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

The operational rules that govern the management of reservoirs and delivery of water under CP4A are identical to those that guided the modeling for CP2. For CP4A, this impact would be the same as Impact Wild-23 (CP2). Because CP4A could substantially reduce available habitat for special-status wildlife, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP4 and CP4A): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes
Implementation of CP4 or CP4A would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the lower Sacramento River. This reduction also would alter the river's geomorphic processes. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. High flows during the nesting season that may cause localized bank and nest failure would not increase. The impact on habitat for bank swallow nesting colonies, and therefore bank swallows themselves, would be less than significant for CP4 or CP4A.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. The effect of CP4 on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP4 on river flows would attenuate with distance downstream. Therefore, this impact would be the same as Impact Wild-24 (CP1), and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

The operational rules that govern the management of reservoirs and delivery of water under CP4A are identical to those that guided the modeling for CP2. This impact would be the same as Impact Wild-24 (CP2). The effect of CP4A on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP4A on river flows would attenuate with distance downstream. Because the extent of bank erosion and flooding of nesting sites is not expected to substantially change under CP4A, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP4 and CP4A): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected

Tributaries, and Changes in Seasonal Water Availability Vernal pools are present in upland areas near the Sacramento River and its tributaries in the extended study area. These pools provide habitat for numerous special-status species. Critical habitat for three special-status species (vernal pool fairy shrimp, vernal pool tadpole shrimp, and Conservancy fairy shrimp) is located within the extended study area. Critical habitat for these species is confined to vernal pool communities (USFWS 2006). However, vernal pools are generally not present within the active floodplain of regulated rivers along the lower Sacramento River and in the Delta.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Because CP4 would not affect this habitat or these species, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

The operational rules that govern the management of reservoirs and delivery of water under CP4A are identical to those that guided the modeling for CP2. Because the sensitive habitat and species are located outside of the area affected by the changes in flows, CP4A would not alter this habitat. Therefore, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP4 and CP4A): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant for CP4 or CP4A.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Therefore, this impact would be the same as Impact Wild-26 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

The operational rules that govern the management of reservoirs and delivery of water under CP4A are identical to those that guided the modeling for CP2. Therefore, this impact would be the same as Impact Wild-26 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP4 and CP4A): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from

Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP4 or CP4A would change flow regimes in several downstream waterways. Modified flow regimes would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant for CP4 or CP4A.

The operational rules that govern the management of reservoirs and delivery of water under CP4 are identical to those that guided the modeling for CP1. Therefore, this impact would be the same as Impact Wild-27 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be similar to Impact Wild-27 (CP2). The CVP and SWP are operated as an integrated system with the same downstream management targets and goals. CVP and SWP operations are constrained by the 2008 USFWS BO and the 2009 NMFS BO. Thus, implementation of CP4A is not anticipated to sufficiently alter flow to the CVP/SWP service areas to have a substantial effect on the riparian habitat upon which special-status wildlife species depend. For these reasons, this impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 would address both the primary and secondary planning objectives. It involves enlarging Shasta Dam by 18.5 feet, which is consistent with the objectives of the 2000 CALFED Programmatic ROD, and also includes the common features described above. Affected wildlife acreages for CP5 are the same as described for CP4 and CP4A. In addition, CP5 involves (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing either additional or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. Formulation of specific environmental restoration features and increased recreation components is included in the Feasibility Report.

CP5 would also include implementing the same gravel augmentation program and the same riparian, floodplain, and side channel habitat restoration at up to six locations along the upper Sacramento River as described for CP4 and CP4A.

Shasta Lake and Vicinity

Impact Wild-1 (CP5): Take and Loss of Habitat for the Shasta Salamander Ground-disturbing activities associated with construction could result in direct take of the Shasta salamander, a State-listed species, USFS sensitive species, S&M species, MSCS-covered species, and BLM sensitive species. In addition, the raising of Shasta Dam would result in the inundation of habitat for this species. This impact would be significant.

This impact would be similar to Impact Wild-1 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-2 (CP5): Impact on the Foothill Yellow-Legged Frog and Tailed Frog and Their Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the foothill yellow-legged frog, a California species of special concern, a USFS sensitive species, an MSCS-covered species, and a BLM sensitive species, and of the tailed frog, a California species of special concern. In addition, the raising of Shasta Dam would result in the conversion of suitable riverine and riparian habitat to unsuitable lacustrine habitat. This impact would be potentially significant.

This impact would be similar to Impact Wild-2 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-3 (CP5): Impact on the Northwestern Pond Turtle and Its Habitat Ground-disturbing activities associated with construction could result in direct take (e.g., because of operation of equipment in or adjacent to riverine or riparian habitat) of the northwestern pond turtle, an MSCS-covered species, a California species of special concern, and a USFS sensitive species. In addition, project implementation could result in the degradation of suitable aquatic habitat because of increased erosion and sedimentation. This impact would be potentially significant.

This impact would be similar to Impact Wild-3 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-4 (CP5): Impact on the American Peregrine Falcon Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of American peregrine falcons, a State fully protected species and MSCS-covered species. This impact would be potentially significant.

This impact would be similar to Impact Wild-4 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-5 (CP5): Take and Loss of Habitat for the Bald Eagle Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas in addition to inundation caused by the raising of Shasta Dam during the nesting season would result in the loss of nest and perch trees used by the bald eagle, a State-listed species, fully protected species, and USFS sensitive species, an MSCS-covered species, and a BLM sensitive species. This impact would be significant.

This impact would be similar to Impact Wild-5 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-6 (CP5): Take and Loss of Dispersal Habitat for the Northern Spotted Owl Construction activities and vegetation removal associated with the dam construction activities, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in the loss of northern spotted owl dispersal habitat, a species Federally listed as threatened and an MSCS-covered species. This impact would be potentially significant.

This impact would be similar to Impact Wild-6 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-7 (CP5): Impact on the Purple Martin and Its Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of purple martins, a California species of special concern. In addition, inundation caused by the raising of Shasta Dam would result in the loss of nest trees. This impact would be significant.

This impact would be similar to Impact Wild-7 (CP3) and would be significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-8 (CP5): Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the willow flycatcher, a species State listed as endangered, USFS sensitive species, and MSCS-covered species; the Vaux's swift, a California species of special concern; and the yellow warbler and yellow-breasted chat, both California species of special concern and MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of habitat, including nesting habitat, for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-8 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-9 (CP5): Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of the long-eared owl, a California species of special concern and an MSCS-covered species; the northern goshawk, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the Cooper's hawk, an MSCS-covered species; the great blue heron, an MSCS-covered species; and the osprey, an MSCS-covered species. In addition, the raising of Shasta Dam would result in the loss of foraging and nesting habitat for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-9 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-10 (CP5): Take and Loss of Habitat for the Pacific Fisher Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the Pacific fisher, a Federal candidate for listing, a California species of special concern, a USFS sensitive species, and a BLM sensitive species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

This impact would be similar to Impact Wild-10 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-11 (CP5): Impacts on Special-Status Bats (Pallid Bat, Spotted Bat, Western Red Bat, Western Mastiff Bat, Townsend's Big-Eared Bat, Long-Eared Myotis, Yuma Myotis, and Fringed Myotis), the American Marten, and Ringtail and Their Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of habitat for the pallid bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the western red bat, a USFS sensitive species; the western mastiff bat, a California species of special concern, an MSCS-covered species, and a BLM sensitive species; the Townsend's big-eared bat, a California species of special concern, a USFS sensitive species, and a BLM sensitive species; the long-eared myotis, a BLM sensitive species; the Yuma myotis, a BLM sensitive species; the fringed myotis, a USFS sensitive species; the American marten, a USFS sensitive species; and the ringtail, a State fully protected and MSCS-covered species. Furthermore, take (including mortality of individuals because of destruction or disturbance of active roost sites or dens) could result from construction activities and vegetation clearing. This impact would be potentially significant.

This impact would be similar to Impact Wild-11 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-12 (CP5): Impacts on Special-Status Terrestrial Mollusks (Church's Sideband, Shasta Sideband, Wintu Sideband, Oregon Shoulderband, Shasta Chaparral, and Shasta Hesperian) and Their Habitat All of these species are designated USFS sensitive and/or S&M species, and the Shasta sideband is also an MSCS-covered species. The Shasta Sideband, Wintu Sideband, Shasta Chaparral, and Shasta Hesperian are also petitioned for Federal listing. Ground-disturbing activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas could result in direct take and/or loss of suitable habitat for special-status terrestrial mollusks. In addition, the raising of Shasta Dam would result in the inundation of suitable habitat and direct take of these species. This would be a significant impact.

This impact would be similar to Impact Wild-12 (CP3) and would be a significant impact. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-13 (CP5): Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a permanent loss of habitat. In addition, inundation caused by the raising of Shasta Dam would result in a permanent loss of habitat. This would be a potentially significant impact.

This impact would be similar to Impact Wild-13 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-14 (CP5): Impacts on Other Birds of Prey (e.g., red-tailed hawk and red-shouldered hawk) and Migratory Bird Species (e.g., American robin, Anna's hummingbird) and their Foraging and Nesting Habitat Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas during the nesting season could result in the incidental loss of fertile eggs or nestlings or otherwise lead to the abandonment of nests of other birds of prey and migratory bird species. In addition, inundation caused by the raising of Shasta Dam could result in the loss of active nests and habitat for these species. This impact would be potentially significant.

This impact would be similar to Impact Wild-14 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-15 (CP5): Loss of Critical Deer Winter and Fawning Range Construction activities and vegetation removal associated with raising the dam, construction activities in the relocation areas, and removal of various amounts of vegetation in the impoundment areas would result in a loss of critical deer winter and fawning range. In addition, inundation caused by the raising of Shasta Dam would result in the loss of critical deer range. This would be a potentially significant impact.

This impact would be similar to Impact Wild-15 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-16 (CP5): Take and Loss of the California Red-Legged Frog Reclamation completed California red-legged frog habitat assessments in coordination with the USFWS in the applicable impoundment and relocations areas, and the potential downstream Sacramento River restoration sites. The assessment results will enable Reclamation and the USFWS to determine if habitat for the species occurs, if impacts are anticipated, and if additional surveys are needed. Impacts on the California red-legged frog will be assessed if surveys are conducted and the California red-legged frog is found. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. Mitigation for this impact is discussed in Section 13.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Wild-17 (CP5): Impacts on Riparian-Associated Special-Status Wildlife Resulting from Modifications to the Existing Flow Regime in the Primary Study Area Implementing CP5 would increase available water storage in Shasta Reservoir and result in a modified flow regime. This modification would reduce the frequency, duration, and magnitude of intermediate to large flows downstream from Shasta Dam during winter and spring in some water years, and would increase the volume of flows in fall of most years. This change in surface and subsurface hydrology could affect habitats adjacent to the river channel and reduce the formation of off-channel habitats, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP5 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

This impact would be similar to Impact Wild-17 (CP1). The pathways by which sensitive species would be affected under CP5 are similar to those for CP1. The differences are in the magnitude of changes. For example, implementing CP5 would result in a reduction in average monthly flow downstream from Keswick Dam of between 2 and 10 percent in December of dry through wet water year types; similar although smaller reductions extend through March (Table 13-48). Because one of the goals of CP5 is increased water supply reliability, average monthly flows in critical water years are generally increased under CP5. As modeled, average monthly flows are substantially higher in April through August of dry water years and in September and October under most types of water years. Sensitive species could be affected by these changes through flow-caused alteration of riparian habitat and altered flow regimes. Because the changes would be substantial, they could result in increased mortality or reductions in reproductive success. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-18 (CP5): Impacts on Bank Swallow in the Primary Study Area Resulting from Modifications of Geomorphic Processes Implementing CP5 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the Sacramento River in the primary study area. This reduction also would alter the river's geomorphic processes, including the rate of bank erosion. However, the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. Therefore, the impact on habitat for bank swallow nesting colonies and the colonies themselves would be less than significant.

This impact would be the same as Impact Wild-18 (CP3). Modeling for CP5 predicts that increases in water surface elevation during the bank swallow nesting season would be at most an average of about 5–6 inches. These increases are not high enough that they would be expected to substantially increase the rate of localized nest failure. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-19 (CP5): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife from Dam Construction and from Changes in Flow Regime As mentioned in Impact Wild-19 (CP1), vernal pools are generally not present within the active floodplain of the upper Sacramento River in the primary study area; vernal pools are found in upland locations outside of the main river channel and the floodplain. Thus, vernal pools are not anticipated to be affected by changes in flows that could result from implementation of CP5. Because CP5 would not affect vernal pool habitat or the species that occur within the habitat, no impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-20 (CP5): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Wild-20 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-21 (CP5): Impacts on Riparian-Associated Special-Status Wildlife Resulting from the Gravel Augmentation Program CP5 includes the gravel augmentation program. Implementing the gravel augmentation program could result in temporary and short-term disturbance or removal of riparian vegetation that has the potential to support special-status wildlife. Gravel augmentation would occur at one to three sites per year over a 10-year period (distributed at up to 15 different sites overall), so the area of impact in a given year would be very small. Thus, gravel placement is not expected to result in any substantial short- or long-term adverse effects on any wildlife species. However, riparian-associated special-status wildlife species could be killed during disturbance or removal of riparian vegetation. This impact would be potentially significant.

This impact would be the same as Impact Wild-21 (CP4 and CP4A) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-22 (CP5): Impacts on Riparian-Associated Special-Status Wildlife Species Resulting from Restoration Projects Under CP5, riparian, floodplain, and side-channel habitat restoration would occur at one or a combination of potential locations along the upper Sacramento River. Restoration measures for the six potential restoration sites would generally involve riparian, floodplain, and side-channel restoration. Restoration actions could require removing vegetation, site grading and excavation, and planting riparian species. This could require the construction of access routes, use of heavy equipment to excavate side channels and restore floodplains, and installation of native riparian plant species when earth-moving is complete, Disturbances would generally be related to construction-related activities, but it would take years for the installed plants to recover to the degree that the new community would function as high-quality riparian habitat. Overall, restoration work could result in disturbance and short-term removal of riparian vegetation that support riparian-associated special-status wildlife species that could be killed during riparian vegetation removal. This impact would be potentially significant.

This impact would be the same as Impact Wild-22 (CP4 and CP4A) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Lower Sacramento River and Delta

Impact Wild-23 (CP5): Impacts on Riparian-Associated and Aquatic Special-Status Wildlife Resulting from Modifications to Existing Flow Regimes in the Lower Sacramento River and Delta Implementing CP5 would modify the flow regime and would reduce the frequency, duration, and magnitude of intermediate to large flows in the lower Sacramento River during winter and spring in some years. It also would increase the volume of flows in fall of most years. Although this change in surface and subsurface hydrology would be of smaller magnitude than in the upper Sacramento River, it could affect habitats adjacent to the river channel and the formation of off-channel habitats along the lower Sacramento River, which would adversely affect the habitat of western pond turtle. Although the total amount of riparian vegetation would not decline substantially, the portion in early successional stages would be reduced. These early successional stages provide habitat for some special-status wildlife species. These changes could result in substantial effects on the distribution or abundance of riparian-nesting special-status bird species. Because CP5 would substantially alter habitat for a variety of riparian-dependent special-status species, this impact would be potentially significant.

This impact would be the same as Impact Wild-23 (CP1). The pathways of the impact under CP5 would be the same as those under CP1. Because flows would be substantially altered under CP5, impacts on sensitive riparian-dependent species would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

Impact Wild-24 (CP5): Impacts on Bank Swallow Along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes Implementing CP5 would cause a small reduction in the magnitude, duration, and frequency of intermediate to large flows in the lower Sacramento River. This reduction also would alter the river's geomorphic processes. The rate of bank erosion would be reduced, but the length of eroding banks would not be substantially altered, and thus, nesting habitat for bank swallows would not decline substantially. High flows during the nesting season that may cause localized bank and nest failure would not increase. The impact on habitat for bank swallow nesting colonies, and therefore bank swallows themselves, would be less than significant.

This impact would be the same as Impact Wild-24 (CP1). The pathways of the impact under CP5 would be the same as those under CP1. The effect of CP5 on bank swallow habitat along the lower Sacramento River would be similar to the effect along the upper Sacramento River, but smaller because the effect of CP5 on river flows would attenuate somewhat with distance downstream. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-25 (CP5): Disturbance or Removal of Vernal Pool Habitat for Special-Status Wildlife Along the Lower Sacramento River and in the Delta from Changes in Flow Regime of the Sacramento River and Affected Tributaries, and Changes in Seasonal Water Availability Vernal pools are present in upland areas near the Sacramento River and its tributaries in the extended study area. These pools provide habitat for numerous special-status species. Critical habitat for three special-status species (vernal pool fairy shrimp, vernal pool tadpole shrimp, and Conservancy fairy shrimp) is located within the extended study area. Critical habitat for these species is confined to vernal pool communities (USFWS 2006). However, vernal pools are generally not present within the active floodplain of regulated rivers along the lower Sacramento River and in the Delta. Because the sensitive habitat and species are located outside of the area affected by the changes in flows, CP5 would not alter this habitat. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Wild-26 (CP5): Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta Several conservation and management plans have been adopted in the primary and extended study areas with goals of promoting riparian habitat along the Sacramento River. Because flow regimes and riverine geomorphic processes could be altered with project implementation, riparian habitat could be affected in such a manner that the goals of the local and regional plans would be more difficult to attain. Therefore, this impact would be potentially significant.

This impact would be the same as Impact Wild-26 (CP1) and would be potentially significant. Mitigation for this impact is proposed in Section 13.3.5.

CVP/SWP Service Areas

Impact Wild-27 (CP5): Impacts on Riparian-Associated or Aquatic Special-Status Wildlife in the CVP/SWP Service Areas Resulting from Modifications to Existing Flow Regimes By altering storage and operations at several reservoirs associated with the CVP and SWP service areas, CP5 would change flow regimes in several downstream waterways. The change in surface and subsurface hydrology could affect habitats adjacent to the river channel that provide habitat for special-status wildlife species. These changes are unlikely to result in substantial effects on the distribution or abundance of riparian-associated or aquatic special-status wildlife species in the CVP and SWP service areas outside of the primary study area. Therefore, this impact would be less than significant.

This impact is similar to Impact Wild-27 (CP1). Modified flow regimes under CP5 would reduce the frequency, duration, and magnitude of intermediate to large flows along the Sacramento River. Most potential noticeable changes in flows and stages would diminish downstream from Red Bluff, but substantial changes are predicted in the Sacramento River downstream as far as Freeport in some water years (Table 13-48). The CVP and SWP are operated as an integrated system with the same downstream management targets and goals. CVP and SWP operations are constrained by the 2008 USFWS BO and the 2009 NMFS BO. Thus, this alternative is not anticipated to sufficiently alter flow to the CVP/SWP service areas to have a substantial effect on riparian habitat upon which special-status wildlife species depend. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

13.3.5 Mitigation Measures

Table 13-49 presents a summary of mitigation measures for wildlife resources.

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts Wild-18 (CP1), Wild-19 (CP1), Wild-21 (CP1), Wild-22 (CP1), Wild-24 (CP1), Wild-25 (CP1), and Wild-27 (CP1). Mitigation is provided below for the remaining impacts of CP1 on wildlife species.

Key:
CP = Comprehensive Plan
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
S = significant
SU = significant and unavoidable
TBD = to be determined

Mitigation Measure Wild-1 (CP1): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander As described in the Preliminary Environmental Commitments and Mitigation Plan Appendix, Reclamation convened an interagency working group to enhance mitigation measures presented in the DEIS. This working group had the benefit of additional information from recent investigations of nearby private lands available for mitigation and refined analyses of potential project impacts. Using this updated information the working group developed and refined mitigation measures for wildlife resources, including land acquisition, habitat management and enhancement, and other measures.

Mitigation measure Wild-1 consists of a program to acquire nearby private lands with similar habitat attributes and species composition as those impacted by the SLWRI project. Reclamation has identified several willing private landowners and specific parcels for purchase in the SLWRI project area vicinity. Preliminary investigations of these lands have shown they contain similar and/or additional habitats and special-status species as those impacted by SLWRI. Special-status wildlife species known to occur on the lands subject to these preliminary investigations include Church's sideband, Klamath shoulderband, Shasta chaparral, Shasta sideband, Shasta hesperian, Shasta salamander, foothill yellow-legged frog, bald eagle, and Pacific fisher. Additionally, the interagency working group identified other private parcels with similar biological resources in the vicinity of the SLWRI project area, some of which have owners willing to discuss purchase agreements.

As discussed during the interagency working group meetings, mitigation measure Wild-3 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. The interagency working group also agreed that additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Inundation Area It is unfeasible to quantify the number of individual Shasta salamanders that would be lost in the impoundment area. Direct loss of individuals and of limestone habitat from inundation cannot be mitigated. As described above, mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-1 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-1 will mitigate for the loss of 1,195 acres of Shasta salamander habitat in the inundation area and 425 acres in the relocation areas by acquiring a minimum of 4,860 acres of mitigation lands containing comparable habitats. Potential mitigation lands containing comparable Shasta salamander habitat have been identified adjacent to the project. Shasta salamander has been found in both limestone and nonlimestone habitat in this site.

Vegetation Removal and Construction Activities

- To minimize impacts on individuals, preconstruction surveys, in consultation with CDFW and USFS, will be conducted by a qualified biologist before construction activities during the wet season. Individuals will be relocated to suitable limestone habitat in the vicinity of detection.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-1 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-2 (CP1): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog To avoid or minimize impacts on the foothill yellow-legged frog and tailed frog, the following measures will be implemented.

Inundation Area Individual foothill yellow-legged frog and tailed frogs will not be affected by the inundation caused by the raise of the dam. Animals will be able to swim upstream to suitable habitat.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-2 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-2 will mitigate for the loss of 35 acres of foothill yellow-legged frog and tailed frog habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 108 acres of mitigation lands containing comparable habitats.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid construction in perennial streams and their associated riparian zones.

- When instream construction activities must occur, a preconstruction survey of the foothill yellow-legged frog and tailed frog adults, larvae, and eggs will be conducted by a qualified biologist before ground-disturbing activities begin in perennial stream and riparian habitat. This survey will be conducted within the construction boundary no more than 1 week before instream or adjacent riparian construction activities begin. If foothill yellow-legged frog or tailed frog adults, larvae, or eggs are detected, the biologist in coordination with CDFW and USFS will relocate them to a suitable stream habitat outside the construction boundary. If frogs are absent, no further surveys will be required.

- If adults are found to use the stream where construction activities are intended to take place, a qualified biologist will relocate all individuals to suitable habitat outside the construction zone daily before instream activities resume.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-2 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-3 (CP1): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle To avoid or minimize impacts on the northwestern pond turtle, the following measures will be implemented.

Inundation Area Individual northwestern pond turtles will not be impacted by the inundation caused by the raise of the dam. Lacustrine is suitable habitat for the northwestern pond turtle. The loss of northwestern pond turtle nests in the inundation zone if inundated while eggs are in the nest is unavoidable.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-3 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-3 will mitigate for the loss of 35 acres of northwestern pond turtle habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 108 acres of mitigation lands containing comparable habitats.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid all suitable aquatic habitat and its associated riparian zone.

- When construction activities are to occur within suitable northwestern pond turtle habitat as defined in Impact Wild-3 (CP1), a qualified biologist will conduct a minimum of one preconstruction survey for northwestern pond turtles and their nests. The survey will be conducted no more than 1 week before construction. If a pond turtle nest is found, the biologist will flag the site and determine whether construction activities can avoid impacting the nest. If the nest cannot be avoided, CDFW and the USFS will be contacted for further direction and construction activities in that location will be halted.

- In the event that a pond turtle is observed within the construction limits, the contractor will temporarily halt construction activities until a qualified biologist has moved the turtle to a safe location within suitable habitat outside of the construction limits.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-3 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-4 (CP1): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers To avoid or minimize impacts on nesting American peregrine falcons, the following measures will be implemented.

Inundation Area Individual American peregrine falcons will not be impacted by the inundation caused by the raise of the dam.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid suitable cliff habitat.

- If vegetation removal or construction occurs outside of the breeding season (August 1 through March 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- For proposed construction activities during the breeding season (February 1 and July 31) within 0.5 mile of a known American peregrine falcon eyrie or suitable habitat identified in Impact Wild-4 (CP1), a qualified biologist will conduct a protocol-level survey. The survey will be conducted no more than 2 weeks before construction begins. If an active nest is found, a qualified biologist, in consultation with CDFW, will determine the construction-free buffer zone to be established around the nest until the young have fledged. In consultation with CDFW, a plan will be developed to monitor whether construction activity is disturbing the nesting process and to determine when the young have fledged.

Implementation of this mitigation measure would reduce Impact Wild-4 (CP1) to a less-than-significant level.

Mitigation Measure Wild-5 (CP1): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers To avoid or minimize impacts on nesting bald eagles, the following measures will be implemented.

Inundation Area This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-5 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations. For bald eagles, emphasis will also be placed on the location of these mitigation lands relative to large water body features to ensure these lands provide potential bald eagle habitat.

Under CP1, Wild-5 will mitigate for the loss of 979 acres of bald eagle habitat in the inundation area and 393 acres in the relocation areas by acquiring a minimum of 4,116 acres of mitigation lands containing comparable habitats. Additional mitigation will be provided by implementing fuels reduction projects within and adjacent to existing bald eagle nest stands at Shasta Lake to help protect those sites from wildfire.

Vegetation Removal and Construction Activities

- For each year of vegetation removal or construction activity, all active bald eagle nests will be located and mapped using the National Bald Eagle Management Guidelines (USFWS 2007).

- If vegetation removal or construction occurs outside of the breeding season (August 2 through December 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If vegetation removal is to occur between January 1 and August 1, a 660-foot to 0.5-mile buffer will be established around active nests in consultation with CDFW and USFS. No vegetation removal or construction activity will occur within the established buffer during the limited operating period.

The avoidance and relocation measures for vegetation removal and construction activities and the nest protection measures within the inundation area would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-5 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-6 (CP1): Acquire and Preserve Mitigation Lands for Northern Spotted Owl To avoid or minimize impacts on northern spotted owl dispersal habitat, the following measures will be implemented.

Inundation Area This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-6 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-6 will mitigate for the loss of 438 acres of northern spotted owl dispersal habitat in the inundation area and 341 acres in the relocation areas by acquiring a minimum of 2,337 acres of mitigation lands containing comparable habitats.

Providing compensatory mitigation by acquiring and conserving habitat mitigation lands for dispersal habitat will minimize this impact. Implementation of this mitigation measure would reduce Impact Wild-6 (CP1) to a less-than-significant level.

Mitigation Measure Wild-7 (CP1): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers Purple martins at Shasta Lake nest in flooded snags within the existing reservoir and snags occurring in recently burned areas at nearby upland locations. To avoid or minimize impacts on nesting purple martins, implement the following mitigation measures:

- To the extent feasible, all snags in the Pit Arm will be retained. Vegetation will not be removed from the Pit Arm from Jones Valley north, with exception of Arbuckle Campground, which will provide snag recruitment from trees that will die from inundation.
- If vegetation removal or construction occurs outside of the breeding season (September 1 through March 31), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.
- If proposed vegetation removal and construction activities are to take place on the Pit Arm from April 1 through August 31, a qualified biologist will conduct a protocol-level survey to locate active nests. The survey will be conducted no more than 2 weeks before construction begins. If an active nest is found, a qualified biologist, in consultation with CDFW, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with CDFW, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

In addition these measures, Reclamation will develop a purple martin management plan that details additional specific actions to minimize impacts in the inundation zone and maintain purple martin habitat in adjacent uplands. At a minimum, the management plan will include the following actions:

- Determine key upland nesting locations and identify vegetation management prescriptions, including prescribed fire and manual/mechanized techniques, which maintain open habitats and snags to preserve purple martin habitat.
- Implement vegetation management that maintains open habitats and snags to preserve purple martin habitat in the key upland locations.
- A minimum of 3 years before project construction and initial (new) inundation, develop an experimental artificial nest box program in upland nesting locations, including monitoring and adaptive management.

Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures would not protect purple martins actively nesting within the impoundment area when the lake reaches maximum inundation and might not fully mitigate the loss of snags used for nesting. Therefore, Impact Wild-7 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-8 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers To avoid or minimize impacts on nesting willow flycatchers, Vaux's swifts, yellow warblers, and yellow-breasted chats, the following measures will be implemented.

Inundation Area Individuals actively nesting within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-8 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-8 will mitigate for the loss of 954 acres of Vaux's swift habitat in the inundation area and 390 acres in the relocation areas by acquiring a minimum of 1,344 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-8 will mitigate for the loss of 28 acres of willow flycatcher, yellow warbler, and yellow-breasted chat habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 87 acres of mitigation lands containing comparable habitats.

Vegetation Removal and Construction Activities

- To the extent feasible, projects planned in relocation areas will be designed to avoid riparian habitat.
- To the extent feasible, construction activities will be avoided within riparian habitat and snags suitable for Vaux's swift nesting.
- If vegetation removal or construction occurs outside of the breeding season (September 1 through March 31), no further mitigation will be

necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to occur within 250 feet of suitable habitat for willow flycatchers, Vaux's swifts, yellow warblers, and yellow-breasted chats between April 1 and August 31, a qualified biologist will conduct a preconstruction survey no more than 2 weeks before construction activities begin. If an active nest is found, a qualified biologist, in consultation with CDFW, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with CDFW, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

- If willow flycatchers are detected during the preconstruction survey, protocol-level surveys using a current approved protocol will be conducted to locate and monitor active nests.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities; however, these measures would not protect individuals actively nesting within the impoundment area when the lake reaches maximum inundation. Also, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-8 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-9 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers To avoid or minimize impacts to these species, the following measures will be implemented.

Inundation Area This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-9 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-9 will mitigate for the loss of 699 acres of long-eared owl and northern goshawk habitat in the inundation area and 327 acres in the relocation areas by acquiring a minimum of 3,078 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-9 will mitigate for the loss of 1,072 acres of Cooper's hawk and great blue heron habitat in the inundation area and 402 acres in the relocation areas by acquiring a minimum of 4,422 acres of mitigation lands containing comparable habitats.

Vegetation Removal and Construction Activities

- To the extent feasible, construction activities will be avoided within riparian habitat.

- If vegetation removal or construction takes place outside of the breeding season (March 31 through September 1), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to take place within 0.25 mile of suitable habitat for the long-eared owl, northern goshawk, Cooper's hawk, and great blue heron between February 1 and August 31, a qualified biologist will conduct a preconstruction survey no more than 2 weeks before construction activities begin. Protocol-level surveys will be conducted in suitable goshawk habitat.

- If vegetation removal is to occur between February 1 and August 31, a construction-free buffer will be established around active nests in consultation with CDFW and USFS. No vegetation removal or construction activity will occur within the established buffer during the limited operating period.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-9 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-10 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Pacific Fisher and Establish Buffers To avoid or minimize impacts on Pacific fisher natal dens, the following measures will be implemented.

Inundation Area Pacific fisher natal dens within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated. However, female fishers often move young to alternate natal dens if threatened or disturbed.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-10 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-10 will mitigate for the loss of 749 acres of Pacific fisher habitat in the inundation area and 330 acres in the relocation areas by acquiring a minimum of 3,237 acres of mitigation lands containing comparable habitats. Potential mitigation lands containing comparable habitat and where Pacific fishers are known to occur have been identified adjacent to the project.

Vegetation Removal and Construction Activities

- If vegetation removal or construction occurs outside of the breeding season (February 1 through May 1), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to occur in suitable habitat for the Pacific fisher between February 1 and May 1, a qualified biologist will conduct a preconstruction survey for potential natal or maternity den trees no more than 2 weeks before construction activities begin. If an active den is found, a qualified biologist, in consultation with USFS, BLM (if on BLM land), and USFWS, will determine a construction-free buffer zone to be established around the den until the mother and young have dispersed. In consultation with USFWS, a plan will be developed to monitor whether construction activity is disturbing the reproductive success and to determine when the young have dispersed.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-10 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-11 (CP1): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for Special-Status Bats, American Marten, and Ringtails and Establish Buffers To avoid or minimize impacts on bats, American martens, and ringtails, the following measures will be implemented.

Inundation Area Maternity colonies or natal dens within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated. However, female western red bats, American martens, and ringtails would be expected to move young to alternate locations if threatened or disturbed.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-11 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-11 will mitigate for the loss of 31 acres of pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat, Yuma myotis, and fringed myotis habitat in the inundation area and 35 acres in the relocation areas by acquiring a minimum of 198 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-11 will mitigate for the loss of 1,201 acres of western red bat and long-eared myotis habitat in the inundation area and 457 acres in the relocation areas by acquiring a minimum of 4,974 acres of mitigation lands containing comparable habitats.

Under CP1, Wild-11 will mitigate for the loss of 1,201 acres of ringtail habitat in the inundation area and 457 acres in the relocation areas by acquiring a minimum of 1,658 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-11 will mitigate for the loss of 724 acres of American marten habitat in the inundation area and 328 acres in the relocation areas by acquiring a minimum of 3,156 acres of mitigation lands containing comparable habitats.

Vegetation Removal and Construction Activities

- A preconstruction survey conducted by a qualified bat biologist for roosting bats will be conducted before the inundation or removal of any bridges, buildings, known caves, or trees 12 inches or larger in diameter at breast height. If no active roosts are found, then no further action will be warranted. If a maternity roost is present, in consultation with CDFW, a qualified bat biologist will determine the extent of construction-free zones around active nurseries. If either a maternity roost or a hibernacula is present, either of the following measures will be implemented.

To the extent feasible, the project will be redesigned to avoid the loss of the maternity or hibernacula roost.

- If the project cannot be redesigned, removal of the occupied tree or structure should begin before maternity colonies form (i.e., before March 1) or after young are volant (flying) (i.e., after July 31). The established disturbance-free buffer will be observed during the maternity roost season (March 1 through July 31).

- If a nonbreeding bat hibernacula is found in a structure or tree scheduled for removal, the individuals will be safely evicted, under the direction of a qualified bat biologist (as determined by a memorandum of understanding with CDFW), by opening the roosting area to allow air flow through the cavity. Removal of the tree or structure will follow not before the following day (i.e., there should be at least 1 night between initial disturbance for air flow and the demolition). This action will allow bats to leave during dark hours, thus increasing their chance of finding new roosts with a minimum of potential predation during daylight. Trees with roosts that need to be removed should first be disturbed at dusk, just before removal that same evening, to allow bats to escape at night.

- For the American marten and ringtail, if vegetation removal or construction occurs outside of the breeding season (May 2 through January 31), no further mitigation is necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If proposed vegetation removal and construction activities are to occur in suitable habitat for the American marten and ringtail between February 1 and May 1, a qualified biologist will conduct a preconstruction survey for potential natal or maternity den trees no more than 2 weeks before construction activities begin. If an active den is found, a qualified biologist, in consultation with CDFW and USFS, will determine a construction-free buffer zone to be established around the den until the mother and young have dispersed. In consultation with CDFW and USFS, a plan will be developed to monitor whether construction activity is disturbing the reproductive success and to determine when the young have dispersed.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the loss of some individuals from inundation cannot be mitigated. Also, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-11 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-12 (CP1): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks To avoid or minimize impacts on special-status terrestrial mollusks, the following measures will be implemented.

Inundated Area It is infeasible to quantify the loss of individuals in the impoundment area. The loss of individuals and loss of limestone habitat (for Shasta and Wintu sideband snails) cannot be mitigated.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). As described in Wild-1 (CP1), mitigation lands will be acquired to mitigate for the loss of habitat. Additionally, opportunities for restoration and enhancement of habitat will be explored and defined. Mitigation measure Wild-12 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. This ratio will be applied specific to each habitat type. Additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-12 will mitigate for the loss of 1,195 acres of Church’s sideband, Oregon shoulderband, and Shasta chaparral habitat in the inundation area and 425 acres in the relocation areas by acquiring a minimum of 4,860 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-12 will mitigate for the loss of 28 acres of Shasta hesperian habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 87 acres of mitigation lands containing comparable habitats.

Under CP1, Wild-12 will mitigate for the loss of 5 acres of Shasta sideband habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 18 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-12 will mitigate for the loss of 1.5 acres of Wintu sideband habitat in the inundation area by acquiring a minimum of 4.5 acres of mitigation lands containing comparable habitats.

Vegetation Removal and Construction Activities

- When feasible, use of heavy equipment and excavation in limestone substrates and riparian or mesic habitats will be avoided.

- Guidelines provided in Management Recommendations for Survey and Manage Terrestrial Mollusks (Burke et al. 1999) will be applied.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the loss of some individuals from inundation cannot be mitigated. Also, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-12 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-13 (CP1): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat Mitigation measure Wild-13 consists of a program to acquire nearby private lands with similar habitat attributes and species composition as those impacted by the SLWRI project. Reclamation has identified several willing private landowners and specific parcels for purchase in the SLWRI project area vicinity. Preliminary investigations of these lands have shown they contain similar and/or additional habitats and special-status species as those impacted by SLWRI. Additionally, the interagency working group identified other private parcels with similar biological resources in the vicinity of the SLWRI project area, some of which have owners willing to discuss purchase agreements.

As discussed during the interagency working group meetings, mitigation measure Wild-13 will begin with a 3:1 minimum replacement ratio of acquired lands to impacted lands. The interagency working group also agreed that additional considerations will be made for other replacement ratios (more or less), depending on habitat quality at a particular site. Emphasis will be placed on lands containing high-value habitats (e.g., riparian, wetland, limestone, blue oak woodlands) and/or special-status species populations.

Under CP1, Wild-13 will mitigate for the loss of 1,227 acres of overall habitats and western bumble bee habitat in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 5,775 acres of mitigation lands containing comparable habitats.

The effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-13 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-14 (CP1): Acquire and Preserve Mitigation Lands and Conduct Preconstruction Surveys for Other Nesting Raptors and Migratory Birds and Establish Buffers To avoid or minimize impacts on nesting raptors and migratory birds, the following measures will be implemented.

Inundation Area Individuals actively nesting within the impoundment area could be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated.

Vegetation Removal and Construction Activities

- To the extent feasible, construction activities will be avoided within riparian habitat.

- If vegetation removal or construction occurs outside of the breeding season (March 31 through September 1), no further mitigation will be necessary. If the breeding season cannot be completely avoided, the following measure will be implemented.

- If project-related vegetation removal or construction will occur during the breeding season (February 1 through August 31), a qualified biologist will conduct a preconstruction survey for nesting birds. For migratory birds (non-raptors), preconstruction surveys will occur within the construction footprint and 250 feet beyond the construction footprint boundary. Surveys will be conducted no more than 2 weeks before construction. For raptors, preconstruction surveys will occur in suitable raptor nesting habitat within 0.25 mile of the construction footprint boundary. If an active nest is found, a qualified biologist, in consultation with CDFW, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with CDFW, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

The avoidance and relocation measures for vegetation removal and construction activities would effectively mitigate impacts caused by those activities. However, the loss of some individuals from inundation cannot be mitigated. Also, the effectiveness of providing compensatory mitigation by acquiring and conserving habitat mitigation lands to mitigate inundation impacts cannot be accurately determined without additional details. Therefore, Impact Wild-14 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-15 (CP1): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range

Inundation Area Habitats providing deer wintering and fawning range within the impoundment area would be flooded when the lake reaches maximum inundation. These potential losses cannot be mitigated. Therefore, Impact Wild-15 (CP1) would remain significant and unavoidable.

Mitigation Measure Wild-16 (CP1) Potential impacts and applicable mitigation have yet to be determined for the California red-legged frog. Impacts for each alternative will not be assessed until USFWS has determined whether suitable habitat is present and whether surveys would be required. At that time, the need for mitigation would be determined and appropriate mitigation described, if necessary.

Mitigation Measure Wild-17 (CP1): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan Reclamation will implement Mitigation Measure Bot-7 (CP1), “Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-17 (CP1) to a less-than-significant level.

Mitigation Measure Wild-20 (CP1): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan
Reclamation will implement Mitigation Measure Bot-7 (CP1), "Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-20 (CP1) to a less-than-significant level.

Mitigation Measure Wild-23 (CP1): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan Reclamation will implement Mitigation Measure Bot-7 (CP1), "Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-23 (CP1) to a less-than-significant level.

Mitigation Measure Wild-26 (CP1): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan Reclamation will implement Mitigation Measure Bot-7 (CP1), "Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities," described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-26 (CP1) to a less-than-significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability
No mitigation is required for Impacts Wild-18 (CP2), Wild-19 (CP2), Wild-21 (CP2), Wild-22 (CP2), Wild-24 (CP2), Wild-25 (CP2), and Wild-27 (CP2). Mitigation is provided below for the remaining impacts of CP2 on wildlife species.

Mitigation Measure Wild-1 (CP2): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP2) is considered significant and unavoidable.

Under CP2, Wild-1 will mitigate for the loss of 1,678 acres of Shasta salamander habitat in the inundation area and 425 acres in the relocation areas by acquiring a minimum of 6,309 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-2 (CP2): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP2) is considered significant and unavoidable.

Under CP2, Wild-2 will mitigate for the loss of 47 acres of foothill yellow-legged frog and tailed frog habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 144 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-3 (CP2): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-3 (CP2) is considered significant and unavoidable.

Under CP2, Wild-3 will mitigate for the loss of 47 acres of northwestern pond turtle habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 144 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-4 (CP2): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of this mitigation measure will reduce Impact Wild-4 (CP2) to a less-than-significant level.

Mitigation Measure Wild-5 (CP2): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project;

however, all nest trees in the inundation zone will be lost. Therefore, Impact Wild-5 (CP2) is considered significant and unavoidable.

Under CP2, Wild-5 will mitigate for the loss of 1,376 acres of bald eagle habitat in the inundation area and 393 acres in the relocation areas by acquiring a minimum of 5,307 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-6 (CP2): Acquire and Preserve Mitigation Lands for Northern Spotted Owl This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts to northern spotted owl dispersal habitat.

Under CP2, Wild-6 will mitigate for the loss of 643 acres of northern spotted owl dispersal habitat in the inundation area and 341 acres in the relocation areas by acquiring a minimum of 2,952 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-7 (CP2): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate the loss of snags used for nesting. Therefore, Impact Wild-7 (CP2) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP2): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP2) is considered significant and unavoidable.

Under CP2, Wild-8 will mitigate for the loss of 1,341 acres of Vaux's swift habitat in the inundation area and 390 acres in the relocation areas by acquiring a minimum of 5,193 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-8 will mitigate for the loss of 37 acres of willow flycatcher, yellow warbler, and yellow-breasted chat habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 114 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-9 (CP2): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP2) is considered significant and unavoidable.

Under CP2, Wild-9 will mitigate for the loss of 987 acres of long-eared owl and northern goshawk habitat in the inundation area and 327 acres in the relocation areas by acquiring a minimum of 3,942 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-9 will mitigate for the loss of 1,505 acres of Cooper's hawk and great blue heron habitat in the inundation area and 402 acres in the relocation areas by acquiring a minimum of 5,721 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-10 (CP2): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP2) is considered significant and unavoidable.

Under CP2, Wild-10 will mitigate for the loss of 1,057 acres of Pacific fisher habitat in the inundation area and 330 acres in the relocation areas by acquiring a minimum of 4,161 acres of mitigation lands containing comparable habitats. Potential mitigation lands containing comparable habitat and where Pacific fishers are known to occur have been identified adjacent to the project.

Mitigation Measure Wild-11 (CP2): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP2) is considered significant and unavoidable.

Under CP2, Wild-11 will mitigate for the loss of 45 acres of pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat, Yuma myotis, and fringed myotis habitat in the inundation area and 35 acres in the relocation areas by acquiring a minimum of 240 acres of mitigation lands containing comparable habitats. Also under CP2, Wild-11 will mitigate for the loss of 1,687 acres of western red bat and long-eared myotis habitat in the inundation area and 457 acres in the relocation areas by acquiring a minimum of 6,432 acres of mitigation lands containing comparable habitats.

Under CP2, Wild-11 will mitigate for the loss of 1,687 acres of ringtail habitat in the inundation area and 457 acre in the relocation areas by acquiring a minimum of 6,432 acres of mitigation lands containing comparable habitats. Also under CP2, Wild-11 will mitigate for the loss of 1,022 acres of American marten habitat in the inundation area and 328 acres in the relocation areas by acquiring a minimum of 4,050 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-12 (CP2): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP2) is considered significant and unavoidable.

Under CP2, Wild-12 will mitigate for the loss of 1,697 acres of Church's sideband, Oregon shoulderband, and Shasta chaparral habitat in the inundation area and 425 acres in the relocation areas by acquiring a minimum of 6,366 acres of mitigation lands containing comparable habitats. Also under CP2, Wild-12 will mitigate for the loss of 37 acres of Shasta hesperian habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 114 acres of mitigation lands containing comparable habitats.

Under CP2, Wild-12 will mitigate for the loss of 7 acres of Shasta sideband habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 24 acres of mitigation lands containing comparable habitats. Also under CP2, Wild-12 will mitigate for the loss of 2 acres of Wintu sideband habitat in the inundation area by acquiring a minimum of 6 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-13 (CP2): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-13 (CP2) is considered significant and unavoidable.

Under CP2, Wild-13 will mitigate for the loss of 1,725 acres of overall habitats and western bumble bee habitat in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 7,269 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-14 (CP2): Acquire and Preserve Mitigation Lands and Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP2) is considered significant and unavoidable.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Under CP2, Wild-14 will mitigate for the loss of 1,725 acres of overall habitats and western bumble bee habitat in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 7,239 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-15 (CP2): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP2) is considered significant and unavoidable.

This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Under CP2, Wild-15 will mitigate for the loss of 1,725 acres of overall habitats and western bumble bee habitat in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 7,239 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-16 (CP2) Potential impacts and applicable mitigation has yet to be determined for the California red-legged frog. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP2): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-17 (CP2) to a less-than-significant level.

Mitigation Measure Wild-20 (CP2): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-20 (CP2) to a less-than-significant level.

Mitigation Measure Wild-23 (CP2): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem

Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-23 (CP2) to a less-than-significant level.

Mitigation Measure Wild-26 (CP2): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP2), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-26 (CP2) to a less-than-significant level.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation is required for Impacts Wild-18 (CP3), Wild-19 (CP3), Wild-21 (CP3), Wild-22 (CP3), Wild-24 (CP3), Wild-25 (CP3), and Wild-27 (CP3). Mitigation is provided below for the remaining impacts of CP3 on wildlife species.

Mitigation Measure Wild-1 (CP3): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP3) is considered significant and unavoidable.

Under CP3, Wild-1 will mitigate for the loss of 2,415 acres of Shasta salamander habitat in the inundation area and 425 acres in the relocation areas by acquiring a minimum of 8,520 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-2 (CP3): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP3) is considered significant and unavoidable.

Under CP3, Wild-2 will mitigate for the loss of 80 acres of foothill yellow-legged frog and tailed frog habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 243 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-3 (CP3): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because the impacts cannot be fully mitigated, Impact Wild-3 (CP3) is considered significant and unavoidable.

Under CP3, Wild-2 will mitigate for the loss of 80 acres of northwestern pond turtle habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 243 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-4 (CP3): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of this mitigation measure will reduce Impact Wild-4 (CP3) to a less-than-significant level.

Mitigation Measure Wild-5 (CP3): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project; however, all nest trees in the inundation zone will be lost. Therefore, Impact Wild-5 (CP3) is considered significant and unavoidable.

Under CP3, Wild-5 will mitigate for the loss of 1,989 acres of bald eagle habitat in the inundation area and 393 acres in the relocation areas by acquiring a minimum of 7,146 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-6 (CP3): Acquire and Preserve Mitigation Lands for Northern Spotted Owl This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts on northern spotted owl dispersal habitat.

Under CP3, Wild-6 will mitigate for the loss of 976 acres of northern spotted owl dispersal habitat in the inundation area and 341 acres in the relocation areas by acquiring a minimum of 3,951 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-7 (CP3): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate for the loss of snags used for nesting; therefore, Impact Wild-7 (CP3) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP3): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher,

Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP3) is considered significant and unavoidable.

Under CP3, Wild-8 will mitigate for the loss of 1,938 acres of Vaux's swift habitat in the inundation area and 390 acres in the relocation areas by acquiring a minimum of 6,984 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-8 will mitigate for the loss of 58 acres of willow flycatcher, yellow warbler, and yellow-breasted chat habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 177 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-9 (CP3): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP3) is considered significant and unavoidable.

Under CP3, Wild-9 will mitigate for the loss of 1,428 acres of long-eared owl and northern goshawk habitat in the inundation area and 327 acres in the relocation areas by acquiring a minimum of 5,265 acres of mitigation lands containing comparable habitats. Also under CP1, Wild-9 will mitigate for the loss of 2,167 acres of Cooper's hawk and great blue heron habitat in the inundation area and 402 acres in the relocation areas by acquiring a minimum of 7,707 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-10 (CP3): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP3) is considered significant and unavoidable.

Under CP2, Wild-10 will mitigate for the loss of 1,533 acres of Pacific fisher habitat in the inundation area and 330 acres in the relocation areas by acquiring a minimum of 5,589 acres of mitigation lands containing comparable habitats. Potential mitigation lands containing comparable habitat and where Pacific fishers are known to occur have been identified adjacent to the project.

Mitigation Measure Wild-11 (CP3): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP3) is considered significant and unavoidable.

Under CP3, Wild-11 will mitigate for the loss of 69 acres of pallid bat, spotted bat, western mastiff bat, Townsend's big-eared bat, Yuma myotis, and fringed myotis habitat in the inundation area and 35 acres in the relocation areas by acquiring a minimum of 312 acres of mitigation lands containing comparable habitats. Also under CP3, Wild-11 will mitigate for the loss of 2,431 acres of western red bat and long-eared myotis habitat in the inundation area and 457 acres in the relocation areas by acquiring a minimum of 8,664 acres of mitigation lands containing comparable habitats.

Under CP3, Wild-11 will mitigate for the loss of 2,431 acres of ringtail habitat in the inundation area and 457 acre in the relocation areas by acquiring a minimum of 8,664 acres of mitigation lands containing comparable habitats. Also under CP3, Wild-11 will mitigate for the loss of 1,482 acres of American marten habitat in the inundation area and 328 acres in the relocation areas by acquiring a minimum of 5,430 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-12 (CP3): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP3) is considered significant and unavoidable.

Under CP2, Wild-12 will mitigate for the loss of 2,415 acres of Church's sideband, Oregon shoulderband, and Shasta chaparral habitat in the inundation area and 425 acres in the relocation areas by acquiring a minimum of 8,520 acres of mitigation lands containing comparable habitats. Also under CP2, Wild-12 will mitigate for the loss of 58 acres of Shasta hesperian habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 177 acres of mitigation lands containing comparable habitats.

Under CP2, Wild-12 will mitigate for the loss of 11 acres of Shasta sideband habitat in the inundation area and 1 acre in the relocation areas by acquiring a minimum of 36 acres of mitigation lands containing comparable habitats. Also under CP2, Wild-12 will mitigate for the loss of 3 acres of Wintu sideband habitat in the inundation area by acquiring a minimum of 9 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-13 (CP3): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because the impacts cannot be fully mitigated, Impact Wild-13 (CP3) is considered significant and unavoidable.

Under CP3, Wild-13 will mitigate for the loss of 2,492 acres of overall habitats and western bumble bee habitat in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 9,570 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-14 (CP3): Acquire and Preserve Mitigation Lands and Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP3) is considered significant and unavoidable.

This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Under CP3, Wild-14 will mitigate for the loss of 2,492 acres of overall habitats and western bumble bee habitat in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 9,570 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-15 (CP3): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP3) is considered significant and unavoidable.

This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Under CP3, Wild-15 will mitigate for the loss of 2,492 acres of overall habitats and western bumble bee habitat in the inundation area and 698 acres in the relocation areas by acquiring a minimum of 9,570 acres of mitigation lands containing comparable habitats.

Mitigation Measure Wild-16 (CP3): Potential impacts and applicable mitigation has yet to be determined for the California red-legged frog. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP3): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-17 (CP3) to a less-than-significant level.

Mitigation Measure Wild-20 (CP3): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-20 (CP3) to a less-than-significant level.

Mitigation Measure Wild-23 (CP3): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-23 (CP3) to a less-than-significant level.

Mitigation Measure Wild-26 (CP3): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP3), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-26 (CP3) to a less-than-significant level.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Wild-18 (CP4 and CP4A), Wild-19 (CP4 and CP4A), Wild-24 (CP4 and CP4A), Wild-25 (CP4 and CP4A), and Wild-27 (CP4 and CP4A). Mitigation is provided below for the remaining impacts of CP4 or CP4A on wildlife species.

Mitigation Measure Wild-1 (CP4 and CP4A): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-2 (CP4 and CP4A): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-3 (CP4 and CP4A): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-3 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-4 (CP4 and CP4A): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of this mitigation measure will reduce Impact Wild-4 (CP4 and CP4A) to a less-than- significant level.

Mitigation Measure Wild-5 (CP4 and CP4A): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project; however, all nest trees in the inundation zone will be lost. Therefore, Impact Wild-5 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-6 (CP4 and CP4A): Acquire and Preserve Mitigation Lands for Northern Spotted Owl This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts on northern spotted owl dispersal habitat.

Mitigation Measure Wild-7 (CP4 and CP4A): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate the loss of snags used for nesting. Therefore, Impact Wild-7 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP4 and CP4A): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-9 (CP4 and CP4A): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers This mitigation measure is identical to Mitigation

Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-10 (CP4 and CP4A): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-11 (CP4 and CP4A): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-12 (CP4 and CP4A): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-13 (CP4 and CP4A): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat This mitigation measure is identical to Mitigation Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-13 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-14 (CP4 and CP4A): Acquire and Preserve Mitigation Lands and Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-15 (CP4 and CP4A): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP4 and CP4A) is considered significant and unavoidable.

Mitigation Measure Wild-16 (CP4 and CP4A): Potential impacts and applicable mitigation has yet to be determined for the California red-legged frog. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP4 and CP4A): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP4 and CP4A), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-17 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Wild-20 (CP4 and CP4A): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP4 and CP4A), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-20 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Wild-21 (CP4 and CP4A): Conduct Preconstruction Surveys for Elderberry Shrubs, Western Pond Turtle, and Nesting Riparian Raptors and Other Nesting Birds; Avoid Removal or Degradation of Elderberry Shrubs; and Avoid Vegetation Removal Near Active Nest Sites To avoid impacts on valley elderberry longhorn beetle, western pond turtle, and nesting raptors, and other nesting birds, Reclamation will implement the following measures at gravel augmentation sites with the potential to affect these species:

Valley Elderberry Longhorn Beetle

- A worker awareness training program for construction personnel will be conducted by a qualified biologist/restoration ecologist before gravel augmentation activities begin. The program will inform all construction personnel about the life history and status of the beetle, the need to avoid damaging the elderberry plants, and the possible penalties for not complying with these requirements. Written documentation of the training will be submitted to USFWS within 30 days of the completion of training.

- Elderberry shrubs shall be protected through establishment of a fenced avoidance area. Fencing will be placed at least 20 feet from the dripline of the shrubs where they occur along any access routes. Signs will be posted along the avoidance area. The signs will state: “This area is the habitat of the valley elderberry longhorn beetle, a threatened species, and must not be disturbed. This species is protected by the Endangered Species Act of 1973, as amended. Violators are subject to prosecution, fines, and imprisonment.” Signs will be readable from a distance of 20 feet. Fencing and signs will be maintained at gravel recruitment sites during construction activities.

- If removal of elderberry shrubs during construction of access routes is unavoidable, Reclamation will consult with USFWS as required under Section 7 of the ESA as appropriate. No project construction will proceed in areas potentially containing valley elderberry longhorn beetle until a BO has been issued by USFWS, and Reclamation has abided by all pertinent conditions in the BO relating to the proposed construction.

- Elderberry shrubs will be mitigated for according to the transplantation guidelines outlined in the Beetle Conservation Guidelines (USFWS 1999). These transplantation guidelines dictate the necessary timing and details of the transplanting. At the discretion of USFWS, shrubs that are unlikely to survive transplantation because of poor condition or location, or a plant that would be extremely difficult to move because of access problems, may be exempted from transplantation. In cases where transplantation is not possible, compensation ratios would be increased to offset the additional habitat loss.

- Relocation of existing elderberry shrubs and planting of new elderberry seedlings will be implemented on a no-net-loss basis. Compensatory mitigation for elderberry shrubs that would be removed from their current locations will be developed in consultation with USFWS during the Section 7 consultation process. Compensatory mitigation may include planting replacement elderberry seedlings or cuttings and associated native plants or purchasing credits at an approved mitigation bank, or a combination thereof. Relocated and replacement shrubs and associated native plantings will be placed in conservation areas providing a minimum of 1,800 square feet per transplanted shrub.

- No insecticides, herbicides, fertilizers, or other chemicals that might harm the beetle or its host plant will be used within 100 feet of elderberry shrubs. Roadways and disturbed areas within 100 feet of elderberry shrubs will be watered at least twice a day and as needed to minimize dust emissions.

Western Pond Turtle

- When construction activities are to occur within suitable western pond turtle habitat as defined in Impact Wild-3 (CP1), a qualified biologist will conduct a minimum of one preconstruction survey for western pond turtles and their nests. The survey will be conducted no more than 1 week before construction. If a pond turtle nest is found, the biologist will flag the site and determine whether construction activities can avoid impacting the nest. If the nest cannot be avoided, CDFW will be contacted for further direction and construction activities in that location will be halted.

- In the event that a pond turtle is observed within the construction limits, the contractor will temporarily halt construction activities until a qualified biologist has moved the turtle to a safe location within suitable habitat outside of the construction limits.

- When feasible, work areas will be surrounded by exclusion fencing consisting of silt fence securely staked into the ground, with the bottom edge buried at least 6 inches to prevent turtles from accessing the work sites from upland locations.

Birds

- For each year of vegetation removal for gravel augmentation activity, all active bald eagle nests will be located and mapped using the National Bald Eagle Management Guidelines (USFWS 2007).

- In consultation with CDFW and USFS, a 660-foot to 0.5-mile buffer will be established around active nests. Vegetation will be retained and no construction activities will occur within this buffer.

- If proposed vegetation removal would occur between April 1 and August 31, a qualified biologist will conduct a preconstruction survey for nesting special-status birds no more than 2 weeks before construction activities begin. If an active nest is found, a qualified biologist, in consultation with CDFW, will determine a construction-free buffer zone to be established around the nest until the young have fledged. In consultation with CDFW, a plan will be developed to monitor whether construction activity is disturbing the reproductive process and to determine when the young have fledged.

Implementation of this mitigation measure would reduce Impact Wild-21 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Wild-22 (CP4 and CP4A): Implement Mitigation Measure Wild-21: Conduct Preconstruction Surveys for Elderberry Shrubs, Western Pond Turtle, and Nesting Riparian Raptors and Other Nesting Birds; Avoid Removal or Degradation of Elderberry Shrubs; and Avoid Vegetation Removal Near Active Nest Sites To avoid impacts on valley elderberry longhorn beetle, western pond turtle, nesting raptors, and other nesting birds, Reclamation will implement the following measures as part of the gravel augmentation activities project at augmentation sites with the potential to affect these species:

Valley Elderberry Longhorn Beetle This mitigation measure is identical to Mitigation Measure Wild-21 (CP4 and CP4A) for valley elderberry longhorn beetle, except that the following additional measures will be implemented:

- Before implementation of any vegetation improvements or other activities associated with gravel augmentation, including constructing access routes, a survey will be conducted to identify and map all elderberry shrubs.
- New roads, trails, and staging areas will be constructed a minimum of 100 feet from elderberry shrubs.
- Removal and disturbance of elderberry shrubs will be avoided, to the extent feasible.

Western Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-21 (CP4 and CP4A) for western pond turtles.

Birds This mitigation measure is identical to Mitigation Measure Wild-21 (CP4 and CP4A) for birds.

Implementation of this mitigation measure would reduce Impact Wild-22 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Wild-23 (CP4 and CP4A): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP4 and CP4A), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-23 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Wild-26 (CP4 and CP4A): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP4 and CP4A), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-26 (CP4 and CP4A) to a less-than-significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impacts Wild-18 (CP5), Wild-19 (CP5), Wild-24 (CP5), Wild-25 (CP5), and Wild-27 (CP5). Mitigation is provided below for the remaining impacts of CP5 on wildlife species.

Mitigation Measure Wild-1 (CP5): Avoid, Relocate, and Acquire Mitigation Lands for Shasta Salamander This mitigation measure is identical to Mitigation Measure Wild-1 (CP1). Implementation of this mitigation measure will reduce impacts on the Shasta salamander; however, because impacts cannot be fully mitigated, Impact Wild-1 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-2 (CP5): Avoid, Relocate, and Acquire Mitigation Lands for Foothill Yellow-Legged Frog and Tailed Frog This mitigation measure is identical to Mitigation Measure Wild-2 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-2 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-3 (CP5): Avoid, Relocate, and Acquire Mitigation Lands for Northwestern Pond Turtle This mitigation measure is identical to Mitigation Measure Wild-3 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-3 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-4 (CP5): Conduct Preconstruction Surveys for the American Peregrine Falcon and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-4 (CP1). Implementation of this mitigation measure will reduce Impact Wild-4 (CP5) to a less-than-significant level.

Mitigation Measure Wild-5 (CP5): Acquire and Preserve Mitigation Lands; Conduct Protocol-Level Surveys for the Bald Eagle and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-5 (CP1). Implementation of this mitigation measure will reduce impacts on individual bald eagles nesting during the implementation of the project; however, all nest trees in the inundation zone will be lost. Therefore, Impact Wild-5 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-6 (CP5): Acquire and Preserve Mitigation Lands for Northern Spotted Owl This mitigation measure is identical to Mitigation Measure Wild-6 (CP1). Implementation of this mitigation measure will reduce impacts on northern spotted owl dispersal habitat.

Mitigation Measure Wild-7 (CP5): Conduct a Preconstruction Survey for the Purple Martin and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-7 (CP1). Implementation of this mitigation measure will reduce impacts on individual purple martins nesting during the implementation of the project; however, these measures might not fully mitigate the loss of snags used for nesting. Therefore, Impact Wild-7 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-8 (CP5): Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-8 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-8 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-9 (CP5): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-9 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-9 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-10 (CP5): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for the Pacific Fisher and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-10 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-10 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-11 (CP5): Acquire and Preserve Mitigation Lands; Conduct Preconstruction Surveys for Special-Status Bats, American Marten, and Ringtails and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-11 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-11 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-12 (CP5): Avoid Suitable Habitat; Acquire and Preserve Mitigation Lands for Special-Status Terrestrial Mollusks This mitigation measure is identical to Mitigation Measure Wild-12 (CP1). Implementation of this mitigation measure will reduce impacts on special-status terrestrial mollusks; however, because impacts cannot be fully mitigated, Impact Wild-12 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-13 (CP5): Acquire and Preserve Mitigation Lands for Permanent Loss of General Wildlife Habitat and Western Bumble Bee Habitat This mitigation measure is identical to Mitigation

Measure Wild-13 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-13 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-14 (CP5): Acquire and Preserve Mitigation Lands and Conduct Preconstruction Survey for Other Nesting Raptors and Migratory Birds and Establish Buffers This mitigation measure is identical to Mitigation Measure Wild-14 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-14 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-15 (CP5): Acquire and Preserve Mitigation Lands for Permanent Loss of Critical Deer Wintering and Fawning Range This mitigation measure is identical to Mitigation Measure Wild-15 (CP1). Implementation of this mitigation measure will reduce impacts on these species; however, because impacts cannot be fully mitigated, Impact Wild-15 (CP5) is considered significant and unavoidable.

Mitigation Measure Wild-16 (CP5) Potential impacts and applicable mitigation has yet to be determined for the California red-legged frog. This impact is considered significant and unavoidable.

Mitigation Measure Wild-17 (CP5): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP5), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-17 (CP5) to a less-than-significant level.

Mitigation Measure Wild-20 (CP5): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat in the Primary Study Area, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP5), described in Chapter 12, "Botanical Resources and Wetlands." Implementation of this mitigation measure would reduce Impact Wild-20 (CP5) to a less-than-significant level.

Mitigation Measure Wild-21 (CP5): Conduct Preconstruction Surveys for Elderberry Shrubs, Western Pond Turtle, and Nesting Riparian Raptors and Other Nesting Birds; Avoid Removal or Degradation of Elderberry Shrubs; and Avoid Vegetation Removal Near Active Nest Sites This mitigation measure is identical to Mitigation Measure Wild-21 (CP4 and CP4A). Implementation of this mitigation measure would reduce Impact Wild-21 (CP5) to a less-than-significant level.

Mitigation Measure Wild-22 (CP5): Implement Mitigation Measure Wild-21: Conduct Preconstruction Surveys for Elderberry Shrubs, Western Pond Turtle, and Nesting Riparian Raptors and Other Nesting Birds; Avoid Removal or Degradation of Elderberry Shrubs; and Avoid Vegetation Removal Near Active Nest Sites This mitigation measure is identical to Mitigation Measure Wild-22 (CP4 and CP4A). Implementation of this mitigation measure would reduce Impact Wild-22 (CP5) to a less-than-significant level.

Mitigation Measure Wild-23 (CP5): To Reduce Impacts on Riparian-Associated and Aquatic Special-Status Wildlife along the Lower Sacramento River Resulting from Modifications of Geomorphic Processes, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP5), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-23 (CP5) to a less-than-significant level.

Mitigation Measure Wild-26 (CP5): To Promote Consistency with Local and Regional Plans with Goals of Promoting Riparian Habitat along the Lower Sacramento River and in the Delta, Implement Mitigation Measure Bot-7: Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan This mitigation measure is identical to Mitigation Measure Bot-7 (CP5), described in Chapter 12, “Botanical Resources and Wetlands.” Implementation of this mitigation measure would reduce Impact Wild-26 (CP5) to a less-than-significant level.

13.3.6 Cumulative Effects

Chapter 3, “Considerations for Describing the Affected Environment and Environmental Consequences,” discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, “Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area,” in Chapter 3, lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level. None of the projects listed in Table 3-1 under Quantitative Analysis would have impacts on wildlife resources in the primary study area, nor would they have overlapping cumulative effects on wildlife resources with any of the action alternatives. Therefore, the following analysis is based on the programs and projects listed in the Qualitative Analysis section of Table 3-1. Projects listed in Table 3-1 that may have cumulative effects in the primary and extended study area include, but are not limited to, the CALFED Ecosystem Restoration Program, Bay-Delta Conservation Plan, Sacramento River Conservation Area Forum Program, Central Valley Flood Protection Plan, PG&E and DWR Hydropower Relicensing Programs, Antlers Bridge Replacement, Moody Flats Quarry, and the Mountain Gate at Shasta Mixed Use Area Plan.

A large number of past actions have occurred in the study area. These past actions have substantially degraded wildlife resources in the primary and extended study areas. This degradation is in part indicated by the number of species that have been listed as threatened or endangered under the CESA and ESA, or considered species of special concern by CDFW.

Past actions have caused these effects by converting habitat to developed or agricultural land uses, altering biotic interactions or physical processes, and damaging or causing mortality from human activities (e.g., vegetation removal during agricultural, road, dam, levee, or utility maintenance).

Flood control and water supply projects have also altered physical processes within the study area's remaining natural vegetation. Levees have isolated large areas of floodplain from rivers and streams throughout the study area, reducing (or entirely eliminating) the frequency of inundation and sediment scour and deposition and altering the extent and quality of riparian habitats. By reducing the magnitude and frequency of winter and spring peak flows and increasing the volume of summer and fall flows, water storage projects have altered the riparian habitats that were not isolated from rivers by levees. In particular, the operation of Shasta Dam (beginning in 1945) and the other major reservoirs of the CVP and SWP has strongly affected aquatic and riparian communities along the Sacramento River, other Central Valley rivers, and in the Delta (Fremier 2003, TNC et al. 2008).

The effects of climate change on operations at Shasta Lake could potentially affect wildlife both at the lake and downstream. As described in the Climate Change Modeling Appendix, climate change could result in higher reservoir releases in the future because of an increase in winter and early-spring inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in flooding frequency, downstream habitat for wildlife, and water temperatures which could affect habitat along the Sacramento River and in the Delta. Climate change is also expected to result in changes to conditions for agricultural land and forest land, which are both habitat types. See Chapter 10, "Agriculture and Important Farmland," for a detailed discussion of effects on these habitat types.

Shasta Lake and Vicinity

The construction of Shasta Dam and the subsequent flooding of the area now known as Shasta Lake affected botanical and wildlife resources endemic to the region. For example, based on population locations, Shasta snow-wreath populations may have connected at the confluence of the Pit River, Squaw Creek, McCloud River, and Sacramento River before inundation. The creation of Shasta Lake fragmented this species habitat and populations. As a result, these populations are more vulnerable to extirpation.

As described in Section 13.3, without mitigation, CP1 through CP5 could cause potentially significant effects on wildlife habitats and special-status wildlife species in the primary and extended study areas. These effects could be caused by project construction activities; increased elevations of the water surface of Shasta Lake; and alteration of the flow regime of the Sacramento River and associated geomorphic processes, and thus of riparian vegetation. Although causing similar effects, CP1 through CP5 differ in the magnitude of their effects. At Shasta Lake and its vicinity, these potential adverse effects would be similar for all alternatives, but differ with the height of the dam raise: the effects of CP2 would be greater than CP1, the same as CP4A, and less than CP3 through CP5 (which would be identical). Along the upper Sacramento River and in the extended study area, potential adverse effects would be the result of altered flow regimes and would differ with both the height of the dam raise and operation of the dam: the effects of CP2 would be greater than CP1 and CP4 (which would be identical), the same as CP4A, and less than CP3 and CP5 (which also would have identical effects).

At Shasta Lake and vicinity, CP1 through CP5 would cause the take and loss of habitat for numerous species, including Shasta salamander, foothill yellow-legged frog, tailed frog, Northwestern pond turtle, American peregrine falcon, bald eagle, northern spotted owl, purple martin, Vaux's swift, yellow warbler, yellow-breasted chat, long-eared owl, northern goshawk, Cooper's hawk, osprey, Pacific fisher, and other special-status species. The wildlife mitigation measures described in Section 13.3.5 would reduce impacts on wildlife resources, although the adverse effects of CP1 through CP5 caused by construction activities and inundation would not be eliminated. Because the overall effect of past actions on these species has been cumulatively significant, and the likely additional effects of reasonably foreseeable future actions on wildlife habitat at Shasta Lake and in its vicinity, the adverse effects under CP1 through CP5 would cause a cumulatively considerable incremental contribution to the significant cumulative impact on wildlife.

Upper Sacramento River and Extended Study Area

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability As described in Chapter 2, "Alternatives," without mitigation, CP1 could cause potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species in the primary and extended study areas. These effects could be caused by alteration of the flow regime of the Sacramento River and associated geomorphic processes in the primary study area or the extended study area, or both. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the adverse effects from CP1 would be a cumulatively considerable incremental contribution to significant cumulative effects on vegetation, wildlife habitats, and special-status wildlife species. With implementation of Mitigation Measure Bot-7, "Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP1 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP1 could contribute to potentially significant effects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP1, CP1 would not make a cumulatively considerable incremental contribution to a significant cumulative effect.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability The cumulative effects of CP2 would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP2 would be a cumulatively considerable incremental contribution to significant cumulative effects on vegetation, wildlife habitats, and special-status wildlife species. With implementation of Mitigation Measure Bot-7, "Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP2 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP2 could contribute to potentially significant effects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP2, CP2 would not make a cumulatively considerable incremental contribution to a significant cumulative effect.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival The cumulative effects of CP3 would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP3 would be a cumulatively considerable incremental contribution to significant cumulative effects on vegetation, wildlife habitats, and special-status wildlife species. With implementation of Mitigation Measure Bot-7, "Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP3 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP3 could contribute to potentially significant effects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP3, CP3 would not make a cumulatively considerable incremental contribution to a significant cumulative effect.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability The cumulative effects of CP4 or CP4A would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP4 or CP4A would be a cumulatively considerable incremental contribution to significant cumulative effects on vegetation, wildlife habitats, and special-status wildlife species. With implementation of Mitigation Measure Bot-7, "Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities" (see Chapter 12, "Botanical Resources and Wetlands"), adverse effects from CP4 or CP4A would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP4 or CP4A could contribute to potentially significant effects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP4 or CP4A, there would not be a cumulatively considerable incremental contribution to a potentially significant cumulative effect.

CP5 – 18.5-Foot Dam Raise, Combination Plan The cumulative effects of CP5 would be similar to those of CP1, but greater in magnitude. Given major past alterations to vegetation and wildlife habitat along the Sacramento River, the contributing adverse effects from CP5 would be a cumulatively considerable incremental contribution to significant cumulative effects on vegetation, wildlife habitats, and special-status wildlife species. With implementation of Mitigation Measure Bot-7, “Implement a Riverine Ecosystem Mitigation and Adaptive Management Plan to Avoid and Compensate for the Impact of Altered Flow Regimes on Riparian and Wetland Communities” (see Chapter 12, “Botanical Resources and Wetlands”), adverse effects from CP5 would no longer result in a cumulatively considerable incremental contribution to significant cumulative effects on these resources.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to downstream habitats. Potentially significant effects on vegetation, wildlife habitats, and special-status wildlife species that would occur with implementation of CP5 could contribute to potentially significant effects of climate change on habitat acreages and distribution. However, with implementation of the mitigation measures listed above to reduce project-related impacts of CP5, CP5 would not make a cumulatively considerable incremental contribution to a significant cumulative effect.

Chapter 14
Cultural Resources

This chapter describes the affected environment and environmental consequences related to cultural resources for the dam and reservoir modifications proposed under SLWRI action alternatives. More detailed discussion of cultural resources is presented in *Cultural Resources Alternatives Assessment for the Shasta Lake Water Resources Investigation, Shasta and Tehama Counties, California* (Byrd et al. 2008) and *Native American Tribal Coordination, Shasta Lake Water Resources Investigation, California* (Nilsson et al. 2008), which were prepared for the project. These Technical Reports will not be publicly distributed because they contain confidential information on the locations of cultural resources.

14.1 Affected Environment

For the cultural resources assessment, studies were limited to the Shasta Lake and vicinity (77,088 acres) and the upper Sacramento River (16,113 acres), for a total of 93,201 acres (Byrd et al. 2008). Project impacts to cultural resources are not expected to extend beyond this primary study area. Shasta Lake and vicinity includes the existing reservoir, the maximum inundation area, and a 0.25-mile buffer. The 0.25-mile buffer encompasses the area around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.). The majority of lands in the reservoir area are under Federal ownership and management responsibilities, and a detailed discussion of this topic can be found in Chapter 17. The upper Sacramento River is defined by the 100-year floodplain from Keswick Dam, north of Redding, southward to the Red Bluff Pumping Plant.

To evaluate the potential effects that the proposed undertaking may have on cultural resources within the 93,201-acre study area, archival and records searches were conducted. Information concerning potential Native American concerns within the study area was gathered from historic and ethnographic literature and from initial discussions with tribes and Native American individuals. The results of these efforts are summarized below, following a brief discussion of the regional context.

14.1.1 Regional Setting

This section provides a regional framework of the study area including sections on the prehistoric, ethnohistorical, and historical context of the study area. Because of the regional nature of cultural resources, the Shasta Lake vicinity and upper Sacramento River area are discussed together.

Prehistoric Context

The following presentation provides a temporally organized discussion of the archaeological record. There is a long history of archaeological investigations in the upper Sacramento Valley region, although the early investigations were sporadic rather than sustained research programs. Notably, a great deal of fieldwork has been carried out around Shasta Lake, largely on USFS lands. Radiocarbon dating and temporally diagnostic artifacts have been used to create a framework for understanding the age of cultural resources in the area as well as changes through time. This framework provides baseline information on how cultural resources can contribute to history and regional research issues.

The Terminal Pleistocene time segment (ca. 13,500-11,600 before present, calibrated using radiocarbon dating (cal BP)) is minimally represented and poorly understood in this region. What little evidence exists suggests that people passing through the area were wide-ranging, mobile hunters and gatherers who periodically exploited large game (Haynes 2002). Archaeological data from this time period, primarily represented by isolated fluted and/or bifacially thinned spear points and Pleistocene fauna remains, is limited to two cave sites in the study area.

The earliest evidence for occupation of the region largely falls between ca. 8000-5000 BP. Most assemblages dating to this interval are affiliated with the Borax Lake Pattern (Fredrickson 1974) and include wide-stemmed projectile points, handstones, milling slabs, and ovoid flake tools, along with a variety of other utilitarian items. The diversified nature of these artifact assemblages indicates people occupying the area were likely foragers who moved their residential bases frequently to exploit seasonal changes in resource distribution (Hildebrandt and Hayes 1983, 1993; Kowta et al. 2000; Sundahl and Henn 1993).

Several new projectile point forms appeared in the archaeological record around 5000 BP, including Squaw Creek Contracting-stemmed, Pollard Diamond-shaped, and McKee series. These points have been assigned to the Squaw Creek Pattern (5700-3200 BP) by Sundahl (1992b). Despite the appearance of these new forms, similarities in the rest of the assemblage composition with the preceding Borax Lake Pattern suggest people occupying the area during this time period were also relatively mobile foragers (Basgall and Hildebrandt 1989, Kowta et al. 2000).

A major change in the regional settlement-subsistence pattern appears to have occurred between ca. 4,000 to 1,600 years ago. This period has been identified as the Whiskeytown Pattern (Sundahl 1992b), and is represented by a wide range of corner- and side-notched projectile points assigned to the Clikapudi series, as well as hand stones, milling slabs, notched pebble net weights, and mortars and pestles (see also the Deadman and Kingsley complexes in Tehama County; Greenway 1982, Johnson 1984). Analysis of data from archaeological sites dating to this time period has led Basgall and Hildebrandt (1989) to propose a shift from the preceding generalized forager strategy to a “fission-fusion” model of subsistence-settlement where larger groups of people occupied residential camps during the fall and winter months, but then split into smaller foraging groups who moved between productive resource patches during the remainder of the year. The fall-winter residential sites are thought to have been concentrated along the northern Sacramento Valley foothills, where salmon and acorns could be readily obtained (Baker 1990, Bevill and Nilsson 1993, Sundahl 1999).

Two distinct patterns have been identified as corresponding with the most recent time period (from 1,600 years ago to contact) in the region. The first, referred to as the Augustine Pattern/Shasta Complex, is thought to reflect a more sedentary subsistence-settlement adaptation than what was practiced in the preceding time periods. Initially, from 1,250 to 750 years ago, square-stemmed Gunther Barbed projectile points (with lower frequencies of expanding-stem variants), winged drills, bipointed fish gorges, bone gaming pieces, incised bone pendants, and varied shell beads are characteristic. These materials have been associated with the arrival of the Wintu in Northern California, and are thought to reflect a sedentary adaptation made possible by a subsistence system dependent on the large-scale storage of salmon and acorns (Broughton 1988; George 1981; Sundahl 1982, 1992a; Wohlgemuth 1992).

During this same time frame, a contrasting record is found in upland areas surrounding the northern Sacramento Valley. It is represented by much smaller sites and rather simple assemblages consisting of small side- and corner-notched projectile points, a limited number of Gunther series forms, hopper mortars and pestles, hand stones, milling slabs, and notched pebble weights. On the east side of the valley, these findings are assigned to the Tehama Pattern (Clewett and Sundahl 1982, Sundahl 1992a), and are thought to reflect a more mobile pattern of settlement by populations speaking Hokan languages (e.g., Yana) pushed to the hinterlands by the late-arriving Wintu, who ultimately restricted access to the Sacramento River.

Ethnohistorical Context

Ethnohistorical investigations indicate that at the end of the prehistoric era and into the historic era, much of the study area was primarily occupied by the Wintu (LaPena 1978), but some of their territorial boundaries have been contested for many years. The most commonly accepted map of Wintu territory was produced by Du Bois (1935), and shows that the Wintu controlled the Sacramento, McCloud, and Squaw Creek drainages, and all but the easternmost segment of the Pit River Arm. This arm crosses into a boundary area between Northern Yana (Johnson 1978, Sapir and Spier 1943) and Achomawi (Pit River) tribes (Olmsted and Stewart 1978). Wintu people also lived along the Sacramento River from Shasta Dam down to the confluence of the river with Cottonwood and Battle creeks. Nomlaki territory took over south of Cottonwood Creek/Battle Creek and extended down past what is now the Red Bluff Pumping Plant (Goldschmidt 1951, 1978).

There has been a great deal of ethnohistoric and ethnographic discussion of the Wintu owing largely to the records amassed by late nineteenth- and early twentieth-century observers. Therefore, the Wintu can be considered one of the best known Native American groups in California. Most of the villages were located on the McCloud and Pit rivers and the general area south of the Pit River to just south of Redding. One hundred and six (43 percent) of the named Wintu ethnographic villages fall within the current study area.

Historical Context

The area that would become Shasta and Tehama counties was not explored by Europeans during the Spanish period of California history. Initial exploration occurred in 1821 when a Mexican expedition explored the Sacramento River nearly as far north as the future site of Redding, encountering Native populations as they traversed the region. Subsequently, European trappers in Northern California spread European diseases that had disastrous effects on the Native Americans. Notably, a devastating epidemic spread through the Sacramento Valley during the 1830s that may have killed as much as 75 percent of the native population.

In 1848, mining (especially for copper) began along the Trinity River and other Sacramento River tributaries, bringing as many as 50,000 people to the area. American immigrants increasingly occupied territory, and new logging and mining operations destroyed hunting grounds and salmon fisheries that were part of the traditional home of Native Americans such as the Wintu. Criminal violence and the policy of relocation to reservations nearly eliminated the Native American population in the upper Sacramento River Valley by 1870. Those who remained lived in the mountains, like the Wintu, who maintained a salmon fishery along the McCloud River.

The mining boom led to the construction of smelters, mills, and towns (such as Keswick) that flourished in the late 1800s and early 1900s. Falling copper prices, growing environmental concerns over pollution from smelters, and the U.S. Government’s efforts at protection and conservation of public lands ended major operations by the 1920s.

Logging started in 1852 and included sugar pine, white pine, red fir, and cedar. Sawmills quickly sprang up, along with associated roads. Transporting logs and milled lumber became easier after the completion of the railroad through Red Bluff and Redding, and the Blue Ridge Flume, completed in 1874. These transportation advances allowed lumber milling to be concentrated in the valley, and Red Bluff and other mill towns to thrive.

Agriculture dominated the valley land along the Sacramento River. Cattle farming was key initially, and remained an important product in the area through the mid-twentieth century, especially with the development of the dairy industry. Early settlers practiced dry farming, growing wheat and fruit, including peaches, pears, and plums. Farmers later diversified and transitioned from wheat to fruits, nuts, vineyards, and vegetable crops in the late 1800s through the 1920s. Ultimately, intensive irrigated agriculture dominated the area.

Throughout the historic era, transportation was an important focus of infrastructure development. Over time, foot travel and transportation by horse or stage coach on a number of historic trails gave way to river, railroad, and ultimately, automobile travel. Hopeful settlers and miners poured into the study area along the California-Oregon Trail between 1840 and 1860, passing through the upper Sacramento River and Pit River valleys. A segment of the Siskiyou Trail was used by the northern railroad in 1877 and Interstate 5 follows this route today. Many early roads in the study area operated in conjunction with ferries across the Sacramento River. Several important bridges are located in the study area, along with the remains of many others, including the Centennial Bridge in Red Bluff and the Dog Creek Bridge in Shasta County.

Towns such as Red Bluff, Redding, Keswick, and Kennett boomed, along with the region’s developing transportation network. The construction of Shasta and Keswick dams promoted a new period of prosperity that carried through the expansion of the lumber industry and the rise of the recreation industry in the mid-twentieth century.

Efforts to preserve the Nation’s forests began in the late 1800s. The Shasta Forest Reserve was created in 1905. The area also included many homesteads and Indian allotments granted to local Wintus in the 1880s. In preparation for inundation by Shasta Lake, the United States purchased land including these allotments, homesteads, and many other properties in the late 1930s. Around the same time, fish were recognized as an important natural resource in California, and the first of several salmon fish hatcheries were constructed in 1872 at the salmon spawning grounds near the confluence of the McCloud and Pit rivers.

Recreation, especially in the mountains, also played an important role in the region’s history. In the early twentieth century, private fishing clubs, such as the Bollibokka Club, flourished. In the 1930s, USFS began to encourage the recreational use of the forests by the broader public, constructing campgrounds and picnic areas. Recreation in the national forests expanded with the formation of Shasta Lake. New campgrounds were added, along with boat launches and access roads.

Hydroelectric power and water storage were also important facets of the region’s history. Starting in 1922, Pacific Gas and Electric Company built dams and power plants in the Pit River area. In 1935, the Federal Government decided to proceed with building the CVP to store and deliver Sacramento River water as far south as Fresno County. Work was completed in the 1940s at Shasta Dam and Keswick Dam and Powerhouse, located downriver from Shasta Dam. Power generated at Shasta Dam and transmitted to the CVP pumps provided electricity to supply the lift pumps raising water into the main canal system. The system used the natural channels of the Delta to move water from Redding to Tracy, the head of the Delta-Mendota Canal.

14.1.2 Archaeological Resources and Historical Structures

This section discusses known archaeological resources and historic structures within the primary study area.

Shasta Lake and Vicinity

A total of 134 cultural resources studies have been previously conducted that intersect or are fully contained within the Shasta Lake area. Of these, 80 percent were surveys, the remainder being overview/research designs, excavations, or other compliance reports. More than half of the surveys are considered to have had systematic coverage; the rest were either reconnaissance efforts or the methods were unknown. Overall, only 8 percent of the study area has been surveyed; 5 percent in a systematic manner and 3 percent using reconnaissance methods.

The records search identified 261 cultural resources within the study area, including 190 prehistoric sites, 45 historic-era resources, and 26 resources with both prehistoric and historic-era components.

The 215 recorded prehistoric-era resources and components are widely distributed throughout the study area and include the following:

- Forty-two major residential sites (thirteen with documented human remains)
- Thirty-seven residential sites
- Fifty-five artifact scatters
- Seventy-seven scatters of flaked stone tools and manufacturing debris
- Two caves
- Two sites of unknown character

The 71 recorded historic-era resources and components include the following:

- Thirteen structures, including seven bridges, one dam, one railroad bridge and grade, one aerial-tramway, one rock wall/alignment complex, one building foundation, and one concentration of wooden A-frames
- Seven linear features consisting of one railroad, five road segments and one line of wooden poles

- Seven mining locales that include two quarries and five sites with various mining-related features and residential elements.
- Fifteen artifact scatters
- Two ranching complexes
- Fourteen residential sites
- Two town complexes – both are mining-related and one includes a cemetery
- Two orchards represented by wooden poles and fruit trees
- One cemetery represented by two grave stones
- Seven historic-era Native American cemeteries, all but one of which is also associated with a major prehistoric residential component. Each of these cemeteries was subject to government removal of burials and reburial in a government cemetery outside the Shasta Lake inundation area and the current project area.
- One historic-era Native American residential site that also has a prehistoric residential component

Another 19 historic-era cemeteries (containing both Native American and Euro-American burials) within the footprint of Shasta Lake have not been formally recorded. They were subject to burial removal and subsequent reburial outside the reservoir area. It is possible that a number of these cemeteries may retain additional human remains, and are potentially subject to periodic exposure when the reservoir level fluctuates.

The vast majority of cultural resources discussed above have never been formally evaluated with respect to the eligibility for listing on the National Register of Historic Places (NRHP). The NRHP (also referred to as the National Register) is the Nation's official list of cultural resources worthy of preservation. Authorized under the National Historic Preservation Act of 1966 (NHPA), the NRHP is part of a national program to coordinate and support public and private efforts to identify, evaluate, and protect our historic and archeological resources. Properties listed in the NRHP include districts, sites, buildings, structures, and objects that are significant in American history, architecture, archeology, engineering, and culture. All properties and districts listed in or determined eligible for listing in the NRHP must be considered in the planning of Federal undertakings.

The Dog Creek Bridge is eligible for the NRHP. Shasta Dam and property has also been determined eligible for the NRHP as part of the CVP through a consensus determination with the State Historic Preservation Officer (SHPO). Another 24 resources have been determined ineligible by consensus determination with the SHPO. These include 15 historic-era resources, seven prehistoric sites, and two resources with both prehistoric and historic-era components. The remaining cultural resources have yet to be evaluated with respect to their eligibility for listing on the NRHP.

Upper Sacramento River (Shasta Dam to Red Bluff)

Based on the records search results, 97 cultural resources studies intersect or are fully contained within this area. Of these, 86 percent are surveys, along with overviews, excavation reports, and historical architectural evaluation reports. Most of the surveys had systematic coverage methods (75 percent). In all, 23 percent of the area has been surveyed, mostly by systematic methods (15 percent), and the rest by reconnaissance methods.

A total of 79 recorded cultural resources fall within this area. These include 45 prehistoric sites, 20 historic-era resources, and 14 resources with both historic-era and prehistoric components.

The 59 prehistoric resources and components within the study area include the following:

- Thirteen major residential sites
- Twenty-two residential sites
- Seven rock shelters
- Five artifact scatters
- Five flaked stone tool and manufacturing debris scatters
- Four rock art (petroglyph) sites
- Three sites of unknown character

The recorded prehistoric sites are concentrated in the southern portion of the study area, from Battle Creek near Table Mountain southward (71 percent), along with a small concentration of sites at the northern end of the upper Sacramento River area near Redding (18.6 percent). Eleven prehistoric sites have been subjected to some form of archaeological excavation.

The 34 recorded historic-era resources and components within the study area include the following:

- Ten structures
- Seven linear features consisting of five roads, one wagon train, and a powerline
- Five flume remnants (two of which were associated with orchards)
- Three mining locales, including a mining complex and two adits
- Five artifact scatters
- One ranching complex
- The historic-era structures include five bridges, a ferry crossing, a rock wall, a dam, one concrete dance pavilion, and a power substation building complex
- Three historic-era Native American residential sites

One archaeological site (referred to as the Benton Track Site or Magmas) is currently listed on the NRHP. In addition, the Diestelhorst Bridge in Redding and the Anderson-Cottonwood Irrigation District Diversion Dam have been determined eligible for the NRHP. Two sites are listed as ineligible for the NRHP by the California Office of Historic Preservation.

14.1.3 Native American Resources

A strong likelihood exists that other important Native American heritage locations are present within the study area, based on ethnohistoric data and initial discussions with Native Americans. The study area was the focus of intensive Native American occupation during historic times, with a variety of religious, economic, historic, and other values identified by Native American groups. Ten groups, including those listed by the Native American Heritage Commission, represent Native American interests in the study area. They include the Grindstone Indian Rancheria, Paskenta Band of Nomlaki Indians, Pit River Environmental Council, Pit River Tribe of California, Redding Rancheria, Shasta Indian Nation, United Tribe of Northern California, Inc., Winnemem Wintu, Wintu Educational and Cultural Council, and the Wintu Tribe of Northern California Toyon-Wintu Center. Notably, the Winnemem Wintu and the Pit River tribes live within the Shasta Lake area, where they continue to actively practice many aspects of their traditional culture. Both groups have related that a complex cultural landscape of village sites, ceremonial areas, burial sites, and resource areas intersects the study area.

The Winnemem Wintu also documented the location of some 155 ancestral villages within the Shasta Lake area. At least 81 village locations are known along the lower McCloud River and lower Pit River. An additional 73 villages are known to have existed on the eastern side of the Sacramento River. These village locations once contained between one and 30 houses each, some had associated cemeteries and each had a power place. Some of these villages are already under the waters of Shasta Lake, while others are just above the current Shasta Lake water level. The Winnemem Wintu have estimated that 120 of the known villages are still accessible (above the current high-water line).

Traditional Cultural Properties

Federal regulation defines Traditional Cultural Properties as properties that have "association with cultural practices or beliefs of a living community that (a) are rooted in that community's history, and (b) are important in maintaining the continuing cultural identity of the community" (Parker and King 1998). Examples of Traditional Cultural Properties include: a location associated with the traditional beliefs of a Native American group about its origins, its cultural history, or the nature of the world; a location where Native American religious practitioners have historically gone, and are known or thought to go today, to perform ceremonial activities in accordance with traditional cultural rules of practice.

The records search at the Information Center revealed that no Traditional Cultural Properties have been formally recorded in the study area.

It is important to note that a traditional cultural properties may not meet the NRHP criteria for a historic property and that, conversely, a historic property may not meet the criteria for a traditional cultural property. However, in those instances where an undertaking may affect a historic property that is also considered by an Indian group to be a site of beliefs, customs, and practices of a living community, circumstances may warrant that in the course of the Section 106 review process, consideration for accommodating access to and ceremonial use of the property and that avoidance of adverse physical effects in accordance with Section 106 are identified.

Tribal consultation has clearly indicated that local Native American groups are deeply concerned regarding the environmental and cultural effects of the project. Native Americans who supplied information for the SLWRI provided general information on the number and nature of resources both in the general region and in specific locations that could meet the definition of Traditional Cultural Properties, which are also supported in ethnohistoric studies.

Members of the Pit River Madesi Band stated that 22 ethnographic villages and associated burial grounds are located within the existing reservoir and proposed reservoir areas. One tribal member also noted that several Traditional Cultural Properties exist within the Pit 6 and Pit 7 Dam areas.

The Winnemem Wintu have identified important localities within the study area, many of which are locations where ceremonies are regularly conducted. Along the McCloud River, these include Children's Rock, Coyote Rock, Dekkas Rock, doctoring pools near Nawtawaket Creek, Eagle Rock and

Samwel Cave, Hirz Bay, *Kaibai* village, North Gray Rocks, Puberty Rock, Saddle Rock, and *Watawacket* village and spiritual area. Along the Sacramento River, important localities include the Antlers area, Delta area, Doney Creek, Gregory Creek, LaMoine area, Packers Bay, Pollard's area, middle Salt Creek, and Sims area. The Winnemem Wintu have strong traditional and contemporary connections with the land, and their ongoing use of many archaeological and religious sites is fundamental to the well-being of their culture, particularly the education of their youth.

Indian Sacred Sites

Executive Order No. 13007 defines an Indian sacred site as "any specific, discrete, narrowly delineated location on Federal land that is identified by an Indian tribe, or Indian individual determined to be an appropriately authoritative representative of an Indian religion, as sacred by virtue of its established religious significance to, or ceremonial use by, an Indian religion; provided that the tribe or appropriately authoritative representative of an Indian religion has informed the agency of the existence of such a site."

Executive Order 13007 pertains only to Federally recognized tribes and Federally managed lands. For groups that are not formally recognized, sacred areas may be listed in the Sacred Lands files of the California Native American Heritage Commission. This commission has reviewed its files and identified sacred lands within the study area, however these lands may or may not meet the definition under EO 13007. Their locations are confidential.

14.2 Regulatory Framework

Under Federal and State of California (State) law, effects to significant cultural resources—which include archaeological remains, historic-period structures, and Traditional Cultural Properties—must be considered as part of the environmental analysis of a proposed project. This section provides a summary of key regulations for the protection of significant resources.

14.2.1 Federal

National Historic Preservation Act

Under Section 106 of the NHPA, Federal agencies must consider effects to eligible resources ("historic properties") from the proposed undertaking, in consultation with SHPO and other parties. This includes affording the Advisory Council a reasonable opportunity to comment on such undertakings. This includes identification (usually through archival research, field inventories, public interpretation, and/or test evaluations) of cultural resources eligible for the NRHP, assessment of adverse effects to eligible properties, and resolution of adverse effects. The implementing regulations at 36 CFR Part 800 define procedures to meet Section 106 responsibilities through consultation among the

Federal agency and other parties with an interest in the effects on historic properties.

Section 106 defines significant archaeological or historical resources as those which are listed on, or eligible for listing on, the NRHP. Eligible properties are those that retain sufficient integrity and meet one or more of the following criteria: “(a)...are associated with events that have made a significant contribution to the broad patterns of our history; or (b) that are associated with the lives of persons significant in our past; or (c) that embody the distinctive characteristics of a type, period, or method of construction, or that represent a significant and distinguishable entity whose components may lack individual distinction; or (d) that have yielded, or may be likely to yield, information important in prehistory or history” (36 Code of Federal Regulations (CFR) 60.4).

Executive Order 13007 – Indian Sacred Sites

Indian Sacred Sites as addressed in Executive Order 13007 (24 May 1996) establishes that Federal agencies are responsible for allowing federally recognized American Indian religious practitioners access to and ceremonial usage of Indian sacred sites on Federal land. An Indian Sacred Site is defined as “any specific, discrete, narrowly delineated location on Federal land that is identified by an Indian tribe, or Indian individual determined to be an appropriately authoritative representative of an Indian religion, as sacred by virtue of its established religious significance to, or ceremonial use by, an Indian religion; provided that the tribe or appropriately authoritative representative of an Indian religion has informed the agency of the existence of such a site.” The agency will keep the locations of such sites confidential and will avoid adversely affecting the integrity of these sites. To assist in the implementation of this Executive Order, an interagency memorandum of understanding was signed to improve the protection of tribal access to Indian Sacred Sites through enhanced and improved interdepartmental coordination and collaboration. The Memorandum of Understanding Among the U.S. Department of Defense, U.S. Department of the Interior, U.S. Department of Agriculture, U.S. Department of Energy, and the Advisory Council on Historic Preservation Regarding Interagency Coordination and Collaboration for the Protection of Indian Sacred Sites, was executed on November 30, 2012, and remains in effect until December 31, 2017.

Native American Graves Protection and Repatriation Act

The Native American Graves Protection and Repatriation Act (Public Law 101-601; 25 United States Code 3001-3013) pertains to Native American burial sites and regulates the removal of human remains, funerary objects, sacred objects, and items of cultural patrimony on Federal and tribal lands. The Act requires permits for intentional removal or excavation of Native American human remains on Federal lands, covers cases of inadvertent discoveries, and dictates the ultimate disposition process of Native American human remains and cultural items.

American Indian Religious Freedom Act

The American Indian Religious Freedom Act (42 United States Code Section 1996) states that it is the policy of the United States to "protect and preserve for American Indians their inherent right of freedom to exercise the traditional religions of the American Indian, Eskimo, Aleut, and Native Hawaiians, including but not limited to access to sites, use and possession of sacred objects, and the freedom to worship through ceremonials and traditional rites." The provisions of American Indian Religious Freedom Act guarantee access to traditional sites on Federal lands for religious practices. Consultation under American Indian Religious Freedom Act with American Indian groups can simultaneously satisfy the requirements of NEPA.

Archaeological Resources Protection Act

The purpose of the Archaeological Resources Protection Act of 1979 (ARPA) (Public Law 95-96 – October 31, 1979) is to protect archaeological resources and sites that are located on public lands and Indian lands, and to foster increased cooperation between governmental authorities, the professional archaeological community, and private individuals in possession of archaeological resources. The act makes it unlawful to excavate, remove, or deface archaeological resources, to sell, purchase, or exchange those resources without applicable permit, and establishes criminal and civil penalties for any such violation.

Archaeological and Historic Preservation Act

This act was formerly known as the Reservoir Salvage Act of 1960, followed by the Moss-Bennet Act (Archaeological Recovery Act). The act can be found under 16 USC 469, and is intended to prevent irreparable loss or destruction of significant scientific, prehistorical, historical, or archeological data involving activities in connection with any Federal construction project or federally-licensed project, activity, or program through the recovery, protection, and preservation of such data, including preliminary survey or other investigation as needed.

14.2.2 State

Under CEQA, the lead non-Federal agency (state, county, city, or other) must consider potential effects to important or unique cultural resources. While the language and consultation process is somewhat different between the NHPA and CEQA, the definitions of eligible properties and of adverse impacts are essentially the same. Evaluations under CEQA consider a resource's potential eligibility to the California Register of Historical Resources.

California law also protects Native American burials, skeletal remains, and associated grave goods regardless of their antiquity, and provides for the sensitive treatment and disposition of those remains (California Health and Safety Code Section 7050.5, California Public Resources Code Sections 5097.94 et seq.).

14.2.3 Regulatory Compliance

Currently, there is no undertaking authorized by Congress involving the raising of Shasta Dam. Federal agencies may conduct nondestructive planning activities without completing Section 106, provided that the actions do not prohibit subsequent consideration of alternatives to avoid, minimize, or mitigate the undertaking's adverse effects on historic properties. This environmental document is in support of a feasibility study. Should the undertaking be authorized, Section 106 would resume early in that planning process (36 CFR Section 800. 1(c)).

Under Section 106, these efforts would include the following:

- A complete pedestrian survey and inventory of cultural resources within the area of potential effect (APE) of the selected alternative
- Ethnographic and ethnohistoric investigations to obtain greater detail regarding areas of importance to Native American tribes and groups
- Evaluations to determine whether cultural resources identified within the APE are eligible for inclusion in the NRHP
- Assessment of potential adverse effects to historic properties and consultation to resolve any identified adverse effects

Cultural resources are evaluated for inclusion in the NRHP based on criteria found at 36 CFR Part 60. Once a resource has been evaluated, the lead Federal agency determines eligibility in consultation with the SHPO and other consulting parties, as applicable. Where appropriate this process will include the USFS in the consultation to ensure appropriate consideration is given to the Shasta-Trinity National Forest Land and Resource Management Plan (STNF LRMP). The overall project actions, as authorized by Congress, may not be consistent with the STNF LRMP standards and guidelines (USFS 1995). A project-specific STNF LRMP amendment may be required for the standards associated with caves, visual quality, late successional reserves, riparian reserves, survey and manage species, and Shasta snow-wreath. The USFS decision would include a project specific exception to these standards.

In this process, previous determinations of eligibility may need to be reevaluated because of the passage of time or other factors, and it is important to acknowledge the special expertise of Indian tribes when assessing the eligibility of properties to which they attach ceremonial and cultural significance. It would be possible to evaluate some cultural resources with survey-level data. However, test excavations may be necessary to accurately evaluate many archaeological resources to determine if they are, in fact, historic properties.

The lead Federal agency is required to consider the effects of any potential project on historic properties within the APE. The criteria for assessing adverse effects are found in 36 CFR Part 800.5(a)(1), which states that “an adverse effect is found when an undertaking may alter, directly or indirectly, any characteristic of a historic property that qualify the property for inclusion in the National Register…” Examples of adverse effects include physical destruction, alteration, a change in the property’s setting, or the introduction of visual, atmospheric, or audible elements that diminish the integrity of the property’s significant historic features (36 CFR Part 800.5(a)(2)).

As part of the Section 106 process, the lead Federal agency is responsible for making a finding regarding whether the undertaking would have an adverse effect on historic properties. This assessment of adverse effects is made in consultation with SHPO, Indian tribes that attach religious and cultural significance to identified historic properties and other consulting parties. Reclamation would then seek concurrence on the findings of effect from the SHPO and the USFS, on National Forest Lands.

Consultation then continues among Reclamation, USFS, other applicable Federal agencies, SHPO, and other consulting parties on possible options for avoiding, minimizing, or mitigating the adverse effects. This includes notifying the Council when adverse effects are found and inviting the Council to participate. If SHPO, Reclamation, USFS, other applicable Federal agencies, and the Council (if participating) agree to measures to resolve adverse effects to historic properties, these are formalized in an MOA. Other consulting parties may be invited to sign the MOA. The Section 106 process (36 CFR Part 800.14) is completed once the terms of the MOA have been met. Alternatively, the Federal agencies may elect to enter into a programmatic agreement (PA) that would be developed as an alternative procedure to implement the Section 106 process (36 CFR Part 800.14). In rare cases, if consultation fails to result in agreement on resolving adverse effects, consultation may be terminated pursuant to the process detailed in 36 CFR Part 800.7.

14.3 Environmental Consequences and Mitigation Measures

This chapter is organized by the project alternatives described in Chapter 2, “Alternatives,” and discusses environmental consequences associated with implementation of the project alternatives. It also describes potential mitigation measures associated with impacts to cultural resources that are significant or potentially significant.

The environmental setting for this chapter includes only the primary study area, Shasta Lake and vicinity, and the upper Sacramento River between Shasta Dam and the Red Bluff Pumping Plant, as explained in Section 14.1. No potential impacts are expected in the extended study area; therefore, only impacts to cultural resources in the primary study area will be discussed. The extended study area is not discussed further in this section.

14.3.1 Impact Assessment Methods and Assumptions

The standard Section 106 process of the NHPA follows a series of steps that are described in the 36 CFR Part 800 regulations that implement the NHPA. These steps are as follows:

- Initiate Section 106 Process, 36 CFR Part 800.3
- Identify Historic Properties, 36 CFR Part 800.4
- Assess Adverse Effects, 36 CFR Part 800.5
- Resolve Adverse Effects, 36 CFR Part 800.6

"Adverse effects" are defined below in Section 14.3.2. In the event that historic properties within the APE for an undertaking would be subject to adverse effects, the lead Federal agency would consider ways to minimize or mitigate ("resolve") such effects, in consultation with the SHPO and other signatories and consulting parties. This often requires an MOA or PA among the consulting parties (Part 800.6).

Section 106 regulations allow Federal agencies to conduct "nondestructive project planning activities before completing compliance with Section 106" (36 CFR Part 800.1[c]), and the regulations encourage Federal agencies to consider a broad range of alternatives during the planning process for the undertaking. The SLWRI feasibility-level study is such a "nondestructive project planning" document, as there is no authorization for raising Shasta Dam at this time. Reclamation will not have a specific undertaking until such time as Congress makes a decision regarding whether to authorize a project that would involve raising the dam and appropriates funding for this purpose.

The purpose of the feasibility study has been to gather existing data that can be used in future environmental documents to estimate the impacts to the types of historic properties known to be present, based on existing data and consultations.

As part of compliance with 36 CFR Part 800 regulations, Reclamation conducted an analysis of the APE to assess which portions of the APE have been previously inventoried, and to identify all previously recorded cultural resources. Methods used for the cultural resources analysis included archival records searches (that identified previously recorded sites, site records, and Native American ethnographic studies), agency consultation, Native American consultations, and comparisons of the study alternatives. Information on archaeological and historical structures was obtained for sites within the primary study area that may be affected by alternative plans. Sensitivity analyses were also conducted for prehistoric and historic-era resources to address data gaps using methods tailored to each data set. Native American issues and resource locations within the primary study area were discussed during meetings with local Native American groups and individuals.

Also included in the analysis was an assessment of the effects of inundation and drawdown on cultural resources located within the pool of a reservoir. Previous reservoir studies have shown that the greatest impacts occur in the zone of inundation and drawdown (fluctuation zone), where cultural resources are repeatedly exposed to scouring, wave action, wet/dry cycles, and de-vegetation. This means that the most significant impacts will occur where an undertaking increases the size of the fluctuation zone–particularly if it includes areas that are above the current high-water line and thus have not previously been subject to inundation.

Archaeological and Historic-Era Structural Resources

The prior cultural resources inventory efforts and the resulting recorded cultural resources had been previously discussed in Section 14.1.2. Overall, the frequency and distribution of recorded sites within the project study area only give a limited and incomplete picture of the actual number of resources. This is because only a very small percentage of the project area has been systematically inventoried for cultural resources. To estimate site densities for the project area as a whole, sensitivity analysis was undertaken. Separate sensitivity analyses for prehistoric and historic-era sites were conducted to predict where unrecorded sites should be concentrated within unsurveyed areas. The resulting site-density predictions provide the most accurate estimate of site sensitivity by alternative available at present. The following discussion presents the methods and approach taken.

The archival research done for this study was designed to identify the types of cultural resources known to be present in the study area. However, the frequency and distribution of formally recorded resources give only a limited and incomplete picture of the actual number of resources. This is mainly due to limited systematic surveys comprising only 5 percent of the Shasta study area and 15 percent of the upper Sacramento River. As such, there are undoubtedly many more cultural resources that have not been identified or formally recorded.

A comparative sensitivity analysis was therefore conducted that took into account both documented and likely but undocumented resources (including archaeological sites and historic-era structures) for each of the alternatives proposed for raising Shasta Dam. The sensitivity analysis was restricted to the Shasta Lake and vicinity, and did not include the upper Sacramento River since no impact differences between alternatives have been identified within this area.

Separate sensitivity analyses using methods tailored to each data set were conducted for prehistoric and historic-era sites to estimate the total number of cultural resources present within each alternative (see Byrd et al. (2008) for methodological details and specific data). The prehistoric sensitivity analysis used a weights-of-evidence quantitative analysis to predict the overall density and distribution of sites. In contrast, the historic-era sensitivity analysis gathered archival data (mainly maps) within the study area to make predictions regarding the number and type of potential unrecorded historic-era resources (both structures and sites) by alternative. Results of the prehistoric and historic-era sensitivity analyses were integrated to provide quantitative estimates of the total number of cultural resources after full inventory. These estimates are for planning purposes only; additional pedestrian surveys would be needed if one of the affirmative alternatives were to go forward.

A second records search was completed to identify recorded cultural resources in specific areas of the upper Sacramento River where construction activities would take place in certain alternatives associated with ecosystem restoration, including spawning gravel augmentation and floodplain and riparian habitat restoration. For these construction areas, existing access roads were excluded, but a records search buffer of 0.25 mile was added to all other project elements. It should be noted that the proposed construction areas are concept-level, and may be relocated or deleted as a result of design development, consultation, or other factors.

Traditional Cultural Properties

Public and stakeholder coordination meetings were conducted on behalf of Reclamation with Indian tribes and Native American groups whose traditional territories overlap the study area to identify Traditional Cultural Properties, ceremonial locations, and other areas of concern to the Native American community. This included meetings and/or workshops with groups and individuals representing major tribes and/or extended family groups in the Shasta/Redding area regarding potential effects to cultural resources from a plan to enlarge Shasta Dam and Reservoir. The primary intent of these meetings was to strengthen communication with tribal groups and individuals; solicit, clarify, and document major concerns and issues; and establish a preferred method/approach to maintaining effective communication during the remainder of the SLWRI and in future endeavors.

Federally recognized Native American tribes were invited to begin the consultation process at an information meeting, followed by additional contact by telephone to learn of their concerns regarding the SLWRI, and to gain an initial sense of where sensitive resource localities are situated within the primary study area. Non-Federally recognized Native American groups and individuals with an interest in the study area were also contacted. There were also in-person visits to tribal members to collect information.

Seven tribal groups were invited to an information meeting held on April 4, 2007, in Redding, California. The purpose of the meeting was to provide general information about the SLWRI, initiate Section 106 consultation with groups desiring to participate in the project, and introduce Elena Nilsson, a consultant for Reclamation, as the Native American Tribal Coordination study lead. Invitations were sent to the groups shown in Table 14-1.

Table 14-1. Native American Groups Involved in Consultations

Native American Group
Grindstone Indian Rancheria of Wintun-Wailaki Indians[1]
Paskenta Band of Nomlaki Indians[1]
Pit River Tribe[1]
Redding Rancheria[1]
Shasta Indian Nation
Winnemem Wintu
Wintu Tribe of Northern California/Toyon-Wintu Center

Note:
[1] Federally recognized tribe as of 2012 (http://www.bia.gov/cs/groups/public/documents/text/idc-041248.pdf)

From August 2007 to March 2008, nine meetings were held with Native American groups whose traditional territories overlap with the SLWRI study area. The purpose of the meetings was to solicit, clarify, and document major concerns and issues regarding the project, and to establish a preferred method/approach to maintaining effective communication during the remainder of the SLWRI study and in future endeavors. Five groups participated in these meetings, including the Grindstone Indian Rancheria (one meeting), Paskenta Band of Nomlaki Indians (one meeting), Pit River Tribe (three meetings), Shasta Indian Nation (one meeting), and Winnemem Wintu (three meetings).

Currently, no formal Traditional Cultural Properties (as defined by Federal regulations) are formally recorded at the Information Center. The California Native American Heritage Commission, however, has stated that sacred lands (as defined by this commission) are present in the study area. Based on consultations, meetings, statements, letters, and public comments provided by Native Americans and previous ethnographic and ethnohistoric studies, it is predicted that a considerable number of Traditional Cultural Properties and other areas of special concern are present in the study area.

14.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State and CEQA Guidelines, Section 15126.4(a)).

Federal Criteria

Under Federal regulation (36 CFR Section 800(a)(1)):

> *"An adverse effect is found when an undertaking may alter, directly or indirectly, any of the characteristics of a historic property that qualify the property for inclusion in the National Register in a manner that would diminish the integrity of the property's location, design, setting, materials, workmanship, feeling, or association. Consideration shall be given to all qualifying characteristics of a historic property, including those that may have been identified subsequent to the original evaluation of the property's eligibility for the National Register. Adverse effects may include reasonably foreseeable effects caused by the undertaking that may occur later in time, be farther removed in distance or be cumulative."*

Examples of adverse effects (36 CFR Section 800(a)(2)) include the following:

- Physical destruction, damage, or alteration, including moving the property from its historic location
- Isolation from, or alteration of, the setting
- Introduction of intrusive elements
- Neglect leading to deterioration or destruction
- Transfer, sale, or lease from Federal ownership

Adverse effects often can be resolved or mitigated through additional research, public education, and/or other means.

State Criteria

California regulations require that effects to cultural resources be considered only for resources meeting the criteria for eligibility to the California Register of Historical Resources, outlined in Section 5024.1 of the California Public Resources Code. Demolition, replacement, substantial alteration, or relocation of an eligible resource are actions that could change those elements of the resource which make it eligible. The following eligibility criteria were developed using guidance provided by the State CEQA Guidelines, and they consider the context and intensity of the environmental effects as required under NEPA. Under the State CEQA Guidelines, impacts on cultural resources may be considered significant if a project alternative would result in any of the following:

- Cause a substantial adverse change in the significance of a historical resource, as defined in Guidelines Section 15064.5
- Cause a substantial adverse change in the significance of an archaeological resource pursuant to Guidelines Section 15064.5
- Disturb human remains, including those interred outside formal cemeteries

According to the above criteria, the project would be considered to have a significant impact on cultural resources if it would result in any of the following:

- Substantial adverse change in the significance of an historical resource
- Substantial adverse change in the significance of a unique archaeological resource
- Disturbance or destruction of unique paleontological resource or site or unique geologic feature
- Disturbance of any human remains, including those interred outside of formal cemeteries
- Elimination of important examples of the major periods of California history or prehistory

Under CEQA an impact to a cultural resource can be reduced to a less-than-significant level through mitigation. Statements of impact significance are relative to both existing conditions (Year 2012) and future conditions (Year 2030), unless stated otherwise. Only those elements of a resource which contribute to its eligibility need to be considered; effects to noncontributing elements are less than significant.

14.3.3 Direct and Indirect Effects

This section describes the environmental consequences of the SLWRI alternatives, and proposed mitigation measures for any impacts determined to be significant or potentially significant.

No-Action Alternative

Dam construction, infrastructure and facilities relocation, additional reservoir area inundation, and construction activities adjacent to the upper Sacramento River would not occur under the No-Action Alternative. Therefore, no additional cultural resources above the current reservoir level would be impacted, and conditions would be the same as existing.

Shasta Lake and Vicinity

Impact Culture-1 (No-Action): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Archaeological sites (as well as historic cemetery locations) within the existing Shasta Lake fluctuation zone will continue to be impacted by fluctuations in the height of the reservoir during ongoing operations with the No-Action Alternative. As stated above, dam construction, infrastructure and facilities relocation, and additional inundation as a result of the proposed action alternatives would not occur under the No-Action Alternative; therefore, no new impacts on cultural resources related to construction or inundation are expected. Mitigation is not required for the No-Action Alternative, as the proposed activities related to the action alternatives would not occur. Responsibilities to manage ongoing impacts from the No-Action Alternative may fall under other Federal or State laws which would be separate from any implementation requirements related to the action alternatives.

Impact Culture-2 (No-Action): Inundation of Traditional Cultural Properties Any Traditional Cultural Properties within the existing Shasta Lake fluctuation zone will continue to be impacted by fluctuations in the height of the reservoir during ongoing operations with the No-Action Alternative. As stated above, additional inundation as a result of the proposed action alternatives would not occur under the No-Action Alternative; therefore, no new impacts on cultural resources related to inundation are expected. Mitigation is not required for the No-Action Alternative. Responsibilities to manage ongoing impacts from the No-Action Alternative may fall under other Federal or State laws which would be separate from any implementation requirements related to the action alternatives.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Culture-3 (No-Action): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction Archaeological sites (as well as historic cemetery locations) in or near the upper Sacramento River will continue to be impacted by water operations with the No-Action Alternative. As stated above, construction activities adjacent to the upper Sacramento River would not occur under the No-Action Alternative; therefore, no impacts on cultural resources related to construction are expected. Mitigation is not required for the No-Action Alternative. Responsibilities to manage ongoing impacts from the No-Action Alternative may fall under other Federal or State laws which would be separate from any implementation requirements related to the action alternatives.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within: (1) the proposed additional 1,229-acre inundation area; (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area; and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.). It should be noted that sites typically extend into the inundation and reservoir area for more than one alternative.

Shasta Lake and Vicinity

Impact Culture-1 (CP1): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. As noted, previous reservoir studies indicate that impacts are greatest in the zone of inundation and drawdown (fluctuation zone), where cultural resources are repeatedly exposed to scouring, wave action, wet/dry cycles, and de-vegetation. This means that the most significant impacts will occur where an undertaking increases the size of the fluctuation zone.

Sensitivity analyses, which are summarized at the beginning of this section, estimate that, with complete surveys, impacts associated with CP1 inundation and areas would include approximately 212±54 prehistoric resources (Table 14-2). The historic-era archival study documented 355 localities that may potentially contain historic-era remains within this inundation area.

Sensitivity analyses estimate that, with complete surveys, the CP1 fluctuation zone would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Table 14-2. Cultural Resources Impacts for CP1

Inundation Area	
Prehistoric sites	212±54
Historic-era archival localities	355
Fluctuation Zone	
Prehistoric sites	675±172
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Fewer than CP2

Notes:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Section 106.

Sensitivity analyses estimate that with complete surveys, the 0.25-mile buffer area for CP1 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may potentially contain historic-era remains. Although the full extent and locations of project impacts within the buffer zone related to construction are not yet available for CP1, impacts would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible for listing under NHPA, and how many of the eligible resources will sustain adverse impacts from this alternative, this impact would be significant. Adverse effects will be avoided, minimized, or mitigated through project redesign, when warranted, or through the development and implementation of an MOA or PA, as discussed in Section 14.3.4.

Impact Culture-2 (CP1): Inundation of Traditional Cultural Properties Due to the confidential nature of sacred land filings, some sites have been identified within the study area, but specific locations are unknown. Several Native American groups have identified Traditional Cultural Properties and important ceremonial locations that would be adversely impacted by CP1. This impact would be significant.

In addition, places used for traditional practices that may be Traditional Cultural Properties have been identified within the study area. These locations are also confidential.

Two particularly important Winnemem Wintu ceremonial locations that would be impacted by CP1 include Puberty Rock and the doctoring pools near Nawtawaket Creek. CP1 could increase the frequency of inundation of Puberty Rock, restricting the Winnemem Wintu from holding the puberty ceremony at this important location during certain periods. Although Puberty Rock would still be accessible for portions of the year, when lake levels are lower, CP1 would increase the frequency of inundation. The relocation of the rock to higher ground is not possible, as, in the Winnemem worldview, its location is preordained and connected with the nearby “two sisters” mountain (Bollibokka Mountain). Puberty Rock also marks the location of an extensive village with housepits and burials. CP1 would inundate additional burials at this location, which would require removal and relocation. The Winnemem Wintu have estimated that 120 ancestral villages still accessible above the current high waterline of Shasta Lake would be adversely impacted by CP1.

The Pit River Madesi Band members state that 22 ethnographic villages, associated burial grounds, and several Traditional Cultural Properties are located within the existing reservoir and proposed inundation or fluctuation areas.

The local Native American community has identified several locations in the study area where ceremonial activities are carried out; notable among these are Puberty Rock and the doctoring pools near Nawtawaket Creek. Inundation or other adverse impacts to these places likely cannot be mitigated because the importance of the identified properties is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible.

Although it is impossible at this stage to say how many of these resources will be adversely impacted due to inundation as a result of implementing CP1, this impact would be potentially significant. These sites cannot be relocated and continue their importance to Native American cultural practices. Adverse effects will be avoided, minimized, or mitigated through project redesign, when warranted, or through the development and implementation of an MOA or PA. However it is unlikely that effects would be resolved for many Traditional Cultural Properties. Mitigation for this impact is proposed in Section 14.3.4, but it is unlikely that adequate mitigation is available to reduce the impact to a less-than-significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Culture-3 (CP1): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction
Construction activities adjacent to the upper Sacramento River associated with downstream ecosystem enhancements would not occur under CP1; therefore, no impacts on significant cultural resources related to construction are expected. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 1,734-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.).

Shasta Lake and Vicinity
Impact Culture-1 (CP2): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam and enlarging Shasta Reservoir would have a direct impact on cultural resources. This impact would be significant. Sensitivity analyses estimate that, with complete surveys, inundation associated with CP2 would include approximately 224±57 prehistoric resources (Table 14-3). The historic-era archival study documented 371 localities that may potentially contain historic-era remains within this inundation area.

Table 14-3. Cultural Resources Impacts for CP2

Inundation Area	
Prehistoric sites	224±57
Historic-era archival localities	371
Fluctuation Zone	
Prehistoric sites	675±172
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Fewer than CP3

Notes:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity analyses estimate that, with complete surveys, the fluctuation zone for CP2 would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Sensitivity analyses estimate that, with complete surveys, the 0.25-mile buffer zone for CP2 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may potentially contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available for this alternative, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts from CP2, this impact would be significant. Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and ceremonial locations is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Adverse effects will be resolved through project redesign, when warranted, or through the development of an MOA or PA, as discussed in Section 14.3.4.

Impact Culture-2 (CP2): Inundation of Traditional Cultural Properties
Alternative CP2 is similar to Alternative CP1 with respect to the potential to cause significant impacts to Traditional Cultural Properties by inundation or affected by the fluctuation zone. The Native American Heritage Commission (NAHC) identified sacred land filings within the study area, and local Native American groups have provided information related to many locations in the inundation and fluctuation zone. These locations are generally confidential, thus making it unclear whether or not they are situated within the CP2 area. For the same reasons that apply to CP1, this impact would be significant. Adverse effects will be avoided, minimized, or mitigated through project redesign, when warranted, or through the development and implementation of an MOA or PA.

However it is unlikely that effects would be resolved for many Traditional Cultural Properties. Mitigation for this impact is proposed in Section 14.3.4, but it is unlikely that adequate mitigation is available to reduce the impact to a less-than-significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Culture-3 (CP2): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction Construction activities adjacent to the upper Sacramento River associated with downstream ecosystem enhancements would not occur under CP2; therefore, no impacts on cultural resources related to construction are expected. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Agricultural Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 2,497-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.).

Shasta Lake and Vicinity

Impact Culture-1 (CP3): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. Sensitivity analyses estimate that, with complete surveys, inundation associated with CP3 would include approximately 243±63 prehistoric resources (Table 14-4). The historic-era archival study documented 391 localities that may potentially contain historic-era remains within this inundation area.

Table 14-4. Cultural Resources Impacts for CP3

Inundation Area	
Prehistoric sites	243±63
Historic-era archival localities	391
Fluctuation Zone	
Prehistoric sites	675±172
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Fewer than CP5, same as CP4

Notes:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity analyses estimate that, with complete surveys, the fluctuation zone for CP3 would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Sensitivity analyses estimate that, with complete surveys, the 0.25-mile buffer zone for CP3 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available for this alternative, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts from CP3, this impact would be significant. Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and ceremonial locations is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Adverse effects will be resolved through project redesign, when warranted, or through the development of an MOA or PA, as discussed in Section 14.3.4.

Impact Culture-2 (CP3): Inundation of Traditional Cultural Properties CP3 is similar to CP1 with respect to the potential to cause significant impacts to Traditional Cultural Properties by inundation or affected by the fluctuation zone. The NAHC identified sacred land filings within the study area, and local Native American groups have provided information related to many locations in the inundation and fluctuation zone. These locations are generally confidential, thus making it unclear whether or not they are situated within the CP3 area. Adverse effects will be avoided, minimized, or mitigated through project redesign, when warranted, or through the development and implementation of an MOA or PA. However it is unlikely that effects would be resolved for many Traditional Cultural Properties. Mitigation for this impact is proposed in Section 14.3.4, but it is unlikely that adequate mitigation is available to reduce the impact to a less-than-significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Culture-3 (CP3): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction Construction activities adjacent to the upper Sacramento River associated with downstream ecosystem enhancements would not occur under CP3; therefore, no impacts on cultural resources related to construction are expected. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 2,497-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.). CP4 and CP4A include downstream ecosystem enhancements with spawning gravel augmentation and floodplain and riparian habitat restoration, both of which would entail construction activities adjacent to the upper Sacramento River.

Shasta Lake and Vicinity

Impact Culture-1 (CP4 and CP4A): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation

Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant for CP4 or CP4A. Sensitivity analyses estimate that with complete surveys, inundation associated with CP4 and CP4A would include approximately 243±63 prehistoric resources (Table 14-5). The historic-era archival study documented 391 localities for CP4 and CP4A that may potentially contain historic-era remains within this inundation area.

Table 14-5. Cultural Resources Impacts for CP4 and CP4A

Inundation Area	**CP4**	**CP4A**
Prehistoric sites	243±63	243±63
Historic-era archival localities	391	391
Fluctuation Zone		
Prehistoric sites	601±154	675±172
Historic-era archival localities	524	529
0.25-Mile Buffer		
All cultural resources	Fewer than CP5, same as CP3	Fewer than CP5, same as CP3

Notes:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity analyses estimate that, with complete surveys, the fluctuation zone for CP4 would include approximately 601±154 prehistoric resources. Sensitivity analyses estimate that, with complete surveys, the fluctuation zone for CP4A would include approximately 675±172 prehistoric resources. The historic-era archival study documented 524 localities for CP4 and 529 localities for CP4A that may potentially contain historic-era remains.

Sensitivity analyses estimate that, with complete surveys, the 0.25-mile buffer zone for CP4 and CP4A would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities for CP4 and CP4A that may potentially contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts, this impact would be significant for CP4.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts, this impact would be significant for CP4A.

Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and ceremonial locations is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Adverse effects will be resolved through project redesign, when warranted, or through the development of an MOA or PA, as discussed in Section 14.3.4.

Impact Culture-2 (CP4 and CP4A): Inundation of Traditional Cultural Properties CP4 and CP4A are similar to CP1 with respect to the potential to cause significant impacts to Traditional Cultural Properties by inundation or affected by the fluctuation zone. The NAHC identified sacred land filings within the study area, and local Native American groups have provided information related to many locations in the inundation and fluctuation zone. These locations are generally confidential, thus making it unclear whether or not they are situated within the CP4 and CP4A area. For the same reasons that apply to CP1, this impact would be significant. Adverse effects will be avoided, minimized, or mitigated through project redesign, when warranted, or through the development and implementation of an MOA or PA. However it is unlikely that effects would be resolved for many Traditional Cultural Properties. Mitigation for this impact is proposed in Section 14.3.4, but it is unlikely that adequate mitigation is available to reduce the impact to a less-than-significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Culture-3 (CP4 and CP4A): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction Previous cultural resource studies indicated the presence of cultural resources in or near proposed downstream construction areas related to spawning gravel augmentation and floodplain and riparian habitat restoration. This impact would be significant for CP4 or CP4A.

A total of 17 cultural resources have been recorded within the records search areas, consisting of eight prehistoric sites, six historic-era resources, and three resources with prehistoric and historic-era components. As mapped, thirteen of these cultural resources exist only in the 1/8-mile buffer areas, and only four of these cultural resources extend into proposed construction areas. It should be noted that the proposed construction areas are concept-level and may be relocated or deleted as a result of design development, consultation, or other factors.

Although it is impossible at this stage to say how many eligible resources will sustain adverse impacts from CP4 or CP4A, this impact would be significant. Adverse effects will be resolved through project redesign, when warranted, or through the development of an MOA or PA, as discussed in Section 14.3.4.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Cultural resources potentially impacted by this alternative include those within (1) the proposed additional 2,497-acre inundation area, (2) the portion of the proposed fluctuation zone for this alternative within the existing reservoir area, and (3) those portions of the 0.25-mile buffer around the reservoir where infrastructure would need to be relocated (recreation facilities, roads, utilities, trails, etc.). CP5 also includes downstream ecosystem enhancements with spawning gravel augmentation and floodplain and riparian habitat restoration, both of which would entail construction activities adjacent to the upper Sacramento River.

Shasta Lake and Vicinity

Impact Culture-1 (CP5): Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation Raising Shasta Dam would have a direct impact on cultural resources. This impact would be significant. Sensitivity analyses estimate that, with complete surveys, inundation associated with CP5 would include approximately 243±63 prehistoric resources (Table 14-6). The historic-era archival study documented 391 localities that may potentially contain historic-era remains within this inundation area.

Table 14-6. Cultural Resources Impacts for CP5

Inundation Area	
Prehistoric sites	243±63
Historic-era archival localities	391
Fluctuation Zone	
Prehistoric sites	675±175
Historic-era archival localities	529
0.25-Mile Buffer	
All cultural resources	Largest quantity

Notes:
Mean prehistoric site estimates are based on weights-of-evidence quantitative analysis.
An undetermined number of sites will actually be subject to mitigation under NHPA Sec. 106.

Sensitivity analyses estimate that, with complete surveys, the fluctuation zone for CP5 would include approximately 675±172 prehistoric resources. The historic-era archival study documented 529 localities that may potentially contain historic-era remains.

Sensitivity analyses estimate that, with complete surveys, the 0.25-mile buffer zone for CP5 would include approximately 728±212 prehistoric resources. The historic-era archival study documented 773 localities that may potentially contain historic-era remains. Although the full extent and locations of project impacts related to construction activities within the buffer zone are not yet available for this alternative, they would occur within only a small percentage of the overall buffer zone concentrated near the reservoir.

Although it is impossible at this stage to say how many of these resources will be determined eligible, and how many of the eligible resources will sustain adverse impacts from CP5, this impact would be significant. Inundation or other adverse impacts to affected resources likely cannot be mitigated because the importance of the identified properties and ceremonial locations is inextricably tied to physical location, and relocation of these features away from the inundation area is not possible. Adverse effects will be resolved through project redesign, when warranted, or through the development of an MOA or PA, as discussed in Section 14.3.4.

Impact Culture-2 (CP5): Inundation of Traditional Cultural Properties
Alternative CP5 is similar to Alternative CP1 with respect to the potential to cause significant impacts to Traditional Cultural Properties by inundation or affected by the fluctuation zone. The NAHC identified sacred land filings within the study area, and local Native American groups have provided information related to many locations in the inundation and fluctuation zone. These locations are generally confidential, thus making it unclear whether or not they are situated within the CP5 area. For the same reasons that apply to CP1, this impact would be significant. Adverse effects will be avoided, minimized, or mitigated through project redesign, when warranted, or through the development and implementation of an MOA or PA. However it is unlikely that effects would be resolved for many Traditional Cultural Properties. Mitigation for this impact is proposed in Section 14.3.4, but it is unlikely that adequate mitigation is available to reduce the impact to a less-than-significant level.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact Culture-3 (CP5): Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction
This impact would be significant. Previous cultural resource studies indicated the presence of cultural resources in or near proposed downstream construction areas related to spawning gravel augmentation and floodplain and riparian habitat restoration.

A total of 17 cultural resources have been recorded within the records search areas, consisting of eight prehistoric sites, six historic-era resources, and three resources with prehistoric and historic-era components. As mapped, thirteen of these cultural resources exist only in the 1/8-mile buffer areas, and only four of these cultural resources extend into proposed construction areas. It should be noted that the proposed construction areas are concept-level and may be relocated or deleted as a result of design development, consultation, or other factors.

Although it is impossible at this stage to say how many eligible resources will sustain adverse impacts from CP5, this impact would be significant. Adverse effects will be resolved through project redesign, when warranted, or through the development of an MOA or PA, as discussed in Section 14.3.4.

14.3.4 Mitigation Measures

This section discusses mitigation measures for each significant impact described in the environmental consequences section, as presented in Table 14-7. In coordination with project designers, there will be opportunities to avoid, minimize, or mitigate adverse effects to historic properties through project redesign or through the development of an MOA or PA. An MOA or PA will ensure compliance with Section 106 and resolution of adverse effects.

Table 14-7. Summary of Mitigation Measures for Cultural Resources

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/ CP4A	CP5
Impact Culture-1: Disturbance or Destruction of Archaeological and Historical Resources Due to Construction or Inundation	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure Culture-1: Develop and Implement measures identified in an NHPA Section 106 MOA or PA				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Culture-2: Inundation of Traditional Cultural Properties	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure Culture-2:Adverse effects will be avoided, minimized, or mitigated through project redesign, when warranted, or through the development and implementation of an MOA or PA				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU

Table 14-7. Summary of Mitigation Measures for Cultural Resources (contd.)

<table>
<tr><th>Impact</th><th></th><th>No-Action Alternative</th><th>CP1</th><th>CP2</th><th>CP3</th><th>CP4/ CP4A</th><th>CP5</th></tr>
<tr><td rowspan="3">Impact Culture-3: Disturbance or Destruction of Archaeological and Historical Resources near the Upper Sacramento River Due to Construction</td><td>LOS before Mitigation</td><td>NI</td><td>NI</td><td>NI</td><td>NI</td><td>S</td><td>S</td></tr>
<tr><td>Mitigation Measure</td><td>None required.</td><td colspan="3">No mitigation needed; thus, none proposed.</td><td colspan="2">Mitigation Measure Culture-3: Implement Mitigation Measure Culture-1: Develop and Implement measures identified in an NHPA Section 106 MOA or PA</td></tr>
<tr><td>LOS after Mitigation</td><td>NI</td><td>NI</td><td>NI</td><td>NI</td><td>LTS</td><td>LTS</td></tr>
</table>

Key:
LOS = level of significance
LTS = less than significant
MOA = Memorandum of Agreement
NHPA = National Historic Preservation Act
NI = No Impact
PA = Programmatic Agreement
S = significant
SU = significant and unavoidable

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP1): Develop and Implement measures identified in an NHPA Section 106 MOA or PA Avoid, minimize, or mitigate adverse effects through project redesign, when warranted, or through the development and implementation of an MOA or PA.

These impacts would be less than significant after mitigation.

Mitigation Measure Culture-2 (CP1) Avoid, minimize, or mitigate adverse effects to Traditional Cultural Properties through project redesign, when warranted, or through the development and implementation of an MOA or PA.

This impact would remain significant and unavoidable after mitigation.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP2): Develop and Implement measures identified in an NHPA Section 106 MOA or PA Avoid, minimize, or mitigate adverse effects through project redesign, when warranted, or through the development and implementation of an MOA or PA.

These impacts would be less than significant after mitigation.

Mitigation Measure Culture-2 (CP2) Avoid, minimize, or mitigate adverse effects to Traditional Cultural Properties through project redesign, when warranted, or through the development and implementation of an MOA or PA.

This impact would remain significant and unavoidable after mitigation.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Agricultural Water Supply Reliability

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP3): Develop and Implement measures identified in an NHPA Section 106 MOA or PA Avoid, minimize, or mitigate adverse effects through project redesign, when warranted, or through the development and implementation of an MOA or PA.

These impacts would be less than significant after mitigation.

Mitigation Measure Culture-2 (CP3) Avoid, minimize, or mitigate adverse effects to Traditional Cultural Properties through project redesign, when warranted, or through the development and implementation of an MOA or PA.

This impact would remain significant and unavoidable after mitigation.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

As CP4 or CP4A are likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP4 and CP4A): Develop and Implement measures identified in an NHPA Section 106 MOA or PA Avoid, minimize, or mitigate adverse effects through project redesign, when warranted, or through the development and implementation of an MOA or PA.

These impacts would be less than significant after mitigation.

Mitigation Measure Culture-2 (CP4 and CP4A) Avoid, minimize, or mitigate adverse effects to Traditional Cultural Properties through project redesign, when warranted, or through the development and implementation of an MOA or PA.

This impact would remain significant and unavoidable after mitigation.

Mitigation Measure Culture-3 (CP4 and CP4A): Implement Mitigation Measure Culture-1 (CP4 and CP4A): Develop and Implement measures identified in an NHPA Section 106 MOA or PA This mitigation measure is the same as Mitigation Measure Culture-1 (CP4 and CP4A). Implementation of Mitigation Measure Culture-1 (CP4 and CP4A) would reduce Impact Culture-3 (CP4 and CP4A) to a less than significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

As this alternative is likely to cause significant, adverse impacts to historic properties, it will be necessary to mitigate those impacts.

Mitigation Measure Culture-1 (CP5): Develop and Implement measures identified in an NHPA Section 106 MOA or PA Avoid, minimize, or mitigate adverse effects through project redesign, when warranted, or through the development and implementation of an MOA or PA.

These impacts would be less than significant after mitigation.

Mitigation Measure Culture-2 (CP5) Avoid, minimize, or mitigate adverse effects to Traditional Cultural Properties through project redesign, when warranted, or through the development and implementation of an MOA or PA.

This impact would remain significant and unavoidable after mitigation.

Mitigation Measure Culture-3 (CP5): Implement Mitigation Measure Culture 1 (CP5): Develop and Implement measures identified in an NHPA Section 106 MOA or PA This mitigation measure is the same as Mitigation Measure Culture-1 (CP5). Implementation of Mitigation Measure Culture-1 (CP5) would reduce Impact Culture-3 (CP5) to a less than significant level.

14.3.5 Cumulative Effects

Chapter 3, “Considerations for Describing the Affected Environment and Environmental Consequences,” gives an overview of the cumulative effects analysis, including significance criteria, and discusses the relationship of this analysis to the CALFED Programmatic Cumulative Impacts Analysis. Table 3-1, “Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area,” in Chapter 3, lists the projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level. None of the programs or projects listed in Table 3-1 under Quantitative Analysis would impact cultural resources in the primary study, nor overlap with resources affected in the extended study area. The remainder of this analysis is focused on programs and projects in the Qualitative Analysis section of Table 3-1.

Past programs and projects have impacted cultural resources in the primary and extended study area through land use changes, inundation, erosion, construction, abandonment and illegal activities. The past projects such as Shasta Dam and Reservoir, road construction, and recreation development have cumulatively impacted cultural resources. Reasonably foreseeable projects listed on Table 3-1 that may impact cultural resources include but are not limited to Antlers Bridge Replacement, Moody Flats Quarry, and Mountain Gate at Shasta Mixed Use Area Plan. The project alternatives would result in a cumulatively considerable incremental contribution to a significant cumulative impact related to effects on cultural resources in the primary study area. Also in the Upper Sacramento River (Shasta Dam to Red Bluff) region of the extended study area, the project would result in a cumulatively considerable incremental contribution to a significant cumulative impact on cultural resources. The SLWRI alternatives would not impact cultural resources in other areas of the extended study area, so there would be no cumulative impacts from the project in these areas.

This page left blank intentionally.

Chapter 15
Indian Trust Assets

15.1 Affected Environment

This section describes the affected environment related to Indian Trust Assets (ITA) for the proposed dam and reservoir modifications under SLWRI action alternatives.

The affected environment for ITAs is the primary study area, within which all construction activities will take place, and which includes Shasta Lake's expanded inundation area, relocations within approximately 0.25 miles of the shoreline, and the upper Sacramento River from Shasta Dam to the Red Bluff Pumping Plant.

The extended study area would only be affected by changes in CVP and SWP operations, and includes the Sacramento River to the Delta and the CVP and SWP water service areas. For additional details on the primary and extended study areas, please refer to Section 1.3 and Figures 1-1 and 1-2 of the EIS. Since the action alternatives are not anticipated to have potential impacts to ITAs as a result of changes in CVP and SWP operations, an analysis of potential impacts to ITAs was determined unwarranted.

Indian Trust Lands in the region around the primary study area are shown in Figure 15-1.

Several Federally recognized tribes are located in the region surrounding the primary study area (Table 15-1).

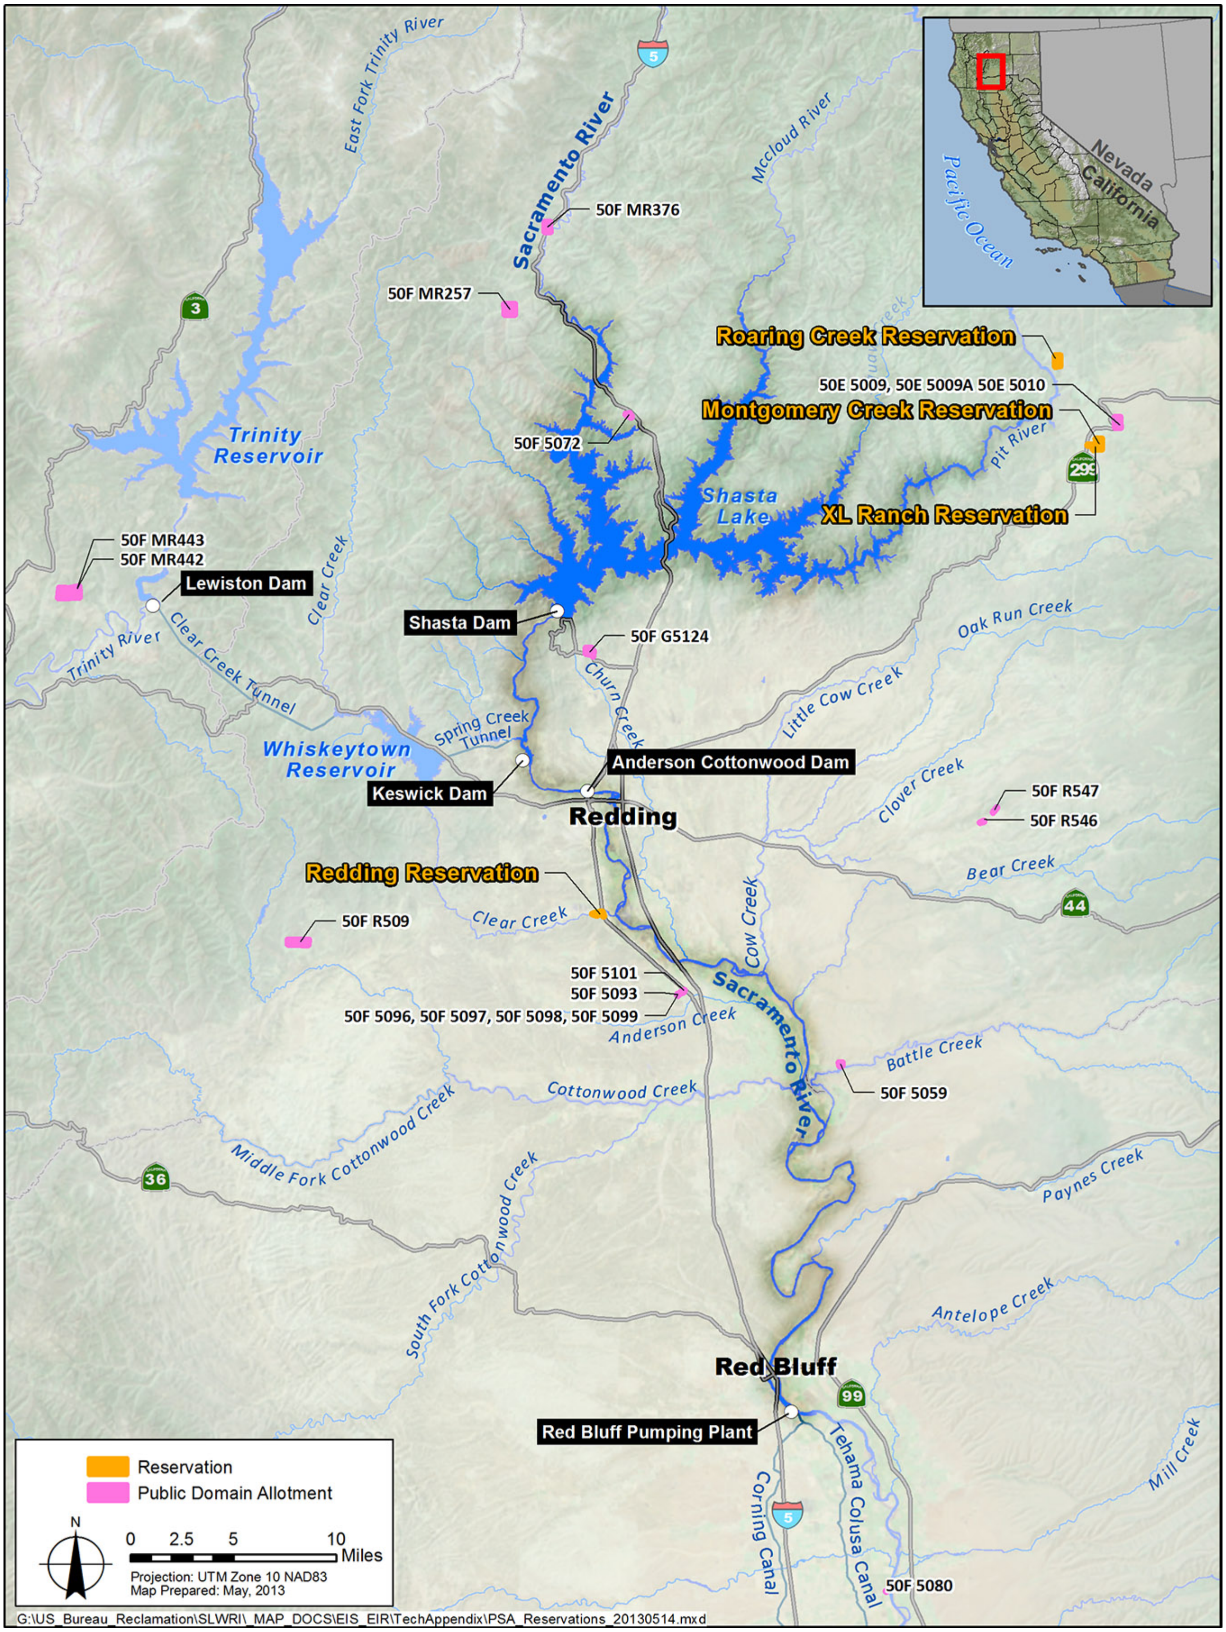

Figure 15-1. Reservations, Rancherias and Public Domain Allotments in Primary Study Area

Table 15-1. Federally Recognized Tribes in Region Surrounding Primary Study Area

Tribe	Affiliation
Grindstone Indian Rancheria of Wintun- Wailaki Indians	Wintun, Wailaki
Paskenta Band of Nomlaki Indians	Nomlaki
Pit River Tribe Environmental Office	Pit River, Wintun
Pit River Tribe	Pit River Achumawi Wintun
Redding Rancheria	Wintu, Pit River, Yana

15.2 Regulatory Framework

ITAs are legal interests in property held in trust by the U.S. for Federally recognized Indian tribes or individual Indians. An Indian trust has three components: (1) the trustee, (2) the beneficiary, and (3) the trust asset. ITAs can include land, minerals, Federally reserved hunting and fishing rights, Federally reserved water rights, and in-stream flows associated with trust land. Beneficiaries of the Indian trust relationship are Federally recognized Indian tribes with trust land; the United States is the trustee. By definition, ITAs cannot be sold, leased, or otherwise encumbered without approval of the United States. The characterization and application of the United States trust relationship have been defined by case law that interprets Congressional acts, executive orders, and historic treaty provisions.

The Federal Government, through treaty, statute, or regulation, may take on specific, enforceable fiduciary obligations that give rise to a trust responsibility to Federally recognized tribes and individual Indians possessing trust assets. Courts have recognized an enforceable Federal fiduciary duty with respect to Federal supervision of Indian money or natural resources, held in trust by the Federal Government, where specific treaties, statutes, or regulations create such a fiduciary duty.

Consistent with President William J. Clinton's 1994 memorandum, *Government-to-Government Relations with Native American Tribal Governments* (Federal Register, Vol. 59, No. 85, May 4, 1994, pages 22951–22952), Reclamation assesses the effect of its programs on tribal trust resources and Federally recognized tribal governments. Reclamation is tasked to actively engage Federally recognized tribal governments and consult with such tribes on a government-to-government level when its actions affect ITAs. The U.S. Department of the Interior Departmental Manual, Part 512.2 (1995), ascribes the responsibility for ensuring protection of ITAs to the heads of bureaus and offices. The Department of the Interior is required to "protect and preserve Indian trust assets from loss, damage, unlawful alienation, waste, and depletion" (Secretarial Order No. 3215, *Principles for the Discharge of the Secretary's Trust Responsibility*, Reclamation 2000). It is the general policy of the

Department of the Interior to perform its activities and programs in such a way as to protect ITAs and avoid adverse effects whenever possible. Reclamation complies with procedures contained in Departmental Manual, Part 512.2, guidelines, which protect ITAs. Reclamation carries out its activities in a manner that protects trust assets and avoids adverse impacts, when possible. When Reclamation cannot avoid adverse impacts, it will provide appropriate mitigation or compensation. Reclamation is responsible for assessing whether action alternatives CP1 through CP5 have the potential to affect ITAs. Reclamation will comply with procedures contained in Departmental Manual, Part 512.2, guidelines, which protect ITAs.

15.3 Environmental Consequences and Mitigation Measures

This section discusses environmental consequences and potential mitigation associated with ITAs that could result from implementing the alternatives described in this EIS.

15.3.1 Methods and Assumptions

A detailed description of both the primary and extended study areas was provided to the Bureau of Indian Affairs' Regional ITA Coordinator. The Regional ITA Coordinator examined both the project area descriptions and records held by the Bureau of Indian Affairs and Reclamation, and determined that the proposed action does not have potential to affect ITAs. There are no ITAs in the primary study area.

15.3.2 Direct and Indirect Effects

The following section describes the potential environmental consequences of the project.

No-Action Alternative

Under the No-Action Alternative, there are no potential impacts to ITAs because no new facilities would be constructed and existing operations would continue as historically.

CP1 Through CP5

There are no tribes possessing legal property interests held in trust by the United States in the study area for any of the proposed comprehensive plans (CP1 through CP5). The nearest ITA is a Public Domain Allotment approximately 5 miles north-northwest of the project location. This property would not be affected by inundation from the enlarged reservoir or have ground disturbing activities.

Cumulative Impacts

There are no potential impacts to ITAs as a result of the proposed action; therefore, the proposed action would not contribute to cumulative impacts to ITAs.

Chapter 16
Socioeconomics, Population, and Housing

16.1 Affected Environment

This chapter describes socioeconomics, population, and housing characteristics in the primary and extended study areas. For a more detailed discussion of the information presented in this chapter, see the *Socioeconomics, Population, and Housing Technical Report*.

16.1.1 Socioeconomics

Socioeconomics covers age, race/ethnicity, income/poverty, employment and labor force, business and industry, and government and finance. For a more detailed discussion of the information presented in this chapter, see the *Socioeconomics, Population, and Housing Technical Report*.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Race/Ethnicity In 2010, the white population represented more than 90 percent of the populations of Shasta and Tehama counties, but substantial increases were observed in many minority groups (U.S. Census Bureau 2010a). Tehama County's minority populations also increased between 2000 and 2010. Trends observed in the two counties generally coincide with statewide trends; Hispanic, Asian-Pacific Islander, and American Indian populations all grew by more than 9 percent over the 10-year period.

Income/Poverty Jurisdictions within the primary study area have underperformed when compared to the statewide averages for income levels and poverty rates. Median household incomes in Shasta and Tehama counties were sizably lower than the statewide average in 2000 and 2010, although Shasta County experienced a substantial increase in the 10-year period. With median household incomes of $42,931 and $39,392 in 2010, respectively, Shasta and Tehama counties had incomes averaging between $17,000 and $20,000 less than the statewide average for 2010 (U.S. Census Bureau 2011a). Overall poverty rates and child poverty rates also have been higher in the primary study area than in the State of California (State) as a whole.

Employment and Labor Force Because of the cyclical nature of the area's natural resource-related industries and other factors, Shasta and Tehama counties were characterized by substantially higher unemployment rates during the 1990s (Shasta County 2004). Unemployment rates in both counties have continued to increase and have exceeded State rates since 2007. From 2007 through 2010, unemployment rates in the two counties ranged between 1.8 percent and 3.3 percent above the statewide rate. The two counties recorded similar unemployment rates (varying between 0.1 and 0.7 percent) since 2007. In 2010, Tehama County registered a 15.6 percent unemployment rate, while unemployment in Shasta County totaled 15.7 percent of the population (EDD 2010a). As a result of its larger population, Shasta County maintained a labor force of just under 84,400 people in 2010, or more than three times that of Tehama County.

Business and Industry Economic activities in the primary study area coincide in many ways with the industrial composition of California as a whole. Education and health services, followed by governmental services, made up the top two industrial sectors both locally and statewide in 2010. In Shasta and Tehama counties, employees in the education and health services, which includes teachers and health workers, and government employees accounted for more than 40 percent of the total workforce. Similarly, retail trade, which includes general merchandise stores, food and beverage stores, and other miscellaneous stores and retailors, also ranks in the top five industries in both counties and California generally.

Some differences also exist between the industrial makeup of the two counties and that of California as a whole. For example, manufacturing plays an important role in Tehama County (7.6 percent) and California (10.0 percent) as a whole, but a comparatively small role in Shasta County. Professional and business services registers as the third largest industry at the statewide level (12.5 percent), but represents a smaller portion of employment in Shasta County (9.7 percent) and Tehama County (7.0 percent). Additionally, farm employment makes up a sizeable portion of the total workforce in Tehama County (8.3 percent), but accounts for a comparatively small portion of the workforce in Shasta County (3.1 percent) and California as a whole (2.3 percent).

Projections of future growth depict slightly different economic trends in Shasta and Tehama counties than at the statewide level. California’s construction industry is expected to grow by 26 percent by 2020 (compared to 2010 levels), and the wholesale trade industry is expected to grow by more than 25 percent in that time. The construction industry represents the fifth largest growth industry in Tehama County (9.4 percent); however, it does not rank in the top growth industries in Shasta County. The wholesale trade industry also represents the fourth and third growth industries in Shasta and Tehama counties, respectively, but growth rates are expected to be less than the State rate (U.S. Census Bureau 2011a).

Established businesses, along with new businesses that locate in the area, will play an important role in the expansion of the local economy, as projected by the State. Table 1-11 in the *Socioeconomics, Population, and Housing Technical Report* displays a number of the major employers in the primary study area. This list of employers includes a range of businesses with a payroll of more than 500 people. Three of the 10 businesses provide health care to local residents. Other employers with a payroll of over 500 people include: a wholesale nursery; insurance, pest management, and fuel management companies; a college; a manufacturer of industrial materials (mill work); and a wholesale distributor, identified as employing more than 1,000 people (EDD 2013a, 2013b).

Government and Finance Shasta and Tehama counties are the critical local governments in the primary study area. Each county has a primary urban center (Redding in Shasta County and Red Bluff in Tehama County), with a limited number of small cities and towns, and large amounts of rural land surrounding it. Because the two counties are largely rural, their total revenues and expenditures are relatively low when compared to other jurisdictions in California.

Revenues generated by Shasta County are used for a range of governmental activities. As described in the *Socioeconomics, Population, and Housing Technical Report*, expenditures increased from $302.8 million in the 2007 – 2008 fiscal year to $319.7 million in the 2008 – 2009 fiscal year. Expenditures decreased substantially in the 2009 – 2010 fiscal year to $309.6 million, as a result of decreased spending on transportation-related projects. Welfare, social services, and other public assistance have consistently been the largest expenditures for Shasta County (totaling more than $94.1 million in 2010), but remained relatively constant between 2007 and 2010. Police, fire, and other public safety activities represented the second largest expenditure category with more than $79.7 million in the 2009 – 2010 fiscal year.

Observed trends in Tehama County's revenues and expenditures have been generally similar to those experienced in Shasta County. Because of its smaller size, Tehama County's total revenues are substantially less than those of Shasta County ($112.3 million in the 2009 – 2010 fiscal year, compared to $309.6 million in Shasta County), but Tehama County experienced an overall decrease in revenue growth between 2007 and 2010.

Expenditures in Tehama County also are consistent with the trends observed in Shasta County.

Lower Sacramento River and Delta

Race/Ethnicity Overall, the majority of people in the nine-county lower Sacramento River and Delta portion of the extended study area are white (57.4 percent), but the proportion of population identified as white varies substantially between counties. In 2010, the white population of Glenn County (71.1 percent) was the highest proportion of any county in the area, while Sacramento and San Joaquin counties had the lowest proportion of white residents (51.0 percent) (U.S. Census Bureau 2010b). These proportions were less than that observed at the statewide level in 2010 (57.6 percent).

Income/Poverty Income and poverty characteristics for the lower Sacramento River and Delta area are similar to those for California as a whole. The median household income of the majority of counties within the nine-county area is similar to or higher than the statewide median household income ($59,641).

Poverty levels for both individuals and children in the lower Sacramento River and Delta counties are similar to the statewide level. Sacramento (16.6 percent), San Joaquin (17.7 percent), Glenn (18.2 percent), Yolo (19.9 percent), and Butte (20.3 percent) had higher overall poverty rates than California as a whole (15.5 percent) in 2010 (U.S. Census Bureau 2011b). The percentage of people below the poverty level is expected to follow national and statewide economic trends.

Employment and Labor Force Employment and labor trends in the nine lower Sacramento River and Delta counties generally are consistent with statewide trends. The area maintains a labor force of more than 1.9 million people, representing approximately 10 percent of California's labor force (18.3 million).

In the nine-county area in 2010, approximately 13.2 percent of the labor force was classified as unemployed, as compared to 12.4 percent statewide for the same period. Although the total unemployment rate was only 0.8 percent greater than the State's unemployment rate, unemployment within the lower Sacramento River and Delta counties varied substantially. Generally, the counties with the highest unemployment rates in 2010 had greater dependence on the agricultural industry and a reduced industrial diversity. Frequently, unemployment rates tend to be higher in rural areas than in urban areas, and farm workers commonly have seasonal and temporary jobs.

Business and Industry Business and industry in the lower Sacramento River and Delta counties are composed primarily of five sectors: government; educational and health services; professional and business services; retail trade; and leisure and hospitality (U.S. Census Bureau 2011b). These consistently rank in the top five sectors of the nine lower Sacramento River and Delta counties.

Government and Finance A total of 55 cities and towns and a range of special districts are located within the nine counties of the lower Sacramento River and Delta. This collection of governmental entities provides valuable public services to the lower Sacramento River and Delta area—education, fire protection, employment development, emergency services, and crime prevention and control. These agencies and special districts rely primarily on tax revenue disbursed by the State government, local sales and property taxes and fees, and the disbursement of Federal funds. This greater reliance on existing tax structures and rates, and a productive economic base, makes relatively reliable and affordable CVP and SWP water and power even more valuable, because its availability and affordability helps foster local business activity, and thus indirectly helps sustain the fiscal health of local service providers. Similarly, flood protection provided by Shasta Dam helps protect and sustain the appraised value of property within the dam's floodplain, again helping to protect the fiscal health of local service providers.

Total revenues and expenditures vary substantially between the nine counties of the lower Sacramento River and Delta because of the relative sizes of the counties and the services they provide. Revenues include payments received through taxes, licenses and permits, grants from other governments, charges for services, and others. Expenditures include payments made by a jurisdiction to buy goods, pay its employees, and provide services to its residents. Glenn County had the smallest total of revenues and expenditures, each at $82.2 million for 2009-2010, while Sacramento County had the greatest total of revenues and expenditures at $2.4 billion and $2.5 billion, respectively, for 2009-2010 (Glenn County 2009; Sacramento County 2009).

CVP/SWP Service Areas

Race/Ethnicity The population within the CVP and SWP service areas continues to diversify. The proportion of the statewide population made up of minority groups has been steadily increasing. The population of individuals in California who identify themselves as Asian–Pacific Islander or multiracial experienced double-digit population growth between 2000 and 2010 (U.S. Census Bureau 2002, 2010b). Hispanics are the largest minority population in California and many members of this ethnic group work on farms that receive some or all of their water from the CVP and SWP.

Income/Poverty Poverty levels for both individuals and children in California increased slightly between 2000 and 2010. The percentage of people below the poverty level is expected to follow national and statewide economic trends.

Employment and Labor Force Employment and labor force trends observed in the CVP and SWP service areas generally are synonymous with the trends observed at the statewide level because of the expanse of the CVP and SWP service areas. California's total labor force increased consistently from year to year between 2007 and 2010. Between 2007 and 2008, the labor force increased by approximately 282,100 individuals, which was the largest annual increase over the 4-year period. Between 2009 and 2010, the labor force increased by approximately 108,100 individuals. California's total labor force exceeded 18.3 million in 2010.

Although increases in the State's total labor force were relatively consistent, the State's unemployment rate fluctuated between 2007 and 2010. The State's unemployment rate was 5.4 percent in 2007 and increased steadily over the next 4 years to 12.4 percent. This increase in the unemployment rate at the State level coincided with similar national employment trends (EDD 2010a).

Business and Industry Business and industry trends for the CVP and SWP service areas are assumed to be equal to those at the statewide level because of the expanse of these service areas. The education and health services sector represents the largest industry in California, measured by total employees. Government is California's second largest work sector, and the retail trade, professional and business services, and leisure and hospitality industries all play important roles in the State's economy.

Government and Finance The State represents the most appropriate level of detail for the CVP and SWP service areas because of the expanse of the service areas and the interdependent nature of government and finance provision. California currently ranks as the seventh largest economy in the world and provides goods and services to more than 38 million people, making it the largest state in the nation. As a result, State government manages a large annual volume of revenues and expenditures. The State's adopted 2012–2013 budget includes a total of approximately $132.9 billion in revenues and transfers and $142.4 billion in total expenditures (State of California 2012). Many of the State's expenditures represent grants and other funding, made available to local jurisdictions throughout California. These funds may be used for a variety of services, such as health and human services, environmental protection, and resource management.

16.1.2 Population

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

The area surrounding Shasta Dam includes generally smaller cities and towns with two larger, primary urban areas in each of the two counties (Shasta County and Tehama County). Almost 39 percent of the population in Shasta County and more than 65 percent in Tehama County lived in unincorporated areas in 2010. By comparison, only 17.2 percent of the population in the entire State lived in unincorporated areas in 2010. In total, the populations of Shasta and Tehama counties make up less than 1 percent of the total population in California.

The cities of Redding and Red Bluff are the two largest urban areas in the primary study area. Redding, with a total of 91,561 residents in 2010, is the most populous city in the region. Red Bluff is the second largest city in the region and the largest city in Tehama County, with a total of 13,825 residents in 2010. Remaining cities within the primary study area – Anderson, Shasta Lake, and Tehama – all contained fewer than 11,000 residents in 2010.

Although Shasta and Tehama counties are still comparatively small, both counties have been growing substantially over the past 15-20 years. Since 1990, the population of Shasta County has increased by more than 25 percent. During that time, the populations of Redding and Anderson have increased by approximately 38 percent and 30 percent, respectively. A similar situation has been observed in Tehama County, where the total population has grown by more than 27 percent since 1990. Most of this new growth has occurred in the unincorporated areas of Tehama County, rather than in its cities.

Shasta and Tehama counties are expected to continue this growth trend, with substantial growth in Tehama County. The State of California projects that Shasta County's population will increase by 27 percent by 2050, to a total of approximately 233,500 residents (DOF 2012). This increase is less than that total expected at the statewide level (32.0 percent). Tehama County is expected to have a larger population increase compared to the state level, where the population is expected to increase approximately 44 percent between 2010 and 2050 (DOF 2012).

Lower Sacramento River and Delta

As described in the *Socioeconomics, Population, and Housing Technical Report*, roughly 4 million people live in the nine-county area that makes up the lower Sacramento River and Delta area (Butte, Colusa, Contra Costa, Glenn, Sacramento, San Joaquin, Solano, Sutter, and Yolo counties). This population represents approximately 11 percent of California's total population. Sacramento County and Contra Costa County are the two largest counties in the area, with approximately 1.4 million and 1.0 million residents, respectively, in 2010 (DOF 2010). All of the nine-county area is expected to grow at a faster rate than California as a whole (32.0 percent increase) through 2050. Population increases of at least 34 percent are expected in all nine counties in the area, over that time (DOF 2012).

CVP/SWP Service Areas

In 2010, California contained a total of 38.7 million residents. Approximately 80 percent of the State's population resided in the incorporated areas of its 58 counties (DOF 2010). Similar to the State as a whole, most of the population of the CVP and SWP service areas is concentrated within urban areas. Outside of these fast-growing population centers, most of the lands within the CVP and SWP service areas are rural, with irrigated agriculture being the predominant land use and driver of the local and regional economies.

California's population has increased by almost 25 percent since 1990, and it is projected to increase by approximately 32 percent to more than 51 million people by 2050. This substantial population increase will result in a sizeable increase in water and energy demand across the State. The proportion of the statewide population made up of minority groups has been steadily increasing.

16.1.3 Housing

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

As shown in the *Socioeconomics, Population, and Housing Technical Report*, as would be expected, provision of housing in the primary study area generally coincides with the population trends discussed above. Shasta County (77,857 units in 2010) maintains almost three times the amount of housing units as that of Tehama County (27,729 units) (DOF 2010). Of the nearby cities, Redding provides the largest supply of housing in the region, with more than 38,000 housing units. Redding's units represent roughly half the total housing units in Shasta County. Red Bluff provides the second largest housing stock in the area, with more than 6,000 units. Within Redding and Anderson, the increase in housing units between 1990 and 2010 was substantially greater than the percentage increase at the State level (21.5 percent). Redding observed the greatest increase in housing units since 1990 (40.9 percent).

Overall, single-family dwelling units are the predominant housing type in the primary study area. Vacancy rates generally were higher than the statewide average (5.9 percent), with the exception of Redding (5.0 percent) and Anderson (5.8 percent). Tehama County registered the highest vacancy rate in the primary study area, with 10.9 percent of all its housing units vacant. The average household size in jurisdictions of the primary study area ranged from as low as 2.33 persons per household (Tehama) to as high as 2.64 persons per household (Anderson and Shasta Lake). All of these totals were lower than the average number of persons per household at the statewide level (2.96 persons).

Lower Sacramento River and Delta

As shown in the *Socioeconomics, Population, and Housing Technical Report*, housing characteristics in the nine lower Sacramento River and Delta counties generally are similar to those at the statewide level. In 2010, the area contained approximately 1.6 million housing units. Similar to population, this total represents approximately 11 percent of California's housing stock (approximately 14 million houses). Overall, single-family housing makes up a larger proportion of the total housing stock in the nine-county area (72.7 percent) than recorded at the statewide level (64.4 percent) in 2010 (DOF 2010).

The vacancy rate in the nine-county area in 2010 was higher (5.3 percent) than the rate observed at the statewide level (4.8 percent). Vacancy in the majority of counties (six of nine counties) within the lower Sacramento River and Delta area was substantially lower than California as a whole (DOF 2010).

Average household size in the lower Sacramento River and Delta area is generally lower than that observed at the statewide level. In total, an average of 2.82 persons lived in the households of the nine-county area in 2010. This compared to an average of 2.96 persons for California as a whole (DOF 2010).

CVP/SWP Service Areas

A description of housing in the CVP and SWP service areas is not included because it would not be affected by the project.

16.2 Regulatory Framework

The analysis of socioeconomic resources is guided primarily by Federal laws and policies. State and local laws and policies typically promote economic development and diversity, environmental justice, public health and safety, and housing, and address the concerns of the residents within their jurisdictions. As noted in the following discussion, NEPA documents must include an assessment of potential conflicts with State and local plans and policies.

16.2.1 Federal

The major Federal laws and regulations guiding the assessment of socioeconomic resources are summarized below.

National Environmental Policy Act

Section 102 of NEPA requires Federal agencies to "insure the integrated use of the natural and social sciences" in planning and decision making (42 U.S. Code Section 4332).

Section 1502.16(c) of NEPA requires Federal agencies to identify potential conflicts between a proposed action and related plans and policies of Federal, State, and local agencies and Indian tribes. This requirement helps Federal agencies identify potential conflicts that may cause adverse effects on the social and economic environment of a study area because many agency and tribal plans and policies are designed to protect the people residing within their jurisdictions and/or the local economy they depend on for their economic livelihoods.

Council on Environmental Quality

The Council on Environmental Quality's "Regulations for Implementing the Procedural Provisions of NEPA" (40 Code of Federal Regulations (CFR) Sections 1500–1508) provide guidance related to social and economic impact assessment by noting that the "human environment" assessed under NEPA is to be "interpreted comprehensively" to include "the natural and physical environment and the relationship of people with that environment" (40 CFR 1508.14). Furthermore, these regulations require agencies to assess "aesthetic, historic, cultural, economic, social, or health" effects, whether direct, indirect, or cumulative (40 CFR 1508.8). Some Federal agencies, including the U.S. Bureau of Land Management and USFS, have developed socioeconomics-related handbooks and instructional memoranda to help EIS preparers comply with NEPA, with respect to socioeconomics resources.

Executive Order 12898 – Environmental Justice

In 1994, President Bill Clinton issued Executive Order 12898 regarding environmental justice. It requires Federal agencies to "identify and address" disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations in the United States. The Council on Environmental Quality issued guidance in 1997, to help Federal agencies incorporate environmental justice concerns into their NEPA procedures. Environmental justice issues are specifically addressed in Chapter 24, "Environmental Justice," of this EIS.

16.2.2 State

Most State and local governments have plans and policies intended to protect and expand local and regional economies affecting the communities and residents within their jurisdictions. Some of these plans and policies also are intended to promote public health and safety while minimizing conflicts between new development projects of all types; their associated traffic, air, and noise impacts; and the social environment within which local residents live and work. State plans and policies also frequently address other social and economic impact topics, including fiscal conditions and related public services that affect local residents' quality of life.

In California, the California Environmental Protection Agency adopted its own environmental justice policy in 2004. Pursuant to Sections 71110–71113 of the California Public Resources Code, the agency has developed this policy (or strategy) to provide guidance to its resource boards, departments, and offices. It is intended to help achieve the State's goal of "achieving fair treatment of people of all races, cultures and incomes with respect to the development, adoption, implementation and enforcement of environmental laws and policies."

16.2.3 Regional and Local

Each of California's counties, including Shasta and Tehama counties, has its own plans, ordinances, and other policies designed to protect and improve a wide range of socioeconomic conditions. Specifically addressed in these plans, ordinances, and policies are housing; employment opportunities for minorities and low-income populations, and others; economic diversification; and business activity in general.

Shasta County

Shasta County General Plan Two primary elements of the Shasta County General Plan (Shasta County 2004) address socioeconomic resources: Housing, and Economic Development. The Housing Element of the Shasta County General Plan (Shasta County 2011) establishes several goals and policies related to ensuring adequate housing provision, especially affordable housing, in the county. Shasta County's housing policies and programs are grouped into six primary categories, each supporting an identified goal. These categories and the goal associated with each are as follows:

- **Housing Supply**
  - **Goal –** To establish and implement policies and programs that will:
    - Contribute to the provision of an adequate supply and diversity of safe, healthy, and affordable housing for all income levels to meet the needs of residents in the unincorporated areas of Shasta County.

- Satisfy the requirements of the Regional Housing Needs Allocation Plan for Shasta County for the 2004-2009 Housing Element period, specifically to realize the construction of new units as follows: Very Low Income – 300 units; Low Income – 255 units; Moderate Income – 1,035 units; and Above Moderate Income – 810 units.

- **Conserve and Improve Existing Affordable Housing**

  - **Goal** – To conserve, improve, and expand the inventory of existing affordable housing stock in the incorporated areas of the County, specifically to realize the conservation and/or rehabilitation of the following units: Rehabilitation (150): 60 units – Very Low Income; 55 units – Low Income; 25 units – Moderate Income; and 10 units – Above Moderate Income; Conservation (150): 90 units – Very Low Income; 53 units – Low Income; and 7 units – Moderate Income.

- **Housing Development Constraints**

  - **Goal** – To continue to remove all County constraints, as is practical and legal, which have the potential to hinder or impede the development of affordable housing projects.

- **Special Needs**

  - **Goal** – To continue to work collectively with local agencies to enhance and expand the outreach programs designed to provide accessible and affordable housing, including supportive services, for those persons with special needs including the elderly, large families, single mothers, children, developmentally and physically disabled persons, the mentally ill, farmworkers, and the homeless.

- **Energy Conservation**

  - **Goal** – To explore, implement, and promote energy conservation practices in all eligible existing and new housing projects.

- **Fair Housing**

  - **Goal** – To continue to use all feasible means to promote, expand, and ensure equal access to available, safe, decent, affordable housing opportunities in the unincorporated area without bias or prejudice for any reason for all economic segments of the County.

The Economic Development Element of the Shasta County General Plan (Shasta County 2004) establishes the following two overall objectives for economic development:

- **ED-1 –** Economic development plans, programs, and policies shall contribute to a stable and healthy economy in Shasta County, which includes provision of a land development pattern, planning process, and regulatory atmosphere conducive to maintaining employment opportunities for County residents and fostering new economic development.

- **ED-2 –** Seek economic diversity that increases the variety, type and scale of business, industrial, and manufacturing activities.

To support these objectives, Shasta County has established three primary policies for implementation. These policies emphasize the reuse and revitalization of existing development and full use of existing infrastructure for new business opportunities. To attract business to Shasta County, a number of incentive programs are employed, including community development block grants, economic assistance through a county redevelopment agency, and business development and retention assistance through an economic development corporation. Additionally, a 50-square-mile, State-defined enterprise zone (one of only 39 in California) has been designated in portions of Redding, Shasta Lake, Anderson, and unincorporated Shasta County. Enterprise zones are generally designated in locations characterized by high poverty rates. Businesses locating within these areas may receive State-supported incentives, such as sales and use tax credits, hiring assistance tax credits, and special business expense deductions (Shasta County 2004).

Tehama County

In the Tehama County General Plan, updated in 2009 (Tehama County 2009), Tehama County set out three “fundamental concepts” that relate to population growth and demographic shifts: (1) accommodating growth, but not limiting growth or accepting uncontrolled growth; (2) locating major growth along the Interstate 5 transportation corridor; and (3) organizing growth according to a range of community types. These concepts emphasize where Tehama County expects to locate new growth and how they plan to accommodate it. Specifically, the Interstate 5 corridor plays a significant role for the placement of new development, and Tehama County attempts to provide a range of housing types for the diversity of needs created within the community. This emphasis on housing diversity may become more crucial as aging residents’ housing preferences change.

The following housing-related goals in the general plan are relevant to the project:

- **Goal HE-3: Adequate Sites –** Ensure the provision of adequate sites and facilities to support future housing needs.

- **Goal HE-5: Housing Conservation –** Work to improve, maintain and conserve the County’s existing housing stock.

- **Goal HE-6: Addressing Constraints –** Address and wherever possible remove, governmental constraints to the maintenance, improvement, or development of housing to meet the needs of County residents.

- **Goal HE-7: Fair Housing/Equal Opportunity –** Promote equal housing opportunities for all persons without discrimination regardless of age, race, sex, marital status, ethnic background, household composition, sources of income, or other arbitrary factors.

Relevant economic development-related goals contained in the draft general plan are as follows:

- **Goal ED-3 –** Expand the economic base while maintaining a healthy and diverse local economy that meets the present and future employment, shopping, recreational, public safety, and service needs of Tehama County residents.

- **Goal ED-4 –** Work toward providing adequate infrastructure to support commercial, industrial, and recreational development within Tehama County including clean-up of contaminated industrial sites.

- **Goal ED-7 –** Protect and enhance environmentally sensitive lands and natural resources while, at the same time, promoting business expansion, retention, and recruitment.

Shasta and Tehama counties function as the primary agencies responsible for implementing policies and programs aimed at addressing employment and labor force issues within the project's primary study area.

16.3 Environmental Consequences and Mitigation Measures

Based on the review of the affected environment provided in Section 16.1 of this chapter, this section describes the potential environmental consequences resulting from each of the proposed alternatives. Direct, indirect, and cumulative effects of the alternatives are discussed below. When potential environmental consequences are identified, specific mitigation measures to offset the potential effects of the alternatives are presented. Potential effects and mitigation measures address topics related to population, demographics, and housing; employment and labor force; business and industry; and government and finance.

16.3.1 Methods and Assumptions

Population, Housing, and Demographics

The analysis of the potential impacts of the project alternatives on population, housing, and demographic characteristics was based on a review of published material pertaining to the primary and extended study areas. California Department of Finance population and demographics databases and projections, U.S. Census Bureau population and demographics data, the general plans of jurisdictions within the study areas, and other similar source documents were reviewed.

Population effects were evaluated based on changes in the total number of temporary and/or permanent residents likely to result from construction and operations activities that would be performed as part of project implementation. Housing effects were assessed based on estimated short- and long-term housing needs resulting from population changes, expected as a result of the project's construction and operational activities. Effects of the project on local and regional demographic characteristics were assessed quantitatively, when available data allowed. When quantitative analysis of effects was not possible at this broader geographic level, qualitative effects were identified based on the projected makeup (e.g., ethnicity, economic class) of any population changes expected to result from project implementation.

Employment and Labor Force

The determination of potential impacts on employment and the labor force was based on a review of relevant information related to current conditions. Documents such as the California Employment Development Department's employment and labor force databases, the Economic Development and Housing elements of the Shasta County General Plan (2004), and the Tehama County General Plan Update (2009) were reviewed, along with estimates of employment (temporary and permanent jobs created) for each proposed alternative.

To quantify the potential job creation resulting from each proposed alternative, IMPLAN (IMpact analysis for PLANning model, Version 3.0.17.2) modeling was performed. IMPLAN modeling uses a branch of economics known as Input/Output analysis originally developed from the analytical work conducted by Wassily Leontief in the late 1930s. Input/Output models are essentially accounting tables that trace the linkages of interindustry purchases and sales within a specific region, and within a given year. The Input/Output model yields "multipliers" that are used to calculate the total direct, indirect, and induced effects on jobs, income, and output generated per dollar of spending on various types of goods and services in the local economic study area. IMPLAN was originally developed by the USFS and now is maintained and marketed by the Minnesota IMPLAN Group, Inc.

The IMPLAN modeling incorporated project construction-related economic activity in the four-county region surrounding Shasta Lake. The primary set of effects analyzed using the regional model was how project construction would affect output, personal income, and employment within the four-county area containing the dam and reservoir. The project costs and duration over which construction activity would take place were developed for each action alternative. The costs were organized into categories to assess the required investment that would take place in certain primary sectors of the local economy, namely concrete- and steel-related manufacturing, rock and aggregate, and dam and non-residential construction.

Several specific assumptions were necessary to complete IMPLAN modeling of the project. The following assumptions were used:

- IMPLAN modeling was completed for CP1 (which involves raising Shasta Dam by 6.5 feet); CP2 (which involves raising the dam by 12.5 feet); and CP3, CP4, CP4A, and CP5 (all of which involve raising the dam by 18.5 feet).

- A construction period of approximately 4.5 years was assumed under CP1, and 5 years under CP2, CP3, CP4, CP4A, and CP5.

- The "local economic study area" was defined as the four-county area of Shasta, Siskiyou, Tehama, and Trinity counties.

- A total labor force of 300 construction workers would be needed for CP1 and CP2; 350 construction workers would be needed for CP3, CP4, and CP4A; and 360 construction workers would be needed for CP5.

- All 300–360 construction workers would be drawn directly from the local economic study area (used in IMPLAN modeling). (High unemployment in the primary study area and the availability of necessary worker skill sets supports this assumption.)

In addition to IMPLAN modeling, the Statewide Agricultural Production (SWAP) model, Version 6, was used to determine the effects of the action alternatives on CVP and SWP agricultural users. The SWAP model is a regional economic model of irrigated agricultural production that simulates the decisions of agricultural producers (farmers) in the Central Valley of California. The model included 27 crop production regions in the Central Valley and 20 categories of crops. Based on the changes in water availability expected with each alternative, the SWAP model predicted cropping patterns, land use, and water use in the Central Valley. These predictions then were used to calculate expected changes in net income resulting from each alternative during dry, wet, and average water years.[1] Although the model's income-related projections were generally used to determine effects on business and industrial activity, the overall change in business net income (or profits) is a good indicator for potential changes in employment opportunities in affected sectors.

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

Additional information on methods and assumptions for the IMPLAN and SWAP models is provided in the Modeling Appendix.

Business and Industry

The discussion of potential impacts on business and industry is based on a review of relevant information on current conditions, specifically California Employment Development Department documents, the Economic Development Element of the Shasta County General Plan (2004), the Tehama County General Plan Update (2009), and estimates of business and industry effects for each action alternative.

To quantify the potential effect on job creation and personal incomes resulting from each action alternative, IMPLAN modeling was completed by Reclamation economists. A description of IMPLAN modeling, generally, and the specific assumptions used, related to the project, are provided in the previous section.

Government and Finance

The determination and discussion of potential impacts on government and finance was based on a review of relevant information on existing conditions, specifically the Economic Development Element of the Shasta County General Plan (2004), the Tehama County General Plan Update (2009), and estimates of local government and finance effects for each dam-raise alternative.

Because no quantitative analysis of the effect of the action alternatives on local government and finance has been completed yet, this analysis depends heavily on a qualitative discussion of potential impacts. Areas of potential impacts were identified by comparing existing conditions and probable future conditions. In many cases, the estimates completed as part of the IMPLAN and SWAP modeling served as the basis for impact estimates. These two models determine expected trends in employment, personal incomes, business incomes, agricultural production, and other data types to quantifiably estimate the impacts of the proposed alternatives. Because these local characteristics directly influence activities at the local level, they represent critical considerations in the analysis and conclusions presented in this section.

16.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on socioeconomics, population, and housing would be significant if project implementation would do any of the following:

- Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure)
- Displace substantial numbers of people or housing, necessitating the construction of replacement housing elsewhere
- Produce a substantial burden on the existing housing stock within the local community because of an increased housing demand created by nonlocal project employees
- Require sizeable numbers of new workers in a particular industrial sector from outside the local area during construction or operation for effective implementation
- Substantially increase the risk of housing or other property damage caused by flooding
- Cause a substantial decrease in the number of opportunities for temporary or long-term direct employment within the primary study area or the extended study area (within Shasta County, Tehama County, or nearby cities and towns, specifically Redding, Anderson, Shasta Lake, and Red Bluff)
- Compete with established industries for workers within the labor force or associated resources to the extent that a shortage of workers available to related businesses would exist
- Cause a substantial decrease in the number of opportunities for temporary or long-term increases in personal and/or disposable incomes within the primary or extended study area (within Shasta County, Tehama County, or nearby cities and towns, specifically Redding, Anderson, Shasta Lake, and Red Bluff)
- Considerably decrease the sales and/or incomes of businesses in the primary or extended study areas

Significance statements are relative to both existing conditions (2005) and future conditions (2030), unless stated otherwise.

16.3.3 Topics Eliminated from Further Discussion

In contrast to the primary study area and the lower Sacramento River and Delta portion of the extended study area, additional flood control capacity provided by the action alternatives is not expected to substantially affect the CVP and SWP service areas beyond the lower Sacramento River and Delta. Dam operations (i.e., storage and release scenarios) in the CVP and SWP service areas are expected to continue, according to management plans similar to those currently in place. Therefore, no flood-related impact on population and housing would occur in the CVP and SWP service areas. This topic is not discussed further under CP1–CP5.

16.3.4 Direct and Indirect Effects

Similar to the approach used in Section 16.1, "Affected Environment," the following discussion of environmental consequences in the primary study area does not separate Shasta Lake and vicinity from the upper Sacramento River (Shasta Dam to Red Bluff) because of the regional interdependence of their socioeconomic characteristics. Instead, environmental consequences are discussed for the entire primary study area and the two counties that encompass it, Shasta and Tehama counties.

No-Action Alternative

Under the No-Action Alternative, no additional Federal action would be taken to address water reliability issues or increase anadromous fish survival. Therefore, Shasta Dam and Shasta Lake would continue to operate as they currently do, with some modifications (currently not known) expected in the future. With the No-Action Alternative, water reliability is expected to become an increasing issue as demand for water increases to meet the needs of California's growing population. Over time, water conservation and reuse efforts would increase, and water provision is expected to shift from such areas as agricultural production to urban uses. Environmental restoration, flood control, and hydropower generation are expected to continue similar to existing conditions. Like water demand, electricity demand in California is expected to increase substantially in the future. This increased demand is expected to create localized shortages in energy availability over time.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) Under the No-Action Alternative, population, demographics, and housing conditions are expected to continue following the current growth trends described in Section 16.1, "Affected Environment." The projected employment and labor force characteristics summarized in Section 16.1 also would continue. The relatively large number of new construction-related jobs that would be created by all of the action alternatives would not be created. Therefore, this alternative would have no impact on population and housing or on employment and the labor force.

In addition, the business and industrial activity in the primary study area would continue, as summarized in Section 16.1, “Affected Environment.” The relatively large and temporary increase in business activity that would occur during project construction would not occur. Therefore, the No-Action Alternative would have no impact on business and industrial activity.

Furthermore, the local government and finance conditions and trends, projected in Section 16.1, “Affected Environment,” would continue because new facilities would not be constructed and existing facilities would not be altered, expanded, or demolished. The positive fiscal effects associated with the increase in sales and income tax revenue from construction-related spending would not occur. Therefore, the No-Action Alternative would have no impact on government and finance.

Lower Sacramento River and Delta Under the No-Action Alternative, the projected population, demographics, and housing conditions as well as development conditions, described in Section 16.1, “Affected Environment,” would remain unchanged. No impact on population, demographics, or housing would occur.

In addition, the local government and finance conditions, described in Section 16.1, “Affected Environment,” would continue because no new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. The positive fiscal effects associated with the increase in sales and income tax revenue resulting from project construction-related spending would not occur. Therefore, the No-Action Alternative would have no impact on government and finance.

The impacts of the No-Action Alternative on employment and the labor force and on business and industrial activity in the lower Sacramento River and Delta area are described below.

Impact Socio-1 (No-Action): Potential for Reduced Employment Opportunities for Lower Sacramento River and Delta Area Residents The No-Action Alternative has the potential to result in periodic water and power supply disruptions from increasing demand on the existing supply caused by population growth. These disruptions could result in adverse economic effects on the lower Sacramento River and Delta portion of the extended study area. This impact would be potentially significant.

Under the No-Action Alternative, the risk of CVP and SWP water supply disruptions as well as Western Area Power Administration and DWR power supply disruptions in the lower Sacramento River and Delta area would be higher than the risk of such disruptions in the long term under the action alternatives. Although the likelihood of such disruptions is difficult to predict, the CalSim-II Version) modeling performed to simulate future water and power supply conditions under 2030 No-Action Alternative conditions, and 2030 conditions under each of the action alternatives, indicates that all of the action alternatives would enhance CVP and SWP water and power supply conditions relative to 2030 No-Action Alternative conditions. (CalSim-II modeling of power supply conditions for the 2030 No-Action Alternative currently is not available.)

An increase in the risk of water and power supply disruptions could, in turn, increase the likelihood that temporary and adverse socioeconomic effects would take place during related reductions in economic activity, including reductions in employment opportunities. Adverse economic effects during times of drought, blackouts, or other types of water or power supply disruptions also could include delays in hiring employees or layoffs, if businesses experience water and/or power rate increases as a result of water and power purveyors seeking other, more expensive replacement sources. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Socio-2 (No-Action): Potential for Temporary Disruptions in Business and Industrial Activity in the Lower Sacramento River and Delta Area If water or power supply disruptions were to occur, they could cause temporary reductions in business and industrial activity, especially where water- and power-intensive industries and businesses are found. This impact would be potentially significant.

As discussed under Impact Socio-1 (No-Action) above, an increase in the risk of water or power supply disruptions could occur in the lower Sacramento River and Delta portion of the extended study area under the No-Action Alternative. If such disruptions were to occur, they could cause temporary reductions in business and industrial activity, especially in areas where water- and power-intensive industries and businesses are found. Because the No-Action Alternative could have adverse effects on businesses and industrial activity in the case of drought, blackouts, or other types of water or power supply disruptions, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas Under the No-Action Alternative, the projected population, demographic, and housing conditions as well as development conditions, described in Section 16.1, “Affected Environment,” would remain unchanged. No impact would occur. Therefore, potential effects of the No-Action Alternative on population, demographics, or housing in this geographic region are not discussed further.

In addition, the local government and finance conditions in the CVP and SWP service areas described in Section 16.1, “Affected Environment,” would continue. The positive fiscal effects associated with the increase in sales and income tax revenue resulting from construction-related spending would not occur. Therefore, no impact would occur under the No-Action Alternative.

Potential effects of this alternative on government and finance in this geographic region are not discussed further.

The impacts of the No-Action Alternative on employment and the labor force and on business and industrial activity in the CVP and SWP service areas are described below.

Impact Socio-3 (No-Action): Potential for Reduced Employment Opportunities for Residents within the CVP and SWP Service Areas The No-Action Alternative has the potential to result in periodic water and power supply disruptions from increasing demand on the existing supply, caused by population growth. These disruptions could result in variability in economic activity, which could reduce or delay employment opportunities in the CVP and SWP service areas. This impact would be potentially significant.

Under the No-Action Alternative, the risk of CVP and SWP water supply disruptions as well as Western Area Power Administration and DWR power supply disruptions would be higher than the risk of such disruptions in the long term under each of the action alternatives. The likelihood of such disruptions is difficult to predict; however, the CalSim-II modeling performed to simulate future water and power supply conditions under 2030 No-Action Alternative conditions, and 2030 conditions under each of the action alternatives, indicates that all of the action alternatives would enhance CVP and SWP water and power supply conditions relative to 2030 No-Action Alternative conditions. (CalSim-II modeling of power supply conditions for the 2030 No-Action Alternative currently is not available.)

An increase in the risk of water and power supply disruptions, including drought, blackouts, or other types of water or power disruptions, could in turn increase the likelihood of temporary and adverse socioeconomic effects. Adverse economic effects during times of these disruptions could reduce economic activity and also result in delays in hiring employees or layoffs if businesses were to experience water and/or power rate increases as a result of water and power purveyors seeking other, more expensive replacement sources. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Impact Socio-4 (No-Action): Potential for Temporary Disruptions in Business and Industrial Activity in the CVP and SWP Service Areas If water or power supply disruptions were to occur, they could cause temporary reductions in business and industrial activity, especially where water- and power-intensive industries and businesses are found. This impact would be potentially significant.

As discussed under Impact Socio-3 (No-Action) above, an increase in the risk of water or power supply disruptions could occur in the CVP and SWP service areas under the No-Action Alternative. If such disruptions were to occur, they could cause temporary reductions in some business and industrial activity, especially in areas where water- and power-intensive industries and businesses are found. Because the No-Action Alternative could have adverse effects on businesses and industrial activity in the case of drought, blackouts, or other types of water or power supply disruptions, this impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability and increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 6.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 8.5 feet and enlarge the total storage capacity in the reservoir by 256,000 acre-feet to 4.81 million acre-feet (MAF). CP1 would increase the maximum surface area of the pool to 30,800 acres. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing municipal and industrial (M&I) deliveries.

Implementing CP1 is expected to result in the replacement or modification of 8 bridges and relocation of approximately 45 existing structures. The total construction cost associated with CP1 would be approximately $990 million.

CP1 would help reduce estimated future agricultural and M&I water shortages and would increase water supply reliability in the CVP/SWP service areas by increasing water supplies for agricultural and M&I deliveries, by at least 47,300 acre-feet per year in dry and critical years, and increasing average annual deliveries by about 31,000 acre-feet per year. The majority of the increased dry and critical year water supplies (i.e., 42,700 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, CP1 would provide hydropower benefits by increasing hydropower generation, by approximately 54 gigawatt-hours (GWh) per year. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP1): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 300 direct jobs would be created as a result of construction activities associated with CP1. All 300 construction workers are expected to come from the local labor force; therefore, a temporary population increase is not expected. This impact would be less than significant.

Approximately 300 construction workers would be needed over the 4.5-year construction period to support the construction activities related to the 6.5-foot raise of Shasta Dam. Because of the availability, experience, and expertise of the existing labor force within the primary study area, the necessary workers are expected to be available in the surrounding two counties (Shasta and Tehama counties). Therefore, no construction workers are expected to be sourced from outside the primary study area, and no employees (or very few) would need to relocate to the project area during the construction period. Even if a relatively small number of workers were to come from outside the local area, sufficient housing capacity (e.g., rental housing, motel, and apartment vacancies) exists in the area. Thus, effects on population and housing in the primary and extended study areas are not expected; if they were to occur, they would be very minor. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP1): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities
Construction activities associated with CP1 would generate approximately 300 construction jobs, 400 indirect jobs in various construction-related support industries, and 610 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs are expected to provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

Concrete workers, workers with large-scale construction experience, general laborers, and others would be drawn from the existing local construction industry. These jobs would represent a relatively small increase (less than 0.3 percent) in the total labor force in the two counties (109,960 employees) of the primary study area, but would represent a substantial increase in employment for many of the cities surrounding the project site, where employment has consistently been below countywide and statewide averages (EDD 2010a, 2010b).

Although the increase in employment would represent a small percentage increase for the two-county area, the employment opportunities created by CP1 would represent a substantial contribution in counties that have consistently registered high unemployment rates. Unemployment rates steadily increased in both Shasta and Tehama counties, from around 7 percent in 2007 to over 15 percent in 2010 (EDD 2010a). Similarly, unemployment rates in the cities of Anderson, Shasta Lake, and Red Bluff steadily increased between 2007 and 2010, with Anderson and Shasta Lake exceeding those recorded at both county levels (EDD 2010b). Within Trinity and Siskiyou counties (i.e., the remaining two counties in the local economic study area, the area used in IMPLAN modeling), the 2010 unemployment rates exceeded 16 percent and 18 percent, respectively (EDD 2010c).

As stated above, IMPLAN modeling calculates “direct” employment generated by individual alternatives as well as “indirect and induced” positions that are created by construction-related and operational activities. Indirect employment may be to support hiring in businesses that provide materials to the construction effort; in service-related industries that provide food, beverages, and other goods to construction workers; or in more technical industries, such as consulting firms and other businesses. Induced employment is jobs that are created in the region because of increased household spending and not limited to construction-related activities.

In addition to the 300 direct, construction-related jobs to be created from CP1, an additional 400 indirect jobs are expected to be created from construction support industries, and 610 induced jobs from increased household spending near the project area. The generation of 1,320 new positions (direct, indirect, and induced) would represent a 1.0 percent increase from the total 2010 labor force of the four counties in the local economic study area used in the IMPLAN modeling (Shasta, Tehama, Trinity, and Siskiyou counties), which totaled approximately 135,100 employees (EDD 2010c). A 1.0 percent increase in employment would represent a substantial increase in total employment, especially for an area experiencing unemployment rates like those observed in the primary study area.

Because CP1 would create direct, indirect, and induced jobs in an area with high unemployment rates, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP1): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 300 construction jobs resulting from CP1, the potential would exist for workers from other industries to move to jobs related to construction at Shasta Dam. Because of the size of the construction industry in the primary study area, and the high unemployment rate in the area, this impact would be less than significant.

As the 300 positions created under CP1 are filled, the potential would exist for the positions to be filled by individuals currently working in related industries within the local community. This transfer of workers from related industries to the Shasta project could create a labor shortage in the related industry, if particularly skilled workers are required. In 2010, Shasta County registered 4,700 employees in the construction industry, while construction industry workers in Tehama County equaled only 1,600 individuals, for a total of 6,300 construction workers in the area (U.S. Census Bureau 2011a). Based on total employment levels and current unemployment trends in the primary study area, the 300 new construction-related jobs are not expected to substantially affect the local labor force. If a high number of workers were to be sourced from Tehama County, a limited effect could be observed because of the small number of workers in the construction industry in that county. Overall, however, this

impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP1): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Based on calculations completed as a part of the IMPLAN socioeconomic model process, more than $85.9 million in personal income is expected to be directly paid to employees in the primary study area each year of construction under CP1. In addition, more than $48.3 million in personal income is expected to be generated from various indirect and induced construction-related and other industries in the primary study area each year of construction under CP1. The combined $134.2 million in personal income to be generated would represent an approximately 92 percent increase in all annual personal income in the local economic study area. This impact would be beneficial.

Based on the results of modeling that was performed using the IMPLAN model, an estimated $85.9 million would be directly paid each year to the approximately 300 construction workers required to complete work for CP1during the proposed 4.5-year construction period. The positions expected from implementation of project construction are anticipated to be union positions, and workers would be paid according to union wage and benefit standards.

Based on the generation of 1,010 indirect and induced jobs resulting from implementation of CP1, $48.3 million in personal income is expected to be available for residents of the local economic study area each year during the proposed 4.5-year construction period. This personal income would be generated in industries that would support the construction efforts at Shasta Dam.

Personal income in the four counties of the local economic study area has substantially decreased, from $8.9 billion in 2007 to $9.8 million in 2010 (EDD 2010d). Most of this decline can be attributed to high unemployment rates and other recessionary factors. With more than $6.2 million in personal income in 2010, Shasta County contributed more than 60 percent of personal income in the four counties.

The combined direct, indirect, and induced personal income resulting from CP1 is expected to exceed $134.2 million per year of construction activities within the local economic study area. This increase in personal income would represent an approximately 92 percent increase in all annual personal income in the local economic study area. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP1): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP1 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 4.5-year construction period. This impact would be beneficial.

A large amount of construction material would be needed to raise Shasta Dam by 6.5 feet, as prescribed in CP1. These purchases may include raw or refined materials, infrastructure-related products, and/or equipment required for the construction process. Most of this material likely would be sourced from businesses within the primary study area. As a result of the large quantity of purchases expected, local businesses would experience temporary increases in sales and profits over the 4.5-year construction period. During the construction period, implementation of CP1 is expected to generate more than $349.8 million per year in sales and profits for construction-related and service-oriented businesses that support the construction industry, with approximately $220.0 million in direct income and $129.8 in indirect and induced income. Increased sales and profits could be reinvested into existing businesses, invested in new ventures or diversification, translated into increased salaries and wages for employees, or used in other ways. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP1): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP1 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) during the construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP1 likely also would result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases would be speculative; however, this impact would be beneficial.

Based on the results of modeling performed using the IMPLAN model, implementation of CP1 is expected to generate more than $603.8 million in total personal income, with approximately $386.5 million in direct income and $217.4 million in indirect and induced income during the proposed 4.5-year construction period (see Impact Socio-4 (CP1), above). In addition to this increase in personal income, most of the construction materials would be purchased within the primary study area, generating a substantial amount of revenue and profits for local businesses (see Impact Socio-5 (CP1), above).

In combination, increased personal income and construction-related spending are expected to substantially increase the total sales tax revenues of local jurisdictions within the primary study area. Larger amounts of local sales tax revenue then could be used to establish new programs and initiatives or bolster existing ones through additional funding. New and improved programs and initiatives would provide benefits to local residents.

As a result of the increased employment and personal income anticipated from implementation of CP1, a temporary increase in State sales and income tax would be likely to occur. During the construction period, more than $603.8 million in personal income is expected to be generated by direct, indirect, and induced employment, produced by the project. The increase in personal income would increase spending at local businesses within the primary study area. The exact amount of State and local sales tax revenue increases would be speculative; however, this additional spending would result in sizeable State sales tax revenues. This increased revenue source would be likely to return to the primary study area via statewide programs and policies.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP1): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP1, the overall risk of flooding below Shasta Dam and its related consequences to the primary study area are expected to be reduced. Although heavy rain events would continue to occur in the region and locally, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

In Reclamation’s Initial Alternatives Information Report (2004), flood control was identified as a secondary objective of the project. Increased flood control is to be emphasized when the two primary objectives of the project, increased anadromous fish survival and increased water supply reliability, can be met. Periodic flood events in the Sacramento Valley frequently cause substantial damage to properties adjacent to the valley’s many waterways. Currently, Shasta Dam provides substantial protection from such flooding damage for downstream residents.

CP1 would increase the storage capacity of Shasta Lake by 256,000 acre-feet. This added capacity would provide greater flexibility in Reclamation’s ability to use the reservoir for flood control purposes, thereby increasing the threshold at which seasonal heavy rain events produce flood conditions downstream from the dam. The benefits of this increase in capacity and related flood control options would be most evident along the upper Sacramento River within the primary study area. Structures and inhabitants in this floodplain experience the most direct effects from storage releases during flood events. CP1 would reduce the frequency, magnitude, and duration of future flood events that have affected structures and their residents in this part of the primary study area in the past.

The loss of jobs and adverse effects on economic well-being and livelihoods is an often overlooked consequence of catastrophic flood events. Avoiding a larger number of these events, and possibly decreasing the magnitude and duration of flooding under certain high-flow events, is expected to reduce the overall economic hardships faced by residents of the primary study area under CP1.

Structures and businesses located on the river and inhabitants of the floodplain experience the most direct effects from flood releases downstream. However, flood events also could affect those not living on the river or in the floodplain but working downstream from the dam at businesses subject to flood damage. The reduced risk of flood events associated with CP1 also is expected to reduce the business and personal income losses resulting from substantial damage to structures and businesses located adjacent to downstream waterways in the primary study area.

Implementation of CP1 would reduce damage to structures, loss of business and personal income, loss of jobs, and other adverse effects on economic well-being in the primary study area. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP1): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, implementation of CP1 is expected to create at least two new maintenance-related positions at the Shasta Dam facilities. These two positions are expected to be permanent and would continue once the 4.5-year construction period is completed. This impact would be minor but beneficial.

Reclamation estimates that with the 6.5-foot increase of Shasta Dam proposed in CP1, at least two new permanent maintenance positions would be required to ensure efficient operation of dam facilities. These two positions are expected to be union positions, and consequently would provide union-level wages and benefits. Both positions would be filled after completion of the construction activities associated with CP1 and would continue for the foreseeable future. This impact, though small, would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP1): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta Construction activities associated with CP1 have the potential to result in a temporary increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction materials sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be minor but beneficial.

As a result of construction activities that would be completed during implementation of CP1, temporary increases in indirect employment would be expected in the lower Sacramento River and Delta portion of the extended study area. A small amount of the construction materials necessary for CP1 would be obtained outside the primary study area. During the construction period, businesses that provide construction materials are expected to increase employment to meet project demand. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP1): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area that Support the Construction Industry A small amount of the construction materials used for CP1 would be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area during the construction period. This impact would be beneficial.

A significant amount of construction materials would be needed to raise Shasta Dam by 6.5 feet, as prescribed in CP1. Of these materials, a small amount would be purchased from construction-related businesses in the extended study area, including the lower Sacramento River and Delta area. These purchases may include raw or refined materials, infrastructure-related products, and/or equipment required for the construction process. As a result of the purchases expected, businesses in the lower Sacramento River and Delta portion of the extended study area are expected to experience a temporary increase in sales and profits during the construction period. Similar to businesses within the primary study area, increased sales and profits could be reinvested into the existing businesses, invested in new ventures or diversification, translated into increased salaries and wages for employees, or used in other ways. The exact scale of the increase in business sales and profits within the lower Sacramento River and Delta area would be speculative, but this amount likely would be substantial. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP1): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP1 is expected to increase short-term, construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial.

As a result of the increased employment and personal income anticipated as a part of implementation of CP1, a short-term increase in State sales and income tax revenues also is expected to occur. In the construction period, more than $603.8million in personal income would be generated by direct, indirect, and induced employment, generated by the project. This large amount of income would direct substantial income tax revenues to the State via State income tax requirements. These additional revenues would contribute substantially to the State budget and would be distributed to jurisdictions within the lower Sacramento River and Delta portion of the extended study area via statewide programs and policies. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP1): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP1, the overall risk of flooding and its related consequences below Shasta Dam is expected to be reduced. Although heavy rain events would continue to occur in the region, CP1 is intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would be expected; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

Residents of the lower Sacramento River and Delta portion of the extended study area would benefit from the additional flexibility and flood control operations during flood events that would occur as a result of CP1. With the additional capacity provided by this alternative, the effects of large rain events would be reduced as a result of the improved management of systemwide flood control operations. Hydroelectric facilities within the lower Sacramento River and Delta area would be likely to experience flood events of somewhat less duration and magnitude, thus reducing the potential effects on vulnerable houses and property within the floodplain.

The loss of jobs and adverse effects on economic well-being and livelihoods often is an overlooked consequence of catastrophic flood events. Avoiding a larger number of these events and possibly decreasing the magnitude and duration of floods under certain high-flow events are expected to reduce the overall economic hardships faced by residents of the lower Sacramento River and Delta areas. The effects of heavy rain events would be better managed and the risk of flood-related effects could be reduced as far downstream as Sacramento.

In addition, fewer flooding events would result in less damage to businesses located adjacent to waterways during some flood events. This reduction in damage would reduce the amount of time employees would be without pay because of flood conditions and damage. This reduction in flood damage would reduce residents' salary and wage losses from these catastrophic events.

Implementation of CP1 would reduce damage to structures, loss of business and personal income, loss of jobs, and other adverse effects on economic well-being in the lower Sacramento River and Delta areas. Therefore, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP1): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas that Support the Construction Industry A small amount of the construction materials used during construction under CP1 would be purchased within the extended study area, including the CVP and SWP service areas. These purchases would result in a minor increase in sales and profits for a few businesses within the CVP and SWP service areas during the construction period of CP1. This impact would be minor but beneficial.

A small amount of the construction materials used during construction under CP1 is expected to be purchased from some construction-related businesses in the extended study area, including the CVP and SWP service areas. These purchases may include raw or refined materials, infrastructure-related products, and/or equipment required for the construction process. As a result of the purchases expected, a few businesses in the CVP and SWP service areas are expected to experience a short-term increase in sales and profits over the construction period. The exact scale of the increase in business sales and profits within the CVP and SWP service areas would be speculative, but would be minor given the large geographic area of the service areas. Therefore, this impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP1): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas during Construction Implementation of CP1 may require temporarily reducing the reservoir level at critical times during the construction period. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

Construction activities implemented as part of CP1 would require adding large quantities of concrete to Shasta Dam. To complete this effort, it may be necessary to reduce the reservoir's water table to accommodate construction. A reduced water table may be needed at critical points in the construction process. Regardless of the approach needed, a reduced water table would limit the amount of water and/or hydropower that would be available from the dam for use in the CVP and SWP service areas. As a result, periods could occur in which water or hydropower availability within the CVP and SWP service areas may be more limited, especially during dry periods.

To address potential temporary shortages in water or hydropower caused by reduced availability at Shasta Dam, replacement water or hydropower supplies would need to be sourced elsewhere to maintain existing service needs. Depending on the conditions of the water or energy markets at the time of need, these replacement resources could be more expensive than water or hydropower obtained from Shasta Dam. The additional expense of obtaining water or hydropower resources could produce a minor negative effect on water and power customers if replacing these resources would be substantially more expensive. This impact would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5, "Mitigation Measures."

Impact Socio-15 (CP1): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases CP1 is expected to increase short-term, construction-related, State sales and income tax revenues received from businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

As a result of the increased employment and personal income anticipated as a part of implementation of CP1, a short-term increase in State sales and income tax revenues would be likely to occur. During the construction period for CP1, more than $603.8 million in personal income would be generated by direct, indirect, and induced employment produced by the project. This large amount of income would direct substantial income tax revenues to the State, to meet State income tax requirements. These additional revenues would contribute substantially to the State budget and would be distributed to jurisdictions within the CVP and SWP service areas via statewide programs and policies. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP1): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on SWAP modeling, improved water availability and reliability expected to result from implementation of CP1 would substantially increase agricultural net income in the CVP and SWP service areas and would increase the number of agricultural positions in these areas. This increase in production and jobs would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

Among CVP and SWP's water consumers, agricultural users benefit the most from increased water availability and reliability because of more consistent irrigation opportunities throughout the year. Based on the outputs of SWAP modeling, CP1 would improve long-term water availability and reliability within the CVP and SWP service areas by adding to water storage capacity. Long-term improvements to the availability and reliability of water are expected to allow farmers within the CVP and SWP service areas to substantially increase agricultural production, especially in dry years. It was estimated that CP1 would increase the net agricultural income within the 27 SWAP regions by more than $1.27 million in a normal year and up to $1.50 million during dry years. In wet years, net income is projected to increase to $1.89 million.

To support the increased agricultural production expected during the implementation of CP1, more agricultural workers would be needed. SWAP does not estimate the number of additional agricultural positions that would be created as a result of improved irrigation, but the resulting increase in water reliability and availability would have the potential to strengthen and extend the existing growing season in the CVP and SWP service areas. This would enable existing employees to work for longer periods in the fields and also would increase the number of workers needed during the growing season. These additional agricultural workers are expected to be distributed across the CVP and SWP service areas. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP1): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability
Implementation of CP1 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP1), this additional storage capacity would improve the long-term availability and reliability of water in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences. This impact would be beneficial.

In addition to improving agricultural production, implementation of CP1 would increase water availability and reliability for industrial and urban users within the CVP and SWP service areas. For these users, the additional 265,000 acre-feet of storage capacity proposed by CP1 is expected to substantially reduce the long-term risk of water and power shortages from periodic flow constraints. As a result, water and power users would be likely to experience fewer water and power shortages caused by reduced reservoir levels, such as those experienced in dry years. This reduction in water and power shortages, along with avoidance of the related loss of economic production, would represent a substantial benefit for users in the CVP and SWP service areas. This benefit would be most pronounced for water- and power-intensive industries that are heavily dependent on consistent water and power availability. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As with CP1, CP2 focuses on increasing water supply reliability and increasing anadromous fish survival. CP2 primarily consists of raising Shasta Dam by 12.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 14.5 feet and enlarge the total storage capacity in the reservoir by 443,000 acre-feet to 5.0 MAF. CP2 would increase the maximum surface area of the pool of the reservoir to 31,600 acres. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries.

Implementing CP2 would result in the replacement or modification of 8 bridges and relocation of approximately 100 existing structures. The total construction cost associated with CP2 would be approximately $1,089 million.

CP2 would help reduce estimated future agricultural and M&I water shortages and would increase water supply reliability in the CVP/SWP service areas, by increasing water supplies for agricultural and M&I deliveries by at least 77,800 acre-feet per year in dry and critical years and increasing average annual deliveries by about 51,300 acre-feet per year. The majority of the increased dry and critical year water supplies (i.e., 67,100 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, CP2 would provide hydropower benefits by increasing hydropower generation by approximately 90 GWh per year. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP2): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 300 new direct jobs would be created as a result of construction activities associated with CP2. All 300 construction workers are expected to come from the local labor force; therefore, a short-term population increase is not expected. This impact would be less than significant.

This impact would be similar to Impact Socio-1 (CP1). Approximately 5 years of work (compared to the 4.5 years proposed under CP1) would be required to complete the construction activities proposed under CP2. As described above under Impact Socio-1 (CP1), a short-term population increase is not expected with implementation of CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP2): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP2 are expected to generate approximately 300 new direct construction jobs, 600 indirect jobs in various construction-related support industries, and 600 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs would be drawn from the local community. These new jobs would provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

This impact would be the same as Impact Socio-2 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP2): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 300 new construction jobs resulting from CP2, the potential would exist for workers from other industries to move to jobs related to construction at Shasta Dam. Because of the size of the construction industry in the primary study area and the high unemployment rate in the area, this impact would be less than significant.

This impact would be the same as Impact Socio-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP2): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Based on calculations completed as a part of the IMPLAN socioeconomic model process, more than $85.1 million in personal income would be directly paid to employees in the primary study area each year of the 5-year construction period under CP2. The combined $132.8 million in personal income that would be generated would represent an approximately 92percent increase in all annual personal income in the local economic study area. In addition, approximately $47.8 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP2. This impact would be beneficial.

This impact would be the same as Impact Socio-4 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP2): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP2 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 5-year construction period. This impact would be beneficial.

This impact would be similar to but more beneficial than Impact Socio-5 (CP1). Because of the longer project duration and larger dam raise proposed under CP2, short-term increases in sales and profits for businesses that support the construction industry in the primary study area would be larger than those under CP1. During the construction period, implementation of CP2 is expected to generate more than $346.3 million per year in sales and profits for construction-related and service-oriented businesses that support the construction industry, with approximately $217.8 million in direct income and $128.5 indirect and induced income. The direct income would be $2.2 million less than under CP1; and, the induced income would be $600,000 less than under CP1. The additional time and materials required to implement CP2 over 5 years would generate more in sales and profits than CP1 for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP2): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP2 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 5-year construction period. This additional income, in combination with construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP2 also would be likely to result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases would be speculative; however, this impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-6 (CP1). Because of the larger total personal income (direct, indirect, and induced) and larger sales and profits for businesses over the construction period expected to result from implementation of CP2, the short-term increase in local sales tax revenues generated by CP2 would be greater than that from CP1 (see Impacts Socio-4 (CP2) and Socio-5 (CP2), above). Construction-related activities under CP2 also are expected to result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. These additional revenues would likely be cycled back to local government coffers through statewide programs and policies. The increases in State sales and income taxes are expected to be larger under CP2 than under CP1. All of these increases would be beneficial for the relevant local jurisdictions. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP2): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP2, the overall risk of flooding below Shasta Dam and its related consequences to the primary study area would be reduced. Although heavy rain events would continue to occur in the region and locally, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-7 (CP1). CP2 would increase the total storage capacity of Shasta Lake by 443,000 acre-feet. Therefore, CP2 would provide approximately 187,000 acre-feet more storage capacity in the reservoir than CP1. This additional capacity provided with the 12.5-foot dam raise would increase the flood control capabilities compared to both existing conditions and CP1, by further reducing the risk of flooding downstream from Shasta Dam. Therefore, the overall risk of flooding and its associated adverse effects on property, housing, and businesses downstream from Shasta Dam and residents throughout the primary study area would be further reduced.

The increased storage capacity proposed as a part of CP2 also would reduce the risk of job loss from flooding and its related effects to a greater extent than the capacity increase proposed under CP1. The increased storage capacity would further reduce the risk of flood-level conditions downstream from the dam. Related effects from flooding on the economic livelihood of residents of the primary study area would be similarly reduced.

Fewer flooding events would occur and less damage would be inflicted on property adjacent to downstream waterways during some flood events. This reduction in flood damage also would reduce residents’ salary and wage losses resulting from these catastrophic events.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP2): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, implementation of CP2 is expected to create at least two new maintenance-related positions at the Shasta Dam facilities. These two positions would be permanent and would continue after the 5-year construction period is completed. This impact would be minor but beneficial.

This impact would be the same as Impact Socio-8 (CP1) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP2): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta Construction activities associated with CP2 would have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction material sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-9 (CP1). A larger potential temporary increase in indirect employment in construction-related businesses of the lower Sacramento River and Delta area would be expected under CP2 than under CP1. Estimated total construction costs for CP2 are approximately 9.5 percent higher than costs for CP1. Therefore, more income would be allocated to indirect positions in construction-related businesses under CP2. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP2): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area that Support the Construction Industry A small amount of the construction materials used for CP2 would be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area over the 5-year construction period of CP1. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-10 (CP1). Because of the longer project duration and larger dam raise proposed under CP2, short-term increases in sales and profits for construction-related businesses in the lower Sacramento River and Delta area would be larger than those under CP1. The exact scale of the increase in business sales and profits within the lower Sacramento River and Delta area would be speculative, but because additional time and materials would be required, implementing CP2 would likely generate more sales and profits for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP2): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP2 would increase short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues would be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-11 (CP1) because the construction period would be longer and more construction materials would be needed. The increased employment and personal incomes anticipated as a part of implementation of CP2 would cause an increase in short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues would be likely to be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP2): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP2, the overall risk of flooding and its related consequences below Shasta Dam would be reduced. Although heavy rain events would continue to occur in the region, CP2 would provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents in or near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as would reduce business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-12 (CP1). CP2 would provide approximately 187,000 acre-feet more storage capacity in the reservoir than CP1. This additional capacity would increase the flood control capabilities beyond the existing capabilities at Shasta Dam and the capabilities proposed under CP1, and would further reduce the risk of flooding downstream from the dam. The overall risk of flooding and its associated adverse effects on property, housing, businesses, and residents of the lower Sacramento River and Delta area would be reduced with implementation of CP2. Flood risk reduction effects identified earlier for CP1 would apply to CP2, but the positive effects would be greater because of the direct relationship between the proposed dam heights, corresponding capacity of the reservoir, and associated increase in flood control operations and management flexibility.

Increased storage capacity proposed as a part of CP2 also would reduce the risk of job loss from flooding and its related effects in the lower Sacramento River and Delta area, when compared to CP1. A reduction in the risk of flood-level conditions downstream from the dam would strengthen the economic livelihood of downstream residents in the lower Sacramento River and Delta area.

Fewer flooding events would occur and less damage would be inflicted on businesses located adjacent to downstream waterways during some flood events. This reduction in flood damage would reduce residents’ salary and wage losses resulting from these catastrophic events.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP2): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas that Support the Construction Industry A small amount of the construction materials used during construction under CP2 would be purchased within the extended study area, including the CVP and SWP service areas. These purchases would result in a minor increase in sales and profits for a few businesses within the CVP and SWP service areas over the 5-year construction period of CP2. This impact would be minor but beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-13 (CP1). Because of the longer project duration and larger dam raise proposed under CP2, short-term increases in sales and profits for some construction-related businesses in the extended study area, including the CVP and SWP service areas, would be larger than those for CP1. These increases have not been quantified, but the additional time and materials required to implement CP2 would be expected to generate more sales and profits for some construction-related and service-oriented businesses. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP2): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas during Construction Implementation of CP2 may require temporarily reducing the reservoir level at critical times during the construction period. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

This impact would be similar to Impact Socio-14 (CP1), except that the project construction period would be longer and reductions in reservoir levels could last longer under CP2. This impact would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5, "Mitigation Measures."

Impact Socio-15 (CP2): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP2 would increase short-term construction-related State sales and income tax revenues received from businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-15 (CP1). Short-term increases in State sales and income taxes would be larger under CP2 than under CP1. All of these increases are expected to be more beneficial for the relevant local jurisdictions. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP2): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on SWAP modeling, improved water availability and reliability expected to result from implementation of CP2 would substantially increase agricultural net income in the CVP and SWP service areas and increase the number of agricultural positions in these areas. This increase in production and jobs would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-16 (CP1). Water supply reliability in the CVP/SWP service areas would be greater under CP2 than under CP1. Because of the increase in the availability and reliability of water associated with implementation of CP2, the long-term increase in indirect employment within the agricultural sector would be larger than under CP1. Based on the outputs of SWAP modeling, CP2 is expected to generate an additional $1.3 million in net income during normal years and up to $2.7 million during dry years, when compared to existing conditions. In wet years, net income under CP2 is projected to increase to $2.9 million. This overall increase in net income is expected to stimulate more employment opportunities in the agricultural sector to support the higher crop production that likely would be the result of additional irrigation deliveries under CP2 (compared to CP1). This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP2): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability Implementation of CP2 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP2), this additional storage capacity would improve the long-term availability and reliability of water in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-17 (CP1). Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3 focuses on increasing agricultural water supply reliability while also increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 18.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet to 5.19 MAF. CP3 would increase the maximum surface area of the pool to 32,300 acres. Because CP3 focuses on increasing agricultural water supply reliability, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, with the additional storage retained for water supply reliability and to expand the cold-water pool for downstream anadromous fisheries.

Implementing CP3 would result in the replacement or modification of 8 bridges and relocation of approximately 130 existing structures. The total construction cost associated with CP3 would be approximately $1,257 million.

CP3 would help reduce estimated future agricultural water shortages and would increase water supply reliability in the CVP service area by increasing water supplies for agricultural deliveries, by at least 63,100 acre-feet per year in dry and critical years and increasing average annual deliveries by about 61,700 acre-feet per year. Almost half of the increased dry and critical year water supplies (i.e., 28,000 acre-feet) would be for south-of-Delta agricultural deliveries, with the remainder for north-of-Delta agricultural deliveries. In addition, CP3 would provide hydropower benefits by increasing hydropower generation, by approximately 90 GWh per year.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP3): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 350 direct jobs would be created as a result of construction activities associated with CP3. All 350 construction workers are expected to come from the local labor force; therefore, a short-term population increase is not expected. This impact would be less than significant.

This impact would be similar to Impacts Socio-1 (CP1) and Socio-1 (CP2). CP3 would add 191,000 acre-feet of storage capacity beyond the capacity anticipated in CP2, for a total increase of 634,000 acre-feet. Approximately 350 construction workers would be needed to complete the 18.5-foot raise proposed for CP3, compared to 300 new construction workers required for CP1 and CP2. Approximately 5 years of work (compared to the 4.5 years proposed under CP1) would be required to complete the construction activities proposed under CP3. Workers for this effort also would come from the local labor pool. This impact

would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP3): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP3 are expected to generate approximately 350 direct construction jobs, 450 indirect jobs in various construction-related support industries, and 700 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These jobs are expected to provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

This impact would be similar to Impact Socio-2 (CP1) and Socio-2 (CP2). Under CP3, approximately 350 short-term, direct construction jobs would be created, in addition to 450 indirect jobs expected to be created in various construction-related support industries, and 700 induced jobs created because of increased household spending near the project area. Total direct, indirect, and induced employment under CP3 would be greater than CP1 and CP2, and these positions would last approximately 5 years under CP3, compared to 4.5 years under CP1. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP3): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 350 construction jobs resulting from CP3, the potential would exist for workers from other industries to move to jobs related to construction at Shasta Dam. Because of the size of the construction industry in the primary study area and the high unemployment rate in the area, this impact would be less than significant.

This impact would be similar to Impacts Socio-3 (CP1) and Socio-3 (CP2). CP3 would require 50 more construction workers than required for CP1 and CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP3): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Based on calculations completed as a part of the IMPLAN socioeconomic model process, more than $98.2 million in personal income would be directly paid to employees in the primary study area each year of the 5-year construction period under CP3. In addition, more than $55.2 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP3. The combined $153.3 million in personal income to be generated would represent an approximately 93 percent increase in all annual personal income in the local economic study area. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-4 (CP1) and Socio-4 (CP2). CP3 would generate $98.2 million in direct personal income each year of construction, from the 350 direct construction-related jobs that would be created. In addition, indirect and induced personal income totaling $55.2 million per year of construction would be generated in various construction-related and other industries in the primary study area that would support construction under CP3. The combined direct, indirect, and induced personal income resulting from CP3 would be approximately $153.3 million per year of construction within the local economic study area. This increase in personal income would represent an approximately 93 percent increase in all annual personal income in the local economic study area.

Direct, indirect, and induced annual personal income under CP3 would be greater than CP1 and CP2. Overall, a total income of $766.6 million would be generated under CP3 over the 5-year construction period, compared to a total of $603.8 million for CP1 and to a total of $664.1 million for CP2. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP3): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP3 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 5-year construction period. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-5 (CP1) and Socio-5 (CP2). CP3 would require the largest dam height increase and, therefore, the greatest construction expenditures over the total construction period. As a result, CP3 would generate more business sales and profits than CP1 and CP2 in construction-related and service-oriented businesses in the primary study area. During the construction period, implementation of CP3 is expected to generate more than $399.7 million per year in sales and profits for businesses that support the construction industry, with approximately $251.4 million in direct income and $148.3 in direct and induced income. CP3 would generate an overall total of $424.5 million and $267.1 million more in sales and profits than CP1 and CP2, respectively, for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP3): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP3 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 5-year construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP3 would be likely also to result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases would be speculative: however, this impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-6 (CP1) and Socio-6 (CP2). CP3 would generate more direct, indirect, and induced personal income and more sales and profits for businesses over the construction period than CP1 and CP2 (see Impacts Socio-4 (CP3) and Socio-5 (CP3), above). This larger amount of personal income generated is expected to result in more local sales tax revenues in the primary study area than under the other two alternatives. Construction-related activities under CP3 also are expected to result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. These additional revenues would be likely to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP3): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP3, the overall risk of flooding and its related consequences below Shasta Dam are expected to be reduced. Although heavy rain events would continue to occur in the region and locally, and potentially increase with global climate change, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-7 (CP1) and Socio-7 (CP2). CP3 would create 634,000 acre-feet more storage capacity than current capacity, more than 40 percent more than would be provided by CP2. CP3 would, therefore, provide substantially more flood protection than either CP1 or CP2. As a result, CP3 would result in a greater reduction than CP1 and CP2 in the risk of damage to property and structures from flooding along the upper Sacramento River.

The increased storage capacity proposed as a part of CP3 would result in a larger decrease in the risk of job loss from flooding and its related effects than would occur under CP1 or CP2. CP3 would increase storage space in Shasta

Lake and would provide approximately 191,000 more acre-feet of storage than either of the two previous alternatives. The increased storage capacity would create a greater reduction in the risk of flood-level conditions downstream from the dam. Related effects from flooding on the economic livelihood of residents of the primary study area would similarly be reduced. In addition, the reduction in flood damage would reduce residents' salary and wage losses resulting from these catastrophic events.

For the reasons described above, this impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP3): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, implementation of CP3 would create at least two new maintenance-related positions at the Shasta Dam facilities. These two positions are expected to be permanent and would continue once the 5-year construction period is completed. This impact would be minor but beneficial.

This impact would be the same as Impacts Socio-8 (CP1) and Socio-8 (CP2) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP3): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta Construction activities associated with CP3 would have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction materials sourced outside of the primary study area, indirect increases in employment within some construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be minor but beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-9 (CP1) and Socio-9 (CP2). A larger potential temporary increase in indirect employment in construction-related businesses of the lower Sacramento River and Delta area would be expected under CP3. Estimated total construction costs for CP3 are approximately 22.3 percent higher than costs for CP1 and 14.2 percent higher than costs for CP2. Therefore, more income would be allocated to indirect positions in construction-related businesses than would be expected under CP1 and CP2. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP3): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area that Support the Construction Industry A small amount of the construction materials used for CP3 would be purchased within the extended study area. These purchases are predicted to increase sales and profits of businesses within the lower Sacramento River and Delta area over the 5-year construction period of CP3. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-10 (CP1) and Socio-1 (CP2). Because of the longer project duration and greater construction expenditures associated with the larger dam raise proposed under CP3, short-term increases in sales and profits for construction-related businesses in the lower Sacramento River and Delta area would be larger than those for CP1 and CP2. These increases have not yet been quantified, but because additional time and materials would be required, implementing CP3 would generate more sales and profits for construction-related and service-oriented businesses. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP3): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Relate Personal Income and Purchases In addition to local tax revenues, CP3 is expected to increase short-term, construction-related, State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-11 (CP1) and Socio-11 (CP2) because the construction period would be longer and more construction materials would be needed. The increased employment and personal incomes anticipated as a part of implementation of CP3 would cause an increase in short-term, construction-related, State sales and income tax revenues received from some businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues likely would be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP3): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP3, the overall risk of flooding and its related consequences below Shasta Dam would be reduced. Although heavy rain events would continue to occur in the region, as well as potentially increase with global climate change, CP3 is intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as would reduce business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-12 (CP1) and Socio-12 (CP2). CP3 would provide approximately 191,000 acre-feet more storage capacity in the reservoir than either of the two previous alternatives. This additional capacity would increase the flood control capabilities beyond the existing capabilities at Shasta Dam and the capabilities proposed under CP1 and CP2, and would further reduce the risk of flooding downstream from the dam. The overall risk of flooding and its associated adverse effects on property, housing, businesses, and residents of the lower Sacramento River and Delta area would be reduced with implementation of CP3. Flood risk reduction effects identified for CP1 and CP2 would apply to CP3, but the positive effects would be greater because of the direct relationship between the proposed dam heights, corresponding capacity of the reservoir, and associated increase in flood control operations and management flexibility.

Increased storage capacity proposed as a part of CP3 also would reduce the risk of job loss from flooding and its related effects in the lower Sacramento River and Delta area. A reduction in the risk of flood-level conditions downstream from the dam would strengthen the economic livelihood of downstream residents in the lower Sacramento River and Delta portion of the extended study area. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP3): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas that Support the Construction Industry A small amount of the construction materials used during construction under CP3 would be purchased within the extended study area. These purchases are predicted to increase sales and profits of some businesses within the CVP and SWP service areas over the 5-year construction period of CP3. This impact would be minor but beneficial.

This impact would be similar to but would be more beneficial than Impact Socio-13 (CP1) because the construction period would be longer and more construction materials would be needed. This impact would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP3): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas during Construction Implementation of CP3 may require temporarily reducing the reservoir level at critical times during the construction period. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

This impact would be similar to Impact Socio-14 (CP1), except that the project construction period would be longer. This impact would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5, "Mitigation Measures."

Impact Socio-15 (CP3): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP3 is expected to increase short-term, construction-related, State sales and income tax revenues received from businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-15 (CP1) and Socio-15 (CP2). Short-term increases in State sales and income taxes are expected to be larger under CP3 than under CP1 and CP2. All of these increases are expected to be more beneficial for the relevant local jurisdictions. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP3): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on SWAP modeling, improved water availability and reliability expected to result from implementation of CP3 would substantially increase agricultural net income in the CVP and SWP service areas and increase the number of agricultural positions in these areas. This increase in production and jobs would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

This impact would be similar to but would be more beneficial than Impacts Socio-16 (CP1) and Socio-16 (CP2). CP3 would increase water supply reliability by increasing dry and critical year water supplies for CVP irrigation deliveries. Because of the increase in the availability and reliability of water associated with implementation of CP3, the long-term increase in indirect employment within the agricultural sector is expected to be larger than under CP1 and CP2. Based on the outputs of SWAP modeling, CP3 would generate an additional $5.1 million in net income during normal years and $8.5 million during dry years, when compared to existing conditions. In wet years, net income under CP3 is projected to decrease to $4.4 million. Overall, CP3 is projected to result in a greater increase in net income during average, dry, and wet years, when compared to net income projected for CP1 and CP2. The projected increase in net income under CP3 is expected to stimulate a greater number of employment opportunities in the agricultural sector than under CP1 and CP2, because higher crop production would be likely. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP3): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability Implementation of CP3 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP3), this additional storage capacity would improve long-term water availability and reliability in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences. This impact would be beneficial.

This impact would be the similar to CP1 and CP2 and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 and CP4A focus on increasing anadromous fish survival while also increasing water supply reliability. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP4 or CP4A would increase the height of the reservoir full pool by 20.5 feet. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would be increased from 4.55 MAF to 5.19 MAF. CP4 or CP4A would involve augmenting spawning gravel and restoring riparian, floodplain, and side-channel habitat at up to six potential locations in the upper Sacramento River.

CP4A is identical to CP4 with the exception of Shasta Dam and Reservoir operations. CP4 and CP4A have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for fisheries purposes; however, the portion of this dedicated storage varies. Approximately 378,000 acre-feet of the increased reservoir storage space of CP4 would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. For CP4, operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1, with 70,000 acre-feet reserved in dry years and 35,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries.

Similarly, approximately 191,000 acre-feet of the increased reservoir storage space of CP4A would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. For CP4A, operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2, with 120,000 acre-feet reserved in dry years and 60,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries. Implementing CP4 or CP4A would result in the replacement or modification of

8 bridges and relocation of approximately 130 existing structures. The total construction cost associated with CP4 or CP4A would be approximately $1,265 million and $1,266 million, respectively.

CP4 would help reduce estimated future agricultural and M&I water shortages and would increase water supply reliability in the CVP/SWP service areas by increasing water supplies for agricultural and M&I deliveries by at least 47,300 acre-feet per year in dry and critical years and increasing average annual deliveries by about 31,000 acre-feet per year. The majority of the increased dry and critical year water supplies (i.e., 42,700 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, CP4 would provide hydropower benefits by increasing hydropower generation by approximately 133 GWh per year. Water supply reliability under CP4A would the same as under CP2. Implementing CP4A would help reduce estimated future agricultural water shortages in the CVP/SWP service areas by increasing water supplies for agricultural deliveries by at least 37,600 acre-feet per year in dry and critical years and increasing average annual deliveries by about 31,400 acre-feet per year. CP4A would provide hydropower benefits by increasing hydropower generation by approximately 130 GWh per year.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP4 and CP4A): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 350 direct jobs would be created as a result of construction activities associated with CP4 or CP4A. All 350 construction workers are expected to come from the local labor force; therefore, a short-term population increase is not expected. This impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Socio-1 (CP3) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact Socio-1 (CP3) and would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP4 and CP4A): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP4 or CP4A are expected to generate approximately 350 construction jobs, 450 indirect jobs in various construction-related support industries, and 700 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs would provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial for CP4 or CP4A.

This impact would be the same as Impact Socio-2 (CP3) and would be beneficial for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact Socio-2 (CP3) and would be beneficial for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP4 and CP4A): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 350 construction jobs resulting from CP4 or CP4A, the potential would exist for workers from other industries to move to jobs related to construction at Shasta Dam. Because of the size of the construction industry in the primary study area and the high unemployment rate in the area, this impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Socio-3 (CP3) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact Socio-3 (CP3) and would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP4 and CP4A): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Construction activities for CP4 or CP4A would last 5-years, compared to 4.5 years for CP1. Additional construction activities would be required for augmenting spawning gravel and restoring riparian, floodplain, and side-channel habitat. Based on calculations completed as a part of the IMPLAN socioeconomic model process, more than $98.7 million and $98.8 million in personal income would be directly paid to employees in the primary study area each year of construction for CP4 and CP4A, respectively. In addition, more than $55.4 million in indirect and induced income would be generated in various construction-related and other industries in the primary study area each year of construction under CP4 or CP4A. The combined $154.2 million and 154.3 million for CP4 and CP4A, respectively, in personal income generated would represent an approximately 93 percent increase in all annual personal income in the local economic study area. This impact would be beneficial for CP4 or CP4A.

This impact for CP4 or CP4A would be similar to Impact Socio-4 (CP3). CP3 is estimated to generate $98.2 million in direct personal income each year of construction from the 350 direct construction-related jobs that would be created. In addition, indirect and induced personal income totaling $55.2 million per year of construction would be generated in various construction-related and other industries in the primary study area that would support construction under CP3. In combination, direct, indirect, and induced personal income resulting from CP3 would be approximately $153.3 million per year of construction within the local economic study area. This increase in personal income would represent an approximately 93 percent increase in all annual personal income in the local economic study area.

Additional construction activities associated with augmenting spawning gravel and restoring riparian, floodplain, and side-channel habitat would occur under CP4 or CP4A. During the 5-year construction period, more than $770.9 million and $771.4 million in personal income would be generated by direct, indirect, and induced employment produced with CP4 and CP4A, respectively, and this would be $4.3 million and $4.8 million more personal income than generated under CP3, respectively.

This impact would be beneficial for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be beneficial for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP4 and CP4A): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry
Most of the construction materials used for CP4 or CP4A would be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 5-year construction period. This impact would be beneficial for CP4 or CP4A.

This impact for CP4 or CP4A would be similar to but more beneficial than Impact Socio-5 (CP3). During the construction period, implementation of CP4 or CP4A would generate more than $401.9 million and $402.2 million, respectively, per year in sales and profits for construction-related and service-oriented businesses that support the construction industry, with approximately $252.8 million and $253.0 million in direct income, respectively, and $149.1 million and $149.3 million in indirect and induced income, respectively. CP4 or CP4A would generate an overall total of $2.2 million and $2.5 million more per year, respectively, in sales and profits than CP3 for construction-related and service-oriented businesses.

This impact would be beneficial for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be beneficial for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP4 and CP4A): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP4 or CP4A is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 5-year construction period. This additional income, in combination with the construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP4 or CP4A would likely result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases would be speculative; however, this impact would be beneficial for CP4 or CP4A.

This impact for CP4 or CP4A would be similar but more beneficial than Impact Socio-6 (CP3). CP4 or CP4A would generate more direct, indirect, and induced personal income and more sales and profits for businesses over the construction period than CP3 (see Impacts Socio-4 (CP4 and CP4A) and Socio-5 (CP4 and CP4A), above).

This impact would be beneficial for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be beneficial for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP4 and CP4A): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP4 or CP4A, the overall risk of flooding and its related consequences below Shasta Dam would be reduced. Although heavy rain events would continue to occur in the region and locally, and potentially increase with global climate change, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as would reduce business and personal income losses from such damage. Therefore, this impact would be beneficial for CP4 or CP4A.

This impact for CP4 would be the same as Impact Socio-7 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be the same as Impact Socio-7 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP4 and CP4A): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, implementation of CP4 or CP4A would create at least two new maintenance-related positions at the Shasta Dam facilities. These two positions would be permanent and would continue once the 5-year construction period is completed. This impact would be minor but beneficial for CP4 or CP4A.

This impact for CP4 would be the same as Impact Socio-8 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be the same as Impact Socio-8 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP4 and CP4A): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta   Construction activities associated with CP4 or CP4A have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction material sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be minor but beneficial for CP4 or CP4A.

This impact for CP4 would be similar to Impact Socio-9 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be similar to Impact Socio-9 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP4 and CP4A): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area that Support the Construction Industry   A small amount of the construction materials used for CP4 or CP4A would be purchased within the extended study area. These purchases are predicted to increase sales and profits of some businesses within the lower Sacramento River and Delta area over the 5-year construction period of CP4 or CP4A. This impact would be minor but beneficial for CP4 or CP4A.

This impact for CP4 would be similar to Impact Socio-10 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be similar to Impact Socio-10 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP4 and CP4A): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP4 or CP4A is expected to increase short-term, construction-related, State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial for CP4 or CP4A.

This impact for CP4 would be similar to Impact Socio-11 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be similar to Impact Socio-11 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP4 and CP4A): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP4 or CP4A, the overall risk of flooding and its related consequences below Shasta Dam would be reduced. Although heavy rain events would continue to occur in the region, and potentially increase with global climate change, CP4 and CP4A are intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as would reduce business and personal income losses from such damage. Therefore, this impact would be beneficial for CP4 or CP4A.

This impact for CP4 would be the same as Impact Socio-12 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be the same as Impact Socio-12 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP4 and CP4A): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas that Support the Construction Industry A small amount of the construction materials used during construction under CP4 or CP4A would be purchased within the extended study area. These purchases are predicted to increase sales and profits of some businesses within the CVP and SWP service areas over the 5-year construction period of CP4 or CP4A. This impact would be minor but beneficial for CP4 or CP4A.

This impact for CP4 would be similar to Impact Socio-13 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be similar to Impact Socio-13 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP4 and CP4A): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas during Construction Implementation of CP4 or CP4A may require temporarily reducing the reservoir level at critical times during the construction period. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant for CP4 or CP4A.

This impact for CP4 would be the same as Impact Socio-14 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5, "Mitigation Measures."

This impact for CP4A would be the same as Impact Socio-14 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5, "Mitigation Measures."

Impact Socio-15 (CP4 and CP4A): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP4 or CP4A is expected to increase short-term, construction-related, State sales and income tax revenues received from some businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial.

This impact for CP4 would be similar to Impact Socio-15 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be similar to Impact Socio-15 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP4 and CP4A): Long-Term Increase in Agricultural Income and Jobs within the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on SWAP modeling, improved water availability and reliability expected to result from implementation of CP4 or CP4A would substantially increase agricultural net income in the CVP and SWP service areas. This increase in production would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial for CP4 or CP4A.

This impact for CP4 would be the same as Impact Socio-16 (CP1) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be similar to, but more beneficial than Impact Socio-16 (CP1) because water supply reliability in the CVP/SWP service areas would be greater under CP2 than under CP1. Because of the increase in the availability and reliability of water associated with implementation of CP4A, the long-term increase in indirect employment within the agricultural sector would be larger than under CP1. Therefore, the impact for CP4A would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP4 or CP4A): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability Implementation of CP4 or CP4A would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP4 and CP4A), this additional storage capacity would improve long-term water availability and reliability in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences. This impact would be beneficial for CP4 or CP4A.

This impact for CP4 would be the similar to Impact Socio-17 (CP1, CP2, and CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

This impact for CP4A would be the similar to Impact Socio-17 (CP1, CP2, and CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily focuses on increasing water supply reliability, anadromous fish survival, Shasta Lake area environmental resources, and recreation opportunities. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP5 would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet to 5.19 MAF. CP5 would increase the maximum surface area of the pool to 32,300 acres. The existing temperature control device would be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 150,000 acre-feet and 75,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries.

CP5 also would involve augmenting spawning gravel and restoring riparian, floodplain, and side-channel habitat at up to six potential locations in the upper Sacramento River. CP5 would involve constructing additional fish habitat in and along the shoreline of Shasta Lake and along the lower reaches of its tributaries, increasing recreation opportunities at Shasta Lake.

Implementing CP5 would result in the replacement or modification of 8 bridges and relocation of approximately 130 existing structures. The total construction cost associated with CP5 would be approximately $1,284 million.

CP5 would help reduce estimated future agricultural and M&I water shortages and would increase water supply reliability in the CVP/SWP service areas by increasing water supplies for agricultural and M&I deliveries by at least 113,500 acre-feet per year in dry and critical years and increasing average annual deliveries by about 75,900 acre-feet per year. The majority of the increased dry and critical year water supplies (i.e., 88,300 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, CP5 would provide hydropower benefits by increasing hydropower generation by approximately 117 GWh per year.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact Socio-1 (CP5): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities According to Reclamation estimates, approximately 360 direct jobs would be created as a result of construction activities associated with CP5. All 360 construction workers are expected to come from the local labor force; therefore, a short-term population increase is not expected. This impact would be less than significant.

This impact would be the similar to Impact Socio-1 (CP3) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-2 (CP5): Short-Term Increases in Direct, Indirect, and Induced Employment in the Primary Study Area Related to Construction Activities Construction activities associated with CP5 are expected to generate approximately 360 direct construction jobs, 470 indirect jobs in various construction-related support industries, and 710 induced jobs because of increased household spending in the primary study area. Individuals to fill these jobs are expected to be drawn from the local community. These new jobs would provide important but temporary employment opportunities to many unemployed construction workers in the primary study area. This impact would be beneficial.

This impact would be very similar to Impact Socio-2 (CP3), varying only with 10 more construction workers. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-3 (CP5): Potential for Temporary Reduction in the Labor Force of Related Industrial Sectors in the Primary Study Area as a Result of Direct Construction-Related Employment With the creation of 360 construction jobs resulting from CP5, the potential would exist for workers from other industries to move to jobs related to construction at Shasta Dam. Because of the size of the construction industry in the primary study area and the high unemployment rate in the area, this impact would be less than significant.

This impact would be similar to Impact Socio-3 (CP3). CP5 would only require 10 more construction workers than required for CP3, and the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-4 (CP5): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities Construction activities for CP5 would last 5 years, compared to 4.5 years for CP1. Additional construction activities would be required for augmenting spawning gravel; restoring riparian, floodplain, and side-channel habitat; and creating fish habitat in and along the shoreline of Shasta Lake and along the lower reaches of its tributaries. Based on calculations completed as a part of the IMPLAN socioeconomic model process, more than $100.2 million in personal income would be directly paid to employees in the primary study area each year of construction. In addition, more than $56.3 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction under CP5. The combined $156.5 million in personal income generated would represent an approximately 94 percent increase in all annual personal income in the local economic study area. This impact would be beneficial.

This impact would be similar to Impact Socio-4 (CP3). Under CP5, more than $100.2 million in personal income would be directly paid to employees in the primary study area each year of construction. In addition, more than $56.3 million in indirect and induced income is expected to be generated in various construction-related and other industries in the primary study area each year of construction. The combined $156.5 million in personal income generated would represent an approximately 94 percent increase in all annual personal income in the local economic study area.

Additional construction activities would be required for augmenting spawning gravel; restoring riparian, floodplain, and side-channel habitat; and creating fish habitat in and along the shoreline of Shasta Lake and along the lower reaches of its tributaries. During the 5-year construction period, more than $782.5 million in personal income is expected to be generated by direct, indirect, and induced employment produced by CP5, and this would be $15.9 million more personal income than generated under CP3. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-5 (CP5): Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry Most of the construction materials used for CP5 are expected to be purchased within the primary study area. These purchases would provide the local economy with increased sales and profits over the 5-year construction period. This impact would be beneficial.

This impact would be similar to Impact Socio-5 (CP3). During the construction period, implementation of CP5 is expected to generate more than $408.0 million per year in sales and profits for construction-related and service-oriented businesses that support the construction industry, with approximately $256.6 million in direct income and $151.3 in direct and induced income. CP5 would generate an overall total of $8.3 million more per year in sales and profits than CP3 for construction-related and service-oriented businesses. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-6 (CP5): Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases As stated above, implementation of CP5 is expected to result in a substantial increase in total personal income (direct, indirect, and induced) over the 5-year construction period. This additional income, in combination with construction-related purchases in the primary study area, would result in a substantial increase in local sales tax revenues from increased consumer spending in nearby cities and counties. Construction-related activities under CP5 also would be likely to result in a temporary increase in State sales and income tax revenues received from businesses and residents of the primary study area. The exact amount of State and local sales tax revenue increases would be speculative; however, this impact would be beneficial.

This impact would be similar to but more beneficial than Impact Socio-6 (CP3). CP5 would generate more direct, indirect, and induced personal income and more sales and profits for businesses over the construction period than CP3 (see Impacts Socio-4 (CP5) and Socio-5 (CP5), above). This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-7 (CP5): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area As a result of the added reservoir capacity created by CP5, the overall risk of flooding and its related consequences below Shasta Dam would be reduced. Although heavy rain events would continue to occur in the region and locally, and potentially increase with global climate change, the project is intended to provide greater flexibility in flood control downstream because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents of the primary study area, as well as would reduce business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be the same as Impact Socio-7 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-8 (CP5): Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations In the long term, implementation of CP5 would create at least two new maintenance-related positions at the Shasta Dam facilities. These two positions would be permanent and would continue once the 5-year construction period is completed. This impact would be minor but beneficial.

This impact would be the same as Impact Socio-8 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact Socio-9 (CP5): Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta Construction activities associated with CP5 would have the potential to result in a short-term increase in indirect employment within the lower Sacramento River and Delta portion of the extended study area. Depending on the location of construction materials sourced outside of the primary study area, indirect increases in employment within construction-related businesses may result in the lower Sacramento River and Delta area. This impact would be minor but beneficial.

This impact would be similar to Impact Socio-9 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-10 (CP5): Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area that Support the Construction Industry A small amount of the construction materials used for CP5 would be purchased within the extended study area. These purchases are predicted to increase sales and profits of some businesses within the lower Sacramento River and Delta area over the 5-year construction period of CP5. This impact would be minor but beneficial.

This impact would be similar to Impact Socio-10 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-11 (CP5): Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases In addition to local tax revenues, CP5 is expected to increase short-term construction-related State sales and income tax revenues received from businesses and residents of the lower Sacramento River and Delta portion of the extended study area. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial.

This impact would be similar to Impact Socio-11 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-12 (CP5): Long-Term Reduction in the Adverse Economic Effects of Flooding in the Lower Sacramento River and Delta Area As a result of the added reservoir capacity under CP5, the overall risk of flooding and its related consequences below Shasta Dam would be reduced. Although heavy rain events would continue to occur in the region, and potentially increase with global climate change, CP5 is intended to provide greater flexibility in flood control in the lower Sacramento River and Delta area because of the increased capacity of the reservoir. As a result, less damage to existing structures and a smaller loss of potential future development would occur; this, in turn, would reduce salary and wage losses for residents in and near the lower Sacramento River floodplain and the Delta resulting from these catastrophic events, as well as would reduce business and personal income losses from such damage. Therefore, this impact would be beneficial.

This impact would be similar to Impact Socio-12 (CP3) and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact Socio-13 (CP5): Short-Term Increases in Sales and Profits for Businesses in the CVP and SWP Service Areas that Support the Construction Industry A small amount of the construction materials used during construction under CP5 would be purchased within the extended study area, including the CVP and SWP service areas. These purchases are predicted to increase sales and profits of some businesses within the CVP and SWP service areas over the 5-year construction period of CP5. This impact would be minor but beneficial.

This impact would be similar to Impact Socio-13 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-14 (CP5): Potential Temporary Reduction in Shasta Project Water or Hydropower Supplied to the CVP and SWP Service Areas During

Construction Implementation of CP5 may require temporarily reducing the reservoir level at critical times during the construction period. This reduction in the reservoir level could temporarily reduce the amount of water or hydropower available from the dam and related hydropower infrastructure. Should this occur, sources of replacement water or hydropower would need to be secured. If these replacement resources were substantially more expensive, a minor negative effect on water or power customers may result. This impact would be potentially significant.

This impact would be similar to Impact Socio-14 (CP3) and would be potentially significant. Mitigation for this impact is proposed in Section 16.3.5, "Mitigation Measures."

Impact Socio-15 (CP5): Short-Term Increase in State Sales and Income Tax Revenues in the CVP and SWP Service Areas from Construction-Related Personal Income and Purchases In addition to local tax revenue, CP5 is expected to increase short-term construction-related State sales and income tax revenues received from some businesses and residents of the CVP and SWP service areas. These additional revenues are expected to be cycled back to local government coffers through statewide programs and policies. This impact would be minor but beneficial.

This impact would be similar to Impact Socio-15 (CP3) and would be minor but beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-16 (CP5): Long-Term Increase in Agricultural Income and Jobs in the CVP and SWP Service Areas as a Result of Improved Water Availability and Reliability Based on SWAP modeling, improved water availability and reliability expected to result from implementation of CP5 would substantially increase agricultural net income in the CVP and SWP service areas. This increase in production would contribute substantially to the continuation of this already strong industry in California. This impact would be beneficial.

This impact would be similar to Impact Socio-16 (CP3). The increase in the availability and reliability of water associated with implementation of CP5 would result in the long-term increase in indirect employment within the agricultural sector; however, this indirect increase is expected to be slightly less than under CP3. Based on the outputs of SWAP modeling, CP5 would generate an additional $2.6 million in net income during normal years and up to $5.7 million during dry years, when compared to existing conditions. In wet years, net income under CP5 is projected to increase to $3.4 million. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact Socio-17 (CP5): Reduction in Risk of Potential Water and Power Shortages (and Related Economic Activity) in the CVP and SWP Service Areas as a Result of Long-Term Improvements to Water and Power Supply Reliability

Implementation of CP5 would substantially increase Shasta Dam's storage capacity. As stated in Impact Socio-16 (CP5), this additional storage capacity would improve long-term water availability and reliability in the CVP and SWP service areas. Beyond increasing agricultural production, this improved availability and reliability would reduce the long-term risk of urban water and power shortages, and their related adverse economic consequences. This impact would be beneficial.

This impact would be the similar to the other CPs and would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

16.3.5 Mitigation Measures

Table 16-1 presents a summary of mitigation measures for socioeconomics, population, and housing.

Table 16-1. Summary of Mitigation Measures for Socioeconomics, Population, and Housing

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/ CP4A	CP5
Impact Socio-1 (No-Action): Potential for Reduced Employment Opportunities for Lower Sacramento River and Delta Area Residents	LOS before Mitigation	PS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
Impact Socio-1 (CP1–CP5): Short-Term Increase in Population and Housing Demand in the Primary Study Area Resulting from Construction-Related Activities	LOS after Mitigation	PS	LTS	LTS	LTS	LTS	LTS

	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NA	B	B	B	B	B

Key:
B = beneficial
CP = Comprehensive Plan
CVP = Central Valley Project
LOS = level of significance
LTS = less than significant
NA = not applicable
PS = potentially significant
SWP = State Water Project

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Socio-1 (CP1) through Socio-13 (CP1) and Impacts Socio-15 (CP1) through Socio-17 (CP1). Mitigation is provided below for the other impact of CP1.

Mitigation Measure Socio-14 (CP1): Secure Replacement Water or Hydropower During Project Construction To address potential temporary shortages in water or hydropower caused by reduced availability at Shasta Dam during construction, replacement water or hydropower supplies would need to be sourced elsewhere to maintain current service needs. Depending on the conditions of the water or energy markets at the time of need, these replacement resources could be more expensive than water or hydropower obtained from Shasta Dam. The additional expense of obtaining water or hydropower resources could potentially produce a minor negative effect on water and power customers, if replacement of these resources is substantially more expensive.

To eliminate the potential impact of project construction on water and/or hydropower purchases, Reclamation will identify the need for replacement water or hydropower early in project implementation and will secure such resources at the lowest cost possible. Replacement water or hydropower would be available from a number of sources within or external to the CVP. Reclamation will provide these replacement resources to business and industry in the CVP and SWP service areas at costs comparable to water or hydropower obtained from Shasta Dam. Reclamation will provide replacement water or hydropower at levels equal to the loss of water or hydropower caused by project construction.

Implementation of this mitigation measure would reduce Impact Socio-14 (CP1) to a less-than-significant level.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts Socio-1 (CP2) through Socio-13 (CP2) and Impacts Socio-15 (CP2) through Socio-17 (CP2). Mitigation is provided below for the other impact of CP2.

Mitigation Measure Socio-14 (CP2): Secure Replacement Water or Hydropower during Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP2) to a less-than-significant level.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation is needed for Impacts Socio-1 (CP3) through Socio-13 (CP3) and Impacts Socio-15 (CP3) through Socio-17 (CP3). Mitigation is provided below for the other impact of CP3.

Mitigation Measure Socio-14 (CP3): Secure Replacement Water or Hydropower During Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP3) to a less-than-significant level.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts Socio-1 (CP4 and CP4A) through Socio-13 (CP4 and CP4A) and Impacts Socio-15 (CP4 and CP4A) through Socio-17 (CP4 and CP4A). Mitigation is provided below for the other impact of CP4 or CP4A.

Mitigation Measure Socio-14 (CP4 and CP4A): Secure Replacement Water or Hydropower During Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP4 and CP4A) to a less-than-significant level.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts Socio-1 (CP5) through Socio-13 (CP5) and Impacts Socio-15 (CP5) through Socio-17 (CP5). Mitigation is provided below for the other impact of CP5.

Mitigation Measure Socio-14 (CP5): Secure Replacement Water or Hydropower During Project Construction This mitigation measure is identical to Mitigation Measure Socio-14 (CP1). Implementation of this mitigation measure would reduce Impact Socio-14 (CP5) to a less-than-significant level.

16.3.6 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," gives an overview of the cumulative effects analysis, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," in Chapter 3, lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level. Projects listed in Table 3-1 that could contribute to cumulative impacts on socioeconomics, population and housing in the primary and extended study area include, but are not limited to, projects listed under Quantitative Analysis and those projects under Qualitative Analysis that include Los Vaqueros Reservoir Expansion, Bay-Delta Conservation Plan, Upper San Joaquin River Basin Storage Investigation, and Mountain Gate at Shasta Mixed Use Area Plan.

Water reliability and electrical demand are expected to become increasingly important issues as demand for water and electricity increases to meet the needs of California's growing population. Over time, water conservation and reuse efforts will increase and water provision is expected to shift from such areas as agricultural production to urban uses. Environmental restoration, flood control, and hydropower generation are expected to continue in a manner similar to existing conditions.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP1 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to overall increases in population and housing demand would not be significant or cumulatively considerable. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of workers from outside the local area. Implementing CP1 would result in beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

Extended Study Area Without mitigation, CP1 could cause a potentially significant adverse effect on business and industrial activity in the CVP and SWP service areas. This adverse effect would be a potential temporary reduction in Shasta project water or hydropower supplied to CVP and SWP service areas during construction. With implementation of Mitigation Measure Socio-14 (CP1), adverse effects from CP1 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not make a cumulatively considerable incremental contribution to a significant cumulative impact related to the temporary construction-related reduction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP1 also would result in beneficial effects on employment and the labor force, business and industrial activity, and government and finance.

Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP2 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to overall increases in population and housing demand would not be significant or cumulatively considerable. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of workers from outside the local area. Implementing CP2 would cause beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP2 in the primary study area would be greater than those of CP1. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

Extended Study Area The adverse effects of CP2 would be the same as those of CP1. With implementation of Mitigation Measure Socio-14 (CP2), adverse effects from CP2 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not make a cumulatively considerable incremental contribution to significant cumulative impacts related to the temporary reduction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP2 would result in less-than-significant impacts on population and housing and also would have beneficial impacts on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP2 in the extended study area would be greater than those of CP1. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP3 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant or cumulatively considerable. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of workers from outside the local area. CP3 would have beneficial impacts on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP3 in the primary study area would be greater than those of CP1 and CP2. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

Extended Study Area The adverse effects of CP3 would be the same as those of CP1. With implementation of Mitigation Measure Socio-14 (CP3), adverse impacts from CP3 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not make a cumulatively considerable incremental contribution to significant cumulative impacts related to the temporary reduction during construction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP3 would result in less-than-significant impacts on population and housing and also would have beneficial effects on employment and the labor force, business and industrial activity, and government and finance. Overall, the beneficial effects of CP3 in the extended study area would be greater than those of CP1 and CP2. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Primary Study Area In the primary study area, effects related to increases in population and housing during the construction of CP4 or CP4A would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant or cumulatively considerable. The combined effect of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of workers from outside the local area. CP4 or CP4A would have beneficial impacts on employment and the labor force, business and industrial activity, and government and finance. Overall, in the primary study area, the beneficial impacts of CP4 or CP4A would be the same as those of CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to cumulative significant impacts on socioeconomic resources.

Extended Study Area The adverse impacts of CP4 would be the same as those of CP1. The adverse impacts of CP4A would be the same as those of CP2.With implementation of Mitigation Measure Socio-14 (CP4 and CP4A), adverse effects from CP4 or CP4A would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not make a cumulatively considerable incremental contribution to significant cumulative impacts related to the temporary reduction in water or hydropower supplies to the CVP and SWP service areas.

The implementation of CP4 or CP4A would result in less-than-significant impacts on population and housing and also would have beneficial impacts on employment and the labor force, business and industrial activity, and government and finance. In the extended study area, the beneficial impacts of CP4 or CP4A for population and housing, employment, and the labor force would be the same as those of CP3. For business and industrial activity, CP4 or CP4A would be more beneficial than CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Primary Study Area In the primary study area, effects related to increases in population and housing during construction under CP5 would be less than significant. In combination with past, present, and reasonably foreseeable future projects, this incremental contribution to increases in population and housing demand would not be significant or cumulatively considerable. The combined effects of these projects and the SLWRI would not induce substantial growth in population, produce a substantial burden on the existing housing stock within the local community, or require sizeable numbers of workers from outside the local area. CP5 would cause beneficial impacts on employment and the labor force, business and industrial activity, and government and finance. Overall, in the primary study area, the beneficial effects of CP5 would be the similar to those of CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

Extended Study Area The adverse effects of CP5 would be the same as those of CP1. With implementation of Mitigation Measure Socio-14 (CP5), adverse effects from CP5 would be fully mitigated because Reclamation would secure replacement water or hydropower during project construction. Therefore, the project would not make a cumulatively considerable incremental contribution to significant cumulative impacts related to the temporary reduction during construction in water or hydropower supplies to the CVP and SWP service areas.

Implementing CP5 would result in less-than-significant impacts on population and housing and also would have beneficial impacts on employment and the labor force, business and industrial activity, and government and finance. Overall, in the extended study area, the beneficial effects of CP5 would be similar to those of CP3. Thus, the project would not result in a cumulatively considerable incremental contribution to significant cumulative impacts on socioeconomic resources.

Chapter 17 Land Use and Planning

17.1 Affected Environment

This chapter describes the affected environment related to land uses and planning for the dam and reservoir modifications proposed under SLWRI action alternatives.

Because of the potential influence of the proposed modification of Shasta Dam and water deliveries over a large geographic area, the SLWRI includes both a primary study area and an extended study area. The primary study area has been further divided into Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff). The extended study area has been further divided into the lower Sacramento River and Delta and the CVP/SWP service areas (Figure 1-3).

The setting for land uses and planning in the Shasta Lake and vicinity portion of the primary study area consists of the portion of Shasta County north of Shasta Dam. This area encompasses Shasta Lake, lands surrounding the lake, and parts of the Pit River, Squaw Creek, McCloud River, and Sacramento River watersheds. Land use and planning in this area are influenced by land ownership, the presence of rural lakeside communities, and topography.

The setting for land uses and planning in the upper Sacramento River portion of the primary study area consists of the portion of Shasta County south of Shasta Dam and Tehama County. The incorporated cities of Shasta Lake, Redding, Anderson, and Red Bluff, all located along the Interstate 5 (I-5) corridor, establish urban settings in the otherwise rural upper Sacramento Valley. The upper Sacramento Valley is characterized by rolling hills with mountains to the north, east, and west. Land use and planning in this area are influenced by land ownership, historic land use patterns, topography, and population densities.

The land use and planning setting for the extended study area consists of 24 counties downstream from the Red Bluff Pumping Plant and encompasses all areas served by the CVP and the SWP. Land use and planning in the extended study area are influenced by the same factors identified for the upper Sacramento River study area. The type and focus of land use and planning may vary, however, in the large urban areas located in the extended study area.

17.1.1 Land Use

Shasta Lake and Vicinity

Land uses in the Shasta Lake and vicinity portion of the primary study area consist primarily of open space and other land uses that support recreational activities in the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). The Shasta-Trinity National Forest (STNF) manages the Shasta Unit of the NRA. Federally managed lands in the NRA total 235,740 acres, including Shasta Lake; lands held in private ownership total 10,347 acres. The U.S. Department of the Interior, Bureau of Land Management (BLM) manages the Shasta-Chappie Off-Highway Vehicle (OHV) area and other public lands immediately west of Shasta Lake; this area extends south towards Keswick Dam on both sides of the Sacramento River. The Federal lands immediately surrounding Shasta Dam and related facilities are managed by Reclamation. In addition, the California Department of Transportation (Caltrans) manages the I-5 corridor and the Union Pacific Railroad (UPRR) manages the rail corridor that crosses the primary study area (Figure 17-1).

The *Shasta-Trinity National Forest Land and Resource Management Plan* (LRMP) (USFS 1995) specifies several land allocations for National Forest System (NFS) lands managed by the Shasta Lake Ranger District within and adjacent to the Shasta Unit of the NRA. NFS lands in the primary study area are allocated as Late-Successional Reserves (LSR), Managed Late-Successional Areas, and other Threatened, Endangered, or Sensitive Species, Riparian Reserves, Administratively Withdrawn Areas, and Matrix.

LSRs and Administratively Withdrawn Areas each account for 20 percent of the land use designations in the NRA. Riparian Reserves, the largest land use designation in the NRA, are located in areas along rivers, streams, lakes, and wetlands, including the area inundated by Shasta Lake. Riparian Reserves were established to provide connectivity between LSRs and the Matrix throughout the NRA.

Approximately 25 percent of the land managed by the STNF within the boundary of the NRA is designated as either Administratively Withdrawn Areas or Matrix. Lands allocated as withdrawn were identified in the STNF LRMP as management emphasis areas where scheduled timber harvest is precluded. The Matrix consists of other Federal lands outside the categories described above that may be managed for timber or other resource purposes and are not subject to certain standards and guidelines.

STNF LRMP direction for the Shasta Unit of the NRA is to: (1) provide public outdoor recreation opportunities; (2) conserve scenic, scientific, historic, and other values that contribute to public enjoyment; and (3) manage, use, and dispose of renewable natural resources, which will promote, but not significantly impair, public recreation or conservation of scenic, scientific, historic or other values contributing to public enjoyment (36CFR292.11).

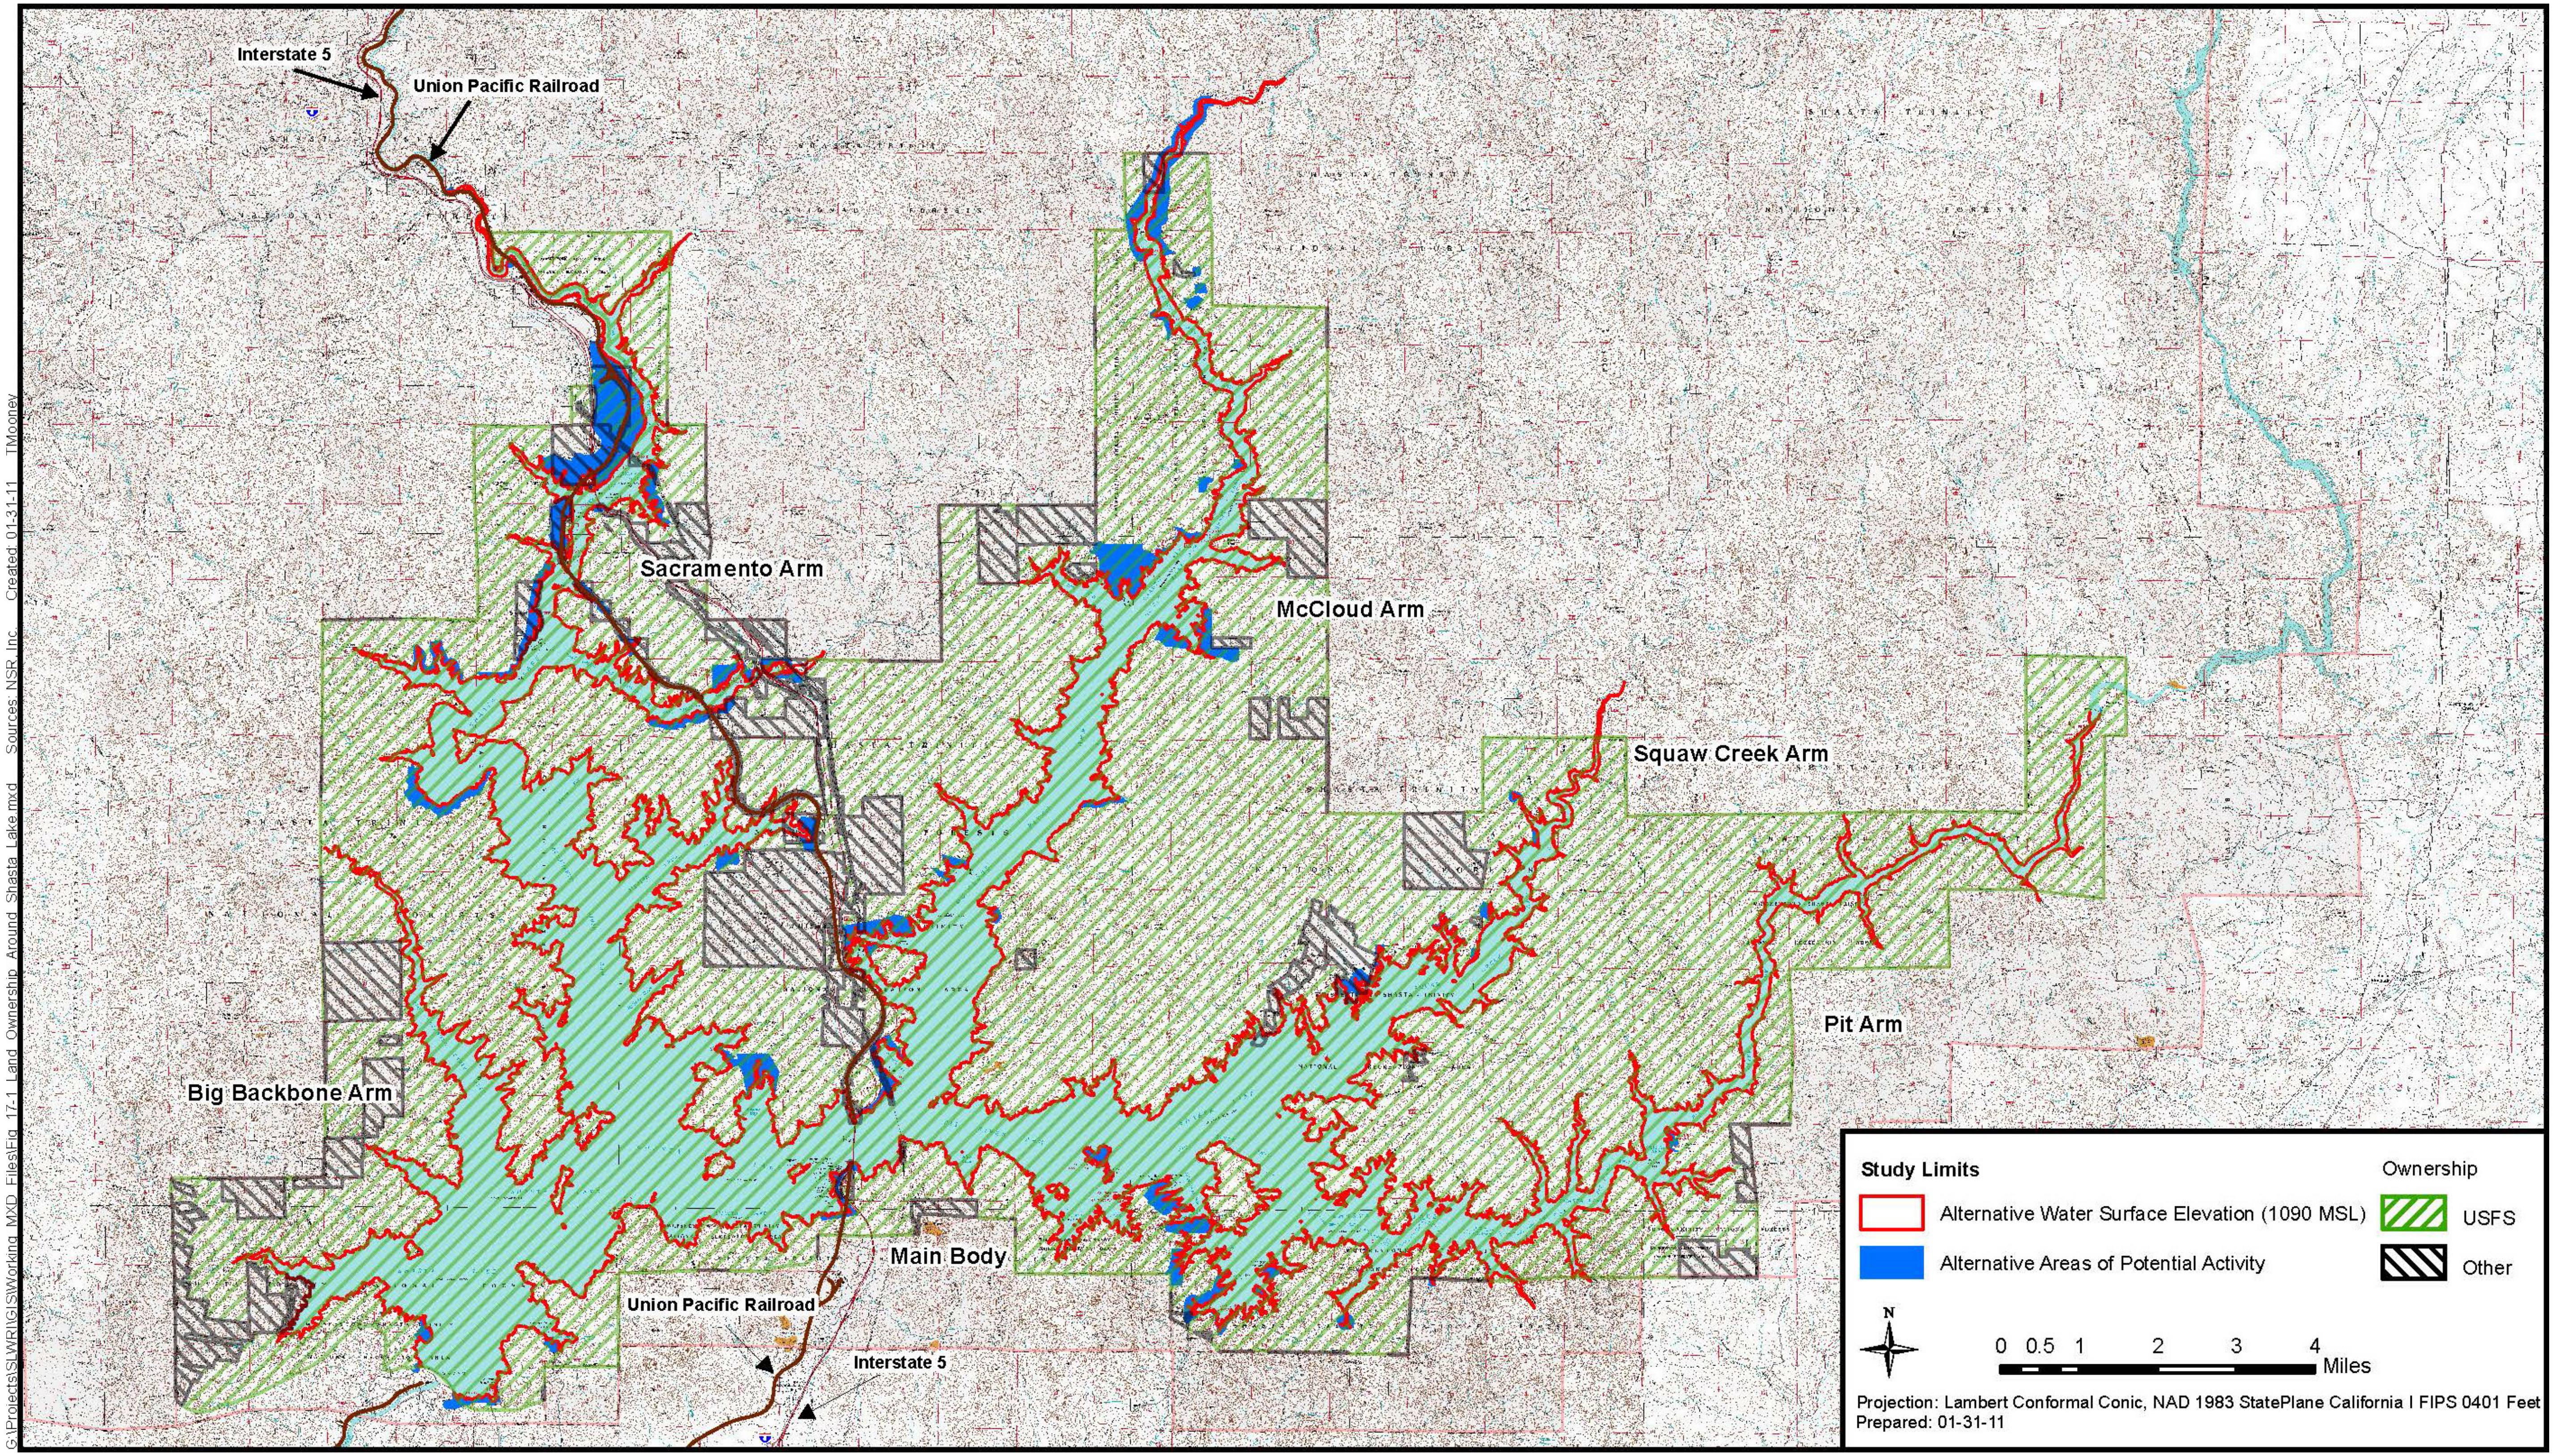

Figure 17-1. Land Ownership Around Shasta Lake

This page left blank intentionally.

Developed recreational and commercial land uses occupy 2 percent of the land managed by the STNF within the Shasta Unit of the NRA. Recreational use in the NRA exceeds 2 million visitor days annually. Water-oriented activities, such as boating, fishing, waterskiing, and houseboating, are the main attractions. Marinas that currently operate on Shasta Lake include Antlers, Sugarloaf, Shasta, Holiday Harbor, Packers Bay, Bridge Bay, Silverthorn, Jones Valley, and Digger Bay. Other recreational land uses include hiking, camping, picnicking, and OHV activities. A planning permit was issued by the STNF to decommission Digger Bay and construct a new marina at Turntable Bay, but the permit was not exercised and has since been revoked.

Commercial land uses in the NRA include resorts, marinas, campgrounds, restaurants, motels, grocery stores, and service stations. Resorts are sometimes operated as stand-alone entities, but are more typically operated in conjunction with a marina. Some resorts on Shasta Lake must move their docks substantial distances from their land-based facilities during periods of low water levels.

USFS manages recreation residence tracts at Salt Creek, Silverthorn, Campbell Creek, and Didallis Creek; these tracts combined contain 160 privately owned cabins on NFS lands. USFS policy is to manage these tracts and residences for individual recreational use and to keep the areas as close as possible to their natural state. Only minimal improvements are permitted, and structures must blend into the natural environment.

Mining and grazing do not take place in the NRA. There are no grazing permits authorized for the Shasta Unit of the NRA, primarily because of a lack of suitable range. Federal lands in the NRA, except those with valid existing rights, were withdrawn from mineral entry by the legislation that created the NRA. Reclamation and USFS conducted validity determinations on most of the claims existing at that time and contested the majority of them based on the absence of a valid discovery. There were five claims in the Shasta Unit of the NRA (See Page II-12 of the NRA Guide, STNF 1996) that predate the withdrawal; these claims have not been developed and are considered closed by the USFS. The lands covered by these claims remain open to mineral leasing. Hard rock minerals in the NRA are available for prospecting, exploration, and development under solid mineral leasing regulations (43 Code of Federal Regulations (CFR) Subpart 3583). Authorization for this land use requires permits and leases subject to approval by the Secretary of Agriculture and terms and conditions of the USFS to protect the values of the NRA.

There are two Inventoried Roadless Areas (IRA) that are managed by the STNF within and adjacent to the NRA boundary. Geographic information system (GIS) information provided by the USFS indicates that the boundaries of these IRAs coincide with the current full-pool elevation of Shasta Lake. The Backbone IRA encompasses 11,464 acres and is adjacent to the shoreline of Shasta Lake at two locations; 1.9 miles along the Big Backbone Arm and 5.8 miles along the Sacramento Arm. The Devils Rock IRA encompasses 16,207 acres on the STNF; 12.9 miles of this IRA are adjacent to the Pit Arm of Shasta Lake.

Land uses on privately owned lands in the NRA generally consist of commercial, recreational, and residential land uses associated with the NRA. Approximately 20 percent of the privately held lands in the NRA are developed. Commercial development consists primarily of service industries supporting residents and recreational visitors.

Residential land uses are typically characterized as low density and rural. Established small communities along Shasta Lake include Lamoine, Lakehead, Lakeshore, and Sugarloaf, which are located on the Sacramento Arm of Shasta Lake. Farther south is the residential community of O'Brien, which is located between the Sacramento and McCloud arms near I-5.

The McCloud River, which flows into Shasta Lake in the primary study area, is eligible for listing as wild and scenic under the Federal Wild and Scenic Rivers Act (Federal WSRA). In addition, although it is not State of California (State)-listed as wild and scenic, the McCloud River receives certain protections under the California Public Resources Code (PRC), Section 5093.542, established through enactment of the California Wild and Scenic Rivers Act, as amended (Sections 5093.50–5093.70). The effects of the proposed enlargement of Shasta Lake on the McCloud River are discussed in Chapter 25, "Wild and Scenic River Considerations for McCloud River," of this EIS.

The Sacramento River above Shasta Dam was also identified as eligible for listing as wild and scenic under the Federal WSRA in Appendix E to the Final EIS for the STNF LRMP. The USFS acknowledged this segment was eligible (Recreation) based on the presence of four outstandingly remarkable values (ORV); Cultural/Historical, Fisheries, Geology, Visual Quality/Scenery. The limited amount of land managed by the STNF along this segment (14 percent of the segment corridor) precluded the USFS decision to move the eligibility process forward; the agency determined it did not have the ability to manage these ORVs.

Upper Sacramento River (Shasta Dam to Red Bluff)

Land uses in the upper Sacramento River area consist of urban, residential, municipal and industrial, and agricultural uses. Urban development is located in the valley and is concentrated along the transportation corridors provided by I-5, State Route 273, and the UPRR. Incorporated cities located in the valley along I-5 in the upper Sacramento River study area are the cities of Shasta Lake, Redding, Anderson, and Red Bluff. Cottonwood, an unincorporated community located along the I-5 corridor, also has residential and commercial development.

Small rural communities characterize development patterns between Cottonwood and Lakehead on either side of the I-5 corridor. Many of these communities have their origins in the early settlement of Shasta County and

Tehama County, as evidenced by the agriculture, grazing, and timber operations typical of the upland areas. These communities usually consist of small community centers surrounded by vast tracts of fields and forest that are dotted with home sites (Shasta County 2004).

The northern, western, and eastern portions of Shasta County are relatively uninhabited because the lands in these areas are managed by USFS for timber, wildlife, and wilderness uses. Lands managed by USFS in the western and southeastern portions of Tehama County are also relatively uninhabited.

The National Park Service manages lands in the upper Sacramento River study area, including the Whiskeytown Unit of the NRA, west of Keswick, and Lassen Volcanic National Park, in the northeastern corner of Tehama County. The BLM manages the 12,194-acre Sacramento River Bend Management Area on the east side of the Sacramento River northeast of Red Bluff.

The National Rivers Inventory (NRI) identified three segments of the Sacramento River that are eligible for inclusion in the national Wild and Scenic River System that could be affected by the proposal to raise Shasta Dam. No segments of river have been designated as a wild and scenic river under Federal law in either the Sacramento or McCloud River systems.

Three segments lie on the Sacramento River below the Shasta Dam. These were evaluated in the BLM's Redding Resource Management Plan (RMP: A-16) and are briefly described in Table 17-1.

Table 17-1. Sacramento River – Eligible Segments From NRI and BLM RMP

River	Potentially Affected Eligible Segment	ORVs	Responsible Federal Agency
Sacramento	Below Shasta Dam, Arnold Bend above Colusa to Red Bluff Diversion Dam.	Recreation and Fishing	Bureau of Land Management; US Fish and Wildlife Service (Corning to Colusa)
Sacramento	Below Shasta Dam, Interstate Highway 5 bridge crossing immediately north of Red Bluff to Interstate Highway 5 bridge crossing at Anderson.	Scenery, Recreation, Fishing, Wildlife and Other Values.	Bureau of Land Management
Sacramento	Below Shasta Dam, Balls Ferry Bridge to gaging station below Sevenmile Creek	Scenery, Recreation, Fishing, Heritage	Bureau of Land Management

Key:
BLM = Bureau of Land Management
NRI = National Rivers Inventory
ORV = outstandingly remarkable value
RMP = Resource Management Plan

Lower Sacramento River and Delta

Land uses in the extended study area vary greatly because of differences in population, economy, and environment. Land uses in the Sacramento Valley are principally agricultural and open space, with urban development focused around the State capital in the Sacramento metropolitan area. The primary private land use in the region is agriculture. Urban development has occurred along major highway corridors, primarily in Sacramento, Placer, El Dorado, Yolo, Solano, and Sutter counties, and has caused some agricultural land to be taken out of production. For those lands that remain agricultural, soil conditions allow a wide variation in the types of crops grown.

The American River flows into the Sacramento River downstream from Nimbus Dam; its watershed is included in the lower Sacramento River and Delta portion of the extended study area. Two sections of the American River, the North Fork American River from its source in the Sierra Nevada to the Iowa Hill Bridge near Colfax and the lower American River from Nimbus Dam to the river’s confluence with the Sacramento River in the City of Sacramento, are listed as wild and scenic under the Federal WSRA and the State PRC.

The listed segment of the North Fork American River is designated as a wild river under the Federal WSRA and the State PRC. The listed segment is above any regulated reaches and is not under the control of the CVP or SWP. The downstream end of the listed segment is more than 70 river miles and 50 air miles upstream from the confluence with the Sacramento River and is thus too far away to be affected by any hydraulic changes in the Sacramento River.

The lower American River is regulated by Folsom Dam, which is approximately seven miles upstream from Nimbus Dam. Both Shasta Dam and Folsom Dam release water in accordance with their operational requirements, including releases to maintain water quality for fisheries, municipal use, and agricultural use, and for exports to the San Joaquin Valley. Both dams have operational requirements for the sections of the Sacramento and lower American rivers above their confluence, and they also have shared operational requirements for the Sacramento River and Delta below the confluence. Therefore, operational changes at one dam could require operational changes at the other. For example, reduced releases from Shasta Dam could require increased releases from Folsom Dam to meet flow requirements in the lower Sacramento River and Delta.

The lower American River is designated as a recreational river under the Federal WSRA and the PRC. Fishing and boating, including rafting and canoeing, are the primary recreational activities on the river. In addition, much of the lower American River's south shore is part of the American River Parkway. Joggers, bicyclists, walkers, and other users take advantage of the riverside trails and beaches of this extensive park system.

As shown on Table 17-1, one segment of the Sacramento River is listed as eligible for consideration under the Federal WSRA. The USFWS manages several wildlife refuges adjacent to this segment of the river between Corning and Colusa, California.

CVP/SWP Service Areas

The CVP, operated by Reclamation, is the largest water storage and delivery system in California, covering 29 of the State's 58 counties. Most of the CVP service area is in the Central Valley, and about 90 percent of the south-of-Delta contractual delivery is for agricultural uses (Reclamation 2007).

Most of the population of the CVP service area is concentrated within urban areas. The CVP service area includes various municipal and industrial water contractors and water districts that serve portions of the Sacramento and Stockton metropolitan areas and the San Francisco Bay Area. Outside these population centers, most of the CVP service area is rural, with irrigated agriculture the predominant land use and economic driver (Reclamation 2007).

SWP water is delivered to contracting agencies in Northern California, the San Francisco Bay Area, the Central Coast, San Joaquin Valley, and Southern California.

Land uses in the CVP/SWP service areas vary and include agricultural, municipal and industrial, commercial, open space, grazing, and timber production.

17.1.2 Planning

Shasta Lake and Vicinity

Federal Land Use Planning Federal lands are not subject to county or city general plans. Land use planning direction for the NRA is guided by Public Law 89-336 and associated regulations (including 36 CFR Part 292, Subpart B), USFS Directives, and management direction found in the STNF LRMP. As a result of more recent Congressional action, BLM manages all public lands west of the NRA including the Chappie-Shasta OHV Area. BLM also manages public lands along the Sacramento River corridor downstream from Shasta Dam to Red Bluff.

Shasta-Trinity National Forest Land and Resource Management Plan The STNF LRMP is based on three broad management strategies: preservation, biodiversity, and sustainable development for people. The objectives of the STNF LRMP are to:

- describe the desired conditions of NFS lands and resources;
- identify strategies to maintain or achieve those conditions;
- identify land areas as generally suitable or unsuitable for various uses;

- identify the guidelines for projects and activities; and
- identify areas with special or unique characteristics.

Projects and activities must be consistent with the applicable plan components. The STNF LRMP provides management direction at four integrated levels: (1) forest-wide direction, (2) land allocations and standards and guidelines, (3) management prescription direction, and (4) management area direction.

In addition to the land allocations described in the preceding section (LSRs, Riparian Reserves, Administratively Withdrawn Areas, and Matrix), there are a number of goals and associated standards and guidelines applicable to the SLWRI project with respect to NFS lands in the primary study area. Goals and associated standards and guidelines that describe the desired future condition of the STNF include:

- Lands
  - Plan for long-range land ownership adjustments that support resource objectives. Within and adjacent to the NRA, acquire available, undeveloped private lands needed to fulfill the management goals and objectives of the recreation resource program. Acquire those parcels of land that are specifically needed: (a) for public development; (b) to protect major visual resource values; (c) to protect prime wildlife habitat; and (d) to preserve important cultural values and make them available for public enjoyment.
  - Provide for continued use and new development of hydroelectric facilities.
  - During the project planning phase, consider the need for construction of trails, roads, and/or recreational facilities.

Seven land allocations apply to the STNF: Congressionally Reserved Areas (Wilderness Areas), LSRs, Managed Late-Successional Areas Administratively Withdrawn Areas, Riparian Reserves, Matrix, and Adaptive Management Areas (USFS 1995). There are no Congressionally Reserved Areas and Adaptive Management Areas in the primary study area so these allocations are not considered in this analysis.

The STNF LRMP requires each type of land use to be managed in accordance with applicable management prescriptions and the respective standards and guidelines pertaining to both land allocations and unique management areas. Lands allocated as LSRs, for example, have specific management objectives and standards and guidelines for air quality, biological diversity, fire and fuels, etc. The applicable management prescriptions for the four land allocations in the primary study are discussed below.

- **Late-Successional Reserves, Managed Late-Successional Areas, and other Threatened, Endangered, or Sensitive Species –** LSRs have been established to protect and enhance conditions of late-successional and old-growth forest ecosystems and to ensure the support of related species, including the northern spotted owl. The applicable management prescription is:
  - Provide special management for Late Successional Reserves and Threatened, Endangered and Selected Sensitive Species that are primarily dependent on late seral stage conditions.
- **Administratively Withdrawn Areas –** These areas are identified in the STNF LRMP and include recreation and visual areas, backcountry, and other areas where management emphasis precludes scheduled timber harvesting. The applicable management prescriptions are:
  - **Unroaded Non-Motorized Recreation –** Provide for semi-primitive non-motorized recreation opportunities in unroaded areas outside existing wilderness areas while maintaining predominantly natural-appearing areas with only subtle modifications.
  - **Limited Roaded Motorized Recreation –** Provide for semi-primitive motorized recreation opportunities while maintaining predominantly natural-appearing areas with some modifications.
  - **Roaded, High Density Recreation –** Provide areas that are characterized by a substantially modified natural environment.
  - **Special Area Management –** Provide for protection and management of special interest areas and research natural areas.
  - **Heritage Resource Management –** The primary theme of this prescription is to protect designated cultural resource values, interpret significant archaeological and historical values for the public, and encourage scientific research of these selected properties.
- **Riparian Reserves –** Provide an area along streams, wetlands, ponds, lakes, and unstable and potentially unstable areas where riparian-dependent resources receive primary emphasis. The applicable management prescription is:
  - **Riparian Management –** Maintain or enhance riparian areas, wildlife and fisheries habitat, and water quality by emphasizing streamside and wetland management.

- **Matrix –** Includes Federal lands outside the categories of the designated areas listed above. There are no Matrix lands in the NRA. Matrix lands are where most timber harvest would occur and where standards and guidelines are in place to ensure appropriate conservation of ecosystems as well as provide habitat for rare and lesser known species. The applicable management prescriptions are:
  - **Roaded Recreation –** Provide for an area where there are moderate evidences of the sights and sounds of humans.
  - **Wildlife Habitat Management –** The primary purpose of this prescription is to maintain and enhance big game, small game, upland game bird, and nongame habitat to provide adequate hunting and viewing opportunities.

The STNF LRMP provides another more specific layer of land use planning guidance for the NRA: the *Management Guide: Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity NRA* (USFS 2014). The Land Use and Ownership section of this document provides the following guidance for NRA lands managed by the STNF:

- Those private lands that would enhance outdoor recreation opportunities and/or the conservation of scenic, scientific, historic, and other values contributing to the public enjoyment of the NRA should be acquired as opportunities arise.
- Land exchanges will be pursued in accordance with the Forest Land Adjustment Guide. Lands directly adjacent to the shoreline will have the highest priority.
- Lands with significant known pollution sources arising from a history of mining discharge will not be acquired.
- Coordination will take place with Shasta County to allow those private land developments and resource production proposals that will maintain or enhance NRA values, and to disallow or phase out private land uses that detract from those values.
- Coordination will take place with county, State, and other Federal agencies on development, management, and regulatory oversight of recreation opportunities and facilities to ensure consistency with NRA objectives.
- Planning will take place with owners and managers of travel and utility corridors through the NRA (railroad, highway, and major power lines) to minimize the visual impacts of these corridors on the aesthetic value of the NRA.

On January 12, 2001, the Department of Agriculture adopted the rule that established prohibitions on road construction, reconstruction, and timber harvest in IRAs because they have the greatest likelihood of altering and fragmenting landscapes, resulting in immediate, long-term loss of IRA values and characteristics. Subsequently, the STNF finalized the boundaries of IRAs, including two areas adjacent to the Shasta Unit of the NRA; Backbone and Devils Rock.

The STNF coordinates with Shasta County to ensure that private development in the NRA maintains or enhances NRA values through local zoning regulations.

Mendocino National Forest Land and Resource Management Plan The management direction, objectives, and standards and guidelines of the Mendocino National Forest LRMP are applicable to an isolated 488-acre parcel of land managed by the Mendocino National Forest along the east bank of the Sacramento River in the general vicinity of the decommissioned Red Bluff Diversion Dam. In addition to a developed recreation area (Sycamore Campground), this parcel provides river access, habitat for special-status species and undeveloped open space used by the public for hiking, biking, and other recreational activities.

U.S. Bureau of Land Management Resource Management Plan As a result of Congressional action, BLM manages all public lands west of the NRA including the Chappie-Shasta OHV Area. BLM also manages public lands along the Sacramento River corridor downstream from Shasta Dam to Red Bluff. The primary study area is within the boundary of the Northern California District; the Central California District manages public lands throughout most of the extended study area. The resource management plans (RMP) of three BLM field offices: Redding, Ukiah, and Mother Lode (BLM 2006) are applicable to most of the public lands within both the primary and extended study areas. The purpose of BLM’s RMPs is to provide an overall direction for managing and allocating public resources in each planning area. Planning issues addressed in the RMPs include land tenure adjustments, such as land acquisition, exchange, and sale; recreation management; access; and forest management, including harvesting, herbicide use, and special-status species.

BLM’s Redding RMP (BLM 1993) provides guidance for the management of cultural resources, fire, grazing, minerals, vegetation, water quality, wildlife and fish habitats, and other resources and issues in Shasta County. The RMP was amended by the 1994 Record of Decision for the *Northwest Forest Plan* (Final Supplemental EIS for Amendments to USFS and BLM Planning Documents within the Range of the Northern Spotted Owl). This amendment required preparation of a Watershed Analysis before initiating BLM activities. Under the respective RMPs, as amended by the *Northwest Forest Plan*, BLM, like USFS, is also required to ensure that projects are consistent with the Aquatic

Conservation Strategy and other management direction specified in the 1994 Record of Decision for the *Northwest Forest Plan*.

The Redding RMP governs land use on BLM lands, including lands in the Sacramento River Management Area. The goal of the lands program of the Redding Field Office is to transform the scattered land base of the Redding Resource Area into consolidated resource management units to meet the needs of public land users. The RMP includes the following management guidance for its land program:

- All lands identified for transfer to another agency or qualified organization are for long-term stewardship by the receiving entity.

- All land acquisitions will be through exchange, purchase, or donation. Acquisitions will be from willing sellers for available unimproved property. In all acquisitions, BLM will strive to gain the local support and understanding for the action.

- All land identified for disposal through exchange, Recreation and Public Purposes Act transfer, or sale meets the criteria set forth in the Federal Land Policy and Management Act of 1976.

- Land use authorizations (rights-of-way, leases, permits) will continue to be issued on a case-by-case basis and in accordance with decisions established in the RMP. Applications for land use authorizations which reduce the marketability of an exchange parcel will not be authorized.

- Rights-of-way will be issued to promote the maximum utilization of existing rights-of-way routes, including joint use whenever possible.

County Land Use Planning Land-use planning on non-Federal land is under the jurisdiction of local governments in California. All cities and counties in California are required by the State to adopt a general plan establishing goals and policies for long-term development, protection from environmental hazards, and conservation of identified natural resources (California Government Code Section 65300). General plans lay out the pattern of future residential, commercial, industrial, agricultural, open-space, and recreational land uses on non-Federal land within a community. To facilitate implementation of planned growth patterns, general plans identify goals and/or policies to establish land use patterns.

Local governments implement general plans by adopting zoning, subdivision, grading, and other ordinances. Zoning ordinances identify specific types of land uses that may be allowed on a given site and establish specific development standards. Zoning regulations vary from jurisdiction to jurisdiction. However, typical standards promulgated in zoning ordinances include the siting of structures relative to parcel boundaries, architectural design (including height limitations), and the percentage of building coverage allowed relative to the overall square footage of a parcel.

The *Shasta County General Plan* (Shasta County 2004) provides planning guidance for privately owned land in Shasta County. Land use directives are provided in the form of goals, policies, objectives, standards, and guidelines. The following land uses described in the general plan are present in the Shasta Lake and vicinity portion of the primary study area:

- **Rural Residential –** Encompasses areas that receive minimal urban services, usually in or near a rural community center and areas with no urban services that are located in areas of the county characterized by one or more of the following conditions:
  - Severe limitations on septic tank use
  - Uncertain long-term availability of water
  - Proximity to lands categorized as timber, grazing, or crop lands
  - Remoteness from urban, town, and rural community centers
  - Extreme wildland fire hazard
  - Inaccessibility via county-maintained roads
- **Existing Residential –** This designation may be applied to residential areas that existed before 1984 and that do not fit the land use designation or density applied to surrounding properties.
- **Mixed Use –** This category recognizes that in a rural setting the strict segregation of different land use types, which is typically found in urban environments, is neither necessary nor practical. At this scale, conflicts that may result from the intermixing of land uses may be addressed by Shasta County zoning and development standards related to screening setbacks and architectural design.
- **Commercial Recreational –** This designation provides opportunities for the development of privately owned lands characterized by the natural environment for the purpose of providing commercial recreation activities that use and provide for the enjoyment of the natural environment. Examples of commercial recreation include campgrounds, fishing and hunting clubs, dude ranches, boating facilities, and recreational vehicle parks. Other uses such as a restaurant or small grocery store may be permitted when accessory to, supportive of, and compatible with the recreation activity.
- **Natural Resources Protection**

- **Community Parks** – Provides for large-scale community recreation facilities
- **Habitat** – Provides for protection of significant wildlife habitat resources

Shasta County land use actions and decisions on non-Federal land in the NRA are subject to STNF review and approval pursuant to 36 CFR Part 292, Subpart B.

Upper Sacramento River (Shasta Dam to Red Bluff)

Land use planning in the upper Sacramento River area consists of general plans adopted by Shasta and Tehama counties and the cities of Shasta Lake, Redding, Anderson, and Red Bluff. BLM lands in this area are managed in accordance with the Redding RMP, discussed in Section 17.2, "Regulatory Framework."

Local Land Use Planning

Shasta County The *Shasta County General Plan* (2004) designates the following land uses along the Sacramento River from Shasta Dam south to the Tehama County line:

- Rural residential
- Greenway
- Habitat resource
- Natural habitat
- Agricultural – cropland
- Agricultural – small-scale crops, grazing
- Mineral resources

Tehama County The *Tehama County General Plan Update 2009–2029* (2009) designates the following land uses along the Sacramento River from the Shasta County line in the north to Red Bluff:

- Habitat Resources
- Valley Floor Agriculture
- Public Facility
- Rural Residential–Small Lot
- Suburban Residential

City of Shasta Lake The *City of Shasta Lake General Plan* was adopted in 1999. The general plan designates the following land uses along Shasta Dam Boulevard, the primary roadway leading up to Shasta Dam:

- Community park
- 100-year floodplain
- Public facilities
- Commercial
- Mixed use
- Rural residential (1 unit/2 acres, 1 unit/5 acres)
- Suburban residential (3 units/acre)
- Urban residential (10 units/acre)
- Urban residential – High (20 units/acre)

City of Redding The City of Redding adopted an updated general plan in 2000 (City of Redding 2000). The general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Greenway
- Park, Park-Golf
- Public Facility; Public Facility-School
- Recreational
- General Office
- General Commercial
- Neighborhood Commercial
- Residential (2–3.5, 3.5–6, 6–10 units/acre)
- Critical Mineral Resource Overlay
- Mixed Use Neighborhood Overlay

City of Anderson The City of Anderson released its updated general plan in May 2007 (City of Anderson 2007). The general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Commercial
- Industrial
- Public/Quasi-Public
- Medium-Density Residential
- Rural Residential/Rural Estate

City of Red Bluff The City of Red Bluff most recently amended its General Plan Land Use Element in 1993; the city is currently updating this plan. The general plan designates the following land uses along the Sacramento River within the city limits and sphere of influence:

- Primary Floodplain
- Exclusive Agriculture
- General Commercial
- Central Business Districts
- Single-Family Residential
- General and Neighborhood Apartment Districts
- General Industrial
- Public Agency District
- Park

Lower Sacramento River and Delta

The lower Sacramento River and Delta are within the planning jurisdiction of Butte, Colusa, Contra Costa, Glenn, Sacramento, Solano, Sutter, Yolo, and Yuba counties. The largest cities in this region are Antioch, Chico, Davis, Fairfield, Martinez, Marysville, Pittsburg, Sacramento, Vacaville, Vallejo, West Sacramento, and Woodland. Each of these entities currently has adopted general plans and zoning ordinances. Land use planning documents are adopted by Federal agencies for federally managed lands in the lower Sacramento River and Delta areas.

CVP/SWP Service Areas

The CVP extends from the Cascade Range near Redding in the north to the Tehachapi Mountains near Bakersfield in the south. The CVP serves farms, homes, and industry in California's Central Valley as well as major urban centers in the San Francisco Bay Area. SWP contractors are in the southern San Joaquin Valley, Central Coastal area, and Southern California. The CVP and SWP service areas include portions of the primary and extended study areas. CVP water irrigates more than 3 million acres of farmland and provides drinking water to nearly 2 million consumers. SWP deliveries are 70 percent urban and 30 percent agriculture, serving 20 million Californians and more than 600,000 irrigated acres, respectively. Each of the counties and incorporated cities in the CVP and SWP service areas has adopted general plans and zoning ordinances. Federally managed lands in the service areas are managed in accordance with land use and planning documents similar to the STNF LRMP and BLM's RMP, and military installations located in the service areas have their own planning processes.

17.2 Regulatory Framework

17.2.1 Federal

Federal land use policies apply only to actions on, or affecting the uses of, Federal lands. Federal lands in the primary study area consist of the following:

- National Forest lands managed by STNF around Shasta Lake
- Lands along the Sacramento River just south of Shasta Dam managed by Reclamation
- Lands managed by BLM along the Sacramento River south of Shasta Dam as far downstream as Red Bluff

Entry upon or use of these Federally administered lands would require approval from the appropriate Federal entity(ies).

Federal Land Policy and Management Act

The Federal Land Policy and Management Act was enacted to change the Federal public lands policy from disposal to retention. The act directs Federal agencies to apply land use principles that emphasize conservation; these include the principles of multiple use and sustained yield land management policies. The Federal Land Policy and Management Act consolidated and articulated BLM's management responsibilities and applies primarily to this Federal land management agency. Title V of the Federal Land Policy and Management Act also granted the Secretary of the Interior and the Secretary of Agriculture the authority to issue rights-of-way for various uses, including reservoirs.

Code of Federal Regulations

USFS personnel administer their responsibilities for regulating use and protecting National Forest lands under Title 36 of the CFR and sections of titles 16, 18, and 21. Public services directives from the code are integrated into the STNF LRMP and include the following topics: fire and fuels management, facilities management, law enforcement, and land management.

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF LRMP is a forest-wide land use plan developed to guide resource management on STNF lands. Six broad categories are used to define management strategies. The management strategies (known as land allocations) are implemented through management prescriptions that provide specific standards and guidelines for forest resource management (USFS 1995).

Management Guide for the Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity National Recreation Area

The 2014 NRA *Management Guide: Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity NRA* (USFS 2014) contains management guidance intended to achieve or maintain desired conditions for the NRA. The document provides specific information about current conditions in the NRA, desired future conditions for the NRA, and management recommendations for the NRA. STNF is responsible for administering the Shasta and Trinity units of the NRA.

Mendocino National Forest Land and Resource Management Plan

The Mendocino LRMP is a forest-wide land use plan developed to guide resource management on NFS lands. Six broad categories are used to define management strategies. The management strategies (known as land allocations) are implemented through management prescriptions that provide specific standards and guidelines for forest resource management (USFS 1995).

U.S. Bureau of Land Management Resource Management Plans

BLM manages a number of public lands adjacent to the Sacramento River corridor downstream from Shasta Dam. The study area falls under two BLM districts (Northern California and Central California) and the RMPs of three BLM field offices: Redding, Ukiah, and Mother Lode (BLM 2006). The purpose of BLM's RMPs is to provide overall direction for managing and allocating public resources in each planning area.

BLM's Redding RMP (BLM 1993) provides guidance for the management of cultural resources, fire, grazing, minerals, vegetation, water quality, wildlife and fish habitats, and other resources and issues in Shasta County. The RMP governs land use on BLM lands, including lands in the Sacramento River Management Area. Planning issues addressed in the RMP include land tenure adjustments, such as land acquisition, exchange, and sale; recreation management; access; and forest management, including harvesting, herbicide use, and special-status species.

The RMP was amended by the 1994 Record of Decision for the *Northwest Forest Plan* (Final Supplemental EIS for Amendments to USFS and BLM Planning Documents within the Range of the Northern Spotted Owl). This amendment required preparation of a Watershed Analysis before initiating BLM activities. As a party to the *Northwest Forest Plan*, BLM, like USFS, is also required to ensure that projects are consistent with the Aquatic Conservation Strategy.

Federal Wild and Scenic Rivers Act

The Federal WSRA, enacted in 1968, established the National Wild and Scenic Rivers System "to preserve rivers with outstanding natural, cultural, and recreational values in a free-flowing condition for the enjoyment of present and future generations." To be eligible for inclusion in the system, a river must be free-flowing and exhibit ORVs. Free-flowing means "existing or flowing in a natural condition without impoundment, diversion, straightening, rip-rapping, or other modification of the waterway" (16 USC Section 1286). ORVs are scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values (16 USC Section 1271). Depending on the specific attributes of a river, it may be designated as "wild," "scenic," or "recreation." Different segments of a single river can receive different designations; in other words, some segments can be designated wild, some scenic, and some recreation or combinations of these designations. Recreation rivers are defined as “rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past” (16 USC Section 1286).

State-designated rivers may be added to the Federal system upon the request of the state’s governor and the approval of the Secretary of the Interior (16 USC Section 1286). Two sections of the American River were added to the Federal system in 1981 under this method. These sections are the lower American River from Nimbus Dam to the river’s confluence with the Sacramento River and the North Fork American River from its source to the Iowa Hill Bridge. The North Fork section is located above Nimbus, Folsom, and Lake Clementine dams many miles upstream from the confluence with Sacramento River. The North Fork is not regulated by Folsom Dam and would not be affected by hydraulic changes in the Sacramento River. The lower American River is designated as a recreational river.

Adding state rivers to the Federal system under (16 USC Section 1286) does not require the approval of the Legislature or Congress. State rivers added to the Federal system under this section are to be managed by the state.

17.2.2 State

California Public Resources Code, Division 6

PRC Division 6 grants the State Lands Commission (SLC) jurisdiction over 4.5 million acres of land held in trust for Californians. SLC’s jurisdiction includes a 3-mile-wide section of tidal and submerged land adjacent to the coast and offshore islands, including bays, estuaries, and lagoons. It also includes the waters and beds of more than 120 rivers, lakes, streams, and sloughs. The State holds these lands for the public trust purposes of water-related commerce, navigation, fisheries, recreation, and open space. SLC may grant dredging permits and issue land use leases for activities within its jurisdiction. SLC does not have a comprehensive use plan for these lands but manages them according to State and Federal laws and regulations. In the primary study area, SLC’s jurisdiction includes areas along the Sacramento River north of Red Bluff.

California Fire Plan

The *California Fire Plan* was prepared by the State Board of Forestry and the California Department of Forestry and Fire Protection to provide a comprehensive strategy for wildland fire protection and prevention in California. The plan provides recommendations for fire-safe land use planning. Preventive measures include using fire-resistant building materials, maintaining a defensible space around structures, vegetation management, and infrastructure planning.

Water Quality Control Plan

The *Water Quality Control Plan for the Sacramento River and San Joaquin River Basins* provides water quality objectives to protect beneficial uses of designated rivers and streams. *Water Quality Control Plan for the Sacramento River and San Joaquin River Basins* objectives are incorporated into county and city general plans, zoning ordinances, and subdivision ordinances.

California Public Resources Code, Sections 5093.50–5093.70

PRC Sections 5093.50–5093.70 were established through 1972 enactment of the State Wild and Scenic Rivers Act, which was subsequently amended on several occasions, to preserve certain rivers that possess extraordinary scenic, recreational, fishery, or wildlife values in their free-flowing state. The PRC identifies, classifies, and provides protection for specific rivers or river segments, as approved by the Legislature. Rivers or river segments that are specifically identified and classified in the PRC compose the State Wild and Scenic Rivers System. As described in PRC Section 5093.50, rivers or river segments included in the State system must possess “extraordinary scenic, recreational, fishery, or wildlife values”; however, the PRC does not define what constitutes “extraordinary.”

Depending on the specific conditions of a river, it may be designated as “wild,” “scenic,” or “recreation.” Different segments of a single river can receive different designations; in other words, some segments can be designated wild, some scenic, and some recreation or combinations of these designations. Recreation river segments are readily accessible by road or railroad, may have some development along their shorelines, and may have been impounded or diverted in the past (PRC Section 5093.53).

With its initial passage, the State system protected segments of eight rivers, including two sections of the American River. These sections include the lower American from Nimbus Dam to its confluence with the Sacramento River and the North Fork from its source to the Iowa Hill Bridge. The North Fork section is located above Nimbus, Folsom, and Lake Clementine dams many miles upstream from the confluence with Sacramento River. The North Fork is not regulated by Folsom Dam and would not be affected by hydraulic changes in the Sacramento River. The lower American is designated as a recreational river.

17.2.3 Regional and Local

Shasta County General Plan

The *Shasta County General Plan* (2004) guides land use planning on non-Federal land for Shasta County through 2025. The Community Organization and Development Pattern element of the *Shasta County General Plan* establishes policies related to the organization and relationships of the community types present in Shasta County, the living environments these communities offer, and the locations of development in relation to these communities. These policies were developed to maintain and enhance the quality of their environments. The Community Organization and Development Pattern element includes several objectives that influence land use decisions in the project study area:

- To promote a development pattern that will accommodate, consistent with the other objectives of the plan, the growth that will be experienced by Shasta County
- To guide development in a pattern that will provide opportunities for present and future county residents to enjoy the variety of living environments that currently exist within the county
- To guide development in a pattern that will respect the natural resource values of county lands and their contributions to the county's economic base
- To guide development in a pattern that will minimize land use conflicts between adjacent land users
- To recognize that the major economic resources for achieving the development pattern will come from the private sector, rather than government, and that the general plan, as the expression of community values, will guide the use of these resources

Tehama County General Plan

The *Tehama County General Plan Update 2009–2029* is used to guide future development in unincorporated areas of the county. The Land Use element of the General Plan Update establishes the goals, policies, and implementation measures that will help guide the growth and development of Tehama County for the next 20 years. This element also contains the General Plan Land Use Map, which delineates those areas of the county where future residential development of varying densities and nonresidential growth is anticipated or will be directed (Tehama County 2009).

City of Shasta Lake General Plan

The planning boundaries for the *City of Shasta Lake General Plan* are within the Shasta Lake and vicinity study area, north of Keswick Dam, east of the Sacramento River, and west of I-5. This general plan was adopted in 1999 and is intended to guide land use planning within the city through the Year 2020 (City of Shasta Lake 1999). The following statement from the Land Use element of the general plan identifies some of the concerns surrounding land use decisions within the City of Shasta Lake:

> *The Land Use Element and the Land Use and Circulation Map constitute the physical framework for the general plan, which designates the proposed location, distribution, and extent of land uses. Land use was a specific area of concern identified as*

> *being key to the development of the City of Shasta Lake. Some of the major issues identified included an evaluation and establishment of urban, rural, and urban reserve boundaries. This was accomplished by identifying areas that currently lack infrastructure that would be required to develop in an orderly manner through the development of Area Plans.*

City of Redding General Plan

The planning boundaries for the *City of Redding General Plan* encompass areas within the city limits and the urban growth boundary. This plan was adopted in 2000 and is intended to guide land use planning through the year 2020 (City of Redding 2000). The Community Development and Design element of the general plan states the following about the role and effects of land use policies:

> *Land use policies and the General Plan Diagram affect every property in the City. They determine how people can use/develop their land and what they can reasonably expect to develop next door, down the street, or across town. They provide for overall consistency and compatibility between land uses and can be a determining factor in quality of life. The policies … also have a direct bearing on traffic, the feasibility of public transportation, and the quality of the air.*

City of Anderson General Plan

The planning boundaries of the *City of Anderson General Pla*n encompass areas within the city limits and the urban growth boundary. The City of Anderson released its updated general plan in May 2007 (City of Anderson 2007). The general plan is intended to guide land use planning within the city through the Year 2027. The following statement from the Land Use element of the general plan identifies some of the concerns surrounding land use decisions within the City of Anderson:

> *The Land Use Element describes the pattern of land development within the City of Anderson and the proposed expansion area and provides direction for the future development envisioned for the City. Also included in this Element are descriptions of geographic areas that are anticipated to be developed over the term of this General Plan and goals and policies to guide the City's decision makers in their review of development proposals. This Element also defines land use categories and provides supporting detail for the uses depicted upon the Anderson General Plan Land Use Diagram.*

Red Bluff General Plan

The planning boundaries for the *City of Red Bluff General Plan* encompass areas within the city limits and the urban growth boundary. The adopted

General Plan elements are as follows: Circulation element (1991), Housing element (2004), and Land Use, Natural Environment, Noise, and Safety elements (1993). The following statement from the Land Use element summarizes concerns relative to land use decisions in Red Bluff (City of Red Bluff 1993):

> *The land use element identifies the spatial arrangement of existing and proposed uses of land including public lands and facilities. It lays out the distribution of classes of land use, the intensity of those uses, and proposes a strategy of goals, objectives, policies and implementation measures to promote a wise use of land to promote the welfare of the community.*

17.3 Environmental Consequences and Mitigation Measures

17.3.1 Methods and Assumptions

To characterize existing land uses in the primary study area, pertinent planning documents were reviewed to identify objectives for the level, type, location, density, and intensity of development and to determine whether the alternatives would be in conflict with current plans and policies. Planning documents that were reviewed include the STNF LRMP (USFS 1995), the Management Guide for the NRA, the BLM RMPs and the general plans for the cities of Shasta Lake, Redding, Anderson, and Red Bluff and Shasta and Tehama counties. Land use maps and zoning maps were consulted to identify planned land uses. The analysis also included a review of aerial photography to determine existing land uses in the primary study area.

The impacts of each alternative are analyzed separately, starting with the analysis of the No-Action Alternative, followed by each of the action alternatives. The impact analysis includes a discussion of both direct and indirect impacts associated with each alternative.

17.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative related to land use and planning would be significant if project implementation would do any of the following:

- Create land uses that are incompatible with existing and planned land uses adjacent to actions described as part of the project
- Introduce substantial nuisance effects on sensitive land uses that would disrupt use over an extended time period
- Conflict with any applicable land use plan, policy, ordinance, or regulation of an agency with jurisdiction over the project (including general plans, specific plans, and zoning ordinances) adopted for the purpose of avoiding or mitigating an environmental effect
- Disrupt or divide the physical arrangement of an established community
- Conflict with any applicable habitat conservation or natural community conservation plan

17.3.3 Topics Eliminated from Further Consideration

Effects of the proposed enlargement of Shasta Lake on the listed segments of the American River have been eliminated from further consideration in this EIS. The listed segment of the North Fork American River has been eliminated because it is above any regulated reaches and is many miles from the confluence of the American and Sacramento rivers. The lower American River has been eliminated because none of the alternatives would adversely affect its designation as a recreational river under the Federal WSRA or the PRC. Under each of the action alternatives, releases from Shasta Dam would increase from late spring through early autumn. Increased releases from Shasta Dam during this period would reduce the volume of water released from Folsom Dam during the primary recreation season on the lower American River (late spring through early autumn). Flow volumes and water levels within the lower American River would, however, remain substantially similar to existing conditions and would remain within the river's typical range of variation during the primary recreation season. During the secondary recreation season (autumn through spring), precipitation is greater, flows in the Sacramento River and Delta are higher, and releases from Shasta Dam would be reduced to increase storage in Shasta Lake. Reclamation may need to occasionally increase releases from Folsom Dam to accommodate demand and offset decreased releases from Shasta Dam. Flow volumes and water levels in the lower American River would, however, remain substantially similar to existing conditions and within the river's typical range of variation during the secondary recreation season.

The effects of the proposed enlargement on two IRAs, Backbone and Devils Rock, have been eliminated from further consideration in this EIS. Under the 18.5 foot increase, 0.3 percent of the Backbone IRA (39.2 acres) would be subject to inundation; Big Backbone Arm – 16.9 acres, Sacramento Arm – 22.3 acres. There would be no new road construction or timber harvest. There would be some vegetation removed in conjunction with the relocation of the Gooseneck Campground (boat-in), as well as removal of hazard trees at select locations identified by the STNF at coves known for high houseboat use. Under the 18.5 foot increase, 0.3 percent of the Devils Rock IRA would be subject to inundation; Pit Arm – 41.9 acres, Sacramento Arm – 22.3 acres. There would be no new road construction or timber harvest. There would be some vegetation removed in conjunction with removal of hazard trees at select locations identified by the STNF at high use houseboat coves. Collectively, approximately 20.6 miles of shoreline within the boundaries of these IRAs will be subject to effects similar to those described elsewhere in this EIS under the No-Action alternative, none of which are precluded in the 2001 Roadless Rule.

17.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity, Upper Sacramento River (Shasta Dam to Red Bluff), Lower Sacramento River and Delta, and CVP/SWP Service Areas
The impact discussion for the No-Action Alternative addresses all of both the primary and extended study areas together, because this alternative would not affect land use in either the primary or extended study area.

Impact LU-1 (No-Action): Disruption of Existing Land Uses No new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact LU-2 (No-Action): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions No new facilities would be constructed and no existing facilities would be altered, expanded, or demolished. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP1 addresses the Shasta Lake and vicinity and upper Sacramento River portions of the primary study area together, because impacts from construction activities would affect both areas.

Impact LU-1 (CP1): Disruption of Existing Land Uses Project construction activities associated with enlarging Shasta Dam and relocating utilities, infrastructure, and public service and recreational facilities could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to certain lands. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites and the demolition and relocation of some utilities. This impact would be potentially significant.

It is anticipated that construction activities would be limited to the Shasta Lake and Vicinity portion of the primary study area; therefore, no impacts associated with disruption of existing land uses would be expected to occur downstream from Shasta Dam.

Construction activities specific to enlarging Shasta Dam would be limited to the existing footprint of the Shasta Dam facilities and areas immediately adjacent. The project construction site would be accessed by existing roadways (I-5, Shasta Dam Boulevard, and Lake Boulevard). The access roads allow commercial truck use and are capable of supporting project-generated traffic. Road modifications would be necessary to accommodate project traffic en route to the construction sites and access restrictions would occur. Noise, air quality, and traffic impacts along these local roadways are evaluated in separate sections of the EIS. Equipment staging areas would be sited to avoid affecting or conflicting with existing land uses.

Project construction activities associated with relocating utilities, infrastructure, and public service and recreational facilities could result in temporary and localized disruptions of existing land uses. Lake inundation resulting from future dam operations could result in long-term disruptions of land uses in the primary study area. The Utilities and Miscellaneous Minor Infrastructure Technical Memorandum provides descriptions and detailed maps of the utilities and infrastructure (e.g., roads, bridges, campgrounds, boat ramps) that would be demolished or relocated in the ancillary areas near Shasta Lake (Reclamation 2007). Chapter 18, “Recreation and Public Access,” evaluates the project’s impacts on recreational use, including short-term disruption of recreational use and/or change in the type and location of recreational use. Chapter 21, “Utilities and Service Systems,” of this EIS evaluates the project’s impacts on utilities and service systems, and the environmental impacts of utilities demolition and relocation are evaluated in the pertinent technical chapters of the EIS (e.g., Water Quality, Air Quality and Climate, and Noise and Vibration).

Construction activities would affect major features around Shasta Lake and vicinity and would require demolition, relocation, modification, or reconstruction to prevent inundation of the features caused by an increased reservoir elevation. The major features affected would include:

- Major roads and road segments (Lakeshore Drive realignment)
- Vehicle bridges (Charlie Creek, Doney Creek, McCloud River, Didallas Creek, and Second Creek)

- Railroad bridge
- Utilities and service systems infrastructure
- Campgrounds and picnic areas
- Boat ramps and associated parking areas
- Buildings (resort/marina, residential, USFS facilities)

The communities of Lakeshore and Sugarloaf would be affected the most by transportation infrastructure relocation activities. Seventy-five small road segments (both paved and unpaved) would need to be modified. CP1 would result in the inundation of Lakeshore Drive at numerous locations south of Charlie Creek Bridge and in two locations between the Charlie Creek and Doney Creek bridges. Relocation of Lakeshore Drive and the UPRR would occur near existing residences and businesses. Road construction activity could result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access.

Seven bridges would need to be replaced. Construction activities associated with bridge modifications and relocations, particularly in areas with existing development such as Bridge Bay Marina and the communities of Lakeshore and Sugarloaf, could result in short-term disruptions of nearby residential, commercial, and industrial land uses. Bridge construction activity could result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access.

Approximately 67,000 feet of power and telecommunications lines would need to be demolished and reconstructed at a number of locations, including powerlines that cross Shasta Lake. Utilities infrastructure relocation activities could result in short-term disruptions of land uses in communities and recreation areas around Shasta Lake. Relocation activities could require partial or full road closures and other access restrictions to ensure public safety. Utilities relocation activities could also result in temporary and localized increases in dust, noise, heavy equipment traffic, and other project traffic.

An estimated 50 buildings would be affected under a 6.5-foot dam raise. The buildings have been categorized as residential (cottages, homes, etc.), commercial (resorts, marinas, stores, etc.), and USFS sites (work stations, campground buildings, recreation site restrooms, etc.). Buildings within the inundation area would be removed, and some would be relocated. Utilities associated with the removed buildings (water systems, septic systems, telecommunications and power facilities) would also require demolition or abandonment. Construction activity related to removal and/or relocation of buildings would result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access. Some existing marinas would need to be modified or relocated, which would disrupt existing commercial and recreational land uses. See the Engineering Summary Appendix for additional details.

Reservoir dikes would be required in the areas of Antlers/Lakeshore and railroad embankments would be required at the UPRR track at the south end of Bridge Bay for protection of existing infrastructure from increased full pool elevations. Additional sites for dike and embankment construction could be added in the future. Dike and embankment construction could serve to lessen long-term land use impacts resulting from the project by eliminating the need to remove and relocate a number of structures. Construction activities associated with dike and embankment construction would result in temporary and localized increases in dust, noise, and construction truck traffic and potential disruption of access.

Project implementation could result in short-term disruptions of land uses of parcels around Shasta Lake and vicinity during construction and relocation activities; long-term disruptions of land use could also result from project operations. This impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

Impact LU-2 (CP1): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation would result in inundating land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

It is anticipated that construction activities would be limited to the Shasta Lake and vicinity portion of the primary study area; therefore, no conflicts with existing land use goals and policies would be expected to occur in planning jurisdictions downstream from Shasta Dam.

Project implementation would result in an increase in reservoir pool elevation during extreme storm events, which could result in the flooding of approximately 1,110 acres in the lower elevations around Shasta Lake. To prevent utilities and infrastructure damage, Reclamation would relocate roads, utilities and service systems, marinas, and other structures and would modify a number of bridges. Relocation plans are based on broad assumptions regarding optimum construction, operation, and environmental conditions. Areas planned for relocation activities could have land use designations that conflict with the land use proposed by the project. It is anticipated that some relocation activities would conflict with land use designations. Although refinements have been made to a number of relocation sites subsequent to the DEIS, additional engineering information will be required for some sites before a detailed analysis can be made. Once relocation sites are finalized, the proposed land use would be compared to the existing land uses and land use designations to determine consistency with the STNF LRMP, BLM RMP, the Shasta County General Plan, and the Shasta County Zoning Ordinance as applicable.

Areas that would be most affected by project implementation are located on the Sacramento Arm of Shasta Lake and include the communities of Sugarloaf and Lakeshore. A number of existing residential land uses would be inundated by a higher full pool elevation in Shasta Lake.

Most recreation facilities that could be inundated by project implementation would be relocated; some recreation facilities would be relocated adjacent to existing recreation facilities. Sites proposed for the relocation of recreational facilities could be inconsistent with the current land use designations. Reclamation would cooperate with USFS and/or BLM to find the most suitable relocation sites that would be consistent with the STNF LRMP, the NRA Management Guide, and the BLM RMP.

The proposed use of Turntable Bay as a developed recreation area would require an amendment to the USFS STNF LRMP (USFS 1995) to change the land management prescription from Roaded Recreation (Prescription III) to Roaded, High Density Recreation (Prescription IV). Under the USFS Planning Regulations, this would be considered a nonsignificant amendment to the STNF LRMP.

Open space lands would be inundated. STNF LRMP land allocations that would be inundated include Riparian Reserve allocations. Loss of the use of NRA lands would be inconsistent with STNF LRMP and NRA goals and policies. Reclamation would coordinate mitigation measures with USFS to minimize the impacts from losing the ability to use lands around Shasta Lake.

The STNF LRMP identified several segments of the Sacramento River upstream from the NRA boundary as eligible for consideration under the Federal WSRA. One of these segments extends from the NRA boundary upstream to Box Canyon Dam. Only 6.7 miles of this 37 mile segment is on NFS lands managed by the STNF; none of these lands are within the segment affected by CP1. Under CP1, approximately 1,100 feet of this segment would be inundated.

Vegetation clearing required for the relocation of structures, marinas, recreation facilities, and utilities could be inconsistent with the STNF LRMP, BLM RMP, the *Shasta County General Plan*, and the Shasta County Zoning Ordinance. Many relocation activities would require vegetation clearing before construction. Specific clearing sites would be dependent on the sites chosen for utilities, building, and infrastructure relocation. The sites have not been determined at this time. Once specific relocation sites are known and the areas requiring vegetation clearance are determined, an analysis would be performed to determine whether the proposed action would be inconsistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the

Shasta County Zoning Ordinance. Reclamation would obtain authorization and/or use permits, or other suitable instruments, from USFS for actions within the jurisdiction of USFS; Reclamation would also obtain authorization and/or use permits from Shasta County and the California Department of Forestry and Fire Protection for vegetation clearing activities within the jurisdiction of Shasta County.

The overall project actions, as authorized by Congress, may not be consistent with the STNF LRMP (USFS 1995) as amended. Project-specific STNF LRMP amendment(s) may be required for standards and guidelines pertaining to the following LRMP elements: caves, visual quality, late successional reserves, riparian reserves, survey and manage species, and special-status species (e.g., Shasta snow-wreath). Scoping efforts to date indicate that amendments to the STNF LRMP are likely to be nonsignificant. The USFS decision would include a project-specific exception to these standards.

The STNF LRMP includes several resource-specific goals and objectives that enable the USFS to balance resource conflicts that could occur as a result of project authorization. One example is the goal to "provide for continued use and new development of hydroelectric facilities." The USFS understands that Congressional authorization may result in amendments or exemptions to land allocations and/or specific LRMP standards and guidelines in a manner that would enable an authorized project to be consistent with the STNF LRMP. If required, Reclamation would cooperate with USFS in support of any efforts to amend the STNF LRMP; this could require additional effort to fully comply with the National Forest Management Act and NEPA.

Site-specific information is needed for all infrastructure, building, and utilities relocation plans to review completely for consistency with existing land use planning documents, primarily the STNF LRMP and the *Shasta County General Plan*. Given the magnitude of facilities that might be relocated, including existing marinas and utilities, it is anticipated that there would be some inconsistencies with existing planning policies. This impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, "Mitigation Measures."

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact LU-3 (CP1): Disruption of Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of existing land uses in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP1): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP2 addresses the Shasta Lake and vicinity and upper Sacramento River portions of the primary study area together, because impacts from construction activities would affect both areas.

Impact LU-1 (CP2): Disruption of Existing Land Uses Project construction activities associated with enlarging Shasta Dam and relocating utilities, infrastructure, and public service and recreational facilities could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to certain lands. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites. Limitations on site use associated with construction at a particular site or facility would also occur. This impact would be potentially significant.

This impact would be similar to Impact LU-1 (CP1). A dam raise of 12.5 feet would result in a larger area of inundation than under CP1, which would, in turn, result in additional relocation of existing structures, infrastructure, and utilities and a longer duration for the impact. Reclamation estimates the construction of CP2 would take 5 years, which would be 6 months longer than for CP1. CP2 would, therefore, result in longer-term disruptions of land use than would CP1. Approximately 500 additional acres would be inundated by CP2, totaling 1,750 acres of land that would be inundated by Shasta Dam operations. Specific information regarding the location and number of structures that would be permanently lost will be incorporated into the land use impact analysis.

Project implementation could result in short-term and long-term disruptions of existing land uses. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

Impact LU-2 (CP2): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

This impact would be similar to Impact LU-2 (CP1). A dam raise of 12.5 feet would create a larger area of inundation than under CP1, which, compared to CP1, would result in additional relocation of structures and infrastructure that would be subject to USFS and Shasta County land use goals and policies.

Under CP2, approximately 1,800 feet of the eligible segment of the Sacramento River would be inundated. The portion of this segment subject to inundation is on private lands, not subject to the STNF LRMP.

A site-specific analysis would be conducted to determine where relocation activities and permanent land base losses resulting from project implementation would be inconsistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the Shasta County Zoning Ordinance.

Project implementation could result in short-term and long-term impacts that could conflict with existing land use goals and policies. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, "Mitigation Measures."

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact LU-3 (CP2): Disruption of Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of existing land uses in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP2): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP3 addresses the Shasta Lake and vicinity and upper Sacramento River portions of the primary study area together, because impacts from construction activities would affect both areas.

Impact LU-1 (CP3): Disruption of Existing Land Uses Project construction activities associated with enlarging Shasta Dam and relocating utilities, infrastructure, and public service and recreational facilities could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to certain lands. Construction activities that could disrupt land uses include the transport of project materials to and from project construction sites. Limitations on site use associated with construction at a particular site or facility would also occur. This impact would be potentially significant.

This impact would be similar to Impact LU-1 (CP1). A dam raise of 18.5 feet would result in a larger area of inundation than under CP1, which would result in additional relocation of existing structures and infrastructure compared to CP1 and a longer duration for the impact. Reclamation estimates that construction of CP3 would take 60 months, which would be 6 months longer than for CP1. Approximately 2,500 acres of land would be inundated by CP3 and, according to the 2003 infrastructure inventory at Shasta Lake, an estimated 130 buildings would be inundated under an 18.5-foot dam raise (Shasta County 2003). Specific information regarding the location and number of structures that would be permanently lost would be incorporated into the land use impact analysis. CP3 would require a more extensive (longer and wider) system of reservoir dikes than CP1 to accommodate increased Shasta Lake elevations resulting from Shasta Dam operations. A dam raise of 18.5 feet would result in the encroachment of 31 road segments. Lakeshore Drive could be inundated for nearly its entire length between Charlie Creek and Doney Creek.

Project implementation could result in short- and long-term disruptions of existing land uses. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

Impact LU-2 (CP3): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies. This impact would be potentially significant.

This impact would be similar to Impact LU-2 (CP1). A dam raise of 18.5 feet would result in a larger area of inundation than CP1, which, compared to CP1, would result in additional relocation of existing structures and infrastructure that would be subject to existing USFS and Shasta County land use goals and policies.

Under CP3, approximately 2,200 feet of the eligible segment of the Sacramento River would be inundated. The portion of this segment subject to inundation is on private lands, not subject to the STNF LRMP.

A site-specific analysis would be conducted to determine where relocation activities and permanent land base losses resulting from project implementation would be inconsistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan,* and the Shasta County Zoning Ordinance.

Project implementation could result in short-term and long-term impacts that could conflict with existing land use goals and policies. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact LU-3 (CP3): Disruption of Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of existing land uses in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP3): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP4 and CP4A addresses the Shasta Lake and vicinity and upper Sacramento River portions of the primary study area together, because impacts from construction activities would affect both areas.

Impact LU-1 (CP4 and CP4A): Disruption of Existing Land Uses Project construction activities associated with enlarging Shasta Dam and relocating utilities, infrastructure, and public service and recreational facilities could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to certain lands. Gravel augmentation and the habitat restoration activities along the upper Sacramento River could also cause minor disruptions of existing land uses in the primary study area. Construction activities that could disrupt land uses include the transport of project materials and equipment to and from project construction sites. Limitations on site use associated with construction at a particular site or facility would also occur. This impact would be potentially significant for CP4 and CP4A.

This impact would be similar to Impact LU-1 (CP1). Therefore, this impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

This impact would be similar to Impact LU-1 (CP1). Therefore, this impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

Impact LU-2 (CP4 and CP4A): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies, resulting in a significant impact. The proposed gravel augmentation and the habitat restoration activities along the upper Sacramento River for CP4 and CP4A would not alter land uses and would not be expected to conflict with existing land use goals and policies. This impact would be potentially significant for CP4 or CP4A.

This impact would be similar to Impact LU-2 (CP3). Therefore, this impact would be potentially significant for CP4. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

This impact would be similar to Impact LU-2 (CP3). Therefore, this impact would be potentially significant for CP4A. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact LU-3 (CP4 and CP4A): Disruption of Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of existing land uses in the extended study area. No impact would occur for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP4 and CP4A): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. No impact would occur for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan
Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff) The impact discussion for CP5 addresses the Shasta Lake and vicinity and upper Sacramento River portions of the primary study area together, because impacts from construction activities would affect both areas.

Impact LU-1 (CP5): Disruption of Existing Land Uses Project construction activities associated with enlarging Shasta Dam and relocating utilities, infrastructure, and public service and recreational facilities could result in short-term and long-term disruptions to land uses by interfering with the ability to use certain lands and interfering with access to certain lands. Gravel augmentation and the habitat restoration activities along the upper Sacramento River could also cause minor disruptions of existing land uses in the primary study area. Construction activities that could disrupt land uses include the transport of project materials and equipment to and from project construction sites. Limitations on site use associated with construction at a particular site or facility would also occur. This impact would be potentially significant.

This impact would be similar to Impact LU-1 (CP1). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, “Mitigation Measures.”

Impact LU-2 (CP5): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Project implementation could result in a permanent loss of inundated land around Shasta Lake, which could conflict with land use goals and policies of affected jurisdictions. Relocation of utilities and service systems resulting from project implementation could also conflict with existing land use goals and policies, resulting in a significant impact. Gravel augmentation and the habitat restoration activities along the upper Sacramento River would not alter land uses and would not be expected to conflict with existing land use goals and policies. This impact would be potentially significant.

This impact would be similar to Impact LU-2 (CP-3). Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 17.3.5, "Mitigation Measures."

Lower Sacramento River and Delta and CVP/SWP Service Areas
Impact LU-3 (CP5): Disruption of Existing Land Uses Construction activities would be limited to the primary study area; therefore, there would be no disruption of existing land uses in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact LU-4 (CP5): Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions Construction activities would be limited to the primary study area; therefore, no conflicts with existing land use goals and policies would occur in the extended study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

17.3.5 Mitigation Measures

Table 17-2 presents a summary of mitigation measures for land use.

Table 17-2. Summary of Mitigation Measures for Land Use

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/ CP4A	CP5
Impact LU-1: Disruption of Existing Land Uses (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	LU-1: Minimize and/or Avoid Temporary Disruptions to Local Communities.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact LU-2: Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions (Shasta Lake and Vicinity and Upper Sacramento River)	LOS before Mitigation	NI	PS	PS	PS	PS	PS
	Mitigation Measure	None required.	LU-2: Minimize and/or Avoid Conflicts with Land Use Goals and Policies.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact LU-3: Disruption of Existing Land Uses (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	NI	NI	NI	NI	NI
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	NI	NI
Impact LU-4: Conflict with Existing Land Use Goals and Policies of Affected Jurisdictions (Lower Sacramento River, Delta, CVP/SWP Service Areas)	LOS before Mitigation	NI	NI	NI	NI	NI	NI
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	NI	NI

Key:
CP = Comprehensive Plan
CVP = Central Valley Project
LOS = level of significance
LTS = less than significant
NI = no impact
PS = potentially significant
SU = significant and unavoidable
SWP = State Water Project

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts LU-3 (CP1) and LU-4 (CP1). Mitigation is provided below for the impacts of CP1 on land uses in the primary study area.

Mitigation Measure LU-1 (CP1): Minimize and/or Avoid Temporary Disruptions to Local Communities To minimize and/or avoid temporary disruption to local communities, the following measures will be implemented during project construction:

- Before construction, Reclamation and its contractor will develop a construction plan for each affected community (i.e., Lakeshore, Sugarloaf), consisting of the following:

  - Alternate access routes will be identified for local residences and businesses affected by project construction activities.

  - Construction and staging areas will be fenced, secured, and clearly marked. Security will be provided to ensure public safety.

  - Public parking areas outside of the construction staging areas will be kept clear of construction-related equipment of materials at all times.

  - Any open trenches will be covered or secured after daily activities to protect worker and public safety.

  - Construction activities near noise-sensitive land uses (e.g., near residences, campgrounds) or land uses that experience high levels of public activity (e.g., boat ramps, marinas) will be restricted to days and hours that minimize land use conflicts to the extent feasible.

- The contractor will provide advance notice of the construction activities schedule to the affected community members (e.g., residences, property owners, business owners, and public facilities operators), including posting of signs in the project area.

- The contractor will provide a phone number and community contact for inquiries about the project throughout the construction period.

- Reclamation and its contractor will coordinate with local jurisdictions and obtain all necessary permits (e.g., encroachment permit, utility excavation permit), will comply with permit conditions established to minimize construction impacts, and will assign an inspector to the project to oversee construction activities.

Implementation of this mitigation measure would substantially reduce land use capability impacts generated by short-term construction activities, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-1 (CP1) would be significant and unavoidable.

Mitigation Measure LU-2 (CP1): Minimize and/or Avoid Conflicts with Land Use Goals and Policies To reduce conflicts with land use goals and policies of affected jurisdictions, Reclamation will implement the following measures:

- Reclamation will coordinate with USFS to find the most suitable relocation sites for recreation facilities with respect to consistency with the STNF LRMP and the NRA Management Guide.

- Reclamation will coordinate with USFS to identify measures to minimize the impacts of the loss of use of USFS lands around Shasta Lake (including open space and Riparian Reserve allocations) caused by inundation, and measures to offset inconsistencies with the STNF LRMP and NRA goals and policies related to the loss of use of NRA lands.

- As utility and facility relocation sites are being refined, Reclamation will evaluate consistency of the relocated land uses with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the county zoning ordinance. To the degree possible, Reclamation will design the relocated utilities and facilities to comply with these plans and ordinances. If needed, Reclamation will seek permits, easements, and/or plan amendments.

Implementation of this mitigation measure would substantially reduce land use plan consistency impacts, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-2 (CP1) would be significant and unavoidable.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is required for Impacts LU-3 (CP2) and LU-4 (CP2). Mitigation is provided below for the impacts of CP2 on land uses in the primary study area.

Mitigation Measure LU-1 (CP2): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1). Implementation of this mitigation measure would substantially reduce land use capability impacts generated by short-term construction activities, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-1 (CP2) would be significant and unavoidable.

Mitigation Measure LU-2 (CP2): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1). Implementation of this mitigation measure would substantially reduce land use plan consistency impacts, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-2 (CP2) would be significant and unavoidable.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is required for Impacts LU-3 (CP3) and LU-4 (CP3). Mitigation is provided below for the impacts of CP3 on land uses in the primary study area.

Mitigation Measure LU-1 (CP3): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1). Implementation of this mitigation measure would substantially reduce land use capability impacts generated by short-term construction activities, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-1 (CP3) would be significant and unavoidable.

Mitigation Measure LU-2 (CP3): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1). Implementation of this mitigation measure would substantially reduce land use plan consistency impacts, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-2 (CP3) would be significant and unavoidable.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is required for Impacts LU-3 (CP4 and CP4A) and LU-4 (CP4 and CP4A) in the extended study area. Mitigation is provided below for the impacts of CP4 or CP4A on land uses in the primary study area.

Mitigation Measure LU-1 (CP4 and CP4A): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1). Implementation of this mitigation measure would substantially reduce land use capability impacts generated by short-term construction activities, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-1 (CP4 and CP4A) would be significant and unavoidable.

Mitigation Measure LU-2 (CP4 and CP4A): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1). Implementation of this mitigation measure would substantially reduce land use plan consistency impacts, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-2 (CP4 and CP4A) would be significant and unavoidable.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impacts LU-3 (CP5) and LU-4 (CP5) for the extended study area. Mitigation is provided below for the impacts of CP5 on land uses in the primary study area.

Mitigation Measure LU-1 (CP5): Minimize and/or Avoid Temporary Disruptions to Local Communities This mitigation measure is identical to Mitigation Measure LU-1 (CP1). Implementation of this mitigation measure would substantially reduce land use capability impacts generated by short-term construction activities, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-1 (CP5) would be significant and unavoidable.

Mitigation Measure LU-2 (CP5): Minimize and/or Avoid Conflicts with Land Use Goals and Policies This mitigation measure is identical to Mitigation Measure LU-2 (CP1). Implementation of this mitigation measure would substantially reduce land use plan consistency impacts, but might not reduce all impacts to a less-than-significant level. As a result, Impact LU-2 (CP5) would be significant and unavoidable.

17.3.6 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level. None of the programs or projects listed in Table 3-1 under Quantitative Analysis would affect land use or planning in the primary study area. In addition, none of the SLWRI alternatives would affect land uses and planning in the extended study area; therefore, there would be no cumulative impacts in the extended study area. The following analysis is based on the reasonably foreseeable programs and projects listed in the Qualitative Analysis section of Table 3-1.

Current land uses have been impacted in the past by water development projects, land use development, transportation improvements, recreation development, and other construction projects that are inconsistent with land use planning documents.

The action alternatives could temporarily affect land use in the Shasta Lake and vicinity portion of the primary study area during construction, and some components might be inconsistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the county zoning ordinance. In addition to the projects identified by the City of Shasta Lake (Moody Flats EIR and Mountain Gate at Shasta Mixed-Use Area Plan EIR) in their comments on the DEIS, there are two present or reasonably foreseeable future actions, the Antlers Bridge replacement and the Iron Mountain Restoration Plan, located in the immediate vicinity of Shasta Lake. With respect to projects currently undergoing CEQA review, these projects are still in the planning phase and there is uncertainty as to what, if any, action alternatives may be selected; therefore, they are not considered as reasonably foreseeable. The Antlers Bridge and Iron Mountain project do have the potential to damage or disrupt utilities and public service systems infrastructure. The Antlers Bridge replacement is currently under construction and is expected to be completed in 2015, which is before any of the action alternatives would begin. With respect to the Iron Mountain Mine Restoration Plan, it is unlikely that this activity would occur simultaneously with the action alternatives, or would considerably and adversely affect use of the same land. Therefore, construction or mitigation activities related to implementation of the proposed SLWRI alternatives would not contribute considerably to significant cumulative impacts related to temporary land use impacts. The cumulative effects of the action alternatives and the two present or reasonably foreseeable future actions on resources managed consistent with the STNF LRMP, the NRA Management Guide, the *Shasta County General Plan*, and the county zoning ordinance are addressed in the other pertinent technical chapters of the EIS.
