Department of the Interior Final

Shasta Lake Water Resources Investigation

Environmental Impact Statement

U.S. Department of the Interior — March 3, 1849

U.S. Department of the Interior — Bureau of Reclamation

December 2014

Mission Statements

Protecting America's Great Outdoors and Powering Our Future

The Department of the Interior protects and manages the Nation's natural resources and cultural heritage; provides scientific and other information about those resources; and honors its trust responsibilities or special commitments to American Indians, Alaska Natives, and affiliated island communities.

The mission of the Bureau of Reclamation is to manage, develop, and protect water and related resources in an environmentally and economically sound manner in the interest of the American public.

Final Environmental Impact Statement
Shasta Lake Water Resources Investigation

United States Department of the Interior
Bureau of Reclamation, Mid-Pacific Region
2800 Cottage Way, MP-700
Sacramento, CA 95825

This Final Environmental Impact Statement (EIS) for the Shasta Lake Water Resources Investigation (SLWRI) has been prepared by the U.S. Department of the Interior, Bureau of Reclamation (Reclamation), Mid-Pacific Region, consistent with requirements of the National Environmental Policy Act (NEPA). Cooperating agencies pursuant to NEPA include the U.S. Forest Service, Bureau of Indian Affairs, Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians, and U.S. Army Corps of Engineers.

The SLWRI is a feasibility study that is one of five studies for potential surface water storage projects included in the 2000 CALFED Bay-Delta Programmatic Record of Decision, and is being conducted under the general authority of Public Laws 96-375, which was reaffirmed under Public Law 108-361, also known as the CALFED Bay-Delta Authorization Act.

This EIS evaluates the potential environmental effects of alternative plans to enlarge Shasta Dam and Reservoir to (1) increase anadromous fish survival in the upper Sacramento River, primarily upstream from Red Bluff Pumping Plant, (2) increase water supplies and water supply reliability for agricultural, municipal and industrial, and environmental purposes, and (3) address related water resource problems, needs, and opportunities. In addition to the No-Action Alternative, this DEIS considers multiple action alternatives, which include potential dam raises ranging from 6.5 to 18.5 feet and related reservoir enlargements ranging from 256,000 to 634,000 acre feet.

In June 2013, Reclamation released the SLRWI Draft Environmental Impact Statement (DEIS) and appendices to the public. The public comment period closed September 2013. Over 600 comment letters were received on the DEIS. The Final EIS and related appendices include responses to public comments (Chapter 33, “Public Comments and Responses”) and related refinements to alternatives and impact evaluations and the identification of the preferred alternative.

For further information, please contact Katrina Chow, Project Manager, at the address above, by telephone at (916) 978-5067, or by e-mail at KChow@usbr.gov.

Shasta Lake Water Resources Investigation, California

Shasta Lake Water Resources Investigation, California Final Environmental Impact Statement

Prepared by:

United States Department of the Interior
Bureau of Reclamation
Mid-Pacific Region

December 2014

Executive Summary

S.1 Introduction and Background

This Environmental Impact Statement (EIS) has been prepared as part of the Shasta Lake Water Resources Investigation (SLWRI) to evaluate the potential physical, biological, cultural, and socioeconomic effects of implementing alternatives to modify the existing Shasta Dam and Reservoir, including taking no action. The SLWRI is a feasibility study being conducted by the U.S. Department of the Interior, Bureau of Reclamation (Reclamation), Mid-Pacific Region.

The SLWRI is being conducted consistent with the National Environmental Policy Act (NEPA), the 1983 U.S. Water Resources Council *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* (P&G) (WRC 1983), and other pertinent Federal, State of California (State), and local laws and policies. Reclamation is serving as the Federal lead agency for compliance with NEPA. Cooperating agencies, pursuant to NEPA, include the U.S. Department of Agriculture, Forest Service (USFS); Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians; U.S. Army Corps of Engineers (USACE); and U.S. Department of the Interior (Interior), Bureau of Indian Affairs (BIA). This document has also been prepared in consideration of California Environmental Quality Act (CEQA) requirements.

Reclamation completed the *SLWRI Draft Feasibility Report* (Draft Feasibility Report), *SLWRI Preliminary Draft EIS* (Preliminary DEIS), and related appendices in November 2011. These documents were released to the public in February 2012 to present potential impacts, costs, and benefits of the action alternatives that had been evaluated at that time; to share information generated since the completion of the *SLWRI Plan Formulation Report* in December 2007; and to provide an additional opportunity for public and stakeholder input.

After the release of the Draft Feasibility Report and Preliminary DEIS, SLWRI alternatives were refined for the Draft EIS (DEIS) based on several factors, including updates to Central Valley Project (CVP) and State Water Project (SWP) water operations, and stakeholder input. Water operations modeling and related evaluations for the DEIS and this Final EIS reflect the following:

- The Reclamation 2008 *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP* (2008 Long-Term Operation Biological Assessment (BA))

- The U.S. Department of Interior, Fish and Wildlife Service (USFWS) 2008 *Formal Endangered Species Act Consultation on the Proposed Coordinated Operations of the CVP and SWP* (2008 USFWS Biological Opinion (BO))

- The National Marine Fisheries Service (NMFS) 2009 *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO)

- Additional changes in CVP and SWP facilities and operations, such as implementation of the San Joaquin River Restoration Program

- Additional changes in non-CVP/SWP facilities and operations, such as the addition of the Freeport Regional Water Project

Reclamation released the DEIS for public review and comment in June 2013. In compliance with NEPA, a Notice of Availability (NOA) was published by Reclamation in the *Federal Register* (Federal Register Vol. 78, No. 126, 39315) on Monday, July 1, 2013, and an associated NOA was published by the U.S. Environmental Protection Agency (EPA) in the *Federal Register* (Federal Register Vol. 78, No. 129, 40474) on Friday, July 5, 2013.

Reclamation held three public workshops and three public hearings during the comment period on the DEIS. Each set of meetings were held in Redding, Sacramento, and Los Banos. Written and verbal comments were accepted at meetings and written comments were accepted throughout the comment period. The comment period on the DEIS began on July 1, 2013 and closed on September 30, 2013.

The public comments have been reviewed and, in accordance with NEPA Council on Environmental Quality (CEQ) Regulations, responses have been developed for all substantive comments and revision of the DEIS have been made to clarify and enhance the text to produce this SLWRI Final EIS. This Final EIS consists of revised chapters 1 through 31, a new Chapter 32, “Final EIS,” a new Chapter 33, “Public Comments and Responses,” and revised and new appendices.

During the process of addressing public comments on the DEIS, some notable content changes were made to this Final EIS, including:

- Refinement of the project purpose statement

- Clarification of the relationship of this EIS and tiering to the CALFED Bay-Delta Program (CALFED) Programmatic Environmental Impact Statement/Environmental Impact Report (PEIS/R)
- Refinement of the operational scenarios focused on anadromous fish survival, and the development, evaluation, and incorporation of Comprehensive Plan 4A (CP4A)
- Refinement of facility plans for recreation relocations, Shasta Dam modifications, Pit 7 Dam and Powerhouse modifications, and other reservoir area relocations (e.g., power transmission lines)
- Incorporation of updated resource information related to physical and biological resources in the primary study area
- Refinement of "maximum" affected areas and refinement of "most likely" affected areas for biological resources, based on facility and construction footprints
- Refinement and enhancement of the mitigation measures, including development of a framework to quantify impacts (where appropriate) and establish mitigation ratios that are applicable to a number of impacts related to biological resources, in conjunction with an interagency, interdisciplinary team

S.1.1 Background

Reclamation completed constructing Shasta Dam and Reservoir in 1945. Reclamation operates Shasta Dam and Reservoir, in conjunction with other facilities, to provide flood damage reduction and irrigation and municipal and industrial (M&I) water supply, maintain navigation flows, protect fish in the Sacramento River and the Sacramento-San Joaquin Delta (Delta), and generate hydropower. The Central Valley Project Improvement Act (CVPIA), enacted in 1992, added "fish and wildlife mitigation, protection, and restoration" as a priority equal to water supply, and "fish and wildlife enhancement" as a priority equal to hydropower generation. Major modifications to Shasta Dam include construction of a temperature control device (TCD) in 1997 for improved management of water temperatures in the upper Sacramento River.

Shasta Dam Under Construction

Shasta Dam and Reservoir were constructed as an integral element of the CVP, with Shasta Reservoir representing about 41 percent of the total reservoir storage capacity of the CVP. The 602-foot-tall Shasta Dam (533 feet above the streambed) and 4.55 million-acre-foot (MAF) Shasta Reservoir are located on the upper Sacramento River in Northern California, north of the City of Redding (see Figure S-1) within the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). Shasta Lake supports extensive water-oriented recreation. Recreation within these lands is managed by USFS.

In 2000, as a result of the CALFED Programmatic Record of Decision (ROD), increasing demands for water supplies, and growing concerns over declines in ecosystem resources in the Central Valley of California, Reclamation reinitiated a feasibility investigation to evaluate the potential for enlarging Shasta Dam and Reservoir.

Figure S-1. Location of Shasta Dam and Reservoir

S.2 Study Authorization

The SLWRI is being conducted under the authority of Public Law 96-375, which was reaffirmed under Public Law 108-361, also known as the CALFED Bay-Delta Authorization Act. Public Law 96-375 (October 3, 1980) provides the authority for conducting a feasibility study for the SLWRI. It allows the Secretary of the Interior to:

> *…engage in feasibility studies relating to enlarging Shasta Dam and Reservoir, Central Valley Project, California or to the construction of a larger dam on the Sacramento River, California, to replace the present structure.*

Section 103(c), "Authorizations for Federal Activities Under Applicable Law," of the CALFED Bay-Delta Authorization Act (Public Law 108-361, October 25, 2004), authorizes the Secretary of the Interior to carry out the activities described in paragraphs (1) through (10) of Subsection (d), which include:

> *…(1)(A)(i) planning and feasibility studies for projects to be pursued with project-specific study for enlargement of (1) the Shasta Dam in Shasta County.*

Also, Section 103(a)(1) of Public Law 108-361 (October 25, 2004) states the following:

> *The Record of Decision is approved as a general framework for addressing the CALFED Bay-Delta Program, including its components relating to water storage, ecosystem restoration, water supply reliability (including new firm yield), conveyance, water use efficiency, water quality, water transfers, watersheds, the Environmental Water Account, levee stability, governance, and science.*

The CALFED Programmatic ROD called for the Secretary of the Interior to conduct feasibility studies for expanding CVP storage in Shasta Lake to:

> *…increase the pool of cold water available to maintain lower Sacramento River temperatures needed by certain fish and provide other water management benefits, such as water supply reliability.*

Other Federal legislation influences the SLWRI. Two laws of special note are Public Law 89-336 (November 8, 1965) and Public Law 102-575 (October 30, 1992). Public Law 89-336 created the Whiskeytown-Shasta-Trinity NRA, which includes Shasta Dam and Reservoir. Public Law 102-575, the CVPIA, directed numerous changes to CVP operations. Among these changes was adding "fish and wildlife protection, restoration, and enhancement" as a project purpose, which would result in substantial changes to water supply deliveries, river flows, and related environmental conditions in the primary and extended study areas.

S.3 Intended Use of Environmental Impact Statement

The purpose of an EIS is not to recommend approval or rejection of a project, but to provide information to aid the public and decision makers/permitting agencies in the decision-making process. An EIS identifies and evaluates alternatives that meet the project objectives, analyzes the potential environmental effects, and identifies measures to reduce or avoid potential environmental effects resulting from the action alternatives (i.e., mitigation measures). An EIS also must disclose adverse environmental impacts that cannot be avoided, cumulative impacts, the relationship of short-term uses and long-term productivity, and irreversible and irretrievable commitments of resources. In addition, NEPA requires that an EIS consider indirect effects of a project, which are often the result of growth inducement.

The SLWRI is one of five surface storage projects recommended for project-specific studies in the 2000 CALFED PEIS/R Preferred Program Alternative and associated CALFED Programmatic ROD. Consistent with guidance in the CALFED Programmatic ROD, this EIS relies on and tiers to the CALFED PEIS/R.

The SLWRI DEIS was released to the public in June 2013 and was circulated for review and comment by agencies, stakeholders, and the public to inform and engage interested persons in the planning and NEPA processes. Public outreach, including public workshops and hearings, was conducted during the 90-day DEIS public review period. Comments received during the public review period were considered and addressed and all comments and responses to comments are included in this Final EIS.

Reclamation posted the Final EIS at http://www.usbr.gov/mp/slwri for public review and issued a notice in the Federal Register and press release describing the public release of the Final EIS. It will be used by the Federal lead agency when considering approval of the proposed action or an alternative to the proposed action. All cooperating agencies and other Federal, State, and local agencies with permitting or approval authority over any aspect of the proposed action are expected to use the information contained in this Final EIS to meet most, if not all, of their information needs to make decisions and/or issue permits with respect to the proposed action.

S.4 Purpose and Need/Project Objectives

NEPA regulations require a statement of “the underlying purpose and need to which the agency is responding in proposing the alternatives, including the proposed action” (Title 40, Code of Federal Regulations (CFR) Part 1502.13). In California, the State CEQA Guidelines require a clearly written statement of objectives, including the underlying purpose of a proposed project (Title 14, California Code of Regulations Section 15124(b)).

S.4.1 Project Purpose and Objectives

Project Purpose

The purpose of the proposed action is to improve operational flexibility of the Sacramento-San Joaquin Delta (Delta) watershed system to meet specified primary and secondary project objectives.

Project Objectives

Two primary project objectives (also referred to as planning objectives) and five secondary project objectives were developed for the SLWRI:

Primary Project Objectives

- Increase the survival of anadromous fish populations in the Sacramento River, primarily upstream from Red Bluff Pumping Plant (RBPP)
- Increase water supply and water supply reliability for agricultural, M&I, and environmental purposes, to help meet current and future water demands, with a focus on enlarging Shasta Dam and Reservoir

Secondary Project Objectives

- Conserve, restore, and enhance ecosystem resources in the Shasta Lake area and along the upper Sacramento River
- Reduce flood damage along the Sacramento River
- Develop additional hydropower generation capabilities at Shasta Dam
- Maintain and increase recreation opportunities at Shasta Lake
- Maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and in the Delta

Primary project objectives are those which specific alternatives are formulated to address. The two primary project objectives are considered to have coequal priority, with each pursued to the maximum practicable extent without adversely affecting the other. Secondary project objectives are considered to the extent possible through pursuit of the primary project objectives.

S.4.2 Project Need

The need for the proposed action is described below and summarized from the 2004 Reclamation *SLWRI Initial Alternatives Information Report*, the 2007 Reclamation *SLWRI Plan Formulation Report*, the 2011 *Draft Feasibility Report* (released in 2012), and the Plan Formulation Appendix.

Anadromous Fish Survival

The Sacramento River system supports four separate runs of Chinook salmon: fall-, late fall-, winter-, and spring-run. The adult populations of the four runs of salmon and other important fish species that spawn in the upper Sacramento

River have declined considerably over the last 40 years. Several fish species in the upper Sacramento River have been listed under the Federal Endangered Species Act: Sacramento River winter-run Chinook salmon (endangered), Central Valley spring-run Chinook salmon (threatened), Central Valley steelhead (threatened), and the Southern Distinct Population Segment of North American green sturgeon (threatened). Two of these species are also listed under the California Endangered Species Act: Sacramento River winter-run Chinook salmon (endangered) and Central Valley spring-run Chinook salmon (threatened).

Unsuitable water temperatures in the upper Sacramento River, especially in dry and critical years,[1] is a critical factor affecting the abundance of Chinook salmon and steelhead in the river. Water temperatures that are too high or, less commonly, too low, can be detrimental to the various life stages of Chinook salmon. Elevated water temperatures can negatively impact holding and spawning adults, egg viability and incubation, preemergent fry, and rearing juveniles and smolts, substantially diminishing the next generation of returning spawners. Stress caused by high water temperatures also may reduce the resistance of fish to parasites, disease, and pollutants. Releases of cold water from Shasta Reservoir can improve seasonal water temperatures in the Sacramento River downstream from Shasta Dam for anadromous fish during critical periods.

Various Federal, State, and local projects are addressing factors contributing to declines in anadromous fish populations. Recovery actions range from changing the timing and magnitude of reservoir releases to structural changes at Shasta Dam. Despite these steps, additional actions are needed to address anadromous fish survival in the upper Sacramento River.

Water Supply Reliability

Demands for water in California exceed available supplies. Reclamation's 2008 *Water Supply and Yield Study* describes dramatic increases in statewide population, land use changes, regulatory requirements, and limitations on storage and conveyance facilities that have resulted in unmet water demands and subsequent increases in competition for water supplies among urban, agricultural, and environmental uses. The California Department of Water Resources (DWR) *California Water Plan Update 2013* concludes that California is facing one of the most significant water crises in its history; drought impacts are growing, and climate change is affecting statewide hydrology. Challenges are greatest during dry years, when water supplies are less available. Despite significant physical improvements in water resource systems and in system management over the past few decades, California still faces unreliable water supplies, continued depletion and degradation of

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

groundwater resources, habitat and species declines, and unacceptable risks from flooding.

As the population of California grows, and the demand for adequate water supplies becomes more acute, the ability to maintain a healthy and viable industrial and agricultural economy while protecting aquatic species will be increasingly difficult. Compounding these issues, potential effects of climate change, such as changed precipitation patterns, less snowfall, and earlier snowmelt, may considerably increase the demands on available water supplies in the future. As owner and operator of the CVP, one of the largest water storage and conveyance systems in the world, Reclamation has identified the need to increase the reliability of CVP water deliveries to its water contractors, particularly during dry and critical water years. Similar needs and challenges are faced by the SWP and other water projects throughout the State. As one of many efforts to improve the reliability of California's water supply, the SLWRI was established to evaluate the potential to improve water supply reliability, primarily by modifying Shasta Dam and enlarging Shasta Lake.

Ecosystem Resources

The quantity, quality, diversity, and connectivity of riparian, wetland, floodplain, and shaded riverine habitat in along the Sacramento River have been severely limited through confinement of the river system by levees, reclamation of adjacent lands for farming, bank protection, construction of dams and reservoirs, channel stabilization, and land development, contributing to a decline in habitat and native species populations. Ecosystem restoration along the Sacramento River has been the focus of several ongoing programs, including the Senate Bill 1086 Program, CVPIA, CALFED, Central Valley Habitat Joint Venture, and numerous local programs within the Central Valley. Despite these efforts, a significant need remains to conserve and restore ecosystem resources along the Sacramento River.

Flood Management

Communities and agricultural lands in the Central Valley are subject to flooding along the Sacramento River that poses risks to human life, health, safety, and property. Physical impacts from flooding include damage to buildings, contents, automobiles, agricultural crops, equipment, etc. Threats from flooding are caused by many factors, including overtopping or sudden failures of levees, which can result in deep and rapid flooding with little warning. In addition, urban development in flood-prone areas has exposed the public to the risk of flooding.

Hydropower

Although California is the most energy-efficient state per capita in the nation, demands for electricity are growing at a rapid pace. According to the California Energy Commission's *2012 Integrated Energy Policy Report Update*, over the next 10 years, California's peak demand for electricity is expected to increase at a rate of approximately 1.5 percent per year through 2022, from about 60,000 megawatts (MW) in 2011 to about 70,000 MW by 2022. Executive Orders S-14-08 and S-21-09, issued in 2008 and 2009, respectively, established a goal of using renewable energy sources, including hydropower, for 33 percent of the State’s energy consumption by 2020. To implement recent California renewable resources mandates, significant increases in non-dispatchable intermittent renewable resources, such as wind and solar generation, will need to be added to California’s power system. This means that other significant flexible generation resources, such as hydropower, will be needed to support and integrate renewable generation. Adding to the need for additional energy sources, existing nuclear power plants are nearing the end of their design lives and some may be offline within the next 10 to 20 years.

Recreation

As California’s population continues to grow, demands will increase substantially for recreation opportunities at and near the lakes, reservoirs, streams, and rivers of the Central Valley. Further increases in demand, accompanied by relatively static recreation resources, will cause issues at existing recreation areas. These challenges will be especially pronounced at Shasta Lake, which is one of the most visited recreation destinations in the State and in the region. Even under current levels of demand, USFS, which manages recreation at Shasta Lake, has expressed concern about seasonal access and capacity problems at existing marinas and USFS facilities. A substantial and increasing need exists to improve recreation-related facilities and conditions at Shasta Lake.

Water Quality

The Sacramento River and the Delta support fish and wildlife while providing water supplies for urban, agricultural, and environmental uses across the State. Saltwater intrusion, municipal discharges, agricultural drainage, and water project flows and diversions have led to water quality issues within the Delta, particularly related to salinity. In the Sacramento River, urban and agricultural runoff, and runoff and seepage from abandoned mining operations, have resulted in elevated levels of pesticides, phosphorous, mercury, and other metals. Additional operational flexibility could provide opportunities to improve Sacramento River and Delta water quality conditions.

S.5 Study Area

Present Shasta Dam

Shasta Dam and Shasta Lake are located on the upper Sacramento River in Northern California, approximately 9 miles northwest of Redding in Shasta County. Because of the potential influence of the proposed modification of Shasta Dam and subsequent system operations and water deliveries on resources over a large geographic area, the SLWRI includes both a primary study area and an extended study area. As shown in Figure S-2, the primary study area includes Shasta Dam and Lake; the lower portions of all contributing major and minor tributaries flowing into Shasta Lake; Trinity and Lewiston reservoirs; and the Sacramento River between Shasta Dam and the RBPP, including tributaries at their confluence. The extended study area includes the Sacramento River downstream from the RBPP, including portions of the American and Feather river basins downstream from CVP/SWP reservoirs and related facilities; the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta); lower portions of the San Joaquin River basin downstream from CVP reservoirs and related facilities (Friant and New Melones reservoirs); and CVP and SWP facilities and water service areas (shown in Figure S-3).

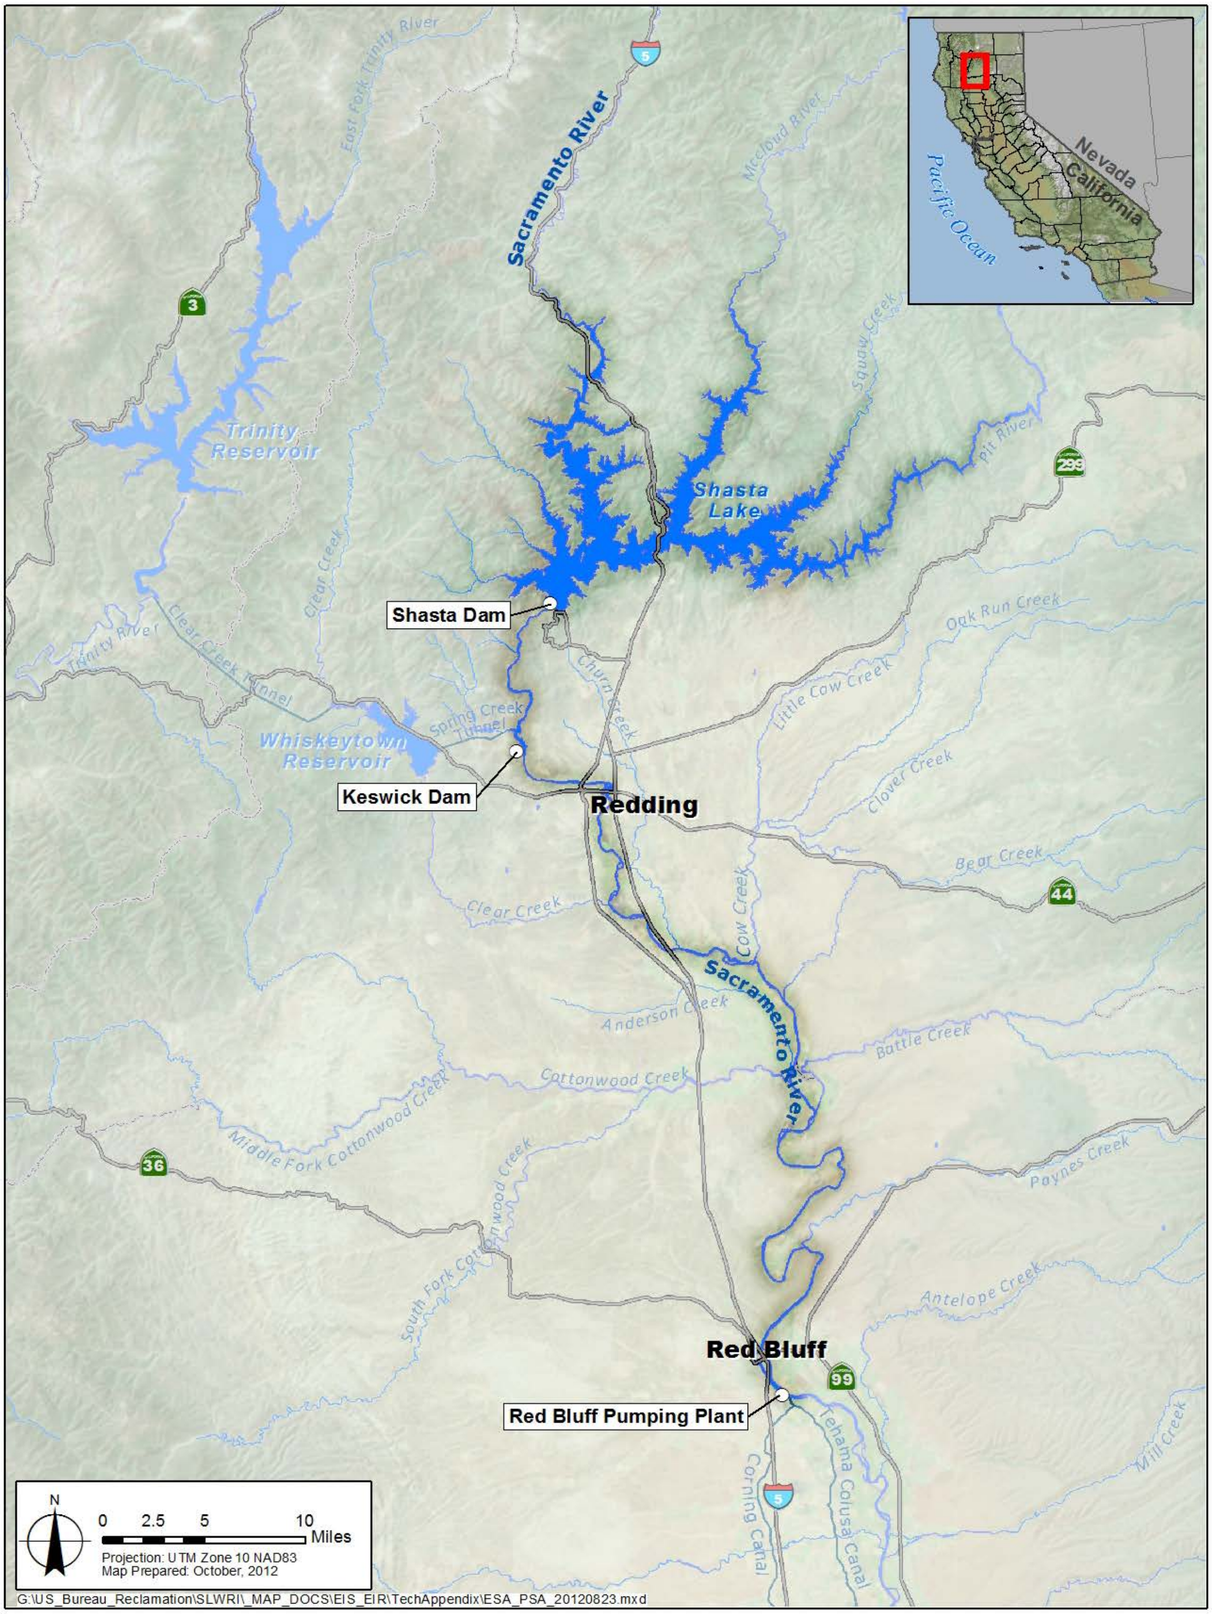

Figure S-2. Primary Study Area – Shasta Lake Area and Sacramento River from Shasta Dam to Red Bluff Pumping Plant

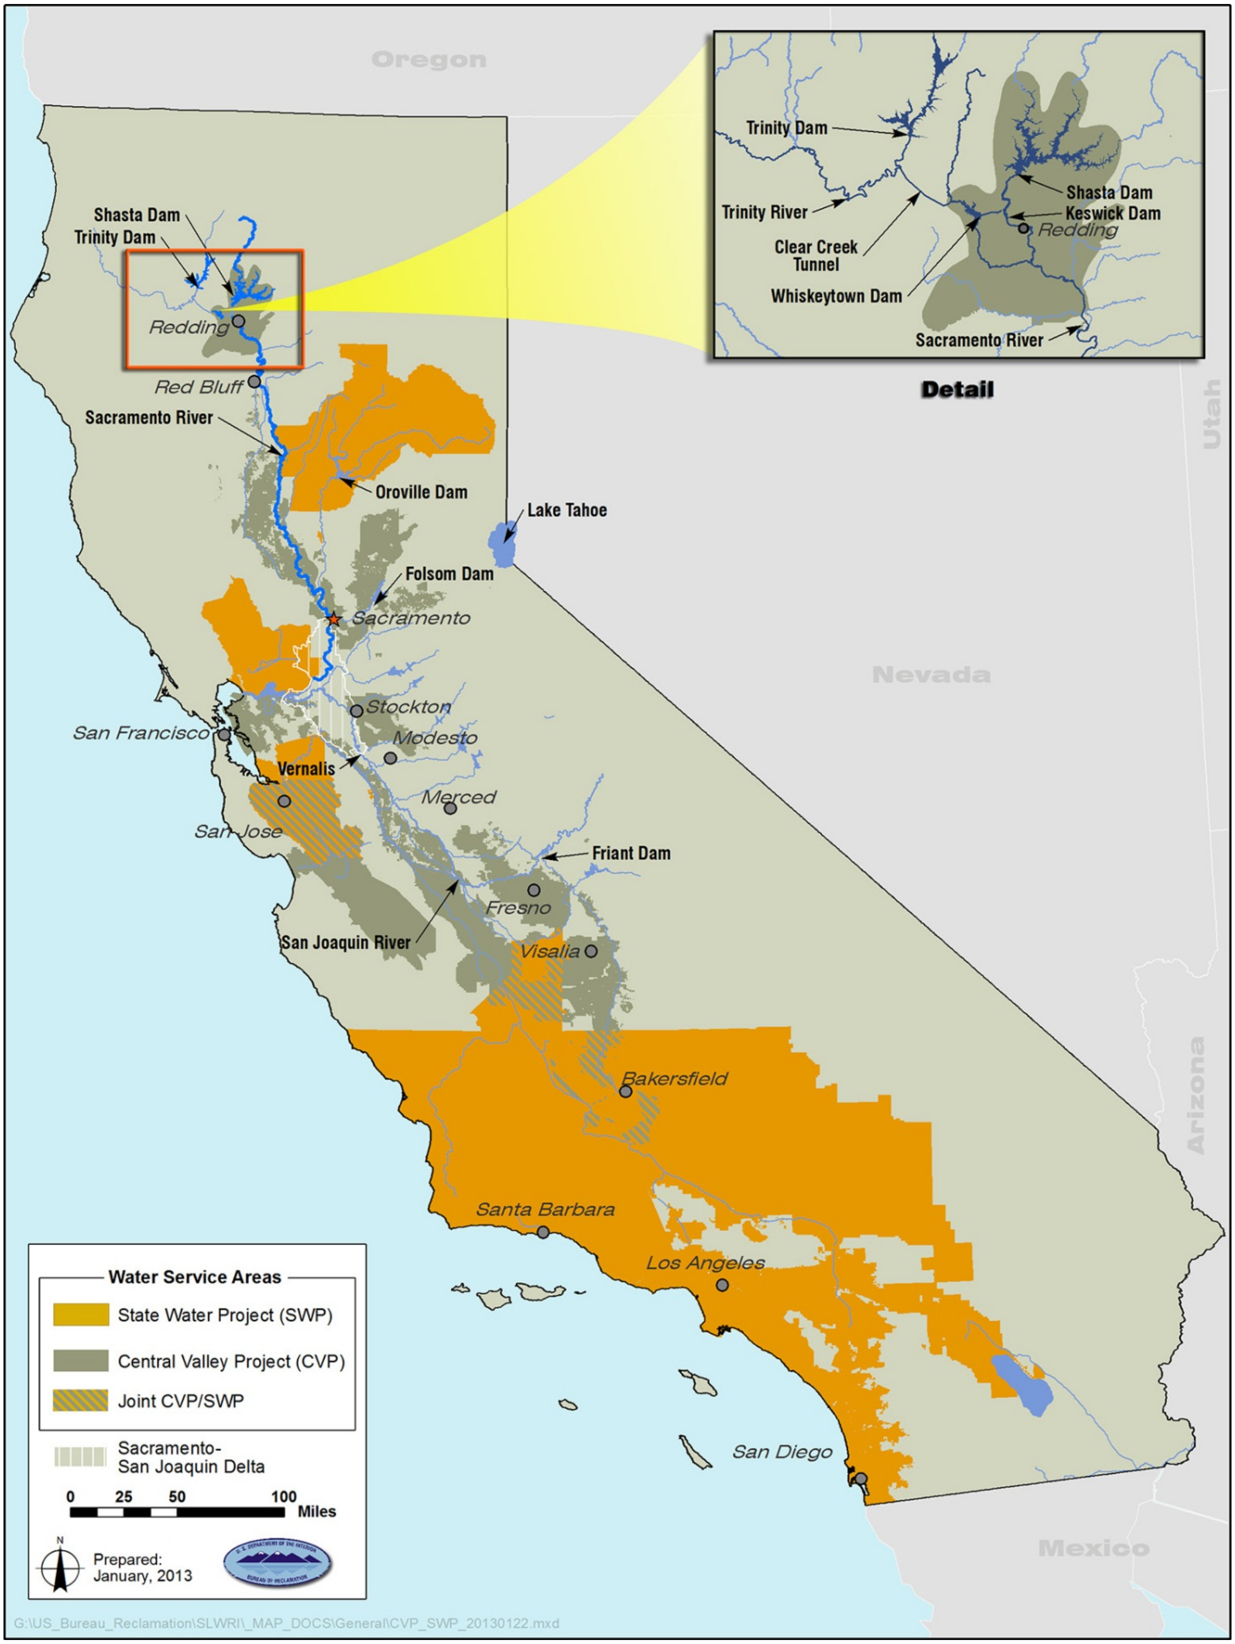

Figure S-3. Central Valley Project and State Water Project Facilities and Water Service Areas

S.6 Summary Description of Alternatives

Consistent with NEPA and the P&G, the plan formulation process for the SLWRI was divided into multiple phases, as shown in Figure S-4. Through this process, comprehensive plans (i.e., action alternatives) were formulated in addition to a No-Action Alternative. Each of the comprehensive plans includes enlarging Shasta Dam and Reservoir and a variety of management measures to address, in varying degrees, all of the project objectives. All of the comprehensive plans include eight common management measures:

- **Enlarge Shasta Lake cold-water pool –** All action alternatives would involve enlarging the cold-water pool by raising Shasta Dam to enlarge Shasta Reservoir.

- **Modify temperature control device –** Minimum modifications to the TCD under all action alternatives would include raising the existing structure and modifying the shutter control.

- **Increase conservation storage –** All action alternatives would increase the conservation storage in Shasta Reservoir by raising Shasta Dam.

- **Reduce demand –** All action alternatives would include a water conservation program for increased water deliveries that would be created by the project to augment current water use efficiency practices.

- **Modify flood operations –** Enlarging Shasta Reservoir would require adjustment of the existing flood operation guidelines, or rule curves, to reflect physical modifications, such as an increase in dam/spillway elevation; the rule curves would be revised with the goal of reducing flood damage and enhancing other objectives to the extent possible.

- **Modify hydropower facilities –** Enlarging Shasta Dam would require various modifications to the dam's existing hydropower facilities to enable their continued efficient use.

- **Maintain and increase recreation opportunities –** Recreation is important to the Shasta Lake region; therefore, existing recreation opportunities would be maintained and/or increased under all action alternatives.

- **Maintain or improve water quality –** All action alternatives would maintain and potentially improve water quality by increasing Delta outflow during drought years and reducing salinity during critical periods, and may also provide additional operational flexibility for responses to Delta emergencies.

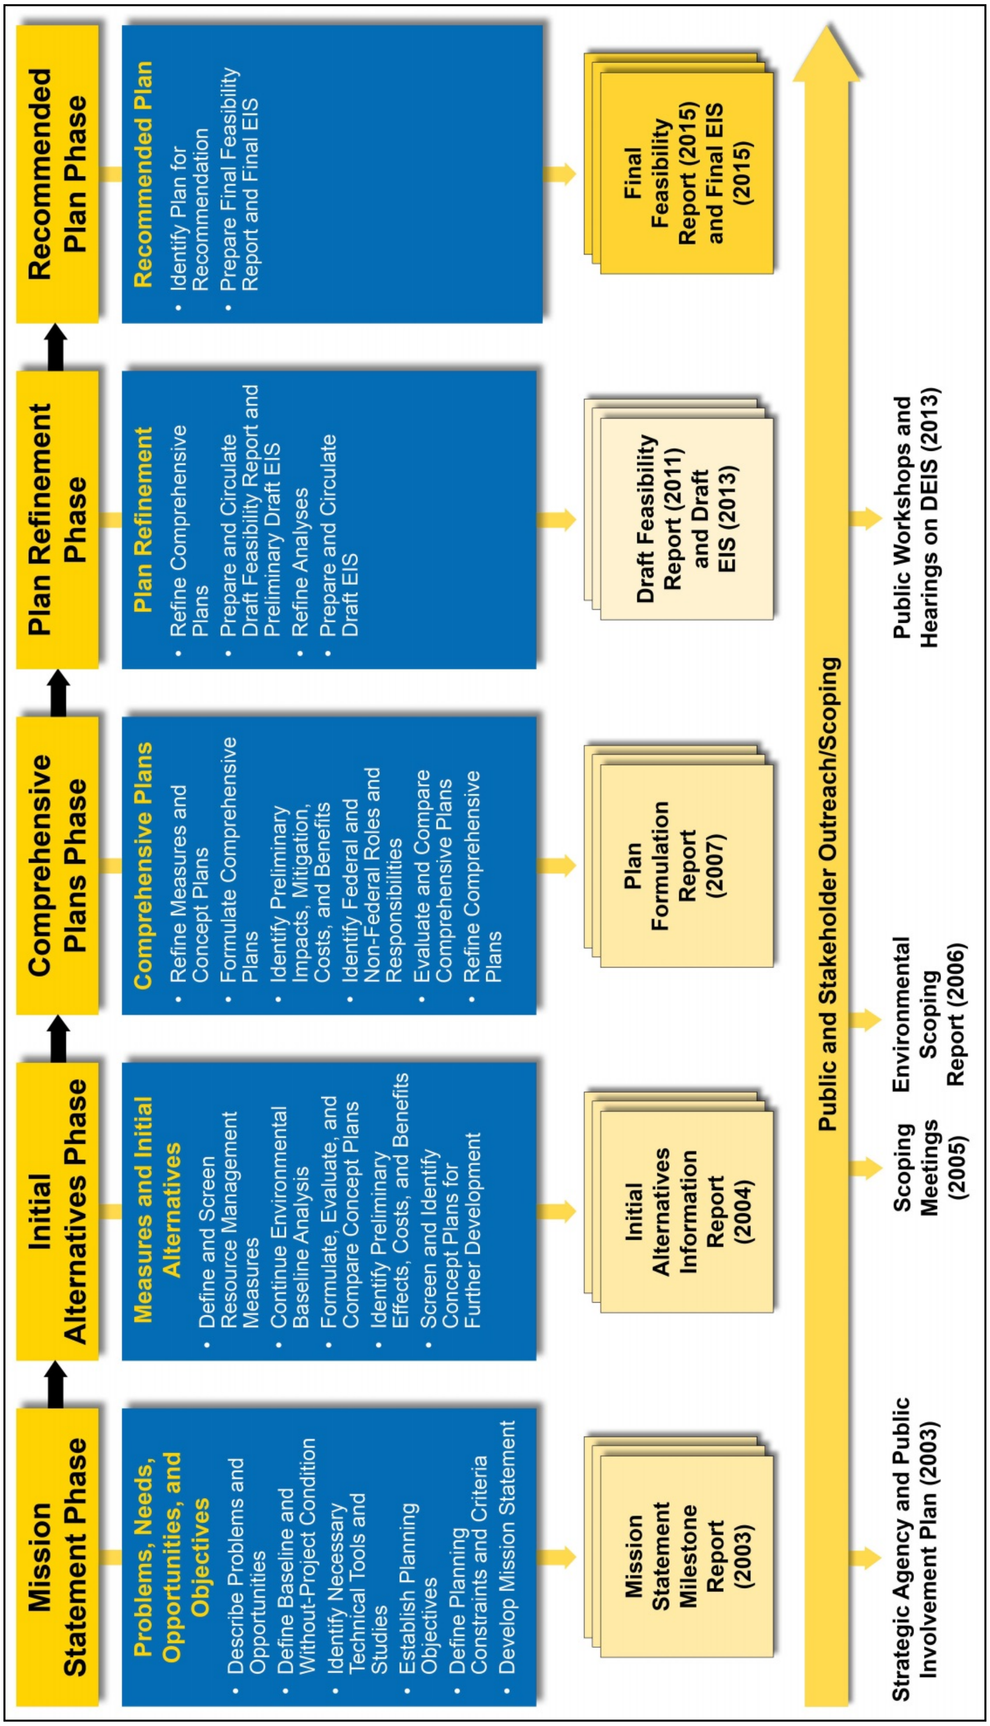

Figure S-4. Plan Formulation Phases

In addition, Reclamation has incorporated environmental commitments into each of the comprehensive plans to avoid or minimize potential impacts. Each comprehensive plan also includes mitigation measures where feasible to avoid, minimize, rectify, reduce, or compensate for significant and potentially significant impacts.

The No-Action Alternative and the comprehensive plans are summarized below.

S.6.1 No-Action Alternative

For the SLWRI, under the No-Action Alternative, the Federal Government would continue to implement reasonably foreseeable actions, including actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete. However, the Federal Government would not take additional actions toward implementing a plan to raise Shasta Dam to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water supply and reliability issues in California. The following discussions highlight the consequences of implementing the No-Action Alternative, as they relate to project objectives.

Anadromous Fish Survival

Much has been done to address anadromous fish survival problems in the upper Sacramento River. Solutions have ranged from changes in the timing and magnitude of releases from Shasta Dam to constructing and operating the TCD at the dam. Actions also include site-specific projects, such as introducing spawning gravel to the Sacramento River, and work to improve or restore spawning habitat in tributary streams. However, to increase anadromous fish survival and reduce the risk of extinction, further water temperatures improvements are needed in the Sacramento River, especially in dry and critical years. According to the NMFS 2014 *Recovery Plan for the Evolutionarily Significant Units of Sacramento River Winter-run Chinook Salmon and Central Valley Spring-run Chinook Salmon and the Distinct Population Segment of Central Valley Steelhead*, prolonged drought that depletes the cold-water pool in Shasta Reservoir could place populations of anadromous fish at risk of severe population decline or extirpation in the long-term. Under the No-Action Alternative, it is assumed that actions to protect fisheries and benefit aquatic environments would continue, including maintaining the TCD, ongoing spawning gravel augmentation programs, and satisfying other existing regulatory requirements.

Water Supply Reliability

Demands for water in California will continue to exceed available supplies, and the need for additional supplies is expected to grow. Competition for available water supplies would intensify as water demands increase to support population growth. Water conservation and reuse efforts are expected to substantially increase, and forced conservation as the result of increasing water shortages would continue. It is likely that with continued and deepening shortages in available water supplies, adverse economic and socioeconomic impacts would increase over time in the Central Valley and elsewhere in California.

Ecosystem Resources, Flood Management, Hydropower, Recreation, and Water Quality

Under the No-Action Alternative, the Federal Government would continue to implement reasonably foreseeable actions, but would not take additional actions to help restore ecosystem resources, develop additional hydropower generation, reduce flood damage, increase recreation opportunities at Shasta Lake, or improve water quality in the Sacramento River and the Delta. This would result in the following conditions:

- As opportunities arise, some efforts would likely continue to improve environmental conditions on tributaries to Shasta Lake and along the upper Sacramento River. However, overall, future environmental-related conditions in these areas would likely be similar to existing conditions.

- The threat of flooding would continue, and may increase as population growth continues.

- California's demand for electricity is expected to increase substantially in the future. No actions would be taken to help meet this growing demand.

- As California's population continues to grow, demands would grow substantially for water-oriented recreation at and near the lakes, reservoirs, streams, and rivers of the Central Valley. This increase in demand would be especially pronounced at Shasta Lake.

- To address the impact of water quality deterioration on the Sacramento River basin and Delta ecosystems, several environmental flow goals have been established through legal mandates. Despite these efforts, these resources would continue to decline and ecosystems would continue to be impacted.

S.6.2 Comprehensive Plan 1 (CP1) – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1	
Dam Raise	*6.5 feet*
Increased Storage	*256,000 acre-feet*
Focus	*Anadromous Fish Survival & Water Supply Reliability*
Major Components	*Dam Modifications & Reservoir Area Relocations*
	Environmental Commitments & Mitigation Measures

CP1 focuses on both anadromous fish survival and water supply reliability. This alternative primarily consists of enlarging Shasta Dam by raising the crest 6.5 feet and implementing the set of eight common management measures described above. CP1 also includes implementing environmental commitments and mitigation measures. By raising Shasta Dam from a crest at elevation 1,077.5 feet above mean sea level (elevation 1,077.5) to elevation 1,084.0 (based on the National Geodetic Vertical Datum 1929 (NGVD29)),[2] in combination with spillway modifications, this alternative would increase the height of the reservoir's full pool by 8.5 feet. This increase in full pool height would add approximately 256,000 acre-feet of additional storage to the overall reservoir capacity. Accordingly, the overall full pool storage would increase from 4.55 MAF to 4.81 MAF.

Under CP1, the additional storage in Shasta Reservoir would be used to increase water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. Enlarging Shasta Reservoir would increase the depth and volume of the cold-water pool, increasing the ability of Reclamation to release cold water from Shasta Dam and regulate seasonal water temperatures for fish in the upper Sacramento River during critical periods. This alternative (and all action alternatives) includes extending the existing TCD for efficient use of the expanded cold-water pool. CP1 would increase water supply reliability for agricultural, M&I, and environmental purposes. CP1 would also help reduce future water shortages through increasing irrigation and M&I deliveries, primarily during drought periods.

CP1 also addresses secondary planning objectives related to hydropower generation, recreation, flood damage reduction, ecosystem restoration, and water quality. Higher water surface elevations in the reservoir would result in an increase in power generation. CP1 includes features to at least maintain the existing recreation capacity at Shasta Lake, and water-oriented recreation experiences would be enhanced due to an increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. Enlarging Shasta Dam would provide for incidental

[2] Dam crest elevations are based on NGVD29. All current feasibility-level designs and figures for Shasta Dam and appurtenant structures are based on NGVD29.

increased reservoir capacity to capture flood flows, which could reduce flood damage along the upper Sacramento River. Improved fisheries conditions as a result of CP1, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Additional storage in Shasta Reservoir would also provide improved operational flexibility for meeting Delta water quality objectives through increased and/or high-flow releases to improve Delta water quality.

Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, except during dry and critical years when a portion of the increased storage in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. In dry years, 70,000 acre-feet of the 256,000 acre-feet increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. In critical years, 35,000 acre-feet of the increased storage capacity would be reserved for increasing M&I deliveries.

S.6.3 Comprehensive Plan 2 (CP2) – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP2	
Dam Raise	*12.5 feet*
Increased Storage	*443,000 acre-feet*
Focus	*Anadromous Fish Survival & Water Supply Reliability*
Major Components	*Dam Modifications & Reservoir Area Relocations*
	Environmental Commitments & Mitigation Measures

CP2 focuses on both anadromous fish survival and water supply reliability. This alternative primarily consists of enlarging Shasta Dam by raising the crest 12.5 feet and implementing the set of eight common management measures described above. CP2 also includes implementing environmental commitments and mitigation measures. A dam raise of 12.5 feet was chosen because it represents a midpoint between the likely smallest dam raise considered and the largest practical dam raise that would not require relocating the Pit River Bridge. By raising Shasta Dam from a crest at elevation 1,077.5 to elevation 1,090.0 (NGVD29), in combination with spillway modifications, CP2 would increase the height of the reservoir's full pool by 14.5 feet. This increase in full pool height would add approximately 443,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would increase from 4.55 MAF to 5.0 MAF.

Under CP2, the additional storage in Shasta Reservoir would be used to increase water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. CP2 would increase the ability of Shasta Dam to regulate seasonal water temperatures for fish, primarily during critical periods, and would increase water supply reliability for agricultural, M&I, and environmental purposes. CP2 would also help reduce future water shortages through increasing irrigation and M&I deliveries, primarily during drought periods.

CP2 also addresses secondary planning objectives related to hydropower generation, recreation, flood damage reduction, ecosystem restoration, and water quality. Higher water surface elevations in the reservoir would result in an increase in power generation. CP2 includes features to at least maintain the existing recreation capacity at Shasta Lake, and water-oriented recreation experiences would be enhanced due to an increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. Enlarging Shasta Dam would provide for incidental increased reservoir capacity to capture flood flows, which could reduce flood damage along the upper Sacramento River. Improved fisheries conditions as a result of CP2, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Additional storage in Shasta Reservoir would also provide improved operational flexibility for meeting Delta water quality objectives through increased and/or high-flow releases to improve Delta water quality.

Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, except during dry and critical years when a portion of the increased storage in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. In dry years, 120,000 acre-feet of the 443,000 acre-feet increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. In critical years, 60,000 acre-feet of the increased storage capacity would be reserved for increasing M&I deliveries.

S.6.4 Comprehensive Plan (CP3) – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3	
Dam Raise	*18.5 feet*
Increased Storage	*634,000 acre-feet*
Focus	*Agricultural Water Supply Reliability & Anadromous Fish Survival*
Major Components	*Dam Modifications & Reservoir Area Relocations*
	Environmental Commitments & Mitigation Measures

CP3 focuses on both agricultural water supply reliability and anadromous fish survival. This alternative primarily consists of enlarging Shasta Dam and Reservoir by raising the dam crest 18.5 feet and implementing the set of eight common management measures described above. CP3 also includes implementing environmental commitments and mitigation measures.

By raising Shasta Dam from a crest at elevation 1,077.5 to elevation 1,096.0 (NGVD29), in combination with spillway modifications, CP3 would increase the height of the reservoir's full pool by 20.5 feet. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would be increased from 4.55 MAF to 5.19 MAF. Although higher dam raises are technically and physically feasible, 18.5 feet is the largest dam raise that would not require extensive and costly reservoir area relocations, such as relocating the Pit River Bridge, Interstate 5, and the Union Pacific Railroad tunnels.

Because CP3 focuses on increasing agricultural water supply reliability and anadromous fish survival, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations. The additional storage would be retained for water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. CP3 would increase the ability of Shasta Dam to regulate seasonal water temperatures for fish, primarily during critical periods, and would increase water supply reliability for agricultural, M&I, and environmental purposes. CP3 would also help reduce future water shortages through increasing irrigation deliveries.

CP3 also addresses secondary planning objectives related to hydropower generation, recreation, flood damage reduction, ecosystem restoration, and water quality. Higher water surface elevations in the reservoir would result in an increase in power generation. CP3 includes features to at least maintain the existing recreation capacity at Shasta Lake, and water-oriented recreation experiences would be enhanced due to an increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. Enlarging Shasta Dam would provide for incidental increased reservoir capacity to capture flood flows, which could reduce flood damage along the upper Sacramento River. Improved fisheries conditions as a result of CP3, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Additional storage in Shasta Reservoir would also provide improved operational flexibility for meeting Delta water quality objectives through increased and/or high-flow releases to improve Delta water quality.

S.6.5 Comprehensive Plan 4 (CP4) and Comprehensive Plan 4A (CP4A) – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 and CP4A	
Dam Raise	*18.5 feet*
Increased Storage	*634,000 acre-feet*
Focus	*Anadromous Fish Survival with Water Supply Reliability*
Major Components	*Dam Modifications & Reservoir Area Relocations*
	Adaptive Management *CP4 –Reserving 378,000 acre-feet of Storage for Cold-Water Pool* *CP4A – Reserving 191,000 acre-feet of Storage for Cold-Water Pool*
	Augment Spawning Gravel
	Restore Riparian, Floodplain, & Side Channel Habitat
	Environmental Commitments & Mitigation Measures

CP4 and CP4A focus on increasing anadromous fish survival, while also increasing water supply reliability. CP4 and CP4A are identical except for Shasta Dam and reservoir operations. CP4 and CP4A have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for fisheries purposes; however, the portion of this dedicated storage varies.

These alternatives primarily consist of enlarging Shasta Dam and Reservoir by raising the dam crest 18.5 feet and implementing the set of eight common management measures described above. CP4 and CP4A also include implementing environmental commitments and mitigations measures. In addition, CP4 and CP4A would dedicate a portion of the increased storage in Shasta Reservoir for maintaining cold-water volumes to benefit anadromous fish in the upper Sacramento River. CP4 and CP4A also include two additional ecosystem restoration features: (1) augmenting spawning gravel in the upper Sacramento River at targeted locations to provide either immediate spawning habitat or long-term recruitment, and (2) restoring riparian, floodplain, and side channel habitat in the upper Sacramento River to provide rearing habitat for juvenile salmonids.

The additional storage created by the 18.5-foot dam raise would be used to improve the ability to meet water temperature objectives and habitat requirements for anadromous fish during drought years and increase water supply reliability. By raising Shasta Dam from a crest at elevation 1,077.5 to elevation 1,096.0 (NGVD29), in combination with spillway modifications, CP4 and CP4A would increase the overall full pool storage from 4.55 MAF to 5.19 MAF. Of the increased reservoir storage space, about 378,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival purposes in CP4; 191,000 acre-feet would be dedicated in CP4A. Operations of the cold-water pool would be subject to an adaptive management plan that may include operational changes to the timing and magnitude of release from Shasta Dam to benefit anadromous fish. For CP4, operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as for CP1, with 70,000 acre-feet reserved in dry years and 35,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries. For CP4A, operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2, with 120,000 acre-feet reserved in dry years and 60,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries.

CP4 and CP4A also address secondary planning objectives related to hydropower generation, recreation, flood damage reduction, ecosystem restoration, and water quality. Higher water surface elevations in the reservoir would result in an increase in power generation. CP4 and CP4A include features to at least maintain the existing recreation capacity at Shasta Lake, and water-oriented recreation experiences would be enhanced due to an increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. Enlarging Shasta Dam would provide for incidental increased reservoir capacity to capture flood flows, which could reduce flood damage along the upper Sacramento River. Improved fisheries conditions as a result of CP4 and CP4A, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Additional storage in Shasta Reservoir would also provide improved operational flexibility for meeting Delta water quality objectives through increased and/or high-flow releases to improve Delta water quality.

S.6.6 Comprehensive Plan 5 (CP5) – 18.5-Foot Dam Raise, Combination Plan

CP5	
Dam Raise	*18.5 feet*
Increased Storage	*634,000 acre-feet*
Focus	*Water Supply Reliability, Anadromous Fish Survival, Ecosystem Restoration, and Recreation*
Major Components	*Dam Modifications & Reservoir Area Relocations*
	Construct Resident Fish Habitat at Shasta Lake & along Tributaries
	Augment Spawning Gravel
	Restore Riparian, Floodplain, & Side Channel Habitat
	Increase Recreation Opportunities
	Environmental Commitments & Mitigation Measures

CP5 focuses on anadromous fish survival, increased water supply reliability, ecosystem enhancements in the Shasta Lake area and the upper Sacramento River upstream from the RBPP, and increased recreation opportunities around Shasta Lake. This alternative primarily consists of raising Shasta Dam 18.5 feet; implementing the set of eight common management measures described above; constructing additional resident fish habitat in Shasta Lake and along the lower reaches of its tributaries (the Sacramento River, the McCloud River, and Squaw Creek); constructing shoreline fish habitat around Shasta Lake; augmenting spawning gravel in the upper Sacramento River; restoring riparian, floodplain, and side channel habitat in the upper Sacramento River; and increasing recreation opportunities at Shasta Lake. CP5 also includes implementing environmental commitments and mitigations measures. By raising Shasta Dam from a crest at elevation 1,077.5 to elevation 1,096.0 (NGVD29), in combination with spillway modifications, CP5 would increase the height of the reservoir's full pool by 20.5 feet, increasing the overall full pool storage from 4.55 MAF to 5.19 MAF.

Under CP5, the additional storage in Shasta Reservoir would be used to increase water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. Enlarging Shasta Reservoir would increase the depth and volume of the cold-water pool, increasing the ability of Reclamation to release cold water from Shasta Dam and regulate seasonal water temperatures for fish in the upper Sacramento River during critical periods. This alternative (and all action alternatives) includes extending the existing TCD for efficient use of the expanded cold-water pool. CP5 would increase water supply reliability for agricultural, M&I, and environmental purposes. CP5 would also help reduce future water shortages through increasing irrigation and M&I deliveries, primarily during drought periods.

CP5 also addresses secondary planning objectives related to hydropower generation, recreation, flood damage reduction, ecosystem restoration, and water quality. Higher water surface elevations in the reservoir would result in an increase in power generation. CP5 includes features to at least maintain the existing recreation capacity at Shasta Lake, and water-oriented recreation experiences would be enhanced due to an increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. Enlarging Shasta Dam would provide for incidental increased reservoir capacity to capture flood flows, which could reduce flood damage along the upper Sacramento River. Improved fisheries conditions as a result of CP5, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Additional storage in Shasta Reservoir would also provide improved operational flexibility for meeting Delta water quality objectives through increased and/or high-flow releases to improve Delta water quality.

Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, except during dry and critical years when a portion of the increased storage in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. In dry years, 150,000 acre-feet of the 634,000 acre-feet increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. In critical years, 75,000 acre-feet of the increased storage capacity would be reserved for increasing M&I deliveries.

S.6.7 Summary of Comprehensive Plan Physical Features and Benefits

The following sections describe the physical features and potential benefits of comprehensive plans (action alternatives) evaluated in this EIS.

Physical Features

Each of the comprehensive plans (action alternatives) involves raising Shasta Dam by 6.5 feet to 18.5 feet, increasing the storage capacity in Shasta Reservoir by 256,000 acre-feet to 634,000 acre-feet, and constructing a common set of features, as shown in Table S-1. Features and related construction activities under all comprehensive plans would include the following:

- Clearing vegetation from portions of the inundated reservoir area
- Constructing the dam, appurtenant structures, reservoir area dikes, and railroad embankments
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure

Table S-1. Summary of Physical Features of Action Alternatives

	Action Alternatives					
Main Features	**CP1**	**CP2**	**CP3**	**CP4**	**CP4A**	**CP5**
Dam and Appurtenant Structures						
Shasta Dam						
Crest Raise (feet)	6.5	12.5	18.5	18.5	18.5	18.5
Full Pool Height Increase (feet)	8.5	14.5	20.5	20.5	20.5	20.5
Elevation of Dam Crest (feet)[1]	1084.0	1090.0	1096.0	1096.0	1096.0	1096.0
Elevation of Full Pool (feet)[2]	1,078.2	1,084.2	1,090.2	1,090.2	1,090.2	1,090.2
Capacity Increase (acre-feet)	256,000	443,000	634,000	634,000	634,000	634,000
Main Dam	Raise dam crest. Construct new parapets and utility gallery. Raise existing elevator tower and hoist tower.	Raise dam crest. Construct new parapets and utility gallery. Raise existing elevator tower and hoist tower.	Raise dam crest. Construct new parapets and utility gallery. Raise existing elevator tower and hoist tower.	Raise dam crest. Table S-1. Summary of Physical Features of Action Alternatives (contd.)

	Action Alternatives					
Main Features	**CP1**	**CP2**	**CP3**	**CP4**	**CP4A**	**CP5**
Ecosystem Enhancements	None	None	None	Reserve 378 TAF of the additional storage for cold-water supply for anadromous fish. Implement adaptive management plan to benefit anadromous fish. Augment spawning gravel in the upper Sacramento River at the rate of up to 10,000 tons per year. Restore riparian, floodplain, and side channel habitat along the upper Sacramento River.	Reserve 191 TAF of the additional storage for cold-water supply for anadromous fish. Implement adaptive management plan to benefit anadromous fish. Augment spawning gravel in the upper Sacramento River at the rate of up to 10,000 tons per year. Restore riparian, floodplain, and side channel habitat along the upper Sacramento River.	Construct shoreline fish habitat around Shasta Lake. Enhance aquatic habitat in tributaries to Shasta Lake to improve fish passage. Augment spawning gravel in the upper Sacramento River at the rate of up to 10,000 tons per year. Restore riparian, floodplain, and side channel habitat along the upper Sacramento River.

Notes:
[1] Dam crest elevations are based on the National Geodetic Vertical Datum of 1929 (NGVD29). All current feasibility-level designs and figures for Shasta Dam and appurtenant structures are based on NGVD29.
[2] Full pool elevations are based on the North American Vertical Datum of 1988 (NAVD88), which is 2.66 feet higher than NGVD29. All current feasibility-level designs and figures for reservoir area infrastructure modifications and relocations to accommodate increased water levels are based on a 2001 aerial survey of the reservoir using NAVD88.

Key:
CP = comprehensive plan
RV = recreational vehicle
TAF = thousand acre-feet
USFS = U.S. Department of Agriculture, Forest Service

CP4, CP4A, and CP5 would also include features and related construction activities associated with gravel augmentation and restoring riparian, floodplain, and side channel habitat along the upper Sacramento River. Additional features and related construction activities associated with Shasta Lake and tributary shoreline enhancements and features to increase Shasta Lake recreation opportunities are included under CP5. Figure S-5 illustrates major features in the Shasta Lake area common to all comprehensive plans.

Benefits

For all of the comprehensive plans, the additional storage would be used to increase the ability of Reclamation to regulate water temperatures for anadromous fish and increase water supply reliability, primarily in drought periods. Table S-2 summarizes the potential benefits for each project objective for each comprehensive plan. As shown in Table S-2, each of the comprehensive plans would contribute in varying degrees to all of the primary and secondary planning objectives.

S.7 Alternatives Considered and Eliminated

Formulation of a range of alternatives for evaluation in this feasibility study began with a review of problems, needs, and opportunities identified and defined previously, study authorities, and other pertinent direction, followed by development of primary and secondary planning objectives, and, finally, development of comprehensive plans (action alternatives) to meet the project purpose and need. Some project alternatives suggested during this process (e.g., raising Shasta Dam by up to 200 feet) were not retained because they did not adequately meet, or were beyond the scope of, the purpose and need statement, did not contribute to both primary planning objectives, had extremely high costs, had high social or environmental impacts, or were previously analyzed in or rejected from consideration by the CALFED agencies in the CALFED PEIS/R.

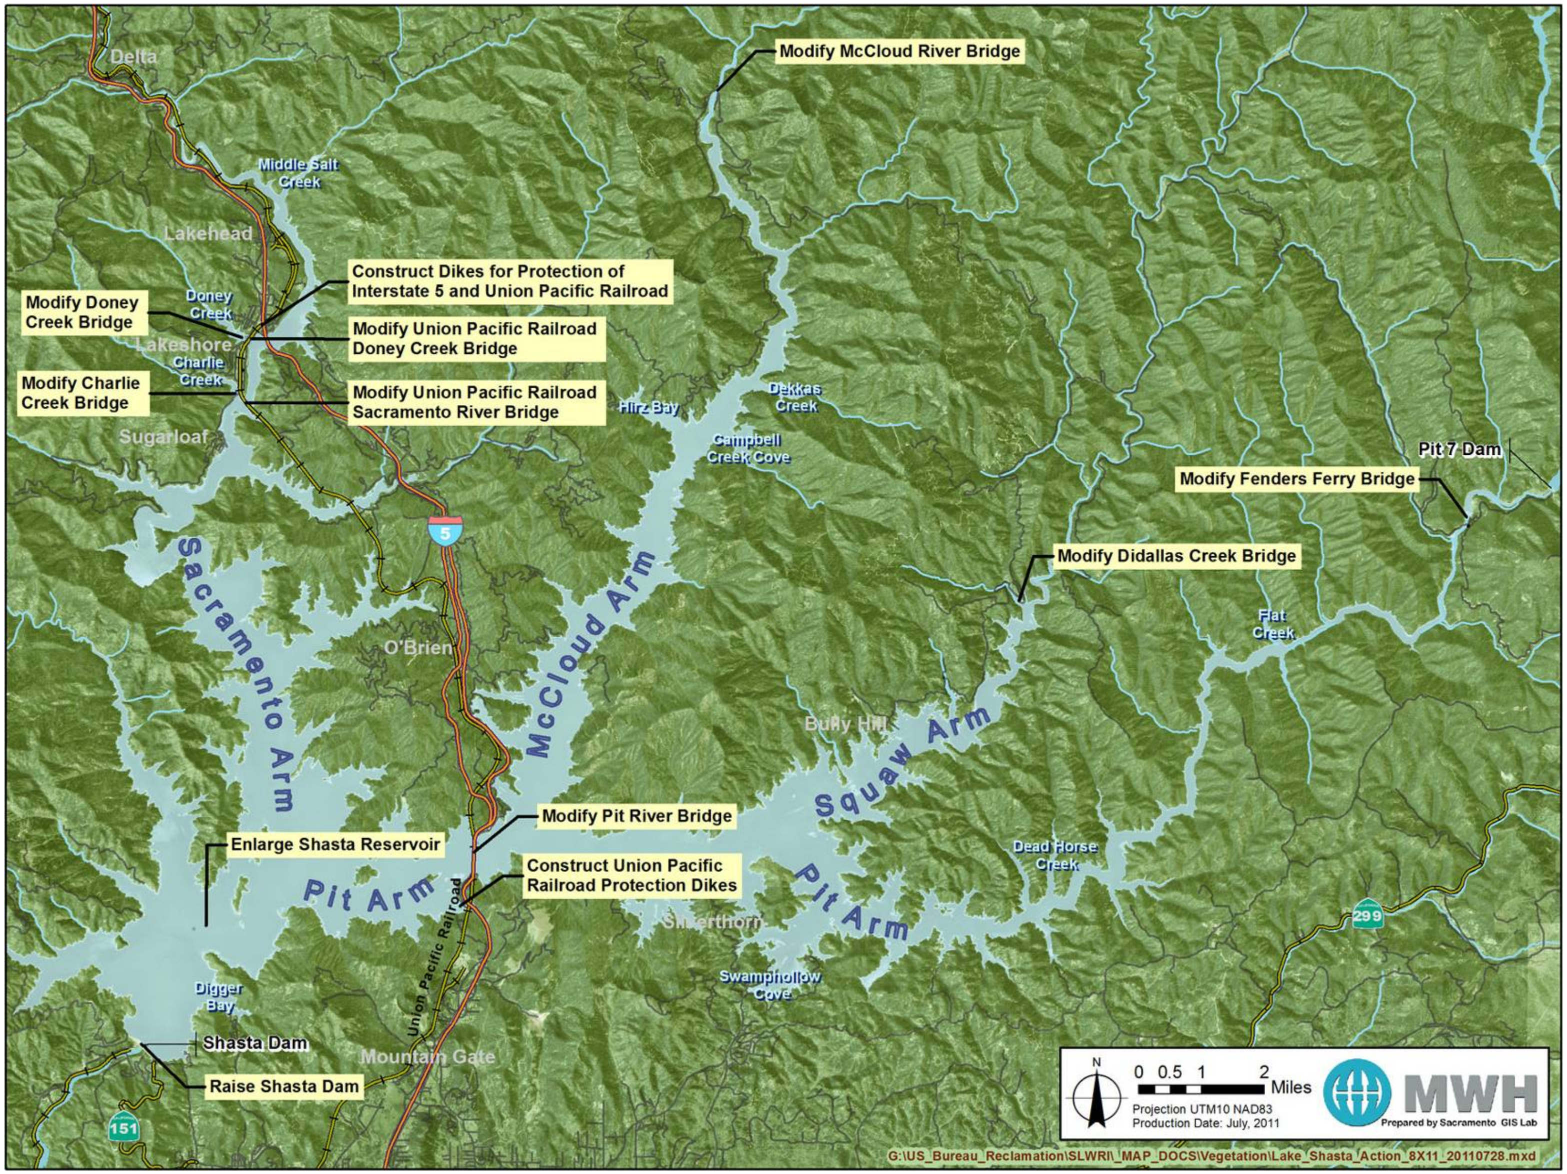

Figure S-5. Major Features Common to All Action Alternatives

Table S-2. Summary of Major Potential Benefits of Action Alternatives

Item	CP1	CP2	CP3	CP4	CP4A	CP5
Shasta Dam Raise (feet)	**6.5**	**12.5**	**18.5**	**18.5**	**18.5**	**18.5**
Total Increased Storage (TAF)	256	443	634	634	634	634
Benefits Related to Project Objectives						
Increase Anadromous Fish Survival						
Dedicated Storage (TAF)	-	-	-	378	191	-
Production Increase (thousand fish)[1]	61	379	207	813	710	378
Spawning Gravel Augmentation (tons)[2]				10,000	10,000	10,000
Side Channel Rearing Habitat Restoration				Yes	Yes	Yes
Increase Water Supply Reliability						
Total Increased Dry and Critical Year Water Supplies (TAF/year)[3]	47.3	77.8	63.1	47.3	77.8	113.5

Increased Water Use Efficiency Funding	Yes	Yes	Yes	Yes	Yes	Yes
Increased Emergency Water Supply Response Capability	Yes	Yes	Yes	Yes	Yes	Yes
Reduce Flood Damage						
Increased Reservoir Storage Capacity	Yes	Yes	Yes	Yes	Yes	Yes
Additional Hydropower Generation[4]						
Increased Hydropower Generation (GWh/year)[5]	52 - 54	87 - 90	86 - 90	127 - 133	125 - 130	112 - 117
Conserve, Restore, and Enhance Ecosystem Resources						
Shoreline Enhancement (acres)	-	-	-	-	-	130
Tributary Aquatic Habitat Enhancement (miles)[6]	-	-	-	-	-	6
Riparian, Floodplain, and Side Channel Restoration Habitat	-	-	-	Yes	Yes	Yes
Increased Ability to Meet Flow and Temperature Requirements Along Upper Sacramento River	Yes	Yes	Yes	Yes	Yes	Yes
Improve Water Quality						
Improved Delta Water Quality	Yes	Yes	Yes	Yes	Yes	Yes
Increased Delta Emergency Response Capability	Yes	Yes	Yes	Yes	Yes	Yes
Increase Recreation						
Recreation (user days, thousands)[7]	85 - 89	116 - 134	201 - 205	307 - 370	246 - 259	142 - 175
Modernization of Recreation Facilities	Yes	Yes	Yes	Yes	Yes	Yes

Table S-2. Summary of Major Potential Benefits of Action Alternatives (contd.)

Notes:

1 Numbers were derived from SALMOD and represent an index of production increase, based on the estimated average annual increase in juvenile Chinook salmon surviving to migrate downstream from Red Bluff Pumping Plant.

2 Average amount per year for 10-year period.

3 Total drought period reliability for Central Valley Project and State Water Project deliveries. Does not reflect benefits related to water use efficiency actions included in all comprehensive plans.

4 In addition to increased hydropower generation, all comprehensive plans provide increased capacity benefits (i.e., the rate at which power can be generated) and ancillary services, which provide the ability to manage the electric grid in a reliable manner.

5 Annual increased in hydropower generation were estimated using two methodologies – at load center (accounting from transmission losses) and at-plant (no transmission losses). To provide a more conservation estimate of potential hydropower benefits, load center generation values were used to estimate potential benefits of increased hydropower generation under comprehensive plans. However, increased generation values reported in Chapter 23, "Power and Energy," of this EIS are based on at-plant generation values to capture the largest potential effects from changes in hydropower generation and pumping.

6 Tributary aquatic enhancement provides for the connectivity of native fish species and other aquatic organisms between Shasta Lake and its tributaries. Estimates of benefits reflect only connectivity with perennial streams and do not reflect additional miles of connectivity with intermittent streams.

7 Annual recreation visitor user days were estimated using two methodologies. The minimum user day value was used to estimate potential recreation benefits to provide a more conservative estimate of the potential benefits of increased recreation under comprehensive plans. However, the maximum user value was used for direct and indirect effects evaluations in each resource area chapter to capture the largest potential effects from increased visitation. These values do not account for increased visitation due to modernization of recreation facilities associated with all comprehensive plans. For more detailed information related to estimated recreation user days, please see Chapter 10, "Recreational Visitation," of the Modeling Appendix.

Key:

- = not applicable
CP = comprehensive plan
Delta = Sacramento-San Joaquin Delta
GWh/year = gigawatt-hours per year
NOD = north of Delta
SOD = south of Delta
TAF = thousand acre feet

S.8 Preferred Alternative and Rationale for Selection

A plan recommending Federal action should be the plan that best addresses the targeted water resources problems considering public benefits relative to costs. It is recognized that most of the activities pursued by the Federal Government will require assessing trade-offs by decision makers and that in many cases, the final decision will require judgment regarding the appropriate extent of monetized and nonmonetized effects.

NEPA CEQ Regulations require the identification of the alternative or alternatives that are environmentally preferable in the ROD (40 CFR 1505.2(b)). The environmentally preferable alternative generally refers to the alternative that would result in the fewest adverse effects to the biological and physical environment. It is also the alternative that would best protect, preserve, and enhance historic, cultural, and natural resources. Although this environmentally preferable alternative must be identified in the ROD, it need not be selected for implementation. For the purposes of NEPA, an environmentally preferable alternative will be identified in the ROD associated with this EIS.

The preferred alternative has been identified in the Final EIS in consideration of public, stakeholder, and agency comments on the DEIS. The alternative recommended for implementation may or may not be identified as the "Environmentally Preferable Alternative" consistent with NEPA, the "Least

Environmentally Damaging Practicable Alternative" consistent with the Clean Water Act, and the "Environmentally Superior Alternative" consistent with CEQA.

Consistent with the above CEQ Regulations and NEPA guidelines, the preferred alternative for implementation has been identified in the Final EIS, as described in the following section.

S.8.1 Preferred Alternative

Each of the action alternatives – CP1, CP2, CP3, CP4, CP4A, and CP5 – includes enlarging Shasta Dam and Reservoir and a variety of management measures to address, in varying degrees, all of the project objectives. The major benefits of the action alternatives are summarized in Table S-2, and the impacts and mitigation measures are summarized in Table S-3. The cost estimates are presented in the Engineering Summary Appendix, Attachment 1, "Cost Estimates for Comprehensive Plans."

In the action alternatives, dam raises of three different heights were evaluated – 6.5 feet, 12.5 feet, and 18.5 feet. While all action alternatives provide benefits for the identified primary and secondary project objectives (to varying degrees), the overall benefits of an 18.5-foot raise (CP3, CP4, CP4A, or CP5) were found to be greater than those of either a 6.5-foot raise (CP1) or 12.5-foot raise (CP2). Therefore, only the 18.5-foot raise action alternatives were retained as possibilities for the preferred alternative. For example, the additional reservoir storage would increase from 256,000 acre-feet with the 6.5-foot raise to 634,000 acre-feet with the 18.5-foot raise – nearly 2.5 times the additional reservoir storage of the 6.5-foot raise for between 15-25 percent greater construction costs. This additional reservoir storage space would support both water supply reliability and fisheries objectives.

Reservoir operations and the resulting benefits were the differentiators amongst the 18.5-foot raise action alternatives (CP3, CP4, CP4A, or CP5). For example, CP3 would maximize agricultural water supply reliability, but would be the least beneficial to fisheries of the 18.5-foot raises. CP4 would provide the best opportunity to address anadromous fish survival in the upper Sacramento River; however, CP4 would provide the lowest benefits to water supply reliability.

Below is a summary of each action alternative weighed by Reclamation during the selection of a preferred alternative.

- CP1, formulated to address both anadromous fish survival and water supply reliability, would result in the lowest benefits of all of the action alternatives. Greater project benefits should be realized with higher dam raises for relatively low increases in costs. Therefore, CP1 was not selected as the preferred alternative.

- CP2, formulated to address both anadromous fish survival and water supply reliability, would have relatively low benefits when compared to the other action alternatives. Greater project benefits should be realized with higher dam raises for relatively low increases in costs. Therefore, CP2 was not selected as the preferred alternative.

- CP3, formulated to address both agricultural water supply reliability and anadromous fish survival, would greatly increase agricultural water supply reliability. However, CP3 would have no M&I water supply benefits and very low anadromous fish survival benefits when compared to the other 18.5-foot raises. Therefore, CP3 was not selected as the preferred alternative.

- CP5, formulated as a combination plan focusing on all objectives, would greatly increase water supply reliability. However, CP5 would have relatively low increased anadromous fish survival benefits in comparison with all other 18.5-foot raises. Therefore, CP5 was not selected as the preferred alternative.

- CP4, formulated to focus on anadromous fish survival while increasing water supply reliability, would have the highest increase in anadromous fish survival of all of the alternatives and the lowest increase in water supply reliability compared to all of the considered alternatives (equal to CP1). CP4 would not best meet both of the primary objectives; water supply reliability would be compromised for increased anadromous fish survival. Therefore, CP4 was not selected as the preferred alternative. However, the evaluation of CP4 did indicate that refinements of operations could be made to optimize the amount of water supply targeted for anadromous fish survival and water supply reliability such that both primary objectives could be substantially achieved with an 18.5-foot raise. This evaluation provided the impetus for Reclamation to develop CP4A, which performs better at simultaneously meeting both the anadromous fish survival and water reliability primary objectives.

CP4A would best balance and meet both of the primary objectives. CP4A, formulated to address both anadromous fish survival and water supply reliability, would have relatively high increases in water supply reliability (equal to CP2) and the second highest increase in anadromous fish survival of all of the alternatives. CP4A would have the ability to meet the secondary project objectives, which were considered to the extent possible through pursuit of the primary project objectives. Secondary objectives include ecosystem enhancement, flood damage reduction, improved Delta water quality, increased hydropower generation and increased recreation. As an 18.5-foot raise, CP4A would best maximize benefits relative to costs. For these reasons, CP4A is the preferred alternative.

S.9 Major Conclusions of Environmental Analysis

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is a determining factor in whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the significance of the environmental effects of a proposed project. As stated in State CEQA Guidelines, Section 15382, a "'[s]ignificant effect on the environment' means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project…"

S.9.1 Methods and Assumptions

This EIS analyzes the direct and indirect effects of the No-Action Alternative and action alternatives for each environmental resource area. Direct effects are those that would be caused by the action and would occur at the same time and place. Indirect effects are reasonably foreseeable consequences that may occur at a later time or at a distance from the project area. Examples of indirect effects are growth inducement and other effects related to changes in land use patterns, population density, or growth rate, and related effects on the physical environment.

The effects of the No-Action Alternative and action alternatives were determined by comparing estimates of resulting conditions with baseline conditions. These baseline conditions differ between NEPA and CEQA. Under NEPA, the No-Action Alternative (i.e., expected future conditions without the project) is the baseline to which the action alternatives are compared; the No-Action Alternative is also compared to existing conditions. Under CEQA, existing conditions are the baseline to which alternatives are compared.

CVP and SWP Operational Assumptions

Reclamation and DWR use CalSim-II, a specific application of the Water Resources Integrated Modeling System (WRIMS) to Central Valley water operations, to study operations, benefits, and effects of new facilities and operational parameters for the CVP and SWP. In this EIS, the quantitative assessment of actions related to water resources relied primarily on two CalSim-II baselines for CEQA and NEPA:

- "Existing cconditions," based on a 2005 level of development and current facilities, as defined in 2012 (a 2005 baseline)

- "Future cconditions," based on without-project forecasted 2020-2030 level of development and reasonably foreseeable future projects and facilities (a 2030 baseline)[3]

Operational assumptions for refinement, modeling, and evaluation of potential effects of the No-Action Alternative and action alternatives included in this EIS were derived from the 2008 Long-Term Operation BA, the 2008 USFWS BO, the 2009 NMFS BO, and the Coordinated Operations Agreement between Reclamation and DWR for the CVP and SWP, as ratified by Congress (Reclamation and DWR 1986).

Despite the uncertainty resulting from ongoing consultation processes, the 2008 Long-Term Operation BA and the 2008 and 2009 BOs issued by the fishery agencies contain the most recent estimate of potential changes in water operations that could occur in the near future. If the revised USFWS and NMFS BOs contain new or amended reasonable and prudent alternatives (RPA), such requirements may result in changes to CVP and SWP operational constraints.

Climate Change

CEQ guidance, issued February 18, 2010, suggests that Federal agencies consider opportunities to reduce greenhouse gas (GHG) emissions caused by proposed Federal actions, adapt their actions to climate change impacts throughout the NEPA process, and address these issues in the agencies' NEPA procedures. Following are the main factors to consider when addressing climate change in environmental documentation:

- Effects of a proposed action and alternative actions on GHG emissions

- Impacts of climate change on a proposed action or alternatives

CEQ notes that "significant" national policy decisions with "substantial" GHG impacts require analysis of their GHG effects. That is, the GHG effects of a Federal agency's proposed action must be analyzed if the action would cause "substantial" annual direct emissions; would implement energy conservation or reduced energy use or GHG emissions; or would promote cleaner, more efficient renewable-energy technologies.

Each resource area analyzed in the EIS evaluates the effects the action alternatives and No-Action Alternative combined with predicted effects of climate change. The ways that the SLWRI could affect GHG production are

[3] The level of development used for future conditions is a composite of multiple land use scenarios developed by DWR and Reclamation. The Sacramento Valley hydrology, which includes the Sacramento and Feather River basins, is based on projected 2020 land use assumptions associated with DWR Bulletin 160-98 (1998) and the San Joaquin Valley hydrology is based on the 2030 land use assumptions developed by Reclamation. Under any 2020 to 2030 level of development scenario, the majority of the CVP and SWP unmet demand is located south of the Delta, including the San Joaquin Valley. Please see Table 2-1 in the Modeling Appendix for additional information on CalSim-II modeling assumptions.

also addressed. The Climate Change Modeling Appendix provides a summary of global climate forecasts and a discussion of the implications of climate change for California water resources. This appendix also includes quantitative analyses of climate change for selected comprehensive plans on resource areas. The discussion of climate change implications provided in the Climate Change Modeling Appendix provides context for consideration of cumulative conditions.

S.9.2 Summary of Impacts

The action alternatives would affect environmental resources in the primary and extended study areas. Some of the impacts would be temporary, construction-related effects that would be less than significant or would be reduced to less-than-significant levels through mitigation. Other impacts would be permanent, some of which would remain significant and unavoidable despite proposed mitigation measures. In addition, some effects of the project would be beneficial. Under CEQA, potentially significant impacts are treated as significant impacts. Therefore, consistent with CEQA, unless feasible mitigation measures have been identified to reduce the magnitude of a significant or potentially significant impact to less than significant, the level of significance after mitigation is considered significant and unavoidable.

Table S-3, included at the end of this Summary, summarizes the environmental impacts of the action alternatives, the duration and quantification of each impact, the level of significance of each impact before mitigation, recommended mitigation measures, and the level of significance of each impact after mitigation.

S.9.3 Significant and Unavoidable Impacts

As shown in Table S-3, after consideration of actions, operations, and features to avoid, mitigate, and/or compensate for adverse effects, the action alternatives would likely result in the following significant and unavoidable direct and indirect impacts:

- **Geology, Geomorphology, Minerals, and Soils –** Loss or diminished availability of known mineral resources that would be of future value to the region; lost or diminished soil biomass productivity; and substantial soil erosion or loss of topsoil due to shoreline processes (all action alternatives).

- **Air Quality and Climate –** Short-term emissions of criteria air pollutants and precursors at Shasta Lake and vicinity during project construction (all action alternatives).

- **Agriculture and Important Farmland –** Direct and indirect conversion of forest land to nonforest uses in the vicinity of Shasta Lake (all action alternatives).

- **Botanical Resources and Wetlands** – Loss of Multi-Species Conservation Strategy covered species; loss of USFS sensitive, U.S. Department of Interior, Bureau of Land Management, sensitive, or California Rare Plant Rank species; loss of jurisdictional waters; and loss of general vegetation habitats (all action alternatives).

- **Wildlife Resources** – Take and loss of habitats for the Shasta salamander, bald eagle, northern spotted owl, and Pacific fisher; impact on the foothill yellow-legged frog, tailed frog, northwestern pond turtle, purple martin, special-status bats, American marten, ringtail, terrestrial mollusks, and their habitat; impact on willow flycatcher, Vaux's swift, yellow warbler, yellow-breasted chat, long-eared owl, northern goshawk, Cooper's hawk, great blue heron, and osprey, and their foraging and nesting habitat; permanent loss of general wildlife habitat; take and loss of foraging and nesting habitat for other birds of prey and migratory bird species; and loss of critical deer winter and fawning range (all action alternatives).

- **Cultural Resources –** Inundation of Traditional Cultural Properties (all action alternatives).

- **Land Use and Planning –** Conflict with existing land use goals and policies of affected jurisdictions (Shasta Lake and vicinity and upper Sacramento River), and disruption of existing land uses (Shasta Lake and vicinity and upper Sacramento River) (all action alternatives).

- **Aesthetics and Visual Resources –** Inconsistency with guidelines for visual resources in the USFS 1995 Shasta-Trinity National Forest Land and Resource Management Plan, degradation and/or obstruction of a scenic view from key observation points, and generation of increased daytime glare and/or nighttime lighting (all action alternatives).

- **Wild and Scenic River Considerations for McCloud River –** Effect on McCloud River's eligibility for listing as a Federal Wild and Scenic River and effects to McCloud River resources identified in the California Public Resources Code, Section 5093.542 (all action alternatives).

The action alternatives could also result in the following significant and unavoidable cumulative impacts (i.e., an impact would make a considerable contribution to a significant cumulative effect):

- **Geology, Geomorphology, Minerals, and Soils –** Cumulative effects from use of soil and mineral resources, leading to diminished regional availability of cement, concrete sand, and aggregate and loss of soil productivity (all action alternatives).

- **Air Quality and Climate –** Cumulative effects from emissions of nitrous oxide (NO_x) during project construction (all action alternatives).

- **Hydrology, Hydraulics, and Water Management –** Cumulative effects on south Delta water levels, X2 position, and Delta outflow (all action alternatives).

- **Botanical Resources and Wetlands –** Cumulative effects from inundation at Shasta Lake, leading to take and loss of habitat for special-status species at Shasta Lake and vicinity; cumulative effects from increased water delivery in the service areas and growth-related loss of sensitive plant communities and special-status plant species (all action alternatives).

- **Wildlife Resources –** Cumulative effects from inundation at Shasta Lake, leading to take and loss of habitat for numerous special-status species at Shasta Lake and vicinity (all action alternatives).

- **Cultural Resources –** Inundation of Traditional Cultural Properties (all action alternatives).

- **Power and Energy Resources –** Changes to net energy values due to energy use for CVP and SWP pumping, and loss of generation (CP1).

- **Aesthetics and Visual Resources –** Changes to aesthetic values and resources at Shasta Lake (all action alternatives).

- **Environmental Justice –** Cumulative effects from disproportionate placement of environmental impacts on Native American populations, leading to disturbance or loss of resources associated with locations considered by the Winnemem Wintu and Pit River Madesi Band members to have religious and cultural significance in the vicinity of Shasta Lake (all action alternatives).

S.9.4 Environmental Commitments

As part of project planning and environmental assessment, Reclamation has incorporated certain environmental commitments and best management practices into the action alternatives to avoid or minimize potential impacts. Reclamation will also coordinate planning, engineering, design and construction, operation, and maintenance phases of the any authorized project modifications with applicable resource agencies and potentially affected public and private landowners, communities, and individuals.

The following environmental commitments would be incorporated into any action alternative for any project-related construction activities:

- Develop and implement a construction management plan to avoid or minimize potential impacts to public health and safety during project construction (e.g., procedures for stockpiling and staging, public access routes, and construction notification).

- Comply with applicable laws, policies, and plans for this project, including all terms and conditions of all required project permits, approvals, and conditions attached thereto.

- Provide relocation assistance services for displaced individuals, families, businesses, and private property owners in accordance with the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended.

- Remain consistent with USFS Built Environment Image Guide for any facilities subject to USFS authorization that are constructed or reconstructed facilities.

- Protect all Public Land Survey System monuments and associated references and all property corners, either by positioning, or, where necessary, creating new references.

- Evaluate and protect paleontological resources discovered during construction.

- Develop and implement a stormwater pollution prevention plan to prevent or minimize the discharge of sediments and other contaminants with the potential to affect beneficial uses or lead to violations of water quality objectives of surface waters.

  – Develop and implement an erosion and sediment control plan to control short-term and long-term erosion and sedimentation effects, and to stabilize soils and vegetation in areas affected by construction activities.

  – Develop and implement a feasible spill prevention and hazardous materials management plan to minimize effects from spills of hazardous, toxic, or petroleum substances for project-related activities occurring in or near waterways.

- Implement efforts to minimize potential adverse effects to water quality, including:

  – Implement in-water construction work windows to occur when instream flows are managed outside the flood season (e.g., June 15 to September 15).

   - Comply with all additional requirements specified in permits relating to water quality protection.
   - Implement best management practices (BMP) to avoid and/or minimize potential impacts to water quality associated with construction and the 10-year-long spawning gravel augmentation program. These BMPs include:
      - Handle spawning gravel to minimize potential water quality impact.
      - Minimize potential impacts associated with equipment contaminants.
      - Implement feasible spill prevention and hazardous materials management.
      - Minimize potential impacts associated with access and staging.
      - Remove temporary fills as appropriate.
      - Remove equipment from river overnight and during high flows.
- Extend and enhance existing fish habitat structures in Shasta Lake through the placement of manzanita brush structures and vegetation cleared for construction to maintain shallow water and transitional riverine habitat.
- Maintain shallow-water and transitional riverine habitat with placement of manzanita brush structures, large woody debris, and rock-boulder clusters for established USFS habitat program.
- Implement fisheries conservation efforts to minimize potential adverse effects on fish species, including:
   - Implement in-water construction work windows to occur when sensitive fish species are not present, or would be least susceptible to disturbance. In-river work between Keswick Dam and the RBPP would be conducted to minimize impacts to Sacramento River winter-run Chinook salmon, i.e., mid-August through September.
   - Monitor potential impacts to important fishery resources throughout all phases of project construction.
   - Perform fish rescue/salvage for fish entrapped within construction structures and cofferdam enclosures, and stop construction activities for spawning activities for sensitive fish species.

  - Prepare a letter report detailing the methodologies used and the findings of fish monitoring and rescue efforts.

- Survey and monitor fish migration between Shasta Lake and Squaw Creek to determine if warm-water fish (bass) actively migrate into and cause adverse effects on native fish, amphibians, and mollusks.

- Prepare a comprehensive revegetation plan to be implemented in conjunction with other management plans (e.g., erosion and sediment control plan).

- Develop and require implementation of a control plan to prevent the introduction of zebra/quagga mussels, invasive plants, and other invasive species to project areas.

- Prepare and implement a fire protection and prevention plan to minimize the risk of wildfire or threat to workers, property, and the public.

- Recycle or reuse demolished construction materials where practical. To reduce risk associated with exposure to hazardous materials and waste:

  - Implement a Hazardous Materials Business Plan (HMBP) to provide information regarding hazardous materials to be used for project implementation and hazardous waste that may be generated.

  - Dispose of soil at a landfill or recycling facilities, transported by a licensed waste hauler.

  - Review all relevant available asbestos survey and abatement reports and supplemental asbestos surveys. Removal and disposal of asbestos-containing materials would be performed in accordance with applicable Federal, State, and local regulations.

  - Conduct a lead-based paint survey to determine areas where lead-based paint is present and the possible need for abatement before construction.

- Demolish and remove all asphaltic roadways and parking lots inundated by the proposed Shasta Dam raise, per California Fish and Game Code 5650 Section (a).

The environmental commitment section of the DEIS included a commitment to develop and implement a mitigation plan to minimize potential impacts to physical, biological, and socioeconomic resources. In conjunction with an interagency, interdisciplinary team, Reclamation refined and enhanced the mitigation measures, including development of a framework to quantify impacts (where appropriate) and establish mitigation ratios that were applicable to a number of impacts related to biological resources. The result of the development of the mitigation plan is documented in the Preliminary Environmental Commitments and Mitigation Plan (an appendix to this EIS).

S.10 Areas of Controversy

Federal, State, and local stakeholders identified several areas of controversy during SLWRI public outreach activities, including public scoping activities, agency meetings and workshops, and related ongoing stakeholder outreach activities. Key topics include potential adverse effects on cultural resources in the Shasta Lake area; recreation and recreation providers in the Whiskeytown-Shasta-Trinity NRA; the lower McCloud River and its special designation under California Public Resources Code Section 5093.542(c); impacts on reservoir area property owners; terrestrial special-status species around Shasta Lake, including State-designated fully protected species; fishery and riparian habitat resources along the upper Sacramento River; aquatic special-status species in the Sacramento River and Delta (including delta smelt); Delta water quality and south Delta water levels; Central Valley hydrology below CVP and SWP facilities and resulting effects on water supplies for water contractors and other water users; and assumptions on CVP and SWP regulatory constraints based on the 2008 USFWS BO and 2009 NMFS BO (discussed above).

S.11 Public Involvement and Next Steps

In accordance with NEPA review requirements, the DEIS was released for public and agency review and comment for a 90-day period. The comment period on the DEIS began on July 1, 2013, and closed on September 30, 2013. Written and verbal comments on the DEIS were accepted at three public workshops and three public hearings, and written comments were accepted throughout the comment period.

More than 5,000 comments were received on the DEIS from elected officials; federal, state, and tribal governments; regional and local governments and agencies; special interest groups, and individuals. The public comments have been reviewed and, in accordance with NEPA CEQ Regulations, responses have been developed for all substantive comments and revision of the DEIS have been made to clarify and enhance the text to produce this Final EIS.

Reclamation posted the Final EIS at http://www.usbr.gov/mp/slwri for public review and issued a notice in the Federal Register and a press release of the Final EIS. Also, elected officials and representatives, government agencies, private organizations, businesses, and individual members of the public on the mailing list have received a copy of this document or a notification of document availability.

The Final EIS and Final Feasibility Report will be used together to support the Federal decision. Typically, a ROD is the final step in the NEPA process and would document any decision on which actions, if any, to take to address the primary objectives.

The Final EIS, Final Feasibility Report, and supporting documents will be submitted by the Principal Deputy Commissioner of Reclamation to the Secretary of the Interior. After review by the Office of Management and Budget, in accordance with Executive Order 12322, the Secretary will transmit a Final EIS and Final Feasibility Report to the U.S. Congress to determine the type and extent of Federal interest in enlarging Shasta Dam and Reservoir if a plan is recommended for implementation. The proposed project would be considered for authorization by Congress and, if authorized, a separate appropriation authorization would be required. The project would be considered for inclusion in the President's budget based on (1) national priorities, (2) magnitude of the Federal commitment, (3) level of local support, (4) willingness of the non-Federal sponsor to fund its share of the project costs, and (5) budgetary constraints that may exist at the time of construction.

While this Final EIS has been prepared in consideration of CEQA requirements, to-date, formal CEQA scoping has not been initiated. This process may commence if and when a State lead agency is identified.

Table S-3. Summary of Impacts and Mitigation Measures

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Geology, Geomorphology, Minerals, and Soils						
Impact Geo-1: Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruptions	N-A	NA	–	NI	NA	NI
	CP1–CP5	Long-term	Pool level increase would inundate 78 acres (CP1), 110 acres (CP2), or 173 acres (CP3, CP4,CP4A and CP5) of mapped slope instability hazard	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Geo-2: Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats	N-A	NA	–	NI	NA	NI
	CP1–CP5	Long-term	–	S	Mitigation Measure Geo-2: Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact.	LTS
Impact Geo-3: Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region	N-A	NA	–	NI	NA	NI
	CP1–CP5	Long-term	–	S	No feasible mitigation is available to reduce impact.	SU

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Geo-4: Lost or Diminished Soil Biomass Productivity	N-A	NA	–	NI	NA	NI
	CP1	Long-term	Loss of 1,954.6 acres of moderate productivity land; 1604.5 acres of low productivity land; 565 acres of nonproductive land	S	No feasible mitigation is available to reduce impact.	SU
	CP2	Long-term	Loss of 2,128 acres of moderate productivity land; 1,751 acres of low productivity land; 638 acres of nonproductive land	S	No feasible mitigation is available to reduce impact.	SU
	CP3–CP5	Long-term	Loss of 2,301 acres of moderate productivity land; 2,092 acres of low productivity land; 760 acres of nonproductive land	S	No feasible mitigation is available to reduce impact.	SU
Impact Geo-5: Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes	N-A	NA	–	NI	NA	NI
	CP1	Short-term and long-term	Soil erosion of approximately 421,000 cubic yards per year for the first 15 years	S	No feasible mitigation is available to reduce impact.	SU
	CP2	Short-term and long-term	Soil erosion of approximately 549,000 cubic yards per year for the first 15 years	S	No feasible mitigation is available to reduce impact.	SU
	CP3-CP5	Short-term and long-term	Soil erosion of approximately 767,000 cubic yards per year for the first 15 years	S	No feasible mitigation is available to reduce impact.	SU
Impact Geo-6: Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes	N-A	NA	–	NI	NA	NI
	CP1–CP5	Long-term	Up to approximately 3,340 acres in the upland portion of the Shasta Lake and vicinity area could be disturbed	LTS	No mitigation needed; thus, none proposed.	LTS

Notes:
1 Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
2 NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
3 NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.

[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact AQ-2: Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation	N-A,	Long-term	–	LTS	NA	LTS
	CP1,	Long-term	Increase of an average of 158 one-way daily trips	LTS	No mitigation needed, thus none proposed.	LTS
	CP2	Long-term	Increase of an average of 238 one-way daily trips	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3	Long-term	Increase of an average of 364 one-way daily trips	LTS	No mitigation needed; thus, none proposed.	LTS
	CP4	Long-term	Increase of an average of 658 one-way daily trips	LTS	No mitigation needed; thus, none proposed.	LTS
	CP4A	Long-term	Increase of an average of 460 one-way daily trips	LTS	No mitigation needed; thus, none proposed.	LTS
	CP5	Long-term	Increase of an average of 311 one-way daily trips	LTS	No mitigation needed; thus, none proposed.	LTS
Impact AQ-3: Exposure of Sensitive Receptors to Substantial Pollutant Concentrations	N-A	NA	–	NI	NA	NI
	CP1–CP5	Short-term and long-term	Exposure to CO, PM_{10}, $PM_{2.5}$, diesel PM	LTS	No mitigation needed; thus, none proposed.	LTS
Impact AQ-4: Exposure of Sensitive Receptors to Odor Emissions	N-A	NA	–	NI	NA	NI
	CP1–CP5	Short-term and long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact AQ-5: Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction	N-A,	NA	–	NI	NA	NI
	CP1–CP3	Short-term	–	NI	No mitigation needed; thus, none proposed.	NI
	CP4–CP5	Short-term	Would add an additional 1 lb/day of ROG, 16 lb/day of NO_X, & 1 lb/day of PM_{10} to construction	LTS	No mitigation needed; thus, none proposed.	LTS
Impact AQ-6: Generation of Greenhouse Gases	N-A	NA	–	LTS	NA	LTS
	CP1–CP5	Short-term	Emission of 15,100 to 83,400 metric tons CO_2e	LTS	No mitigation needed; thus, none proposed.	LTS
Hydrology, Hydraulics, and Water Management						
Impact H&H-1: Change in Frequency of Flows Above 100,000 cfs on the Sacramento River Below Bend Bridge	N-A	NA	–	NI	NA	NI
	CP1–CP5	Long-term	–	B	No mitigation needed; thus, none proposed.	B
Impact H&H-2: Place Housing or Other Structures Within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map	N-A	NA	–	NI	NA	NI
	CP1–CP5	NA	–	NI	No mitigation needed; thus, none proposed.	NI

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact H&H-3: Place Within a 100-Year Flood Hazard Area Structures That Would Impede or Redirect Flood Flows	N-A	NA	–	NI	NA	NI
	CP1–CP5	NA	–	NI	No mitigation needed; thus, none proposed.	NI
Impact H&H-4: Change in Water Levels in the Old River near Tracy Road Bridge	N-A	Long-term	Lower water levels	LTS	NA	LTS
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
H&H-5: Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier	N-A	Long-term	Lower water levels	LTS	NA	LTS
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact H&H-6: Change in Water Levels in the Middle River near the Howard Road Bridge	N-A	Long-term	Lower water levels	LTS	NA	LTS
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact H&H-7: Change in X2 Position	N-A	NA	–	NI	NA	NI
	CP1 & CP4	NA	–	NI	No mitigation needed; thus, none proposed.	NI
	CP2, CP3, CP4A, & CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact H&H-8: Change in Recurrence of Delta Excess Conditions	N-A	Long-term	Reduced frequency	LTS	NA	LTS
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact H&H-9: Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges	N-A	Long-term	Reduced frequency	PS	NA	PS
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact H&H-10: Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges	N-A	Long-term	Reduced frequency	PS	NA	PS
	CP1, CP3–CP5	Long-term	–	B	No mitigation needed; thus, none proposed.	B
	CP2	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact H&H-11: Change in Deliveries to SWP Table A, Contractors	N-A	Long-term	Reduced frequency	B	NA	B
	CP1–CP5	Long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact H&H-12: Change in Groundwater	N-A	NA	–	LTS	NA	LTS
	CP1–CP5	Short-term and long-term	Increased groundwater levels	B	No mitigation needed; thus, none proposed.	B
Impact H&H-13: Change in Groundwater Quality	N-A	Short-term and long-term	–	LTS	NA	LTS
	CP1–CP5	Short-term and long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Water Quality						
Impact WQ-1: Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses	N-A	NA	–	NI	NA	NI
	CP1	Short-term	Short-term changes in the amount of exposed area that would be subject to erosion	PS	Mitigation Measure WQ-1: Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area.	LTS
	CP2	Short-term	Similar to CP1, but greater area and longer duration	PS	Mitigation Measure WQ-1: Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area.	LTS
	CP3–CP5	Short-term	Similar to CP1 and CP2, but greater area and longer duration	PS	Mitigation Measure WQ-1: Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact WQ-2: Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses	N-A	NA	–	NI	NA	NI
	CP1	Short-term	Some areas potentially subject to surface disturbance, including jurisdictional waters	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Short-term	Similar to CP1, but greater area and longer duration	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3–CP5	Short-term	Similar to CP1 and CP2, but greater area and longer duration	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-3: Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses	N-A	NA	–	NI	NA	NI
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact WQ-4: Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries	N-A	NA	–	NI	NA	NI
	CP1–CP5	Long-term	–	PS	Mitigation Measure WQ-4: Implement Mitigation Measure WQ-1 (CP1): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area.	LTS

Notes:

[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.

[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.

[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.

[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.

[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact WQ-5: Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries	N-A	NA	–	NI	NA	NI
	CP1	Long-term	5 percent increase in the end-of-month storage on an annual basis compared to No-Action Alternative	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2	Long-term	10 percent increase in the end-of-month storage on an annual basis compared to No-Action Alternative	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3	Long-term	14 percent increase in the end-of-month storage on an annual basis compared to No-Action Alternative	LTS	No mitigation needed; thus, none proposed.	LTS
	CP4	Long-term	17 percent increase in the end-of-month storage on an annual basis compared to No-Action Alternative	LTS	No mitigation needed; thus, none proposed.	LTS
	CP4A	Long-term	16 percent increase in the end-of-month storage on an annual basis compared to No-Action Alternative	LTS	No mitigation needed; thus, none proposed.	LTS
	CP5	Long-term	13 percent increase in the end-of-month storage on an annual basis compared to No-Action Alternative	LTS	No mitigation needed; thus, none proposed.	LTS
WQ-6: Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries	N-A	NA	–	LTS	NA	LTS
	CP1–CP5	Long-term	–	PS	Mitigation Measure WQ-6: Prepare and Implement a Site-Specific Remediation Plan for Historic Mine Features Subject to Inundation in the Vicinity of the Bully Hill and Rising Star Mines.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact WQ-7: Temporary Construction-Related Sediment Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses	N-A	NA	–	NI	NA	NI
	CP1–CP3	Temporary	–	PS	Mitigation Measure WQ-7 (CP1–CP3): Implement Mitigation Measure WQ-1 (CP1): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area.	LTS
	CP4 & CP4A	Temporary	Similar to CP1–CP3, but greater	PS	Mitigation Measure WQ-7 (CP4): Implement Mitigation Measure WQ-1 (CP1): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area.	LTS
	CP5	Temporary	Similar to CP4, but greater	PS	Mitigation Measure WQ-7 (CP5): Implement Mitigation Measure WQ-1 (CP1): Develop and Implement a Comprehensive Multi-scale Sediment Reduction and Water Quality Improvement Program Within Watersheds Tributary to the Primary Study Area.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.

[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact WQ-20: X2 Position	N-A	NA	–	PS	NA	SU
	CP1–CP5	Long-term	No increase in number of months in which X2 is out of compliance in extended study area (Delta)	LTS	No mitigation needed; thus, none proposed.	LTS
Noise and Vibration						
Impact Noise-1: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Construction Noise	N-A	Long-term	–	LTS	NA	LTS
	CP1–CP3	Short-term	On-site heavy duty construction equipment at other project sites – exterior noise levels at noise-sensitive receptors located within 75 – 7,000 feet of construction activity could exceed applicable standards	S	Mitigation Measure Noise-1: Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites.	LTS
	CP4–CP5	Short-term	Similar to CP1–CP3, but greater noise related to gravel augmentation and habitat restoration along the upper Sacramento River	S	Mitigation Measure Noise-1: Implement Measures to Prevent Exposure of Sensitive Receptors to Temporary Construction Noise at Project Construction Sites.	LTS
Impact Noise-2: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Vibration During Construction	N-A	Long-term	–	LTS	NA	LTS
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Noise-3: Exposure of Sensitive Receptors in the Primary Study Area to Project-Generated Mobile Source Noise During Operations	N-A	Long-term	–	LTS	NA	LTS
	CP1–CP5	Short-term and long-term	–	LTS	No mitigation needed; thus, none proposed.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Hazards and Hazardous Materials and Waste						
Impact Haz-1: Wildland Fire Risk (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	–	NI	NA	NI
	CP1	Short-term	Increased risk of ignition during construction	PS	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.	LTS
	CP2	Short-term	Similar to CP1, but greater and longer construction duration	PS	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.	LTS
	CP3	Short-term	Similar to CP1 & CP2, but greater and longer construction duration	PS	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.	LTS
	CP4–CP5	Short-term	Similar to CP3, but greater and longer construction duration	PS	Mitigation Measure Haz-1: Coordinate and Assist Public Services Agencies to Reduce Fire Hazards.	LTS
Impact Haz-2: Release of Potentially Hazardous Materials or Hazardous Waste (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	–	NI	NA	NI
	CP1	Short-term	Risk of release of hazardous materials during construction	PS	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.	LTS
	CP2	Short-term	Similar to CP1, but greater and longer construction duration	PS	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.	LTS
	CP3	Short-term	Similar to CP1 & CP2, but greater and longer construction duration	PS	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.	LTS
	CP4–CP5	Short-term	Similar to CP3, but greater construction	PS	Mitigation Measure Haz-2: Reduce Potential for Release of Hazardous Materials and Waste.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.

Impact Wild-8: Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat	N-A	NA	–	NI	NA	NI
	CP1	Short-term and permanent	Loss of nests and habitat	PS	Mitigation Measure Wild-8: Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers.	SU
	CP2	Short-term and permanent	Similar to CP1, but greater (larger area of inundation)	PS	Mitigation Measure Wild-8: Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers.	SU

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Wild-8: Impacts on the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Their Foraging and Nesting Habitat (contd.)	CP3–CP5	Short-term and permanent	Similar to CP1 & CP2, but greater (larger area of inundation)	PS	Mitigation Measure Wild-8: Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Willow Flycatcher, Vaux's Swift, Yellow Warbler, and Yellow-Breasted Chat and Establish Buffers.	SU
Impact Wild-9: Impacts on the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Their Foraging and Nesting Habitat	N-A	NA	–	NI	NA	NI
	CP1	Short-term and permanent	Loss of nests and habitat	PS	Mitigation Measure Wild-9: Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers.	SU
	CP2	Short-term and permanent	Similar to CP1, but greater (larger area of inundation)	PS	Mitigation Measure Wild-9: Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers.	SU
	CP3–CP5	Short-term and permanent	Similar to CP1 & CP2, but greater (larger area of inundation)	PS	Mitigation Measure Wild-9: Acquire and Preserve Mitigation Lands; Conduct a Preconstruction Survey for the Long-Eared Owl, Northern Goshawk, Cooper's Hawk, Great Blue Heron, and Osprey and Establish Buffers.	SU

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. “–“ = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Socio-4 (No-Action): Potential for Temporary Disruptions in Business and Industrial Activity in the CVP and SWP Service Areas Impact Socio-4 (CP1–CP5): Short-Term Increases in Direct, Indirect, and Induced Personal Income Paid to Employees in the Primary Study Area Hired for Construction-Related Activities	N-A	Temporary	Potential water or power supply disruptions	PS	NA	PS
	CP1	Short-term	$134.2 million in personal annual incomes in the local economic study area	B	No mitigation needed; thus, none proposed.	B
	CP2	Short-term	$132.8million in personal annual incomes	B	No mitigation needed; thus, none proposed.	B
	CP3	Short-term	$153.3 million in personal annual incomes	B	No mitigation needed; thus, none proposed.	B
	CP4	Short-term	$154.2 million in personal annual incomes	B	No mitigation needed; thus, none proposed.	B
	CP4 A	Short-term	$154.3 million in personal annual incomes			
	CP5	Short-term	$156.5 million in personal annual incomes	B	No mitigation needed; thus, none proposed.	B
Impact Socio-5: Short-Term Increases in Sales and Profits for Businesses in the Primary Study Area that Support the Construction Industry	N-A	NA	–	NA	NA	NA
	CP1	Short-term	– (4.5-year construction period)	B	No mitigation needed; thus, none proposed.	B
	CP2	Short-term	Similar to CP1, but more beneficial (5-year construction period)	B	No mitigation needed; thus, none proposed.	B
	CP3–CP5	Short-term	Similar to CP1 & CP2, but more beneficial (5-year construction period)	B	No mitigation needed; thus, none proposed.	B

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Socio-6: Short-Term Increase in State and Local Sales Tax Revenues in the Primary Study Area from Construction-Related Personal Income and Purchases	N-A	NA	–	NA	NA	NA
	CP1	Short-term	Increased personal income, direct income and indirect and induced income during the construction period	B	No mitigation needed; thus, none proposed.	B
	CP2	Short-term	Similar to, but more beneficial than CP1	B	No mitigation needed; thus, none proposed.	B
	CP3	Short-term	Similar to, but more beneficial than CP2	B	No mitigation needed; thus, none proposed.	B
	CP4-CP5	Short-term	Similar to, but more beneficial than CP3	B	No mitigation needed; thus, none proposed.	B
Impact Socio-7: Long-Term Reduction in the Adverse Economic Effects of Flooding in the Primary Study Area	N-A	NA	–	NA	NA	NA
	CP1	Long-term	Reduced risk of flooding below Shasta Dam	B	No mitigation needed; thus, none proposed.	B
	CP2	Long-term	Similar to, but more beneficial than CP1	B	No mitigation needed; thus, none proposed.	B
	CP3–CP5	Long-term	Similar to, but more beneficial than CP1 & CP2	B	No mitigation needed; thus, none proposed.	B
Impact Socio-8: Long-Term Increases in Direct Employment in the Primary Study Area Related to Project Operations	N-A	NA	–	NA	NA	NA
	CP1–CP5	Long-term	Two or more new maintenance-related positions for the Shasta Dam facilities	B	No mitigation needed; thus, none proposed.	B

Notes:

[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.

[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.

[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.

[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.

[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Socio-9: Potential Temporary Increase in Indirect Employment in Construction-Related Businesses of the Lower Sacramento River and Delta	N-A	NA	–	NA	NA	NA
	CP1	Short-term	Temporary increase in short-term, construction-related, State sales and income tax revenues	B	No mitigation needed; thus, none proposed.	B
	CP2	Short-term	Similar to CP1, but more beneficial than CP1	B	No mitigation needed; thus, none proposed.	B
	CP3–CP5	Short-term	Similar to, but more beneficial than CP1 & CP2	B	No mitigation needed; thus, none proposed.	B
Impact Socio-10: Short-Term Increases in Sales and Profits for Businesses in the Lower Sacramento River and Delta Area That Support the Construction Industry	N-A	NA	–	NA	NA	NA
	CP1	Short-term	Some local purchase of construction materials	B	No mitigation needed; thus, none proposed.	B
	CP2	Short-term	Similar to CP1, but more beneficial	B	No mitigation needed; thus, none proposed.	B
	CP3–CP5	Short-term	Similar to CP1 & CP2, but more beneficial	B	No mitigation needed; thus, none proposed.	B
Impact Socio-11: Short-Term Increase in State Sales and Income Tax Revenues in the Lower Sacramento River and Delta Area from Construction-Related Personal Income and Purchases	N-A	NA	–	NA	NA	NA
	CP1	Short-term	Short-term increase in State sales and income tax revenues	B	No mitigation needed; thus, none proposed.	B
	CP2	Short-term	Similar to CP1, but more beneficial	B	No mitigation needed; thus, none proposed.	B
	CP3–CP5	Short-term	Similar to CP1 & CP2, but more beneficial	B	No mitigation needed; thus, none proposed.	B

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Rec-11 (CP1–CP5): Changes in Usability of Reading Island Fishing Access Boat Ramp and Enhanced Recreation at Upper Sacramento River Restoration Sites	N-A	NA	–	NI	NA	NI
	CP1–CP3	Long-term	–	NI	No mitigation needed; thus, none proposed.	NI
	CP4–CP5	Long-term	–	B	No mitigation needed; thus, none proposed.	B
Impact Rec-12 (CP1–CP5): Seasonal Inundation of Portions of River Recreation Facilities or Informal River Access Sites on the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows	N-A	NA	–	NI	NA	NI
	CP1 & CP4	Long-term	Flows would increase but would remain below winter and spring high flows experienced in most years –	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2 & CP4A	Long-term	Similar to CP1, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3	Long-term	Similar to CP1 & CP2, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP5	Long-term	Similar to CP1, CP2, & CP3, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Rec-13 (CP1–CP5): Increased Difficulty for Boaters in Using the Lower Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows	N-A	NA	–	NI	NA	NI
	CP1 & CP4	Long-term	Increased mean monthly flows within the extended study area	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2 & CP4A	Long-term	Similar to CP1, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3	Long-term	Similar to CP1 & CP2, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP5	Long-term	Similar to CP1, CP2, & CP3, but greater	LTS	No mitigation needed; thus, none proposed.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Rec-14 (CP1–CP5): Increased Difficulty for Swimmers and Waders in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Increased River Flows	N-A	NA	–	NI	NA	NI
	CP1 & CP4	Long-term	Increased mean monthly flows within the extended study area	LTS	No mitigation needed; thus, none proposed.	LTS
	CP2 & CP4A	Long-term	Similar to CP1, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP3	Long-term	Similar to CP1 & CP2, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
	CP5	Long-term	Similar to CP1, CP2, & CP3, but greater	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Rec-15 (CP1–CP5): Increased Difficulty for Boaters and Anglers in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Decreased River Flows	N-A	NA	–	NI	NA	NI
	CP1 & CP4	Long-term	Increased mean monthly flows within the extended study area	PS	Mitigation Measure Rec-15: Implement Mitigation Measure Aqua-15: Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements.	LTS
	CP2 & CP4A	Long-term	Similar to but potentially greater than CP1	PS	Mitigation Measure Rec-15: Implement Mitigation Measure Aqua-15: Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Rec-15 (CP1–CP5): Increased Difficulty for Boaters and Anglers in Using the Sacramento River and Rivers Below CVP and SWP Reservoirs as a Result of Decreased River Flows (contd.)	CP3	Long-term	Similar to but potentially greater than CP1 & CP2	PS	Mitigation Measure Rec-15: Implement Mitigation Measure Aqua-15: Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements.	LTS
	CP5	Long-term	Similar to but potentially greater than CP1, CP2, & CP3	PS	Mitigation Measure Rec-15: Implement Mitigation Measure Aqua-15: Maintain Flows in the Feather River, American River, and Trinity River Consistent with Existing Regulatory and Operational Requirements and Agreements.	LTS
Aesthetics and Visual Resources						
Impact Vis-1: Consistency with Guidelines for Visual Resources in the STNF LRMP (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	–	NI	NA	NI
	CP1–CP5	Short-term and long-term	Degraded visual character and quality of primary study area	S	Mitigation Measure Vis-1: Amend the STNF LRMP to Include Revised VQOs for developments at Turntable Bay area.	SU
Impact Vis-2: Degradation and/or Obstruction of a Scenic View from Key Observation Points (Shasta Lake and Vicinity and Upper Sacramento River)	N-A	NA	–	NI	NA	NI
	CP1	Short-term	Scenic views obstructed or degraded in primary study area	S	Mitigation Measure Vis-2: Minimize Construction-Related Visual Impacts on Scenic Views From Key Observation Points.	SU
	CP2	Short-term	Similar to CP1, but greater (acres, miles, duration)	S	Mitigation Measure Vis-2: Minimize Construction-Related Visual Impacts on Scenic Views From Key Observation Points.	SU
	CP3–CP5	Short-term	Similar to CP1& CP2, but greater (acres, miles, duration)	S	Mitigation Measure Vis-2: Minimize Construction-Related Visual Impacts on Scenic Views From Key Observation Points.	SU

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.

2 NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
3 NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
4 LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
5 NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact PS-4: Short-Term Disruption of Public Services (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	–	NI	NA	NI
	CP1–CP5	Short-term	–	NI	No mitigation needed; thus, none proposed.	NI
Impact PS-5: Degraded Levels of Public Services (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	–	NI	NA	NI
	CP1–CP5	Short-term	–	LTS	No mitigation needed; thus, none proposed.	LTS
Impact PS-6: Relocation of Public Services Facilities (Lower Sacramento River, Delta, CVP/SWP Service Areas)	N-A	NA	–	NI	NA	NI
	CP1–CP5	Long-term	–	NI	No mitigation needed; thus, none proposed.	NI
Power and Energy						
Impact Hydro-1: Decrease in Shasta Powerplant Energy Generation	N-A,	Long-term	Increase in Shasta Powerplant energy generation	B	NA	B
	CP1–CP5	Long-term	Increase in Shasta Powerplant energy generation	B	No mitigation needed; thus, none proposed.	B
Impact Hydro-2: Decrease in CVP System Energy Generation	N-A,	Long-term	Decrease in energy generation of <1%	LTS	NA	LTS
	CP1–CP5	Long-term	<5% decrease in CVP system energy generation	B	No mitigation needed; thus, none proposed.	B

Notes:

[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.

[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.

[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.

[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.

[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact Hydro-3: Decrease in SWP System Energy Generation	N-A,	Long-term	Increase in SWP system energy generation	B	NA	B
	CP1, CP2, CP4 – CP5	Long-term	Increase in SWP system energy generation	B	No mitigation needed; thus, none proposed.	B
	CP3	Long-term	<5% decrease in SWP system energy generation	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Hydro-4: Increase in CVP System Pumping Energy Use	N-A,	Long-term	<5% increase in CVP energy system pumping energy use	LTS	NA	LTS
	CP1–CP5	Long-term	<5% increase in CVP energy system pumping energy use	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Hydro-5: Increase in SWP System Pumping Energy Use	N-A	Long-term	<5% increase in SWP energy system pumping energy use	LTS	NA	LTS
	CP1–CP5	Long-term	<5% increase in SWP energy system pumping energy use	LTS	No mitigation needed; thus, none proposed.	LTS
Impact Hydro-6: Decrease in Pit 7 Powerplant Energy Generation	N-A	Long-term	<5% decrease in Pit 7 Powerplant energy generation	NI	NA	NI
	CP1–CP5	Long-term	<5% decrease in Pit 7 Powerplant energy generation	LTS	No mitigation needed; thus, none proposed.	LTS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Environmental Justice						
Impact EJ-1: Potential Disproportionate High and Adverse Effect on Minority and Low-Income Populations in the Vicinity of Shasta Lake	N-A	NA	–	NDHA	NA	NDHA
	CP1–CP5	Short-term	–	NDHA	No mitigation needed; thus, none proposed.	NDHA
Impact EJ-2: Potential Disproportionate High and Adverse Effect on Native American Populations from Disturbance or Loss of Sacred Locations in the Vicinity of Shasta Lake	N-A	NA	–	NDHA	NA	NDHA
	CP1–CP5	Short-term and long-term	–	DHA	No feasible mitigation is available to reduce impact.	DHA
Impact EJ-3: Potential Disproportionate High and Adverse Effect on Minority and Low-Income Populations in the Upper Sacramento River Area	N-A	Long-term	–	NDHA	NA	NDHA
	CP1–CP5	Long-term	–	NDHA	No mitigation needed; thus, none proposed.	NDHA
Impact EJ-4: Potential Disproportionate High and Adverse Effect on Minority and Low-Income Populations in the Lower Sacramento River and Delta Area	N-A	NA	–	NDHA	NA	NDHA
	CP1–CP5	Long-term	–	NDHA	No mitigation needed; thus, none proposed.	NDHA
Impact EJ-5: Potential Disproportionate High and Adverse Effect on Minority and Low-Income Populations in the CVP/SWP Service Areas	N-A	NA	–	NDHA	NA	NDHA
	CP1–CP5	Long-term	–	NDHA	No mitigation needed; thus, none proposed.	NDHA

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable. NDHA = not disproportionately high and adverse. DHA = disproportionately high and adverse.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Wild and Scenic River Considerations for McCloud River						
Impact WASR-1: McCloud River's Eligibility for Listing as a Federal Wild and Scenic River	N-A	NA	–	NI	NA	NI
	CP1	Permanent	11 percent of Segment 4 would be periodically inundated	S	No feasible mitigation available to reduce impact.	SU
	CP2	Permanent	21 percent of Segment 4 would be periodically inundated	S	No feasible mitigation available to reduce impact.	SU
	CP3–CP5	Permanent	39 percent increase over the current transition reach), inundating larger portion of the lower McCloud River and Segment 4	S	No feasible mitigation available to reduce impact.	SU
Impact WASR-2: Conflict with Shasta-Trinity National Forest, Land and Resource Management Plan	N-A	NA	–	NI	NA	NI
	CP1–CP5	Permanent	–	NI	No mitigation needed; thus, none proposed.	NI

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable. TS = too speculative for meaningful consideration. NDHA = not disproportionately high and adverse. DHA = disproportionately high and adverse.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact WASR-3: Effects to McCloud River Wild Trout Fishery, as Identified in the California Public Resources Code, Section 5093.542	N-A	NA	–	NI	NA	NI
	CP1	Long-term	Increased inundation could affect the wild trout fishery (access and ecology) of the lower McCloud River identified in the State Public Resources Code.	PS	Mitigation Measure WASR-3 (CP1-CP5): Develop and Implement a Comprehensive Multi-scale Fishery Protection, Restoration and Improvement Program for the Lower McCloud River Watershed.	PS
	CP2	Long-term	Similar to CP1, but greater inundation.	PS	Mitigation Measure WASR-3 (CP1-CP5): Develop and Implement a Comprehensive Multi-scale Fishery Protection, Restoration and Improvement Program for the Lower McCloud River Watershed.	PS
	CP3–CP5	Long-term	Similar to CP1 and CP2, but greater inundation.	PS	Mitigation Measure WASR-3 (CP1-CP5): Develop and Implement a Comprehensive Multi-scale Fishery Protection, Restoration and Improvement Program for the Lower McCloud River Watershed.	PS

Notes:
[1] Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
[2] NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
[3] NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
[4] LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable. TS = too speculative for meaningful consideration. NDHA = not disproportionately high and adverse. DHA = disproportionately high and adverse.
[5] NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Table S-3. Summary of Impacts and Mitigation Measures (contd.)

Resource Topic/Impact	Alt[1]	Impact Duration[2]	Quantification/ Relative Magnitude of Impact[3]	LOS Before Mitigation[4]	Mitigation Measure[5]	LOS After Mitigation[4]
Impact WASR-4: Effects to McCloud River Free-Flowing Conditions, as Identified in the California Public Resources Code, Section 5093.542	N-A	NA	–	NI	NA	NI
	CP1	Long-term	Increased inundation could affect the free-flowing conditions of the McCloud River, as identified in the State Public Resources Code.	S	Mitigation Measure WASR-4: Develop and Implement Protection, Restoration, and Improvement Measures to Benefit Hydrologic Functions Within the Lower McCloud River Watershed	SU
	CP2	Long-term	Similar to CP1, but greater inundation.	S	Mitigation Measure WASR-4: Develop and Implement Protection, Restoration, and Improvement Measures to Benefit Hydrologic Functions Within the Lower McCloud River Watershed	SU
	CP3–CP5	Long-term	Similar to CP1 and CP2, but greater inundation.	S	Mitigation Measure WASR-4: Develop and Implement Protection, Restoration, and Improvement Measures to Benefit Hydrologic Functions Within the Lower McCloud River Watershed	SU

Notes:
1 Alt = alternative. N-A = No-Action Alternative. CP = Comprehensive Plan.
2 NA = not applicable. Short-term = construction-related or persisting from one to several years. Long-term = persisting for years to decades. Permanent = effectively irreversible.
3 NA = not applicable. "–" = the least impact among the action alternatives or an impact that is comparable in type and magnitude to the least impact among the alternatives.
4 LOS = level of significance. B = beneficial. NA = not applicable. NI = no impact. LTS = less than significant. PS = potentially significant. S = significant. SU = significant and unavoidable. TS = too speculative for meaningful consideration. NDHA = not disproportionately high and adverse. DHA = disproportionately high and adverse.
5 NA = not applicable, because under the No-Action Alternative, the Federal Government would not implement a plan to raise Shasta Dam, and no mitigation would be required.

Key:
BLM = U.S. Bureau of Land Management
BMP = best management practice
CDFW = California Department of Fish and Wildlife
cfs = cubic feet per second
CO = carbon monoxide
CO_2e = carbon dioxide equivalent
CP = Comprehensive Plan
CRMP = Coordinated Resources Management Plan
CRPR = California Rare Plant Rank
CVP = Central Valley Project
dBA = A-weighted decibels
Delta = Sacramento–San Joaquin Delta
GHG = greenhouse gas
ITA = Indian Trust Assets
lb = pound
L_{eq} = equivalent noise level
LRMP = Land and Resource Management Plan
MOA = Memorandum of Understanding
MSCS = Multi-Species Conservation Strategy
NHPA = National Historic Preservation Act
NO_X = oxides of nitrogen
PA = Programmatic Agreement
PM = particulate matter
PM_{10} = respirable particulate matter with an aerodynamic resistance diameter of 10 micrometers or less
$PM_{2.5}$ = respirable particulate matter with an aerodynamic resistance diameter of 2.5 micrometers or less
ROG = reactive organic gas
SR = State Route
STNF = Shasta-Trinity National Forest
SWP = State Water Project
TBD = to be determined
USFS = U.S. Forest Service
X2 = distance in kilometers from the Golden Gate Bridge to the location where salinity concentration is 2 parts per thousand

Shasta Lake Water Resources Investigation, California

Shasta Lake Water Resources Investigation, California Final Environmental Impact Statement

Prepared by:

United States Department of the Interior
Bureau of Reclamation
Mid-Pacific Region

December 2014

Chapter 1 Introduction

This Environmental Impact Statement (EIS) has been prepared as part of the Shasta Lake Water Resources Investigation (SLWRI) to evaluate the potential physical, biological, cultural, and socioeconomic effects of implementing alternatives to modify the existing Shasta Dam and Reservoir, including taking no action. The SLWRI is led by the U.S. Department of the Interior, Bureau of Reclamation (Reclamation), Mid-Pacific Region.

Reclamation is serving as the Federal lead agency for compliance with the National Environmental Policy Act (NEPA). Under NEPA, a cooperating agency is any agency, other than the lead agency, that has jurisdiction by law or special expertise with respect to any environmental impact involved in an action requiring an EIS. Cooperating agencies pursuant to NEPA include the U.S. Department of Agriculture, Forest Service (USFS); Colusa Indian Community Council of the Cachil Dehe Band of Wintun Indians; U.S. Army Corps of Engineers (USACE); and U.S. Department of the Interior, Bureau of Indian Affairs (BIA). This document has also been prepared in consideration of California Environmental Quality Act (CEQA) requirements and could be used by State of California (State) permitting agencies that would be involved in reviewing and approving the project.

Reclamation completed the Draft *SLWRI Feasibility Report* (Draft Feasibility Report), Preliminary Draft EIS (Preliminary DEIS), and related appendices in November 2011. These documents were released to the public in February 2012 to present potential impacts, costs, and benefits of the action alternatives that had been evaluated at that time; to share information generated since the completion of the SLWRI Plan Formulation Report in December 2007; and to provide an additional opportunity for public and stakeholder input.

After the release of the Draft Feasibility Report and Preliminary DEIS, SLWRI alternatives were refined for the Draft EIS (DEIS) based on several factors, including updates to Central Valley Project (CVP) and State Water Project (SWP) water operations, and stakeholder input. Water operations modeling and related evaluations for the DEIS and this Final EIS reflect the following:

- The 2008 Biological Assessment on the Continued Long-Term Operations of the CVP and SWP (2008 Long-Term Operation Biological Assessment (BA)) (Reclamation 2008a)

- The U.S. Department of the Interior, Fish and Wildlife Service (USFWS) 2008 *Formal Endangered Species Act Consultation on the*

Proposed Coordinated Operations of the CVP and SWP (2008 USFWS Biological Opinion (BO)) (USFWS 2008)

- The National Marine Fisheries Service (NMFS) 2009 *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO) (NMFS 2009)

- Additional changes in CVP and SWP facilities and operations, such as implementation of the San Joaquin River Restoration Program

- Additional changes in non-CVP/SWP facilities and operations, such as the addition of the Freeport Regional Water Project

Reclamation released the DEIS for public review and comment in June 2013. During the process of addressing public comments on the DEIS, some notable content changes were made to the Final EIS, including:

- Refinement of the project purpose statement

- Clarification of the relationship of this EIS and tiering to the CALFED Bay-Delta Program (CALFED) Programmatic Environmental Impact Statement/Environmental Impact Report (PEIS/R)

- Refinement of the operational scenarios focused on anadromous fish survival, and the development, evaluation, and incorporation of Comprehensive Plan 4A (CP4A) Refinement of facility plans for recreation relocations, Shasta Dam modifications, Pit 7 Dam and Powerhouse modifications, and other reservoir area relocations (e.g., power transmission lines)

- Incorporation of updated resource information related to physical and biological resources in the primary study area

- Based on facility and construction footprints, refinement of "maximum" affected areas and refinement of "most likely" affected areas for biological resources

- In conjunction with an interagency, interdisciplinary team, refinement and enhancement of the mitigation measures, including development of a framework to quantify impacts (where appropriate) and establish mitigation ratios that are applicable to a number of impacts related to biological resources

1.1 Background

Reclamation was established in 1902 to help meet the increasing water demands of the West. Today, Reclamation is the largest water provider in the country and the second largest producer of hydroelectric power in the western United States. Reclamation's Mid-Pacific Region is responsible for managing the CVP, which stores and delivers about 20 percent of California's developed water—7 million acre-feet (MAF)—to more than 250 water contractors throughout California.

Shasta Dam and Reservoir were constructed between September 1938 and June 1945. Water storage in Shasta Reservoir began in December 1943, and Shasta Dam was fully operable in April 1949. Reclamation operates Shasta Dam and Reservoir in conjunction with other facilities to provide for the management of floodwater, irrigation water supply, municipal and industrial (M&I) water supply, hydropower generation, and maintenance of navigation flows. The Central Valley Project Improvement Act (CVPIA) added "fish and wildlife mitigation, protection, and restoration" as a Reclamation priority equal to water supply and "fish and wildlife enhancement" as a priority equal to hydropower generation.

Shasta Dam and Reservoir are integral elements of the CVP, with Shasta Reservoir representing about 41 percent of the total reservoir storage capacity of the CVP. The 602-foot-tall Shasta Dam (533 feet above the streambed) and 4.55-MAF Shasta Reservoir are located on the upper Sacramento River in northern California, north of the City of Redding (see Figure 1-1) and within the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). Shasta Lake supports extensive water-oriented recreation. Recreation in this area is managed by the USFS. Shasta Reservoir and Shasta Lake are used interchangeably within this EIS. Generally, however, Shasta Reservoir is used in references related to water operations for water supply, flood control, and environmental and related regulatory requirements (e.g., operations of the reservoir). In addition, Shasta Reservoir is often used in discussions related to broader CVP and SWP operations or facilities. Members of the public often refer to both the reservoir and its location as Shasta Lake.

In 2000, as a result of increasing demands for water supplies and growing concerns over declines in ecosystem resources in California's Central Valley, Reclamation reinitiated a feasibility investigation to evaluate the potential for enlarging Shasta Dam and Reservoir. In conducting the SLWRI, including preparing multiple SLWRI planning documents, Reclamation determined that expanding the capacity of Shasta Reservoir by modifying Shasta Dam could (1) increase survival of anadromous fish in the Sacramento River, and (2) improve water supply reliability for agricultural, M&I, and environmental water users; these are the two primary purposes of the SLWRI. In addition, implementing the proposed action would address other related resource needs.

Figure 1-1. Location of Shasta Dam and Reservoir

1.1.1 Study Authorization

Public Law 96-375 (October 3, 1980) provides the authority for conducting a feasibility study for the SLWRI. It allows the Secretary of the Interior to:

> *(a)…engage in feasibility studies relating to enlarging Shasta Dam and Reservoir, Central Valley Project, California or to the construction of a larger dam on the Sacramento River, California, to replace the present structure.*
>
> *(b) The Secretary of the Interior is further authorized to engage in feasibility studies for the purpose of determining the potential costs, benefits, environmental impacts, and feasibility of using the Sacramento River for conveying water from the enlarged Shasta Dam and Reservoir or the larger dam to points of use downstream from the dam.*

Section 103(c), "Authorizations for Federal Activities under Applicable Law," of the CALFED Bay-Delta Authorization Act (Public Law 108-361, October 25, 2004), authorizes the Secretary of the Interior to carry out the activities described in paragraphs (1) through (10) of Subsection (d), which include:

> *...(1)(A)(i) planning and feasibility studies for projects to be pursued with project-specific study for enlargement of (1) the Shasta Dam in Shasta County.*

Also, Section 103(a)(1) of Public Law 108-361 (October 25, 2004) states:

> *The Record of Decision is approved as a general framework for addressing the CALFED Bay-Delta Program, including its components relating to water storage, ecosystem restoration, water supply reliability (including new firm yield), conveyance, water use efficiency, water quality, water transfers, watersheds, the Environmental Water Account, levee stability, governance, and science.*

The CALFED Programmatic Record of Decision (ROD) (CALFED 2000a) called for the Secretary of the Interior to conduct feasibility studies for expanding CVP storage in Shasta Lake to:

> *…increase the pool of cold water available to maintain lower Sacramento River temperatures needed by certain fish and provide other water management benefits, such as water supply reliability.*

Other Federal legislation influences the SLWRI. Two laws of special note are Public Law 89-336 (November 8, 1965) and Public Law 102-575 (October 30, 1992). Public Law 89-336 created the Whiskeytown-Shasta-Trinity NRA, which includes Shasta Dam and Reservoir. Public Law 102-575, the CVPIA, directed numerous changes to CVP operations. Among these changes was adding "fish and wildlife protection, restoration, and enhancement" as a project purpose, which would result in substantial changes to water supply deliveries, river flows, and related environmental conditions in the primary and extended study areas. To minimize impacts to CVP water contractors, the CVPIA also directed the Secretary of the Interior to develop a least-cost plan to increase water supplies for CVP deliveries by the amount dedicated to fish and wildlife purposes.

1.1.2 Major Previous Studies and Reports

Major previous Reclamation studies and reports investigating potential enlargement of Shasta Dam and Reservoir include *Enlarged Shasta Lake Investigation Preliminary Findings Report* (1983); *Shasta Dam and Reservoir Enlargement: Appraisal Assessment of the Potential for Enlarging Shasta Dam and Reservoir* (1999a); *SLWRI Strategic Agency and Public Involvement Plan* (2003b); *SLWRI Mission Statement Milestone Report* (2003a); *SLWRI Initial Alternatives Information Report* (2004); *SLWRI Environmental Scoping Report* (2006); and *SLWRI Plan Formulation Report* (2007).

As described above, Reclamation completed the Preliminary DEIS, Draft Feasibility Report, and supporting technical appendices for the SLWRI in November 2011. These documents were released to the public in February 2012. Reclamation completed the DEIS and supporting technical appendices for the SLWRI in June 2013 and released the documents to the public in the same month.

1.2 Purpose and Need/Project Objectives

NEPA regulations require a statement of “the underlying purpose and need to which the agency is responding in proposing the alternatives, including the proposed action” (Title 40, Code of Federal Regulations (CFR) Part 1502.13). In California, the State CEQA Guidelines require a clearly written statement of objectives, including the underlying purpose of a proposed project (Title 14, California Code of Regulations (CCR) Section 15124(b)).

1.2.1 Project Purpose and Objectives

Project Purpose

The purpose of the proposed action is to improve operational flexibility of the Sacramento-San Joaquin Delta (Delta) watershed system to meet specified primary and secondary project objectives.

Project Objectives

Two primary project objectives (also referred to as planning objectives) and five secondary project objectives were developed for the SLWRI:

Primary Project Objectives

- Increase the survival of anadromous fish populations in the Sacramento River, primarily upstream from the Red Bluff Pumping Plant (RBPP)
- Increase water supply and water supply reliability for agricultural, M&I, and environmental purposes to help meet current and future water demands, with a focus on enlarging Shasta Dam and Reservoir

Secondary Project Objectives

- Conserve, restore, and enhance ecosystem resources in the Shasta Lake area and along the upper Sacramento River
- Reduce flood damage along the Sacramento River
- Develop additional hydropower generation capabilities at Shasta Dam
- Maintain and increase recreation opportunities at Shasta Lake

- Maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and in the Delta

Primary project objectives are those which specific alternatives are formulated to address. The two primary project objectives are considered to have coequal priority, with each pursued to the maximum practicable extent without adversely affecting the other. Secondary project objectives are considered to the extent possible through pursuit of the primary project objectives.

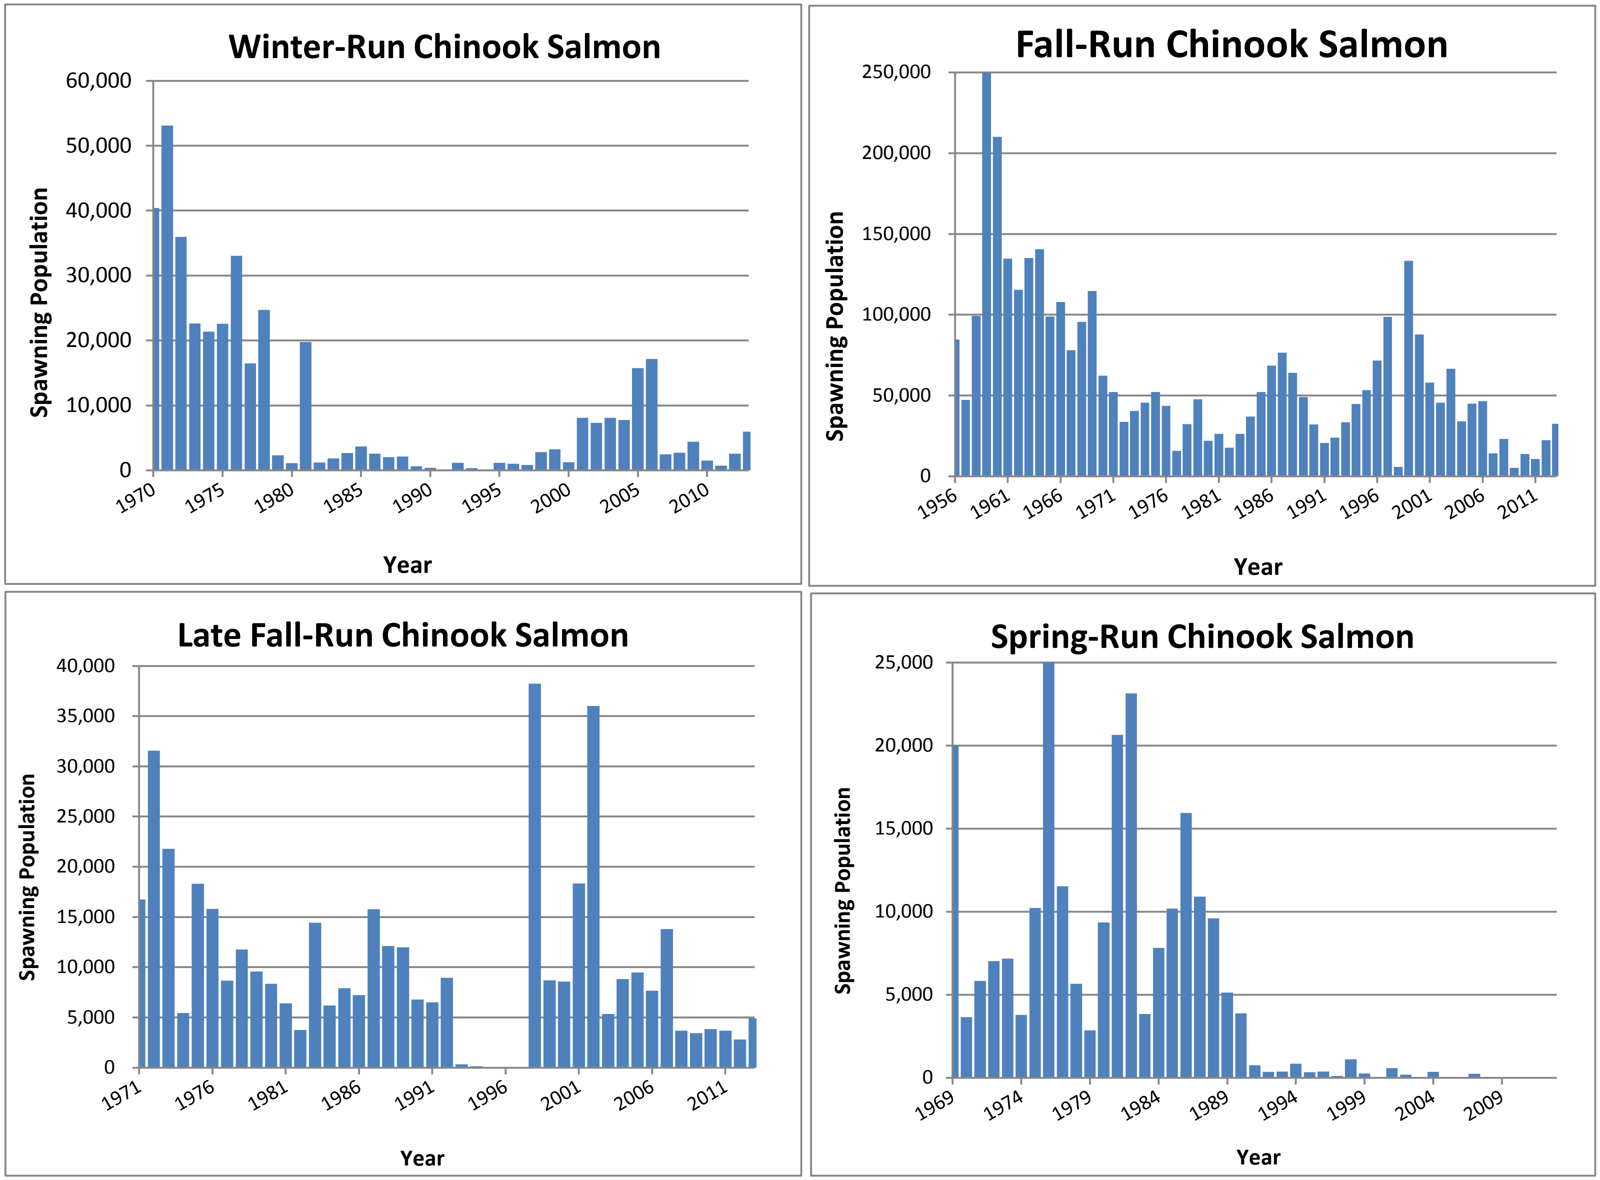
1.2.2 Project Need

Anadromous Fish Survival

The Sacramento River system supports four separate runs of Chinook salmon: fall-, late fall-, winter-, and spring-run. The adult populations of the four runs of salmon and other important fish species that spawn in the upper Sacramento River have declined considerably over the last 40 years (Figure 1-2) (CDFW 2014).

Several fish species in the upper Sacramento River have been listed as endangered or threatened under the Federal Endangered Species Act (ESA): Sacramento River winter-run Chinook salmon (endangered), Central Valley spring-run Chinook salmon (threatened), Central Valley steelhead (threatened), and the Southern Distinct Population Segment (DPS) of North American green sturgeon (threatened). Two of these species also are listed as endangered or threatened, as defined by the California Endangered Species Act (CESA): Sacramento River winter-run Chinook salmon (endangered) and Central Valley spring-run Chinook salmon (threatened).

Numerous factors have contributed to these declines. One of the most significant environmental factors affecting the number of Chinook salmon in the upper Sacramento River is unsuitable water temperature (NMFS 2014). Water temperatures that are too high or, less commonly, too low, can be detrimental to the various life stages of Chinook salmon. Elevated water temperatures can negatively affect holding and spawning adults, egg viability and incubation, preemergent fry, and rearing juveniles and smolts, substantially diminishing the next generation of returning spawners. Stress caused by high water temperatures also may reduce the resistance of fish to parasites, disease, and pollutants.



Source: CDFW 2014

Figure 1-2. Chinook Salmon Historic Spawning Populations in the Sacramento River

Releases of cold water from Shasta Reservoir can considerably improve seasonal water temperatures during critical periods for anadromous fish in the Sacramento River downstream from Shasta Dam. The *Recovery Plan for the Evolutionarily Significant Units of Sacramento River Winter-run Chinook Salmon and Central Valley Spring-run Chinook Salmon and the Distinct Population Segment of Central Valley Steelhead* (Recovery Plan) (NMFS 2014) states that prolonged droughts depleting the cold-water stored in Shasta Reservoir, or some related failure to manage cold-water storage, could put populations of anadromous fish at risk of severe population decline or extirpation in the long-term (NMFS 2014). The risk associated with a prolonged drought is especially high in the Sacramento River, as Shasta Reservoir is intended to maintain only one year of carryover storage. The recovery plan emphasizes that, under current conditions, even two consecutive years of drought could reduce Shasta Reservoir storage to levels insufficient to support the Sacramento River winter-run Chinook salmon spawning and incubation season.

In May 1990, the State Water Resources Control Board (State Water Board) issued Water Right Order 90-5, which included temperature objectives for the Sacramento River to protect winter-run Chinook salmon. Three NMFS BO documents (NMFS 1993, 2004, 2009) for Sacramento River winter-run Chinook salmon reinforced this order and established certain operating parameters for Shasta Reservoir. The State Water Board action and the NMFS BOs set minimum flows in the river downstream from Keswick Dam and minimum Shasta Reservoir carryover storage targets, primarily to affect water temperatures during key periods.

In addition to changes in flow requirements, structural changes were made at Shasta Dam to change the temperature of released water, such as construction of a temperature control device (TCD), completed in 1997. The TCD can be used to selectively draw water from different depths in the lake, including the deepest, to help maintain river water temperatures beneficial to salmon. The TCD is effective in helping to reduce winter-run Chinook salmon mortality in some critical water years[1] and for fall- and spring-run Chinook salmon in below-normal water years.

With the exception of spring-run Chinook salmon, the average Chinook salmon spawning population in the Sacramento River since 1999 has increased compared with the previous 20 years (1979 to 1998) (CDFW 2014a). This increase in salmon populations is likely due primarily to minimum release requirements at Shasta Dam and the TCD. Additionally, changes in operating the Red Bluff Diversion Dam and the RBPP have benefited Chinook salmon populations in the Sacramento River. However, there is a continual need for

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

cool water in the Sacramento River, especially in dry and critical years, to promote anadromous fish survival and reduce the risk of extinction.

Water Supply Reliability

California's water supply system faces critical challenges with demands exceeding supplies for agricultural, M&I, and environmental water uses across the State. The California Department of Water Resources (DWR) *California Water Plan Update 2013* (DWR 2014) concludes that California is facing one of the most significant water crises in its history; drought impacts are growing, and climate change is affecting statewide hydrology. Despite significant physical improvements in water resource systems and in system management over the past few decades, California still faces unreliable water supplies, continued depletion and degradation of groundwater resources, habitat and species declines, and unacceptable risks from flooding (DWR 2014). Compounding these issues, Reclamation's *Water Supply and Yield Study* (2008b) describes dramatic increases in statewide population, land use changes, regulatory requirements, and limitations on storage and conveyance facilities, further straining available water supplies and infrastructure to meet water demands. Furthermore, projected unmet water demands are expected to increase competition for water supplies among agricultural, M&I, and environmental uses.

Estimated Water Supply Shortages Table 1-1 displays estimated water demands, available supplies, and shortages for the Central Valley and the State under existing conditions (Reclamation 2008b). Current water supply shortages for the State are estimated at 2.3 and 4.1 MAF for average and dry years, respectively. As shown in Table 1-2, without further investment in water management and infrastructure, future shortages are expected to increase to approximately 4.9 and 6.1 MAF in average and dry years, respectively, by 2030. Representative demands for dry and average years were based on water use data from the *California Water Plan Update 2005* (DWR 2005), adjusted for population growth, increasing urban water use, and reductions in irrigated acreage and environmental flow due to insufficient water supplies. Shortages were determined on a regional basis, assuming that limitations on conveyance and storage would prevent surpluses from one region or use category from filling shortages in another.

Table 1-1. Estimated Water Demands, Supplies, and Shortages Under Existing Conditions[1]

Item	Hydrologic Basin						State of California	
	Sacramento		San Joaquin		Two-Basin Total			
	Average Year[2]	Dry Year[2]	Average Year[2]	Dry Year[2]	Average Year[2]	Dry Year[2]	Average Year[2]	Dry Year[2]

Total Shortage (MAF)[4]	**0.4**	**0.8**	**0.7**	**0.5**	**1.1**	**1.3**	**2.3**	**4.1**

Notes:

[1] Water demands, supplies, and shortages are from the 2008 Reclamation Water Supply and Yield Study

[2] Representative dry and average year supplies and demands were based on adjusted water use and supply data from the California Water Plan Update 2005 (DWR 2005).

[3] Year 2005 population estimates are from the California Department of Finance (2010)

[4] Total shortages are calculated as the sum of shortages for each category by region (e.g., North Coast, Sacramento River) and, therefore, may not equal the difference between total demands and supplies. Shortages were determined on a regional basis, assuming that limitations on conveyance and storage would prevent surpluses from one region or use category from filling shortages in another. Detailed estimates of shortages for each region can be found in the 2008 Reclamation Water Supply and Yield Study in Table A-1 (dry year) and Table A-2 (average year). For categories where supply is greater than demand, the shortage is equal to zero.

[2] Representative dry and average year supplies and demands were based on water use and supply data from the California Water Plan Update 2005 (DWR 2005) adjusted for population growth, increasing urban water use, and reductions in irrigated acreage and environmental flow due to insufficient water supplies.
[3] 2030 Population estimates are from the California Department of Finance (2007)
[4] Total shortages are calculated as the sum of shortages for each category by region (e.g., North Coast, Sacramento River) and, therefore, may not equal the difference between demands and supplies. Shortages were determined on a regional basis, assuming that limitations on conveyance and storage would prevent surpluses from one region or use category from filling shortages in another. Detailed estimates of shortages for each region can be found in the 2008 Reclamation Water Supply and Yield Study in Table A-4 (dry year) and Table A-5 (average year). For categories where supply is greater than demand, the shortage is equal to zero.
Key:
MAF = million acre-feet

Potential Effects of Population Growth on Water Demands A major factor in California's future water picture is population growth. California's population is expected to increase by just over 60 percent above 2005 levels by 2050 (DOF 2007) and could force some of the existing water supplies currently identified for agricultural uses to be redirected to urban uses. A portion of the increased population in the Central Valley would occur on lands currently used for irrigated agriculture. Water that would have been needed for these lands for irrigation would instead be used to serve urban demands. However, since much of the growth would occur on non-irrigated agricultural lands, the required agricultural-to-urban water conversion needed to sustain projected urban water demands would be only partially offset.

The *California Water Plan Update 2013* (DWR 2014) estimates changes in future water demands by 2050, considering three different population growth scenarios as well as climate change. Assuming that recent population growth trends will continue until 2050, Table 1-3 shows the results of this study for an average water year (DWR 2014) for one of three scenarios, the Current Trends scenario.

Table 1-3. Estimated Annual Change in Water Demand in California for 2050

Item	Current Trends
Population (million)	51.0
Irrigated Crop Acreage (million)	8.9
Water Demand Change[1] (MAF)	
Urban	2.9
Agricultural	-3.6
Total	***3.5***

Note:

[1] Estimated water demand change is the difference between the average demands for 2043—2050 and 1998—2005.

Key:

MAF = million acre-feet

Potential Effects of Climate Change Another potentially significant factor affecting water supply reliability is climate change. Potential effects of climate change are many and complex (DWR 2006), varying through time and geographic location across the State (Reclamation 2011a). Changes in geographic distribution, timing, and intensity of precipitation are projected for the Central Valley (Reclamation 2011a), which could broadly impact rainfall runoff relationships important for flood management as well as water supply. Additionally, there is potential for climate change to increase annual water demand compared to a repeat of historical climate (DWR 2014). Other possible impacts range from potential sea level rise, which could impact coastal areas and water quality, to impacts to overall system storage for water supply.

A reduction in total system storage is widely predicted with climate change. Less water held in snowpack and demand for more flood control space in reservoirs is expected with future climate change. During drought periods, supplies could be further reduced, and expected shortages would be substantially greater.

System Flexibility The CVP and SWP were designed and constructed to accommodate the variability of precipitation in California, seasonally, temporally, and spatially. However, the projects' flexibility has been fully used by population growth and increased environmental and ecosystem commitments and requirements since the projects were constructed (Reclamation 2008b).

Chronic water shortages since the early 1900s have led to groundwater overdraft in many regions across the State. Portions of the CVP and SWP were constructed to reduce groundwater overdraft; however, increasing water supply demands that cannot be met by the CVP or SWP are causing modern-day overdraft conditions.

Increasing CVP and SWP operational constraints have led to growing competition for limited system resources among various users and uses. Urban and required environmental water uses have each increased, resulting in increased competition and conflicting demands for limited water supplies. For example, the CVPIA, implemented in 1993, dedicated project water supplies to environmental purposes. Existing NMFS and USFWS BOs, resulting in increased Delta pumping constraints and other operational restrictions, coupled with drought conditions, have even further decreased CVP deliveries.

Potential Approaches to Address Water Supply Needs As noted by Reclamation's *Water Supply and Yield Study* (Reclamation 2008b), the *California Water Plan Update 2013* (DWR 2014), and the CALFED Programmatic ROD (2000a), an integrated portfolio of solutions, regional and statewide, is needed to meet future water supply needs. The *Water Supply and Yield Study* stated that a "variety of storage and conveyance projects and water management actions have the potential to help fill [the] gap" between water supply and demand in California. The *California Water Plan Update 2013* concluded that to improve public safety, foster environmental stewardship, and support economic stability, California must continue its commitment to integrated water management, promote better alignment of government agency efforts at all levels, and encourage greater investment in innovation and infrastructure, including increased surface storage. Accordingly, California must invest in reliable, high quality, and affordable water conservation; efficient water management; and development of water supplies. Major efforts by multiple agencies are needed to address the complex water resources issues in the State, as demands are expected to continue to exceed supplies in the future.

Ecosystem Resources

The health of the Sacramento River ecosystem, as elsewhere in the Central Valley, has been impacted in the last century by conflicts over the use of limited natural resources, particularly water resources. Many of California's rivers and streams have been harnessed for beneficial uses such as hydropower, flood damage reduction, and water supply, contributing to a decline in habitat and native species populations, and a resulting increase in endangered or threatened species listings under the ESA and CESA.

Constructing Shasta Dam has had both negative and positive effects on environmental resources in the region. While the dam displaced valuable riverine and upland habitat, it also created shoreline and shallow water habitat for aquatic, terrestrial, and avian species in the reservoir area. For example, Shasta Lake is home to a substantial concentration of nesting bald eagles in California.

Shasta Lake Area Various activities have impacted natural resources upstream from Shasta Dam, within the lake, on adjacent lands, and in and near tributary streams. Historical mining, ore processing practices and resulting acid mine drainage, fire suppression, and development in the watershed are among the activities causing the greatest degradation to ecosystem resources in this area. Although most mines in this area are no longer operational and many are currently undergoing remediation, they continue to remain a documented source of metals, acidity, and sediments in the reservoir area.

Aquatic habitats in tributaries to Shasta Lake have been affected by passage barriers and human disturbances that have caused various types of habitat degradation. Fish passage barriers are caused by the presence of road crossings and culverts, grade controls, and adverse water quality conditions, particularly high water temperature or toxic materials. Human disturbances have resulted in downcutting of stream channels, a reduction of shaded riparian habitat, and increased water temperatures. Other types of disturbance (e.g., wildland fire, road construction) have resulted in increased sediment transport into streams and a reduction in spawning habitat due to sedimentation of spawning gravels.

To guide management of the Shasta-Trinity National Forest (STNF), USFS prepared the *Shasta-Trinity National Forest Land and Resource Management Plan* (LRMP) (USFS 1995). Primary goals of the STNF LRMP, which was implemented in 1995, are to integrate a mix of management activities that allows use and protection of forest resources; meets the requirements of guiding legislation; and addresses local, regional, and national issues. The STNF LRMP is intended to guide implementation of the *Aquatic Conservation Strategy of the Northwest Forest Plan* (USFS 1994) for protection and management of riparian and aquatic habitats adjacent to Shasta Lake. However, opportunities exist to further support ongoing USFS programs. These opportunities include improving and restoring environmental conditions by developing self-sustaining natural habitat in the area of Shasta Lake and its tributaries to benefit fish and wildlife resources.

Downstream from Shasta Dam Land and water resources development has caused major resource problems and challenges in the Sacramento River basin, including decreases in anadromous fish and wildlife populations and losses of riparian, wetland, floodplain, and shaded riverine habitat. These decreases and losses have resulted in reduced populations of many plant and animal species.

The quantity, quality, diversity, and connectivity of riparian, wetland, floodplain, and shaded riverine habitat along the Sacramento River have been severely limited through confinement of the river system by levees, reclamation of adjacent lands for farming, bank protection, channel stabilization, and land development. Modification of seasonal flow patterns by dams and water diversions also has inhibited the natural channel-forming processes that drive riparian habitat succession. It is estimated that less than 5 percent of the historical riparian vegetation habitat within the Sacramento River basin remains today (USFWS 2014).

Decreases in quality and quantity of habitat have resulted in reduced populations of various fish and wildlife species. Introduction of nonnative species has also contributed to the decline in native animal and plant species. In addition, the lack of linear continuity of riparian habitat has impacted the movement of wildlife species among habitat areas, adversely affecting dispersal, migration, emigration, and immigration. For many species, these conditions have resulted in reduced wildlife numbers and population viability.

Ecosystem restoration along the Sacramento River has been the focus of several ongoing programs, including the Senate Bill 1086 Program, CVPIA, CALFED, and Central Valley Habitat Joint Venture. Despite these efforts, a significant need remains to conserve and restore ecosystem resources along the Sacramento River.

Endangered and threatened fish and wildlife populations, critical habitat, and sensitive Delta ecosystems are also declining. The decline is especially pronounced in the case of pelagic fish species in the Delta, including delta smelt, striped bass, threadfin shad, and longfin smelt. Monitoring results indicate that the threatened delta smelt population continues to remain at or near all-time lows. In 2006, the USFWS was petitioned to upgrade the status of delta smelt to endangered (The Center for Biological Diversity et al. 2006). In 2010, the USFWS conducted a 5-year review and found delta smelt warranted the upgrade in status; however, the listing was precluded by other higher priority listing actions (Volume 75, Federal Register (FR), page 17667 (75 FR 17667 (April 7, 2010)). Longfin smelt were petitioned for listing as endangered in 2007 (The Center for Biological Diversity et al. 2007). The USFWS found that the Bay-Delta DPS does warrant listing; however, as with the delta smelt, the listing is precluded by other higher priority actions. Therefore, longfin smelt have been added to the candidate list (77 FR 19756 (April 2, 2012)). Current planning efforts, such as the Bay Delta Conservation Plan (BDCP)/Delta Habitat Conservation and Conveyance Program are focused on developing ecological solutions to protect Delta fisheries while providing a sustainable and reliable water conveyance system for the CVP and SWP.

Flood Management

Large and small communities and agricultural lands in the Central Valley are subject to flooding along the Sacramento River. The comprehensive flood control system in the Sacramento River basin includes river, canal, and stream channels; levees; flood relief bypasses; weirs; flood relief structures; a natural overflow area; outfall gates; and drainage pumping plants.

Flooding poses risks to human life, health, safety, and property. Physical impacts from flooding include damage to buildings, contents, automobiles, agricultural crops, equipment, etc. Threats from flooding are caused by many factors, including overtopping or sudden failures of levees, which can cause deep and rapid flooding with little warning, threatening lives and public safety. In addition, urban development in flood-prone areas has exposed the public to the risk of flooding.

Hydropower

While California is the second largest consumer of electricity in the nation, it is also the most energy efficient. Although California has 12 percent of the nation's population, it uses only 7 percent of the nation's electricity (DOE 2014). Even so, demands for electricity are growing at a rapid pace. California's peak demand for electricity is expected to increase at a rate of approximately 1.5 percent per year through 2022, from about 60,000 megawatts (MW) in 2011 to about 70,000 MW by 2022 (California Energy Commission 2012). There are, and will continue to be, increasing demands for new electrical energy supplies, including clean energy sources, such as hydropower. Executive Orders S-14-08 and S-21-09, issued in 2008 and 2009, respectively, established a goal of using renewable energy sources, including hydropower, for 33 percent of the State's energy consumption by 2020 (California Public Utilities Commission 2011). To meet renewable energy goals, significant increases in non-dispatchable intermittent renewable resources, such as wind and solar generation, will need to be added to California's power system. This means that other significant flexible generation resources will be needed to support and integrate renewable generation. Adding to the need for additional energy sources, existing nuclear power plants are nearing the end of their design lives and some may be offline within the next 10 to 20 years. For example, the San Onofre Nuclear Generating Station in San Diego County is in the process of decommissioning.

Recreation

As the population of the State continues to grow, demands will increase substantially for water-oriented recreation at and near the lakes, reservoirs, streams, and rivers of the Central Valley. According to the *California Water Plan Update 2013* (DWR 2014), the Central Valley is experiencing dramatic population growth, but currently has insufficient access to recreation opportunities. Further increases in demand, accompanied by relatively static recreation resources, will cause additional issues at existing recreation areas. These challenges will be especially pronounced at Shasta Lake, which is one of the most visited recreation destinations in the State and in the region. Even under current levels of demand, USFS, which manages recreation at Shasta Lake, has expressed concern about seasonal access and capacity problems at existing marinas and USFS facilities. A substantial and increasing need exists to improve recreation-related facilities and conditions at Shasta Lake.

Water Quality

The Sacramento River and the Delta support fish and wildlife while providing water supplies for urban, agricultural, and environmental uses across the State. Saltwater intrusion, municipal discharges, agricultural drainage, and water project flows and diversions have led to water quality issues within the Delta, particularly related to salinity, that have resulted in significant declines in pelagic populations (Regional Water Boards, State Water Board, and CalEPA 2006). Urban and agricultural runoff, and runoff and seepage from abandoned mining operations, have resulted in elevated levels of pesticides, phosphorous, mercury, and other metals in the Sacramento River.

Planning efforts, such as the BDCP, are intended to allow implementation of projects that restore and protect water supply and reliability, water quality, and ecosystem health in the Delta to proceed within a stable regulatory framework. Additional operational flexibility could provide further opportunities to improve Sacramento River and Delta water quality conditions.

1.3 Setting and Location

Shasta Dam and Shasta Lake are located on the upper Sacramento River in northern California, approximately 9 miles northwest of Redding in Shasta County. The SLWRI includes both a primary and extended study area because of the potential influence of the proposed modification of Shasta Dam and subsequent system operations and water deliveries on resources over a large geographic area. The primary study area includes the following:

- Shasta Dam and Shasta Lake
- Lower reaches of three primary tributaries flowing into Shasta Lake (Sacramento, McCloud, and Pit rivers) and all smaller tributaries flowing into the lake
- Sacramento River between Shasta Dam and RBPP, including tributaries at their confluence
- Trinity and Lewiston reservoirs

The extended study area includes the following:

- Sacramento River downstream from RBPP, including portions of major tributaries, namely the American and Feather river basins downstream from CVP and SWP facilities
- Delta
- San Joaquin River basin at and downstream from CVP facilities (Friant and New Melones reservoirs)
- CVP and SWP facilities and water service areas

The SLWRI study area includes other parts of California with resource programs or projects that could potentially be directly or indirectly influenced by modifying Shasta Dam and Reservoir. As discussed above, the study area includes the Sacramento and San Joaquin rivers and the Delta system, plus the CVP and SWP facilities and water service areas. For analyses of each resource that may be directly or indirectly affected by the project, the study area is subdivided into specific geographic areas, as described in the following sections.

1.3.1 Primary Study Area

The primary study area includes Shasta Dam and Shasta Lake, the lower portions of all contributing major and minor tributaries that would be affected by increasing storage in the reservoir, and the Sacramento River upstream from RBPP to Shasta Dam. Figure 1-3 shows the portion of the primary study area downstream from Shasta Dam.

Shasta Dam

Shasta Dam is a curved gravity concrete dam on the Sacramento River north of Redding, California. The dam is 602 feet high and 3,460 feet long, with a base width or thickness of 543 feet. Upon construction, Shasta Dam was the second tallest and second largest concrete dam in the world, exceeded only by Hoover Dam (located in Clark County, Nevada) in height and by Grand Coulee Dam (located in Grant County, Washington) in volume and surface area (Reclamation 2004).

Shasta Lake and Vicinity

Created by Shasta Dam, Shasta Lake is the largest reservoir in California, with a surface area of approximately 29,500 acres, a volume of 4.55 MAF, and approximately 400 miles of shoreline. The reservoir's watershed receives a substantial amount of precipitation relative to the rest of California; only a limited region in the State's far northwest corner receives more. The three major tributaries to Shasta Lake are the Sacramento, McCloud, and Pit rivers. Many smaller tributary creeks and streams (both seasonal and perennial) flow into these major tributaries and the reservoir itself. The major tributaries are described in more detail below.

Sacramento River The Sacramento River drains an area of approximately 430 square miles. Its headwaters include portions of Mount Shasta and the Trinity and Klamath mountains. The Sacramento River flows south from its headwaters for about 40 miles before entering Shasta Lake.

McCloud River The McCloud River drains an area of approximately 600 square miles. Its headwaters are at Colby Meadows near Bartle, California. The McCloud River flows southwesterly from its headwaters for about 50 miles to its terminus at Shasta Lake. As part of the McCloud-Pit Hydroelectric Project, the majority of the McCloud River flows are diverted to the Pit River at the McCloud Dam, through the McCloud-Iron Canyon Diversion Tunnel and Iron Canyon Reservoir.

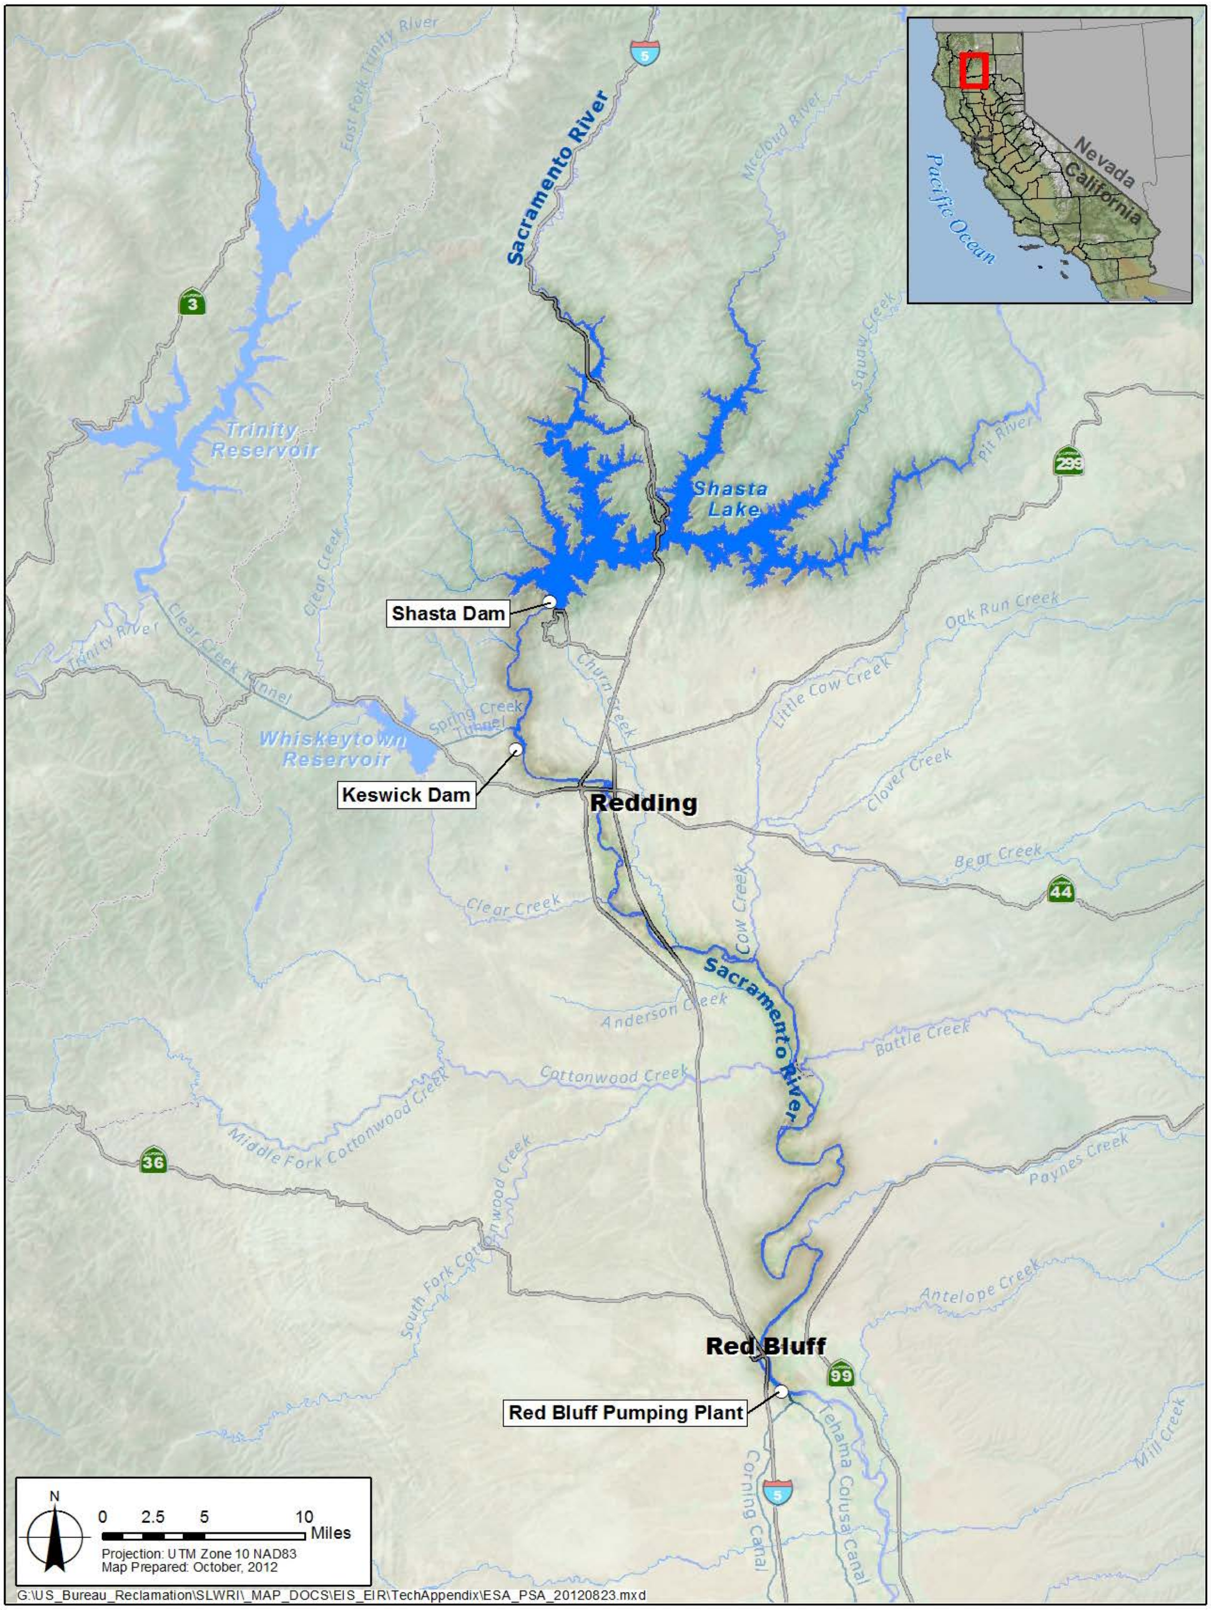

Figure 1-3. Primary Study Area—Shasta Lake Area and Sacramento River from Shasta Dam to Red Bluff Pumping Plant

Pit River The Pit River watershed is located in northeastern California and southeastern Oregon. The north and south forks of the Pit River drain the northern portion of the watershed. The North Fork Pit River originates at the outlet of Goose Lake, and the South Fork originates in the south Warner Mountains at Moon Lake in Lassen County. The Pit River is joined by the Fall River in Shasta County and has 21 named tributaries, totaling approximately 1,050 miles of perennial streams and encompassing approximately 4,700 square miles.

Upper Sacramento River — Shasta Dam to Red Bluff Pumping Plant

This portion of the primary study area includes an approximately 65-mile-long stretch of the Sacramento River corridor from Shasta Dam to RBPP, including tributaries at their confluence. The Sacramento River corridor within this reach also includes proposed sites for riparian, floodplain, and side channel habitat restoration and areas proposed for gravel augmentation. Communities located along this stretch of the river are Redding, Anderson, and Red Bluff. The northern portion of this reach is located in Shasta County and the southern portion is in Tehama County.

Shasta Dam, Keswick Dam, Anderson-Cottonwood Irrigation District Dam, and Red Bluff Diversion Dam are located on the Sacramento River in this area. The RBPP is directly adjacent to the Red Bluff Diversion Dam, which is currently operated year round with all of the gates permanently raised. Urban, residential, industrial, and agricultural land uses predominate along the upper Sacramento River between Shasta Dam and RBPP.

The location of the RBPP was chosen as the downstream boundary of the primary study area because cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBPP (NMFS 1993). After the RBPP, the river landscape changes to a broader alluvial stream system. The broader, slower nature of an alluvial stream system allows ambient air temperature to have a greater effect on the temperature of the Sacramento River.

Trinity and Lewiston Reservoirs Trinity and Lewiston reservoirs impound the upper Trinity River approximately 60 and 67 miles, respectively, southwest of the headwaters near Mount Eddy (USFS 2005). Trinity Reservoir has a watershed of approximately 165 square miles and a usable storage capacity of approximately 2,438,000 acre-feet. Flow into Lewiston Reservoir, with a capacity of approximately 14,700 acre-feet, is completely regulated by releases from Trinity Dam (USFS 2005). At Lewiston Dam, a portion of Trinity River flows are diverted to the Sacramento River basin through Clear Creek Tunnel and Whiskeytown Lake (See Figure 1-4).

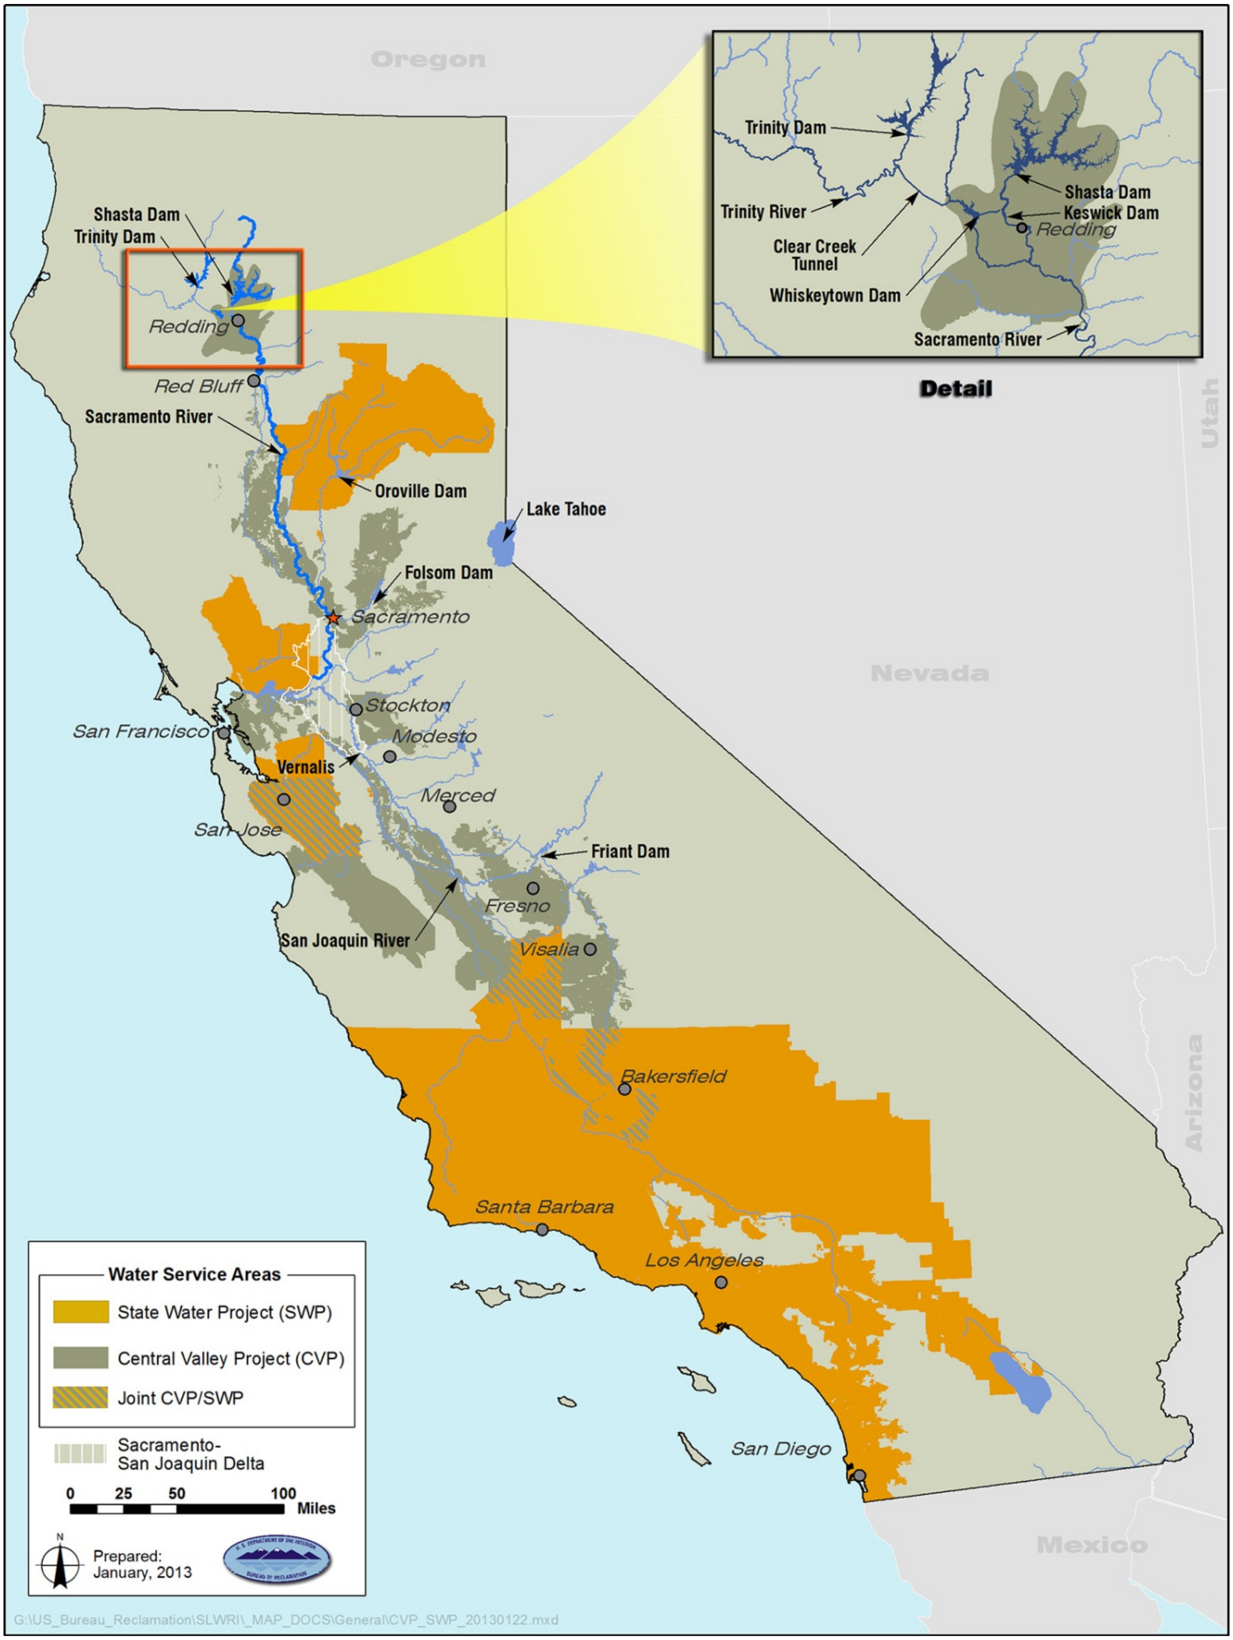

Figure 1-4. Central Valley Project and State Water Project Facilities and Water Service Areas

1.3.2 Extended Study Area

The extended study area includes the Sacramento River downstream from RBPP south (along the Sacramento River) to the Delta. It also includes the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) area and portions of the American and Feather river basins, the San Joaquin River basin, and the CVP and SWP facilities and water service areas (Figure 1-4).

Sacramento River from Red Bluff Pumping Plant to the Delta

The segment of the extended study area between RBPP and the Delta includes the Sacramento River, tributaries at their confluence, and portions of major tributaries that may be affected by the project, namely, the Feather and American rivers. The Yuba River is a major tributary to the Feather River, but the Yuba River is not considered part of this segment of the extended study area for two reasons: it is geographically separated from the Sacramento River, and its watershed has no CVP or SWP facilities that could be indirectly affected by increased storage at Shasta Lake. Lake Oroville is a major SWP facility on the Feather River, and Folsom Lake is a major CVP facility on the American River.

The middle reach of the Sacramento River between Red Bluff and Colusa is approximately 100 miles long. The lower reach of the Sacramento River between Colusa and the Delta is approximately 84 miles long.

The Sacramento River Hydrologic Region, as defined by DWR, is the main water supply for much of California's urban and agricultural areas. Annual runoff averages about 22.4 MAF, which is nearly one-third of California's total runoff. M&I and agricultural supplies to the Sacramento Valley region are about 8 MAF, with groundwater providing approximately 2.5 MAF of that total. Much of the remainder of the runoff in the Sacramento River watershed goes to dedicated in-channel flows that support various environmental requirements, including instream flow and Delta salinity requirements (DWR 2003).

Sacramento-San Joaquin Delta

Surface water resources in the Delta are influenced by the interaction of tributary inflows, tides, Delta hydrodynamics, local Delta diversions and exports, and water transfers. The Delta receives runoff from a watershed that includes more than 40 percent of California's land area and covers approximately 750,000 acres. Tributaries that discharge directly into the Delta include the Sacramento, San Joaquin, Mokelumne, Cosumnes, and Calaveras rivers. Existing surface water conditions in the Delta are the result of the many changes that have occurred as the Delta and its watershed have been developed over the past 150 years.

Tides move water twice daily from San Francisco Bay into the Delta. The location of the mixing zone between freshwater from the Delta and saline water from the San Francisco Bay varies with the amount of Delta outflow and tides. Saltwater intrusion into the Delta during summer is controlled by tides, freshwater inflows from reservoir releases, and Delta pumping. Average incoming and outgoing Delta tidal flow is approximately 170,000 cubic feet per second, and average net Delta outflow is about 30,000 cubic feet per second, or about 21 MAF per year, measured at Chipps Island.

San Joaquin River Basin to Delta

The San Joaquin River basin includes the Central Valley south of the Delta. This area is drier than the Sacramento Valley, and flows into the Delta from the San Joaquin River are considerably smaller than those from the Sacramento River. The river also is subject to extreme variations in flow and water quality.

The San Joaquin River watershed above Vernalis (the point at which the river enters the Delta) is 13,356 square miles. Inflows from the Merced (farthest upstream), Tuolumne, and Stanislaus rivers contribute more than 60 percent of the flows in the San Joaquin River, as measured at Vernalis. Upstream from the Merced River, nonflood flows in the San Joaquin River consist primarily of Restoration Flows released under the San Joaquin River Restoration Program (SJRRP). Restoration Flows are currently recaptured from the river at Mendota Pool (approximately 87 miles upstream from the Merced River confluence). As the capacity of the San Joaquin River downstream from Mendota Pool is gradually increased as part of the SJRRP, Restoration Flows will increase downstream from Mendota Pool, and will ultimately reach the Delta.

The major rivers of the San Joaquin system have contributed an average of about 5.5 MAF to Delta inflow, with an annual range of 1.1 to 15 MAF. Historical unimpaired flows on the Stanislaus, Tuolumne, Merced, and San Joaquin rivers averaged a total of 5.6 MAF. Numerous dams, reservoirs, and diversions are located on these rivers and others in the San Joaquin system. New Melones Reservoir on the Stanislaus River and Friant Dam on the San Joaquin River are part of Reclamation's CVP system.

Central Valley Project Facilities and Water Service Areas

The CVP supplies irrigation water to the Sacramento and San Joaquin valleys; domestic water to cities and industries in Sacramento County and the east and South San Francisco Bay area; and water to fish hatcheries and wildlife refuges throughout the Central Valley. The CVP delivers approximately 7 MAF of water per year. CVP facilities include 20 dams and reservoirs with a combined storage capacity of more than 11 MAF, 39 pumping plants, 2 pumping-generating plants, 11 power plants, and more than 500 miles of major canals and aqueducts. CVP divisions include Trinity River, Shasta Lake, Sacramento River, American River, Delta, West San Joaquin, San Felipe, East Side, and Friant.

The CVP has three primary storage facilities in northern California: Shasta Dam and Shasta Lake, Trinity Dam and Clair Engle Lake, and Folsom Dam and Folsom Lake. Major CVP storage facilities south of the Delta are New Melones Reservoir on the Stanislaus River, Millerton Lake on the San Joaquin River, and

San Luis Reservoir, which is a pumped-storage reservoir on the west side of the San Joaquin Valley and is shared with the SWP.

The Delta-Mendota Canal is the main conveyance facility of the CVP. This canal conveys water from the C.W. “Bill” Jones Pumping Plant (formerly known as the Tracy Pumping Plant) in the south Delta near Byron to agricultural lands in the San Joaquin Valley. Water not delivered directly is diverted from the Delta-Mendota Canal at the O’Neill Pumping Plant into O’Neill Forebay. The water then flows along the San Luis Canal to CVP contractors in the San Joaquin Valley or is lifted into San Luis Reservoir through the Gianelli Pumping/Generating Plant for later use. The majority of the remaining water continues to the southern Central Valley, with some water being diverted to Santa Clara County.

State Water Project Facilities and Water Service Areas

The SWP is the largest state-built, multipurpose water project in the country. DWR operates and maintains the SWP, which conveys an annual average of 2.5 MAF of water through 20 pumping plants, 4 pumping-generating plants, 5 hydroelectric powerhouses, 34 storage facilities, and about 700 miles of open canals and pipelines. The SWP is operated in conjunction with the CVP according to the 1986 *Agreement Between the United States and the State of California for the Coordinated Operation of the Central Valley Project and the State Water Project*, commonly known as the “Coordinated Operations Agreement.” This agreement defines how Reclamation and DWR share their joint responsibility to meet Delta water quality standards and the water demands of senior water right holders, and how the two agencies share surplus flows.

DWR operates the SWP to export Delta flows and store and transfer water from the Feather River basin to the San Joaquin Valley, South San Francisco Bay, areas north of Suisun Bay, coastal counties, and ultimately to southern California. In 1951, the State Legislature authorized the SWP for water supply, flood control, hydropower generation, recreation, and fish and wildlife purposes. Approximately 25 million of California’s estimated 37 million residents benefit from SWP water, which also irrigates about 750,000 acres of farmland, mainly in the southern San Joaquin Valley. Of the contracted water supply, M&I users have received about half of the total water delivered over the last 20 years; the remainder is supplied for agricultural use. A total of 29 contracting agencies receive water from the SWP.

In the southern Delta, the SWP diverts water from Clifton Court Forebay for delivery south of the Delta. Harvey O. Banks Pumping Plant lifts water from Clifton Court Forebay into Bethany Reservoir. Some of the water delivered to Bethany Reservoir is pumped at South Bay Pumping Plant for delivery through the South Bay Aqueduct to SWP contracting agencies in the San Francisco Bay Area. Most of the water delivered to Bethany Reservoir flows into the California Aqueduct, the main conveyance facility of the SWP. Along the western San Joaquin Valley, the California Aqueduct transports water through

Gianelli Pumping/Generating Plant for storage in San Luis Reservoir until it is needed for later use. The 444-mile-long California Aqueduct conveys water to the agricultural lands of the San Joaquin Valley and the urban regions of southern California. The west branch of the aqueduct ends in Castaic Lake, and the east branch terminates at Lake Perris in southern California.

1.4 NEPA Compliance

NEPA requires a planning process to inform stakeholders, public agencies, and decision makers of the significance of potential environmental effects that may result from taking an action or implementing a Federal action. These processes disclose the significance of the impacts of a proposed action on the human environment, including the natural and physical environment and the relationship of people with that environment. The environmental impacts of a range of reasonable alternatives, including a no-action alternative, are analyzed in this EIS as required under NEPA.

1.4.1 NEPA Process

Reclamation is the Federal lead agency for NEPA compliance (42 U.S. Code 4321 et seq.). Based on a review of technical data and the scope of the SLWRI, Reclamation determined that the proposed action would result in significant impacts and that an EIS was the appropriate NEPA document to be prepared. Consequently, the DEIS was made available for public review and comment in June 2013, followed by the release of this Final EIS.

The EIS satisfies NEPA requirements for formulating and evaluating alternative actions, disclosing environmental impacts, and identifying potential mitigation measures. Section 1.5, "Intended Use of EIS," describes the roles and responsibilities of Federal, State, and local agencies, and includes a list of agencies that may use the EIS for NEPA compliance or to inform decisions regarding resources within their jurisdictions. Chapter 32, "Final EIS," provides an overview of the Final EIS, including public involvement, consultation, and coordination efforts for the EIS; a description of the preferred alternative; document availability and distribution; and next steps.

1.5 Intended Use of EIS

The purpose of an EIS is not to recommend approval or rejection of a project, but to provide information to aid the public and decision makers/permitting agencies in the decision-making process. An EIS identifies and evaluates alternatives that meet the project objectives, analyzes the potential environmental effects, and identifies measures to reduce or avoid potential environmental effects resulting from the action alternatives (i.e., mitigation measures). An EIS also must disclose adverse environmental impacts that cannot be avoided, cumulative impacts, the relationship of short-term uses and long-term productivity, and irreversible and irretrievable commitments of resources. In addition, NEPA requires that an EIS consider indirect effects of a project, which are often the result of growth inducement.

The DEIS was released to the public in June 2013 and was circulated for review and comment by agencies, stakeholders, and the public to inform and engage interested persons in the planning and NEPA processes. Public outreach, including public workshops and hearings, was conducted during the 90-day public review period for the DEIS. Comments received during the public review period were considered and addressed and all comments and responses to comments are included in this Final EIS in Chapter 33, “Public Comments and Responses.”

1.5.1 CALFED Tiering

The 2000 CALFED PEIS/R Preferred Program Alternative and associated CALFED Programmatic ROD recommended five surface water storage projects to be pursued with project specific studies. These studies included Shasta Lake Enlargement, Los Vaqueros Reservoir Enlargement, Sites Reservoir, In-Delta Storage, and development of storage in the upper San Joaquin River Basin. As described in the CALFED Programmatic ROD:

> *For actions contained within the Preferred Program Alternative that are undertaken by a CALFED Agency or funded with money designated for meeting CALFED purposes, environmental review will tier from the [CALFED] Final Programmatic EIS/R.*

Accordingly, since the SLWRI is an action contained within the CALFED Preferred Program Alternative, this EIS tiers to the CALFED PEIS/R. The CALFED Programmatic ROD describes tiering as follows:

> *Whenever a broad environmental impact analysis has been prepared and a subsequent narrower analysis is then prepared on an action included within the entire program or policy, the subsequent analysis need only summarize the issues discussed in the broader analysis and incorporate discussions from the broader analysis by reference. This is known as tiering. Tiered documents focus on issues specific to the subsequent action and rely on the analysis of issues already decided in the broader programmatic review. Absent new information or substantially changed circumstances, documents tiering from the CALFED Final Programmatic EIS/R will not revisit the alternatives that were considered alongside CALFED’s Preferred Program Alternative nor will they revisit alternatives that were rejected during CALFED’s alternative development process.*

As discussed in more detail in Chapter 2, Section 2.1.3, "Planning Constraints and Other Considerations," preliminary studies in support of the CALFED PEIS/R considered more than 50 surface water storage sites throughout California and recommended more detailed study of the five sites identified in the CALFED Programmatic ROD (CALFED 2000a, 2000b, 2000c). Consistent with the above guidance in the CALFED Programmatic ROD, this EIS relies on evaluations and alternatives development and screening included in the CALFED PEIS/R, and focuses on the subsequent action of evaluating the enlargement of Shasta Lake.

Although conditions have changed since the CALFED Programmatic ROD was issued in July 2000, the Bay-Delta problems for which the alternatives were formulated persist today. The purpose of CALFED was to develop and implement a long-term comprehensive plan that would restore ecological health and improve water management for beneficial uses of the Bay-Delta system. The goal of CALFED was to concurrently and comprehensively address problems of the Bay-Delta system within four critical resource categories: ecosystem quality, water quality, water supply reliability, and levee system integrity. Although conditions have changed in the system since 2000 and progress has been made towards the CALFED goals, the fundamental needs for which the CALFED alternatives were formulated to address are still relevant today. For example, unreliable water supply, declining fish and wildlife habitat, continuing water quality issues, and the levee system are still key concerns for the Bay-Delta system. Accordingly, there is no new information or substantially changed circumstances that require Reclamation to revisit the CALFED alternatives as the alternatives, analyses, and recommended actions remain relevant today.

The CALFED PEIS/R was a programmatic-level document to select a long-term plan – Preferred Program Alternative – for implementation over a 30-year time frame. As described in the CALFED Programmatic ROD:

> *The Preferred Program Alternative is a set of programmatic actions, studies, and conditional decisions. It includes the broadly described actions that set the long-term overall direction of the Program. The description of the alternative is programmatic in nature, intended to help agencies and the public make decisions on the broad methods to meet program purposes. The Preferred Program Alternative description is an important legal element of compliance with CEQA and NEPA. The Preferred Program Alternative is not intended to define the site specific actions that will ultimately be implemented.*

This EIS builds on the CALFED PEIS/R analysis to account for updates to hydrology, demands, facilities, and CVP and SWP water operations; recent and relevant BOs; and reasonably foreseeable actions expected to occur in the study area to provide more specific information about the potential for the action alternatives to cause wide-ranging effects.

1.5.2 Intended Use of Final EIS

Reclamation posted the Final EIS at http://www.usbr.gov/mp/slwri for public review and issued a notice in the Federal Register and press release describing the public release of the Final EIS. It will be used by the Federal lead agency when considering approval of the proposed action or an alternative to the proposed action. All cooperating agencies and other Federal, State, and local agencies with permitting or approval authority over any aspect of the proposed action are expected to use the information contained in this Final EIS to meet most, if not all, of their information needs, to make decisions and/or issue permits with respect to the proposed action. Table 1-4 presents the roles and responsibilities of Federal, State, and local agencies that may use the Final EIS to support their decision-making needs.

This Final EIS is being published along with the Final Feasibility Report. The Final Feasibility Report incorporates information contained in this Final EIS by reference, and will be used to determine the type and extent of Federal interest in enlarging Shasta Dam and Reservoir. This Final EIS and the Final Feasibility Report will be used together to support the Federal decision. Typically, a ROD is the final step in the NEPA process and would document any decision on which actions, if any, to take to address the primary objectives.

Table 1-4. Agency Roles and Responsibilities

Agency	Role/Responsibility
Federal	
U.S. Department of the Interior Secretary	Ultimate responsibility for recommending actions to Congress. Also responsible for ROD.
U.S. Army Corps of Engineers (cooperating agency)	Permitting under Section 404 of the Clean Water Act; permitting under Sections 9, 10, and 13 of the Rivers and Harbors Act
U.S. Department of the Interior, Bureau of Indian Affairs (cooperating agency)	Participating in the SLWRI feasibility study
U.S. Department of the Interior, Bureau of Land Management	Reviewing SLWRI studies for consistency of project facilities with management of the Sacramento River Bend Management Area
U.S. Department of the Interior, Bureau of Reclamation	Serving as NEPA lead agency
U.S. Fish and Wildlife Service	Completing Federal Endangered Species Act consultation and incidental take authorization; verifying compliance with the Fish and Wildlife Coordination Act
National Marine Fisheries Service	Completing Federal Endangered Species Act consultation and incidental take authorization; verifying compliance with the Magnuson-Stevens Act

Table 1-4. Agency Roles and Responsibilities (contd.)

Agency	Role/Responsibility
Federal (contd.)	
U.S. Department of Agriculture, Forest Service (cooperating agency)	Verifying consistency of project facilities with management of the Shasta-Trinity National Forest and Whiskeytown-Shasta-Trinity National Recreation Area; regulating occupancy and use of National Forest System (NFS) lands under the Federal Land Policy Management Act and other authorities as appropriate
U.S. Environmental Protection Agency	Reviewing impacts on air quality for compliance with the Clean Air Act and State Implementation Plan; verifying compliance with the Safe Drinking Water Act; reviewing and filing the EIS
State	
California Air Resources Board	Verifying compliance with criteria pollutant standards
California Department of Boating and Waterways	Verifying compliance with the California Harbors and Navigation Code
California Department of Conservation	Designating Important Farmland for the State
California Department of Fish and Wildlife (trustee agency)	Completing California Endangered Species Act consultation and incidental take authorization; permitting under Section 1602 of the Fish and Game Code (streambed alteration agreement); completing consultation as a trustee agency
California Department of Forestry and Fire Protection	Providing fire protection services to unincorporated areas
California Department of Parks and Recreation	Verifying consistency with management of State Park lands
California Department of Transportation	Issuing an encroachment permit and/or approving a transportation management plan
California Department of Water Resources	Operating the SWP; participating in the SLWRI feasibility study
California Department of Toxic Substances Control	Verifying compliance with regulations for generation, transportation, treatment, storage, and disposal of hazardous waste
California Energy Commission	Verifying compliance with State energy policies
California Highway Patrol	Verifying that the project would not interfere with any emergency response plan or emergency response times
California Natural Resources Agency	Verifying that California's natural and cultural resources are protected, and complying with the California Wild and Scenic River Act
Central Valley Flood Protection Board (formerly The Reclamation Board)	Issuing levee and floodway encroachment permits
California Office of Historic Preservation	Conducting consultation pursuant to Section 106 of the National Historic Preservation Act
State Lands Commission	Verifying consistency with the management of lands managed by the commission; possibly issuing a State Lands lease

Table 1-4. Agency Roles and Responsibilities (contd.)

Agency	Role/Responsibility
State (contd.)	
Native American Heritage Commission	Identifying sacred sites and Most Likely Descendants for Native American burials; providing Native American contact information
State Water Resources Control Board, Regional Water Quality Control Boards	Issuing National Pollutant Discharge Elimination System permitting under Section 402 of the Clean Water Act; issuing certification under Section 401 of the Clean Water Act; issuing water right permits
Delta Stewardship Council	Consistency with the Delta Plan
California Water Commission	Quantification of public benefits of water storage projects
Local	
Shasta County Air Quality Management District	Reviewing impacts on air quality and granting authority to construct/permit to operate
Shasta County	Verifying compliance with the State's Surface Mining and Reclamation Act; issuing other possible construction authorizations/ encroachment permits
Tehama County	Verifying compliance with the State's Surface Mining and Reclamation Act; issuing other possible construction authorizations/ encroachment permits
Resource Conservation Districts	Verifying consistency with protected agricultural lands in the project's primary and extended study areas

Key:
EIS = environmental impact statement
NEPA = National Environmental Policy Act
NFS = National Forest System
SLWRI = Shasta Lake Water Resources Investigation
SWP = State Water Project
ROD = Record of Decision
State = State of California

1.5.3 USFS Use of EIS

The following sections describe the USFS purpose and need, proposed USFS permitting actions, and related actions that may be required if a project is authorized for construction.

Background

Reclamation is evaluating the feasibility of raising Shasta Dam to increase water storage capacity in Shasta Lake. The increased reservoir would expand the inundation area onto National Forest System (NFS) lands within the NRA. The USFS has jurisdiction over the NFS lands within the NRA. Expansion of the reservoir would require modifications or relocations of USFS facilities, revisions to special use permits, and amendments to the STNF LRMP that would be affected by the expansion of the reservoir. Reclamation and the USFS would work cooperatively to implement the decisions identified below.

Purpose and Need for USFS Permitting Actions

The purpose of the proposed action is to respond to a proposal from Reclamation to modify Shasta Dam and expand Shasta Lake. The USFS action is needed because much of the increased reservoir inundation and connected actions would occur on NFS lands which are under USFS jurisdiction. The USFS manages the NRA to provide, in a manner coordinated with the other purposes of the CVP, for public outdoor recreation use and enjoyment of NRA lands, and conservation of scenic, scientific, historic, and other values contributing to public enjoyment of such lands and waters.

USFS Decision Framework

Subject to Congressional authorization of a project, the USFS decision would:

- Determine how to remove merchantable timber or other vegetation that would be cleared as part of this project Identify the specific modifications or relocations of USFS facilities

- Identify the specific permits authorizing improvements on NFS lands that are affected by the project and that will require new authorization or permit amendment

- Amend the STNF LRMP standards and guidelines as necessary

Reclamation and the USFS entered into a Memorandum of Agreement (MOA) in 1986 for the coordinated administration of the Shasta and Trinity Units of the NRA with the CVP. Reclamation and the USFS will develop a supplemental agreement that will address agency specific responsibilities for management of resources affected by project implementation.

Proposed USFS Actions

If Congress authorizes a project involving modifications of Shasta Dam and Reservoir, the following actions would be subject to USFS jurisdiction if they are located on NFS land.

Vegetation Clearing in the Inundation Zone Vegetation would be managed within the inundation zone, consistent with the treatments proposed for vegetation management areas described in Chapter 2 of this EIS. Treatments would range from no treatment to full removal. The merchantable timber may be cut and sold without advertisement, as provided by 36 CFR Section 223.12.

Constructing Dikes on NFS lands to Protect Local Infrastructure Dikes would be constructed by Reclamation in select areas to protect local infrastructure from inundation. Reclamation would also develop local sources for fill material. Both dikes and associated borrow sites are proposed on NFS lands in the following areas: dikes in the vicinity of Lakeshore and Bridge Bay, and various locations for the borrow areas.

Relocation or Replacement of Recreation Facilities Recreation facilities impacted by increased inundation would be relocated or replaced by Reclamation. This includes facilities operated under permit such as resorts and marinas, and USFS-operated facilities such as campgrounds and boat ramps. The USFS would have a connected action to amend the affected permits or issue new permits for privately operated recreation facilities. Facilities impacted include USFS administrative facilities including Turntable Bay and Lakeshore Fire Station; USFS recreation facilities; and permitted recreation facilities.

Relocation, Modification, or Protection of Infrastructure Reclamation would relocate or modify infrastructure such as roads, trails, water systems, and sewer systems impacted by the inundation zone. This includes facilities operated under permit such as power lines and local roads, and USFS infrastructure such as roads and trails. For these facilities, the USFS action would include amending the affected permits for the infrastructure relocated or modified as part of the project. Potential modified or relocated infrastructure may include the following or similar: USFS roads, USFS trails, other permitted roads (e.g., Shasta County, private property access roads, utility access road, railroad access roads), power line permits, water systems (e.g., Lakeshore Heights water storage, Shasta County Service Areas 2 and 6), and telecommunications. For some facilities, dikes would be constructed by Reclamation to protect local infrastructure from inundation. Reclamation would also develop local sources for fill material. Both dikes and associated borrow sites are proposed on NFS lands in the following areas: dikes in the vicinity of Lakeshore and Bridge Bay, and various locations for the borrow areas.

Shasta-Trinity National Forest Land and Resource Management Plan The overall project actions, as authorized by Congress, may not be consistent with the STNF LRMP (USFS 1995) standards and guidelines. A project-specific STNF LRMP amendment may be required to resolve conflicts with USFS actions described above and the LRMP standards associated with caves, visual quality, late successional reserves, riparian reserves, survey and manage species, and Shasta snow-wreath. The USFS decision would include a project-specific exception to these standards if a conflict exists.

Caves The STNF LRMP adopted a standard for cave management that states:

> *Manage these unique habitats on a site-by-site basis to protect their existing micro environments and the viability of dependent animal and plant species. Manage nearby water sources to perpetuate natural cave processes.*

Visual Quality The STNF LRMP adopted Visual Quality Objectives (VQO) for the planning area. VQOs that may be affected by action alternatives include retention, partial retention, and modification.

Late-Successional Reserves The STNF LRMP adopted standards for the development of new facilities that may adversely affect Late-Successional Reserves. The STNF LRMP specifies:

> *New development proposals that address public needs or provide significant public benefits, such as powerlines, pipelines, reservoirs, recreation sites, or other public works projects will be reviewed on a case-by-case basis and may be approved when adverse effects can be minimized and mitigated. These will be planned to have the least possible adverse impacts on Late-Successional Reserves. Developments will be located to avoid degradation of habitat and adverse effects on identified late-successional species.*

Riparian Reserves The STNF LRMP direction for surface water developments in Riparian Reserves states:

> *For hydroelectric and other surface water development proposals, give priority emphasis to in-stream flows and habitat conditions that maintain or restore riparian resources, favorable channel conditions, and fish passage. Coordinate this process with the appropriate state agencies.*

Survey and Manage The STNF LRMP direction for survey and manage species generally requires protection of known sites and surveys of other areas before ground-disturbing activities. This direction was updated in the *Record of Decision and Standards and Guidelines for Amendments to the Survey and Manage, Protection Buffer, and Related Mitigation Measures Standards and Guideline*s (USFS and BLM 2001). These standards are intended to reduce or eliminate (mitigate) potential effects from agency actions to identified flora and fauna species including mosses, liverworts, fungi, lichens, vascular plants, slugs, snails, salamanders, great gray owl, and red tree voles. This ROD is being implemented consistent with the species list and exceptions identified in the *Settlement Agreement in Litigation over the Survey and Manage Mitigation Measure in Conservation Northwest et al. v. Sherman et al., Case No. 08-1067-JCC* (USFS and BLM 2011). Several known occurrences of survey and manage species occur within the project area, including the Shasta salamander. The STNF LRMP direction requires that most known sites be managed for persistence of the referenced survey and manage species and protected from disturbance during management.

Shasta Snow-Wreath The STNF LRMP supplemental direction that applies to all Sensitive and Endemic plant species, including specific direction pertaining to the Shasta snow-wreath and Scott Mountain fawn lily states:

Search for additional populations of Shasta snow-wreath and Scott Mountain fawn lily. Avoid disturbance pending completion of a conservation strategy.

To date, a conservation strategy has not been developed for the Shasta snow-wreath by USFS.

1.6 Areas of Controversy

Federal, State, and local stakeholders identified several areas of controversy during SLWRI public outreach activities, including public scoping activities, agency meetings, and related ongoing public outreach activities. Major concerns include:

- **Impacts on Cultural Resources –** Sites of cultural and religious significance exist in and around Shasta Lake, including sites related to historical activities of Native Americans. The Winnemem Wintu, a non-federally recognized Native American group, continue to raise concerns about impacts of the original construction of Shasta Dam and potential impacts of enlarging Shasta Dam on sites they value for historical and cultural significance.

  Reclamation has invited Federally recognized tribes and non-Federally recognized Native American groups to be consulting parties to the National Historic Preservation Act Section 106 process. The Winnemem Wintu would continue to have the opportunity to participate, and are anticipated to continue to provide input as an invited consulting party, through the Section 106 process, as well as, through the NEPA process.

- **Impacts on Recreation –** Shasta Lake is the principal recreation destination in Shasta County, which annually realizes well over $160 million related to outdoor recreation. Shasta Lake has attracted development of 9 private marinas with 1,040 houseboats and 18 public campgrounds. Stakeholders are concerned about possible adverse effects on recreation at Shasta Lake, such as inundation impacts on concessionaires and their facilities and related potential impacts on the regional economy.

- **Impacts on McCloud River's Free-Flowing Condition or Wild Trout Fishery –** The McCloud River is not formally designated as either a National or State wild and scenic river; however, Section 5093.542 of the California Public Resources Code includes provisions that are intended to protect the free-flowing condition and wild trout fishery of the McCloud River. Section 5093.542(a) of the California Public Resources Code states that "maintaining the McCloud River in its free-flowing condition to protect its fishery is the highest and most beneficial use of the waters of the McCloud River within the segments designated in subdivision (b).” Section 5093.542(b) prohibits any “dam, reservoir, diversion, or other water impoundment facility ” from 0.25 miles below McCloud Dam downstream to the McCloud River Bridge. Section 5093.542 was established through enactment of the Wild and Scenic Rivers Act, as amended (California Public Resources Code, Sections 5093.50 through 5093.70). Up to about 3,500 feet of the lower McCloud River above the McCloud River Bridge and within the special designation area would be occasionally inundated if Shasta Dam were modified. Thus, action alternatives related to enlargement of Shasta Dam and Reservoir would have some effect on the free-flowing condition of the lower McCloud River and the wild trout fishery within the part of the lower McCloud River protected by Section 5093.542 of the California Public Resources Code. DWR and other State agencies, landowners, and various environmental groups have expressed concerns about potential impacts on McCloud River resources, resulting from enlarging Shasta Dam and Lake.

Additionally, it is possible that State agency participation may be limited for projects that could have an adverse effect on the McCloud River’s free-flowing conditions or its wild-trout fishery. Section 5093.542(c) of the California Public Resources Code states the following:

> *Except for participation by DWR in studies involving the technical and economic feasibility of enlargement of Shasta Dam, no department or agency of the state shall assist or cooperate with, whether by loan, grant, license, or otherwise, any agency of the federal, state, or local government in the planning or construction of any dam, reservoir, diversion, or other water impoundment facility that could have an adverse effect on the free-flowing condition of the McCloud River, or on its wild trout fishery.*

In addition, Section 5093.542(d) of the California Public Resources Code states the following:

> *All state agencies exercising powers under any other provision of law with respect to the protection and restoration of fishery resources shall continue to exercise those powers in a manner to protect and enhance the fishery [of the protected segments of the McCloud River]*.

Participation by various State agencies in planning and potential construction activities associated with modifying Shasta Dam and Reservoir, including related permitting and approval processes, has varied by the agency's mandate and Section 5093.542 of the California Public Resources Code. The California Department of Fish and Wildlife (CDFW, formerly known as the California Department of Fish and Game [CDFG]), has taken the position that it must participate in preparing the EIS to comply with Section 5093.542(d). Other State agencies, including DWR and the State Water Board, have participated to a limited extent or expressed their intent to participate in the SLWRI. The CALFED Program Plan (CALFED 2000b) concluded that although Section 5093.542 seeks to protect the free-flowing condition of the McCloud River, it also provides for investigations of enlarging Shasta Dam. If the preferred alternative or an action alternative is ultimately authorized and approved, it is possible that some State agencies will be unable to process and issue permits and approvals identified above in Table 1-4. This could preclude Reclamation from obtaining State approvals and permits, which could impede a project and frustrate Congressional intent.

In addition, effects to the McCloud River and related provisions in the Public Resources Code are also relevant to the recently passed Proposition 1. California voters approved Proposition 1, "Water Bond. Funding for Water Quality, Supply, Treatment, and Storage Projects," on November 4, 2014, for $7.5 billion, which includes $2.7 billion for storage projects. However, Proposition 1, section 79751 specifies:

> *Projects for which the public benefits are eligible for funding under this chapter consist of only the following:*
>
> *(a) Surface storage projects identified in the CALFED Bay-Delta Program Record of Decision, dated August 28, 2000, except for projects prohibited by Chapter 1.4 (commencing with Section 5093.50) of Division 5 of the Public Resources Code.*

Accordingly, these provisions in Proposition 1 may limit bond funding for a project if the State or its agencies determine that such actions are prohibited by Chapter 1.4 of the Public Resources Code. Section 79751 does not amend or modify the State Public Resources Code. Whether the State of California can use Proposition 1 funds in support of any alternative potentially authorized related to enlargement of Shasta Dam and Reservoir is outside of Reclamation's authority and to be determined by the State of California.

- **Impacts on Reservoir-Area Property Owners –** Raising Shasta Dam would affect privately owned real estate. The raise would: (1) inundate additional lands around Shasta Lake; (2) affect existing structures, requiring acquisition of private property or relocation of displaced parties; and (3) require replacement of bridges and segments of existing paved and unpaved roads. These potential impacts concern property owners around Shasta Lake.

- **Impacts on the Environment, Especially Biological Resources –** Raising Shasta Dam or modifying project operations would affect a broad range of environmental resources, some adversely and some beneficially. Concern has been expressed about potential impacts on all of the following:

  – Wildlife habitat, special-status plant and animal species, and State-designated fully protected species along the shoreline

  – Fishery habitat on several creeks and streams that flow into Shasta Lake

  – Fishery and riparian habitat resources along the upper Sacramento River below Shasta Dam

  – Delta smelt and other sensitive aquatic species in the Delta

  – Delta water quality and south Delta water levels

  – Central Valley hydrology below CVP and SWP facilities, and resulting effects on water supplies for water contractors and other water users.

- **CVP and SWP Operational Assumptions –** Operational constraints for the CVP and SWP are affected by changing regulatory conditions in California. For this EIS, CVP and SWP operational assumptions were based on operations described in Reclamation's 2008 Long-Term Operation BA, the 2008 USFWS BO, the 2009 NMFS BO, and the Coordinated Operations Agreement between Reclamation and DWR, as ratified by Congress. However, the ongoing remand processes for the 2008 USFWS and 2009 NMFS BOs have resulted in some uncertainty about future CVP and SWP operational constraints.

1.7 Documents Used to Prepare EIS

This EIS considers and relies on the assessments in the *CVPIA Final* PEIS (Reclamation 1999b) and CALFED Final PEIS/R (CALFED 2000b). In addition, the CVPIA and the overall goals and objectives of CALFED were considered throughout the SLWRI study process.

1.7.1 CVPIA EIS

The CVPIA is a Federal statute enacted in 1992 with the following purposes:

> *To protect, restore, and enhance fish, wildlife, and associated habitats in the Central Valley and Trinity River basins of California; to address impacts of the CVP on fish, wildlife and associated habitats; to improve the operational flexibility of the CVP; to increase water-related benefits provided by the CVP to the state of California through expanded use of voluntary water transfers and improved water conservation; to contribute to the state of California's interim and long-term efforts to protect the Bay-Delta; and to achieve a reasonable balance among competing demands for use of CVP water, including the requirements of fish and wildlife, agricultural, municipal and industrial and power contractors.*

A Final PEIS (Reclamation 1999b) was prepared by Reclamation and USFWS in October 1999 to address the potential impacts of implementing the CVPIA. Although not tiering to that document, this EIS uses information contained in the CVPIA PEIS, updated to reflect current and project-specific conditions.

1.7.2 CALFED PEIS/R

CALFED is a collaboration of numerous Federal and State agencies with regulatory and management responsibilities in the Bay-Delta to develop and implement a long-term comprehensive plan to restore ecological health and improve water management for beneficial uses of the Bay-Delta system. The objective of the collaborative planning process is to identify comprehensive solutions to the problems of ecosystem quality, water delivery reliability, water quality, and Delta levee integrity.

In July 2000, the CALFED agencies released the Final PEIS/R (CALFED 2000b), which analyzed a range of alternatives to solve Bay-Delta system problems. In August 2000, the CALFED agencies issued the CALFED Programmatic ROD which identified 12 action plans. Specifically, plans were identified for the Governance, Ecosystem Restoration, Watersheds, Water Supply Reliability, Storage, Conveyance, Environmental Water Account, Water Use Efficiency, Water Quality, Water Transfer, Levees, and Science programs (CALFED 2000a). The CALFED agencies then began implementing Stage 1 of the Programmatic ROD, including the first 7 years of a 30-year program to establish a foundation for long-term actions. The SLWRI studies to-date and this associated EIS are consistent with applicable components of the CALFED PEIS/R, and the SLWRI EIS tiers to that PEIS/R.

1.8 Organization of EIS

Chapter 1, "Introduction," summarizes the purpose, need, objectives, authorization, and location of the proposed action; provides an overview of the environmental review process and background for the project; summarizes the intended use of the EIS and areas of controversy, and discusses documents used to prepare this EIS.

Chapter 2, "Alternatives," summarizes the methods used for selecting alternatives, describes the project alternatives, discusses alternatives that have been eliminated from further discussion, and describes the preferred alternative.

Chapter 3, "Considerations for Describing Affected Environment and Environmental Consequences," describes the approach to describing the affected environment and environmental consequences, defines impact levels, and describes the methodology for cumulative effects, including projects considered in the cumulative effects analysis. This chapter also presents the regulatory framework for the resource chapters that follow.

Chapters 4 – 25 describe the existing environmental and resource-specific regulatory frameworks for each resource area analyzed in this EIS, in the following order:

- **Chapter 4, "Geology, Geomorphology, Minerals, and Soils"**
- **Chapter 5, "Air Quality and Climate"**
- **Chapter 6, "Hydrology, Hydraulics, and Water Management"**
- **Chapter 7, "Water Quality"**
- **Chapter 8, "Noise and Vibration"**
- **Chapter 9, "Hazards and Hazardous Materials and Waste"**
- **Chapter 10, "Agriculture and Important Farmland"**
- **Chapter 11, "Fisheries and Aquatic Ecosystems"**
- **Chapter 12, "Botanical Resources and Wetlands"**
- **Chapter 13, "Wildlife Resources"**
- **Chapter 14, "Cultural Resources"**
- **Chapter 15, "Indian Trust Assets"**
- **Chapter 16, "Socioeconomics, Population, and Housing"**

- **Chapter 17, “Land Use and Planning”**
- **Chapter 18, “Recreation and Public Access”**
- **Chapter 19, “Aesthetics and Visual Resources”**
- **Chapter 20, “Transportation and Traffic”**
- **Chapter 21, “Utilities and Service Systems”**
- **Chapter 22, “Public Services”**
- **Chapter 23, “Power and Energy”**
- **Chapter 24, “Environmental Justice”**
- **Chapter 25, “Wild and Scenic River Considerations for McCloud River”**

Each resource chapter listed above also describes project-level impacts of the No-Action Alternative and action alternatives on the resource or issue area, mitigation measures for those impacts, and cumulative effects of all of the alternatives.

Chapter 26, “Other Required Disclosures,” describes any significant adverse effects of the project that cannot be avoided, irreversible and irretrievable commitments of resources, growth-inducing effects, and compliance with applicable laws.

Chapter 27, “Public Involvement, Consultation, and Coordination,” describes the public scoping process, agencies and organizations consulted, and areas of controversy, and identifies issues to be resolved.

Chapter 28, “DEIS Distribution List,” lists the elected officials; government departments; Federal, State, and local agencies; and interested parties that received notice of the availability of the SLWRI DEIS.

Chapter 29, “List of EIS Preparers,” lists individuals who participated in preparation of this EIS, and provides the qualifications of those individuals, in order of organization and agency.

Chapter 30, “References,” lists the sources of information used to prepare this EIS.

Chapter 31, “Index,” lists important terms and topics and gives page numbers of relevant discussions.

Chapter 32, "Final EIS," provides an overview of the Final EIS, including public involvement and consultation and coordination efforts for the EIS, a description of the preferred alternative, document availability and distribution, and next steps.

Chapter 33, "Public Comments and Responses," contains the comments received on the DEIS and responses to those comments.

Chapter 2 Alternatives

NEPA and CEQA require consideration of the potential effects of a range of action alternatives that would feasibly attain the majority of a project's basic objectives and accomplish the specified project purpose and need, while avoiding and/or minimizing adverse environmental impacts, in addition to the No-Action Alternative (which also constitutes the No-Project Alternative under CEQA). The purpose of including alternatives in an EIS is to offer a clear basis for choice by decision makers and the public about whether to proceed with a proposed action or project.

NEPA requires that alternatives be evaluated at a comparable level of detail (Title 40, Code of Federal Regulations (CFR) Part 1502.14(b)). Similarly, the Council on Environmental Quality (CEQ) regulations for implementing NEPA (Title 40, CFR Part 1502.14) require a range of reasonable alternatives to be objectively evaluated in an EIS so that each alternative is evaluated at an equal level of detail. Alternatives that cannot reasonably meet the project purpose and need do not require detailed analysis.

CEQA requires that the lead agency consider alternatives that would avoid or reduce one or more of the significant impacts identified for a project in an EIR. The State CEQA Guidelines state that an EIR needs to describe and evaluate only those alternatives necessary to permit a reasonable choice and to foster informed decision making and informed public participation (Section 15126.6(f)). Consideration of alternatives focuses on those that can either eliminate significant adverse environmental impacts, or reduce them to less-than-significant levels; alternatives considered in this context may include those that are more costly, and those that could impede, to some degree, the attainment of all the project objectives (Section 15126.6(b)). CEQA does not require the alternatives to be evaluated at the same level of detail as a proposed project.

NEPA and CEQA require consideration of future conditions No-Action/No Project Alternative as a basis of comparison with the action alternatives.

This chapter documents compliance with NEPA requirements for alternatives analysis and the alternatives development process, and describes the action alternatives evaluated in detail in this EIS. This chapter was also generally prepared in consideration of CEQA requirements. This chapter includes the following sections:

- **Section 2.1, Alternatives Development Process**, describing the overall plan formulation process and phases for the SLWRI, project objectives, planning constraints and considerations, management measures, and development and refinement of alternatives.

- **Section 2.2, No-Action Alternative**, describing the No-Action/No Project Alternative, representing a scenario in which a project is not implemented.

- **Section 2.3, Action Alternatives**, describing the comprehensive plans (action alternatives) evaluated in this EIS, including major components, potential benefits, operations and maintenance, and physical features/construction activities for each action alternative.

- **Section 2.4, Alternatives Considered and Eliminated from Further Analysis**, describing alternatives considered but eliminated from further development and consideration during formulation of initial alternatives and comprehensive plans.

- **Section 2.5, Summary of Potential Benefits of Action Alternatives**, summarizing the major potential benefits of proposed comprehensive plans (action alternatives).

- **Section 2.6, Preferred Alternative and Rationale for Selection**, describing the basis for selecting a plan for recommendation, including the criteria and considerations used in selecting a recommended course of action by the Federal Government.

2.1 Alternatives Development Process

This section describes the alternatives development process for the SLWRI. A more detailed description of this process is included in the Plan Formulation Appendix.

The SLWRI is one of five surface water storage studies recommended in the 2000 CALFED Bay-Delta Program (CALFED) Programmatic Environmental Impact Statement/Environmental Impact Report (PEIS/R) Preferred Program Alternative and associated Programmatic Record of Decision (ROD). As described in Chapter 1, "Introduction," consistent with guidance in the CALFED Programmatic ROD, the SLWRI EIS tiers to the CALFED PEIS/R. Preliminary studies in support of the CALFED PEIS/R considered more than 50 surface water storage sites throughout California and recommended more detailed study of the five sites identified in the CALFED Programmatic ROD (CALFED 2000a, 2000b, 2000c). The CALFED Programmatic ROD states that:

> *Tiered documents focus on issues specific to the subsequent action and rely on the analysis of issues already decided in the broader programmatic review. Absent new information or substantially changed circumstances, documents tiering from the CALFED Final Programmatic EIS/R will not revisit the alternatives that were considered alongside CALFED's Preferred Program Alternative nor will they revisit alternatives that were rejected during CALFED's alternative development process.*

Consistent with this guidance, the SLWRI EIS relies on the evaluations and alternatives development and screening included in the CALFED PEIS/R, and focuses on the subsequent action of evaluating the enlargement of Shasta Lake.

2.1.1 Plan Formulation Process

Consistent with NEPA, the plan formulation process for Federal water resources studies and projects identified in the *Economic and Environmental Principles and Guidelines for Water and Related Land Resources Implementation Studies* (P&G) (WRC 1983) begins with identifying existing and projected future resources conditions likely to occur in a study area. This is followed by defining water resources problems, needs, and opportunities to be addressed, and developing planning objectives, constraints, and criteria.

For the SLWRI, the above process was separated into five phases, all of which have been completed. These planning phases are shown in Figure 2-1 and described below:

- **Mission Statement Phase –** This study phase consisted of projecting without-project future conditions, defining resulting resource problems and needs, defining a specific set of planning objectives, and identifying constraints and criteria for addressing the planning objectives. These activities were documented in the 2003 *SLWRI Mission Statement Milestone Report*.

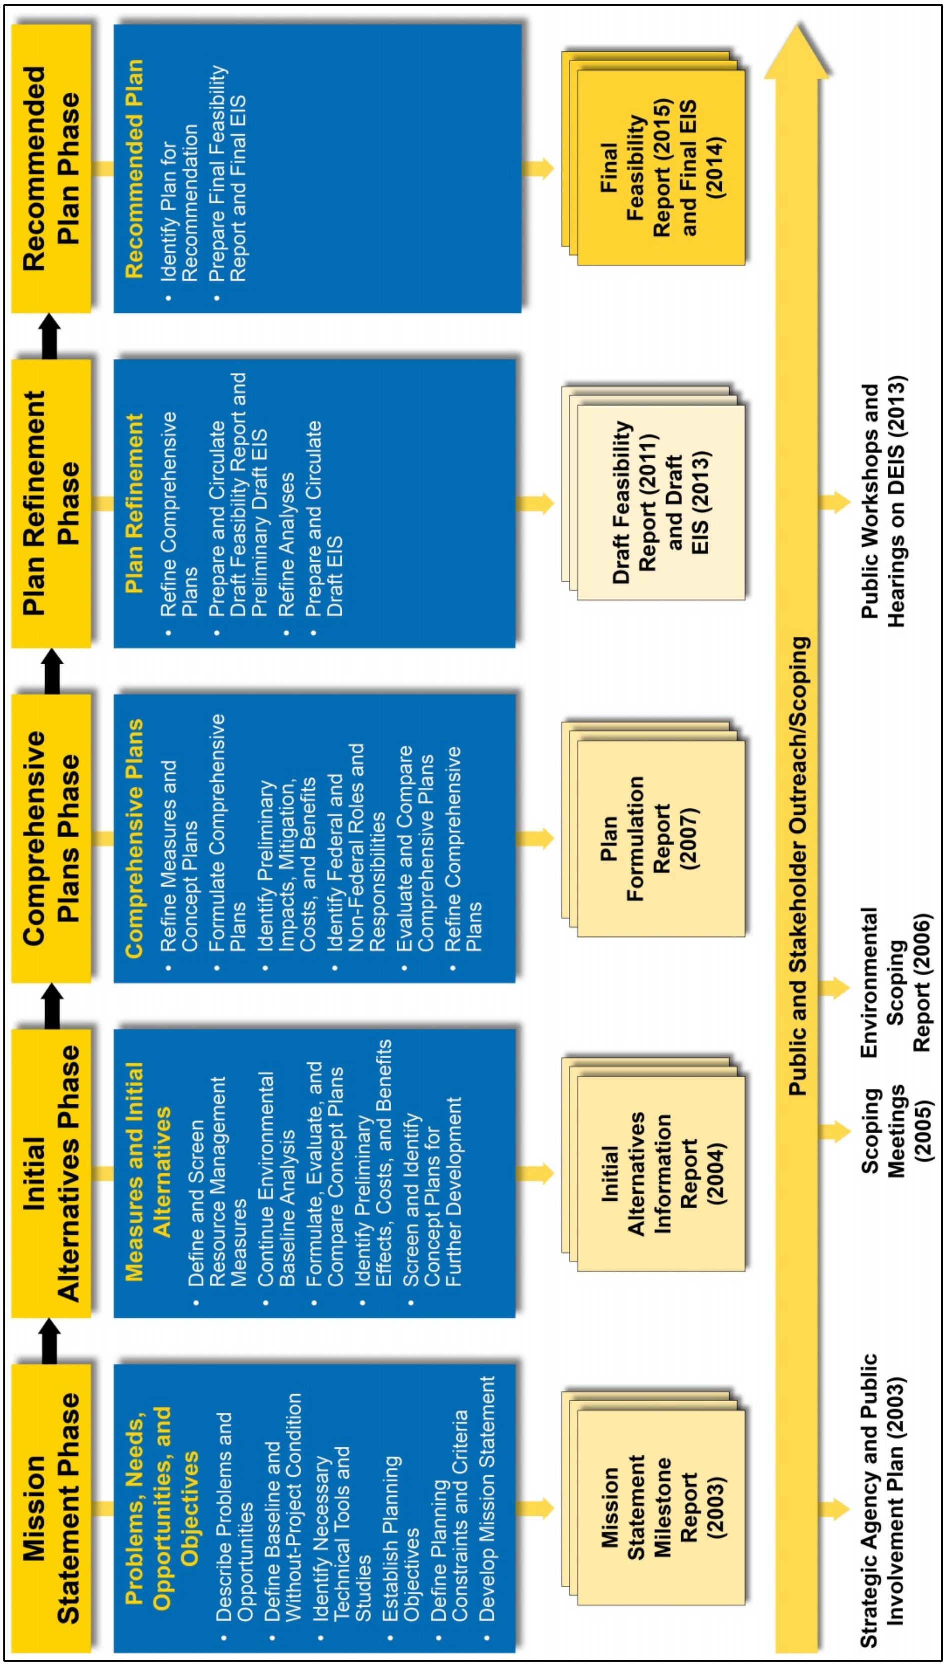
- **Initial Alternatives Phase –** This phase included developing a number of potential management measures, or project actions or features designed to address planning objectives. These measures were then used to formulate a set of plans that were conceptual in scope (concept plans). These initial plans were evaluated and compared to the planning objectives to identify the most suitable plans for further development. This phase concluded with the release of the 2004 *SLWRI Initial Alternatives Information Report* describing the formulation and evaluation of management measures and initial plans.

- **Comprehensive Plans Phase –** The measures and concept plans carried forward were further refined and developed with more specificity to formulate comprehensive alternative plans to address the planning objectives. These plans were then evaluated and compared. This phase included the release of the 2007 *SLWRI Plan Formulation Report* describing the formulation, evaluation, and comparison of comprehensive plans.

- **Plan Refinement Phase –** This phase focused on further refinement and iterative evaluation of the potential effects of the comprehensive plans. This phase included preparing and circulating a Draft Feasibility Report, which was completed in November 2011 and released to the public in February 2012, and the DEIS, which was released to the public in June 2013 for public review and comment.

- **Recommended Plan Phase –** This phase of the SLWRI planning process focuses on identifying a plan for recommendation and preparing and processing the Final Feasibility Report, to support a Federal decision, and this Final EIS.

Public and stakeholder outreach was performed concurrently with the above phases, as shown in Figure 2-1. Major reports include the *SLWRI Strategic Agency and Public Involvement Plan*, published in 2003 (Reclamation), and the *SLWRI Environmental Scoping Report*, published in 2006 (Reclamation).



Key: DEIS = Draft Environmental Impact Statement   EIS = Environmental Impact Statement

Figure 2-1. Plan Formulation Phases

2.1.2 Project Objectives

On the basis of the problems, needs, and opportunities identified in the plan formulation process, study authorities, and other pertinent direction, including information contained in the CALFED PEIS/R and Programmatic ROD (CALFED 2000a, 2000b), primary and secondary project objectives (also referred to as planning objectives) were developed. Primary objectives are those which specific alternatives are formulated to address. The primary objectives are considered to have equal priority, with each pursued to the maximum practicable extent without adversely affecting the other. Secondary objectives are considered to the extent possible through pursuit of the primary objectives.

- **Primary Objectives**:
  - Increase the survival of anadromous fish populations in the Sacramento River, primarily upstream from the Red Bluff Pumping Plant (RBPP)
  - Increase water supply and water supply reliability for agricultural, municipal and industrial (M&I), and environmental purposes to help meet current and future water demands, with a focus on enlarging Shasta Dam and Reservoir
- **Secondary Objectives**:
  - Conserve, restore, and enhance ecosystem resources in the Shasta Lake area and along the upper Sacramento River
  - Reduce flood damage along the Sacramento River
  - Develop additional hydropower generation capabilities at Shasta Dam
  - Maintain and increase recreation opportunities at Shasta Lake
  - Maintain or improve water quality conditions in the Sacramento River downstream from Shasta Dam and in the Delta

2.1.3 Planning Constraints and Other Considerations

The P&G provides fundamental guidance for the formulation of Federal water resources projects. In addition, basic constraints and considerations specific to this investigation were developed and identified. Following is a summary of the constraints and considerations relevant to the SLWRI.

Planning Constraints

Planning constraints help guide the plan formulation process. Some planning constraints are more rigid than others. Examples of more rigid constraints include congressional direction in study authorizations; other current applicable laws, regulations, and policies; and physical conditions (e.g., topography, hydrology). Other planning constraints are less restrictive but are still influential in guiding the process. Several key constraints identified for the SLWRI are as follows:

- **Study Authorizations –** On August 30, 1935, in the Rivers and Harbors Bill, an initial amount of Federal funds was authorized for constructing Kennett (now Shasta) Dam. Initial authorization for the SLWRI derives from Public Law 96-375 of 1980. This law authorized the Secretary of the Interior to engage in feasibility studies relating to (1) enlarging Shasta Dam and Reservoir, or constructing a replacement dam on the Sacramento River and (2) using the Sacramento River to convey water from an enlarged dam. Additional guidance is contained in Public Law 108-361 of 2004, which authorized the Secretary of the Interior to carry out "…planning and feasibility studies for projects to be pursued with project-specific study for enlargement of the Shasta Dam in Shasta County…"

- **CALFED PEIS/R and Programmatic ROD –** CALFED was established to "develop and implement a long-term comprehensive plan that would restore ecological health and improve water management for beneficial uses of the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) system." The 2000 CALFED PEIS/R and Programmatic ROD (CALFED 2000a, 2000b) include program goals, objectives, and projects primarily to benefit the Bay-Delta system. The objectives for the SLWRI are consistent with the CALFED Programmatic ROD (CALFED 2000a) for Shasta enlargement, as follows:

  > *Expand CVP storage in Shasta Lake by approximately 300,000 acre-feet. Such an expansion will increase the pool of cold water available to maintain lower Sacramento River temperatures needed by certain fish and provide other water management benefits, such as water supply reliability.*

  The CALFED Programmatic ROD has been adopted by various Federal and State of California (State) agencies as a framework for further consideration. In addition to objectives for potential enlargement of Shasta Dam and Reservoir, the Preferred Program Alternative in the CALFED PEIS/R and Programmatic ROD includes four other potential surface water and various groundwater storage projects to help reduce the gap between water supplies and projected demands. Expanding water storage capacity is critical to the successful implementation of all aspects of the program. Water supply reliability rests on capturing peak flows, especially during wet years. New storage must be strategically located to provide the needed flexibility in the current water system to improve water quality, support fish restoration goals, and meet the needs of a growing population. The CALFED Programmatic ROD also includes numerous other projects to help improve the ecosystem functions of the Bay-Delta system. Developed plans should address the goals, objectives, and programs and projects of the CALFED PEIS/R and Programmatic ROD (CALFED 2000a, 2000b).

CALFED conducted an initial screening of a list of 52 potential surface water storage sites to reduce the number of sites to a more manageable number for more detailed evaluation during project-specific studies (2000b). CALFED eliminated sites providing less than 200,000 acre-feet storage and those that conflicted with CALFED solution principles, objectives, or policies. Further, based on existing information, CALFED identified some potential surface water storage sites that were more promising in contributing to CALFED goals and objectives and more implementable due to relative costs and stakeholder support. Surface water storage sites recommended by CALFED for subsequent evaluation focused on those with the most potential for helping meet CALFED goals and objectives: Shasta Lake Enlargement, Los Vaqueros Reservoir Enlargement, Sites Reservoir, In-Delta Storage, and development of storage in the upper San Joaquin River Basin (CALFED 2000b) (Figure 2-2).

CALFED = CALFED Bay-Delta Program
Delta = Sacramento-San Joaquin Delta
PEIS/R = Program Environmental Impact Statement/Report
ROD = Record of Decision

Figure 2-2. CALFED Surface Water Storage Investigations Screening

- **Laws, Regulations, and Policies** – Numerous laws, regulations, executive orders, and policies need to be considered, among them: the P&G, NEPA, Fish and Wildlife Coordination Act, Federal Clean Air Act (CAA), Federal Clean Water Act (CWA), National Historic Preservation Act (NHPA), California Public Resources Code, Federal and State Endangered Species Acts, CEQA, and Central Valley Project Improvement Act (CVPIA). The CVPIA, including the associated

Anadromous Fish Restoration Program, is pertinent because it identified specific actions for fish and wildlife mitigation, protection, restoration, and enhancement which influence water supply deliveries, river flows, and related environmental conditions in the primary and extended study areas.

- Table 1-5 in the Plan Formulation Appendix summarizes many of the applicable laws, policies, plans, and permits potentially affecting the project.

Planning Considerations

Planning considerations were specifically identified to help formulate, evaluate, and compare initial plans and, later, detailed alternatives:

- Alternatives should incorporate results of coordination with other Federal and State agencies such as the USFWS; NMFS; USFS; U.S. Department of Interior, Bureau of Indian Affairs; U.S. Department of Interior, Bureau of Land Management (BLM); DWR; and CDFW.
- A direct and significant geographical, operational, and/or physical dependency must exist between major components of alternatives.
- Alternatives should address, at a minimum, each of the identified primary planning objectives and, to the extent possible, the secondary planning objectives.
- Measures to address secondary planning objectives should be either directly or indirectly related to the primary planning objectives (i.e., plan features should not be independent increments).
- Alternatives should strive to first avoid potential adverse effects to environmental resources, or then should include features to mitigate for unavoidable adverse effects through enhanced designs, construction methods, and/or facilities operations.
- Alternatives should avoid any increases in flood damage or other significant, adverse hydraulic effects to areas downstream along the Sacramento River.
- Alternatives should strive to first avoid potential adverse effects to present or historical cultural resources, or then include features to mitigate unavoidable adverse effects.
- Alternatives should not result in significant adverse effects to existing and future water supplies, hydropower generation, or related water resources conditions.

- Alternatives should strive to balance increased water supply reliability between agricultural and M&I uses.
- Alternatives should not result in a reduction in existing recreation capacity at Shasta Lake.
- Alternatives are to consider the purposes, operations, and limitations of existing projects and programs and be formulated to not adversely impact those projects and programs.
- Alternatives are to be formulated and evaluated based on a 100-year period of analysis.
- Construction costs for alternatives are to reflect current prices and price levels, and annual costs are to include the current Federal discount rate and an allowance for interest during construction.
- Alternatives are to be formulated to neither preclude nor enhance development and implementation of other elements included in the CALFED Programmatic ROD or other water resources programs and projects in the Central Valley.
- Alternatives should have a high certainty for achieving intended benefits and not significantly depend on long-term actions (past the initial construction period) for success. Alternatives that require future and ongoing action specific for success have a higher uncertainty than other plans.

2.1.4 Management Measures

Following development of objectives, constraints, and other considerations for the SLWRI, the next major step in plan formulation was to identify and evaluate potential management measures. A management measure is any structural or nonstructural project action or feature that could address the objectives and satisfy the other applicable planning considerations. Numerous potential management measures were identified based on coordination with agencies, public and stakeholder outreach activities, and previous studies, programs, and projects. These measures were developed through SLWRI study team meetings, field inspections, outreach, and environmental scoping for the SLWRI. Management measures are listed in Table 2-1 and described in detail in the Plan Formulation Appendix.

Table 2-1. Management Measures to Address Objectives

Objectives		Management Measure	Retained	Deleted
		Primary Objectives		
Increase Anadromous Fish Survival	Improve Fish Habitat	Restore abandoned gravel mines along the Sacramento River		X
		Construct instream aquatic habitat downstream from Keswick Dam	X	
		Replenish spawning gravel in the Sacramento River	X	
		Construct instream fish habitat on tributaries to the Sacramento River		X
		Remove instream sediment along Middle Creek		X
		Rehabilitate inactive instream gravel mines along Stillwater and Cottonwood creeks		X
	Improve Water Flows and Quality	Make additional modifications to Shasta Dam for temperature control	X	
		Enlarge Shasta Lake cold-water pool	X	
		Modify storage and releases operations at Shasta Dam	X	
		Modify ACID diversions to reduce flow fluctuations		X
		Increase instream flows on Clear, Cow, and Bear creeks		X
		Construct a storage facility on Cottonwood Creek to augment spring instream flows		X
		Transfer existing Shasta Reservoir storage from water supply to cold-water releases		X
		Remove Shasta Dam and Reservoir		X
	Improve Fish Migration	Improve fish trap below Keswick Dam		X
		Screen diversions on Old Cow and South Cow creeks		X
		Remove or screen diversions on Battle Creek		X
		Construct a migration corridor from the Sacramento River to the Pit River		X
		Cease operating or remove the Red Bluff Diversion Dam		X
		Reoperate the CVP to improve overall fish management		X
		Construct a fish ladder on Shasta Dam		X
		Reintroduce anadromous fish to areas upstream from Shasta Dam		X
Increase Water Supply Reliability	Increase Surface Water Storage	Increase conservation storage space in Shasta Reservoir by raising Shasta Dam	X	
		Construct new conservation storage reservoir(s) upstream from Shasta Reservoir		X
		Construct new conservation storage on tributaries to the Sacramento River downstream from Shasta Dam		X
		Construct new conservation offstream surface storage near the Sacramento River downstream from Shasta Dam		X
		Construct new conservation surface water storage south of the Delta		X
		Increase total or seasonal conservation storage at other CVP facilities		X
		Dredge bottom of Shasta Reservoir		X

Table 2-1. Management Measures to Address Objectives (contd.)

Objectives		Management Measure	Retained	Deleted
Increase Water Supply Reliability (continued)	Reoperate Reservoir	Increase effective conservation storage space in Shasta Reservoir by increasing efficiency of reservoir operation for water supply reliability	X	
		Increase the conservation pool in Shasta Reservoir by encroaching on dam freeboard		X
		Increase conservation storage space in Shasta Reservoir by reallocating space from flood control		X
	Improve Conjunctive Water Management	Develop conservation offstream surface storage near the Sacramento River downstream from Shasta Dam		X
		Develop conservation groundwater storage near the Sacramento River downstream from Shasta Dam		X
		Develop additional conservation groundwater storage south of the Delta		X
	Coordinate Operation and Precipitation Enhancement	Improve Delta export and conveyance capability through coordinated CVP and SWP operations		X
		Implement additional precipitation enhancement		X
	Reduce Demand	Implement water use efficiency methods	X	
		Retire agricultural lands		X
	Improve Water Transfers and Purchases	Transfer water between users		X
	Expand Delta Export and Conveyance Facilities	Expand Banks Pumping Plant		X
		Construct Delta-Mendota Canal/California Aqueduct intertie		X
	Improve Surface Water Treatment	Implement treatment/supply of agricultural drainage water		X
		Construct desalinization facility		X

Table 2-1. Management Measures to Address Objectives (contd.)

Objectives		Management Measure	Retained	Deleted
Secondary Objectives				
Conserve, Restore, and Enhance Ecosystem Resources	Improve Cold-Water and Warm-Water Fishery Habitat	Construct shoreline fish habitat around Shasta Lake	X	
		Construct instream fish habitat on tributaries to Shasta Lake	X	
		Increase instream flows on the lower McCloud River		X
		Reduce acid mine drainage entering Shasta Lake		X
		Reduce motorcraft access to upper reservoir arms		X
		Increase instream flows on the Pit River		X
	Restore and Conserve Riparian and Wetland Habitat	Restore riparian and floodplain habitat along the Sacramento River	X	
		Restore wetlands along the Fall River and Hat Creek		X
		Conserve upper Pit River riparian areas		X
		Restore riparian and floodplain habitat on lower Clear Creek		X
		Promote Great Valley cottonwood regeneration along the Sacramento River		X
		Conserve riparian corridor along Cow Creek		X
		Remove and control nonnative vegetation in the Cow Creek and Cottonwood Creek watersheds		X
	Improve Other Fish and Wildlife Habitat	Create a parkway along the Sacramento River		X
		Enhance forest management practices to conserve bald eagle nesting habitat		X
		Remove and control nonnative plants around Shasta Lake		X
		Control erosion and restore affected habitat in the Shasta Lake area		X
		Develop geographic information system for Shasta to Red Bluff reach		X
		Implement erosion control in tributary watersheds		X
Reduce Flood Damage		Update Shasta Dam and Reservoir flood management operations	X	
		Increase flood management storage space in Shasta		X
		Implement nonstructural flood damage reduction measures		X
		Implement traditional flood damage reduction measures		X
		Route PMF from top of conservation pool		X

Table 2-1. Management Measures to Address Objectives (contd.)

Objectives	Management Measure	Retained	Deleted
Develop Additional Hydropower Generation	Modify existing/construct new generation facilities at Shasta Dam to take advantage of increased hydraulic head	X	
	Construct new hydropower generation facilities		X
Maintain and Increase Recreation Opportunities	Maintain and enhance recreation capacity, facilities, and opportunities	X	
	Develop new NRA recreation plan		X
	Reoperate reservoir for recreation	X	
Maintain or Improve Water Quality	Improve operational flexibility for Delta water quality by increasing storage in Shasta Reservoir	X	

Key:
ACID = Anderson-Cottonwood Irrigation District
Banks Pumping Plant = Harvey O. Banks Pumping Plant
CVP = Central Valley Project
Delta = Sacramento-San Joaquin Delta
NRA = National Recreation Area
PMF = probable maximum flood
SWP = State Water Project

In the context of SLWRI management measures and project actions, the term "enhancement" specifically refers to restoration actions that improve environmental conditions above the baseline (without-project condition). Correspondingly, the term "mitigation" refers to restoration actions that improve environmental conditions toward the baseline to compensate for unavoidable adverse project impacts. The relationship between enhancement and mitigation is illustrated in Figure 2-3.

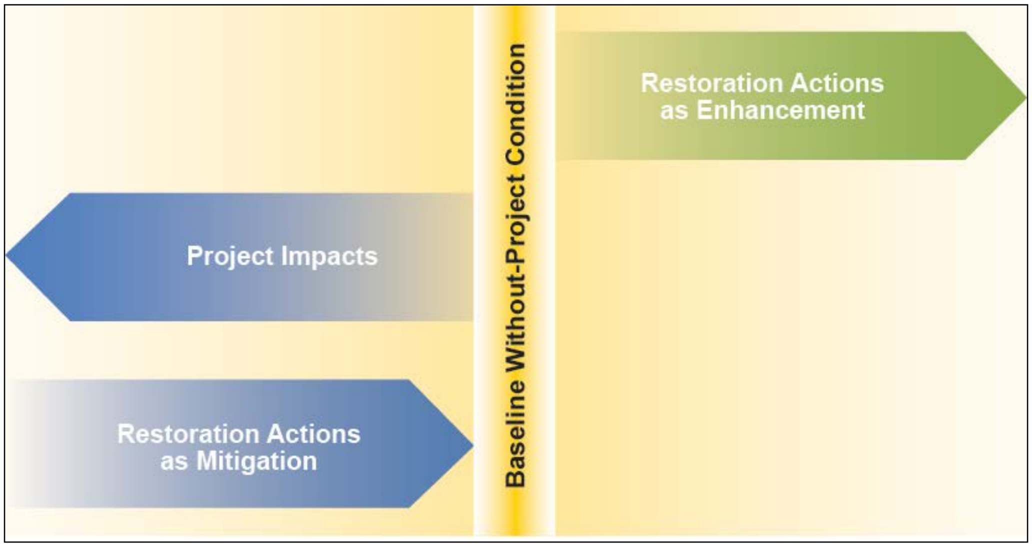

Figure 2-3. Conceptual Schematic of Restoration Actions as Enhancement Versus Restoration Actions as Mitigation

The SLWRI study team and stakeholders reviewed the management measures for their ability to address the primary and secondary objectives. Retained management measures were combined to formulate concept plans. As detailed in the Plan Formulation Appendix, measures were retained for possible inclusion in an alternative plan or deleted from further consideration for various reasons. One important factor for retention in alternative plans was the potential for a measure to directly address an objective without adversely impacting other objectives.

Of the management measures listed in Table 2-1, eight measures addressing primary objectives were selected for further consideration and potential inclusion in alternative plans. In addition, eight measures addressing secondary objectives were also selected for potential inclusion in alternative plans. Measures that have been carried forward are believed to best address the project objectives, with consideration of planning constraints and criteria.

2.1.5 Initial Alternatives Phase

The retained measures were used to formulate a preliminary set of plans that were conceptual in scope. Each concept plan was reviewed for impacts, costs, and benefits and compared to objectives to determine whether the plan should be eliminated or carried forward into the comprehensive plans phase. The purpose of this phase of the formulation process was to (1) explore an array of different strategies to address the primary objectives, constraints, and criteria, and (2) identify concept plans that would warrant further development in the comprehensive plans phase.

First, two sets of plans were developed that focused on either anadromous fish survival (AFS) or water supply reliability (WSR) as the single primary objective. Three AFS plans and four WSR plans were developed. Although the AFS and WSR plans focused on single objectives, each generally contributed to both primary objectives. In the three AFS plans, for example, emphasis was placed on combinations of measures that could best address the fish survival goals while considering incidental benefits to water supply reliability, if possible. Second, five plans were developed that included measures to address both primary and, to a lesser degree, secondary objectives, termed combined objective (CO) plans. All 12 concept plans are listed in Table 2-2, and are explained in detail in the Plan Formulation Appendix.

The 12 concept plans were compared considering two basic planning criteria: effectiveness and efficiency. Effectiveness is the extent to which an alternative alleviates problems and achieves objectives; efficiency is the measure of how efficiently an alternative alleviates identified problems and meets specified objectives to protect the nation's environment. These, along with completeness and acceptability, are the four general criteria identified in the P&G (WRC 1983). Based on this comparison, and the relative ability of plans to address both primary objectives, five of the concept plans were initially recommended for further development as comprehensive plans: WSR-1, WSR-2, WSR-4, CO-2, and CO-5. None of the AFS plans were recommended for further development because AFS-1 did not contribute to the primary objective of increasing water supply reliability, and evaluations indicated that AFS-2 and AFS-3 would result in fewer benefits to anadromous fish survival than any of the WSR and CO plans. This is because AFS-2 and AFS-3 focused on increasing minimum flows in the upper Sacramento River, which resulted in a reduced cold-water pool during drought periods in comparison to WSR and CO plans.

Through subsequent evaluations, CO-2 was also eliminated from further consideration because it was concluded that restoration of existing gravel mines would have a low efficiency and likelihood of successfully benefiting salmon resources. Subsequent analysis of WSR-4 and the conjunctive use component of CO-5 indicated tradeoffs between conjunctive use water supply benefits and critical gains in fisheries benefits. The resulting reduction in benefits to fisheries operations in dry and critical years[1] was deemed unacceptable in terms of

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

meeting primary project objectives. Thus, WSR-4 and the conjunctive use component of CO-5 were eliminated from further consideration.

Table 2-2. Summary of Concept Plan Features

Plan	Features												
	Dam Raise	Primary Objective Focus							Secondary Objectives Addressed[4]				
		Water Supply Reliability[2]		Anadromous Fish Survival					Environmental Restoration			Flood Control and Hydropower	
		Increase Conservation Storage	Perform Conjunctive Water Management[3]	Reoperate Shasta Dam	Modify TCD	Replenish Spawning Gravel	Enlarge Shasta Lake Cold-Water Pool	Increase Minimum Flows[3]	Restore Shoreline Aquatic Habitat	Restore Tributary Aquatic Habitat	Restore Riparian Habitat	Modify Flood Control Operations and Implement Shasta Public Safety[3] Features	Modify Hydropower Facilities
AFS-1	6.5	*		Changes to water supply operations and modification of the TCD would likely be included, to some extent, in any alternative that includes raising Shasta Dam.			X					Changes to flood control operations at Shasta Dam, Public Safety,[3] and hydropower facilities would likely be part of any alternative that includes physically modifying Shasta Dam; the degree and details of these changes will be included in feasibility level alternative plans.	
AFS-2	6.5	*					*	X					
AFS-3	6.5	*				X	*	X					
WSR-1	6.5	X					*						
WSR-2	18.5	X					*						
WSR-3	202.5	X					*						
WSR-4	18.5	X	X				*						
CO-1	6.5	X				X	X						
CO-2	18.5	X				X	X						
CO-3	18.5	X				X	X	X					
CO-4	6.5	X	X			X	X		X	X	X		
CO-5	18.5	X	X			X	X		X	X	X		

Notes:

[1] Raising Shasta Dam provides both water supply and temperature benefits, regardless of how the additional storage is exercised. While the anadromous fish survival measures focus on use of the additional space for anadromous fish survival, they also provide water supply benefits. Similarly, the water supply reliability measures focus on water supply reliability but the reservoir enlargements also provide benefits to anadromous fish.

[2] All concept plans include water demand reduction.

[3] These measures were used for evaluation because they were retained at the time of plan formulation. However, they have since been removed from consideration.

[4] Water quality and recreation were added as secondary objectives after development of concept plans, and are not considered in this table.

Key:
* Coincidental benefit, although not a primary focus of the concept plan.
AFS-x = anadromous fish survival
CO-x = combined objectives
TCD = temperature control device
WSR-x = water supply reliability
X = Primary focus of concept plan

The eight concept plans eliminated from further consideration are described in Section 2.4, “Alternatives Considered and Eliminated from Further Analysis.” Although these concept plans were not further considered as stand-alone plans, major features of some of these plans were refined for further development into alternatives. Concept plans eliminated from further consideration, and rationale for their elimination, are discussed in greater detail in the Plan Formulation Appendix.

2.1.6 Development and Refinement of Comprehensive Plans

Through continued refinement of management measures and concept plans carried forward, the following plan types were identified for further development into comprehensive plans:

- Plan(s) to raise Shasta Dam between 6.5 feet and 18.5 feet, focusing on both water supply reliability and anadromous fish survival but with benefits to various secondary objectives
- Plan(s) to raise Shasta Dam by about 18.5 feet, focusing on anadromous fish survival, but also including water supply reliability and other various secondary objectives
- Plan(s) to raise Shasta Dam by about 18.5 feet, focusing on all objectives

Considering results of initial plan formulation efforts, the approach was to first formulate plans focusing on different dam raise heights within the range of 6.5 feet to 18.5 feet to address the first plan type listed above. A dam raise of 12.5 feet was chosen because it represented a midpoint between the smallest and largest practical dam raises. Next, the approach was to identify the most efficient and effective of the identified dam raise heights, and formulate comprehensive plans to focus on anadromous fish survival and other objectives at this height.

Comprehensive Plans in the Draft Feasibility Report and Supporting Documents

Using the general rationale described above, and incorporating input from the public scoping process and continued coordination with resource agencies and other interested parties, five comprehensive plans were developed for the Draft Feasibility Report and Preliminary DEIS:

- **Preliminary Comprehensive Plan 1 (PCP1) –** 6.5-foot dam raise, enlarging the reservoir by 256,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.
- **Preliminary Comprehensive Plan 2 (PCP2) –** 12.5-foot dam raise, enlarging the reservoir by 443,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.

- **Preliminary Comprehensive Plan 3 (PCP3) –** 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.

- **Preliminary Comprehensive Plan 4 (PCP4) –** 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, focusing on anadromous fish survival while increasing water supply reliability.

- **Preliminary Comprehensive Plan 5 (PCP5) –** 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, a combination plan focusing on all objectives.

As described further in Chapter 3, "Considerations for Describing Affected Environment and Environmental Consequences," Section 3.2.3, "Methods and Assumptions," due to uncertainty related to CVP and SWP operational constraints, water operations modeling and related evaluations in the 2011 Draft Feasibility Report and Preliminary DEIS were based on available modeling analyses at the time. This modeling reflected CVP and SWP operations and constraints described in:

- The Reclamation 2004 *Long-Term CVP and SWP Operations Criteria and Plan Biological Assessment* (2004 OCAP Biological Assessment (BA)) (Reclamation 2004)

- The NMFS 2004 *Biological Opinion on the Long-Term Central Valley Project and State Water Project Operations Criteria and Plan NMFS Biological Opinion* (2004 NMFS Biological Opinion (BO)) (NMFS 2004)

- The USFWS 2005 *Reinitiation of Formal and Early Section 7 Endangered Species Consultation on the Coordinated Operations of the Central Valley Project and State Water Project and the Operational Criteria and Plan to Address Potential Critical Habitat Issues* (2005 USFWS BO) (USFWS 2005)

These analyses were suitable for comparison purposes, and reflected expected variation among the alternatives, including the type and relative magnitude of anticipated impacts and benefits.

Because of the large number of possibilities for increasing anadromous fish survival, additional analyses were conducted to determine the combination of actions that would provide the greatest overall benefits within PCP4. These analyses are described below.

Refinement of Plan for Anadromous Fish Survival Focus with Water Supply Reliability Primarily using the SALMOD model, and based on output from the water operations (CalSim-II), reservoir temperature, and river temperature models, a suite of flow- and temperature-focused actions (scenarios) were investigated to assess which combination of actions would likely result in the maximum increase in fish populations.

To formulate PCP4, three dam height raises were considered (6.5 feet, 12.5 feet, and 18.5 feet), resulting in 256,000 acre-feet, 443,000 acre-feet, and 634,000 acre-feet of increased storage, respectively. For each of these proposed dam raises, several combinations for allocating the increased storage were analyzed. For instance, assuming a dam raise of 12.5 feet, three options were considered: (1) no increase in the minimum pool, (2) an increase in the minimum pool similar to a 6.5-foot dam raise, and (3) all of the increased space dedicated to increased fisheries. The combinations considered represent scenarios developed to focus on increasing the cold-water pool, and are listed in Table 2-3.

Table 2-3. Scenarios Considered for Cold-Water Storage – Anadromous Fish Survival Focus with Water Supply Reliability

Scenario	Dam Raise (feet)	Enlarged Reservoir	Description
A (PCP1)	6.5	256,000 acre-feet	No increase in minimum pool.
B	6.5	256,000 acre-feet	Dedicate 256,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.
C (PCP2)	12.5	443,000 acre-feet	No increase in minimum pool.
D	12.5	443,000 acre-feet	Dedicate 187,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.
E	12.5	443,000 acre-feet	Dedicate 443,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.
F (PCP3/PCP5)	18.5	634,000 acre-feet	No increase in minimum pool.
G	18.5	634,000 acre-feet	Dedicate 191,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.
H (PCP4)	18.5	634,000 acre-feet	Dedicate 378,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.
I	18.5	634,000 acre-feet	Dedicate 634,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.

Note:
Water operations based on the NMFS 2004 *Biological Opinion on the Long-Term Central Valley Project and State Water Project Operations Criteria and Plan NMFS Biological Opinion* (NMFS 2004); and the USFWS 2005 *Reinitiation of Formal and Early Section 7 Endangered Species Consultation on the Coordinated Operations of the Central Valley Project and State Water Project and the Operational Criteria and Plan to Address Potential Critical Habitat Issues* (USFWS 2005)
Key:
NMFS = National Marine Fisheries Services
PCP1 = Preliminary Comprehensive Plan 1
PCP2 = Preliminary Comprehensive Plan 2
PCP3 = Preliminary Comprehensive Plan 3
PCP4 = Preliminary Comprehensive Plan 4
PCP5 = Preliminary Comprehensive Plan 5
USFWS = U.S. Department of the Interior, Fish and Wildlife Service

Additional scenarios focusing on increasing Sacramento River flows with an 18.5-foot raise were also analyzed. The flow combinations were based primarily on flows identified as part of the Anadromous Fish Restoration Plan (USFWS 2001). These scenarios are listed in Table 2-4.

Table 2-4. Scenarios Considered to Augment Flows – Anadromous Fish Survival Focus Plan

Flow Augmentation Scenario	Dam Raise (feet)	Enlarged Reservoir	Description
1	18.5	634,000 acre-feet	October – March AFRP flows or 500 cfs increase, whichever is less.
2	18.5	634,000 acre-feet	October – March AFRP flows or 750 cfs increase, whichever is less.
3	18.5	634,000 acre-feet	October – March AFRP flows or 1,000 cfs increase, whichever is less.
4	18.5	634,000 acre-feet	Increase August flows to 10,000 cfs and September flows to 6,000 cfs for temperature control.

Note:
Water operations based on the NMFS 2004 *Biological Opinion on the Long-Term Central Valley Project and State Water Project Operations Criteria and Plan NMFS Biological Opinion* (NMFS 2004); and the USFWS 2005 *Reinitiation of Formal and Early Section 7 Endangered Species Consultation on the Coordinated Operations of the Central Valley Project and State Water Project and the Operational Criteria and Plan to Address Potential Critical Habitat Issues* (USFWS 2005)
Key:
AFRP = Anadromous Fish Restoration Plan (USFWS 2001)
cfs = cubic feet per second
NMFS = National Marine Fisheries Services
USFWS = U.S. Department of the Interior, Fish and Wildlife Service

Quantitative analysis indicated that increasing the minimum pool in Shasta Reservoir would have the greatest net fishery benefit. By increasing the minimum pool, the allowable carryover pool storage would increase in the reservoir. This carryover would act to conserve cold water that could be managed to better benefit anadromous fish. Scenarios 1, 2, 3, and 4 (flow augmentation scenarios) showed limited benefits to anadromous fish compared with other scenarios, and were eliminated from further analysis. Scenarios B, E, and I would not contribute to increased water supply reliability. Although PCP4 focuses on anadromous fish survival, because these three scenarios would not contribute to a primary objective, they were deleted from further consideration. Of the remaining scenarios, Scenarios D and H were deemed to be the most cost-effective. Based on further analysis, Scenario H was chosen to represent reservoir operations in PCP4 because this scenario would provide the greatest benefit to anadromous fish and still meet the primary objective of water supply reliability. Scenario comparison and selection are discussed further in the Plan Formulation Appendix.

Refinement of Comprehensive Plans for the DEIS and Final EIS

Comprehensive plans were further refined for the DEIS based on several factors, including updates to CVP and SWP water operations and stakeholder input. Since the release of the Draft Feasibility Report and Preliminary DEIS, water operations modeling in CalSim-II and related analyses were updated to include the following:

- The USFWS 2008 *Formal Endangered Species Act Consultation on the Proposed Coordinated Operations of the CVP and SWP* (2008 USFWS BO) (USFWS 2008)
- The NMFS 2009 *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO) (NMFS 2009)
- Additional changes in CVP and SWP facilities and operations, such as the enlarged Los Vaqueros Reservoir and implementation of the San Joaquin River Restoration Program
- Additional changes in non-CVP/SWP facilities and operations, such as the addition of the Freeport Regional Water Project

Preliminary analyses based on these updated operations indicated shifts in the distribution of water supply benefits from M&I to agricultural uses, resulting in decreased M&I water supply benefits for the Draft Feasibility Report comprehensive plans.

To improve the balance between agricultural and M&I water supply benefits, a portion of the increased storage capacity in Shasta Reservoir was reserved to specifically focus on increasing M&I deliveries during dry and critical years under Comprehensive Plan 1 (CP1), Comprehensive Plan 2 (CP2), Comprehensive Plan 4 (CP4), and Comprehensive Plan 5 (CP5). Operations targeting increased M&I deliveries were based on existing and anticipated future demands, operational priorities, and facilities of the SWP, which provides M&I water to a majority of the State’s population.

In addition, to provide a greater range of focus and operations within the set of comprehensive plans, water supply operations for Comprehensive Plan 3 (CP3) were focused on agricultural water supply reliability and anadromous fish survival. Accordingly, for CP3, none of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries.

Refinement of Operational Scenario for Plan Focused on Anadromous Fish Survival with Water Supply Reliability Based on public comments on the Draft Feasibility Report and DEIS, a refined operational scenario (Comprehensive Plan 4A (CP4A)) was developed for the anadromous fish focused plan. This new operational scenario is a refinement of the operations for CP4, based on several factors, including the updated CVP and SWP operations, described above, which are based on the 2008 USFWS BO and 2009 NMFS BO. A suite of temperature and flow-focused actions (scenarios) were investigated to assess which combination of actions would likely maximize increases in anadromous fish populations. These investigations primarily used the SALMOD model, and were based on output from the water operations (CalSim-II), reservoir temperature, and river temperature models. Similar scenario refinements were considered for the Draft Feasibility Report, as summarized in Table 2-3 and Table 2-4. However, Draft Feasibility Report scenarios were based on CVP and SWP operational scenarios including the 2004 NMFS BO and 2005 USFWS BO, which have been since updated.

A range of scenarios were considered during the development of CP4A. For these scenarios, several combinations for allocating the increased storage were analyzed, focusing on either increasing the volume of the cold-water pool in Shasta Reservoir or augmenting flows downstream from Shasta Dam. Flow augmentation scenarios were based primarily on flows identified as part of the Anadromous Fish Restoration Plan (USFWS 2001). Table 2-5 highlights the range of scenarios considered and estimated benefits to water supply reliability and anadromous fisheries under each scenario.

CP4A was selected as the refined operational scenario for CP4, as it allows for improved balance between water supply benefits and fisheries benefits compared to other scenarios.

Table 2-5. Scenarios Considered for Refinement of Final EIS Comprehensive Plans

Scenario	Dam Raise (feet)	Enlarged Reservoir (acre-feet)	Description	Production Increase (number of fish)[1]	Total Increase in Water Supply Reliability[2] Average (acre-feet/year)	Total Increase in Water Supply Reliability[2] Dry/Critical (acre-feet/year)
Scenarios Considered for Cold-Water Storage as Part of Fish Focus Plan						
A (CP1)	6.5	256,000	No increase in minimum cold-water pool for fishery benefit. 70,000 acre-feet and 35,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	61,300	31,000	47,300
B	6.5	256,000	Dedicate 256,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit. No increased storage capacity in Shasta Reservoir reserved for water supply.	673,000	0	0
C (CP2)	12.5	443,000	No increase in minimum cold-water pool for fishery benefit. 100,000 acre-feet and 50,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	379,200	51,300	77,800
D	12.5	443,000	Dedicate 187,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit. 70,000 acre-feet and 35,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	428,700	31,000	47,300
E	12.5	443,000	Dedicate 443,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit. No increased storage capacity in Shasta Reservoir reserved for water supply.	999,900	0	0
F (CP3)	18.5	634,000	No increase in minimum cold-water pool for fishery benefit. Increased storage capacity in Shasta Reservoir dedicated to agricultural deliveries.	207,400	61,700	63,100
F (CP5)	18.5	634,000	No increase in minimum cold-water pool for fishery benefit. 150,000 acre-feet and 75,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	377,800	75,900	113,500

Table 2-5. Scenarios Considered for Refinement of Final EIS Comprehensive Plans (contd.)

Scenario	Dam Raise (feet)	Enlarged Reservoir (acre-feet)	Description	Production Increase (number of fish)[1]	Total Increase in Water Supply Reliability[2] Average (acre-feet/year)	Total Increase in Water Supply Reliability[2] Dry/Critical (acre-feet/year)
4[4]	18.5	634,000	Increase August flows to 10,000 cfs and September flows to 6,000 cfs for temperature control. 150,000 acre-feet and 75,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	63,900	73,000	122,800
F (CP4A)	18.5	634.000	Dedicate 191,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit. 100,000 acre-feet and 50,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	710,000	51,300	77,800
C (CP4)	18.5	634,000	Dedicate 378,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit. 70,000 acre-feet and 35,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	812,600	31,000	47,300
I	18.5	634.000	Dedicate 634,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit. No increased storage capacity in Shasta Reservoir reserved for water supply.	971,400	0	0
Scenarios Considered to Augment Flows as Part of Fish Focus Plan						
1[3]	18.5	634,000	October - March AFRP flows or 500 cfs increase, whichever is lower. Increased storage capacity in Shasta Reservoir dedicated to agricultural deliveries.	348,700	54,600	57,200
1[4]	18.5	634,000	October - March AFRP flows or 500 cfs increase, whichever is lower. 150,000 acre-feet and 75,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	319,300	65,000	91,300
3[3]	18.5	634,000	October - March AFRP flows or 1,000 cfs increase, whichever is lower. Increased storage capacity in Shasta Reservoir dedicated to agricultural deliveries.	222,800	42,200	35,700
3[4]	18.5	634,000	October - March AFRP flows or 1,000 cfs increase, whichever is lower. 150,000 acre-feet and 75,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	309,500	54,600	69,300
4[3]	18.5	634,000	Increase August flows to 10,000 cfs and September flows to 6,000 cfs for temperature control. Increased storage capacity in Shasta Reservoir dedicated to agricultural deliveries.	88,400	62,600	76,400

Table 2-5. Scenarios Considered for Refinement of Final EIS Comprehensive Plans (contd.)

Scenario	Dam Raise (feet)	Enlarged Reservoir (acre-feet)	Description	Production Increase (number of fish)[1]	Total Increase in Water Supply Reliability[2] Average (acre-feet/year)	Total Increase in Water Supply Reliability[2] Dry/Critical (acre-feet/year)
4[4]	18.5	634,000	Increase August flows to 10,000 cfs and September flows to 6,000 cfs for temperature control. 150,000 acre-feet and 75,000 acre-feet of the increased storage capacity in Shasta Reservoir was reserved for increasing M&I deliveries in dry and critical years, respectively.	63,900	73,000	122,800

Note:

[1] Estimates of increased anadromous fish survival were based on simulations using the SALMOD model. These estimates represent an index of production increase, based on the simulated average annual increase in juvenile Chinook salmon surviving to migrate downstream from the Red Bluff Pumping Plant.

[2] Increased water supply reliability was simulated with CalSim-II based on October to September water years. Water Year Types Based on the Sacramento Valley Water Year Hydrologic Classification. Water operations based on the USFWS 2008 *USFWS 2008 Formal Endangered Species Act Consultation on the Proposed Coordinated Operations of the CVP and SWP (*USFWS 2008) and NMFS 2009 *Biological Opinion and Conference Opinion on the Long-Term Operations of the CVP and SWP* (NMFS 2009).

[3] Refined operational scenario based on CP3 and corresponding distribution of water supply benefits.

[4] Refined operational scenario based on CP5 and corresponding distribution of water supply benefits.

Key:
AFRP = Anadromous Fish Restoration Program
cfs = cubic feet per second
CP = Comprehensive Plan
CVP = Central Valley Project
EIS = Environmental Impact Statement
M&I = municipal and industrial
NMFS = National Marine Fisheries Service
SWP = State Water Project
USFWS = U.S. Department of the Interior, Fish and Wildlife Service

Based on the refinements described above, this EIS includes the following comprehensive plans:

- **CP1 –** 6.5-foot dam raise, enlarging the reservoir by 256,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.
- **CP2 –** 12.5-foot dam raise, enlarging the reservoir by 443,000 acre-feet, focusing on both anadromous fish survival and water supply reliability.
- **CP3 –** 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, focusing on both agricultural water supply reliability and anadromous fish survival.
- **CP4 and CP4A –** 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, focusing on anadromous fish survival while increasing water supply reliability.
- **CP5 –** 18.5-foot dam raise, enlarging the reservoir by 634,000 acre-feet, a combination plan focusing on all objectives.

Comprehensive plans for this EIS are described in detail in Section 2.3, "Action Alternatives," below.

2.2 No-Action Alternative

NEPA and CEQA require the analysis of a baseline alternative, representing a scenario in which the project is not implemented. For all Federal feasibility studies of potential water resources projects, the NEPA No-Action Alternative is intended to account for existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area. Reasonably foreseeable actions include actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete.

Under CEQA, the No-Project Alternative is similar to NEPA's No-Action Alternative, but it involves the review of two scenarios: the existing condition baseline, which represents only current conditions at the time the Notice of Preparation is published, and "reasonably foreseeable" future conditions without the project (which is equivalent to the NEPA No-Action Alternative).

For the SLWRI, the No-Action Alternative (which also constitutes the No-Project Alternative under CEQA, as previously mentioned) is based on CVP and SWP operational conditions described in the 2008 *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP* (2008 Long-Term Operation BA), and the BOs issued by USFWS and NMFS in 2008 and 2009, respectively. The No-Action Alternative also includes continued implementation of actions identified under the CVPIA. In addition, the No-Action Alternative includes key projects assumed to be in place and operating in the future, including the Freeport Regional Water Project, Delta Water Supply Project, South Bay Aqueduct Improvement and Enlargement Project, a functional equivalent of the Vernalis Adaptive Management Plan, full restoration flows under the San Joaquin River Restoration Program, and full implementation of the Grassland Bypass Project. The existing and future conditions for the SLWRI are further described in Chapter 3, "Considerations for Describing Affected Environment and Environmental Consequences," Section 3.2.3, "Methods and Assumptions." In addition, Table 2-1 of the Modeling Appendix shows which actions were assumed to be part of the existing condition and the future condition (or No-Action /No-Project Alternative) in the SLWRI 2012 CalSim-II model.

For this EIS, the No-Action Alternative is considered to be the basis for comparison with potential action alternatives, consistent with NEPA and P&G guidelines. Thus, if no proposed action is determined to be feasible, the No-Action Alternative is the default option.

Under the No-Action Alternative, the Federal government would continue to implement reasonably foreseeable actions, as defined above, but would not take additional actions toward implementing a plan to raise Shasta Dam to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water supply and reliability issues in California. The following discussions highlight the consequences of implementing the No-Action Alternative, as they relate to the project objectives.

In addition to comparing the No-Action Alternative to potential action alternatives, the potential action alternatives were also compared to the existing condition baseline (as described above) in consideration of CEQA requirements.

2.2.1 Anadromous Fish Survival

Much has been done to address anadromous fish survival problems in the upper Sacramento River. Solutions have ranged from changes in the timing and magnitude of releases from Shasta Dam to constructing and operating the temperature control device (TCD) at the dam. Actions also include site-specific projects, such as introducing spawning gravel to the Sacramento River, and work to improve or restore spawning habitat in tributary streams. However, to increase anadromous fish survival and reduce the risk of extinction, further water temperature improvements are needed in the Sacramento River, especially in dry and critical years. Increased demand for water for agricultural, M&I, and environmental uses is also expected to reduce the reliability of cold water for anadromous fish. Prolonged drought that depletes the cold-water pool in Shasta Reservoir could put populations of anadromous fish at risk of severe population decline or extinction in the long-term (NMFS 2014). The risk associated with a prolonged drought is especially high in the Sacramento River because Shasta Reservoir is operated to maintain only 1 year of carryover storage.

Under the No-Action Alternative, it is assumed that actions to protect fisheries and benefit aquatic environments would continue, including maintaining the TCD, ongoing spawning gravel augmentation programs, and satisfying other existing regulatory requirements.

2.2.2 Water Supply Reliability

Demands for water in the Central Valley and throughout California exceed available supplies, and the need for additional supplies is expected to grow. There is growing competition for limited system resources among various users and uses, including agricultural, M&I, and environmental. M&I water demands and environmental water requirements have each increased, resulting in greater competition for limited water supplies. As mentioned, the population of California is expected to increase by more than 60 percent above 2005 levels by 2050. Significant increases in population also are expected to occur in the Central Valley, nearly 130 percent above 2005 levels by 2050 (California Department of Finance 2007). As these population increases occur, and are coupled with the need to maintain a healthy and vibrant industrial and agricultural economy, the demand for water would continue to significantly exceed available supplies. Competition for available water supplies would intensify as water demands increase to support this population growth.

Water conservation and reuse efforts are expected to substantially increase, and forced conservation resulting from increasing water shortages would continue. Without developing cost-effective new sources, however, the growing urban population would increasingly rely on shifting water supplies from such areas as agricultural production to satisfy M&I demands. In the urban sector, reduced supplies or increased supply uncertainty could cause water rates to increase as agencies seek to remedy supply shortfalls by implementing measures to reduce demand and/or augment supplies.

It is likely that with continued and deepening shortages in available water supplies, adverse economic and socioeconomic impacts would increase over time in the Central Valley and elsewhere in California. One example could include higher water costs, resulting in a further shift in agricultural production to areas outside California and/or outside the United States. Another example could include water supply shortages resulting in changes in land use patterns, loss and destruction of permanent crops, and/or decreased production of existing crops. In response to reduced water supplies, farmers may fallow fields, reducing agricultural productivity directly, resulting in layoffs, reduced hours for agricultural employees, and increased unemployment in agricultural communities. Reduced water supplies and the resulting employment losses could also cause socioeconomic impacts in affected communities.

Under the No-Action Alternative, Shasta Dam would not be modified and the CVP would continue operating similarly to existing conditions. The No-Action Alternative would continue to meet water supply demands at levels similar to existing conditions, but would not be able to meet the expected increased demand in California.

2.2.3 Ecosystem Resources, Flood Management, Hydropower Generation, Recreation, and Water Quality

As opportunities arise, some efforts would likely continue to improve environmental conditions on tributaries to Shasta Lake and along the upper Sacramento River. However, overall, future environmental conditions in these areas would likely be similar to existing conditions. The quantity, quality, diversity, and connectivity of riparian, wetland, and riverine habitats along the Sacramento River have been limited by confinement of the river system by levees, reclamation of adjacent lands for farming, bank protection, channel stabilization, and land development.

Shasta Dam and Reservoir have greatly reduced flood damage along the Sacramento River. Shasta Dam and Reservoir were constructed at a total cost of about $36 million in 1936 (about $2 billion in 2014 dollars). Shasta Dam, in combination with the Sacramento River Flood Control Project, protects about 1 million people and over $60 billion in assets. However, residual risks to human life, health, and safety along the Sacramento River remain. Development in flood-prone areas has exposed the public to the risk of flooding. Storms producing peak flows, and volumes greater than the existing flood management system was designed for, can occur, and result in extensive flooding along the upper Sacramento River. Under the No-Action Alternative, the threat of flooding would continue, and may increase as population growth continues.

California's demand for electricity is expected to substantially increase in the future. Under the No-Action Alternative, no actions would be taken to help meet this growing demand.

As California's population continues to grow, demands would grow substantially for water-oriented recreation at and near the lakes, reservoirs, streams, and rivers of the Central Valley. This increase in demand would be especially pronounced at Shasta Lake.

To address the impact of water quality deterioration on the Sacramento River basin and Delta ecosystems and endangered and threatened fish populations, several environmental flow goals and objectives in the Central Valley (including the Delta) have been established through legal mandates aimed at maintaining and recovering endangered and threatened fish and wildlife, and protecting designated critical habitat. Despite these efforts, under the No-Action Alternative, these resources would continue to decline and ecosystems would continue to be impacted. In addition, Delta water quality may continue to decline.

2.3 Action Alternatives

The comprehensive plans designated as the action alternatives for the purpose of this EIS include:

- **CP1 –** 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability
- **CP2 –** 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability
- **CP3 –** 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival
- **CP4 and CP4A –** 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability
- **CP5 –** 18.5-Foot Dam Raise, Combination Plan

Management measures and environmental commitments common to all action alternatives are described first, in Sections 2.3.1, "Management Measures Common to All Action Alternatives," and 2.3.2, "Environmental Commitments Common to All Action Alternatives." Then, major components, potential benefits, and operations and maintenance for each action alternative are described in Sections 2.3.3, "CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability," through 2.3.7, "CP5 – 18.5-Foot Dam Raise, Combination Plan." Physical features and related construction activities for each action alternative are described in Section 2.3.8, "Comprehensive Plan Construction Activities." Detailed discussions of potential effects and proposed mitigation measures for each action alternative are included in Chapters 4 through 25 of the EIS. A compilation of all mitigation measures for all action alternatives is included in the Preliminary Environmental Commitments and Mitigation Plan Appendix. If any action alternative was authorized by Congress, Reclamation would implement the components of the plans, environmental commitments, mitigation measures, and permit and approval conditions, as described throughout this EIS and in any required permits or approvals issued for implementation.

The environmental commitment section of the DEIS included a commitment to develop and implement a mitigation plan to minimize potential impacts to physical, biological, and socioeconomic resources. In conjunction with an interagency, interdisciplinary team, Reclamation refined and enhanced the mitigation measures, including developing a framework to quantify impacts (where appropriate) and establish mitigation ratios that were applicable to a number of impacts related to biological resources. For this Final EIS, the refined and enhanced mitigation measures have been incorporated into Chapters 4 through 25 and are presented in the Preliminary Environmental Commitments and Mitigation Plan Appendix.

2.3.1 Management Measures Common to All Action Alternatives

Eight of the management measures retained during the alternatives development process are included, to some degree, in all of the action alternatives. These measures were included because they (1) would either be incorporated or required with any dam raise, (2) were logical and convenient additions that would significantly improve any alternative, or (3) should be considered with any new water increment developed in California. The eight measures include enlarging the Shasta Lake cold-water pool, modifying the TCD, increasing conservation storage, reducing demand, modifying flood operations, modifying hydropower facilities, maintaining or increasing recreation opportunities, and maintaining or improving water quality.

Enlarge Shasta Lake Cold-Water Pool

Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBPP. At a minimum, all comprehensive plans would include enlarging the cold-water pool by raising Shasta Dam to enlarge Shasta Reservoir. Some alternatives would also increase the seasonal carryover storage in Shasta Lake.

Modify Temperature Control Device

For all action alternatives, the TCD would be modified to account for an increased dam height and to reduce leakage of warm water into the structure. Minimum modifications to the TCD include raising the existing structure and modifying the shutter control. This measure would increase the ability of operators at Shasta Dam to meet downstream temperature requirements, and provide more operational flexibility to achieve desirable water temperatures during critical periods for anadromous fish.

Increase Conservation Storage

All action alternatives would include increasing the amount of space available for water conservation storage in Shasta Reservoir by raising Shasta Dam. Conservation storage is the portion of the reservoir capacity available to store water for subsequent release to increase water supply reliability for agricultural, M&I, and environmental purposes. All action alternatives would include a range of dam enlargements and increases in conservation space.

Reduce Demand

All action alternatives would include a water conservation program for increased water deliveries that would be created by the project to augment current water use efficiency practices. The proposed program would consist of a 10-year initial program to which Reclamation would allocate approximately $1.6 million to $3.8 million to fund water conservation efforts. Funding would be proportional to additional water supplies delivered and would focus on assisting project beneficiaries (agencies receiving increased water supplies because of the project), with developing new or expanded urban water conservation, agricultural water conservation, and water recycling programs. Program actions would be a combination of technical assistance, grants, and loans to support a variety of water conservation projects, such as recycled wastewater projects, irrigation system retrofits, and urban utilities retrofit and replacement programs. Reclamation, in collaboration with project beneficiaries, would identify and develop water conservation projects for funding under the program. Reclamation would then implement an investment strategy, in coordination with project beneficiaries, to identify and prioritize projects which, in conjunction with other water conservation activities, would cost-effectively reduce water demand and increase water conservation. This process would result in developing, evaluating, and prioritizing projects for funding. The program could be established as an extension of existing Reclamation programs, or as a new program through teaming with cost-sharing partners. Combinations and types of water use efficiency actions funded would be tailored to meet the needs of identified cost-sharing partners, including consideration of cost-effectiveness at a regional scale for agencies receiving funding.

Modify Flood Operations

Potential modification of flood operations would be considered for all action alternatives. Enlargement of Shasta Reservoir would require alterations to existing flood operation guidelines or rule curves, to reflect physical modifications, such as an increase in dam/spillway elevation. The rule curves would be revised with the goal of reducing flood damage and enhancing other objectives to the extent possible.

Modify Hydropower Facilities

Under each action alternative, enlargement of Shasta Dam would likely require various minimum modifications, commensurate with the magnitude of the enlargement, to the existing hydropower facilities at the dam to enable their continued efficient use. These modifications, in conjunction with increased lake surface elevations, may provide incidental benefits to hydropower generation. Although modifications could also be included to further increase the power production capabilities of the reservoir (e.g., additional penstocks and generators), they are believed to be a detail beyond the scope of this investigation and are not considered further at this level of planning.

Maintain and Increase Recreation Opportunities

In addition to the measures described above, all action alternatives would address, to some extent, the secondary objective of maintaining or increasing recreation opportunities at Shasta Lake. Outdoor recreation, and especially recreation at Shasta Lake, represents a major source of enjoyment to millions of people annually and is a major source of income to the northern Sacramento Valley. Shasta Dam and Reservoir are within the Shasta Unit of the Whiskeytown-Shasta-Trinity National Recreation Area (NRA). Recreation within these lands is managed by USFS. As part of this administration, USFS either directly operates and maintains, or manages through special use permits, numerous public campgrounds, marinas, boat launching facilities, and related water-oriented recreation facilities. Enlarging Shasta Dam and Reservoir would affect some of these facilities. Consistent with the position of USFS, and planning conditions described in this chapter, all of the action alternatives would include features to, at a minimum, maintain the overall recreation capacity of the existing facilities. All action alternatives would also provide for modernization of relocated recreation facilities, including, at a minimum, modifications to comply with current standards of health and safety.

Maintain or Improve Water Quality

All action alternatives could contribute to improved Delta water quality conditions and Delta emergency response. Additional storage in Shasta Reservoir would provide improved operational flexibility. Shasta Dam has the ability to provide increased releases and high-flow releases to improve Delta water quality. Improved Delta water quality conditions could provide benefits for both water supply reliability and ecosystem restoration by potentially increasing Delta outflow during drought years and reducing salinity during critical periods.

2.3.2 Environmental Commitments Common to All Action Alternatives

Reclamation and/or its contractors would incorporate certain environmental commitments and best management practices (BMP) into any action alternative identified for implementation to avoid or minimize potential impacts. Reclamation would also coordinate planning, engineering, design and construction, operation, and maintenance phases of any authorized project modifications with applicable resource agencies.

The following environmental commitments would be incorporated into any action alternative for any project-related construction activities. This section does not include mitigation measures.

Develop and Implement Construction Management Plan

Reclamation would develop and implement a construction management plan to avoid or minimize potential impacts on public health and safety during project construction, to the extent feasible. The construction management plan would inform contractors and subcontractors of work hours, modes and locations of transportation, and parking for construction workers; location of overhead and underground utilities; worker health and safety requirements; truck routes; stockpiling and staging procedures; public access routes; terms and conditions of all required project permits and approvals; and emergency response services contact information.

The construction management plan would also include construction notification procedures for the police, public works, and fire departments in the area where construction would occur. In addition, the construction management plan would include similar procedures for Federal and State agencies with similar jurisdictions, including USFS. Notices would also be distributed to neighboring property owners. The health and safety component of the construction management plan would be monitored for the implementation of the plan on a day-to-day basis by a Certified Industrial Hygienist.

The construction management plan would include effort to notify businesses, residents, and visitors associated with recreation activities on and surrounding Shasta Lake. In addition to information available at the Shasta Lake Visitors Center, informational signs and booths would be placed at key locations to be identified by Reclamation in conjunction with agencies and local business organizations. Reclamation will also develop and maintain a project-specific website that will be used for a wide range of informational purposes.

Comply with Permit Terms and Conditions

If any action alternative is approved and authorized for construction, Reclamation would require its contractors and suppliers, its general contractor, and all of the general contractor's subcontractors and suppliers to comply with all of the terms and conditions of all required project permits, approvals, and conditions attached thereto. If necessary, additional information (e.g., detailed designs and additional documentation) would be prepared and provided for review by decision makers and the public. Reclamation would ultimately be responsible for the actions of its contractors in complying with permit conditions. Compliance with applicable laws, policies, and plans for this project is discussed in Chapter 26, "Other Required Disclosures ," Section 26.7, "Compliance with Applicable Laws, Policies, and Plans," of this EIS.

Provide Relocation Assistance Through Federal Relocation Assistance Program

All Federal, State, and local government agencies and others receiving Federal financial assistance for public programs and projects that require the acquisition of real property must comply with the policies and provisions set forth in the Uniform Relocation Assistance and Real Property Acquisition Policies Act of 1970, as amended (Uniform Act) (Title 49, CFR, Part 24). All relocation and property acquisition activities would be performed in compliance with the Uniform Act. Any individual, family, or business displaced by implementation of any of the action alternatives would be offered relocation assistance services for the purpose of locating a suitable replacement property, to the extent consistent with the Uniform Act.

Under the Uniform Act, relocation services for residences would include providing a determination of the housing needs and desires, a list of comparable properties, transportation to inspect housing referrals, and reimbursement of moving costs and related expenses. For business relocation activities, relocation services would include providing a determination of the relocation needs and requirements; a determination of the need for outside specialists to plan, move, and reinstall personal property; advice as to possible sources of funding and assistance from other local, State, and Federal agencies; listings of commercial properties; and reimbursement for costs incurred in relocating and reestablishing the business. No relocation payment received would be considered as income for the purpose of the Internal Revenue Code.

Remain Consistent with USFS Built Environment Image Guide

Any facilities subject to USFS authorization that are constructed or reconstructed would be consistent with USFS Built Environment Image Guide. The architectural character of facilities on National Forest System lands would be constructed using materials and design that keep with the visual and cultural identity of the landscape in which they are constructed. Reclamation would seek to maintain the quality of visitor experiences by replacing affected facilities with facilities providing equivalent visual resource quality and amenities.

Protect Public Land Survey System Monuments and Property Corners

Reclamation would identify Public Land Survey System (PLSS) monuments or survey property corners affected by either inundation due to increased lake levels or construction activities. Reclamation or its contractors would protect all PLSS monuments and associated references and all property corners, either by positioning, or, where necessary, creating new references. The results would be filed with BLM and Shasta County.

Evaluate and Protect Paleontological Resources Discovered During Construction

If paleontological resources are discovered during construction activities, all work in the immediate vicinity of the discovery would stop immediately and Reclamation would be notified (as applicable). A qualified paleontologist would be retained to evaluate the find and recommend appropriate conservation measures, such as data recovery or protection in place. The conservation measures would be implemented before reinitiation of activities in the immediate vicinity of the discovery.

Develop and Implement Stormwater Pollution Prevention Plan

Any project authorized for construction would be subject to the construction-related stormwater permit requirements of the CWA National Pollutant Discharge Elimination System program. Reclamation would obtain any required permits through the Central Valley Regional Water Quality Control Board before any ground-disturbing construction activity. According to the requirements of Section 402 of the CWA, Reclamation and/or its contractors would prepare and implement a Stormwater Pollution Prevention Plan (SWPPP) before construction, identifying BMPs to prevent or minimize erosion and the discharge of sediments and other contaminants with the potential to affect beneficial uses of or lead to violations of water quality objectives for surface waters. The SWPPP would include site-specific structural and operational BMPs to prevent and control impacts on runoff quality, and procedures to be followed before each storm event. BMPs would control short-term and long-term erosion and sedimentation effects and stabilize soils and vegetation in areas affected by construction activities. The SWPPP would contain a site map that shows the construction site perimeter, existing and proposed buildings, lots, roadways, stormwater collection and discharge points, drainage patterns across the project, and general topography both before and after construction. Additionally, the SWPPP would contain a visual monitoring program, a chemical monitoring program for “non-visible” pollutants that would be implemented if a BMP fails, and a sediment monitoring plan to be implemented if a particular site discharges directly to a water body listed on the CWA 303(d) list for sediment. BMPs for the project could include, but would not be limited to, silt fencing, straw bale barriers, fiber rolls, storm drain inlet protection, hydraulic mulch, and stabilized construction entrances.

Develop and Implement Erosion and Sediment Control Plan Reclamation would prepare and implement an erosion and sediment control plan to control short-term and long-term erosion and sedimentation effects, and to stabilize soils and vegetation in areas affected by construction activities. The plan would include all of the necessary local jurisdiction requirements regarding erosion control, and would implement BMPs for erosion and sediment control, as required. Types of BMPs may include, but would not be limited to, earth dikes and drainage swales, stream bank stabilization, and use of silt fencing, sediment basins, fiber rolls, and sandbag barriers.

Develop and Implement Feasible Spill Prevention and Hazardous Materials Management As part of the SWPPP, Reclamation and/or its contractors would develop and implement a spill prevention and control plan to minimize effects from spills of hazardous, toxic, or petroleum substances for project-related construction activities occurring in or near waterways. The accidental release of chemicals, fuels, lubricants, and nonstorm drainage water into water bodies would be prevented to the extent feasible. Spill prevention kits would always be close by when hazardous materials would be used (e.g., crew trucks and other logical locations). Feasible efforts would be implemented so that hazardous materials would be properly handled and the quality of aquatic resources would be protected by all reasonable means during work in or near any waterway. No fueling would be done within the ordinary high-water mark, immediate floodplain, or full pool inundation area, unless equipment stationed in these locations could not be readily relocated. Any equipment that could be readily moved out of the water body would not be fueled in the water body or immediate floodplain. For all fueling of stationary equipment done at the construction site, containments would be installed so that any spill would not enter the water, contaminate sediments that may come in contact with the water, or damage wetland or riparian vegetation. Any equipment that could be readily moved out of the water body would not be serviced within the ordinary high-water mark or immediate floodplain.

Additional BMPs designed to avoid spills from construction equipment and subsequent contamination of waterways would also be implemented. These could include, but would not be limited to, the following:

- Storage of hazardous materials in double-containment and, if possible, under a roof or other enclosure.
- Disposal of all hazardous and nonhazardous products in a proper manner.
- Monitoring of on-site vehicles for fluid leaks and regular maintenance to reduce the chance of leakage.
- Containment (using a prefabricated temporary containment mat, a temporary earthen berm, or other feature can provide containment) of bulk storage tanks.

Haulers delivering materials to the project site would be required to comply with regulations on the transport of hazardous materials codified in Title 49, CFR Part 173; Title 49, CFR Part 177; and Title 26, California Code of Regulations (CCR) Division 6. These regulations provide specific packaging requirements, define unacceptable hazardous materials shipments, and prescribe safe-transit practices, including route restrictions, by carriers of hazardous materials.

Water Quality Protection for In-River Construction

The efforts discussed below would be implemented to minimize potential adverse effects to water quality.

Implement In-River Construction Work Windows All construction activities along the Sacramento River would be conducted during months when instream flows were managed outside the flood season (e.g., June to September). In-river work between Keswick Dam and the RBPP would be conducted to minimize impacts to Sacramento River winter-run Chinook salmon (i.e., mid-August through September).

Comply with All Water Quality Permits and Regulations Project activities would be conducted to comply with all additional requirements specified in required permits relating to water quality protection. Relevant permits anticipated to be obtained for the proposed action include a CWA Section 401 certification and CWA Section 404 compliance through the USACE.

Implement Water Quality Best Management Practices BMPs that would be implemented to avoid and/or minimize potential impacts associated with construction and the 10-year-long spawning gravel augmentation program are described below.

Handle Spawning Gravel to Minimize Potential Water Quality Impacts Gravel would be sorted and transported in a manner that minimizes potential water quality impacts (e.g., management of fine sediments). Gravel would be washed at least once and have a cleanliness value of 85 or higher based on California

Department of Transportation (Caltrans) Test No. 227. Gravel would also be completely free of oils, clay, debris, and organic material.

Minimize Potential Impacts Associated with Equipment Contaminants For in-river work, all equipment would be steam-cleaned every day to remove hazardous materials before the equipment entered the water. Biodegradable hydrocarbon products would be used in the heavy equipment in the stream channel.

Implement Feasible Spill Prevention and Hazardous Materials Management The accidental release of chemicals, fuels, lubricants, and non-storm drainage water into channels would be prevented to the extent feasible. Spill prevention kits would always be in close proximity when using hazardous materials (e.g., crew trucks and other logical locations). Feasible efforts would be implemented to ensure that hazardous materials are properly handled and the quality of aquatic resources is protected by all reasonable means. No fueling would be done within the ordinary high-water mark or immediate floodplain, unless equipment stationed in these locations was not readily relocated (i.e., pumps, generators). For stationary equipment that must be fueled on site, containments would be provided in such a manner that any accidental spill of fuel would not be able to enter the water or contaminate sediments that could come in contact with water. Any equipment that was readily moved out of the channel would not be fueled in the channel or immediate floodplain. All fueling done at the construction site would provide containment to the degree that any spill would be unable to enter the channel or damage wetland or riparian vegetation. No equipment servicing would be done within the ordinary high-water mark or immediate floodplain, unless equipment stationed in these locations could not be readily relocated (i.e., pumps, generators). Additional BMPs designed to avoid spills from construction equipment and subsequent contamination of waterways would also be implemented.

Minimize Potential Impacts Associated with Access and Staging Existing access roads would be used to the extent possible. Equipment staging areas would be located outside of the Sacramento River ordinary high water mark or the Shasta Dam full pool inundation area, and away from sensitive resources.

Remove Temporary Fills as Appropriate Temporary fill for access, side channel diversions, and/or side channel cofferdams, would be completely removed after completion of construction.

Remove Equipment from River Overnight and During High Flows Construction contractors would remove all equipment from the river on a daily basis at the end of the workday. Construction contractors would also monitor Reclamation’s Central Valley Operations Office Web site daily for forecasted flows posted there to determine and anticipate any potential changes in releases. If flows were anticipated to inundate a work area that would normally be dry, the contractor would immediately remove all equipment from the work area.

Extend and Enhance Existing Fish Habitat Structures in Shasta Lake

Reclamation and USFS, in conjunction with resource management agencies, would identify areas at appropriate elevations to replace, extend, and enhance existing structural fish habitat. The structures would be installed concurrently with construction activities in the vicinity of construction sites or at locations identified by resource agencies. These activities would include maintaining shallow water and transitional riverine habitat with the placement of manzanita brush structures, large woody debris, and rock-boulder clusters. To the extent feasible, vegetation cleared for construction and borrow pit areas would be used to extend and enhance fish habitat structures. Excess vegetative materials cleared from construction and borrow pit areas would be stockpiled for future fish habitat enhancement. Additionally, areas within the enlarged reservoir having appropriate conditions to establish living plants, including willow (*Salix* sp.), buttonbush (*Cephalanthus* sp.), and cottonwood (*Populus* sp.), would be identified for the purposes of providing structural fish habitat when the established plants are inundated.

Fisheries Conservation

The efforts discussed below would be implemented to minimize potential adverse effects on fish species.

Implement In-Water Construction Work Windows Reclamation would identify and implement feasible in-water construction work windows in consultation with NMFS, USFWS, and CDFW. In-water work windows would be timed to occur when sensitive fish species were not present or would be least susceptible to disturbance.

Monitor Construction Activities A qualified biologist would monitor potential impacts to important fishery resources throughout all phases of project construction. Monitoring may not be necessary during the entire duration of the project if, based on the monitor’s professional judgment (and with concurrence from Reclamation), a designated on-site contractor would suffice to monitor such activities and would agree to notify a biologist if aquatic organisms are in danger of harm. However, the qualified biologist would need to be available by phone and Internet and be able to respond promptly to any problems that arose.

Perform Fish Rescue/Salvage If spawning activities for sensitive fish species were encountered during construction activities, the biologist would be authorized to stop construction activities until appropriate corrective activities were completed or it was determined that the fish would not be harmed.

A qualified biologist would identify any fish species that may be affected by the project. The biologist would facilitate rescue and salvage of fish and other aquatic organisms that become entrapped within construction structures and cofferdam enclosures in the construction area. Any rescue, salvage, and handling of listed species would be conducted under appropriate authorization (i.e., incidental take statement/permit for the project, Federal Endangered

Species Act Section 4(d) scientific collection take permit, or a Memorandum of Understanding).

If fish were identified as threatened with entrapment in construction structures, construction would be stopped and efforts made to allow fish to leave the project area before resuming work. If fish were unable to leave the project area of their own volition, then fish would be collected and released outside the work area. Fish entrapped in cofferdam enclosures would be rescued and salvaged before the cofferdam area was completely dewatered. Appropriately sized fish screens would be installed on the suction side of any pumps used to dewater in-water enclosures.

Reporting A qualified biologist would prepare a letter report detailing the methodologies used and the findings of fish monitoring and rescue efforts. Monitoring logs would be maintained and provided, with monitoring reports. The reports would contain, but not be limited to, the following: summary of activities; methodology for fish capture and release; table with dates, numbers, and species captured and released; photographs of the enclosure structure and project site conditions affecting fish; and recommendations for limiting impacts during subsequent construction phases, if appropriate.

Survey and Monitor Fish Migration between Shasta Lake and Squaw Creek

Reclamation would fund and implement an adaptive management effort to survey and monitor fish migration between Shasta Lake and Squaw Creek, within and immediately upstream from the new inundation zone, before and immediately after project completion, to determine if warm-water fish (bass) actively migrated into and cause adverse effects on native fish, amphibians, and mollusks. These study and monitoring activities would be warranted due to uncertainties associated with the potential for warm-water fish accessing tributary stream reaches currently isolated by passage barriers near the head of the existing reservoir. The surveys would document occurrences and abundances of warm-water fish species and USFS special-status species in lower Squaw Creek before and immediately after project completion to evaluate if reservoir enlargement coincides with increases in warm-water predator species and declines of special-status indicator species. If warm-water fish abundance increases or adverse effects attributed to warm-water fish predation on native fish, amphibians or mollusks is documented within 3-5 years after the project was completed, a fish barrier or other acceptable feature would be implemented to prevent or minimize further invasions and colonization by warm-water fish.

Revegetation Plan

Reclamation, in conjunction with cooperating agencies and private landowners, would prepare a comprehensive revegetation plan to be implemented in conjunction with other management plans (e.g., SWPPP). This plan would apply to any area included as part of an action alternative, such as inundation, relocation, or mitigation activities. Overall objectives of the revegetation plan would be to reestablish native vegetation to control erosion, provide effective ground cover, minimize opportunities for nonnative plant species to establish or expand, and provide habitat diversity over time. Reclamation would work closely with cooperating agencies, private landowners, and revegetation specialists to develop the sources of native vegetation, site-specific planting patterns and species assemblages necessary for a revegetation effort of this magnitude.

Invasive Species Management

Reclamation would develop and implement a control plan to prevent the introduction of zebra/quagga mussels, invasive plants, and other invasive species to project areas. The control plan would cover all workers, vehicles, watercraft, and equipment (both land and aquatic) that would come into contact with Shasta Reservoir, the shoreline of Shasta Reservoir, the Sacramento River, and any riverbanks, floodplains, or riparian areas. Plan activities could include, but would not be limited to, the following:

- Preinspection and cleaning of all construction vehicles, watercraft, and equipment before being shipped to project areas
- Reinspection of all construction vehicles, watercraft, and equipment on arrival at project areas
- Inspection and cleaning of all personnel before work in project areas

All inspections would be conducted by trained personnel and would include both visual and hands-on inspection methods of all vehicle and equipment surfaces, up to and including internal surfaces that have contacted raw water.

Approved cleaning methods would include a combination of the following:

- **Precleaning –** Draining, brushing, vacuuming, high-pressure water treatment, thermal treatment
- **Cleaning –** Freezing, desiccation, thermal treatment, high-pressure water treatment, chemical treatment

On-site cleanings would require capture, treatment, and/or disposal of any and all water needed to conduct cleaning activities.

Fire Protection and Prevention Plan

Reclamation would prepare and implement a fire protection and prevention plan to minimize the risk of wildfire or threat to workers, property, and the public. The USFS will maintain a plan similar to this Fire Protection and Prevention Plan which addresses preventing and controlling wildfires in the NRA as described by the interagency agreement with the California Department of

Forestry and Fire Protection (Cal Fire) and other associated entities. Reclamation's contractors would follow relevant safety standards/procedures related to fire prevention, which would be incorporated into the project design and used during construction activities and project operation and maintenance. Safety standards and procedures include the California Building Code; the Shasta County Fire Plan; USFS safety requirements regarding fire hazards; Cal Fire requirements for private lands; California Public Utilities Code General Order 95, which provides procedures for proper removal, disposal, and placement of poles, wires, and associated infrastructure; and the National Electric Safety Code (a voluntary code that provides safety procedures for electric utility installation and operation). Precautionary activities to prevent construction-related fires would include locating utilities a safe distance from vegetation and structures, proper construction of power lines, and construction worker safety training. Postconstruction infrastructure operation and maintenance would follow current safety practices associated with fire prevention and would include clearing vegetation from power utility facilities and other sources using combustion engines (e.g., water pumps) on a regular basis.

Construction Material Disposal

Reclamation's contractors would recycle or reuse demolished materials, such as steel or copper wire, concrete, asphalt, and reinforcing steel, as required and where practical. Other demolished materials would be disposed of in local or other identified permitted landfills in compliance with applicable requirements.

To reduce the risk to construction workers, the public, and the environment associated with exposure to hazardous materials and waste, Reclamation would implement the following:

- A Hazardous Materials Business Plan (HMBP) would be developed and implemented to provide information regarding hazardous materials to be used for project implementation and hazardous waste that would be generated. The HMBP would also define employee training, use of protective equipment, and other procedures that provide an adequate basis for proper handling of hazardous materials to limit the potential for accidental releases of and exposure to hazardous materials. All procedures for handling hazardous materials would comply with all Federal, State, and local regulations.

- Soil to be disposed of at a landfill or recycling facility would be transported by a licensed waste hauler.

- All relevant available asbestos survey and abatement reports and supplemental asbestos surveys would be reviewed. Removal and disposal of asbestos-containing materials would be performed in accordance with applicable Federal, State, and local regulations.

- A lead-based paint survey would be conducted to determine areas where lead-based paint is present and the possible need for abatement before construction.

Asphalt Removal

Per California Fish and Game Code 5650 Section (a), all asphaltic roadways and parking lots inundated by project implementation would be demolished and removed according to Shasta County standards. Asphalt would be disposed of at an approved and permitted waste facility. Dirt roads inundated by project implementation would remain in place.

2.3.3 CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 consists primarily of enlarging Shasta Dam by raising the crest 6.5 feet and enlarging the reservoir by 256,000 acre-feet.

Major Components of CP1

CP1 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 6.5 feet
- Implementing the set of eight common management measures described above
- Implementing the common environmental commitments described above

By raising Shasta Dam 6.5 feet, from a crest elevation of 1,077.5 feet to 1,084.0 feet (based on the National Geodetic Vertical Datum 1929 (NGVD29)),[2] CP1 would increase the height of the reservoir full pool by 8.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications, including replacing the three drum gates with six sloping, fixed-wheel gates. This increase in full pool height would add approximately 256,000 acre-feet of additional storage to the overall reservoir capacity. Accordingly, the overall full pool storage would increase from 4.55 million acre-feet (MAF) to 4.81 MAF. Table 2-6 summarizes major physical features associated with CP1.

[2] Dam crest elevations are based on NGVD29. All current feasibility-level designs and figures for Shasta Dam and appurtenant structures are based on NGVD29.

Ecosystem Enhancements	None	None	None	Reserve 378 TAF of the additional storage for cold-water supply for anadromous fish. Implement adaptive management plan to benefit anadromous fish. Augment spawning gravel in the upper Sacramento River at the rate of up to 10,000 tons per year. Restore riparian, floodplain, and side channel habitat along the upper Sacramento River.	Reserve 191 TAF of the additional storage for cold-water supply for anadromous fish. Implement adaptive management plan to benefit anadromous fish. Augment spawning gravel in the upper Sacramento River at the rate of up to 10,000 tons per year. Restore riparian, floodplain, and side channel habitat along the upper Sacramento River.	Construct shoreline fish habitat around Shasta Lake. Enhance aquatic habitat in tributaries to Shasta Lake to improve fish passage. Augment spawning gravel in the upper Sacramento River at the rate of up to 10,000 tons per year. Restore riparian, floodplain, and side channel habitat along the upper Sacramento River.

Notes:

[1] Dam crest elevations are based on the National Geodetic Vertical Datum of 1929 (NGVD29). All current feasibility-level designs and figures for Shasta Dam and appurtenant structures are based on NGVD29.

[2] Full pool elevations are based on the North American Vertical Datum of 1988 (NAVD88), which is 2.66 feet higher than NGVD29. All current feasibility-level designs and figures for reservoir area infrastructure modifications and relocations to accommodate increased water levels are based on a 2001 aerial survey of the reservoir using NAVD88.

Key:
CP = comprehensive plan
RV = recreational vehicle
TAF = thousand acre-feet
USFS = U.S. Department of Agriculture, Forest Service

Under CP1, the additional storage in Shasta Reservoir would be used to increase water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. This alternative (and all comprehensive plans) involves extending the existing TCD for efficient use of the expanded cold-water pool. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, except during dry and critical years when a portion of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. In dry years, 70,000 acre-feet of the 256,000 acre-feet increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. In critical years, 35,000 acre-feet of the increased storage capacity would be reserved for increasing M&I deliveries.

CP1 would also include the potential to revise the operational rules for flood control at Shasta Dam and Reservoir, which could reduce the potential for flood damage, and benefit recreation. Although the volume of the flood control pool would remain the same as under existing operations (1.3 MAF), the bottom of the flood control pool elevation would likely be increased based on increased dam height and reservoir capacity. Because of reservoir geometry, this would decrease the depth of the flood control pool, allowing higher winter and spring water levels. Increased reservoir capacity could have further flood damage reduction benefits in years when water levels are below the new flood control pool elevation.

In some years, when the flood control requirements guided reservoir releases, potential would also exist for changes in flood control rules to allow more operational flexibility in reservoir drawdown requirements in response to storms, resulting in a net increase in the rate of spring reservoir filling during some years.

In addition, higher spring water levels, reduced drawdown (distance to water) during the recreation season, and associated increases in reservoir surface area would benefit recreation.

Potential Benefits of CP1

Major potential benefits of CP1, related to contributions to the project objectives and broad public services, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors affecting anadromous fish survival in the Sacramento River. CP1 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperatures for fish in the upper Sacramento River, primarily in dry and critical water years. This would be accomplished by raising Shasta Dam 6.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBPP. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBPP. It is estimated that under CP1, improved water temperature and flow conditions could result in an average annual increase in the salmon population of about 61,300 out-migrating juvenile Chinook salmon.

Increase Water Supply Reliability CP1 would increase water supply reliability by increasing water supplies for CVP and SWP irrigation and M&I deliveries. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA. CP1 would help reduce estimated future water shortages by increasing dry and critical year water supplies for agricultural and M&I deliveries by at least 47,300 acre-feet per year and average annual deliveries by about 31,000 acre-feet per year. The majority of increased dry and critical year water supplies (42,700 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continue to grow and available supplies continue to remain relatively static, more effectively using these supplies could reduce potential critical impacts on agricultural and urban areas resulting from water shortages. Under CP1, approximately $1.6 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in an increase in power generation of about 52 gigawatt-hours (GWh) per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities. Other power benefits include additional capacity (i.e., the rate at which power can be generated) and ancillary services, which provide the ability to manage the electric grid in a reliable manner.

Maintain and Increase Recreation Opportunities CP1 includes features to at least maintain the existing recreation capacity at Shasta Lake. Although CP1 does not include specific features to further increase recreation capacity, benefits to the water-oriented recreation experience at Shasta Lake would likely occur because of the increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. The maximum surface area of the lake would increase by about 1,110 acres (4 percent), from 29,700 acres to about 30,800 acres. The average surface area of the lake during the recreation season from May through September would increase by about 800 acres (3 percent), from 23,900 acres to 24,700 acres. There would also be limited potential to provide additional benefits to recreation by allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other Project Objectives CP1 could also provide benefits related to flood damage reduction, ecosystem restoration, and water quality. Enlarging Shasta Dam would provide for incidental increased reservoir capacity to capture flood flows, which could reduce flood damage along the upper Sacramento River. Improved fisheries conditions as a result of CP1, as described above, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. For example, CP1 would result in improved flow and water temperature conditions, particularly during drought periods, in the upper Sacramento River for other resident fish species, such as the Sacramento splittail. Furthermore, CP1 could potentially benefit ecosystem restoration through improved Delta water quality conditions by increasing Delta outflow during drought years and reducing salinity during critical periods. CP1 may also contribute to improving Delta water quality through increased Delta emergency response capabilities. When Delta emergencies occur, additional water in Shasta Reservoir could improve operational flexibility for increasing releases to supplement existing water sources to reestablish Delta water quality. In addition to Delta emergency response, increased storage in Shasta Reservoir could increase emergency response capability for CVP/SWP water supply deliveries.

Construction for CP1

Construction activities associated with physical features under CP1 would include land-based construction activities associated with the following:

- Clearing vegetation from portions of the inundated reservoir area
- Constructing the dam raise, appurtenant structures, reservoir area dikes, and railroad embankments
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure

Construction activities for CP1 are described in Section 2.3.8, "Comprehensive Plan Construction Activities."

Operations and Maintenance for CP1

Shasta Dam is operated in conjunction with other CVP facilities and SWP facilities to manage floodwater, storage of surplus winter runoff for irrigation in the Sacramento and San Joaquin valleys, M&I use, maintenance of navigation flows, protection and conservation of fish in the Sacramento River and Delta, and generation of hydroelectric energy. Storage in Shasta Reservoir fluctuates greatly throughout the year; storage is typically highest in April and May, as the need for flood control reservation space in the reservoir decreases. Storage is typically at its lowest in September and October, after the irrigation season and before winter refill begins. Shasta Reservoir capacity is currently 4.55 MAF, with a maximum objective release capacity of 79,000 cubic feet per second (cfs). Storage levels are lowest by October to provide sufficient flood risk reduction and capture capacity during the following wet months. The storage target gradually increases beginning in October to full pool in May; storage is then withdrawn for high water demand (e.g., agricultural, M&I, fishery, and water quality uses) during summer.

A series of rules and regulations in the form of flood control requirements, flow requirements, water quality requirements, and water supply commitments governs operations at Shasta Dam. Federal and State laws, regulations, standards, and plans regulating Shasta Dam operations are described in detail in Chapter 6, “Hydrology, Hydraulics, and Water Management,” and include the following:

- 2009 NMFS BO (NMFS 2009)
- 2008 USFWS BO (USFWS 2008)
- CVPIA PEIS (Reclamation 1999)
- CVP long-term water service contracts (see the Hydrology, Hydraulics, and Water Management Technical Report, Table 1-25, in the Physical Resources Appendix)
- Trinity River ROD (Reclamation 2000)
- Reclamation’s 2008 Long-Term Operation BA (Reclamation 2008)
- Flood management requirements in accordance with the Water Control Manual (USACE 1977)
- State Water Resources Control Board (State Water Board) Water Right Orders 90-05 and 91-01
- California Department of Fish and Game (CDFG) and Reclamation Memorandum of Agreement (CDFG and Reclamation 1960)
- Water Quality Control Plan for the San Francisco Bay/San Joaquin Delta Estuary (State Water Board 1995)
- State Water Board Water Right Revised Decision 1641 (State Water Board 2000)
- CVP and SWP Coordinated Operations Agreement (Reclamation and DWR 1986)

In addition, Shasta Dam and Reservoir are operated according to the *Standing Operating Procedures for Shasta Dam and Reservoir*. However, due to sensitivity regarding this information, including security and public health and safety concerns, this document is not available to the general public.

Under CP1, the additional storage would be retained to increase water supply reliability and to expand the cold-water pool in Shasta Reservoir for fisheries benefits. Shasta Dam operational guidelines would continue unchanged, except during dry and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the 256,000 acre-feet increased storage capacity in Shasta Reservoir would be operated primarily to increase M&I deliveries. Operations targeting increased M&I deliveries were based on existing and anticipated future demands, operational priorities, and facilities of the SWP, which provides M&I water to a majority of the State's population. For this EIS, these operations were simulated in CalSim-II by using the reserved storage capacity to provide deliveries for previously unmet SWP demands during dry and critical years. For CP1, existing water quality and temperature requirements would typically be met in most years; therefore, additional water in storage would be released primarily for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports were constrained, or when flow was not required for water supply purposes.

In comparison to current operations, CP1 would store some additional flows behind Shasta Dam during periods when downstream needs would have already been met, but flows would have been released because of storage limitations. The resulting increase in storage would be released downstream when there were opportunities for beneficial use of the water, either to meet water supply reliability demands or to improve Reclamation's abilities to meet its environmental objectives. The additional water in storage would also expand the cold-water pool and increase end-of-September carryover storage in Shasta Reservoir, increasing the ability of Shasta Dam to improve water temperatures for anadromous fish in the upper Sacramento River.

Conversely, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Releases from Shasta Dam under CP1 would typically increase in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage space could be used to capture additional runoff rather than releasing water to the downstream river, as would occur under Shasta Reservoir's current operations.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

Operation of pumping facilities downstream from Shasta Dam would vary slightly from current operations and would result in higher costs. In addition, Reclamation would provide in kind power to offset the reduced generation at Pit 7 Dam and related facilities.

2.3.4 CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP2 consists primarily of enlarging Shasta Dam by raising the crest 12.5 feet and enlarging the reservoir by 443,000 acre-feet.

Major Components of CP2

CP2 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 12.5 feet.
- Implementing the set of eight common management measures previously described.
- Implementing the common environmental commitments previously described.

A dam raise of 12.5 feet was chosen because it represents a midpoint between the likely smallest dam raise considered and the largest practical dam raise that would not require relocating the Pit River Bridge. By raising Shasta Dam from a crest elevation of 1,077.5 feet to 1,090.0 feet (based on NGVD29), CP2 would increase the height of the reservoir's full pool by 14.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications similar to the modifications proposed under CP1. This increase in full pool height would add approximately 443,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would increase from 4.55 MAF to 5.0 MAF. Table 2-6 summarizes major physical features associated with CP2.

Under CP2, the additional storage in Shasta Reservoir would be used to increase water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. The existing TCD would also be extended for efficient use of the expanded cold-water pool. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, except during dry and critical years when a portion of the increased storage in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. In dry years, 120,000 acre-feet of the 443,000 acre-feet increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. In critical years, 60,000 acre-feet of the increased storage capacity would be reserved for increasing M&I deliveries.

As described for CP1, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

Potential Benefits of CP2

Major potential benefits of CP2, related to contributions to the project objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors affecting anadromous fish survival in the Sacramento River. CP2 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperatures for fish in the upper Sacramento River, primarily in dry and critical water years. This would be accomplished by raising Shasta Dam 12.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBPP. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBPP. It is estimated that improved water temperature and flow conditions under CP2 could result in an average annual increase in the salmon population of about 379,200 out-migrating juvenile Chinook salmon.

Increase Water Supply Reliability CP2 would increase water supply reliability by increasing water supplies for CVP and SWP irrigation and M&I deliveries. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA. CP2 would help reduce estimated future water shortages by increasing the reliability of dry and critical year water supplies for agricultural and M&I deliveries by at least 77,800 acre-feet per year and average annual deliveries by about 51,300 acre-feet per year. The majority of increased dry and critical year water supplies (67,100 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continued to grow and available supplies continued to remain relatively static, more effectively using these supplies could reduce potential critical impacts on agricultural and urban areas resulting from water shortages. Under CP2, approximately $2.6 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 87 GWh per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities. Other power benefits include additional capacity (i.e., the rate at which power can be generated) and ancillary services, which provide the ability to manage the electric grid in a reliable manner.

Maintain and Improve Recreation Opportunities CP2 includes features to, at minimum, maintain the existing recreation capacity at Shasta Lake. Although CP2 does not have specific features to further increase recreation capacity, benefits to the water-oriented recreation experience at Shasta Lake would likely occur because of the increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. The maximum surface area of the lake would increase by about 1,900 acres (6 percent), from 29,700 acres to about 31,600 acres. The average surface area of the lake during the recreation season from May through September would increase by about 1,300 acres (5 percent), from 23,900 acres to 25,200 acres. There would also be limited potential to provide additional benefits to recreation by allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other Project Objectives CP2 could also provide benefits related to flood damage reduction, ecosystem restoration, and water quality, as described for CP1, but to a greater extent because of increased capacity and associated overall system flexibility.

Construction for CP2

Construction activities associated with physical features under CP2 would include land-based construction activities associated with the following:

- Clearing vegetation from portions of the inundated reservoir area
- Constructing the dam raise, appurtenant structures, reservoir area dikes, and railroad embankments
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure

Construction activities for CP2 are described in Section 2.3.8, "Comprehensive Plan Construction Activities."

Operations and Maintenance for CP2

Operations under CP2 would be governed by the same regulatory constraints as described for CP1. Similar to CP1, the additional storage would be retained to increase water supply reliability and to expand the cold-water pool in Shasta Reservoir for fisheries benefits. Shasta Dam operational guidelines would continue unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the 443,000 acre-feet increased storage capacity in Shasta Reservoir would be operated primarily to increase M&I deliveries. Operations targeting increased M&I deliveries were based on existing and anticipated future demands, operational priorities, and facilities of the SWP. For CP2, existing water quality and temperature requirements would typically be met in most years; therefore, additional water in storage would be released primarily for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports were constrained, or when flow was not usable for water supply purposes.

In comparison to current operations, CP2 would store some additional flows behind Shasta Dam during periods when downstream needs would have already been met, but flows would have been released because of storage limitations.

The resulting increase in storage would be released downstream when there were opportunities for beneficial use of the water, either to meet water supply reliability demands or to improve Reclamation's abilities to meet its environmental objectives. The additional water in storage would also expand the cold-water pool and increase end-of-September carryover storage in Shasta Reservoir, increasing the ability of Shasta Dam to improve water temperatures for anadromous fish in the upper Sacramento River.

Conversely, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Releases from Shasta Dam under CP2 would typically increase in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage space could be used to capture additional runoff rather than releasing water to the downstream river, as would occur with Shasta Reservoir's current operations.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

Operation of pumping facilities downstream from Shasta Dam would vary slightly from current operations and would result in higher costs. In addition, Reclamation would provide in-kind power to offset reduced generation at Pit 7 Dam and related facilities.

2.3.5 CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3 focuses on increasing agricultural water supply reliability and increasing anadromous fish survival by raising Shasta Dam 18.5 feet and enlarging Shasta Reservoir by 634,000 acre-feet.

Major Components of CP3

CP3 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 18.5 feet
- Implementing the set of eight common management measures previously described
- Implementing the common environmental commitments previously described

By raising Shasta Dam 18.5 feet, from a crest elevation of 1,077.5 feet to 1,096.0 feet (based on NGVD29), CP3 would increase the height of the reservoir full pool by 20.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications similar to the modifications proposed under CP1. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would increase from 4.55 MAF to 5.19 MAF. Although higher dam raises are technically and physically feasible, 18.5 feet is the largest dam raise that would not require extensive and costly reservoir area relocations, such as relocating the Pit River Bridge, Interstate 5 (I-5), and the Union Pacific Railroad (UPRR) tunnels. Table 2-6 summarizes major physical features associated with CP3.

Because CP3 focuses on increasing agricultural water supply reliability and anadromous fish survival, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations. The additional storage would be retained for water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. The existing TCD would also be extended for efficient use of the expanded cold-water pool.

As described for the above alternatives, this alternative would also include the potential to revise flood control operational rules, which could reduce the potential for flood damage and benefit recreation.

Potential Benefits of CP3

Major potential benefits of CP3, related to contributions to the project objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors affecting anadromous fish survival in the Sacramento River. CP3 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperatures for fish in the upper Sacramento River, primarily in dry and critical water years. This would be accomplished by raising Shasta Dam 18.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBPP. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBPP. It is estimated that improved water temperature and flow conditions under CP3 could result in an average annual increase in the Chinook salmon population of about 207,400 out-migrating juvenile fish.

Increase Water Supply Reliability CP3 would increase water supply reliability by increasing water supplies for CVP irrigation deliveries. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA. CP3 would help reduce estimated future water shortages by increasing the reliability of dry and critical year water supplies for agricultural deliveries by at least 63,100 acre-feet per year and average annual deliveries by about 61,700 acre-feet per year. Almost half of the increased dry and critical year water supplies (28,000 acre-feet) would be for south-of-Delta agricultural deliveries, with the remainder for north-of-Delta agricultural deliveries. In addition, water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continued to grow and available supplies continued to remain relatively static, more effectively using these supplies could reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP3, approximately $3.1 million would be allocated over an initial 10-year period to fund agricultural water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 86 GWh per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities. Other power benefits include additional capacity (i.e., the rate at which power can be generated) and ancillary services, which provide the ability to manage the electric grid in a reliable manner.

Maintain and Increase Recreation Opportunities CP3 includes features to, at a minimum, maintain the existing recreation capacity at Shasta Lake. Although CP3 does not include specific features to further increase recreation capacity, benefits to the water-oriented recreation experience at Shasta Lake would likely occur because of the increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. The maximum surface area of the lake would increase by about 2,600 acres (9 percent), from 29,700 acres to about 32,300 acres. The average surface area of the lake during the recreation season from May through September would increase by about 2,000 acres (8 percent), from 23,900 acres to 25,900 acres. There would also be limited potential for reservoir reoperation to provide additional benefits to recreation by allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other Project Planning Objectives CP3 could also provide benefits related to flood damage reduction, ecosystem restoration, and water quality, as described for CP1, but to a greater extent because of increased capacity and associated overall system flexibility.

Construction for CP3

Construction activities associated with physical features under CP3 would include land-based construction activities associated with the following:

- Clearing vegetation from portions of the inundated reservoir area

- Constructing the dam raise, appurtenant structures, reservoir area dikes, and railroad embankments
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure

Construction activities for CP3 are described in Section 2.3.8, "Comprehensive Plan Construction Activities."

Operations and Maintenance for CP3

Operations under CP3 would be governed by the same regulatory constraints as described for CP1. Under CP3, Shasta Dam operational guidelines would continue unchanged, with the additional storage retained for agricultural water supply reliability and to expand the cold-water pool in Shasta Reservoir for fisheries benefits. Unlike CP1 and CP2, none of the increased storage space in Shasta Reservoir would be reserved for increasing M&I deliveries under CP3. Existing water quality and temperature requirements would be met in most years; therefore, additional water in storage would be released primarily for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports were constrained, or when flow was not usable for water supply purposes.

In comparison to current operations, CP3 would store some additional flows behind Shasta Dam during periods when downstream needs would have already been met, but flows would have been released because of storage limitations. The resulting increase in storage would be released downstream when there were opportunities for beneficial use of the water, either to meet water supply reliability demands or to improve Reclamation's abilities to meet its environmental objectives. The additional water in storage would also expand the cold-water pool and increase end-of-September carryover storage in Shasta Reservoir, increasing the ability of Shasta Dam to improve water temperatures for anadromous fish in the upper Sacramento River.

Conversely, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Releases from Shasta Dam under CP3 would typically increase in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage space could be used to capture additional runoff rather than releasing water to the downstream river, as would occur with Shasta Reservoir's current operations.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

Operation of pumping facilities downstream from Shasta Dam would vary slightly from current operations and would result in higher costs. In addition, Reclamation would provide in-kind power to offset reduced generation at Pit 7 Dam and related facilities.

2.3.6 CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 and CP4A focus on increasing anadromous fish survival by raising Shasta Dam 18.5 feet while also increasing water supply reliability. CP4 and CP4A are identical except for Shasta Dam and reservoir operations. CP4 and CP4A would have similar reservoir operations in that they each dedicate a portion of the new storage in Shasta Lake for fisheries purposes; however, the portion of this dedicated storage varies.

Major Components of CP4 and CP4A

CP4 and CP4A include the following major components:

- Raising Shasta Dam and appurtenant facilities by 18.5 feet
- Reserving a portion of the increased storage in Shasta Lake for maintaining cold-water volume or augmenting flows as part of an adaptive management plan for anadromous fish survival (378,000 acre-feet for CP4, 191,000 acre-feet for CP4A)
- Augmenting spawning gravel in the upper Sacramento River
- Restoring riparian, floodplain, and side channel habitat in the upper Sacramento River
- Implementing the set of eight common management measures previously described
- Implementing the common environmental commitments previously described

By raising Shasta Dam 18.5 feet, from a crest elevation of 1,077.5 feet to 1,096.0 feet (based on NGVD29), CP4 or CP4A would increase the height of the reservoir full pool by 20.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications similar to the modifications proposed under CP1. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would be increased from 4.55 MAF to 5.19 MAF.

The additional storage created by the 18.5-foot dam raise would be used to improve the ability to meet temperature objectives and habitat requirements for anadromous fish during drought years and increase water supply reliability. Of the increased reservoir storage space of CP4, about 378,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Of the increased storage space of CP4A, about 191,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Table 2-6 summarizes major physical features associated with CP4 and CP4A.

The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool for CP4 or CP4A. For CP4, operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1, with 70,000 acre-feet reserved in dry years and 35,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries. For CP4A, operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2, with 120,000 acre-feet reserved in dry years and 60,000 acre-feet reserved in critical years to specifically focus on increasing M&I deliveries.

As described for the above alternatives, both CP4 and CP4A include the potential to revise the operational rules for flood control for Shasta Dam and Reservoir, which could reduce the potential for flood damage and benefit recreation.

CP4 and CP4A also include an adaptive management plan for the cold-water pool, and augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat at one or more sites in the upper Sacramento River.

Adaptive Management of Cold-Water Pool The adaptive management plan may include operational changes to the timing and magnitude of releases from Shasta Dam to benefit anadromous fish, as long as there were no conflicts with current operational guidelines or adverse impacts on water supply reliability. Adaptive management of the cold-water pool for anadromous fish is discussed further below under "Operations and Maintenance for CP4 and CP4A."

Augment Spawning Gravel in Upper Sacramento River Gravel suitable for spawning has been identified as a significant influencing factor in the recovery of anadromous fish populations in the Sacramento River (USFWS 2001, NMFS 2014). Under CP4 and CP4A, spawning-sized gravel would be placed at multiple locations along the Sacramento River between Keswick Dam and the RBPP.

Gravel augmentation would occur at one to three locations every year, for a period of 10 years, unless unusual conditions or agency requests precluded placement during a single year. This program, in addition to the ongoing CVPIA gravel augmentation program, would help address the gravel deficit in the upper Sacramento River. However, this reach may continue to be gravel-limited in the future. Therefore, the proposed gravel augmentation program would be reevaluated after the 10-year period to assess the need for continued spawning gravel augmentation, and to identify opportunities for future gravel augmentation actions or programs.

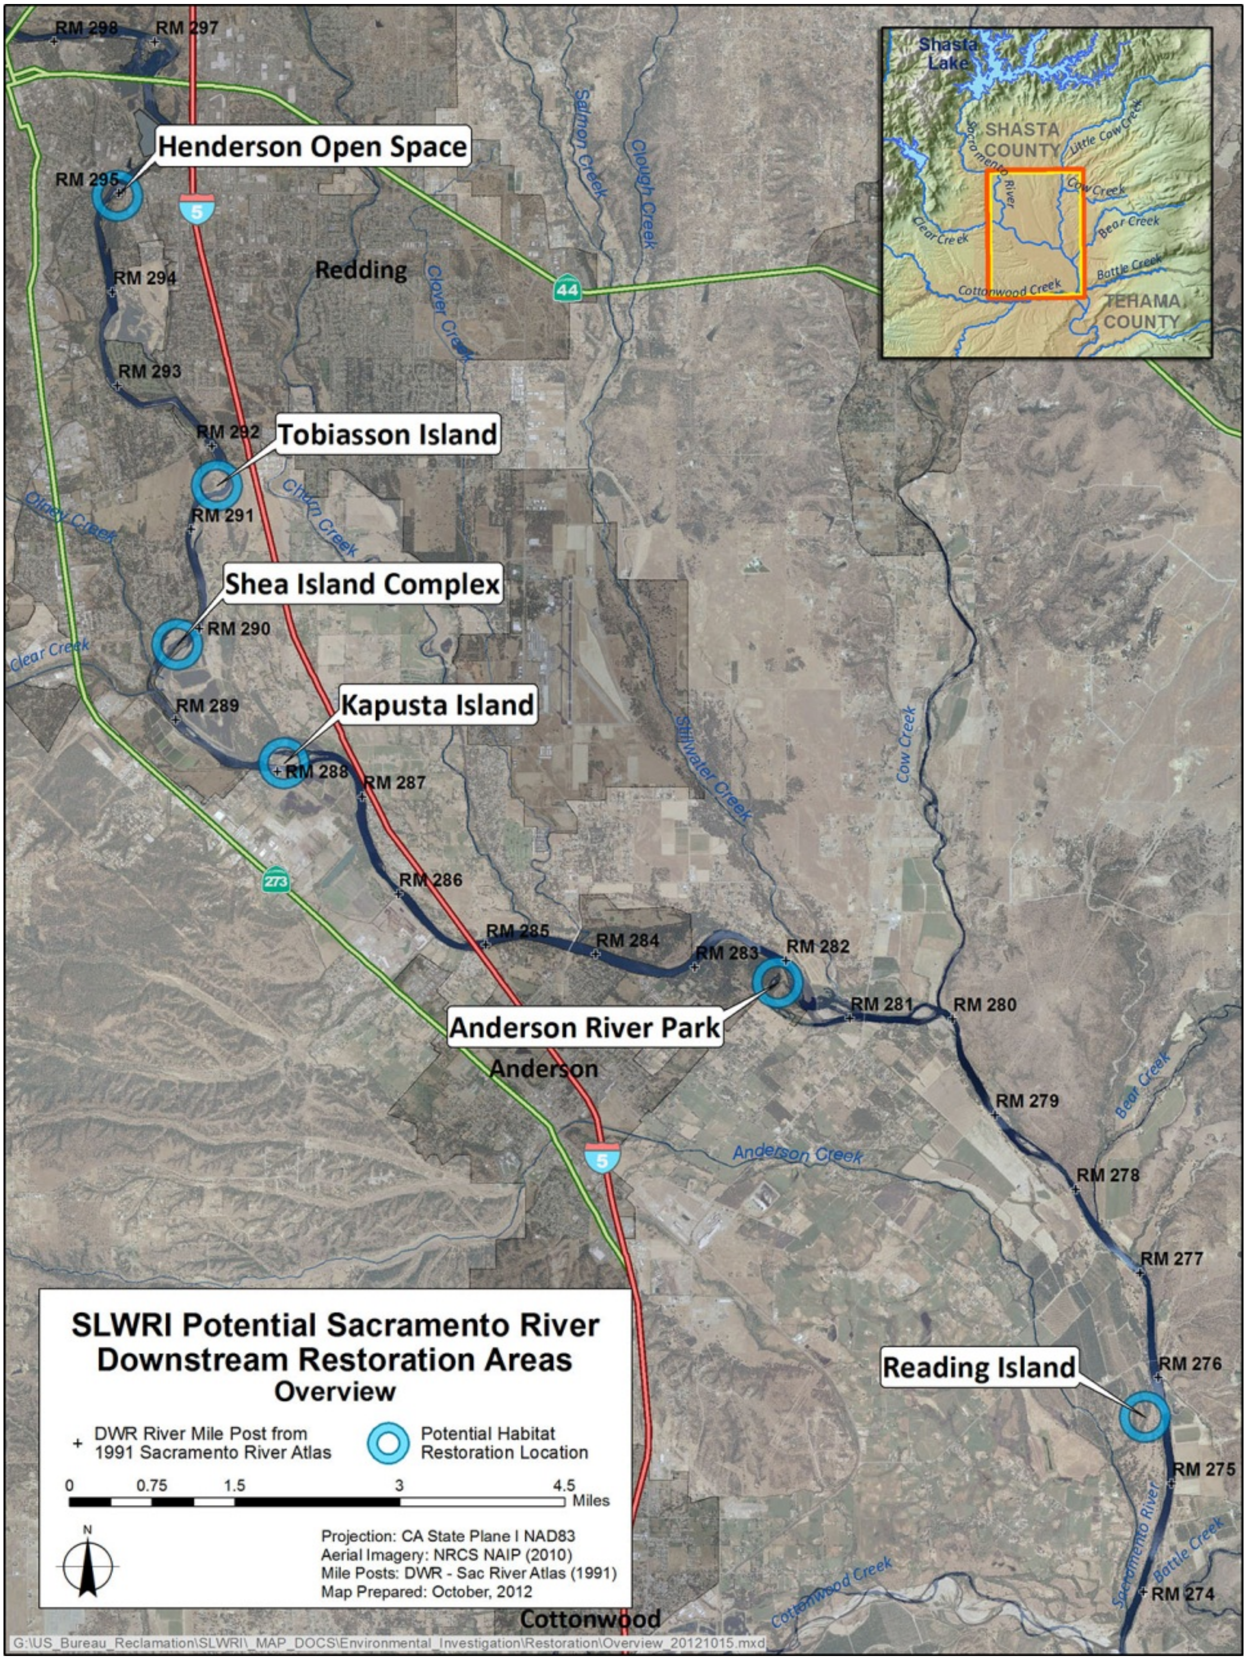
On average, 5,000 to 10,000 tons of gravel would be placed each year, although the specific quantity of gravel placed in a given year may vary from that range. Gravel would be obtained as uncrushed, rounded river rock, free of debris and organic material, from local, commercial sources. To maximize the benefit to anadromous fish, gravel would be washed and sorted to meet specific size criteria. To minimize impacts on salmonid spawning activity, gravel placement within the active river channels would occur between August and September each year, consistent with the time frame for the ongoing CVPIA gravel augmentation program.

Fifteen preliminary locations for spawning gravel augmentation were identified in the Sacramento River between Keswick Dam and Shea Island. Each site would be eligible for gravel placement one or more times during the 10-year program. Selection of these locations was based on potential benefits to anadromous fish and site accessibility. Gravel placement would provide either immediate spawning habitat or long-term recruitment.

Although preliminary sites have been identified, specific gravel augmentation site(s) and volume(s) would be selected each year in the spring or early summer through discussions among Reclamation, USFWS, CDFW, and NMFS. The discussions would include topics such as avoiding redundancy with planned CVPIA gravel augmentation activities in a given year; identifying hydrology or morphology issues that could affect the potential benefit of placing gravel at any particular site; identifying changes in spawning trends based on ongoing CVPIA monitoring efforts; evaluating potential new sites; and appropriately distributing selected gravel sites along the river reach(es).

Restore Riparian, Floodplain, and Side Channel Habitat Under CP4 and CP4A, riparian, floodplain, and side channel habitat restoration would occur at one or a combination of potential locations along the upper Sacramento River. Restoration measures for six potential sites, referred to collectively as “upper Sacramento River restoration sites,” are described below. The sites under consideration for habitat restoration are shown in Figure 2-4.

Henderson Open Space The City of Redding Henderson Open Space area is located south of Cypress Bridge on the east side of the Sacramento River at River Mile (RM) 295. Riparian and side channel restoration at the Henderson Open Space site could consist of enhancing an existing side channel to activate the frequency and duration of flows for Chinook salmon spawning habitat throughout the side channel. This potential modification would create up to 2,000 more linear feet of spawning habitat near areas of the Sacramento River that are actively used by anadromous fish for spawning.



Key: DWR = California Department of Water Resources

Figure 2-4. Potential Sacramento River Habitat Restoration Areas

Tobiasson Island Tobiasson Island is located downstream from South Bonnyview Bridge in the center of the Sacramento River at RM 292. Riparian, floodplain, and side channel habitat enhancement at this site would involve creating a side channel through the island to be activated at Sacramento River flows for Chinook salmon spawning. Riparian vegetation would be established along the course of the new side channel, adding approximately 1,350 linear feet of spawning and floodplain habitat to this section of the Sacramento River.

Shea Island Complex The Shea Island Complex is located on the west side of the Sacramento River upstream from the river's confluence with Clear Creek at RM 291. Restoration at the Shea Island Complex to improve side channel, riparian, and floodplain habitat would involve enhancing a major side channel through the site to keep the side channel hydraulically connected with the main stem of the Sacramento River at a broader range of flows. Adding channel complexity and enhancing riparian vegetation throughout the length of the side channel would improve Chinook salmon habitat along an additional 1,930 feet of the Sacramento River.

Kapusta Island Kapusta Island is located adjacent to the Kapusta Open Space area upstream from the I-5 crossing of the Sacramento River at RM 288. Restoration of riparian, side channel and floodplain habitat at Kapusta Island would involve enhancing an existing side channel by allowing it to carry water at a broader range of flows specifically to increase spawning habitat for winter-run and spring-run Chinook salmon. Allowing flow through the island, and increasing floodplain habitat would increase potential spawning habitat in this area of the river by about 1,590 linear feet.

Anderson River Park Anderson River Park is an open space area on the south bank of the Sacramento River downstream from Churn Creek, and upstream from the Deschutes Road crossing at RM 283. Restoration at this site would involve hydraulically reconnecting a remnant Sacramento River side channel with the Sacramento River. Regularly flowing water throughout the length of this side channel would increase anadromous fish rearing habitat along 4,750 feet of side channel in this section of the river.

Reading Island Reading Island lies along the Sacramento River just north of Cottonwood Creek at RM 274. The channel for Anderson Creek, a remnant Sacramento River side channel, defines the western edge of Reading Island. Construction of a levee on Anderson Creek has blocked the channel's connectivity with the Sacramento River and has created Anderson Slough, an area of still water. Riparian, floodplain, and side channel restoration on Reading Island would involve restoring flows in Anderson Creek and through Anderson Slough. These activities, alongside removal of invasive aquatic vegetation in the channel and reestablishment of riparian vegetation would aid in restoring rearing habitat for winter-run Chinook, and spawning habitat for steelhead along 4,225 feet of channel in this area of the river.

Potential Benefits of CP4 and CP4A

Major potential benefits of CP4 and CP4A, related to the project objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors affecting anadromous fish survival in the Sacramento River. CP4 or CP4A would significantly increase the ability of Shasta Dam to make cold-water releases and regulate water temperature in the upper Sacramento River, primarily in dry and critical water years. This would be accomplished by raising Shasta Dam 18.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBPP. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBPP.

It is estimated that improved water temperature and flow conditions under CP4 could result in an average annual increase in Chinook salmon population of nearly 812,600 out-migrating juvenile fish. It is estimated that improved water temperature and flow conditions under CP4A could result in an average annual increase in Chinook salmon population of nearly 710,000 out-migrating juvenile fish.

Under CP4 and CP4A, an increase in the cold-water pool would allow Reclamation to operate Shasta Reservoir to provide not only a more reliable source of water during dry and critical water years, but also to provide more cool water for release into the Sacramento River to improve conditions for anadromous fish. Of the increased storage space for CP4, about 378,000 acre-feet (60 percent) would be dedicated to increasing the cold-water supply for anadromous fish survival purposes. Of the increased storage space for CP4A, about 191,000 acre-feet (30 percent) would be dedicated to increasing the cold-water supply for anadromous fish survival purposes.

In addition, CP4 and CP4A include a gravel augmentation program. Gravel augmentation would occur on average at one or more locations in the Sacramento River between Keswick Dam and the RBPP for a period of 10 years. On average, 5,000 to 10,000 tons of gravel would be placed each year, although the specific quantity of gravel placed in a given year may vary from that range. Spawning gravel augmentation is expected to positively influence anadromous fish populations in the Sacramento River.

Potential benefits to anadromous fish survival through conserving, restoring, and enhancing ecosystem resources are described below.

Increase Water Supply Reliability CP4 or CP4A would increase water supply reliability by increasing water supplies for CVP and SWP irrigation and

M&I deliveries. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA. CP4 would help reduce estimated future water shortages by increasing the reliability of dry and critical year water supplies for agricultural and M&I deliveries by at least 47,300 acre-feet per year and average annual deliveries by about 31,000 acre-feet per year. CP4A would help reduce estimated future water shortages by increasing the reliability of dry and critical year water supplies for agricultural and M&I deliveries by at least 77,800 acre-feet per year and average annual deliveries by about 51,300 acre-feet per year. The majority of increased dry and critical year water supplies (42,700 acre-feet for CP4 and 67,100 acre-feet for CP4A) would be for south-of-Delta agricultural and M&I deliveries. In addition, water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continued to grow and available supplies continued to remain relatively static, more effectively using these supplies could reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP4 and CP4A, approximately $1.6 million and $2.6 million, respectively, would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 127 GWh per year for CP4 and 125 GWh for CP4A. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities. Other power benefits for both CP4 and CP4A include additional capacity (i.e., the rate at which power can be generated) and ancillary services, which provide the ability to manage the electric grid in a reliable manner.

Conserve, Restore, and Enhance Ecosystem Resources In the upper Sacramento River, the addition of spawning gravel and the restoration of riparian, floodplain, and side channel habitat would be expected to improve the complexity of aquatic habitat and its suitability for anadromous salmonid spawning and rearing habitat. Riparian areas would provide habitat for a diverse array of plant and animal communities along the Sacramento River, including several threatened or endangered species. Riparian areas would also provide shade and woody debris that increase the complexity of aquatic habitat and its suitability for spawning and rearing. Lower floodplain areas, river terraces, and gravel bars would play an important role in the health and succession of riparian habitat. Restoration would support the goals of the Sacramento River Conservation Area Forum and other programs associated with riparian restoration along the Sacramento River. In addition, improved fisheries conditions as a result of cold-water carryover storage in CP4 or CP4A, as described above, and increased flexibility to meet flow and temperature requirements, could also enhance overall ecosystem resources in the Sacramento River. Side channels could support important habitat for anadromous salmonids, including rearing and spawning habitat. Side channel habitats would also provide refuge from predators and productive foraging habitat for juvenile anadromous salmonids.

Maintain and Increase Recreation Opportunities CP4 and CP4A include features to, at a minimum, maintain the existing recreation capacity at Shasta Lake. Potential recreation benefits would be as stated for CP3. Although neither CP4 nor CP4A include specific features to further increase recreation capacity, benefits to the water-oriented recreation experience at Shasta Lake would likely occur because of the increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. For CP4, the maximum surface area of the lake would increase by about 2,600 acres (9 percent), from 29,700 acres to about 32,300 acres. The average surface area of the lake during the recreation season from May through September would increase by about 2,600 acres (11 percent), from 23,900 acres to 26,500 acres. For CP4A, the average surface area of the lake during the recreation season from May through September would increase by about 2,300 acres (10 percent), from 23,900 acres to 26,200 acres. .There would also be limited potential to provide additional benefits to recreation by allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other Project Objectives CP4 and CP4A could also provide benefits related to flood damage reduction and water quality, similar to CP1 and CP2, respectively.

Construction for CP4 and CP4A

Construction activities for CP4 and CP4A would be identical to one another. Construction activities associated with physical features under CP4 or CP4A would include land-based construction activities associated with the following:

- Clearing vegetation from portions of the inundated reservoir area
- Constructing the dam raise, appurtenant structures, reservoir area dikes, and railroad embankments
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure
- Augmenting spawning gravel in the upper Sacramento River
- Restoring riparian, floodplain, and side channel habitat

Construction activities for CP4 and CP4A are described in Section 2.3.8, “Comprehensive Plan Construction Activities.”

Operations and Maintenance for CP4 and CP4A

Operations would differ between CP4 and CP4A, as described below. The anticipated maintenance for CP4 and CP4A would be identical to one another.

Operations for CP4 Operations under CP4 would be governed by the same regulatory constraints as described for CP1. Under CP4, the additional storage would be retained to increase water supply reliability and to expand the cold-water pool in Shasta Reservoir for fisheries benefits. Of the 634,000 acre-feet of additional storage, 378,000 acre-feet of water (60 percent) would be dedicated to increasing the cold-water supply for anadromous fish survival purposes. This would be in addition to any storage targets set by regulations described in Chapter 6, "Hydrology, Hydraulics, and Water Management." Similar to CP1, Shasta Dam operational guidelines would continue unchanged under CP4, except during dry and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be operated primarily to provide increased M&I deliveries. Operations targeting increased M&I deliveries were based on existing and anticipated future demands, operational priorities, and facilities of the SWP.

As modeled for CP4, the 378,000 acre-feet of additional water would be the first increment of the reservoir filled after the reservoir was enlarged. This amount of water would be available as additional water for the cold-water pool each year regardless of water year type, unless Reclamation elected to use the additional water to augment flows protecting anadromous fish in the Sacramento River, as part of a proposed adaptive management plan, as explained below. An additional 256,000 acre-feet of the increased storage space would be used primarily to improve water supply reliability; operations of Shasta Dam related to the 256,000 acre-feet of storage would be similar to operations under CP1.

As stated above, of the total 634,000 acre-feet of additional storage, 378,000 acre-feet of water would be used to increase the cold-water pool for fisheries. Reclamation is currently working with NMFS, USFWS, and CDFW through the Sacramento River Temperature Task Group (SRTTG), a multiagency group established to adaptively manage flows and water temperatures in the Sacramento River, to improve and stabilize Chinook salmon populations in the upper Sacramento River. The additional 378,000 acre-feet of cold-water pool would be managed by Reclamation in coordination with the SRTTG.

Current analysis indicates that the most beneficial use of the additional 378,000 acre-feet of storage for fisheries protection would be as an expanded cold-water pool; however, Reclamation has agreed to adaptively manage the 378,000 acre-feet of water, as appropriate, to increase benefits to anadromous fish as part of CP4. Adaptive management is an approach allowing decision makers to take advantage of a variety of strategies and techniques that are adjusted, refined, and/or modified based on an improved understanding of system dynamics.

Adaptive management, if applied appropriately, allows for flexible operations based on best available science and new information as it becomes available.

The adaptive management plan may include operational changes to the timing and magnitude of releases primarily to improve the quality and quantity of aquatic habitat. These changes may include increasing minimum flows, timing releases from Shasta Dam to mimic more natural seasonal flows, meeting flow targets for side channels, or retaining the additional 378,000 acre-feet of water in storage to meet temperature requirements. Reclamation would work cooperatively with the SRTTG to determine the best use of the cold-water pool each year under an adaptive management plan. Reclamation would manage the cold-water pool and operate Shasta Dam each year based on recommendations from the SRTTG. Because adaptive management would be predicated on using best available science and new information to make decisions, a monitoring program would be implemented as part of the adaptive management plan. SRTTG members would conduct monitoring, develop monitoring protocols, and set performance standards to determine the success of adaptive management actions.

Under the currently proposed operations, the 378,000 acre-feet of additional storage would be the first increment of water in the reservoir to fill after dam enlargement. This water would be available each year independent of water year type if used exclusively to enlarge the cold-water pool. If the 378,000 acre-feet of stored water were used to augment flows based on recommendations from the SRTTG, this water would not be guaranteed to be available for use the following year because of uncertainty in hydrologic conditions. Once water was released to augment flows as part of the adaptive management plan, the 378,000 acre-feet of additional storage space would be refilled after the 256,000 acre-feet of additional storage space was filled for the primary purpose of increasing water supply reliability. Each year that the 378,000 acre-feet of additional water was held in storage as part of an increase in the cold-water pool, the allocated amount would be available as long as the cold-water pool continued to provide benefits to fisheries.

SALMOD modeling and related analysis indicated that in most cases, providing an increased cold-water pool would benefit Chinook salmon populations in the Upper Sacramento River more than increasing flows. Therefore, the impacts and benefits of increasing flows under CP4 are not presented in this EIS. Per recommendations in Title 43, CFR Part 46, Section 46.145, substantive increases in flows associated with the adaptive management plan would be evaluated in subsequent NEPA analysis.

Operation of pumping facilities downstream from Shasta Dam would vary slightly from current operations and would result in higher costs. In addition, Reclamation would provide in-kind power to offset reduced generation at Pit 7 Dam and related facilities.

Operations for CP4A As modeled for CP4A, the 191,000 acre-feet of additional water would be the first increment of the reservoir filled after the reservoir was enlarged. This amount of water would be available as additional water for the cold-water pool each year regardless of water year type, unless Reclamation elected to use the additional water to augment flows protecting anadromous fish in the Sacramento River, as part of a proposed adaptive management plan, as explained below. An additional 443,000 acre-feet of the increased storage space would be used primarily to improve water supply reliability; operations of Shasta Dam related to the 443,000 acre-feet of storage would be similar to operations under CP2.

As stated above, of the total 634,000 acre-feet of additional storage, 191,000 acre-feet of water would be used to increase the cold-water pool for fisheries. Reclamation is currently working with NMFS, USFWS, and CDFW through the SRTTG, a multiagency group established to adaptively manage flows and water temperatures in the Sacramento River, to improve and stabilize Chinook salmon populations in the upper Sacramento River. The additional 191,000 acre-feet of cold-water pool would be managed by Reclamation in coordination with the SRTTG.

Current analysis indicated that the most beneficial use of the additional 191,000 acre-feet of storage for fisheries protection would be as an expanded cold-water pool; however, Reclamation has agreed to adaptively manage the 191,000 acre-feet of water, as appropriate, to increase benefits to anadromous fish as part of CP4A. Adaptive management is an approach allowing decision makers to take advantage of a variety of strategies and techniques that are adjusted, refined, and/or modified based on an improved understanding of system dynamics. Adaptive management, if applied appropriately, allows for flexible operations based on best available science and new information as it becomes available.

The adaptive management plan may include operational changes to the timing and magnitude of releases primarily to improve the quality and quantity of aquatic habitat. These changes may include increasing minimum flows, timing releases from Shasta Dam to mimic more natural seasonal flows, meeting flow targets for side channels, or retaining the additional 191,000 acre-feet of water in storage to meet temperature requirements. Reclamation would work cooperatively with the SRTTG to determine the best use of the cold-water pool each year under an adaptive management plan. Reclamation would manage the cold-water pool and operate Shasta Dam each year based on recommendations from the SRTTG. Because adaptive management would be predicated on using best available science and new information to make decisions, a monitoring program would be implemented as part of the adaptive management plan. SRTTG members would conduct monitoring, develop monitoring protocols, and set performance standards to determine the success of adaptive management actions.

Under the currently proposed operations, the 191,000 acre-feet of additional storage would be the first increment of water in the reservoir to fill after dam enlargement. This water would be available each year independent of water year type if used exclusively to enlarge the cold-water pool. If the 191,000 acre-feet of stored water was used to augment flows based on recommendations from the SRTTG, this water would not be guaranteed to be available for use the following year because of uncertainty in hydrologic conditions. Once water was released to augment flows as part of the adaptive management plan, the 191,000 acre-feet of additional storage space would be refilled after the 443,000 acre-feet of additional storage space was filled for the primary purpose of increasing water supply reliability. Each year that the 191,000 acre-feet of additional water was held in storage as part of an increase in the cold-water pool, the allocated amount would be available as long as the cold-water pool continued to provide benefits to fisheries.

SALMOD modeling and related analysis indicated that in most cases, providing an increased cold-water pool would benefit Chinook salmon populations in the Upper Sacramento River more than increasing flows. Therefore, the impacts and benefits of increasing flows under CP4A are not presented in this EIS. Per recommendations in Title 43, CFR Part 46, Section 46.145, substantive increases in flows associated with the adaptive management plan would be evaluated in subsequent NEPA analysis.

Operation of pumping facilities downstream from Shasta Dam would vary slightly from current operations and would result in higher costs. In addition, Reclamation would provide in-kind power to offset reduced generation at Pit 7 Dam and related facilities.

Maintenance for CP4 and CP4A Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

2.3.7 CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily focuses on increased water supply reliability, anadromous fish survival, Shasta Lake area and upper Sacramento River environmental resources, and increased recreation opportunities.

Major Components of CP5

CP5 includes the following major components:

- Raising Shasta Dam and appurtenant facilities by 18.5 feet
- Constructing additional resident fish habitat in Shasta Lake and along the lower reaches of its tributaries (Sacramento River, McCloud River, and Squaw Creek)
- Constructing shoreline fish habitat around Shasta Lake

- Augmenting spawning gravel in the upper Sacramento River
- Restoring riparian, floodplain, and side channel habitat in the upper Sacramento River
- Increasing recreation opportunities at Shasta Lake
- Implementing the set of eight common management measures previously described
- Implementing the common environmental commitments previously described

By raising Shasta Dam 18.5 feet, from a crest elevation of 1,077.5 feet to 1,096.0 feet (based on NGVD29), CP5 would increase the height of the reservoir full pool by 20.5 feet. The additional 2-foot increase in the height of the full pool above the dam raise height would result from spillway modifications similar to the modifications proposed under CP1. This increase in full pool height would add approximately 634,000 acre-feet of storage to the reservoir's capacity. Accordingly, storage in the overall full pool would be increased from 4.55 MAF to 5.19 MAF. Table 2-6 summarizes major physical features associated with CP5.

Under CP5, the additional storage in Shasta Reservoir would be used to increase water supply reliability and to expand the cold-water pool for downstream anadromous fisheries. The existing TCD would be extended to achieve efficient use of the expanded cold-water pool. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, except during dry and critical years when a portion of the increased storage in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. In dry years, 150,000 acre-feet of the 634,000 acre-feet increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. In critical years, 75,000 acre-feet of the increased storage capacity would be reserved for increasing M&I deliveries.

As described for the above alternatives, this alternative also would include the potential to revise the flood control operational rules for Shasta Dam and Reservoir, which could reduce the potential for flood damage and benefit recreation.

CP5 also involves (1) restoring resident fish habitat in Shasta Lake; (2) restoring fisheries and riparian habitat at several locations along the lower reaches of the tributaries to Shasta Lake; (3) augmenting spawning gravel in the upper Sacramento River; (4) restoring riparian, floodplain, and side channel habitat in the upper Sacramento River; and (5) increasing recreation opportunities at Shasta Lake.

Construct Reservoir Shoreline Enhancement The ecosystem enhancement goal for the shoreline environment of Shasta Lake is to improve warm-water fish habitat associated with the transition between the reservoir's aquatic and terrestrial habitats. Shoreline enhancement entails a range of enhancement opportunities along the Shasta Lake shoreline below the full pool elevation of 1,090 feet (based on the North American Vertical Datum of 1988 (NAVD88))[3] that would occur with an 18.5-foot dam raise. This area is typically between 0.1 mile and 1.5 miles upslope from the current full pool elevation of 1,070 feet (based on NAVD88). The shoreline is defined as the area encompassing nearshore aquatic habitat within the reservoir itself and vegetation and other habitat components adjacent to the reservoir.

Two categories of potential nearshore warm-water fish habitat enhancement activities would be (1) structural enhancements, which entail placing artificial structures in the Shasta Lake littoral zone; and (2) vegetative enhancements, which entail planting and seeding to provide submerged and partly submerged vegetative cover when the reservoir is at full pool capacity during the winter/spring months.

Construction activities common to all action alternatives would include stockpiling manzanita for fish habitat (see Section 2.3.2, "Environmental Commitments Common to All Action Alternatives"). CP5 would involve clearing additional manzanita from above the new full pool inundation zone to create further structural enhancements for fish habitat in the Shasta Lake littoral zone.

Vegetative enhancements associated with CP5 would include planting willows (*Salix*) to enhance nearshore fish habitat, and single-treatment aerial and hand seeding of annual native grasses to treat shoreline areas at Shasta Lake. Treatment with native grasses would provide only short-term cover, but would be cost-effective across large areas and can be implemented quickly and efficiently. The annual native grasses would provide cover for young fish and also nutrients for plankton as the grasses decompose. The plankton in turn would be a valuable food source for juvenile fish.

Construct Reservoir Tributary Aquatic Habitat Enhancement The primary goal for the enhancement of aquatic habitat in the watershed is to improve the connectivity for native fish species and other aquatic organisms between Shasta Lake and its tributaries. Two categories of potential aquatic habitat enhancement in tributaries would be (1) fish passage enhancements, which entail identifying and correcting barriers to fish passage, particularly at culverts and other human-made barriers; and (2) aquatic habitat enhancements, which entail identifying and implementing feasible habitat improvements

[3] Shasta Lake water surface elevations are based on NAVD88. All current feasibility-level designs and figures for reservoir area infrastructure modifications and relocations to accommodate increased water levels are based on a 2001 aerial survey of the reservoir which was completed using NAVD88.

intended to conserve or restore degraded aquatic and riparian habitat in tributaries to Shasta Lake.

Fish passage enhancements associated with CP5 would include opportunities to restore and/or enhance five perennial stream crossings. Barriers to fish passage in the watersheds above Shasta Lake would be associated primarily with culverts or other types of stream crossings.

Aquatic habitat enhancements associated with CP5 would involve enhancing aquatic connectivity and reducing sediment related to roads constructed across intermittent streams. The preliminary site survey identified opportunities to enhance 14 intermittent stream crossings. Based on the information obtained in the survey, these crossings would provide opportunities for meeting the objectives of enhancing aquatic connectivity and/or reducing the potential for road-related sediment. Two sites have been identified in the Salt Creek watershed, two sites have been identified in the Sugarloaf Creek watershed, and 10 sites have been identified in the McCloud River Arm watershed.

Augment Spawning Gravel in Upper Sacramento River As described in CP4 and CP4A, spawning gravel would be added to the upper Sacramento River. This measure would be identical to that proposed under CP4 and CP4A.

Restore Riparian, Floodplain, and Side Channel Habitat As described in CP4 and CP4A, riparian, floodplain, and side channel habitat restoration would occur at suitable locations along the Sacramento River. This measure would be identical to that proposed under CP4 and CP4A.

Recreation Enhancements A total of 18 miles of new hiking trails and 6 trailheads would be constructed to enhance recreation under CP5.

Potential Benefits of CP5

Major potential benefits of CP5, related to the project objectives, are described below.

Increase Anadromous Fish Survival Water temperature is one of the most important factors affecting anadromous fish survival in the Sacramento River. CP5 would increase the ability of Shasta Dam to make cold-water releases and regulate water temperature in the upper Sacramento River, primarily in dry and critical water years. This would be accomplished by raising Shasta Dam 18.5 feet, thus increasing the depth of the cold-water pool in Shasta Reservoir and resulting in an increase in seasonal cold-water volume below the thermocline (layer of greatest water temperature and density change). Cold water released from Shasta Dam significantly influences water temperature conditions in the Sacramento River between Keswick Dam and the RBPP. Hence, the most significant water temperature benefits to anadromous fish would occur upstream from the RBPP. It is estimated that improved water temperature and flow conditions under CP5 could result in an annual average increase in the Chinook salmon population of about 377,800 out-migrating juvenile fish.

Increase Water Supply Reliability CP5 would increase water supply reliability by increasing water supplies for CVP and SWP irrigation and M&I deliveries. This action would contribute to replacement of supplies redirected to other purposes in the CVPIA. CP5 would help reduce estimated future water shortages by increasing the reliability of dry and critical year water supplies for agricultural and M&I deliveries by at least 113,500 acre-feet per year, and average annual deliveries by about 75,900 acre-feet per year. The majority of increased dry and critical year water supplies (88,300 acre-feet) would be for south-of-Delta agricultural and M&I deliveries. In addition, increased water use efficiency could help reduce current and future water shortages by allowing a more effective use of existing supplies. As population and resulting water demands continued to grow and available supplies continued to remain relatively static, more effective use of these supplies could reduce potential critical impacts to agricultural and urban areas resulting from water shortages. Under CP5, approximately $3.8 million would be allocated over an initial 10-year period to fund agricultural and M&I water conservation programs, focused on agencies benefiting from increased reliability of project water supplies.

Develop Additional Hydropower Generation Higher water surface elevations in the reservoir would result in a net increase in power generation of about 112 GWh per year. This generation value is the expected increased generation from Shasta Dam and other CVP/SWP facilities. Other power benefits include additional capacity (i.e., the rate at which power can be generated) and ancillary services, which provide the ability to manage the electric grid in a reliable manner.

Conserve, Restore, and Enhance Ecosystem Resources CP5 would provide for habitat improvements both in the reservoir area and downstream from Shasta Dam on the upper Sacramento River.

Along the Shasta Lake shoreline, shallow warm-water fish habitat would be improved by using manzanita cleared from above the inundation zone to create structural enhancements, planting willows to enhance nearshore fish habitat, and seeding of native grasses to treat shoreline areas. Once established, the willows and native grasses would provide submerged and partly submerged vegetative cover when the reservoir is at full pool during the winter/spring months. These improvements would help provide favorable spawning conditions, and juvenile fish leaving the tributaries would benefit from improved adjacent shoreline habitat. Placing manzanita brush structures near the shoreline would enhance the diversity of structural habitat available for the warm-water fish species that occupy Shasta Lake. Establishing vegetation also could benefit terrestrial species that inhabit the shoreline of Shasta Lake.

The lower reaches of perennial tributaries to Shasta Lake would be the focus for aquatic restoration under CP5 because they provide year-round fish habitat. Native fish species require connectivity to the full range of habitats offered by Shasta Lake and its tributaries. Improved fish passage would address the requirement to provide access and/or modify barriers to improve ecological conditions that support these native fish assemblages. Aquatic habitat improvements would include enhancing aquatic connectivity and reducing sediment related to roads constructed across intermittent streams.

In the upper Sacramento River, the addition of spawning gravel and the restoration of riparian, floodplain, and side channel habitat would be expected to improve the complexity of aquatic habitat and its suitability for spawning and rearing. Riparian areas would provide habitat for a diverse array of plant and animal communities along the Sacramento River, including numerous threatened or endangered species. Riparian areas would also provide shade and woody debris that increase the complexity of aquatic habitat and its suitability for spawning and rearing. Lower floodplain areas, river terraces, and gravel bars would play an important role in the health and succession of riparian habitat. Restoration would support the goals of the Sacramento River Conservation Area Forum and other programs associated with riparian restoration along the Sacramento River. Side channels could support important habitat for anadromous salmonids, including rearing and spawning habitat. Side channel habitats would also provide refuge from predators and productive foraging habitat for juvenile anadromous salmonids.

Maintain and Increase Recreation Opportunities CP5 includes features to, at a minimum, maintain the existing recreation capacity at Shasta Lake. In addition, this alternative involves construction of 18 miles of new trails and 6 trailheads to enhance recreation opportunities at Shasta Lake. As with the other alternatives, benefits to the water-oriented recreation experience at Shasta Lake would likely occur because of the increase in average lake surface area, reduced drawdown during the recreation season, and modernization of recreation facilities. The maximum surface area of the lake would increase by about 2,600 acres (9 percent), from 29,700 acres to about 32,300 acres. The average surface area of the lake during the recreation season from May through September would increase by about 1,900 acres (8 percent), from 23,900 acres to 25,800 acres. There would also be limited potential for reservoir reoperation to provide additional benefits to recreation by allowing more reliable filling of the reservoir during the spring.

Benefits Related to Other Project Objectives CP5 could also provide benefits related to flood damage reduction and water quality, similar to CP3.

Construction for CP5

Construction activities associated with physical features under CP5 would include land-based construction activities associated with the following:

- Clearing vegetation from portions of the inundated reservoir area
- Constructing the dam raise, appurtenant structures, reservoir area dikes, and railroad embankments
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure
- Augmenting spawning gravel in the upper Sacramento River
- Restoring riparian, floodplain, and side channel habitat
- Enhancing Shasta Lake and tributary shoreline

Construction activities for CP5 are described in Section 2.3.8, "Comprehensive Plan Construction Activities."

Operations and Maintenance for CP5

Operations under CP5 would be governed by the same regulatory constraints as described for CP1. Similar to CP1, the additional storage would be retained to increase water supply reliability and to expand the cold-water pool in Shasta Reservoir for fisheries benefits. Similar to CP1, Shasta Dam operational guidelines would continue unchanged, except during dry and critical years, when 150,000 acre-feet and 75,000 acre-feet, respectively, of the 634,000 acre-feet increased storage capacity in Shasta Reservoir would be operated primarily to provide increased M&I deliveries. Operations targeting increased M&I deliveries were based on existing and anticipated future demands, operational priorities, and facilities of the SWP. For CP5, existing water quality and temperature requirements would typically be met in most years; therefore, additional water in storage would be released primarily for water supply purposes. Accordingly, minimal increases in flow would be expected in months when Delta exports were constrained, or when flow was not usable for water supply purposes.

In comparison to current operations, CP5 would store some additional flows behind Shasta Dam during periods when downstream needs would have already been met, but flows would have been released because of storage limitations. The resulting increase in storage would be released downstream when there were opportunities for beneficial use of the water, either to meet water supply reliability demands or to improve Reclamation's abilities to meet its environmental objectives. The additional water in storage would also expand the cold-water pool and increase end-of-September carryover storage in Shasta

Reservoir, increasing the ability of Shasta Dam to improve water temperatures for anadromous fish in the upper Sacramento River.

Conversely, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Releases from Shasta Dam under CP5 would typically increase in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage space could be used to capture additional runoff rather than releasing water to the downstream river, as would occur with Shasta Reservoir's current operations.

Maintenance of facilities related to the proposed dam and reservoir enlargement would be similar to maintenance activities currently conducted at Shasta Dam and Reservoir.

Operation of pumping facilities downstream from Shasta Dam would vary slightly from current operations and would result in higher costs. In addition Reclamation would provide in-kind power, to offset the reduced generation at Pit 7 Dam and related facilities

2.3.8 Comprehensive Plan Construction Activities

Construction activities under all comprehensive plans would include land-based construction activities associated with the following:

- Clearing vegetation from portions of the inundated reservoir area
- Constructing the dam raise, appurtenant structures, reservoir area dikes, and railroad embankments
- Relocating roadways, bridges, recreation facilities, utilities, and miscellaneous minor infrastructure

CP4, CP4A, and CP5 would also include construction activities associated with gravel augmentation and restoring riparian, floodplain, and side channel habitat. Additional construction activities associated with Shasta Lake and tributary shoreline enhancements are included under CP5. Construction activities under the proposed action alternatives are described below. For additional considerations, please refer to the Engineering Summary Appendix.

Clearing Portions of Inundated Reservoir Area

A portion of the acreage inundated at the new reservoir full pool would need to be cleared. This would involve removing trees and other vegetation from around the reservoir shoreline at select areas. Willows, cottonwoods, and buttonbush would not be removed in and along riparian areas. Manzanita removed in cleared areas would be stockpiled and used for fish habitat structures placed in designated locations. Structures, utilities, and other infrastructure would also need to be removed and/or relocated, as described below in more detail.

Fifteen vegetation management areas have been delineated to facilitate efficient removal of vegetation around the reservoir perimeter, including 11 areas of complete vegetation removal and 4 areas of overstory removal (see Figure 2-5). The acreages of each vegetation management area affected by identified reservoir clearing treatments are summarized in Table 2-7 below.

Vegetation management activities would need to be complete before inundation of new areas created by enlarging the reservoir. A single staging area (landing) would serve each vegetation management area. Access for vegetation removal activities would most likely be limited to late summer and fall, when water levels are low and recreation use has decreased. Removal by helicopter would generally be limited to spring and fall because of the limited availability of helicopters during the summer fire season. Vegetation removal would also be limited during bird nesting season, typically early spring through mid-summer. Breeding bird surveys in suitable habitats would be performed to determine the appropriate time frame for vegetation removal activities. Because of distance and/or safety constraints, helicopters would not be used in the following vegetation management areas: Bridge Bay, Lakeshore East, Pit Arm, and McCloud Arm. Slash burning could take place during the winter seasons following vegetation treatment and would comply with all regulations set forth by the Shasta County Air Quality Management District. Methods for clearing the reservoir area are summarized below.

Complete Vegetation Removal Complete vegetation removal would clear all existing vegetation from the designated treatment area and would generally be applied to locations along and adjacent to developed recreation areas, including boat ramps, day use areas, campgrounds, marinas, and resorts. Exceptions would be made in areas with high shoreline erosion potential, or habitat for special-status species.

Timber would be harvested and removed to landings by ground-skidding equipment if road access is available and slopes are less than 35 percent; otherwise, trees would be yarded by helicopter and residual vegetation and activity-created slash would be piled and burned by hand. Where possible, trees would be felled into the reservoir during removal to minimize damage to reservoir embankments. Tree stumps would be cut to within 24 inches of the ground surface and brush stumps would be cut flush to the ground. Stumps would be left in place to reduce shoreline erosion. Complete vegetation removal is intended to maximize shoreline access and minimize the risk to visitors from snags and water hazards.

Key:
CP = comprehensive plan

Overstory Removal Overstory removal involves removing all trees from the treatment area that are greater than 10 inches in diameter at breast height, or 15 feet in height, generally in houseboat mooring areas or narrow arms of the reservoir where snags pose the greatest risk to boaters. Trees would be harvested and removed to landings by ground-skidding equipment if road access is available and slopes are less than 35 percent; otherwise, trees would be yarded by helicopter and activity-created slash would be piled and burned by hand. The remaining understory vegetation would be left in place. As for complete vegetation removal, where possible, trees would be felled into the reservoir during removal to minimize damage to reservoir embankments. Tree stumps would be cut to within 24 inches of the ground surface. Stumps would be left in place to reduce shoreline erosion. Overstory removal is intended to minimize the risk to visitors from snags and water hazards.

No Treatment Designated areas of the inundation zone would be left untreated with no vegetation removed. This prescription would generally be applied to stream inlets, the upper end of major drainages, the shoreline of wider arms of the reservoir, and special habitat areas. This treatment is intended to maximize the habitat benefits of inundated and residual vegetation.

Construction of Dam and Appurtenant Structures

This section summarizes major features associated with enlarging Shasta Dam and Reservoir and modifying its appurtenances (i.e., spillway and outlet works) for all comprehensive plans (action alternatives). Total surface area that would be required for work limits and permanent features, and an estimate of materials needed to modify Shasta Dam and its appurtenances under each comprehensive plan are shown in Table 2-8. For more detailed explanations of design considerations, please refer to the Engineering Summary Appendix.

Table 2-8. Physical Features for Proposed Modifications of Shasta Dam and Appurtenances for Action Alternatives

Physical Features	CP1	CP2	CP3, CP4, CP4A, and CP5
Quantity of Concrete (cubic yards)	57,000	77,300	100,800
Quantity of Cement (tons)	128,600	170,500	213,000
Quantity of Metalwork (pounds)	19,654,400	20,435,900	21,751,200
Volume of Imported Fill Material (cubic yards)	61,200	94,400	130,500
Volume of Excavation to Waste Material (cubic yards)	1,600	1,600	1,600
Quantity of Demolished Material (cubic yards)	25,400	29,200	31,600
Area of Permanent Structures (square feet)	412,600	412,600	412,600
Area of Work Limits (square feet)	460,900	460,900	460,900

Key:
CP = comprehensive plan

Dam Crest Structure Removal Before enlargement of Shasta Dam, existing structures on the dam crest would need to be removed. These structures include the gantry crane, existing spillway drum gates and frames, the spillway bridge, concrete in the spillway crest and abutments, upstream parapet walls, sidewalks, curbing, crane rails, and control equipment. This preparatory work would be similar for all comprehensive plans.

Modifying the main dam would require the demolition, removal, and transportation of top-of-dam materials to an approved disposal area. This would include the demolition and removal of the upstream reinforced-concrete parapet wall and curb. Sawcuts would be used to aid in removing the upstream reinforced-concrete parapet wall and curb. In addition, sawcuts would be required along the upstream face and crest of the dam to embed a polyvinyl chloride waterstop. The existing dam crest would be prepared by using a high-pressure water jet on the concrete surface to facilitate bonding with the new concrete to be placed. Existing roadway drains would be backfilled with cement grout.

Drain holes would be drilled from two different locations: from the existing dam crest to drain the surface contact and from the existing dam crest for surface drainage at the downstream overhang. A vertical shaft would be excavated through the concrete from the existing dam crest to the hoist gallery to install electrical conduit.

The existing spillway drum gates and piers would require removal according to a phased construction plan that would minimize impacts to reservoir operations during construction. Two drum gates and one pier would be removed to construct three new piers and install three new sloping fixed-wheel gates. This would be followed by removal of the remaining drum gate and pier to construct two new piers and install three new sloping fixed-wheel gates.

The spillway bridge and dam crest access road would be out of service for an extended period of time (over two years) during construction of the new spillway and dam crest raise. A detour route would be provided below the dam across an existing bridge. Modifications to the TCD would be performed to minimize impacts to reservoir operations to the extent possible, but supplemental cold water releases may be required through the river outlets during a portion of the construction period. Control equipment for the TCD would be removed, stored, and reinstalled for the higher dam crest. The elevator tower would be out of service for about 4 months for construction of the dam crest raise and for replacement of the elevator car and hoist equipment.

Main Gravity Dam and Wing Dams Enlargement of Shasta Dam under all action alternatives would require raising Shasta Dam (the main gravity dam) and its left and right wing dams as indicated in Table 2-9. Construction activities to raise the main gravity dam and the left and right wing dams are summarized below.

Table 2-9. Physical Features for Proposed Modifications of Shasta Dam and Appurtenances for Action Alternatives

Feature	Existing	CP1	CP2	CP3, CP4, CP4A, CP5
Main Gravity Dam				
Crest Raise (feet)	0	6.5	12.5	18.5
Crest Elevation[1]	1077.5	1,084.0	1,090.0	1,096.0
Upstream Parapet Wall Elevation[1]	1079.1	1,087.5	1,093.5	1,099.5
Full Pool Elevation[2]	1069.7	1,078.2	1,084.2	1,090.2
Left Wing Dam				
Crest Raise (feet)	0	8.5	14.5	20.5
Crest Elevation[1]	1077.5	1,086.0	1,092.0	1,098.0
Upstream Parapet Wall Elevation[1]	1079.1	1,089.5	1,095.5	1,101.5
Right Wing Dam				
Crest Raise (feet)	0	6.5	12.5	18.5
Crest Elevation[1]	1077.5	1,084.0	1,090.0	1,096.0
Upstream Parapet Wall Elevation[1]	1079.1	1,087.5	1,093.5	1,099.5
Spillway				
Crest Raise (feet)	0	0.5	6.5	12.5
Crest Elevation[1]	1037.0	1,037.5	1,043.5	1,049.5

Notes:
[1] Main dam and wing dam crest elevations are based on the National Geodetic Vertical Datum of 1929 (NGVD29). All current feasibility-level designs and figures for Shasta Dam and appurtenant structures are based on NGVD29.
[2] Full pool elevations are based on the North American Vertical Datum of 1988 (NAVD88), which is 2.66 feet higher than NGVD29. All current feasibility-level designs and figures for reservoir area infrastructure modifications and relocations to accommodate increased water levels are based on a 2001 aerial survey of the reservoir using NAVD88.
Key:
CP = comprehensive plan

Shasta Dam would be raised by placing mass concrete corresponding in width to the existing dam monolith blocks on the existing dam crest (concrete gravity section and spillway crest section). Structural concrete would be placed for the top of the dam, including for the roadway, the upstream and downstream parapets, and the walkway. Reinforcing steel would be used around the utility gallery, and nominal temperature steel would be used for the exposed structural concrete surfaces. Steel top-of-dam drains would be furnished and installed in each block to drain to the upstream face. Surface area and features of the new dam crest would be similar to the existing dam crest, including gantry crane rails and surface drains. A new upstream parapet wall would provide additional flood protection. The dam raise would include a new utility gallery.

Zoned embankment wing dams were originally constructed on both abutments of the main dam to protect the contact between the concrete and the excavated foundation surface. The left wing dam would be raised to maintain the same height above the top of joint-use storage, as for existing conditions. This would involve extending the existing reinforced-concrete core wall to the raised dam crest, and placing a thick layer of large rockfill downstream from the core wall. The upstream face would consist of a reinforced concrete or mechanically stabilized earth wall, and a concrete parapet wall. The road from the concrete dam crest would be ramped up through the left wing dam to the new embankment crest. Roadways and security features on the existing dam crest would be relocated to the new dam crest. The existing rotunda on the left abutment of the dam would be removed and reconstructed.

A building housing a visitor center and Reclamation offices, a parking lot, picnic areas, and vista points have been incorporated into the left abutment design. The visitor center building would provide adequate space for visitors, storage, staff, and security functions, and feature a panoramic view of all facilities. The existing roadways, lawns, sidewalks, trees, and other features on the left wing dam crest would be restored to a configuration similar to existing conditions. Existing facilities would be removed from the site before construction, and replaced after the raise is completed.

The right wing dam would be raised to match the main gravity dam crest. Concrete was selected for the right wing dam in lieu of embankment to facilitate construction. The new right wing dam crest would provide surface area and features similar to the existing dam crest, including gantry crane rails and surface drains. A new upstream parapet wall would provide additional flood protection. The right wing dam would include a new utility gallery and a foundation drainage curtain. Right abutment access roads would be modified to match the new dam crest.

Spillway Structural concrete would be used to raise the existing spillway crest and to shape the raised spillway crest as indicated in Table 2-9. The existing spillway bridge, two existing spillway piers, cantilever wall sections, and three existing drum gates and operating equipment would be removed. Five new spillway piers would be constructed at locations within the spillway, designed to avoid existing overflow block contraction joints, and a new concrete spillway crest would be constructed between them. The locations of the new piers would result in different widths of spillway gates. The three existing 110-foot by 28-foot drum gates would be replaced with six sloping, fixed-wheel gates. The total spillway crest length would be reduced from 330 feet to 300 feet as a result. A new bridge would be required over the spillway to allow for vehicular traffic and for a gantry crane to travel from one end of the dam to the other.

Temperature Control Device Modifications to the TCD would be needed for all action alternatives. Modifications would primarily involve extending the main steel structure to the new full pool elevation; raising the TCD operating equipment, including gate hoists, electrical equipment, miscellaneous metalwork, and hoist platform above the new top of joint-use elevation; installation of additional cladding on the existing and raised sections of the TCD; and lengthening/replacing shutter operating cables.

Shasta Powerplant Penstock Intake and Penstock Modifications The centerline of the existing penstock intakes would remain at the current level, but the gate hoists would require relocation with a higher dam crest. The existing steel penstock pipes have been determined to be adequate for the higher reservoir loads and no penstock modifications are anticipated.

Pit 7 Facilities The Pit 7 Dam and Powerhouse, which is owned and operated by Pacific Gas and Electric Company (PG&E), is located on the upper Pit River at the northeast end of Shasta Lake. The complex consists of three main features: a main dam with integral spillway, a two-unit hydroelectric powerhouse immediately downstream from the main dam, and an afterbay dam. The expected modifications to the Pit 7 facilities associated with any action alternative include main dam spillway, powerhouse, and afterbay dam modifications.

Pit 7 Dam spillway backwater conditions have the possibility of creating wave action that could undermine the powerhouse and dam when flows are released over the spillway. It is recommended that both the left and right concrete training walls be increased in height to prevent this from occurring.

For Pit 7 Powerhouse, new sump pumps and a tailwater depression system are recommended. To ensure that proper operation of equipment in the powerhouse, the dewatering capacity of the existing sump pumps will need to be increased to address any additional seepage. This can be achieved with the installation of a new submersible pump. A tailwater depression system will need to be installed. During high flows, a tailwater depression system would introduce compressed air into the turbine runner pit to depress the tailwater to a level that does not interfere with turbine operation, thereby allowing continued turbine operation. The tailwater depression system would include air compressors, air discharge piping with control valves, water-level sensors, power supply, and electrical controls. Air compressors would be of the high-volume, low-pressure type, referred to as "blowers." Blowers would be driven by electric motors supplied with available power from the Pit 7 Powerhouse.

The Pit 7 Afterbay Dam may require the placement of rock dowels and rip rap for slope stability to meet the necessary safety standards. Ancillary facilities will need to be addressed near the Pit 7 Afterbay Dam including relocating the gaging station and cableway that would be inundated by the new high water line, extending the boat barriers, relocating security fences and signs, rehabbing the existing boat ramp, and relocating the warning siren.

Reservoir Area Dikes and Railroad Embankments

The physical features for the proposed dikes and railroad embankments under each comprehensive plan are shown in Table 2-10. The proposed dikes would be constructed using common earthmoving equipment and methods. Additional excavation to provide working surfaces and keys for the embankment fill would be required along the slope of the upstream foundation for some of the proposed dikes. Ground treatment and/or over-excavation may be necessary in some areas to remove and/or treat pervious material. Riprap would be placed on the upstream face of each dike to the crest of the dike to protect against wave run-up and erosion. Reservoir area dikes and railroad embankments are further described in the Engineering Summary Appendix.

Table 2-10. Physical Features for Proposed Dikes and Railroad Embankments by Action Alternative

Dike Features	CP1	CP2	CP3, CP4, CP4A, and CP5
Lakeshore Dikes/Railroad Embankments			
Doney Creek Dike			
Volume of Fill Material (core, drain, filter) (cubic yards)	-	12,200	75,000
Volume of Riprap (cubic yards)	-	1,000	5,900
Volume of Excavated Material (cubic yards)	-	3,100	10,200
Site Clearing and Grubbing Below Dike (acres)	-	1.5	7.2
Antlers Dike			
Volume of Fill Material (core, drain, filter) (cubic yards)	-	-	4,900
Volume of Riprap (cubic yards)	-	-	400
Volume of Excavated Material (cubic yards)	-	-	300
Site Clearing and Grubbing Below Dike (acres)	-	-	0.9
North Railroad Embankment			
Volume of Fill Material (core, filter) (cubic yards)	17,100	17,100	17,100
Volume of Riprap (cubic yards)	400	400	400
Volume of Excavated Material (cubic yards)	1,500	1,500	1,500
Site Clearing and Grubbing Below Dike (acres)	1.2	1.2	1.2
Middle Railroad Embankment			
Volume of Fill Material (core, filter) (cubic yards)	13,400	13,400	13,400
Volume of Riprap (cubic yards)	300	300	300
Volume of Excavated Material (cubic yards)	4,000	4,000	4,000
Site Clearing and Grubbing Below Dike (acres)	2.9	2.9	2.9
South Railroad Embankment			
Volume of Fill Material (core, filter) (cubic yards)	101,900	101,900	101,900
Volume of Riprap (cubic yards)	2,500	2,500	2,500
Volume of Excavated Material (cubic yards)	8,500	8,500	8,500
Site Clearing and Grubbing Below Dike (acres)	6.2	6.2	6.2
Bridge Bay Dikes			
West Dike			
Volume of Fill Material (core, drain, filter) (cubic yards)	3,000	7,700	69,000
Volume of Riprap (cubic yards)	200	800	23,600
Volume of Excavated Material (cubic yards)	2,100	5,000	15,300
Site Clearing and Grubbing Below Dike (acres)	0.8	1.4	2.2
East Dike			
Volume of Fill Material (core, drain, filter) (cubic yards)	1,000	3,000	40,100
Volume of Riprap (cubic yards)	40	160	7,400
Volume of Excavated Material (cubic yards)	900	2,000	16,900
Site Clearing and Grubbing Below Dike (acres)	0.4	0.6	1.1

CP = comprehensive plan

Relocations

As a result of the proposed Shasta Dam raise under the comprehensive plans, the following major features would be inundated by the increase in full pool elevation:

- Roadways
- Vehicle bridges
- Railroad bridges
- Recreation facilities
- Utilities and miscellaneous minor infrastructure

Existing infrastructure affected by enlarging Shasta Dam and Reservoir under any of the comprehensive plans would need to be removed and/or relocated.

Roadways Physical features associated with proposed road relocations under each comprehensive plan are shown by major focus area in Table 2-11. Road design criteria and construction characteristics are discussed in detail in the Engineering Summary Appendix.

Table 2-11. Physical Features for Proposed Road Relocations by Major Road Focus Area for Action Alternatives

Road Relocation Features	CP1	CP2	CP3, CP4, CP4A, and CP5
Lakeshore Drive			
Number of Road Segments Affected	4	6	8
Length (linear feet)	8,100	13,100	13,700
Clearing and Grubbing (acres)	4	7	7
Excavation to Embankment (cubic yards)	46,100	55,100	55,500
Embankment Fill (cubic yards)	122,800	171,800	174,900
Closure Expected	No	No	No
Turntable Bay Area			
Number of Road Segments Affected	3	3	3
Length (linear feet)	6,200	6,200	6,200
Clearing and Grubbing (acres)	2	2	2
Excavation to Embankment (cubic yards)	19,000	19,000	19,000
Embankment Fill (cubic yards)	76,200	76,200	76,200
Closure Expected	Yes	Yes	Yes

Table 2-11. Physical Features for Proposed Road Relocations by Major Road Focus Area for Action Alternatives (contd.)

Road Relocation Features	CP1	CP2	CP3, CP4, CP4A, and CP5
Gillman Road			
Number of Road Segments Affected	-	3	3
Length (linear feet)	-	1,200	1,200
Clearing and Grubbing (acres)	-	1	1
Excavation to Embankment (cubic yards)	-	0	0
Embankment Fill (cubic yards)	-	22,800	22,800
Closure Expected	-	Yes	Yes
Jones Valley and Silverthorn Area			
Number of Road Segments Affected	-	-	3
Length (linear feet)	-	-	1,600
Clearing and Grubbing (acres)	-	-	1
Excavation to Embankment (cubic yards)	-	-	1,500
Embankment Fill (cubic yards)	-	-	13,200
Closure Expected	-	-	Yes
Salt Creek Road			
Number of Road Segments Affected	-	4	5
Length (linear feet)	-	4,300	5,100
Clearing and Grubbing (acres)	-	1	1
Excavation to Embankment (cubic yards)	-	4,100	5,500
Embankment Fill (cubic yards)	-	31,700	33,100
Closure Expected	-	Yes	Yes
Remaining Road Relocations			
Number of Road Segments Affected	3	5	8
Length (linear feet)	2,500	3,500	5,200
Clearing and Grubbing (acres)	0.4	1	2
Excavation to Embankment (cubic yards)	15	120	600
Embankment Fill (cubic yards)	36,400	70,000	81,000
Closure Expected	Yes	Yes	Yes

Key:
- = not applicable
CP = comprehensive plan

Roadway construction activities would involve, but not be limited to, demolition of existing roadways as required; clearing, grubbing, and site preparation of work areas, as required; grading road alignments to meet finished grades; placing road subgrade; paving operations; installing storm drain culverts; constructing retaining wall systems; installing road appurtenances such as guardrails; performing construction-related traffic control; and establishing and maintaining a SWPPP. Noisy equipment, such as pile drivers, is anticipated for road construction work. Typical noise would result from trucks and diesel-powered equipment.

Replacement roadways would be constructed by excavating the existing up-grade slope to provide fill material for the embankment fill portion of road construction; bench-excavating into the up-grade slope above the existing roadway to establish the new road finished grade; building the new road on an engineered fill embankment from imported borrow material; or building the new road directly above the existing road on an engineered fill embankment from imported borrow material. A road alignment may either use a single method of construction for the entire alignment, or use all four methods at different locations along an alignment. To limit impacts on existing roadways, road closures would be avoided whenever possible.

Estimated work limits for road segment relocation are described in the Engineering Summary Appendix. Estimated work limits depend on the surrounding terrain, and vary from a minimum of 5 feet to 30 feet wide, measured from the extent of earthwork. Where the road would be constructed as an embankment fill against an existing steep hillside, a 5-foot-wide minimum work area would be used. Where the terrain beyond the limit of earthwork was flat enough to be used as work areas for construction equipment, the work limits would range from 15 feet to 30 feet wide.

Vehicle Bridges As a result of raising Shasta Dam for any of the action alternatives, the following local road vehicle bridges would be replaced:

- Charlie Creek Bridge
- Doney Creek Bridge
- McCloud River Bridge
- Didallas Creek Bridge

Criteria and assumptions considered in determining structure type and length for the replacement structures are included in the Engineering Summary Appendix. Based on the design criteria and assumptions, and considering preliminary horizontal alignments and profile grades developed for the relocated roadways, Table 2-12 summarizes proposed bridge characteristics for the four road bridges requiring replacement under all comprehensive plans.

Table 2-12. Physical Features of Proposed Vehicular Bridge Relocations Common to All Action Alternatives

Bridge Feature	Charlie Creek Bridge	Doney Creek Bridge	McCloud River Bridge	Didallas Creek Bridge
Bridge Length (linear feet)	782	760	490	115
Number of Abutments	2	2	2	2
Number of Piers	4	4	4	0
Pier Diameter (linear feet)	14	14	6	N/A
Volume of Backfill (cubic yards)	480	400	530	180
Volume of Concrete (cubic yards)	3,530	3,320	2,320	760
Quantity of Steel (tons)	575	516	380	104
Number of Class 140 Piles	24	24	24	24
Number of 24-inch Cast-In-Steel-Shell Piles	72	72	32	N/A
Volume of Excavated Material (cubic yards)	1,200	550	820	440
Quantity of Demolished Material (cubic yards)	3,500	3,300	2,300	800

Key:
N/A = not applicable
SLWRI = Shasta Lake Water Resources Investigation

Construction would take place during the low-water season, and is expected to last between 6 and 8 months. The waterway would remain clear for navigation during construction. Bridge construction would begin with piers and abutments. To allow underwater construction of pier foundations, steel pile shells would be driven into the lake bed to create a temporary cofferdam. It may be necessary to dewater the shells during drilling if water seeps in. A hole would then be drilled to the specified foundation depth. Reinforcing steel would be installed within the shells before concrete was poured. After completion of the piers and abutments, construction of the superstructure and bridge deck would begin via the balanced cantilever method. This process entails forming and constructing the horizontal structure outward from the piers in each direction, in equal (balanced) proportions, until the superstructure/deck segments meet at midspan.

Traffic would continue on the existing bridges during construction. It is likely that barges would be used extensively for vehicular bridge foundation construction, bridge assembly, transport of materials, workers, and equipment, and demolition of the existing bridges. Concrete would be poured from barges. A staging area would be required on the lakeshore, from which barges could be loaded and unloaded.

Although Fender's Ferry Bridge would not need to be replaced as a result of the Shasta Dam raises, modifications to the bridge would be necessary. The Fender's Ferry Bridge is a three-span structure with a steel plate girder superstructure supported on riveted steel tower bents and reinforced concrete piers with spread footings. As a result of differences in east and west riverbank topography, the western pier steel tower is supported at a much lower elevation than the eastern pier tower. Thus, at the proposed full pool elevations, the eastern pier steel tower would be inundated.

The existing reinforced concrete pier and footing would be enlarged and extended, and the existing steel tower modified to prevent inundation as a result of the higher full pool levels associated with the dam raise alternatives under consideration. Proposed modifications include the following:

- Enlarging the existing reinforced concrete footing
- Enlarging and extending the existing reinforced concrete columns and pier wall
- Removing some of the lower portion of the eastern pier steel tower (based on location of existing cross bracing)
- Reusing the existing steel bearing assemblies

Quantities for the major items of work are estimated in the Engineering Summary Appendix.

Construction activities would likely be completed from the existing embankment without constructing cofferdams around the pier because average water surface elevations are below the existing eastern pier bottom-of-footing elevation for all months, with the exception of April and May. Construction of temporary bents to support the superstructure would be necessary to facilitate construction of the pier modifications. During construction activities, temporary traffic controls may be needed to facilitate delivery of materials and construction of temporary support bents.

Railroad Bridges

Pit River Bridge Pier Modification The Pit River Bridge is a multipurpose structure, carrying both UPRR and I-5 traffic. The bridge is both a steel-through truss and a deck truss. UPRR and Caltrans have joint operation and maintenance responsibility. The new full pool elevations would inundate the existing bridge bearings and low-chord steel truss members. To prevent the existing steel bearings and lower portions of the steel truss members from being submerged, a watertight concrete tub structure (bearing protection structure) would be required. The reinforced concrete structure would be attached to the top of two existing concrete piers. The structure footprint would be rectangular, with the top of the structure above the full pool elevation. Elevations for the top of the bearing protection structure and material quantities for Pit River Bridge modifications under each comprehensive plan are shown in Table 2-13.

Table 2-13. Physical Features for Proposed Bearing Protection Structure for Action Alternatives

Item	CP1	CP2	CP3, CP4, CP4A, and CP5
Top of Bearing Protection Structure Elevation (feet)[1]	1082.2	1088.2	1094.2
Concrete (cubic yards)	2,100	2,900	4,000
Reinforcing Steel (pounds)	618,000	876,000	1,200,000

Notes:
[1] Bearing protection structure elevations are based on the North American Vertical Datum of 1988 (NAVD88), which is 2.66 feet higher than the National Geodetic Vertical Datum of 1929. All current feasibility-level designs and figures for reservoir area infrastructure modifications and relocations to accommodate increased water levels are based on a 2001 aerial survey of the reservoir using NAVD88.

Key:
CP = comprehensive plan

Because the existing bridge superstructure and top-of-pier are exposed to the elements, a structure cover would not be required; however, two submersible sump pumps would be installed to keep the water level in the new concrete protective structure from rising near the bearings. Check valves and ball valves would prevent pumped water from draining out of the line back into the sump. Protective grates would prevent large objects from entering the sump area.

Union Pacific Railroad Sacramento 2nd Crossing and Doney Creek Bridge Replacement The superstructures for the existing Sacramento River Second Crossing and Doney Creek railroad bridges consist of deck truss bridges with a single track. The piers and abutments were designed to accommodate a future parallel single-track superstructure. Portions of both bridges would be submerged for any reservoir raise and would need to be replaced with new, higher superstructures. Structural analyses of the existing bridge piers under design earthquake loads indicated that new bridge piers would be required. Therefore, the existing bridges will be removed and replaced with new bridges. The feasibility designs would permit uninterrupted rail service during construction.

The proposed new bridge superstructures would be composite superstructures consisting of steel plate girders and a reinforced concrete deck. In general, the bridge superstructures would be designed to be continuous over the piers. However, with a requirement for 16 feet of vertical clearance between the two westernmost piers for the Sacramento River 2nd Crossing railroad bridge (with a minimum width of 30 feet), to allow for the passage of houseboats, this span is a simply supported span. No minimum clearance for houseboat traffic would be required for the Doney Creek railroad bridge; large-diameter concrete columns with drilled shafts would support the superstructure and be founded on bedrock. The Sacramento River Second Crossing railroad bridge would require nine spans, with a total length of 982 feet between concrete abutments. The Doney Creek railroad bridge would require five spans, with a total length of 537.5 feet between concrete abutments. Construction quantities for major items of work for these features under comprehensive plans are summarized in Table 2-14.

Table 2-14. Physical Features of Proposed Railroad Bridges Common to All Action Alternatives

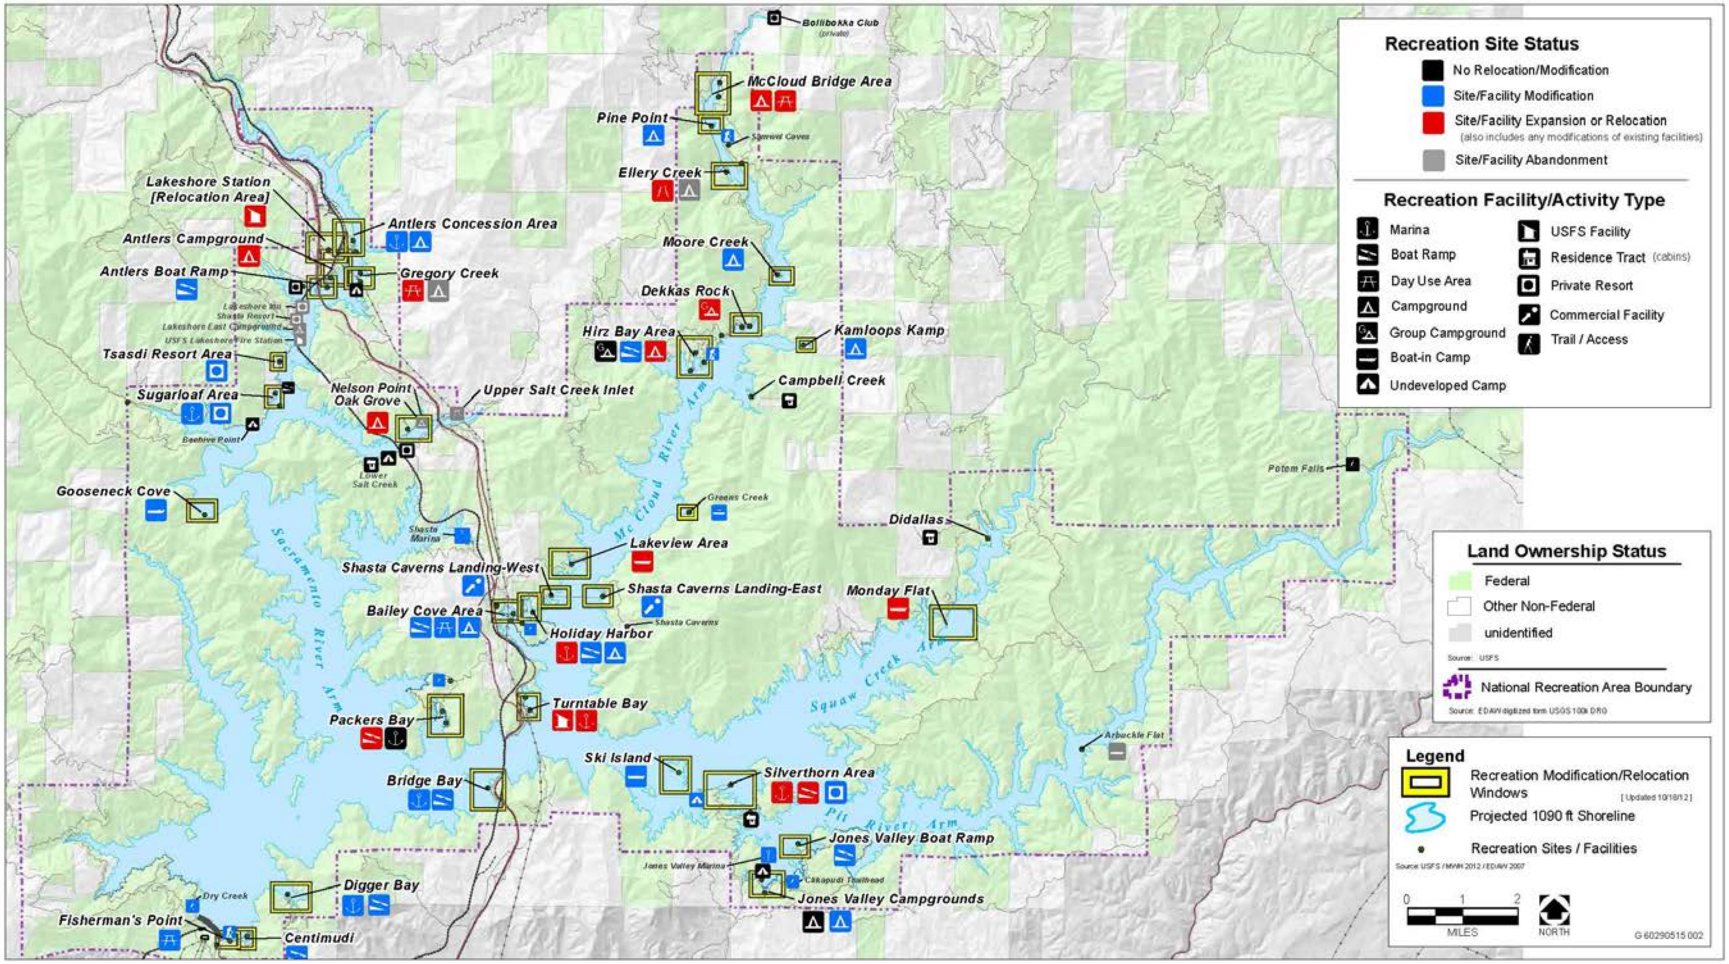
Item	Sacramento River Second Crossing Bridge Quantities	Doney Creek Bridge Quantities
Steel Truss Bridge Removal (pounds)	3,300,000	2,000,000
Concrete Removal (cubic yards)	15,310	4,570
Excavation (cubic yards)	2,100	630
Backfill (cubic yards)	1,900	2,200
Concrete, including Shafts (cubic yards)	11,700	7,080
Reinforcing Steel (pounds)	3,420,000	1,760,000
Structural Steel in Girders (pounds)	4,750,000	2,250,000

The proposed relocation of the UPRR bridges would require that the railroad tracks be realigned between the two bridges. This realignment would parallel the existing tracks with a 25-foot offset to the east. Construction quantities for major items of work for the railroad realignment between the UPRR bridges are summarized in Table 2-15. Any required embankments for this realignment are described under the “Reservoir Area Dikes and Railroad Embankments” section above.

Table 2-15. Physical Features of Proposed Railroad Realignment Common to All Action Alternatives

Item	Railroad Realignment Between Bridges
Length of Track Realignment (linear feet)	8,400
Railroad Track Removal (tons)	370
Ballast Removal (tons)	6,400
Excavation (cubic yards)	35,000
Compacted Backfill (cubic yards)	7,500
Railroad Track (tons)	390
Ballast (tons)	26,500

Recreation Facilities Any raise of Shasta Dam would have some effect on the many recreation features found along the reservoir shoreline. These features include marinas/boat ramps, resorts, campgrounds/day use areas, cabins, trails, and USFS facilities. Areas for potential recreation relocations (referred to as windows) and corresponding relocation plans for each window have been developed. Figure 2-6 details the location of these windows and existing recreation sites with proposed modification, expansion, or relocation activities.



Source: AECOM 2012

Exhibit: Recreation Mitigation Sudy – Summary

Figure 2-6. Recreation Study Windows

The primary goal of the relocation plans is to verify that with any dam raise, the existing recreation capacity could be maintained. Reclamation and USFS will continue to work together to refine recreation relocations and develop a recreation plan that is suitable for the NRA. For recreation facilities on Federal lands, the USFS will consider relevant laws, regulations, policy, special use permits and master development plans to develop and/or provide final approval for any proposed recreation facility relocations. Action alternatives would, at minimum, maintain the existing recreation capacity at Shasta Lake. Inundated recreation facilities and associated utilities would be relocated before demolition to the extent practicable. Scheduling and sequencing of recreation facility relocation construction activities will strive to minimize or avoid interruption to public recreation activities and access to recreation sites. Recreation facilities proposed for relocation are included below in the detailed description of each action alternative. Table 2-16 presents a summary of the recreation facilities to be modified or relocated under each comprehensive plan. Quantities of demolition and construction materials associated with modification and relocation of recreation facilities are listed in Table 2-17.

Table 2-16. Recreation Facilities to be Modified or Relocated Under Action Alternatives

Recreation Facilities	CP1	CP2	CP3, CP4, and CP4A	CP5
Marinas/Public Boat Ramps				
Number of Affected Facilities (marinas/boat ramps)	9/6	9/6	9/6	9/6
Relocation Needed[1] (acres)	8.5	8.5	8.5	8.5
Replacement Structures (square feet)	49,900	49,900	49,900	49,900
Campsites and Day-Use Sites				
Number of Affected Facilities (resorts/campsites and day-use sites)	202	261	328	328
Relocation Needed[1] (acres)	32	34	39	39
Replacement Structures (square feet)	6,200	6,200	6,200	6,200
Resorts/USFS Facilities				
Number of Affected Facilities (resorts/USFS facilities)	6/2	6/2	6/2	6/2
Relocation Needed[1] (acres)	19	19	19	19
Replacement Structures (square feet)	41,000	52,800	68,900	68,900

Table 2-16. Recreation Facilities to be Modified or Relocated Under Action Alternatives (contd.)

Recreation Facilities	CP1	CP2	CP3 and CP4	CP5
Trailheads/Trails				
Number of Affected Facilities (trailheads/trails)	2/9	2/9	2/9	2/9
Relocation Needed[1] (miles)	8.1	9.9	11.6	11.6
Recreation Enhancement[3] (trailheads/trails[miles])	-	-	-	6/18

Note:
[1] Does not include on-site modification of facilities.
[2] For some trails, trailheads are integrated into other recreation facilities. Estimates for standalone trailheads only.
[3] Additional recreation facilities for CP5 only.

Table 2-17. Recreation Demolition and Construction Material Quantities for Action Alternatives

Material	CP1	CP2	CP3, CP4, CP4A, and CP5
Imported Fill (cubic yards)	236,200	384,200	552,800
Excavation to Waste (cubic yards)	592,300	430,600	315,400
Structure Demolition (square feet)	130,700	146,700	164,200
Demolition Waste (cubic yards)	99,200	102,100	105,200

Key:
CP = comprehensive plan

Marina Modifications Several marinas around Shasta Lake would be affected by raising Shasta Dam. Typically, marinas consist of a parking area, a boat ramp, various structures (e.g., retail, restrooms, maintenance facilities, storage, administration), and utilities (power, water, and septic). Most of the effects of the dam raise would result from the inundation of boat ramps, parking lots, structures, and utilities. Boat ramps would be modified in place, on fill, where possible. Parking areas would be replaced on fill, or relocated above the new reservoir elevation. Existing structures that would be inundated would be demolished, and either replaced above the reservoir elevation (upslope or on placed fill), or moved to a floating structure on the water to provide better access for recreational users. Any access roads would be relocated above the new full pool for continued access around the marinas. Existing septic systems that would be inundated would be demolished and removed from the area or relocated. New facilities could also be connected to new localized wastewater treatment facilities. Power lines would be installed to accommodate new structures.

To maintain shoreline accessibility and facility distribution around the lake, each affected marina would be relocated in the immediate vicinity of its existing location. Relocation of marinas in their existing location is the most cost effective approach to maintaining marina-related recreation capacity at Shasta Lake. If unforeseen circumstances prevent affected marinas from being maintained in their current location, relocating or consolidating with other marinas would be reconsidered. Although not anticipated, potential new or expanded areas that could be used include:

- Silverthorn Marina Area
- Turntable Bay Area
- Holiday Harbor Marina Area

Public Boat Ramp Modifications Six public boat ramps that could be inundated would be modified or relocated in the immediate vicinity. Public boat ramps that could not be modified in place would be relocated to adjacent areas that can provide the necessary grade and access for ramps. To maintain current recreation capacity of public boat ramps the following potential new or expanded areas could be used:

- Antlers Public Boat Ramp Area
- Packers Bay Public Boat Ramp Area

Resort Modifications Raising Shasta Dam would affect approximately six resorts around the reservoir to some degree. Inundated structures and structures within 3 vertical feet of the new full pool would be demolished. Septic systems would also be demolished, and remaining structures would either be connected to new localized wastewater treatment facilities or be relocated to other septic systems. To maintain the current recreation capacity of the resorts, the Antlers Concession Area could be used.

Campground/Day Use Area Modifications Many undeveloped areas have been identified as potential campgrounds to replace capacity lost because of inundation. While some inundated campgrounds would be relocated on fill at their existing location, others would be moved around the reservoir to new locations identified as potential campground sites. To maintain the current recreation capacity of campgrounds, the following potential new or expanded areas could be used:

- Antlers Campground
- Oak Grove Campground

- Hirz Bay Campground
- McCloud Bridge Area

The following potential new or expanded areas could be used to meet the need for boat-in campgrounds:

- Former Lakeview Marina Area
- Monday Flat Boat-In Camp

The following potential new or expanded areas could be used to meet the need for day-use areas:

- Ellery Creek Campground
- Gregory Creek Campground
- McCloud Bridge Area

USFS Facilities Modifications Recreation within the NRA is managed by USFS, which has several facilities located throughout the reservoir area. USFS facilities consist of various storage and maintenance buildings and equipment, fire protection equipment, customer service facilities, office space, and employee living facilities. Two USFS facilities would be inundated and would require relocation or replacement. The station located in the Lakeshore area would be inundated by a Shasta Dam raise, and would be relocated to an area above the new full pool. The new facility would contain all of the features that exist at the current facility. The inundated facility would be demolished, and hauled to waste. Turntable Bay, another USFS facility, would be inundated by a Shasta Dam raise. Additional space at Turntable Bay would allow the facility to be relocated on fill in its current location.

Nonrecreation Structures Under all comprehensive plans, nonrecreational residential and commercial structures affected by inundation would require demolition. These structures would be demolished by appropriately licensed contractors. All utilities would be disconnected, capped, and/or removed per permit requirements and governing utility standards. The structure and foundation would then be demolished. Asbestos material, if discovered, would be removed and taken to an approved landfill for disposal per permit requirements. General demolition waste would also be removed and trucked to an approved landfill. Table 2-18 shows the total volume of demolished material for nonrecreational structures by comprehensive plan.

Table 2-18. Nonrecreation Structures Demolition Quantities for Action Alternatives

Demolition	CP1	CP2	CP3, CP4, CP4A, and CP5
Structure Demolition (square feet)	8,700	21,500	27,000
Total Volume of Material (cubic yards)	1,300	3,200	4,000

Key:
CP = comprehensive plan

Utilities and Miscellaneous Minor Infrastructure Gas/petroleum facilities, potable water facilities, power and telecommunications infrastructure, and wastewater facilities would be relocated if affected physically by inundation or if the facilities (such as septic systems) would no longer meet Shasta County Development Standards. The relocation numbers or lengths of facility features to be relocated during proposed utility relocations are shown for each comprehensive plan in Table 2-19. New facilities would be designed and constructed in accordance with applicable Federal, State, and local codes and requirements. Relocated facilities would be of the same types, sizes, and materials as existing facilities where feasible. For relocation of wastewater treatment facilities, new septic systems may be constructed on the property if they meet Shasta County requirements for separating septic systems from the lake. Otherwise, the comprehensive plans include facilities for pressurized sewer collection systems to transport wastewater flows to centralized package wastewater treatment plants.

Demolished facilities would not be reused to construct relocated facilities. Demolished and relocated utilities are summarized as part of the detailed description of each action alternative. The approach and methodology for demolition, design, and relocation criteria for each category of utilities are discussed in greater detail in the Engineering Summary Appendix.

Table 2-19. Physical Features for Proposed Utilities Relocations for Action Alternatives

Utility Type	CP1	CP2	CP3, CP4, CP4A, and CP5
Potable Water Facilities			
Length of Waterlines Relocated (linear feet)	7,200	8,500	11,000
Wells/Tanks Relocated (number)	12	13	10
Pump Stations Relocated (number)	2	2	3
Length of Waterline Demolished (linear feet)	8,900	11,200	14,800
Wells/Tanks Demolished (number)	16	28	25
Pump Stations Demolished (number)	2	2	3

Table 2-19. Physical Features for Proposed Utilities Relocations for Action Alternatives (contd.)

Utility Type	CP1	CP2	CP3, CP4, CP4A, and CP5
Gas/Petroleum Facilities			
Tanks Relocated (number)	7	10	10
Tanks Demolished (number)	7	10	10
Wastewater Facilities			
Septic Systems Relocated[1] (number)	14	19	19
Vault/Pit Toilets Relocated (number)	2	2	2
Pump Stations Relocated (number)	1	1	1
Length of Wastewater Pipe Relocated (linear feet)	400	400	430
Septic Systems Demolished[2] (number)	211	239	266
Vault/Pit Toilets Demolished (number)	2	2	2
Pump Stations Demolished (number)	2	2	2
Length of Wastewater Pipe Demolished (linear feet)	2,300	2,300	2,400
Package Wastewater Treatment Plants[3] (number)	Up to 6	Up to 6	Up to 6
Power Distribution Facilities			
Power Lines Relocated (linear feet)	34,520	40,565	42,050
Power Towers Relocated (number)	11	11	11
Power Lines Demolished (linear feet)	33,227	44,565	43,045
Power Towers Demolished (number)	26	26	26
Telecommunications			
Copper Wire Relocated (linear feet)	27,900	30,200	33,400
Fiber-Optic Cable Relocated (linear feet)	4,300	5,800	5,800
Copper Wire Demolished (linear feet)	23,600	27,800	31,200
Fiber-Optic Cable Demolished (linear feet)	3,600	5,200	5,200

Note:
[1] Does not include septic systems replaced with new sewer connections.
[2] Includes demolition of septic systems to be relocated, replaced with new sewer connections, and removed without relocation or replacement.
[3] Includes additional lift stations, force main, laterals, and holding tank pumps/valves not shown.

CP = comprehensive plan

Spawning Gravel Augmentation Under CP4, CP4A, and CP5

Under CP4, CP4A, and CP5, gravel augmentation would occur at one to three locations between Keswick Dam and the RBPP every year for a period of 10 years, unless unusual conditions or agency requests precluded placement during a single year. Construction activities would vary significantly by location, but generally would include clearing, grubbing, and some grading of new access routes to allow construction vehicles to access the river. At several locations, clearing and grubbing of the riverbank would be required to allow gravel to be placed on the bank for recruitment. Gravel would be delivered to the locations by dump trucks. In most cases, gravel would be stockpiled in a staging area and moved with bulldozers, loaders, and/or excavators. Dust control trucks would be present during all construction activities.

Several locations would require in-water construction work. Generally, this involves building gravel out into the river channel “step-wise,” meaning that gravel is dumped and leveled, and the leveled area serves as a working platform for the next step of construction. This practice is common for spawning gravel placement, and minimizes the extent to which construction vehicles drive directly through an active river channel. One or two locations, however, would require construction activity in the active river channel, where construction vehicles would deposit gravel and raise the grade of the river near existing riffles.

Riparian, Floodplain, and Side Channel Habitat Restoration Under CP4, CP4A, and CP5

Under CP4, CP4A, and CP5, riparian, floodplain, and side channel habitat restoration would be constructed at one or more suitable locations along the upper Sacramento River to benefit anadromous fish and other aquatic and riparian species. Several potential sites exist along the upper Sacramento River between Keswick Dam and RBPP that would be suitable for these restoration measures. Construction activities for riparian, floodplain, and side channel habitat restoration would vary depending on the location or locations selected and type of restoration measure to be implemented at the site. In general, construction activities would include earth moving activities with bulldozers, loaders, excavators, and/or compactors. Vegetation removal may also be necessary at some sites, either for channel deepening/widening, or where water with aquatic vegetation is present in a channel pending modification.

Special precautions for restoration at these sites will primarily involve:

- Maintaining the active spawning areas in proximity to the site
- Avoiding the creation of habitat for predacious fish
- Minimal disruptions to navigability of the river
- Preventing the spread of invasive, non-native plant species
- Ensuring the safety of homes located along the Sacramento River downstream from the sites

The following are examples of construction measures proposed for restoration of riparian, floodplain, and side channel habitat at each of the potential restoration sites.

Henderson Open Space An existing side channel to the main stem of the Sacramento River would be enhanced to activate the frequency and duration of flows for Chinook salmon spawning habitat throughout a portion of Henderson Open Space Park. The enhancement would involve modifying the northern opening to the existing side channel to restore connectivity with the river at flows greater than 8,000 cfs. Minor grading and channel slope modification would be necessary to rework the existing (sometimes inundated) channel to a point at which flows may be activated for spawning habitat.

The existing Henderson Open Space side channel is heavily vegetated. Floodplain terraces and adjacent riparian areas would be replanted with native vegetation after the completion of earth-moving activities. A more detailed site analysis would determine the mix, composition, and density of the riparian vegetation plantings. To varying degrees, temporary fencing and irrigation would be necessary to protect and sustain newly established riparian vegetation.

Tobiasson Island A regularly flowing side channel would be created to increase spawning habitat for all runs of Chinook salmon at Tobiasson Island. Creating this side channel would involve excavating a trapezoidal-shaped channel, the base of which would correspond to an elevation that would allow flows of 5,000 cfs or greater to enter the side channel, hence hydraulically connecting it to the Sacramento River. If created, this new side channel would add approximately 1,350 linear feet of salmonid spawning habitat to this section of the Sacramento River.

The potential site for the channel to be cut does not currently have flowing water or riparian vegetation: therefore, vegetation removal would not be necessary. However, upon completion of earth-moving activities, it would be necessary to establish native vegetation throughout the side channel on the newly created floodplain terraces. A more detailed site analysis would determine the mix, composition, and density of the riparian vegetation plantings. Temporary irrigation and fencing for vegetation planting at this site is not feasible because the site lacks water supply and electricity.

Shea Island Complex Restoration at the Shea Island Complex would involve lowering a section of the upstream end of the major side channel through the site. The objective would be to keep water moving through the channel when the Sacramento River reaches flows of 10,000 cfs or greater, thus enhancing salmonid spawning habitat.

Additionally, removal of vegetation and debris would be necessary in both the excavated portion of the channel and other portions of the channel to insure the connectivity of flows. Minor grading activity could increase channel complexity along the length of the corridor. Upon completion of earth-moving activities, it would be necessary to establish native vegetation throughout the side channel on the newly created floodplain terraces. A more detailed site analysis would determine the mix, composition, and density of the riparian vegetation plantings. Temporary irrigation and fencing for vegetation planting at this site is because the site lacks a water supply and electricity.

Kapusta Island An existing side channel on Kapusta Island would be enhanced to increase spawning habitat for winter-run and spring-run Chinook salmon in the Sacramento River. This enhancement would involve lowering the channel bed so that the channel may be hydraulically connected to the Sacramento River when the river is flowing in excess of 10,000 cfs.

A trapezoidal cut would need to occur along the course of the side channel, which is inundated only infrequently; in addition, vegetation and debris would need to be removed. Upon completion of earth-moving activities, establishing vegetation on new floodplain terraces and adjacent riparian areas with native plants would be necessary. A more detailed site analysis would determine the mix, composition, and density of the riparian vegetation plantings. Temporary fencing or irrigation at this site for newly established riparian vegetation is highly infeasible and a planting mix would need to be selected with this limitation in mind.

Anderson River Park Restoring floodplain, riparian and side channel habitat at Anderson River Park would involve altering a relic Sacramento River side channel located in the southeastern portion of the park at river flows of, or above 8,000 cfs or more. The side channel rearing habitat would be created by altering the upstream end of the side channel to capture flows. At present, the side channel is seasonally inundated, but likely by way of seepage from the river through alluvial material. Riparian vegetation and appurtenant biota are at this site; therefore, removal of vegetation to lower the channel bed would be necessary, followed by post excavation replanting of native riparian vegetation.

Reading Island Restoring floodplain, riparian, and side channel habitat at Reading Island would involve hydraulically reconnecting Anderson Creek with the Sacramento River at flows ranging between 4,000 cfs and 6,000 cfs. To restore Sacramento River flows through Anderson Creek, it would first be necessary to breach the levee that creates Anderson Slough. Additionally, clearing and excavation of the side channel would be necessary to ensure flows through the channel. This would involve removing vegetation and debris and deepening the existing channel.

After excavation, floodplain terraces and adjacent riparian areas would need to be vegetated with native plants. This would require temporary irrigation and fencing to sustain plantings and keep livestock off site. A more detailed site analysis would determine the mix, composition, and density of the riparian vegetation plantings.

Shasta Lake Tributary and Shoreline Enhancement Under CP5

Structural enhancements associated with CP5 include placing brush structures constructed from whiteleaf manzanita (*Arctostaphylos manzanita*) in the Shasta Lake littoral zone. Because of manzanita's density, installation would not require using anchor or cabling techniques that could result in ancillary negative impacts (e.g., maintenance, hazards to boaters). The brush structures would be assembled in the drawdown zone of the reservoir in an area that would be inundated as the reservoir surface elevation rises in fall. The brush structures are expected to be about 1,800 cubic feet in size. The establishment period would be the first year after construction; life span of the brush structures is projected to be 10 years.

Table 2-20 identifies the general area, number, and size of proposed structural enhancement locations for the main body of Shasta Lake, and the Pit, Sacramento, McCloud, Big Backbone, and Squaw arms. Selection of specific locations has been deferred so that enhancement locations are consistent with other project objectives. The level of proposed treatment is based on the proportion of available manzanita surrounding Shasta Lake. In general terms, these locations would incorporate available material at locations with preferred topographic features; preferred locations are coves that offer steep drawdown areas during the primary use period (spring, early summer).

Table 2-20. Proposed Structural Enhancement of Shasta Lake's Main Body and by Arms Under CP5

Area	Area Treated (acres)	Number of Locations
Main Body	17	595
Pit	12	420
Sacramento	43	1,505
McCloud	8	280
Big Backbone	3	105
Squaw	17	595
Total	**100**	**3,500**

Key:
CP = Comprehensive Plan

Vegetative enhancements associated with CP5 include planting willows to enhance nearshore fish habitat, and aerial and hand seeding of annual native grasses to treat shoreline areas at Shasta Lake.

More than 30 acres could be available to enhance the willow recruitment adjacent to Shasta Lake. Rooted willows would be planted in draws and other moist sites, such as springs, to provide long-term live cover. The establishment period for willows would be the first year after construction; life span is projected to be 5 to 50 years. The establishment period for native grasses would also be the first year of construction, with the life span projected to be 1 to 3 years. This approach would require native seed and nursery stock; several years of advanced preparation would be needed before planting could take place.

Table 2-21 summarizes proposed enhanced treatment with native willows and grasses for the main body of Shasta Lake and by the lake's arms.

Table 2-21. Proposed Vegetative Enhancement Treatment of Shasta Lake's Main Body and Arms under CP5

Area	Willow Planting (acres)	Native Grass Seeding (acres)
Main Body	1	2
Pit	1	4
Sacramento	7	4
McCloud	1	2
Big Backbone	3	2
Squaw	1	2
Total	**14**	**16**

Key:
CP = Comprehensive Plan

Construction Staging

Reclamation would establish staging areas for equipment storage and maintenance, construction materials, fuels, lubricants, solvents, and other possible contaminants in coordination with the resource agencies. Staging areas would likely be located within disturbed areas or at existing facilities that are expected to be inundated, such as campgrounds, recreation parking facilities, the top of Shasta Dam, and the parking area along the left wing dam, where feasible.

Staging areas would have a stabilized entrance and exit and would be located at least 100 feet from bodies of water, if possible. Should an off-road site be chosen, qualified biological and cultural resources personnel would survey the selected site to verify that no sensitive resources would be disturbed by staging activities. Should sensitive resources be found, an appropriate spatial and temporal buffer zone would be staked and flagged to avoid impacts. Where possible, no equipment refueling or fuel storage would take place within 100 feet of a body of water.

Construction Schedule, Equipment, and Workforce

The total duration of construction for major facilities is estimated to range from 4.5 to 5 years for all comprehensive plans. An overlap is expected in the timing of a majority of the construction components. Construction would be phased, when feasible, to avoid environmental impacts. Depending on the amount of concurrent work allowed, the critical work elements that would allow for additional storage of water in the reservoir could be completed in 3.5 years.

Construction would typically occur during daylight hours, Monday through Friday. However, construction contractors may extend these hours and schedule construction work on weekends, if necessary, to complete aspects of the work within a given time frame. Construction would require typical heavy construction equipment including excavators, backhoes, bulldozers, scrapers, graders, water trucks, front-end loaders, dump trucks, drill rigs, pump trucks, truck-mounted cranes, pickup trucks, barges, helicopters, and miscellaneous equipment.

Daily highway truck trips would be required to bring construction material to the site, and carry construction debris and waste material to a suitable landfill. Estimated daily highway truck trips for each comprehensive plan are shown in Table 2-22. Table 2-22 also shows the estimated construction period and annual construction labor force for each comprehensive plan.

Table 2-22. Estimated Construction Period, Truck Trips, and Construction Labor Force for Action Alternatives

Construction Item	CP1	CP2	CP3	CP4/ CP4A	CP5
Construction Period (years)	4.5	5	5	5	5
Construction Labor Force (number/year)	300	300	350	350	360
Daily Truck Trips for Materials (trips/day)	95	118	168	175	177
Daily Truck Trips for Waste (trips/day)	75	56	52	53	54
Total Daily Truck Trips (trips/day)	170	173	220	228	230

Key:
CP = comprehensive plan

Borrow Sources

Multiple borrow sources are available to meet project needs for concrete, sand and gravel, core and homogenous fill, shell fill, riprap, and filter and drain materials for reservoir area embankments. Potential borrow sources were examined at a preliminary level and would need further sampling and testing to determine suitability and refine quantity estimates. Potential borrow sources include areas of the dike construction sites, areas located below the reservoir's inundation zone, and commercial sources. Commercial sources are located within approximately 2 to 30 miles of the Bridge Bay site, and within approximately 15 to 43 miles of the Lakeshore sites. Potential borrow sources are identified in Figure 2-7. Available fill material from potential borrow sources are described in the Engineering Summary Appendix.

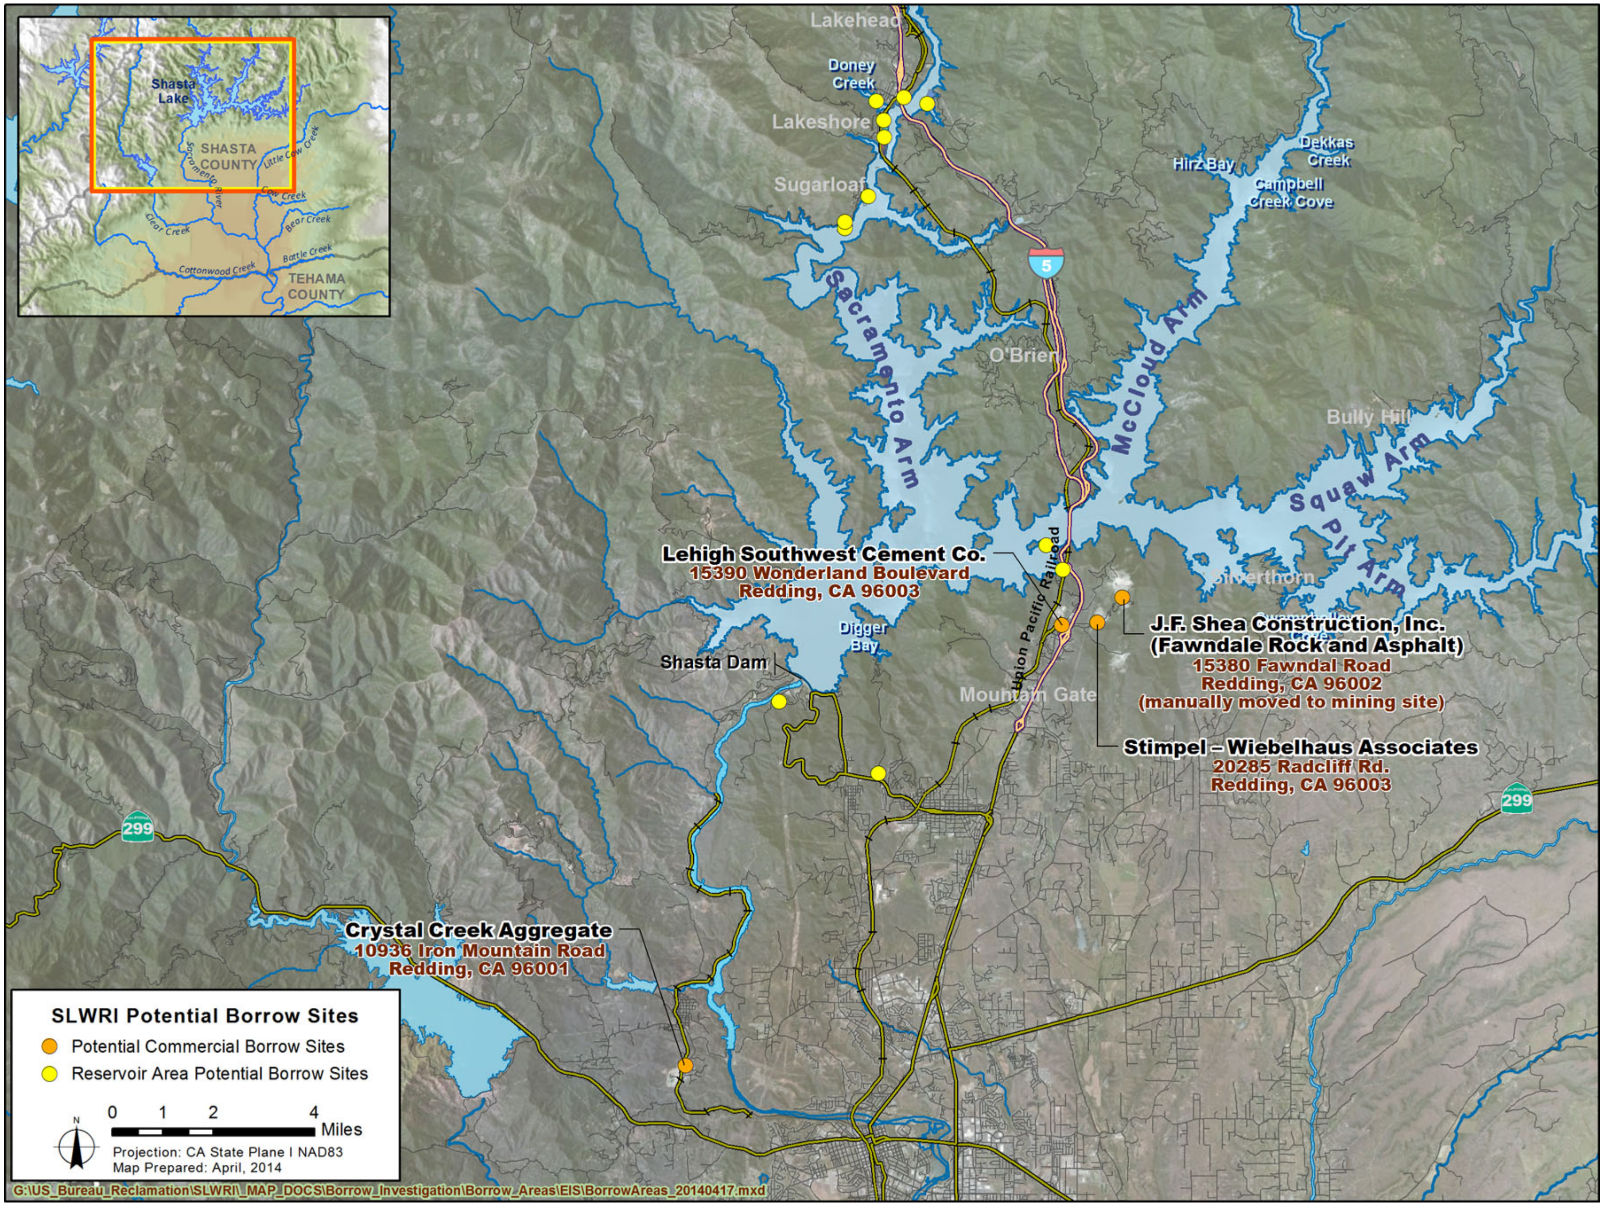

Figure 2-7. Potential Borrow Sources

2.4 Alternatives Considered and Eliminated from Further Analysis

As noted above, this EIS tiers to the CALFED EIS/R, and the CALFED agencies considered more than 50 water supply alternatives through the CALFED process. The CALFED Programmatic ROD directed that five storage projects be further studied, including Shasta Dam and Reservoir. The CALFED Programmatic ROD further recognizes that CALFED agencies "will not revisit the alternatives that were considered alongside CALFED's Preferred Program Alternative nor will they revisit alternatives that were rejected during CALFED's alternative development process."

In addition to the action alternatives described in Section 2.3, "Action Alternatives," Reclamation examined numerous other alternatives through its plan development process, which is detailed in the Plan Formulation Appendix.

Alternatives considered but eliminated from further analysis are described below. The plans described were developed during the initial alternatives phase and the comprehensive plans phase, consistent with the alternatives development process discussed previously.

As part of the SLWRI plan formulation process, Reclamation identified, evaluated, and screened more than 60 potential management measures (shown in Table 2-1) to address the primary and secondary planning objectives and satisfy the other applicable planning constraints, considerations, and criteria. In addition to modifying or raising Shasta Dam, Reclamation considered management measures including constructing instream fish habitat on tributaries to the Sacramento River; increased instream flows on Clear, Cow, and Bear creeks; constructing a migrating corridor from the Sacramento River to the Pit River; new reservoirs in other locations, such as on the Sacramento River upstream from Shasta Reservoir, on tributaries downstream from Shasta Dam (e.g., Cottonwood Creek and Auburn Dam Projects); offstream storage near the Sacramento River downstream from Shasta Dam (e.g., Sites Reservoir); and many others. Management measures deleted from further consideration were summarized previously and are described in detail in the Plan Formulation Appendix, along with reasons for deleting measures from further consideration and development.

2.4.1 Initial Alternatives Phase

The following concept plans were eliminated from further consideration as stand-alone plans.

- **AFS-1 – Increase Cold Water Assets with Shasta Operating Pool Raise (6.5 feet) –** AFS-1 focused on maintaining cooler water temperatures in the upper Sacramento River by increasing the minimum end-of-October carryover storage target. This would allow additional cold water to be stored for use in the following year. No changes would be made to the existing seasonal temperature targets for anadromous fish on the upper Sacramento River, but the ability to meet these targets would be improved.

It was found that AFS-1 had a significant potential to benefit anadromous fish in the upper Sacramento River, but there would be no additional increase in water supply reliability. This plan had two major components: (1) Raising Shasta Dam by 6.5 feet for the primary purpose of enlarging the cold-water pool and regulating water temperature in the upper Sacramento River: and (2) increasing the size of the minimum operating pool to 880,000 acre-feet.

AFS-1 was not retained for further development as a stand-alone plan because, although it had considerable benefits for anadromous fish survival, it did not meet the primary planning objective of increasing water supply reliability.

- **AFS-2 – Increase Minimum Anadromous Fish Flow with Shasta Enlargement (6.5 feet) –** AFS-2 focused on the primary planning objective of anadromous fish survival by using the additional reservoir storage to increase minimum seasonal flows in the upper Sacramento River from the current 3,250 cfs to about 4,200 cfs. The primary component of AFS-2 included raising Shasta Dam by 6.5 feet for the primary purpose of enlarging the volume of water available to meet minimum flows for winter-run Chinook salmon on the upper Sacramento River. No changes would be made to the carryover target volume or minimum operating pool.

  Subsequent evaluation indicated that although increasing minimum flows would be beneficial for fish at various stages of development, it would be detrimental at other life stages. Accordingly, this plan was deleted from further development.

- **AFS-3 – Increase Minimum Anadromous Fish Flow with Shasta Enlargement (6.5 feet) and Restore Aquatic Habitat –** AFS-3 was similar to AFS-2, except that it also involved acquiring, restoring, and reclaiming one or more inactive gravel mines along the upper Sacramento River to restore about 150 acres of aquatic and floodplain habitat. AFS-3 had two major plan components: (1) Raising Shasta Dam by 6.5 feet for the primary purpose of enlarging the volume of water available to meet minimum flows for winter-run Chinook salmon on the upper Sacramento River: and (2) acquiring, restoring, and reclaiming one or more inactive gravel mining operations along the upper Sacramento River to restore about 150 acres of aquatic and floodplain habitat.

Increasing minimum flows was not found to significantly benefit to anadromous fish, and concerns were expressed regarding significant uncertainties about offstream areas being able to successfully support viable fish spawning and rearing. Further, during public scoping activities in late 2005, little to no interest was demonstrated for restoring inactive gravel mines along the Sacramento River above the current location of the RBPP. Accordingly, this plan element was deleted from further consideration at this time.

- **WSR-3 – Increase Water Supply Reliability with Shasta Enlargement (High Level) –** WSR-3 focused on water supply reliability by increasing the volume of water stored in Shasta Lake by the maximum amount technically feasible. WSR-3 had two major components: (1) Raising Shasta Dam by about 202.5 feet for the primary purpose of creating 9.3 MAF of additional storage available for water supply: and (2) major modifications to or replacing, dam appurtenances, including hydropower facilities and the TCD.

  Raising the dam to this level would require extensive and very costly reservoir area relocations such as moving the Pit River Bridge, I-5, and UPRR tracks, and would require modifying Keswick Dam and its powerplant. This plan would provide a major increase in water supply reliability, anadromous fish, hydropower, flood damage reduction, and recreation resources. However, the plan is not financially feasible because the construction cost is estimated at more than $6 billion (at October 2008 price levels). Accordingly, WSR-3 was deleted from further development.

- **WSR-4 – Increase Water Supply Reliability with Shasta Enlargement (18.5 feet) and Conjunctive Water Management –** WSR-4 focused on the primary objective of water supply reliability by raising Shasta Dam 18.5 feet in combination with conjunctive water management. WSR-4 had two major components: (1) Raising Shasta Dam by 18.5 feet for the primary purpose of creating 636,000 acre-feet of additional storage available for water supply and (2) implementing a conjunctive water management program, consisting largely of contracts between Reclamation and certain Sacramento River basin water users. The conjunctive water management component included downstream facilities, such as additional river diversions and transmission and groundwater pumping facilities, to facilitate exchanges. Reclamation would provide additional surface supplies to participating CVP users in wet and normal water years, in exchange for reducing deliveries in dry and critical years, when users would rely more on groundwater supplies.

  Preliminary estimates of the conjunctive water management component associated with this alternative indicated that water supplies for system deliveries could be increased by between 10 and 20 percent. However, few to no fishery benefits would result and no strong indication of non-Federal participation in a conjunctive water management component was identified. Accordingly, WSR-4 was deleted from further consideration.

- **CO-1 and CO-2 – Increase Anadromous Fish Habitat and Water Supply Reliability with Shasta Enlargement (6.5 feet and 18.5 feet) –** CO-1 and CO-2 addressed both primary objectives by restoring anadromous fish habitat and raising Shasta Dam. Both CO-1 and CO-2 would dedicate some of the added reservoir space from the dam raise to increasing the minimum carryover storage in Shasta Reservoir to make more cold-water releases for regulating water temperature in the upper Sacramento River. CO-1 and CO-2 had three major components: (1) Raising Shasta Dam by 6.5 feet (CO-1) or 18.5 feet (CO-2), for the purposes of expanding the cold-water pool and creating 260,000 acre-feet (CO-1) or 630,000 acre-feet (CO-2) of additional storage available for water supply; (2) acquiring, restoring, and reclaiming one or more inactive gravel mining operations along the upper Sacramento River to create about 150 acres of aquatic and floodplain habitat, and (3) revising flood control operations to benefit water supply reliability by managing floods more efficiently.

  For reasons similar to those described for AFS-3, both CO-1 and CO-2 were eliminated as stand-alone plans, and the gravel mine restoration components of both plans were deleted from further consideration.

- **CO-3 –** Increase Anadromous Fish Flow/Habitat and Water Supply Reliability with Shasta Enlargement (18.5 feet). CO-3 is similar to CO-2, except that a portion of the additional storage would be dedicated to managing flows for winter-run Chinook salmon on the upper Sacramento River. Under this preliminary plan, approximately 320,000 acre-feet would be dedicated to increasing minimum flows from approximately 3,250 cfs to about 4,200 cfs between October 1 and April 30.

  Subsequent evaluation indicated that although increasing minimum flows would be beneficial for fish at various stages of development, it would be detrimental at other life stages. Accordingly, CO-3 was deleted from further development.

- **CO-4 – Multipurpose with Shasta Enlargement (6.5 feet) –** This plan addressed both the primary and secondary objectives through a combination of measures, raising Shasta Dam, restoring habitat, and adding recreation facilities in the Shasta Lake area. Enlargement of the reservoir and limited reservoir reoperation would also help improve operations for flood management and recreation. Major components of

CO-4 involved increasing water supply reliability with a 6.5-foot dam raise, increasing anadromous fish survival by increasing cold-water pool depth and volume in Shasta Reservoir, and restoring inactive gravel mines and floodplain habitat along the Sacramento River. CO-4 involved further investigation of and potential modifications to the existing TCD at Shasta Dam for enhanced temperature management, and increasing the operational efficiencies of Shasta Dam and Reservoir for water supply reliability and flood control. Finally, the plan involved implementing conjunctive water management, as in WSR-4, constructing shoreline and tributary fish habitat improvements in the Shasta Lake area, and restoring one or more riparian habitat areas between Redding and the current location of the RBPP on the Sacramento River.

CO-4 was eliminated from further consideration primarily because of its low effectiveness and efficiency and redundancies with WSR-1 and CO-5, both of which were recommended for further development.

2.4.2 Comprehensive Plans Phase

The scenarios presented in Tables 2-23 and 2-24, related to the formulation of the anadromous fish survival focus plan (CP4/CP4A), were eliminated from further consideration during the comprehensive plans phase.

Table 2-23. Eliminated Scenarios Considered to Augment Flows – Anadromous Fish Survival Focus Plan

Scenario	Description	Reason for Elimination
1	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. October – March AFRP flows or 500 cfs increase, whichever is less.	Analysis indicated limited benefits to fish compared with overall cost of the project.
2	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. October – March AFRP flows or 750 cfs increase, whichever is less.	Analysis indicated limited benefits to fish compared with overall cost of the project.
3	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. October – March AFRP flows or 1,000 cfs increase, whichever is less.	Analysis indicated limited benefits to fish compared with overall cost of the project.
4	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. Increase August flows to 10,000 cfs and September flows to 6,000 cfs for temperature control.	Analysis indicated limited benefits to fish compared with overall cost of the project.

Source: USFWS 2001
Key:
AFRP = Anadromous Fish Restoration Plan
cfs = cubic feet per second

Table 2-24. Eliminated Scenarios Considered for Cold-Water Storage – Anadromous Fish Survival Focus Plan

Scenario	Description	Reason for Elimination
B	Dam raise of 6.5 feet. Additional 256,000 acre-feet of storage. Dedicating 256,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it did not considerably contribute to other objectives.
D	Dam raise of 12.5 feet. Additional 443,000 acre-feet of storage. Dedicating 187,000 acre-feet of the additional water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it was not as cost-effective as an 18.5-foot raise.
E	Dam raise of 12.5 feet. Additional 443,000 acre-feet of storage. Dedicating 443,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it did not considerably contribute to other objectives.
I	Dam raise of 18.5 feet. Additional 634,000 acre-feet of storage. Dedicating 634,000 acre-feet of water from increased storage to increase the size of the cold-water pool for fishery benefit.	Although this scenario had considerable benefits for anadromous fish survival, it did not considerably contribute to other objectives.

Further information about the SLWRI plan formulation process, including detailed descriptions of deleted and retained measures, initial plans, and scenarios used to formulate CP4/CP4A, are presented in the Plan Formulation Appendix.

2.5 Summary of Potential Benefits of Action Alternatives

Table 2-25 summarizes the overall potential benefits of all comprehensive plans. The quantified benefits were based on modeling efforts that are described in several parts of the EIS: Chapter 6, “Hydrology, Hydraulics, and Water Management;” Chapter 11, “Fisheries and Aquatic Resources;” Chapter 23, “Power and Energy;” and the modeling appendices.

Table 2-25. Summary of Major Benefits of Action Alternatives

Item	CP1	CP2	CP3	CP4	CP4A	CP5
Shasta Dam Raise (feet)	6.5	12.5	18.5	18.5	18.5	18.5
Total Increased Storage (TAF)	256	443	634	634	634	634
Benefits						
Increase Anadromous Fish Survival						
Dedicated Storage (TAF)	-	-	-	378	191	-
Production Increase (thousand fish)[1]	61	379	207	813	710	378
Spawning Gravel Augmentation (tons)[2]	-	-	-	10,000	10,000	10,000
Side Channel Rearing Habitat Restoration	-	-	-	Yes	Yes	Yes

Table 2-25. Summary of Major Benefits of Action Alternatives (contd.)

Item	CP1	CP2	CP3	CP4	CP4A	CP5
Increase Water Supply Reliability						
Total Increased Dry and Critical Year Water Supplies (TAF/year)[3]	47.3	77.8	63.1	47.3	77.8	113.5
Increased NOD Dry and Critical Year Water Supplies (TAF/year)[3]	4.5	10.7	35.2	4.5	10.7	25.2
Increased SOD Dry and Critical Year Water Supplies (TAF/year)[3]	42.7	67.1	28.0	42.7	67.1	88.3
Increased Water Use Efficiency Funding	Yes	Yes	Yes	Yes	Yes	Yes
Increased Emergency Water Supply Response Capability	Yes	Yes	Yes	Yes	Yes	Yes
Reduce Flood Damage						
Increased Reservoir Storage Capacity	Yes	Yes	Yes	Yes	Yes	Yes
Additional Hydropower Generation[4]						
Increased Hydropower Generation (GWh/year)[5]	52 - 54	87 - 90	86 - 90	127 - 133	125 - 130	112 - 117
Conserve, Restore, and Enhance Ecosystem Resources						
Shoreline Enhancement (acres)	-	-	-	-	-	130
Tributary Aquatic Habitat Enhancement (miles)[6]	-	-	-	-	-	6
Riparian, Floodplain, and Side Channel Restoration Habitat	-	-	-	Yes	Yes	Yes
Increased Ability to Meet Flow and Temperature Requirements Along Upper Sacramento River	Yes	Yes	Yes	Yes	Yes	Yes
Improve Water Quality						
Improved Delta Water Quality	Yes	Yes	Yes	Yes	Yes	Yes
Increased Delta Emergency Response Capability	Yes	Yes	Yes	Yes	Yes	Yes
Increase Recreation						
Recreation (user days, thousands)[7]	85 - 89	116 - 134	201 - 205	307 - 370	246 - 259	142 - 175
Modernization of Recreation Facilities	Yes	Yes	Yes	Yes	Yes	Yes

Notes:

[1] Numbers were derived from SALMOD and represent an index of production increase, based on the estimated average annual increase in juvenile Chinook salmon surviving to migrate downstream from the Red Bluff Pumping Plant.

[2] Average amount per year for 10-year period.

[3] Total drought period reliability for Central Valley Project and State Water Project deliveries. Does not reflect benefits related to water use efficiency actions included in all comprehensive plans.

[4] In addition to increased hydropower generation, all comprehensive plans provide increased capacity benefits (i.e., the rate at which power can be generated) and ancillary services, which provide the ability to manage the electric grid in a reliable manner.

[5] Annual increases in hydropower generation were estimated using two methodologies – at load center (accounting for transmission losses) and at-plant (no transmission losses). To provide a more conservative estimate of potential hydropower benefits, load center generation values were used to estimate potential benefits of increased hydropower generation under comprehensive plans. However, increased generation values reported in Chapter 23, “Power and Energy,” of this Environmental Impact Statement are based on at-plant generation values to capture the largest potential effects from changes in hydropower generation and pumping.

[6] Tributary aquatic enhancement provides for the connectivity of native fish species and other aquatic organisms between Shasta Lake and its tributaries. Estimates of benefits reflect only connectivity with perennial streams and do not reflect additional miles of connectivity with intermittent streams.

[7] Annual recreation visitor user days were estimated using two methodologies. The minimum user day value was used to estimate potential recreation benefits to provide a more conservative estimate of the potential benefits of increased recreation under comprehensive plans. However, the maximum user value was used for direct and indirect effects evaluations in each resource area chapter to capture the largest potential effects from increased visitation. These values do not account for increased visitation due to modernization of recreation facilities associated with all comprehensive plans. For more detailed information related to estimated recreation user days, please see Chapter 10, “Recreational Visitation,” of the Modeling Appendix.

Key:
- = not applicable
CP = comprehensive plan
Delta = Sacramento-San Joaquin Delta
GWh/year = gigawatt-hours per year
NOD = north of Delta
SOD = south of Delta
SLWRI = Shasta Lake Water Resources Investigation
TAF = thousand acre feet

2.6 Preferred Alternative and Rationale for Selection

A plan recommending Federal action should be the plan that best addresses the targeted water resources problems considering public benefits relative to costs. The basis for selecting the recommended plan/preferred alternative is to be fully reported and documented, including the criteria and considerations used in selecting a recommended course of action by the Federal Government. It is recognized that most of the activities pursued by the Federal Government will require assessing trade-offs by decision makers and that in many cases, the final decision will require judgment regarding the appropriate extent of monetized and nonmonetized effects.

The needed rationale to support Federal investment in water resources projects is described in the 2009 CEQ Draft *Proposed National Objectives, Principles, and Standards for Water and Related Resources Implementation Studies (CEQ 2009)*:

> *The presentations shall summarize and explain the decision rationale leading from the identification of need through the recommendation of a specific alternative. This shall include the steps, basic assumptions, analysis methods and results, criteria and results of various screenings and selections of alternatives, peer review proceedings and results, and the supporting reasons for other decisions necessary to execute the planning process. The information shall enable the public to understand the decision rationale, confirm the supporting analyses and findings, and develop their own fully-informed opinions and/or decisions regarding the validity of the study and its recommendations.*
>
> *Opportunities shall be provided for public reaction and input prior to key study decisions, particularly the tentative and final selection of recommended plans. The above information shall be presented in a decision document or documents, and made available to the public in draft and final forms. The document(s) shall demonstrate compliance with the National Environmental Policy Act (NEPA) and other pertinent Federal statutes and authorities.*

NEPA CEQ Regulations require the identification of the alternative or alternatives that are environmentally preferable in the ROD (40 CFR 1505.2(b)). The environmentally preferable alternative generally refers to the alternative that would result in the fewest adverse effects to the biological and physical environment. It is also the alternative that would best protect, preserve, and enhance historic, cultural, and natural resources. Although this environmentally preferable alternative must be identified in the ROD, it need not be selected for implementation. For the purposes of NEPA, an environmentally preferable alternative will be identified in the ROD associated with this EIS.

The preferred alternative has been identified in this Final EIS in consideration of public, stakeholder, and agency comments on this EIS. Ultimately, the alternative that best meets the stated objectives and maximizes net public benefits will be identified with supporting rationale and documentation. The alternative recommended for implementation may or may not be identified as the "Environmentally Preferable Alternative" consistent with NEPA, the "National Economic Development (NED) Plan" consistent with the P&G, the "Least Environmentally Damaging Practicable Alternative" consistent with the CWA, and the "Environmentally Superior Alternative" consistent with CEQA.

Consistent with the above CEQ guidance and NEPA guidelines, the preferred alternative for implementation has been identified for the Final EIS. The preferred alternative and the basis for selecting the preferred alternative can be found in Chapter 32, "Final EIS," Section 32.4, "Preferred Alternative and Rationale for Selection."

This page left blank intentionally.

Chapter 3
Considerations for Describing Affected Environment and Environmental Consequences

3.1 Introduction

Chapters 4 through 25 of this EIS are organized by environmental resource area. Each chapter discusses the affected environment and potential environmental consequences (short- and long-term impacts, direct and indirect impacts, mitigation measures, and cumulative impacts) that could result from implementing the proposed action alternatives.

3.2 Chapter Contents and Definition of Terms

Chapters 4 through 25 are organized into the following resource and issue areas:

- **Chapter 4 –** Geology, Geomorphology, Minerals, and Soils
- **Chapter 5 –** Air Quality and Climate
- **Chapter 6 –** Hydrology, Hydraulics, and Water Management
- **Chapter 7 –** Water Quality
- **Chapter 8 –** Noise and Vibration
- **Chapter 9 –** Hazards and Hazardous Materials and Waste
- **Chapter 10 –** Agriculture and Important Farmland
- **Chapter 11 –** Fisheries and Aquatic Ecosystems
- **Chapter 12 –** Botanical Resources and Wetlands
- **Chapter 13 –** Wildlife Resources
- **Chapter 14 –** Cultural Resources

- **Chapter 15 –** Indian Trust Assets
- **Chapter 16 –** Socioeconomics, Population, and Housing
- **Chapter 17 –** Land Use and Planning
- **Chapter 18 –** Recreation and Public Access
- **Chapter 19 –** Aesthetics and Visual Resources
- **Chapter 20 –** Transportation and Traffic
- **Chapter 21 –** Utilities and Service Systems
- **Chapter 22 –** Public Services
- **Chapter 23 –** Power and Energy
- **Chapter 24 –** Environmental Justice
- **Chapter 25 –** Wild and Scenic River Considerations for McCloud River

For some of these resource and issue areas, there is also an appendix containing a technical report of the same name. The technical reports describe the affected environment in more detail than the summarized information presented in the main body of this EIS. Related modeling results are presented, where appropriate, in the appendices.

3.2.1 NEPA Requirements

Council on Environmental Quality (CEQ) regulations for implementing NEPA include the following requirements for an EIS (Title 40, Code of Federal Regulations (CFR) Section 1502.15):

> *[An] EIS shall succinctly describe the environment of the area(s) to be affected or created by the alternatives under consideration. The descriptions shall be no longer than is necessary to understand the effects of the alternatives. Data and analyses in a statement shall be commensurate with the importance of the impact, with less important material summarized, consolidated, or simply referenced.*

On February 18, 2010, CEQ issued guidance on including greenhouse gas (GHG) emissions and climate change impacts in environmental review documents under NEPA. CEQ guidance suggests that Federal agencies consider opportunities to reduce GHG emissions caused by proposed Federal actions, adapt their actions to climate change impacts throughout the NEPA process, and address these issues in the agencies' NEPA procedures. The following are the two main factors to consider when addressing climate change in environmental documentation:

- Effects of a proposed action and alternative actions on GHG emissions
- Impacts of climate change on a proposed action or alternatives

CEQ notes that "significant" national policy decisions with "substantial" GHG impacts require analysis of their GHG effects. That is, the GHG effects of a Federal agency's proposed action must be analyzed if the action would cause "substantial" annual direct emissions; would implement energy conservation or reduced energy use or GHG emissions; or would promote cleaner, more efficient renewable-energy technologies.

3.2.2 Approach to Affected Environment

Chapters 4 through 25 provide an overview of the existing physical environment and socioeconomic conditions that could be affected by the action alternatives and the No-Action Alternative considered in this EIS. This information was obtained from technical studies prepared by Reclamation for some resource and issue areas; those studies are attached to this EIS. Additional information was obtained from published environmental and planning documents, books, Web sites, journal articles, field surveys, and communications with technical experts. Descriptions of the affected environment are organized by geographic region. Conditions in the primary study area – Shasta Lake and vicinity and the upper Sacramento River (Shasta Dam to Red Bluff) – are described first. These discussions are followed by descriptions of conditions in the extended study area, which consists of the lower Sacramento River and Delta and CVP/SWP facilities and water service areas.

In certain resource areas, the geographic regions are organized slightly differently than how they are defined in Chapter 1, "Introduction." For example, when effects would occur solely because of operational changes, the Trinity, American, and Feather rivers may all be discussed with the extended study area geography for CVP/SWP facilities and service areas, because the impacts would be similar in nature.

3.2.3 Methods and Assumptions

Chapters 4 through 25 analyze the direct and indirect effects of the No-Action Alternative and action alternatives for each environmental resource area. Direct effects are those that would be caused by the action and would occur at the same time and place. Indirect effects are reasonably foreseeable consequences that may occur at a later time or at a distance from the project area. Examples of indirect effects are growth inducement or other effects related to changes in land use patterns, population density, or growth rate, and related effects on the physical environment.

The effects of the No-Action Alternative and action alternatives were determined by comparing estimates of resulting conditions with baseline conditions. These baseline conditions differ between NEPA and CEQA. Under NEPA, the No-Action Alternative (i.e., expected future conditions without the project) is the baseline to which the action alternatives are compared; the No-Action Alternative is also compared to existing conditions. Under CEQA, existing conditions are the baseline to which alternatives are compared.

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is a determining factor in whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the significance of the environmental effects of a proposed project. As stated in Section 15382 of the State of California (State) CEQA Guidelines, a "[s]significant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project.

The information included in this EIS is based on the best available information. Reclamation, through the scoping process and discussions with agencies and stakeholders, gathered information and performed focused studies to document resource conditions and evaluate the potential impacts of the No-Action and action alternatives. To perform the appropriate level of analysis for an EIS, Reclamation used the best available information on resources and took the requisite hard look at potential impacts of the SLWRI based on the best available technical data. The tools used to evaluate impacts of the alternatives were selected based on Reclamation's standard practices and input from responsible Federal, State, and local agencies and subject matter experts. Interdisciplinary subject matter experts, including engineers, geologists, biologists, cultural resources specialists, architects, and economists, etc., were consulted during the development of the EIS. These experts identified data needed, developed information if data gaps existed, and vetted information through the project team, peer and public review. For a full list of preparers see Chapter 29, "List of Preparers."

CVP and SWP Operational Assumptions

Reclamation and DWR use CalSim-II, a specific application of the Water Resources Integrated Modeling System (WRIMS) to Central Valley water operations, to study operations, benefits, and effects of new facilities and operational parameters for the CVP and SWP. In this EIS, the quantitative assessment of actions related to water resources relied primarily on two CalSim-II baselines for CEQA and NEPA:

- "Existing conditions," based on a 2005 level of development and current facilities, as defined in 2012 (a 2005 baseline)

- "Future conditions," based on without-project forecasted 2020-2030 level of development and reasonably foreseeable future projects and facilities (a 2030 baseline)[1]

Operational assumptions for refinement, modeling, and evaluation of potential effects of the No-Action Alternative and action alternatives included in this EIS were derived from the:

- The Reclamation 2008 Biological Assessment on the Continued Long-Term Operations of the CVP and SWP (2008 Long-Term Operation BA) (Reclamation 2008)

- The USFWS 2008 *Formal ESA Consultation on the Proposed Coordinated Operations of the CVP and SWP* (2008 USFWS Biological Opinion (BO)) (USFWS 2008)

- The NMFS 2009 *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO) (NMFS 2009)

- Coordinated Operations Agreement between Reclamation and DWR for the CVP and SWP, as ratified by Congress (Reclamation and DWR 1986)

As Reclamation has advanced the SLWRI, the environmental, hydrologic, and regulatory conditions in the Sacramento River basin and Delta have changed considerably. Among these changes have been substantial declines in the populations of key fish species that use the basin's waterways and the Delta, such as the delta smelt and Chinook salmon. These changes have led to a series of documents and decisions that have affected CVP and SWP operations. The following sections describe the historical decisions related to CVP and SWP operations, the ways in which they have influenced the SLWRI, and the related operational and modeling assumptions for this EIS.

ESA Consultation on CVP and SWP Long Term Operation In June 2004, Reclamation prepared the 2004 Operations Criteria and Plan (OCAP) to provide a description of facilities and the operating environment of the CVP and SWP.

[1] The level of development used for future conditions is a composite of multiple land use scenarios developed by DWR and Reclamation. The Sacramento Valley hydrology, which includes the Sacramento and Feather River basins, is based on projected 2020 land use assumptions associated with DWR Bulletin 160-98 (1998) and the San Joaquin Valley hydrology is based on the 2030 land use assumptions developed by Reclamation. Under any 2020 to 2030 level of development scenario, the majority of the CVP and SWP unmet demand is located south of the Delta, including the San Joaquin Valley. Please see Table 2-1 in the Modeling Appendix for additional information on CalSim-II modeling assumptions.

Using operational information presented in the 2004 OCAP, Reclamation and DWR developed the 2004 OCAP Biological Assessment (BA), prepared as part of the consultation process required by Section 7 of the Federal Endangered Species Act (ESA).

Reclamation consulted with NMFS and USFWS on the 2004 OCAP, and the two agencies issued the 2004 NMFS Biological Opinion (BO) (NMFS 2004) and 2005 USFWS BO (USFWS 2005), respectively. In 2007, the District Court for the Eastern District of California (District Court), in *Natural Resources Defense Council v. Kempthorne*, found the 2005 USFWS BO to be unlawful and inadequate. In May 2008, in *Pacific Coast Federation of Fishermen's Associations v. Gutierrez*, the District Court found the 2004 NMFS BO to be unlawful and inadequate. The District Court remanded both BOs to the agencies.

In 2008, Reclamation provided the USFWS and NMFS the *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP* (2008 Long-Term Operation BA). USFWS and NMFS released their BOs in 2008 and 2009, respectively.

In the 2008 USFWS BO, the USFWS concluded that the long-term operations of the CVP and SWP would jeopardize the continued existence of delta smelt and adversely modify its critical habitat. Consequently, the USFWS developed an RPA to avoid jeopardy.

In the 2009 NMFS BO, NMFS similarly concluded that the long-term operations of the CVP and SWP would jeopardize the continued existence of listed salmonids, steelhead, green sturgeon, and killer whales; it also developed an RPA to avoid jeopardy to the species. The RPA included conditions for revised water operations, habitat restoration and enhancement actions, and fish passage actions. Actions were brought challenging the USFWS and NMFS BOs (2008 and 2009) under ESA and the Administrative Procedure Act (APA), concerning the effects of the CVP and SWP on endangered fish species.

2008 USFWS BO Litigation On December 27, 2010, the District Court entered an "Amended Order on Cross-Motions for Summary Judgment" (Doc. 761), remanding the 2008 USFWS BO to the USFWS without vacatur. On May 4, 2011, the District Court issued an amended Final Judgment, ordering the USFWS to complete a final revised BO by December 1, 2013.

In August 2011, the District Court enjoined implementation of USFWS RPA Component 3 (Action 4), the fall X2 requirements, which require a monthly average position of not greater than 74 km in wet years or 81 km in above normal water years eastward of the Golden Gate Bridge. That injunction is no longer in-effect.

The United States and NRDC appealed the District Court's decision invalidating the 2008 USFWS BO. NRDC also challenged the District Court's finding that Reclamation was required to prepare an EIS on its provisional acceptance of the RPA included in the 2008 USFWS BO. Water user plaintiffs cross-appealed the District Court's opinion. On March 13, 2014, the Ninth Circuit Court of Appeals reversed that part of the District Court's opinion that questioned the validity of the 2008 USFWS BO, but affirmed the District Court's finding that Reclamation violated in NEPA in failing to prepare an EIS on its provisional acceptance of the RPA included in the 2008 USFWS BO.

2009 NMFS BO Litigation In September 2011, the District Court remanded the 2009 BO to NMFS, without vacatur, finding in favor of the Federal government on some counts and in favor of water contractor plaintiffs on other counts. The District Court has ordered NMFS to prepare a draft BO no later than October 1, 2016. To meet that schedule, Reclamation must issue a draft EIS evaluating the environmental impacts associated with implementing the draft NMFS BO by April 1, 2017 (six months after receiving the draft BO), and a final EIS no later than March 28, 2018. Reclamation must prepare an EIS on any RPA included in the draft NMFS BO by February 1, 2018; NMFS must release a final BO by that same date. Reclamation must issue a Record of Decision (ROD), deciding whether to accept the RPA or an alternative, by April 29, 2018. The United States has appealed the District Court's decision, and that appeal is still pending in the Ninth Circuit Court of Appeals.

Summary In February 2013, Reclamation requested reinitiation of ESA Section 7 consultation, to which USFWS and NMFS agreed.

Currently, although the Ninth Circuit Court of Appeals upheld the validity of the 2008 USFWS BO, the USFWS is obligated to issue (or reissue) a BO by December 1, 2015. On that same date, Reclamation must issue a Final EIS analyzing the environmental impacts associated with operating the CVP and SWP under the USFWS BO.

On the NMFS side, NMFS must issue a draft BO to Reclamation no later than October 1, 2016. Reclamation must issue a final EIS no later than February 1, 2018. On that same date, February 1, 2018, NMFS must release a final BO. Reclamation has until April 29, 2018 to issue a ROD.

Operational and Modeling Assumptions for this EIS These legal challenges have resulted in uncertainty with regard to operational constraints for the CVP and SWP. As a result, evaluations of potential effects of the alternatives in the Preliminary DEIS were based on available modeling analysis at that time, which reflected operations described in the 2004 OCAP BA and the Coordinated Operations Agreement between Reclamation and DWR for the CVP and SWP. These analyses were suitable for comparison purposes, and reflected expected variation among the alternatives, including the type and relative magnitude of anticipated impacts and benefits.

In 2012 Reclamation updated the operational assumptions and modeling for the SLWRI to reflect operations described in the 2008 Long-Term Operation BA (as updated due to new facilities, the passage of time, legislation, and litigation), the 2008 USFWS BO, and the 2009 NMFS BO. These assumptions were used to guide refinement, modeling, and evaluation of alternatives and were used as the basis of analysis in the DEIS and this Final EIS. Water operations defined in the RPA were included in existing and future conditions SLWRI modeling evaluations, as described in Table 2-2 of the Modeling Appendix. As described in Table 2-2 of the Modeling Appendix, restoration and enhancement actions and fish passage actions for the Sacramento River and its tributaries were not included in existing or future conditions operations modeling.

Despite the uncertainty resulting from the ongoing consultation process, the 2008 Long-Term Operation BA and the 2008 and 2009 BOs issued by the fishery agencies contain the most recent estimate of potential changes in water operations that could occur in the near future.

3.2.4 Significance Criteria

Significance criteria for each resource area are provided in each resource chapter of this EIS. These criteria are based on the checklist presented in Appendix G of the State CEQA Guidelines; factual or scientific information and data; and regulatory standards of Federal, State, and local agencies. These criteria also encompass the factors taken into account under NEPA to determine the significance of an action in terms of the context and the intensity of its effects.

3.2.5 Impact Comparisons and Definitions

Mechanisms that could cause impacts are discussed for each issue area. General categories of impact mechanisms are construction and activities related to future operation and maintenance, as described in Chapter 2, “Alternatives.” Project-related impacts are categorized as follows, to describe the intensity or duration of the impact:

- A **temporary** impact would last less than 3–4 years and typically would occur only during construction.
- A **short-term** impact could occur during construction and could last from the time construction ceases to within 3–5 years after construction.
- A **long-term** impact would last longer than 5 years after the completion of construction. In some cases, a long-term impact could be a permanent impact.

- A **direct** impact is an impact that would be caused by an action and would occur at the same time and place as the action.

- An **indirect** impact is an impact that would be caused by an action but would occur later in time or at another location, yet is reasonably foreseeable to occur.

- A **cumulative** impact is a project's impact combined with impacts from other past, present, and reasonably foreseeable future projects. A project's incremental impacts are not "cumulatively considerable" solely because other projects would have a significant cumulative impact; rather, the project would also need to contribute considerably to a significant cumulative impact (State CEQA Guidelines, Section 15064(h)(1)).

3.2.6 Impact Levels

The terminology listed below is used to denote the significance of environmental impacts of the No-Action Alternative and action alternatives. This section is intended to allow the use of this EIS for CEQA purposes.

- **No impact** would occur if the construction, operation, and maintenance of the alternative under consideration would not have any direct or indirect effects on the environment. "No impact" means no change from existing conditions. This impact level does not need mitigation.

- An impact that would not result in a substantial and adverse change in the environment would be **less than significant**. This impact level does not require mitigation under CEQA, even if applicable measures are available.

- A **significant** impact is defined by California Public Resources Code (PRC) Section 21068 as "a substantial, or potentially substantial, adverse change in the environment." Levels of significance can vary by project, based on the change in the existing physical condition. This EIS uses the CEQA definition of "significant impact."

- A **potentially significant** impact is one that, if it were to occur, would be considered a significant impact as described above; however, the occurrence of the impact cannot be immediately determined with certainty. For CEQA purposes, a potentially significant impact is treated as if it were a significant impact. Therefore, under CEQA, feasible mitigation measures or alternatives to the proposed action must be identified, where applicable, to reduce the magnitude of potentially significant impacts.

- A **significant and unavoidable** impact is a substantial or potentially substantial adverse effect on the environment that cannot be reduced to a less-than-significant level even with any feasible mitigation. Under CEQA, a project with significant and unavoidable impacts could proceed, but the lead agency would be required to do the following:

  - Conclude in findings that there are no feasible means of substantially lessening or avoiding the significant impact in accordance with Section 15091(a)(3) of the State CEQA Guidelines (i.e., Title 14, California Code of Regulations (CCR) Section 15091(a)(3)).

  - Prepare a statement of overriding considerations, in accordance with Section 15093 of the State CEQA Guidelines, explaining why the lead agency would proceed with a project in spite of the potential for significant impacts.

- A **significant cumulative** impact would occur when the project would make a "cumulatively considerable incremental contribution" to an overall significant cumulative impact. If an overall cumulative impact would not be significant, even when the project would make a cumulatively considerable incremental contribution to the cumulative impact, then it is determined that the project would not cause a significant cumulative impact.

- A **beneficial** impact is a positive change or improvement in the environment, for which no mitigation measures are required.

- An impact may have a level of significance that is too uncertain to be reasonably determined. Such an impact would be designated **too speculative for meaningful evaluation**, in accordance with Section 15145 of the State CEQA Guidelines. Where some degree of evidence points to the reasonable potential for a significant effect, the EIS may explain that a determination of significance is uncertain, but is still assumed to be "potentially significant," as described above. In other circumstances, after thorough investigation, the determination of significance may still be too speculative to be meaningful. This is an effect for which the degree of significance cannot be determined for specific reasons. For example, aspects of the impact itself may be unpredictable or the severity of consequences cannot be known at this time.

3.2.7 Mitigation Development Process and Objectives

Mitigation measures are presented where feasible to avoid, minimize, rectify, reduce, or compensate for significant and potentially significant impacts of the action alternatives, in accordance with Section 15126.4 of the State CEQA

Guidelines and NEPA regulations (Title 40, CFR Section 1508.20). Each mitigation measure is identified numerically to correspond with the number of the impact being mitigated by the measure. No mitigation measures are needed when an impact is determined to be "less than significant" or "beneficial," or where no impact would occur. Where sufficient feasible mitigation is not available to reduce an impact to a less-than-significant level, the impact is identified as "significant and unavoidable."

3.2.8 Significance After Mitigation

For every impact that would be significant or potentially significant, mitigation is applied, if feasible, to avoid or reduce the impact to a less-than-significant level and one of two conclusions is reached:

- The mitigation would reduce the impact to a less-than-significant level.

or

- No feasible mitigation (relevant and reasonable mitigation measures that could be accomplished in a successful manner within a reasonable time period) has been identified to reduce the impact to a less-than-significant level, and thus the impact would be significant and unavoidable.

Impact significance is reevaluated after application of mitigation in this EIS.

3.2.9 Cumulative Effects

This section provides an analysis of overall cumulative effects of the action alternatives and the No-Action Alternative. Cumulative effects are determined by analyzing the potential for project impacts to combine with the impacts of other past, present, and reasonably foreseeable future projects to produce project-related impacts. This analysis follows applicable guidance provided by CEQ in *Considering Cumulative Effects under the National Environmental Policy Act* (CEQ 1997) and *Guidance on the Consideration of Past Actions in Cumulative Effects Analysis* (CEQ 2005).

Definitions of Cumulative Effects

The CEQ regulations that implement NEPA provisions define a cumulative effect as "the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions regardless of what agency (federal or nonfederal) or person undertakes such other actions" (Title 40, CFR Section 1508.7).

Cumulative impacts can result from individually minor but collectively significant actions over time, and they differ from indirect impacts (Title 40, CFR Section 1508.8). They are caused by the incremental increase in total environmental effects that occurs when the evaluated project is added to other past, present, and reasonably foreseeable future actions. Cumulative effects can thus arise from causes that are totally unrelated to the project being evaluated, and the analysis of cumulative effects looks at the life cycle of the effects, not the project at issue. These effects can be either adverse or beneficial.

Cumulative impacts are defined in the State CEQA Guidelines (Title 14, CCR Section 15355) as “two or more individual effects which, when considered together, are considerable or which compound or increase other environmental impacts.” A cumulative impact occurs from “the change in the environment which results from the incremental impact of the project when added to other closely related past, present, and reasonably foreseeable future projects. Cumulative impacts can result from individually minor but collectively significant projects taking place over a period of time (Title 14, CCR Section 15355(b)).

Consistent with the State CEQA Guidelines (Title 14, CCR Section 15130(a)), the discussion of cumulative impacts in Chapters 4 through 25 focuses on significant and potentially significant cumulative impacts. The State CEQA Guidelines (Title 14, CCR Section 15130(b)) state that:

> *The discussion of cumulative impacts shall reflect the severity of the impacts and their likelihood of occurrence, but the discussion need not provide as great detail as is provided for the effects attributable to the project alone. The discussion should be guided by the standards of practicality and reasonableness, and should focus on the cumulative impact to which the identified other projects contribute rather than the attributes of other projects which do not contribute to the cumulative impact.*

Effects of Project Implementation with Climate Change

Each resource area evaluates the effects of the action alternatives and No Action Alternative combined with predicted effects of climate change. The ways that the SLWRI could affect GHG production are described in Chapter 5, “Air Quality and Climate.” The Climate Change Modeling Appendix provides a summary of global climate forecasts and a discussion of the implications of climate change for California water resources. This appendix also includes quantitative analyses of climate change for selected comprehensive plans on resource areas. The discussion of climate change implications provided in the Climate Change Modeling Appendix provides context for consideration of cumulative conditions.

Relationship to CALFED Programmatic Cumulative Impacts Analysis

The analysis of cumulative effects in this EIS relies on and tiers to the cumulative effects assessment in the CALFED Bay-Delta Program (CALFED) Programmatic EIS/ Environmental Impact Report (PEIS/R). The “Shasta Lake

Enlargement" project was included in the cumulative impacts analysis of the CALFED PEIS/R as a project in CALFED's Storage Program (CALFED 2000).

This project-specific analysis fully considers and builds upon the analysis of cumulative effects in the CALFED PEIS/R (CALFED 2000). This analysis focuses on issues resulting from the effects of the SLWRI combined with other reasonably foreseeable future projects. This EIS considers CALFED projects that have been implemented, are being implemented, or are reasonably foreseeable future projects. The projects that have been implemented are considered as part of existing conditions; reasonably foreseeable future projects are considered as part of future conditions.

In compliance with Section 1502.20 of the CEQ regulations that implement NEPA, the analysis of cumulative effects tiers to the CALFED Final PEIS/R and the Programmatic ROD issued August 28, 2000. The analysis and assumptions in the CALFED Final PEIS/R and Programmatic ROD are applicable to the SLWRI cumulative analysis. First, the analysis of cumulative impacts in the CALFED Final PEIS/R considered the long-term environmental impacts of the CALFED Preferred Program Alternative and alternatives, including those that would be less than significant, together with similar impacts of other projects. The CALFED Final PEIS/R and Programmatic ROD evaluated, at a programmatic level, five surface water storage projects to be pursued with project specific studies. These studies included Shasta Lake Enlargement, Los Vaqueros Reservoir Enlargement, Sites Reservoir, In-Delta Storage, and development of storage in the upper San Joaquin River Basin. The CALFED PEIS/R analysis of cumulative effects describes the effects of these storage projects with past, present, and reasonably foreseeable projects in the Delta region, Bay region, Sacramento River region, San Joaquin River region, and other SWP and CVP service areas. To that point, storage projects (e.g., Los Vaqueros Reservoir Enlargement) have proceeded as described in the CALFED Final PEIS/R while no other large storage projects have been implemented that were not described in the CALFED analysis. Second, because CALFED actions affected a large geographic area over a 30-year time frame, this analysis of cumulative impacts, growth inducement, and area-wide impacts assessment builds upon the CALFED PEIS/R analysis of cumulative effects to include an updated analysis of reasonably foreseeable projects, recent and relevant BOs, and more specific information about the potential for the action alternatives to cause wide-ranging effects.

Methods and Assumptions

For purposes of this EIS, cumulative impacts of an action alternative would be significant if implementing the alternative would make a considerable incremental contribution to a significant cumulative effect. The alternative's contribution is evaluated in combination with the effects of other past, present, and reasonably foreseeable future projects to determine whether (1) the overall cumulative effect would be significant and (2) the alternative's contribution would be considerable. Cumulatively significant impacts would do any of the following:

- Cause a significant adverse effect on a resource (using the criteria for significance described in the "Environmental Consequences and Mitigation Measures" sections of Chapters 4 through 25 of this EIS)
- Adversely affect a resource that already has a degraded or declining condition because of substantial adverse effects that have already occurred
- Cause effects that initially were not significant, but would be part of an irreversible degrading or declining trend

Following CEQ guidance, Reclamation has identified associated actions (past, present, or future) that, when viewed with the proposed or alternative actions, may have significant cumulative impacts. Table 3-1 lists the plans, projects, and programs that were considered for each resource area.

The State CEQA Guidelines identify two basic methods for establishing the cumulative environment in which the project is to be considered: using a list of past, present, and probable future projects (the "list approach") or using adopted projections from a general plan, other regional planning document, or certified Environmental Impact Report (EIR) for such a planning document (the "plan approach"). For this analysis of cumulative impacts, the list approach and the plan approach have been combined in quantitative and qualitative assessments to generate the most comprehensive future projections possible. The methodology for each of these assessments is described following Table 3-1.

Table 3-1. Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area

Cumulative Projects
Quantitative
Forecasted 2030 Level of Demands for Water Supplies
Freeport Regional Water Project
Delta Water Supply Project
DWR South Bay Aqueduct Improvement and Enlargement Project
Vernalis Adaptive Management Plan
San Joaquin River Restoration Program – Full Restoration Flows
Grassland Bypass Project
Qualitative Assessment of Actions Related to Water/ Natural Resource Management and Restoration
Central Valley Project Improvement Act
Refuge Water Supply Program
Clear Creek Actions of the CVPIA Anadromous Fish Restoration Program
CALFED Ecosystem Restoration Program
Qualitative Assessment of Actions Related to the 2009 NMFS Biological Opinion
Clear Creek Actions: Spawning Gravel Augmentation -Spring Creek Temperature Control Curtain -Adaptively Manage to Habitat Suitability/IFIM Study
Fish Passage Program (Action V) at Shasta and Folsom Dams
Sacramento River Basin Salmonid Rearing Habitat Improvements: -Restoration of Floodplain Rearing Habitat -Near Term Actions at Liberty Island/Lower Cache Slough and Lower Yolo Bypass -Lower Putah Creek Enhancements
The Water Quality Control Plan for the California Regional Water Quality Control Board: Central Valley Region, the Sacramento River Basin and San Joaquin River Basin
The California Air Resources Board Climate Change Scoping Plan: A Framework for Change
Bay Delta Conservation Plan
San Joaquin River Restoration Program
Trinity River Mainstem Fishery Restoration Program
Sacramento River Conservation Area Forum Program
Iron Mountain Mine Restoration Plan
Deer Creek Flow Enhancement Program
Lower Deer Creek Falls Fish Passage Improvement Project
Battle Creek Salmon and Steelhead Restoration Project
Butte Regional Conservation Plan
North-of-Delta Offstream Storage Investigation

Natomas Levee Improvement Program Landslide Improvement Project
West Sacramento Levee Improvement Program
Delta Islands and Levees Feasibility Study

Table 3-1. Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area (contd.)

Cumulative Projects
Qualitative Assessment of Actions Related to Energy
Increased Hydropower Generation Capacity at Lewiston Dam
Pacific Gas & Electric Company Pit River 3, 4 & 5 Hydroelectric Projects License Implementation
Pacific Gas & Electric Company McCloud and Pit Rivers 6 and 7 FERC Relicensing
California Department of Water Resources Oroville Facilities FERC Relicensing
Sacramento Municipal Utility District Upper American River Project
Qualitative Assessment of Actions Related to Land Use Planning and Infrastructure
Antlers Bridge Replacement
Jellys Ferry Bridge Replacement
Moody Flats Quarry
Mountain Gate at Shasta Mixed-Use Area Plan

Key:
CALFED = CALFED Bay-Delta Program
CVPIA = Central Valley Project Improvement Act
DWR = California Department of Water Resources
FERC = Federal Energy Regulatory Commission
IFIM = Instream Flow Incremental Methodology
NMFS = National Marine Fisheries Service
TMDL = total maximum daily load

Quantitative Assessments Quantitative assessments were completed for each of the resource areas in this EIS, where feasible. The effects of actions related to water resources and effects of development projects were assessed quantitatively. Numerical changes to water resources and air quality were considered qualitatively in the consideration of cumulative impacts on related resources. The methodologies for the quantitative assessments are described below.

Quantitative Assessment of Actions Related to Water Resources In this EIS, the quantitative assessment of actions related to water resources relied primarily on CalSim-II modeling of hydrologic conditions that could affect the environment. The model was run using two different baselines:

- "Existing conditions," based on 2005 a level of development and current facilities, as defined in 2012 (a 2005 baseline)
- "Future conditions," based on without-project forecasted 2020-2030 level of development and reasonably foreseeable future projects and facilities (a 2030 baseline)[2]

The 2030 baseline does not account for potential changes in water demands resulting from the effects of climate change. Potential changes in water demand due to climate change are described qualitatively in the "Qualitative Assessments" section. The 2030 baseline includes the following reasonably foreseeable future projects and conditions, described separately below:

- Forecasted 2030 level of demands for water supplies
- Freeport Regional Water Project
- Delta Water Supply Project
- DWR South Bay Aqueduct Improvement and Enlargement Project
- Vernalis Adaptive Management Plan (VAMP) (as a representation of future San Joaquin River flow objectives)
- San Joaquin River Restoration Program (SJRRP) – Full Restoration Flows

[2] The level of development used for future conditions is a composite of multiple land use scenarios developed by DWR and Reclamation. The Sacramento Valley hydrology, which includes the Sacramento and Feather River basins, is based on projected 2020 land use assumptions associated with DWR Bulletin 160-98 (1998) and the San Joaquin Valley hydrology is based on the 2030 land use assumptions developed by Reclamation. Under any 2020 to 2030 level of development scenario, the majority of the CVP and SWP unmet demand is located south of the Delta, including the San Joaquin Valley. Please see Table 2-1 in the Modeling Appendix for additional information on CalSim-II modeling assumptions.

- Grassland Bypass Project

Forecasted 2030 Level of Demands for Water Supplies Reclamation and DWR developed assumptions for evaluating systemwide hydrologic and water supply conditions with CalSim-II under existing and future conditions. Detailed descriptions of the CalSim-II model, the modeling methodology used in evaluations, and key assumptions (including forecasted 2030 facilities and demands) are provided in the Modeling Appendix. For a summary of the analysis and modeling results, see the Hydrology, Hydraulics, and Water Management Technical Report (in the Physical Resources Appendix).

To quantify cumulative effects on hydrologic conditions, modeling runs with No-Action Alternative (2030) conditions were compared to modeling runs with existing (2005) conditions. For example, the No-Action Alternative (2030 baseline) was compared to existing conditions (2005 baseline) to identify the cumulative impacts of reasonably foreseeable future projects and conditions on hydrologic conditions. The impacts of action alternatives were added to cumulative impacts of reasonably foreseeable future projects and conditions (No-Action Alternative) to identify the combined cumulative effects. The No-Action Alternative (2030) includes forecasted year-2030 demands for water. These forecasted demands are considered to be reasonably foreseeable for determining cumulative impacts.

Freeport Regional Water Project The Freeport Regional Water Project is intended to provide water for East Bay Municipal Utility District (EBMUD) customers in dry years and needed water for the Sacramento region by drawing water from the Sacramento River near the town of Freeport. Construction was completed in 2011 and project operations have been coming online incrementally since 2012. The project consists of a new 185-million-gallon-per-day water intake structure and pumping plant on the Sacramento River, a new large-diameter pipeline to transport water eastward from the intake to a new Sacramento County Water Agency water treatment plant and to the existing Folsom South Canal. The Freeport Regional Water Project is included only in future conditions for the SLWRI.

Delta Water Supply Project The Delta Water Supply Project provides a new supplemental high-quality water supply for the Stockton metropolitan area. The project, once completed, is intended to replace declining surface water resources, protect groundwater supplies, and provide for current and future water needs in the Stockton metropolitan area. Construction for Phase 1 of this project was completed in 2012, and associated project facilities are currently in use. The project includes a new intake and pump station that will divert water from the San Joaquin River through miles of underground pipeline to a new 30-million-gallon-per-day water treatment plant. The project will help meet Stockton's water needs, as detailed in the City of Stockton's general plan, through 2025. The Delta Water Supply Project is included only in future conditions for the SLWRI.

DWR South Bay Aqueduct Improvement and Enlargement Project The South Bay Aqueduct conveys water from the Delta through more than 40 miles of pipelines and canals to the Zone 7 Water Agency and the Alameda County and Santa Clara Valley water districts. Those three water districts, in turn, serve the cities of Livermore, Dublin, Pleasanton, San Ramon, Fremont, Newark, Union City, Milpitas, Santa Clara, and San Jose, among others.

The first conveyance facility constructed for the SWP, the South Bay Aqueduct, was designed for a capacity of 300 cubic feet per second (cfs). Recent flow tests and studies have shown that the actual capacity is 270 cfs. The purpose of the South Bay Aqueduct Enlargement Project is to increase the aqueduct's capacity to 430 cfs to meet the Zone 7 Water Agency's future needs and provide operational flexibility to reduce the SWP's peak power consumption.

The following are the principal features of this project:

- Add four 45 cfs pumps to the South Bay Pumping Plant, and expand the existing plant structure and add a new service bay and switchyard.
- Construct a third (Stage 3) Brushy Creek pipeline and surge tank parallel to the existing two barrels.
- Construct a 500-acre-foot reservoir (425 acre-feet of active storage) to be served by the Stage 3 Brushy Creek Pipeline.
- Raise the height of the canal embankments, canal lining, and canal overcrossing structures and bridges along the Dyer, Livermore, and Alameda canals and at the Patterson Reservoir.
- Modify check structures and siphons along the Dyer, Livermore, and Alameda canals.
- Construct new drainage overcrossing structures to eliminate drainage into the canals.

Construction is proceeding on enlargement of the South Bay Pumping Plant to make room for the four new pump units (DWR 2011a). The South Bay Aqueduct Improvement and Enlargement Project is included only in future conditions for the SLWRI.

Vernalis Adaptive Management Plan The VAMP was a 12-year experimental management program proposed under the 1998 San Joaquin River Agreement (SJRA), which was adopted by the State Water Resources Control Board (State Water Board) in Water Right Decision 1641 (December 1999). Although VAMP expired in 2011, VAMP requirements are included in SLWRI modeling to represent interim actions and likely future State Water Board objectives for San Joaquin River flows at Vernalis.

VAMP was initiated to protect juvenile Chinook salmon emigrating through the San Joaquin River and Delta, and to evaluate how Chinook salmon survival rates change in response to alterations in San Joaquin River flows and exports at CVP and SWP facilities in the south Delta when the Head of Old River Barrier is installed. A water acquisition program for instream flows and a monitoring program for VAMP were implemented through the SJRA, which was adopted in 2000 and twice extended, finally expiring in December 2011. Signatories to the SJRA included Reclamation, DWR, CDFW, USFWS, San Joaquin River Group Authority and member agencies, Exchange Contractors, and select CVP and SWP Contractors, San Francisco Public Utilities Commission, and several environmental interest groups.

VAMP provided guidance for flows in the lower San Joaquin River during a 31-day pulse-flow period during April and May. The predicted April 15 San Joaquin River flows at Vernalis were increased by 1 to 2 predefined “steps,” ranging from 1,200 cfs to 1,300 cfs between each step, depending on the average of water-year conditions for the current year and the previous year. For more information on VAMP flows, see the expiration of VAMP in 2011 introduced uncertainty regarding responsibility for meeting San Joaquin River flow standards set forth in the 1995 Bay Delta Plan until new San Joaquin River flow standards are identified. In the interim (2012 and 2013), Reclamation implemented a “single-step” VAMP, in which flows were increased by only one step in all water year types. Single-step VAMP operations are reflected in the SLWRI’s modeling of existing conditions.

It is anticipated that future State Water Board objectives will be as protective as the original VAMP requirements and will remain in place through 2030. Additionally, the 2009 NMFS BO RPAs include requirements for a continuation of VAMP-like flow objectives. It specifies minimum flow requirements in the San Joaquin River at Vernalis and restricts CVP and SWP export pumping amounts and ratios dependent on San Joaquin River flow at Vernalis. Accordingly, the SLWRI’s modeling of future conditions has incorporated full VAMP flow requirements.

San Joaquin River Restoration Program – Full Restoration Flows   The SJRRP was established in 2006 to implement the Stipulation of Settlement in *NRDC, et al., v. Kirk Rodgers, et al.* (Settlement). (See also the discussion of the SJRRP in “Qualitative Assessment of Actions Related to Water Resources,” later in this chapter.) Federal authorization for implementing the Settlement is provided in the San Joaquin River Restoration Settlement Act, included in Public Law 111-11.

The Settlement calls for releases of water from Friant Dam to the confluence of the Merced River, referred to as Interim and Restoration flows; a combination of channel-related and structural modifications along the San Joaquin River below Friant Dam; and reintroduction of Chinook salmon. Restoration Flows are specific volumes of water to be released from Friant Dam during different year types, according to Exhibit B of the Settlement. Interim Flows were experimental flows that were implemented from 2009 until Restoration Flows were implemented in 2014. Interim Flows allowed the SJRRP to collect relevant data about flows, temperatures, fish needs, seepage losses, recirculation, recapture, and reuse.

The release of Interim Flows began in October 2009; however, the release of Interim Flows was limited by channel capacity constraints between Friant Dam and the Merced River confluence. The release of Restoration Flows began on January 1, 2014, but is currently restricted due to capacity constraints. Full Restoration Flows are intended to include annual releases from Friant Dam of up to 840,000 acre-feet, depending on year type. In some years, peak releases from Friant Dam could reach as much as 8,000 cfs for several hours, within the constraints of channel capacity. For the SLWRI, existing conditions include Interim Flows and future conditions include full Restoration Flows.

Grassland Bypass Project The Grassland Bypass Project is a stakeholder initiative designed to improve water quality in the channels used to deliver water to the San Joaquin River and wetland areas in the Grassland watershed. Irrigation of soils containing high levels of salt and selenium has caused high levels of selenium to leach into the subsurface drainage water in the 97,000-acre Grassland Drainage Area. Before the Grassland Bypass Project began, this agricultural drainage water ultimately discharged into the San Joaquin River through Salt Slough, Mud Slough, and other channels used to deliver water to wetland areas in the Grassland watershed. The San Joaquin River is included on the Federal Clean Water Act (CWA) Section 303(d) list of impaired waters as impaired for 18 different pollutants, with total maximum daily load (TMDL) set for 6 of these pollutants within the watershed (selenium, dissolved oxygen, diazinon, chlorpyrifos, salt, and boron). Approximately 8,200 acres of Grasslands watershed marshes, a portion of the lower San Joaquin River (from the confluence with Mud Slough to the Merced River confluence), and Mud Slough are listed on the CWA Section 303(d) list of impaired waters for exceeding water quality objectives for selenium.

The Grassland Bypass Project has been implementing agricultural best management practices and measures to reroute drainage water to reduce total selenium loading to impaired waters. The objectives of the project have been to achieve short-term load reductions by 2010 (partial implementation) and to prohibit all discharges exceeding selenium objectives by 2019 (full implementation). Between 1998 and 2009, best management practices implemented by Grassland area farmers prevented the discharge of more than 22,000 pounds of selenium to listed waters. As a result, Salt Slough and a portion of the lower San Joaquin River have been removed from the 303(d) list of impaired waters. In 2012, the volume of agricultural drainage water discharged from the Grassland Drainage Area into the San Luis Drain was reduced by 12,000 acre-feet through displacement across the San Joaquin River Water Quality Improvement Project reuse area.

For the SLWRI, the water operations models for existing conditions and future conditions include partial implementation and full implementation, respectively, of the Grassland Bypass Project.

Quantitative Assessment of Effects on Air Quality For this analysis of cumulative impacts, regional impacts on air quality are analyzed quantitatively using the plan approach. As described in Chapter 5, "Air Quality and Climate," significance thresholds for the Shasta County Air Quality Management District (SCAQMD) are defined in the *Shasta County General Plan* (SCAQMD 2004). The analysis of local cumulative impacts is based on both the plan approach, which defines impact thresholds, and the list approach, which identifies projects that may emit pollutants in the same area as the SLWRI. SCAQMD standards for criteria pollutants have been established to limit the emissions of individual projects when considering the cumulative effect of all projects on regional pollutant concentrations. Therefore, a significant direct project impact would also be a cumulatively considerable incremental contribution to a significant cumulative impact.

The 2007 Urban Emissions model (URBEMIS) was used to estimate emissions of pollutants from construction activities. Among the inputs to the model for construction analysis were the types and quantities of construction equipment to be used, along with the hours of use; areas of land to be graded; number of truck trips and trip distances for export of spoils and import of materials; volumes of buildings to be demolished; areas of buildings to be built; and areas of land to be paved. For postconstruction activities, the principal inputs were the number of vehicle trips and average trip distances. The methods and results of this analysis are described in greater detail in Chapter 5, "Air Quality and Climate."

Qualitative Assessments Past, present, and reasonably foreseeable future actions were assessed qualitatively. Information on current and historical conditions was used to evaluate the combined effects of past actions on resource areas and issues. For present and reasonably foreseeable future actions, a list of related actions was compiled. The combined effects of past, present, and reasonably foreseeable future actions were then evaluated with effects of the project.

A large number of past actions have occurred in the study area. These past actions have strongly influenced existing conditions, and some past actions created "legacies" that are still affecting resources. Among the legacies is the sediment released by hydraulic mining and the metal contamination that is still being generated by abandoned mines. The following are the most important combined effects of these past actions:

- Population growth and associated development of socioeconomic resources and infrastructure

- Conversion of natural vegetation to agricultural and developed land uses
- Introduction of nonnative plant and animal species
- Resource extraction (e.g., mining, grazing, and timber harvests)
- Development of water supply, particularly the construction and operation of Shasta Dam, the rest of the CVP, and the SWP

Present projects and reasonably foreseeable future projects include projects that are currently under construction, approved for construction, or in the final stages of formal planning. The present and reasonably foreseeable future actions considered in this analysis of cumulative impacts are those actions located within the primary or extended study area that have been identified as potentially affecting resources that also may be affected by the SLWRI.

A preliminary list of actions was compiled by reviewing available information regarding planned projects (including agency Web sites). Actions were then reviewed for inclusion in the cumulative impacts analysis based on this criteria:

- The action has an identified sponsor actively pursuing project development; the sponsor has completed or issued NEPA and/or CEQA compliance documents such as a DEIS or Draft EIR (DEIR); and the action appears to be “reasonably foreseeable,” given other considerations such as public and stakeholder controversy.
- Available information defines the action in sufficient detail to allow meaningful analysis.
- The action could affect resources that could be potentially affected by the project.
- Any action that could affect resources that would be potentially affected by the project and is under construction was also considered “reasonably foreseeable.”

Based on this review, the effects of the actions described below were considered qualitatively in the assessment of cumulative effects of action alternatives. This list is organized into four categories of actions: water resources, resource management and restoration, levee, and development actions. Some unknown subset of the following projects, though not strictly meeting the criteria above, would likely be implemented, such as the Bay Delta Conservation Plan (BDCP), the North-of-Delta Offstream Storage Facility (Sites Reservoir), and the Upper San Joaquin River Basin Storage Investigation (Temperance Flat Reservoir). For example, the BDCP DEIR/DEIS (DEIR/S), which was released in December 2013, evaluates 15 action alternatives, including a No-Action alternative, and a range of 20 potential conservation measures; a BDCP preferred alternative was not identified in the 2013 BDCP DEIR/S. In August 2014, it was announced that a partially Recirculated Draft BDCP, EIR/S, and Implementing Agreement will be published in early 2015; it is unknown if a preferred alternative will be identified in the BDCP 2015 Recirculated DEIR/S. Therefore, the selection of any one alternative is speculative at this point in time. It would be speculative to consider these projects at any more than a conceptual level because these projects and their effects are not defined in sufficient detail to allow meaningful analysis.

The combined effects of past actions and the list of related present and reasonably foreseeable future projects are described further below.

Qualitative Assessment of Actions Related to Water/Natural Resource Management and Restoration In addition to the water resources actions described above in the section “Quantitative Assessment of Actions Related to Water Resources,” the water/natural resources-related management and restoration actions described below were identified as present or reasonably foreseeable.

Central Valley Project Improvement Act The CVPIA (Title 34, Sections 3401 through 3408(h) of Public Law 102-575) is concerned with restoring anadromous fish populations, providing water supplies for Federal and State refuges, mitigating effects of the CVP on other fish and wildlife, and retiring drainage-impaired farmlands. To fulfill these provisions, the CVPIA established an ongoing program creating a fund for restoration actions. The program is financed by the CVP’s water and power users and administered by Reclamation. Funds are contributed to multiple restoration actions annually to finance restoration of aquatic, riparian, and other habitats and modify CVP operations.

The CVPIA directs the Secretary of the Interior to develop and implement a program that makes all reasonable efforts to double natural production of anadromous fish in Central Valley streams (Section 3406(b)(1)). The general objectives of the CVPIA Anadromous Fish Restoration Program are as follows:

- Improve anadromous fish habitat through physical habitat parameters as well as suitable flow parameters.
- Reduce the entrainment of juvenile fish at diversions.
- Collect fisheries data in a way that provides for the evaluation of restoration actions.
- Integrate restoration efforts with harvest and hatchery management.
- Involve stakeholders in the implementation and evaluation of restoration actions.

The Clear Creek Actions of the CVPIA Anadromous Fish Restoration Program involve modifying flow releases and replenishing gravels in the river downstream from Whiskeytown Dam to enhance spawning, egg incubation, and emigration by spring-, fall-, and late fall-run Chinook salmon. These actions also include gravel restoration, spring flushing, temperature control, and channel maintenance. Additionally, requirements of the Clear Creek Actions – all implemented to benefit anadromous fish habitat – include restoring habitat damaged by gravel mining in the area, decommissioning McCormick-Saeltzer Dam, developing a stream corridor protection program to prevent habitat degradation caused by sedimentation and urbanization, and developing a watershed management and analysis plan.

CVPIA Section 3406. Fish, Wildlife, and Habitat Restoration CVPIA Section 3406 (d) states that "…the Secretary [of the Interior] shall provide, either directly or through contractual agreements with other appropriate parties, firm water supplies of suitable quality to maintain and improve wetland habitat areas on units of the National Wildlife Refuge System in the Central Valley of California; on the Gray Lodge, Los Banos, Volta, North Grasslands, and Mendota state wildlife management areas; and on the Grasslands Resources Conservation District in the Central Valley of California."

Refuge Water Supply Program The goal of the Refuge Water Supply Program (RWSP), which consists of three important components – water acquisitions, conveyance, and facilities' construction, is to ensure that all CVPIA-identified wetland habitat areas (refuges), annually receive water of specified quantity, of suitable flow rate and timing, and suitable quality to support their wetland and aquatic environments. The RWSP serves 19 refuges in the Central Valley.

The RWSP is administered and implemented by Reclamation in close collaboration with the USFWS, Region 8. Reclamation and the USFWS also work cooperatively with the California Department of Fish & Wildlife (CDFW), Grassland Water District (GWD), and the Central Valley Habitat Joint Venture (CVHJV) in implementing the RWSP.

The RWSP delivers two water types defined as Level 2 (L2) water and Incremental Level 4 (IL4) water:

- L2 is the amount of water required for minimum wetlands and wildlife habitat management based on historic average annual deliveries before 1989. Reclamation is required to provide full L2 water supplies annually. The L2 annual water delivery target is 422,251 acre-feet, including 26,007 acre-feet of replacement water. Replacement water was originally provided by tailwater and groundwater but is now included in L2 water supplies due to water quality concerns.

- IL4 water is the difference between L2 and Full Level 4 (L4) water supplies; it equals 133,264 acre-feet.

Full L4 is the total annual amount of water identified for each refuge in CVPIA as required for optimum wetlands and wildlife habitat development and management. The Full L4 water delivery target for the 19 refuges is 555,515 acre-feet and is met when L2 and IL4 water targets are met in full.

The CVPIA specifies that Reclamation must acquire IL 4 water "…through voluntary measures such as water conservation, conjunctive use, purchase, lease, donations, or similar activities, or a combination of such activities which do not require involuntary reallocations of project yield" (CVPIA, Section 3406 (d)(2)). The amount of IL4 water acquired varies from year to year, depending on annual hydrology, water availability, water market pricing, and funding.

To ensure reliability for refuge managers, Reclamation entered into long-term water supply contracts with the three refuge managers: CDFW, USFWS, and GWD. These contracts have performance periods of 25 years and are renewable, representing Reclamation's obligation under CVPIA to provide identified quantities of water to certain refuges in the Central Valley.

From Fiscal Year 2002 – 2013, the RWSP has delivered an annual average of 383,603 acre-feet of L2 water (91 percent of the 422,251 acre-feet target) and 66,588 acre-feet of IL4 water (50 percent of the 133,264 acre-feet target) (Reclamation 2014). Fiscal Year 2002 was the first year that CVPIA mandated Full L4 deliveries for all refuges (CVPIA Section 3406 (d)(2)).

American Basin Fish Screen and Habitat Improvement Project The American Basin Fish Screen and Habitat Improvement Project is a river intake facility, including the fish screen, 434 cfs pumping plant, access bridges, canal connection, irrigation canal, connections to existing canals, and hibernacula and wetlands plantings on and near the Sacramento River completed by the Natomas Central Mutual Water Company as part of CVPIA 3406(b)(21).

CALFED Ecosystem Restoration Program USFWS and NMFS implement CALFED's Ecosystem Restoration Program (ERP) with guidance from the Delta Stewardship Council and the Delta Plan, and in coordination with the Sacramento-San Joaquin Delta Conservancy. The ERP works to improve the ecological health of the San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) watershed by restoring and protecting habitats, ecosystem functions, and native species. Since the program's inception, ERP agencies have identified more than 600 programmatic actions and 119 milestones throughout the Bay-Delta watershed. The program includes all projects authorized, funded, and permitted (even if not constructed) to date, particularly in the Delta, that aim to do any of the following:

- Recover at-risk native species dependent on the Delta, Suisun Bay, and San Francisco Bay
- Minimize the downward population trends of native species that are not listed
- Protect and restore functional habitat types in the Bay-Delta estuary and its watershed for ecological and public values
- Prevent the establishment of additional nonnative invasive species and reduce the negative ecological and economic impacts of established nonnative species in the Bay-Delta estuary
- Improve and/or maintain water and sediment quality conditions that fully support healthy and diverse aquatic ecosystems in the Bay-Delta estuary and watershed

2009 NMFS Biological Opinion Sacramento River Habitat Restoration and Enhancement and Fish Passage Actions The 2009 NMFS BO included RPAs to improve conditions for anadromous fish in the Sacramento River basin. These RPAs included revised water operations, habitat restoration and enhancement actions, and fish passage actions. Water operations defined in RPAs were included, as appropriate, in the modeling evaluations for both existing and future conditions, and therefore were included in cumulative effects analyses. However, the following restoration and enhancement actions and fish passage actions for the Sacramento River and its tributaries were not included in existing or future conditions operations modeling. The actions related to the 2009 NMFS BO described below were identified as present or reasonably foreseeable actions.

Clear Creek Actions Certain Clear Creek RPAs were designed to prevent spring-run Chinook salmon from hybridizing with fall-run Chinook salmon in the Sacramento River. To prevent this hybridization, the following projects have been developed to attract early spring-run adults far upstream in Clear Creek where reservoir holding has maintained cooler water temperatures throughout the summer:

- **Spawning Gravel Augmentation –** This effort includes the continued augmentation of spawning gravels in Clear Creek to enhance spawning habitat for fall-run, late fall-run, and spring-run Chinook salmon as well as steelhead.
- **Spring Creek Temperature Control Curtain –** This project is the replacement of the Spring Creek Temperature Control Curtain in Whiskeytown Lake, in an effort to maintain the Spring Creek Tunnel's releases of cold water to Keswick Reservoir for winter-run Chinook salmon spawning and incubation.

- **Adaptively Manage to Habitat Suitability/Instream Flow Incremental Methodology Study Results –** This action is to develop a state-of-the-art scientific analysis of habitat suitability to enable the continuation of flows adequate for anadromous fish migration and the maintenance of spawning gravels and suitable water temperatures for anadromous fish survival.

Fish Passage Program (Action V) at Shasta and Folsom Dams The elements identified in the Fish Passage Program are near-term and long-term goals to provide passage for Sacramento River winter-run, spring-run, and Central Valley steelhead above Shasta and Folsom dams. Substantial areas of high-quality habitat exist above these dams, with colder water in high-elevation areas that represents a suitable refuge for cold-water fish in the face of climate change. The assessment will develop information necessary for consideration and development of fish passage options for the Basalt and Porous Lava Groups of Central Valley steelhead and spring-run Chinook salmon and Sacramento River winter-run Chinook salmon.

<u>Sacramento River Basin Salmonid Rearing Habitat Improvements</u>
This suite of actions consists of near-term and long-term actions to restore floodplain rearing habitat for juvenile winter-run, spring-run, and Central Valley steelhead in the lower Sacramento River basin. These actions are consistent with Reclamation's broad authorities in the CVPIA. The objective may be achieved at the Yolo Bypass, as part of the BDCP, or among other actions. The following actions in this suite were not included in modeling analyses for existing conditions, the No-Action Alternative, and action alternatives:

- **Restoration of Floodplain Rearing Habitat –** The intent of this action is to restore floodplain rearing habitat for juvenile winter-run, spring-run, and Central Valley steelhead through a substantial increase in acreage of seasonal floodplain rearing habitat.

- **Near-Term Actions at Liberty Island/Lower Cache Slough and Lower Yolo Bypass –** These actions include the steps necessary to enhance the use of Liberty Island/Lower Cache Slough by juvenile salmonids.

- **Lower Putah Creek Enhancements –** These enhancements, to be completed by the end of 2015, include stream realignment and floodplain restoration for fish passage improvement and multispecies habitat development on existing public lands.

Reduction of Migratory Delays and Loss of Salmon, Steelhead, and Sturgeon at Fremont Weir and Other Structures in the Yolo Bypass Actions
This action involves the completion of planning-related and physical modifications that will provide high-quality, reliable migratory passage through

the Yolo Bypass for Sacramento River basin adult and juvenile anadromous fishes. These actions may include steps to provide fish passage by altering Fremont Weir and/or other facility-related or operational requirements of the Sacramento River Flood Control Project or Yolo Bypass facility.

The Water Quality Control Plan for the California Regional Water Quality Control Board: Central Valley Region, the Sacramento River Basin and San Joaquin River Basin The preparation and adoption of water quality control plans (basin plans) is required by the California Water Code (Section 13240) and supported by the Federal CWA. State law also requires that basin plans conform to the policies set forth in the California Water Code, beginning with Section 13000, and any State policy for water quality control. Because beneficial uses, together with their corresponding water quality objectives, can be defined per Federal regulations as water quality standards, the basin plans are regulatory references for meeting the State and Federal requirements for water quality control (Title 40, CFR Section 131.20). The *Water Quality Control Plan for the California Regional Water Quality Control Board: Central Valley Region, the Sacramento River Basin and San Joaquin River Basin* (Basin Plan) covers the entire Sacramento and San Joaquin River basins. The Basin Plan was first adopted in 1975. In 1989, a second edition was published. The third edition, published in 1994, incorporated all amendments approved between 1989 and 1994, included new State policies and programs, edited and restructured the Basin Plan to make it consistent with other regional and State plans, and substantively amended sections dealing with beneficial uses, objectives, and implementation programs. The Basin Plan was last revised in October 2011 (CVRWQCB 2011).

The California Air Resources Board Climate Change Scoping Plan: A Framework for Change The Global Warming Solutions Act of 2006 (Assembly Bill 32) required the California Air Resources Board to prepare a scoping plan to achieve reductions in California's GHG emissions. The scoping plan was originally approved in 2008. In 2011, the Functional Equivalent Document for the scoping plan was amended. The scoping plan, including the final supplement to the Functional Equivalent Document, was reapproved by the California Air Resources Board on August 24, 2011. The scoping plan provides the outline for actions to reduce California's GHG emissions (ARB 2008).

Bay Delta Conservation Plan The BDCP is a long-term multiple purpose plan that consists of a Habitat Conservation Plan and a Natural Community Conservation Plan. DWR is currently developing the BDCP in application for take permits from USFWS and NMFS for Federally listed species in the Delta. The BDCP would also allow for the authorization of take from the CDFW for species covered in the BDCP, including species protected by State law. The BDCP consists of a comprehensive conservation strategy for the Delta that includes conservation measures for new SWP water conveyance facilities combined with adaptive water conveyance operations; conservation, protection, restoration, and enhancement of habitats for native fish, wildlife, and plants in the Delta; and actions related to reducing other stressors on the Bay-Delta ecosystem. The BDCP conservation measures are specific actions that would be implemented to achieve the biological goals and objectives of the proposed plan. The conservation measures and effects assessment related to achieving the BDCP's overall planning goals are incorporated by reference into the December 2013 BDCP DEIR/S (DWR 2013). The BDCP conservation strategy consists of multiple components that are designed to collectively achieve the overall BDCP planning goals of ecosystem health and water supply reliability. The conservation strategy includes biological goals and objectives, conservation measures, avoidance and minimization measures, and monitoring, research, and adaptive management programs. The BDCP would also provide the basis for future Section 7 consultation between Reclamation, USFWS and NMFS over future operations of the CVP.

Four broad concepts have been studied to address urban water quality, water supply reliability, and environmental concerns in the Delta: physical barriers, hydraulic barriers, through-Delta facilities, and isolated facilities. Several alternative Delta conveyance facilities are being evaluated as part of the plan. Depending on the alternative, the water conveyance facility components would create a new conveyance mechanism to divert water from the north Delta to existing SWP and CVP export facilities in the south Delta, interacting with operational guidelines to achieve the planning goal outlined above.

The Draft BDCP and BDCP DEIR/S were made available to the public for a review and comment period, effective December 13, 2013 through July 29, 2014. On August 27, 2014 it was announced that a partially Recirculated Draft BDCP, EIR/S, and Implementing Agreement will be published in early 2015. The recirculated documents will include those portions of each document that warrant another public review before publication of final documents.

Trinity River Mainstem Fishery Restoration Program The Trinity River Mainstem Fishery Restoration Program is located in the CVP service area at Lewiston Dam on the Trinity River. This program is designed to benefit anadromous salmonids and their habitat by developing a properly functioning, diverse floodplain and riverine habitat. The program's plan has two restoration goals: reestablish the natural physical processes that create and maintain high-quality aquatic habitat; and create spawning and rearing conditions downstream from the dams, including adequate water temperatures to best compensate for lost habitat upstream.

The plan includes direct in-channel actions, continued watershed restoration activities, replacement of bridges and structures within the floodplain, and a program to monitor and improve restoration activities. Some of the actions and activities have been implemented and are operational. The pending phases of the projects incorporated into the DEIR encompass work at 29 rehabilitation sites in Trinity County along the 40-mile reach of the mainstem Trinity River from Lewiston Dam to the North Fork Trinity River. The remaining six Phase 1 sites are concentrated between Lewiston and Douglas City (about a 16-mile reach) and the 23 Phase 2 sites are located between Rush Creek and the North Fork Trinity River near Helena, California.

San Joaquin River Restoration Program As described previously (see the discussion of full SJRRP Restoration Flows in "Quantitative Assessment of Actions Related to Water Resources," above), the SJRRP was established based on the 2006 Settlement of the *Natural Resources Defense Council et al., v. Rodgers, et al.* lawsuit. The SJRRP will restore and maintain fish populations in "good condition" in the mainstem San Joaquin River below Friant Dam to the confluence of the Merced River, including naturally reproducing and self-sustaining populations of salmon and other fish; and reduce or avoid adverse water supply impacts on all of the Friant Division long-term contractors that may result from the Interim Flows and Restoration Flows provided for in the Settlement.

The Settlement followed an 18-year lawsuit that involved the U.S. Departments of the Interior and Commerce, the Natural Resources Defense Council, and the Friant Water Users Authority. The Settlement received Federal court approval in October 2006. Federal legislation was passed in March 2009 authorizing Federal agencies to implement the Settlement. The SJRRP consists of releases of water from Friant Dam to the confluence of the Merced River (Interim and Restoration flows), a combination of channel and structural modifications along the San Joaquin River below Friant Dam, and reintroduction of Chinook salmon (Reclamation and DWR 2012). The SJRRP's channel and structural modifications include modifications to channel and flow-control structures and habitat along the San Joaquin River and Lower San Joaquin Flood Control Project between Friant Dam and the Merced River confluence. They also involve actions to support the water management goal of the Settlement, including constructing and operating new infrastructure to facilitate the recapture of Restoration releases to the San Joaquin River below the confluence of the Merced River.

Sacramento River Conservation Area Forum Program The nonprofit Sacramento River Conservation Area Forum works to protect, restore, and enhance the fisheries and riparian habitat along the Sacramento River in the primary and extended study areas, from Keswick Dam downriver to Verona. This is a cooperative effort to ensure that habitat restoration and management addresses not only the dynamics of riparian ecosystems, but also the realities of local agricultural and recreational issues associated with land use changes occurring along the river. The program (Resources Agency 2003) has goals to protect, restore, and enhance fisheries and riparian habitat along the Sacramento River and its tributaries. The Sacramento River Conservation Area Forum develops and implements site-specific and subreach plans for areas within the conservation area.

Iron Mountain Mine Restoration Plan The Iron Mountain Mine Restoration Plan identifies restoration actions to address injuries to or lost use of natural resources caused by acid mine drainage from the Iron Mountain Mine complex, located west of the upper Sacramento River in the primary study area. The plan involves restoring salmonid populations, riparian habitat, and instream ecological functions, as well as implementing restoration projects to compensate for the lost use of public areas and public services. The aquatic and riparian habitats affected by releases of hazardous substances at or from the Iron Mountain Mine site include the site's creeks (Boulder, Slickrock, Flat, and Spring) and the mainstem and tributaries of the Sacramento River from Keswick Reservoir to Red Bluff. As additional compensation for damage to natural resources, this project includes an option for the Federal government to acquire approximately 1,250 acres to be transferred into public ownership and administered by the U.S. Department of the Interior, Bureau of Land Management (BLM) (IMMTC 2002; NOAA 2009). The Iron Mountain Mine Trustee Council has allocated funds to several projects designed to meet the goals of the *Iron Mountain Mine Restoration Plan*.

Lower Deer Creek Falls Fish Passage Improvement Project The Lower Deer Creek Falls Fish Passage Improvement Project will improve access to 5.75 stream miles for fall-run, late fall-run, and spring-run Chinook salmon as well as steelhead. Work is under way by Deer Creek Irrigation District, DWR, and CDFW to develop an environmental flow enhancement program in lower Deer Creek. The goal of the program is to increase fish transportation flows downstream from Deer Creek Irrigation District. More than 25 miles of prime spawning habitat are available upstream from the Deer Creek Irrigation District diversion dam. Detailed topographic surveys of the area and preliminary engineering investigations have been suspended until additional funding becomes available.

Battle Creek Salmon and Steelhead Restoration Project The intent of the Battle Creek Salmon and Steelhead Restoration Project is to create habitat that can sustain additional populations of winter-run Chinook salmon to minimize the species' high risk of extinction. Upon its completion, the project will have reestablished approximately 42 miles of prime salmon and steelhead habitat on Battle Creek, plus an additional 6 miles on its tributaries; removed several hydroelectric dams; and developed and implemented a long-term adaptive management plan with dedicated funding sources to ensure the continued success of restoration efforts. The project is to be completed no later than 2019.

Butte Regional Conservation Plan The Butte Regional Conservation Plan (BRCP) is both a Federal habitat conservation plan and a State natural communities conservation plan. The BRCP, a voluntary plan coordinated by the Butte County Association of Governments, covers approximately the western half of Butte County, including all of the county's vernal pool landscapes. The BRCP will provide streamlined ESA permitting for transportation projects, land development, and other covered activities over the 30- to 50-year term of the permits. It will also provide comprehensive species, wetlands, and ecosystem conservation and contribute to the recovery of endangered species within the plan area.

The development of the BRCP is a complex multiyear effort that will replace the existing environmental permitting process. The release of the BRCP and EIS/R for public review is scheduled for fall 2014. The formal public draft BRCP and EIS/R were submitted to the USFWS regional office in April 2014 for review.

North-of-Delta Offstream Storage Investigation The North-of-Delta Offstream Storage Investigation is a feasibility study being performed by Reclamation and DWR, in partnership with local interests. Pursuant to the CALFED solution principles, storage locations that would not add a new dam on a major stream were considered and evaluated. As its name indicates, the North-of-Delta Offstream Storage Investigation focuses on offstream storage north of the Delta – specifically, potential projects for offstream storage of surface water at Sites Reservoir in the Sacramento River basin.

Offstream storage located north-of-the-Delta would require conveying water from the Sacramento River or one of its major tributaries to the new storage location. An offstream storage conveyance system could use either existing diversions and canals or new diversions and conveyance. Water would be diverted during periods of relatively higher flow through the conveyance system, into the new offstream storage reservoir, and stored until it is needed to meet the planning objectives.

Such storage could increase water supply reliability for all beneficial uses (agricultural, urban, and environmental). The Sites Reservoir Project could contribute to cumulative effects on water supplies and associated resources. The project could increase water supplies available for export in years when export supplies otherwise would be limited. This project also could modify the timing and magnitude of upstream reservoir releases in wet years.

A notice of intent/notice of preparation for this project was issued in November 2001 and public scoping for the environmental document occurred in January 2002. The complete plan formulation report was published in September 2008 and the Final EIS/R and Feasibility Report are anticipated for release in 2014.

Fremont Landing Conservation Bank The 100-acre Fremont Landing Conservation Bank in Yolo County functions as a mitigation bank providing credits for riparian floodplain forest or shaded riverine aquatic habitat. The mitigation bank serves portions of Tehama, Shasta, Glenn, Butte, Colusa, Sutter, Yuba, Yolo, Placer, Solano, Sacramento, Amador, Contra Costa, San Joaquin, Calaveras, Alameda, Stanislaus, Tuolumne, Merced, and Mariposa counties. Credits may be designated to provide habitat for special-status anadromous salmonids – Sacramento River winter-run, Central Valley spring-run, and Central Valley fall/late fall-run Chinook salmon as well as Central Valley steelhead. NMFS approved the site as part of an umbrella agreement that covers several Central Valley mitigation banking sites (Conservation Fund 2010). A mitigated negative declaration was issued in 2009 (BDCP 2012).

Yuba Salmon Forum Fish Passage Studies (Upper Yuba River Studies Program) The purpose of the Yuba Salmon Forum Fish Passage Studies is to take two sets of actions concurrently: (1) identify, evaluate, recommend, and seek to achieve implementation of effective near-term and long-term actions to achieve viable salmonid populations in the Yuba River watershed to contribute to recovery goals; and (2) consider other beneficial uses of water resources and habitat values in neighboring watersheds, as part of Central Valley salmonid recovery actions. The Yuba Salmon Forum adopted the *Draft Yuba River Salmon Forum Studies* on June 24, 2011. These six studies provide information to Yuba Salmon Forum members that they may find useful in making decisions about the introduction of anadromous salmonids (Chinook salmon (*Oncorhynchus tshawytscha*) and central Valley steelhead (*O. mykiss*)) into the Yuba River basin upstream from USACE's Englebright Dam. The Forum's Technical Work Group also completed the *Assessment of Infrastructure and Related Items to Support Anadromous Fish Passage to the Yuba River Watershed* in March 2013.

Davis-Woodland Water Supply Project The Davis-Woodland Water Supply Project will replace deteriorating groundwater supplies with safer, more reliable surface water supplies from the Sacramento River. The three primary objectives of the project are to provide a reliable water supply to meet existing and future needs, to improve water quality for drinking water supplies, and to improve the quality of treated wastewater effluent discharged by the project partners (the Cities of Woodland and Davis and the University of California, Davis) through 2040. Once complete, the project will serve more than two-thirds of the urban population of Yolo County.

Project plans include a jointly owned and operated intake on the Sacramento River, raw-water pipelines connecting the intake to a new regional water treatment plant, and separate pipelines delivering treated water to the project partners. Improvements to existing water supply systems will vary for Woodland and Davis and will include facilities such as distribution pipelines, water storage tanks, and booster pump stations.

The project will divert up to 45,000 acre-feet of water per year from the Sacramento River. Water rights were granted in March 2011 and will be subject to conditions imposed by the State. Water diversions will be limited during summer and other dry periods. A more senior water right for 10,000 acre-feet was purchased to provide summer water supply. Groundwater will continue to be used by Woodland and Davis when demand for water cannot be met by surface water supplies alone. The regional water supply project is currently under construction and operations are anticipated beginning in 2017.

North Bay Aqueduct Alternative Intake Project DWR proposes to implement the North Bay Aqueduct Alternative Intake Project to improve water quality and to provide reliable deliveries of SWP supplies to its contractors, the Solano County Water Agency and the Napa County Flood Control and Water Conservation District. This proposed project would include the construction and operation of an alternative intake on the Sacramento River, generally upstream from the Sacramento Regional Wastewater Treatment Plant, and connect it to the existing North Bay Aqueduct system by a new segment of pipe. The proposed alternative intake would be operated in conjunction with the existing North Bay Aqueduct intake at Barker Slough. The North Bay Aqueduct Alternative Intake Project would include the following facilities:

- A new alternative intake structure and pump station on the Sacramento River with state-of-the-art, positive-barrier fish screens
- A new pipeline segment to convey the water from the alternative intake to a point of connection with the existing North Bay Aqueduct near the North Bay Regional Water Treatment Plant
- Other project-related support facilities such as surge tanks

The notice of preparation for the North Bay Aqueduct Alternative Intake Project EIR was published in November 2009 (DWR 2009). A scoping report was released in February 2010 (ESA 2010). It is anticipated that the public review DEIR will be available in 2014.

Lower Clear Creek Anadromous Fish Restoration and Management Project The anadromous fish restoration and management actions of the Lower Clear Creek Anadromous Fish Restoration and Management Project will occur on public and private lands in the lower Clear Creek watershed, located west of Redding in Shasta County.

Beginning in the early 1990s, multiple Federal, State, and local agencies and private stakeholder groups concerned about lower Clear Creek began to plan and implement watershed restoration activities to reverse the effects of Whiskeytown Dam, Saeltzer Dam, placer and dredger gold mining, instream aggregate mining, road-related erosion, and decades of fire suppression. Since that time, the groups that formed the Clear Creek Restoration Team have implemented multiple resource inventories and restoration projects, including dam removal, gravel augmentation, flow augmentation, channel and floodplain restoration, erosion control, fuels reduction, and control of nonnative vegetation.

North Delta Flood Control and Ecosystem Restoration Project DWR certified the EIR for the North Delta Flood Control and Ecosystem Restoration Project in 2010 and filed a notice of determination with the Governor's Office of Planning and Research on November 9, 2010. This project will implement flood control improvements in the north Delta, principally on and around McCormack-Williamson Tract, Dead Horse Island, and Grizzly Slough, in a manner that benefits aquatic and terrestrial habitats, species, and ecological processes. Flood control improvements are needed to reduce damage to land uses, infrastructure, and the Bay-Delta ecosystem caused by catastrophic levee failures in the Delta.

Two-Gates Fish Protection Demonstration Project Reclamation is currently studying the proposed Two-Gates Demonstration Project, a 5-year experiment to validate a new behavioral model for delta smelt and study the effects of modifying Delta flows to protect delta smelt and other sensitive aquatic species from entrainment in CVP and SWP export pumps. Research suggests that the pre-spawning migration of adult delta smelt is tied to sediment and suspended particles in the water (turbidity). Temporary gates would be placed across Old River and Connection Slough in the central Delta. These gates would operate at two times of year: from December to March, to keep turbid water away from the CVP and SWP export pumps, thus keeping adult delta smelt away from the pumps; and in March and June, to prevent entrainment of larvae and juvenile delta smelt by the export pumps.

Franks Tract Project Reclamation and DWR propose to implement the Franks Tract Project to improve water quality and fisheries conditions in the Delta. Reclamation and DWR are evaluating installing operable gates to control the flow of water at key locations (Threemile Slough and/or West False River) to limit the entry of fish species of concern and higher salinity water into Franks Tract and other areas of the Delta with high fish mortalities. In addition to improving water quality, the gates would limit migration of delta smelt into the central and south Delta, where their survival rates are reduced. By protecting fish resources, this project also would improve the operational reliability of the CVP and SWP because curtailments (pumping restrictions) in project operations would likely be less frequent.

A plan of study for the Franks Tract Project was completed in August 2007. The notice of intent was published September 22, 2008, the Initial Alternatives Information Report was completed in February 2010, and the Plan Formulation Report was completed in 2013. The project is still under consideration by Reclamation and DWR.

Dutch Slough Tidal Marsh Restoration Project This proposed project is a cooperative partnership between DWR, CALFED, the California Coastal Conservancy, landowners, the Natural Heritage Institute, the City of Oakley, Ironhouse Sanitary District, and private consultants. The project entails restoring wetlands and uplands and providing public access to the 1,166-acre Dutch Slough property owned by DWR. The property comprises three parcels, separated by narrow human-made sloughs, that were historically used for agricultural uses and grazing.

The primary goal of the Dutch Slough Tidal Marsh Restoration Project is to provide ecosystem benefits, including habitats for sensitive aquatic species. The project will be designed to maximize opportunities to assess the development of those habitats and measure ecosystem responses so that future Delta restoration projects will be more successful. This proposed project also provides an important opportunity to improve planners' understanding of restoration science in tidal marsh wetland ecosystems in the region (DWR 2010). Construction is scheduled to begin in summer 2014 with levee breaching anticipated in 2015.

Suisun Marsh Management, Preservation, and Restoration Plan Federal and State agencies jointly developed this comprehensive 30-year regional plan to address the use of resources on about 52,000 acres of wetland and upland habitats in Suisun Marsh near Fairfield. The focus of the *Suisun Marsh Management, Preservation, and Restoration Plan* is to achieve an acceptable multiple-stakeholder approach to the restoration of tidal wetlands and the enhancement of managed wetlands and their functions. The plan balances implementation of the CALFED Program, the Suisun Marsh Preservation Agreement, and other management and restoration programs for Suisun Marsh and is based on voluntary participation by private landowners.

DWR and Reclamation have collaboratively prepared the environmental documents with NMFS, CDFW, and the Suisun Resource Conservation District. The notice of intent/notice of preparation was published in November 2003. The Final EIS/R was made available in December 2011 (DOI et al. 2011) and the ROD was signed in April 2014.

In-Delta Storage Program (Delta Wetlands Project) DWR, in coordination with the California Bay-Delta Authority and with technical assistance from Reclamation, completed the State feasibility study for the In-Delta Storage Program in the south Delta, within the extended study area. The In-Delta Storage Project would provide capacity to store approximately 217 thousand acre-feet of water in the south Delta for a wide array of water supply, water quality, and ecosystem benefits. The project would consist of two storage islands (Webb Tract and Bacon Island) and two habitat islands (Holland Tract and Bouldin Island), an embankment design, consolidated inlet and outlet structures, project operations, and habitat management plans. The objectives of the project are to enhance water supply reliability and the operational flexibility of the CVP/SWP system, contribute to ecosystem restoration, and provide water for the Environmental Water Account (DWR 2011b). Detailed planning work by the State on the In-Delta Storage Project has been suspended since July 2006 when State funding was cut (DWR 2011b); however, a Final EIR was certified in 2012 by Semitropic Water Storage District and other environmental documentation is under way.

Los Vaqueros Reservoir Expansion Project Los Vaqueros Reservoir was completed in 1997 to provide 100,000 acre-feet of offstream water storage to improve water quality and provide emergency storage for Contra Costa Water

District (CCWD) customers. The purpose of this project is to enhance the Delta environment and improve the San Francisco Bay Area's (Bay Area) water supply reliability and water quality by developing water supplies for environmental water management and helping to meet municipal and industrial water demands during drought and emergency periods by expanding the existing reservoir.

To date, the project has consisted of an expansion of Los Vaqueros Reservoir from 100,000 acre-feet to 160,000 acre-feet, which required a dam raise, the relocation of recreation facilities, and an upgrade of the pumps at the Transfer Pump Station. The dam raise to 160,000 acre-feet was completed in 2012 and mitigation activities are scheduled for completion in 2013. Los Vaqueros Reservoir could be further expanded up to a total of 500,000 acre-feet. New Delta intakes, pumps, and pipelines would be required to fill the additional reservoir capacity, and water deliveries would be made from the expanded reservoir to Bay Area beneficiaries through new conveyance facilities.

Completion of the Draft Federal Feasibility Report is planned for 2014 and a final report is to be completed in 2015. A final decision on further expansion of the reservoir beyond 160,000 acre-feet is expected to occur in 2016, depending on the level of participation by other Bay Area water agencies, Reclamation, and DWR. Project implementation will also consider the CCWD Board Principles and the additional assurances, commitments, and requirements adopted by the CCWD Board on June 25, 2003.

East Bay Municipal Utility District Water Supply Management Program 2040 The Water Supply Management Program 2040 (WSMP 2040) is a program-level effort that estimates EBMUD's water supply needs over a 30-year planning horizon and proposes a diverse portfolio of policy initiatives and potential projects to ensure that those needs can be met in dry years. On October 13, 2009, the EBMUD Board of Directors approved the WSMP 2040. The CEQA analysis was challenged in court, and in a ruling issued on April 11, 2011, EBMUD was directed to analyze certain plan components in more detail. On May 24, 2011, the EBMUD Board set aside certification of the WSMP 2040 Program EIR and directed staff members to revise the program. That revision effort has since been completed, and on April 24, 2012, the EBMUD Board of Directors certified the revised program EIR and adopted the revised final plan for the WSMP 2040 (EBMUD 2012).

Bay Area Regional Desalination Project The Bay Area's largest water agencies (CCWD, EBMUD, the San Francisco Public Utilities Commission, the Santa Clara Valley Water District, and the Alameda County Flood Control and Water Conservation District – Zone 7) are working together to develop a regional desalination project to serve the needs of more than 5.6 million residents and businesses in the region. The project under consideration would use water from the Delta withdrawn at CCWD's Mallard Slough Pump Station, located in eastern Contra Costa County, to produce 20 million gallons per day of desalinated water for delivery to residential and business customers in the region. Water produced by this project could be blended with supplies from CCWD, EBMUD (Mokelumne Aqueduct), or both. Other parties would receive project water through transfers or wheeling. The water from the Bay Area Regional Desalination Project could be fully treated (two-pass reverse osmosis) or require further treatment (one-pass reverse osmosis), depending on the delivery point into either the CCWD or EBMUD system. The project would operate continuously in all water year types, with the possibility of storing water (including by exchange or transfer) in CCWD's Los Vaqueros Reservoir when demand is less than plant capacity.

Upper San Joaquin River Basin Storage Investigation (Temperance Flat Reservoir) The Upper San Joaquin River Basin Storage Investigation is a feasibility study being performed by Reclamation and DWR. The purpose of the Upper San Joaquin River Basin Storage Investigation is to determine the type and extent of Federal, State, and regional interests in a potential project in the upper San Joaquin River watershed with the following goals: expand water storage capacity; improve water supply reliability and flexibility for agricultural, urban, and environmental uses; and enhance San Joaquin River water temperature and flow conditions to support efforts for anadromous fish restoration. This investigation is one of five surface water storage studies recommended in the August 2000 Programmatic ROD for the CALFED Final PEIS/R. A plan formulation report for the project was released in October 2008 (Reclamation and DWR 2008). A public draft feasibility report was released in early 2014.

San Luis Drainage Reevaluation Program The San Luis Unit (drainage study area) was authorized by Congress in Public Law 86-488 (74 Statutes 156), June 3, 1960, and amended by Section 101(e) of the Act of October 18, 1986, Public Law 99-500. The project purpose is to provide agricultural drainage service to the San Luis Unit to achieve a long-term, sustainable salt and water balance in the root zone of irrigated lands in the San Luis Unit and adjacent areas. Of the 730,000 acres in the drainage study area, about 379,000 acres are drainage-impaired and constitute the drainage service area. Reclamation estimates that installing subsurface drainage systems in two-thirds of this area by the end of the 50-year planning horizon would maintain the arability of the root zone throughout the entire 379,000 acres. The alternatives are the In-Valley/Drainage-Impaired Area Land Retirement Alternative and the In-Valley/Water Needs Land Retirement Alternative. Common features proposed for both alternatives are a drainage collection system, regional drainage reuse facility, conveyance system, selenium biotreatment, evaporation ponds, mitigation facilities, and land retirement.

Central Valley Salinity Alternatives for Long-Term Sustainability (CV-SALTS) The CV-SALTS initiative is a collaborative effort among 26 stakeholder groups to realize reductions in salt accumulation in the Central Valley. These groups represent a broad coalition of agriculture, municipalities, industry, and regulatory agencies. Represented by the Central Valley Salinity Coalition, they are working with the Central Valley Regional Water Quality Control Board (CVRWQCB) to address the valley's salinity problems. The goal of the CV-SALTS initiative is to adopt long-term solutions to salt management that will enhance water quality and economic sustainability in the valley. The CV-SALTS initiative has completed pilot studies on the sources and effects of salts in 13 percent of the affected areas; working in partnership with Reclamation, it will complete salts studies for the east and west sides of the San Joaquin River.

San Joaquin River at Vernalis Salt and Boron TMDL and Basin Plan Amendment The CV-SALTS stakeholder initiative was created to develop new approaches to protect soils and water from salt that has been slowly and steadily accumulating in the San Joaquin River watershed. The CV-SALTS stakeholder initiative will initiate a research effort that will review and determine the appropriate salinity concentration for the San Joaquin River to maintain all of the beneficial uses of the river. Reclamation is currently collaborating with CV-SALTS and the Regional Water Board to implement a real-time salinity management system that will satisfy the TMDL requirement for San Joaquin River salinity concentration.

B. F. Sisk Dam Corrective Action Project B.F. Sisk Dam (also known as San Luis Dam) is a 300-foot-high, compacted earthfill embankment located on the west side of the Central Valley approximately 12 miles west of Los Banos. Owned by Reclamation and operated by DWR, the dam is more than 3.5 miles long. B.F. Sisk Dam impounds San Luis Reservoir, which has a total capacity of more than 2 million acre-feet. The dam was built between 1963 and 1967 to provide supplemental storage of irrigation water for the CVP and municipal and industrial water for the SWP. The Gianelli Pumping-Generating Plant lifts water from both the California Aqueduct and the Delta-Mendota Canal (via O'Neill Forebay) into San Luis Reservoir for storage.

The dam and reservoir are located in an area of high potential for severe earthquakes on active faults, primarily the Ortigalita Fault, which crosses the reservoir. A series of studies and analyses that culminated in a seismic-risk analysis completed in 2006 found justification to act to reduce the risk to the downstream public of seismic damage to the dam. The current phase of the Safety of Dams project is referred to as a corrective action study and is ongoing. The study will include feasibility-level designs, environmental documentation, selection of a preferred alternative, and a modification report to the Federal Office of Management and Budget and the U.S. Congress.

San Luis Reservoir Low Point Improvement Project Reclamation is investigating 3 alternatives to address water quality problems within the CVP's San Felipe Division (Santa Clara and San Benito counties) that arise when San Luis Reservoir levels drop below 300 thousand acre-feet during late summer in dry water years, resulting in large algal blooms. Santa Clara Valley Water

District has proposed the San Luis Reservoir Low Point Improvement Project to maintain a high-quality, reliable, and cost-effective water supply for the water district and other contractors of the San Felipe Division. Santa Clara Valley Water District wants to ensure that it and other San Felipe Division contractors receive their annual CVP contract allocations at the time and the level of quality needed to meet water supply commitments. The project objectives are as follows:

- Avoid supply interruptions when water is needed by increasing the certainty of meeting the requested delivery schedule throughout the year to south-of-Delta contractors dependent on San Luis Reservoir.
- Increase the reliability and quantity of yearly allocations to south-of-Delta contractors dependent on San Luis Reservoir.
- Minimize the downward population trends of native species that are not listed.
- Announce higher allocations earlier in the season to south-of-Delta contractors dependent on San Luis Reservoir without sacrificing accuracy of the allocation forecasts.

Shasta-Trinity National Forest Land and Resource Management Plan The Shasta-Trinity National Forest Land and Resource Management Plan (LRMP) was most recently revised in 1995 (USFS 1995). This document is revised every 10–15 years; it supersedes any previous forest plans, timber management plans, or National Recreation Area (NRA) plans. This is a forest-wide land use plan developed to guide resource management within the forest. It contains the goals and objectives for Shasta-Trinity National Forest, its standards and guidelines, management prescriptions to be applied to land areas, and management area direction. It also sets forth requirements for monitoring and implementation of the plan. The allocations associated with this plan not only reflect the capability and suitability of the land for various uses, but also respond to the public issues (such as recommendations for wild and scenic river designations) and development opportunities identified during the planning process.

Mendocino National Forest Land and Resources Management Plan The management direction, objectives, and standards and guidelines of the Mendocino National Forest LRMP are applicable to an isolated 488-acre parcel of land managed by the Mendocino National Forest along the east bank of the Sacramento River in the general vicinity of the decommissioned Red Bluff Diversion Dam. In addition to a developed recreation area (Sycamore Campground), this parcel provides river access, habitat for special-status species and undeveloped open space used by the public for hiking, biking, and other recreational activities.

Qualitative Assessment of Actions Related to Flood Management The actions related to flood management described below were identified as present or reasonably foreseeable.

Central Valley Flood Protection Plan Legislation passed in 2007 directs DWR to develop three documents that will guide improvement of integrated flood management:

- *State Plan of Flood Control Descriptive Document* to inventory and describe the flood management facilities, land, programs, conditions, and mode of operations and maintenance for the State/Federal flood protection system in the Central Valley.
- *Flood Control System Status Report* to assess the status of the facilities included in the State Plan of Flood Control Descriptive Document, identify deficiencies, and make recommendations.
- *Central Valley Flood Protection Plan* (CVFPP) to describe a sustainable, integrated flood management plan that reflects a systemwide approach for protecting areas of the Central Valley that currently receive protection from flooding by existing facilities of the State Plan of Flood Control. It is supported by the *State Plan of Flood Control Descriptive Document*, the *Flood Control System Status Report*, and the *CVFPP Final Program Environmental Impact Report*.

The CVFPP is a sustainable, integrated flood management plan that describes the existing flood risk in the Central Valley and recommends actions to reduce the probability and consequences of flooding. Produced in partnership with Federal, tribal, local, and regional partners and other interested parties, the CVFPP also identifies the mutual goals, objectives, and constraints important in the planning process; distinguishes plan elements that address mutual flood risks; and recommends improvements to the State/Federal flood protection system. The 2012 CVFPP was completed by DWR and adopted by the Central Valley Flood Protection Board in July 2012 (DWR 2012). It is currently being implemented through two basin-wide feasibility studies for the Sacramento and San Joaquin river basins, respectively.

CALFED Levee System Integrity Program DWR, CDFW, and USACE implement the CALFED Levee System Integrity Program, which maintains and improves the integrity of the Bay-Delta estuary's levee system. The goal of the Levee System Integrity Program is to reduce risks to land use and associated economic activities, water supply, agricultural and residential uses, infrastructure, and the ecosystem from the effects of catastrophic breaching of Delta levees. Resources protected by the program include water quality, ecosystem health, infrastructure such as utilities and transportation corridors, agriculture, and recreational industries.

Protection and maintenance of nearly 700 miles of Delta levees has increased since 2000. Maintenance has been ongoing along more than 600 miles of eligible project and nonproject levees, and levee stability has been improved for more than 45 additional miles of levees. Large levee rehabilitation projects have been undertaken on numerous islands. Projects have also been implemented to grow native vegetation, reuse more than 2 million cubic yards of dredged material for levee stability and habitat development, and develop approximately 50 acres of riparian and wetland habitat and 3,000 linear feet of shaded riverine aquatic habitat (CALFED 2011).

Sacramento River Bank Protection Project The Sacramento River Bank Protection Project is a continuing construction project authorized by Section 203 of the Flood Control Act of 1960. USACE is responsible for implementation of this project in conjunction with its non-Federal partner, the Central Valley Flood Protection Board. The project's purpose is to provide protection to the existing levee and flood control facilities of the Sacramento River Flood Control Project. The project is to be completed in three phases. To date, a total of about 820,000 feet of riverbank has been stabilized under the project. During Phase III, USACE and the Central Valley Flood Protection Board will consider multiple objectives – not only controlling bank erosion, but also addressing other threats to the flood risk management system such as through-seepage, underseepage, and levee height deficiencies, while providing ecosystem restoration. Implementing Phase III will be critical to ensure that project levees seriously threatened by erosion will continue to receive corrective measures to prevent levee failure, catastrophic damage, and possible loss of life. Planning and development of Phase III began recently and will include a comprehensive sediment study, a thorough economic analysis, continued biological studies, a comprehensive cultural resources survey, a detailed real estate plan, and an updated mitigation site inventory.

Folsom Dam Joint Federal Project Folsom Dam regulates flows in the American River for flood control, and releases from Folsom Reservoir are used for irrigation, power, municipal and industrial, fish and wildlife, water quality, and other purposes. The "Folsom Facility" comprises Folsom Dam and Reservoir, left and right earthfill wing dams, Mormon Island Auxiliary Dam, and eight earthfill dikes that protect the surrounding communities, Folsom and Granite Bay.

The Folsom Joint Federal Project is a collaborative effort by Reclamation and USACE to address the hydrologic risk related to dam safety at the Folsom Facility, and to improve flood protection. This project includes construction of a new auxiliary spillway southwest of the existing main concrete dam. When completed in 2017, the auxiliary spillway will include a 1,000-foot-long approach channel beginning in Folsom Reservoir, a concrete control structure with 6 gates, a 2,100-foot-long auxiliary spillway chute, and a stilling basin that will act as an energy dissipation structure as water discharges enter the American River below the main concrete Folsom Dam. The new facility will allow Reclamation's dam operators to better manage large floods by safely releasing more water from Folsom Reservoir earlier during a large storm through both the spillway gates on Folsom Dam and the new control structure's six gates, thus reducing hydrologic risk and leaving more storage capacity in the reservoir. The Folsom Joint Federal Project also includes improvements to appurtenant structures, including several dikes and Mormon Island Auxiliary Dam. Construction on the appurtenant structures began in December 2007 and is expected to be completed in late 2017.

Natomas Levee Improvement Program Landside Improvement Project The Sacramento Area Flood Control Agency, acting in conjunction with USACE, is implementing the multiple-phase Natomas Levee Improvement Program Landside Improvements Project along the lower Sacramento River in the extended study area. The project involves improving the perimeter levee system of the Natomas basin in Sutter and Sacramento counties and modifying associated landscaping and irrigation/drainage infrastructure. The project objectives are to provide at least a 100-year level of flood protection to the Natomas basin as quickly as possible, provide "200-year" protection to the basin over time, and avoid any substantial increase in expected annual damages as new development occurs in the basin (SAFCA 2007, 2010).

Multiple CEQA and NEPA documents have been issued by the Sacramento Area Flood Control Agency and USACE for various phases of this project since 2008. The Final EIS for Phase 4a of the project was issued by USACE in February 2010. Some phases of the project have been completed. Further construction and completion of the project is contingent on Federal funding.

West Sacramento Levee Improvement Program The West Sacramento Levee Improvement Program involves constructing improvements to the levees that protect West Sacramento to meet local and Federal flood protection criteria. The program area includes the entire boundaries of the West Sacramento Area Flood Control Agency, which encompass portions of the Sacramento River, the Yolo and Sacramento bypasses, and the Sacramento Deep Water Ship Channel. The levee system associated with these waterways includes more than 50 miles of levees in Reclamation Districts 900, 537, and 811; DWR's Maintenance Area 4; and the Sacramento Deep Water Ship Channel. These levees completely surround West Sacramento. The Final EIS/R for the West Sacramento Levee Improvements Program has been completed (City of West Sacramento 2012). Construction began in 2008 and is ongoing.

Delta Islands and Levees Feasibility Study The Delta Islands and Levees Feasibility Study is USACE's mechanism to participate in a cost-shared solution to address ecosystem restoration needs, flood risk management problems, and related water resources in the Delta and Suisun Marsh area. A Feasibility Cost Share Agreement was executed on May 26, 2006 with DWR, the non-Federal sponsor. The USACE-DWR study team meets regularly to move the study forward and holds periodic agency coordination meetings with associated Federal, State, and local agencies. The study will culminate in a feasibility report that will make recommendations on construction projects and/or additional studies for authorization by Congress (USACE 2012). The project is on USACE's priority list and the scope is currently being revised.

Qualitative Assessment of Actions Related to Energy The actions related to energy that are described below were identified as present or reasonably foreseeable.

Increased Hydropower Generation Capacity at Lewiston Dam In March 2011, the U.S. Department of the Interior released the results of an internal study that shows it could generate up to 1,000 gigawatt-hours of electricity annually by adding hydropower capacity at 70 of its existing dams, canals, tunnels, and other water-handling facilities. The report, *Hydropower Resource Assessment at Existing Reclamation Facilities*, studied 530 sites throughout Reclamation's jurisdiction and preliminarily identified the 70 facilities with the most potential to add hydropower. The Trinity Public Utilities District and Reclamation intend to boost the power-generating capacity at the Lewiston Dam from the existing 350 kilowatts. This upgrade would allow for better control of the flow from the dam to the river, and would provide an increase in revenue from power generation (Reclamation 2011).

Federal Energy Regulatory Commission Project Licensing The Federal Energy Regulatory Commission (FERC) regulates non-Federal hydropower projects. FERC is responsible for the issuance of licenses for new hydropower projects, the continuance of existing projects (relicensing), and oversight of all ongoing project operations. Ongoing operations include dam safety inspections and environmental monitoring. Additionally, FERC may issue a preliminary permit for up to 3 years, which does not authorize construction but maintains the priority of application for license while the permittee studies the site and prepares to apply for a license. The permittee must submit periodic reports on the status of its studies. It is not necessary to obtain a permit to apply for or receive a license.

Shasta Dam is a Federal project and thus is not subject to FERC oversight; however, numerous hydropower projects in the primary and extended study areas are subject to this oversight and permitting process.

Pacific Gas & Electric Company Pit River 3, 4 & 5 Hydroelectric Projects License Implementation The Pit River 3, 4 & 5 Hydroelectric Projects' license implementation involves three developments with a total of four dams, four reservoirs, and three powerhouses. Pit River 3, 4 & 5 is a 312.33-megawatt project located on the Pit River (the Sacramento River's largest tributary) that occupies 4,330 acres of both publicly owned and privately owned land.

Pacific Gas & Electric Company McCloud and Pit Rivers 6 and 7 FERC Relicensing The McCloud and Pit Rivers 6 and 7 FERC Relicensing includes the McCloud and Iron Canyon storage reservoirs, the Pit River 6 and 7 regulating reservoirs, the Pit 7 afterbay, two tunnels, three powerhouses, and transmission facilities. In 2010, the FERC Final EIS recommended the relicensing of the McCloud-Pit hydroelectric project, a total of 382 megawatt-hours, on the McCloud and Pit rivers in Shasta County. The McCloud and Pit 6, 7 is currently being operated under a preliminary permit.

California Department of Water Resources Oroville Facilities FERC Relicensing The 762-megawatt project is located on the Feather River in Butte County and occupies 6,240 acres of Federal lands. The Final EIR and notice of determination were issued in July 2008. The Final EIS was issued in May 2007 (DWR 2007). DWR is currently undergoing the relicensing process with FERC and operating under annual licenses.

Sacramento Municipal Utility District Upper American River Project FERC Relicensing The Sacramento Municipal Utility District's Upper American River Project is a hydroelectric facility located on the western slope of the Sierra Nevada. The facility is composed of several reservoirs and powerhouses located along streams and rivers within the American River basin. The FERC relicensing included the Iowa Hill Pumped Storage Development, a 400-megawatt pumped storage generating facility using the Slab Creek Reservoir as the lower reservoir and a new reservoir to be located on the top of Iowa Hill. The size of the Iowa Hill reservoir is under consideration and will range from 2,100 to 6,400 acre-feet.

Qualitative Assessment of Actions Related to Land Use Planning and Infrastructure Land use plans and policies are described in Chapter 17, "Land Use and Planning." Inconsistency with land use plans and policies does not necessarily indicate that adverse effects on the environment would occur. However, land use plans and policies guide development and land management activities that would affect the physical environment, and SLWRI actions could have additive or combined effects.

Antlers Bridge Replacement The California Department of Transportation (Caltrans), in cooperation with the Federal Highway Administration, is replacing Antlers Bridge over Shasta Lake, which is located on Interstate 5 near the community of Lakehead in Shasta County, in the primary study area. This project involves constructing a 1,942-foot, 5-lane segmental bridge with deep-pile foundations measuring 12 feet in diameter. The project also involves realigning a 0.4-mile-long segment of Interstate 5, which requires hillside excavation, construction of a 5-lane freeway section, and demolition of the existing 1,500 feet of steel deck truss bridge. The new bridge is being constructed next to the existing bridge, which will remain open to traffic until the new bridge is completed. This project will affect visual resources, fish and wildlife, and water quality standards. However, incorporation of mitigation will reduce these impacts to a less-than-significant level. The project is not expected to have any other significant impacts (Caltrans and FHWA 2007). Construction began in 2009 and is expected to be completed in 2015.

Jellys Ferry Bridge Replacement The Tehama County Department of Public Works in cooperation with Caltrans is proposing to replace the existing the Jellys Ferry Bridge over the Sacramento River, north of Red Bluff, in northern Tehama County, California. After conducting a seismic assessment, as part of the Local Bridge Seismic Safety Retrofit Program (LSSRP), the bridge was classified structurally and seismically deficient (Quincy 1997). Based on the results of the assessment, the Tehama County Department of Public Works determined (with Caltrans concurrence) to replace rather than retrofit the existing bridge. The bridge will span the Sacramento River with abutments on adjacent sides of the river.

Moody Flats Quarry Shasta County is the Lead Agency under the California Environmental Quality Act (CEQA) and is in the process of preparing a DEIR for the project identified as Moody Flats Quarry. The project site is located about one mile south of Shasta Lake, about one mile west of Interstate 5, and adjacent to the north side of the City of Shasta Lake. The Union Pacific Railroad runs in a general northeast-southwest direction through the site. Access to the project would be via a proposed access road connecting to the east side of Wonderland Boulevard at a point approximately 0.4 miles south of the intersection of Wonderland Boulevard and Old Oregon Trail. The site is currently undeveloped (Shasta County 2011).

This project would develop a 345-acre hardrock quarry (including a 60-acre overburden fill area), a 75-acre processing area, and a 10-acre railroad cut area. This project would include an aggregate processing facility, ancillary aggregate product facilities (e.g., concrete plant, asphalt batch plant, and recycled construction materials plant) and aggregate truck and railcar load-out facility within the approximately 1,900-acre property. A total of about 430 acres would be disturbed, and about 370 acres would be reclaimed. Production and distribution goals include approximately 1.5 million tons of aggregate shipped by rail to regional markets annually, and 0.5 million tons of aggregate and finished products to be distributed to local markets by trucks. Maximum proposed annual aggregate sales for the project would be 2 million tons per year. The proposed term of the use permit would be 100 years (Shasta County 2011).

Mountain Gate at Shasta Mixed-Use Area Plan The City of Shasta Lake is the Lead Agency under CEQA has prepared a DEIR for the project identified as the Mountain Gate at Shasta Mixed-Use Area Plan. The proposed project would develop the 590-acre property with approximately 1,604 housing units, up to 195,584 square feet of nonresidential development, and 236 acres of open space, parks and trails. The project site is located in the northeast portion of the City of Shasta Lake, approximately 8 miles north of the City of Redding and approximately three miles from the south shore of Shasta Lake. The site is undeveloped with the exception of foot trails and vehicle tracks. The project vicinity has emergent wetlands and riverine habitats, including Moody Creek and Rancheria Creek and several unnamed ephemeral tributaries (City of Shasta Lake 2014).

3.3 Resources Eliminated from Further Consideration

CEQA and the State CEQA Guidelines provide for identification and elimination from detailed study of the issues that are not significant or that have been covered by prior environmental review (PRC Section 21002.1; State CEQA Guidelines, Section 15143). The NEPA regulations provide similar provisions (Title 40, CFR Section 1501.7(a)(3)).

During initial scoping with the public and governmental agencies, and based on information obtained through literature review, agency correspondence, consultations, and field data collection, it was determined that no resource areas could be eliminated from detailed study. Therefore, all resource areas covered by NEPA and CEQA are addressed in this EIS.

3.4 Regulatory Framework

The following section generally describes the Federal, State, and local regulatory framework for the SLWRI. For a more detailed discussion of the "Regulatory Framework" by resource area, see Chapters 4 through 25. In addition, Chapter 26, "Other Required Disclosures," further describes the Federal and State laws, rules and regulations, Executive Orders, and compliance requirements that may be required if an alternative is selected for implementation.

3.4.1 Federal

National Environmental Policy Act

NEPA is the nation's broadest environmental law, applying to all Federal agencies and most of the activities they manage, regulate, or fund that affect the environment. This law requires Federal agencies to disclose and consider the environmental implications of their proposed actions. NEPA establishes environmental policies for the nation, provides an interdisciplinary framework for Federal agencies to avoid or minimize environmental impacts, and contains action-forcing procedures to ensure that Federal agency decision makers take environmental factors into account.

Federal Clean Water Act

Section 404 Section 404 of the CWA requires that a permit be obtained from USACE for the discharge of dredged or fill material into "waters of the United States, including wetlands." Waters of the United States are wetlands and lakes, rivers, streams, and their tributaries. Waters of the United States are defined for regulatory purposes, at Title 33, CFR Section 328.3, as follows:

> *(1) All waters which are currently used, or were used in the past, or may be susceptible to use in interstate or foreign commerce, including all waters which are subject to the ebb and flow of tide; (2) All interstate waters, including interstate wetlands; (3) All other waters such as intrastate lakes, rivers, streams, mudflats, sandflats, wetlands, sloughs, prairie potholes, wet meadows, playa lakes, or natural ponds, the use, degradation or destruction of which could affect interstate or foreign commerce; (4) All impoundments of waters otherwise defined as waters of the United States under the definition; (5) Tributaries of waters identified in paragraphs 1–4 in this section; (6) The territorial seas; and (7) Wetlands adjacent to waters identified in paragraphs 1–6 in this section.*

CWA Section 404(b) requires that USACE process permits in compliance with guidelines developed by the U.S. Environmental Protection Agency (EPA). These guidelines (the CWA Section 404(b)(1) Guidelines) require the analysis of available alternatives that meet the project’s purpose and need, including those alternatives that avoid and minimize discharges of dredged or fill materials in waters. Once alternatives deemed to be practicable have been identified, the only action that USACE can permit must be the least environmentally damaging practicable alternative.

Actions typically subject to Section 404 requirements are those that would take place in wetlands or stream channels, including intermittent streams, even if they have been realigned. For actions occurring within stream channels, a permit under Section 404 would be needed for any discharge activity below the ordinary high-water mark. (The ordinary high-water mark is the line on the shore established by the fluctuations of water. It is indicated by physical characteristics such as a clear, natural line impressed on the bank; shelving; changes in the character of soil; destruction of terrestrial vegetation; or the presence of litter or debris.)

The Programmatic ROD for the CALFED Final PEIS/R includes a CWA Section 404 memorandum of understanding signed by Reclamation, EPA, USACE, and DWR. Under the terms of the memorandum of understanding, when a project proponent applies for a Section 404 individual permit for CALFED projects, the proponent is not required to reexamine program alternatives already analyzed in the CALFED PEIS/R. USACE and EPA will focus on project-level alternatives that are consistent with the CALFED PEIS/R when they select the least environmentally damaging practicable alternative at the time of a Section 404 permit decision.

Section 401 Under CWA Section 401, applicants for a Federal license or permit to conduct activities that may discharge a pollutant into waters of the United States must obtain certification from the state in which the discharge would originate. If appropriate, the certification must be obtained from the interstate water pollution control agency with jurisdiction over affected waters at the point where the discharge would originate. Therefore, all projects that have a Federal component and may affect state water quality (including projects that require approval from a Federal agency, such as issuance of a Section 404 permit) must also comply with CWA Section 401.

In California, the authority to grant water quality certification has been delegated to the State Water Board. Applications for water quality certification under CWA Section 401 are typically processed by the regional water quality control board with local jurisdiction – in this case, the CVRWQCB. For a project to receive water quality certification, the project's potential impacts must be evaluated in light of water quality standards and CWA Section 404 criteria that govern discharges of dredged and fill materials into waters of the United States.

Endangered Species Act

USFWS and NMFS share responsibility for implementing the ESA. Generally, USFWS manages terrestrial and freshwater species, while NMFS manages marine and anadromous species such as Chinook salmon. Both agencies ensure that ESA requirements are followed and evaluate projects that may affect the continued existence of a Federally listed (threatened or endangered) species.

Section 9 of the ESA prohibits the take of Federally listed species. "Take" is defined under the ESA, in part, as killing, harming, or harassing. Under Federal regulations, take is further defined to include habitat modification or degradation where it actually results in death or injury to wildlife by significantly impairing essential behavioral patterns – breeding, feeding, or sheltering.

Section 7 of the ESA outlines procedures for Federal interagency cooperation to conserve Federally listed species and designated critical habitat. Section 7(a)(2) requires Federal agencies to consult with USFWS to ensure that they are not undertaking, funding, permitting, or authorizing actions likely to jeopardize the continued existence of listed species. NMFS also ensures that projects will not adversely affect essential fish habitat, as defined in the 1996 Sustainable Fisheries Act (Public Law 104-297). The goal is to stop or reverse the continued loss of fish habitats by protecting, conserving, and enhancing habitat.

Magnuson-Stevens Fishery Conservation and Management Act

The Magnuson-Stevens Fishery Conservation and Management Act (commonly known as Magnuson-Stevens Act) establishes a management system for national marine and estuarine fishery resources. This legislation requires Federal agencies to consult with NMFS regarding actions or proposed actions permitted, funded, or undertaken that may adversely affect "essential fish habitat." Essential fish habitat is defined as "waters and substrate necessary to fish for spawning, breeding, feeding, or growth to maturity."

The Magnuson-Stevens Act states that migratory routes to and from the spawning grounds of anadromous fish are considered essential fish habitat. The phrase "adversely affect" refers to the creation of any impact that reduces the quality or quantity of essential fish habitat.

The concept of essential fish habitat is similar to that of "critical habitat" under the ESA; however, measures recommended by NMFS to protect essential fish habitat are advisory, not prescriptive. Federal activities that occur outside of essential fish habitat but that may nonetheless affect waters and substrate that constitute essential fish habitat must also be considered in the consultation process.

Under the Magnuson-Stevens Act, effects on habitat managed under the *Pacific Salmon Fishery Management Plan* must also be considered. The Magnuson-Stevens Act states that where appropriate, consultation regarding essential fish habitat should be consolidated with the interagency consultation, coordination, and environmental review procedures required by other Federal statutes, such as NEPA, the Fish and Wildlife Coordination Act, the CWA, and the ESA.

Fish and Wildlife Coordination Act

Coordination under the Fish and Wildlife Coordination Act is intended to promote conservation of fish and wildlife resources by preventing their loss or damage. It also provides for development and improvement of fish and wildlife resources in connection with water projects. Federal agencies that undertake water projects must fully consider recommendations made by USFWS, NMFS, and the appropriate fish and wildlife agency – in this case, CDFW – in their project reports and include measures to reduce impacts on fish and wildlife in project plans.

Rivers and Harbors Appropriation Act of 1899

The Rivers and Harbors Appropriation Act of 1899 (commonly known as the Rivers and Harbors Act) addresses activities that involve constructing dams, bridges, dikes, or other obstructions across any navigable water. To place any obstruction to navigation outside established Federal lines, or to excavate from or deposit material in such waters, a permit must be obtained from USACE. Navigable waters are defined in Title 33, CFR Section 329.4 as follows:

> *Those waters that are subject to the ebb and flow of the tide and/or are presently used, or have been used in the past, or may be susceptible for use to transport interstate or foreign commerce. A determination of navigability, once made, applies laterally over the entire surface of the waterbody, and is not*

extinguished by later actions or events which impede or destroy navigable capacity.

Sections of the River and Harbors Act applicable to the SLWRI are described below.

Section 9 Section 9 (Title 33, U.S. Code (USC) Section 401) prohibits the construction of any dam or dike across any navigable water of the United States without consent from Congress and approval of the plans by the Chief of Engineers and the Secretary of the Army. Where the navigable portions of the water body lie wholly within the limits of a single state, the structure may be built under authority of that state's legislature if the location and plans, or any modification thereof, are approved by the Chief of Engineers and by the Secretary of the Army.

Section 10 Section 10 (Title 33, USC Section 403) prohibits the unauthorized obstruction or alteration of any navigable water of the United States. Construction of any structure in or over any navigable water of the United States, or the accomplishment of other work affecting the course, location, condition, or physical capacity of such waters, is unlawful unless the work has been authorized by the Chief of Engineers.

Section 13 Section 13 (Title 33, USC Section 407) states that the Secretary of the Army may permit the discharge of refuse into navigable waters if the Chief of Engineers has determined that the discharge will not injure anchorage and navigation. Discharges of refuse are prohibited unless a permit has been obtained. Although the prohibition in this section – known as the Refuse Act – is still in effect, the Secretary of the Army's permit authority has been superseded by the permit authority given to the EPA Administrator and the states under Sections 402 and 405 of the CWA, respectively.

Safe Drinking Water Act

The Safe Drinking Water Act mandates that EPA establish regulations to protect human health from contaminants in drinking water. This law authorizes EPA to develop national standards for drinking water and to create a joint Federal/state/tribal system to ensure compliance with these standards. The law also directs EPA to protect underground sources of drinking water by controlling the underground injection of liquid wastes.

EPA has developed primary and secondary drinking water standards under its Safe Drinking Water Act authority. EPA and authorized states and tribes enforce the primary drinking water standards, which are contaminant-specific concentration limits that apply to certain public supplies of drinking water. The primary standards consist of two elements: goals for maximum contaminant levels, which are nonenforceable health-based goals; and maximum contaminant levels, which are enforceable limits set as close to the maximum contaminant level goals as possible, considering the cost and feasibility of attainment.

Federal Water Project Recreation Act

The Federal Water Project Recreation Act requires that Federal agencies with authority to approve water projects include recreation development as a condition of approving permits. Recreation development must be considered along with any navigation, flood control, reclamation, hydroelectric, or multipurpose water resource project. The act states that "consideration shall be given to the opportunities, if any, which the project affords for outdoor recreation and for fish and wildlife enhancement…wherever any such project can reasonably serve either or both of these purposes consistently" (Title 16, USC Section 460l-12).

Federal Clean Air Act

The Federal Clean Air Act (CAA) was enacted to protect and enhance the nation's air quality to promote public health and welfare and the productive capacity of the nation's population. The CAA requires that Federal actions be evaluated to determine their potential impacts on air quality in the project region. California has a corresponding law, which also must be considered during the EIS/R process.

For specific projects, Federal agencies must coordinate with the appropriate air quality management district and EPA. This coordination determines whether the project conforms to the CAA and the state implementation plan.

Section 176 of the CAA prohibits Federal agencies from engaging in or supporting an action or activity that does not conform to an applicable state implementation plan. Actions and activities must conform to the plan's purposes of eliminating or reducing violations of national ambient air quality standards, reducing the severity of violations, and attaining those standards expeditiously.

National Historic Preservation Act

Section 106 of the National Historic Preservation Act of 1966 and its implementing regulations (Title 36, CFR Part 800, as amended in 2004) requires Federal agencies to consider the effects of their actions, or those they fund or permit, on properties that are listed or eligible for listing in the National Register of Historic Places (NRHP). The NRHP is a register of districts, sites, buildings, structures, and objects of significance in American history, architecture, archaeology, engineering, and culture. The regulations provided in 36 CFR Part 60.4 describe the criteria to evaluate cultural resources for inclusion in the NRHP. Cultural resources can be significant on the national, state, or local level. Properties may be listed in the NRHP if they possess integrity of location, design, setting, materials, workmanship, feeling, and association, and meet any one of the following criteria:

1. Are associated with events that have made a significant contribution to the broad patterns of our history

2. Are associated with the lives of persons significant in our past

3. Embody the distinctive characteristics of a type, period, or method of construction, or represent the work of a master, or possess high artistic values, or represent a significant and distinguishable entity whose components may lack individual distinction

4. Have yielded, or may be likely to yield, information important in prehistory or history

Generally, properties are not considered eligible for the NRHP if they have achieved significance within the past 50 years. Certain exceptions are made in the regulation, such as a religious property deriving primary significance from its architectural distinction, or a grave of a historical figure of outstanding importance if there is no appropriate site directly associated with his productive life.

Native American Graves Protection and Repatriation Act

The Native American Graves Protection and Repatriation Act (Public Law 101-601; 25 United States Code 3001-3013) pertains to Native American burial sites and regulates the removal of human remains, funerary objects, sacred objects, and items of cultural patrimony on Federal and tribal lands. The Act requires permits for intentional removal or excavation of Native American human remains on Federal lands, covers cases of inadvertent discoveries, and dictates the ultimate disposition process of Native American human remains and cultural items.

Archaeological Resources Protection Act

The purpose of the Archaeological Resources Protection Act of 1979 (Public Law 95-96 – October 31, 1979) is to protect archaeological resources and sites that are located on public lands and Indian lands, and to foster increased cooperation between governmental authorities, the professional archaeological community, and private individuals in possession of archaeological resources. The act makes it unlawful to excavate, remove, or deface archaeological resources, to sell, purchase, or exchange those resources without applicable permit, and establishes criminal and civil penalties for any such violation.

Farmland Protection Policy Act

The Farmland Protection Policy Act requires that a Federal agency examine the potential impacts of a proposed action on Prime Farmland and Unique Farmland, as defined by the U.S. Natural Resources Conservation Service. If the action would adversely affect farmland preservation, the Federal agency must consider alternatives to lessen the adverse effects.

Migratory Bird Treaty Act

The Migratory Bird Treaty Act, first enacted in 1918, implements domestically a series of treaties between the United States and Great Britain (on behalf of Canada), Mexico, Japan, and the former Soviet Union that provide international protection of migratory birds. The act authorizes the Secretary of the Interior to regulate the taking of migratory birds. It is unlawful, except as permitted by regulations, "to pursue, take, or kill any migratory bird, or any part, nest or egg of any such bird…" (Title 16, USC Section 703). This prohibition includes both direct and indirect acts, although harassment and habitat modification are not included unless they result in the direct loss of birds, nests, or eggs. Several hundred species, essentially including all native birds, are currently protected by the Migratory Bird Treaty Act. The act offers no statutory or regulatory mechanism for obtaining an incidental take permit for the loss of nongame migratory birds.

Bald and Golden Eagle Protection Act

The Bald and Golden Eagle Protection Act, enacted in 1940 and amended multiple times since, prohibits the taking of bald and golden eagles without a permit from the Secretary of the Interior. Similar to the ESA, the Bald and Golden Eagle Protection Act defines "take" to include "pursue, shoot, shoot at, poison, wound, kill, capture, trap, collect, molest or disturb" (Title 16, USC Sections 668-668c). Any disturbance that would injure an eagle, decrease productivity, or cause nest abandonment – including habitat alterations that could have these results – is considered take and can result in civil or criminal penalties.

National Forest Management Act

The National Forest Management Act requires USFS to "provide for a diversity of plant and animal communities" (Title 16, USC Section 1604(g)(3)(B)) as part of its multiple-use mandate. USFS must maintain "viable populations of existing native and desired nonnative species in the planning area" (Title 36, CFR Section 219.19). The Sensitive Species program is designed to meet this mandate and to demonstrate USFS's commitment to maintaining biodiversity on National Forest System lands.

A key requirement of the National Forest Management Act is preparation of land and resource management plans that establish the goals, objectives, and standards and guidelines for managing the lands and resources of National Forest System lands managed by the various National Forests.

Federal Land Policy and Management Act

Sections 201 and 202 of the Federal Land Policy and Management Act of 1976 (FLPMA) (Title 43, USC Sections 1711–1712) and the regulations in Title 43, CFR Section 1600 provide guidance and direction for implementing BLM's land use planning requirements, as established by resource management plans. Resource management plans and subsequent planning decisions are the basis for every on-the-ground action undertaken by BLM.

Resource management plans ensure that public lands are managed in accordance with the intent of Congress as stated in the FLPMA, under the principles of multiple use and sustained yield. As required by the FLPMA and BLM policy, public lands must be managed in a manner that will do all of the following:

- Protect the quality of ecological and scientific values
- Preserve and protect certain public lands in their natural condition, where appropriate
- Provide food and habitat for fish and wildlife and domestic animals
- Provide for outdoor recreation and human occupancy and use
- Recognize the nation’s need for domestic sources of minerals, food, timber, and fiber from the public lands by encouraging collaboration and public participation throughout the planning process

Resource management plans are among the primary mechanisms for guiding BLM activities to achieve compliance with the FLPMA.

Federal Wild and Scenic Rivers Act

The Federal Wild and Scenic Rivers Act of 1968, as amended (Public Law 90-542; Title 16, USC Sections 1271–1287), established the National Wild and Scenic Rivers System. This system identifies distinguished rivers of the nation that possess outstandingly remarkable scenic, recreational, geologic, fish and wildlife, historic, cultural, or other similar values. The Federal Wild and Scenic Rivers Act preserves the free-flowing condition of designated rivers and protects their local environments. Section 5(d)(1) of the act requires Federal agencies to consider potential national wild, scenic, and recreational river areas when planning for the use and development of water and related land resources. Wild, scenic, and recreational river areas are defined as follows:

- *“Wild” river areas* are rivers or sections of rivers that are free of impoundments and generally inaccessible except by trail, with watersheds or shorelines essentially primitive and waters unpolluted. These represent vestiges of primitive America.
- *“Scenic” river areas* are rivers or sections of rivers that are free of impoundments, with shorelines or watersheds still largely primitive and shorelines largely undeveloped, but accessible by roads in places.
- *“Recreational” river areas* are rivers or sections of rivers that are readily accessible by road or railroad, that may have some development along their shorelines, and that may have undergone some impoundment or diversion in the past.

Designation as a National wild and scenic river explicitly prohibits the Federal government from licensing or permitting new hydroelectric dams or major diversions on these rivers. Federal agencies are also prohibited from assisting any water resource projects that may directly affect the resources for which the river was designated. Public lands within a corridor averaging one-quarter mile on both sides of the rivers are managed to protect resources designated as outstandingly remarkable for their scenic, recreational, historical/cultural, fish, wildlife, ecological, geological, or hydrologic value.

Indian Trust Assets

All Federal agencies have a responsibility to protect Indian trust assets. Indian trust assets are legal interests in assets held in trust by the Federal government for Native American tribes or individuals. Assets may be owned property, physical assets, intangible property rights, a lease, or the right to use something. Typically, they include lands, minerals, water rights, hunting and fishing rights, natural resources, money, and claims.

Executive Order 11988 (Flood Hazard Policy)

Executive Order 11988 is a flood hazard policy for all Federal agencies that manage Federal lands, sponsor Federal projects, or provide Federal funds to state or local projects. The order requires that Federal agencies take necessary action to reduce the risk of flood loss; restore and preserve the natural and beneficial values served by floodplains; and minimize the impacts of floods on human safety, health, and welfare.

Executive Order 11990 (Protection of Wetlands)

Executive Order 11990 is an overall wetlands policy for all Federal agencies that manage Federal lands, sponsor Federal projects, or provide Federal funds to state or local projects. The order requires that Federal agencies follow avoidance, mitigation, and preservation procedures with public input before they propose new construction in wetlands. Executive Order 11990 can restrict the sale of Federal land containing wetlands; however, it does not apply to Federal discretionary authority for non-Federal projects (other than funding) on non-Federal land.

Executive Order 12898 (Environmental Justice Policy)

Executive Order 12898 requires Federal agencies to identify and address the disproportionately high and adverse human health and environmental effects of Federal programs, policies, and activities on minority and low-income populations. The requirements of Executive Order 12898 apply to all Federal actions that are located on Federal lands, sponsored by a Federal agency, or funded with Federal monies and may affect minority or low-income populations.

Executive Order 13007 (Indian Sacred Sites) and April 29, 1994, Executive Memorandum

Executive Order 13007 (May 24, 1996) requires Federal agencies with land management responsibilities to accommodate access to and ceremonial use of Indian sacred sites by Indian religious practitioners and avoid adversely affecting the physical integrity of such sacred sites. Where appropriate, agencies are to maintain the confidentiality of sacred sites. Among other things, Federal agencies must provide reasonable notice of proposed actions or land management policies that may restrict future access to or ceremonial use of, or adversely affect the physical integrity of, sacred sites. The agencies must comply with the April 29, 1994, executive memorandum, "Government-to-Government Relations with Native American Tribal Governments."

Executive Order 13112 (National Invasive Species Management Plan)

Executive Order 11312 directs all Federal agencies to prevent and control introductions of invasive nonnative species in a cost-effective and environmentally sound manner to minimize their economic, ecological, and human health impacts. Executive Order 11312 established the national Invasive Species Council, made up of Federal agencies and departments, and the supporting Invasive Species Advisory Committee, composed of state, local, and private entities. The Invasive Species Council and Advisory Committee oversee and facilitate implementation of the executive order, including preparation of a national invasive-species management plan.

Federal Transit Administration

To address the human response to ground-borne vibration, the Federal Transit Administration has set forth guidelines for maximum-acceptable vibration criteria for different types of land uses (FTA 2006):

- 65 vibration decibels for land uses where low ambient vibration is essential for interior operations (e.g., hospitals, high-tech manufacturing, and laboratory facilities)
- 80 vibration decibels for residential uses and buildings where people normally sleep
- 83 vibration decibels for institutional land uses with primarily daytime operations (e.g., schools, churches, clinics, and offices)

Standards have also been established to address the potential for ground-borne vibration to cause structural damage to buildings. These standards were developed by the Committee of Hearing, Bio Acoustics, and Bio Mechanics at the request of EPA (FTA 2006). For fragile structures, this committee recommends a maximum limit of 0.25 inch per second peak particle velocity (FTA 2006). (Peak particle velocity is a measure of the intensity of ground vibration, specifically the time rate of change of the amplitude of ground vibration.)

Federal Land Use Policies

Federal land use policies apply only to actions on or affecting the uses of Federal lands. The following are the Federal lands located in the vicinity of the study area:

- National Forest System lands administered by the Shasta-Trinity National Forest
- Reclamation-owned lands along the Sacramento River, just south of Shasta Dam
- BLM-owned lands along the Sacramento River, just north of Red Bluff

Access to these Federal properties would require approval from these entities.

Shasta-Trinity National Forest Land and Resource Management Plan

The *Shasta-Trinity National Forest Land and Resource Management Plan* was most recently revised in 1995 (USFS 1995). This document is revised every 10–15 years; it supersedes any previous forest plans, timber management plans, or NRA plans. It contains the goals and objectives for Shasta-Trinity National Forest, its standards and guidelines, management prescriptions to be applied to land areas, and management area direction. It also sets forth requirements for monitoring and implementation of the plan. The allocations associated with this plan not only reflect the capability and suitability of the land for various uses, but also respond to the public issues (such as recommendations for wild and scenic river designations) and development opportunities identified during the planning process.

Whiskeytown-Shasta-Trinity National Recreation Area Management Plan

The Whiskeytown-Shasta-Trinity NRA consists of the Shasta and Trinity units on the Shasta-Trinity National Forest (managed by the USFS) and the Whiskeytown Unit located outside the National Forest (managed by the National Park Service).The Whiskeytown-Shasta-Trinity NRA was established on November 8, 1965 with the signing of Public Law 89-336 by President Lyndon Johnson. The legislation provides that administration of the NRA be carried out under separate management plans, and that these plans are to be reviewed and revised periodically. The *Management Guide: Shasta and Trinity Units of the Whiskeytown-Shasta-Trinity NRA* (USFS 2014) provides a general framework to guide management of the Shasta and Trinity Units of the NRA, and by which to evaluate and gauge the appropriate NRA management efforts and analysis. This guide is not a decision document or an assessment under NEPA, and does not implement site-specific projects.

The NRA Guide relies on the Forest Plan for a broad umbrella of direction and is incorporated by reference into the Forest Plan. The periodic updates to the NRA Guide respond to changes in environmental conditions, public concern, and recreation use patterns, providing better management of the resources in the

NRA and continued implementation of the management direction in the Forest Plan.

Redding Resource Management Plan

BLM owns lands along the Sacramento River just north of Red Bluff. This land is managed by BLM in accordance with the *Redding Resource Management Plan*, which covers more than 250,000 acres in north-central California in Butte, Shasta, Siskiyou, Tehama, and Trinity counties. Many Areas of Critical Environmental Concern and national wild and scenic river corridors are included within these easily accessed and heavily used public lands. Completed in 1993, the *Redding Resource Management Plan* primarily addresses recreation, land tenure, access, and forest management.

Federal Energy Regulatory Commission

Changes to hydroelectric facilities on the Pit River – instream flow releases or modifications to downstream structures – may necessitate an amendment to a FERC license. Typical modifications that require an amendment to a license or exemption include capacity changes, design changes, operational changes, land status changes, and time extensions. Before issuing a license amendment, FERC ensures that proposed changes to hydropower facilities comply with NEPA. For noncapacity-related amendments, other factors – the nature of the proposed change, project type (based on proposed capacity), and construction status – determine which items outlined in the FERC Division of Hydropower Administration and Compliance's *Compliance Handbook* to include in the amendment application. If any item in the original license would be modified as a result of the project, a revised version must be filed along with the amendment application.

Once the need for an amendment is determined, the appropriate resource agencies are consulted. The extent of agency consultation depends on whether the amendment is capacity-related or noncapacity-related. After pre-filing consultation is completed, the licensee files the amendment application. The FERC Division of Hydropower Administration and Compliance then determines whether a public notice is warranted and whether NEPA review is required. NEPA review entails preparing an environmental assessment and/or an EIS. The license amendment process is detailed in the *Compliance Handbook.*

3.4.2 State

The section below describes potential State or local agency requirements under CEQA if the preferred alternative or action alternatives is authorized and approved. It is possible that some state or local agencies will be unable to process and issue permits and approvals identified below.

California Environmental Quality Act

Prompted by the passage of NEPA in 1969, CEQA was signed into law in 1970 as California's counterpart to NEPA. CEQA requires State and local agencies to identify the significant environmental impacts of their actions and to avoid or mitigate those impacts, if feasible. The objectives of CEQA are to do all of the following:

- Disclose to decision makers and the public the significant environmental effects of proposed activities
- Identify ways to avoid or reduce environmental damage
- Prevent environmental damage by requiring implementation of feasible alternatives or mitigation measures
- Disclose to the public the reasons for agency approval of projects with significant environmental effects
- Foster interagency coordination in the review of projects
- Enhance public participation in the planning process

California Endangered Species Act

Pursuant to the California Endangered Species Act (CESA), a permit from CDFW is required for projects that could result in the take of a plant or animal species that is State-listed as threatened or endangered. Under the CESA, “take” is defined as an activity that would directly or indirectly kill an individual of a species, but the CESA definition of take does not include “harming” or “harassing,” as the Federal ESA definition does. As a result, the threshold for take is higher under the CESA than under the Federal ESA (i.e., habitat modification is not necessarily considered take under the CESA). However CESA requires full mitigation of effects to listed species, a higher standard than Federal ESA.

Sections 3503 and 3503.5 of the California Fish and Game Code state that it is unlawful to take, possess, or needlessly destroy the nest or eggs of any bird, or to take, possess, or destroy any raptors (i.e., species in the orders Falconiformes and Strigiformes), including their nests or eggs. Destruction of active nests caused by removal of vegetation in which the nests are located is a typical violation of these codes. Violation of Section 3503.5 could also include failure of active raptor nests that results from disturbance of nesting pairs by nearby project construction. This statute does not provide for the issuance of any type of incidental take permit.

California Fish and Game Code – Fully Protected Species

Protection of fully protected species is described in Sections 3511, 4700, 5050, and 5515 of the California Fish and Game Code. These statutes prohibit take or possession of fully protected species. CDFW is unable to authorize incidental take of fully protected species when activities are proposed in areas inhabited by those species. CDFW has informed non-Federal agencies and private parties that they must avoid take of any fully protected species in carrying out projects.

California Fish and Game Code Section 1602 – Streambed Alteration

All diversions, obstructions, or changes to the natural flow or bed, channel, or bank of any river, stream, or lake in California that supports wildlife resources are subject to regulation by CDFW under Section 1602 of the California Fish and Game Code. Under Section 1602, it is unlawful for any person, governmental agency, or public utility to do the following without first notifying CDFW:

> *…substantially divert or obstruct the natural flow of, or substantially change or use any material from the bed, channel, or bank of any river, stream, or lake, or deposit or dispose of debris, waste, or other material containing crumbled, flaked, or ground pavement where it may pass into any river, stream, or lake.*

A stream is defined as a body of water that flows at least periodically or intermittently through a bed or channel that has banks and supports fish or other aquatic life. This definition includes watercourses with a surface or subsurface flow that supports or has supported riparian vegetation. CDFW's jurisdiction within altered or artificial waterways is based on the value of those waterways to fish and wildlife.

California Fish and Game Code Sections 5900–5904, 5930–5948, 7261, and 7370 – Fish Passage

The California Fish and Game Code includes the following provisions intended to protect fish passage:

- *Sections 5900–5904* prohibit constructing or maintaining any device or contrivance in any stream that prevents, impedes, or tends to prevent or impede the passing of fish upstream and downstream.
- *Sections 5930–5948* require CDFW to inspect California's dams to ensure that dam owners are maintaining fish passage. CDFW may require dam owners to install a suitable fishway if passage is impeded.
- *Section 7261* authorizes the California Fish and Game Commission to designate as "Heritage Trout Waters" any waters that provide anglers with an opportunity to catch native trout, consistent with the conservation of the California native trout. The McCloud River redband trout occurs in the McCloud River upstream from McCloud Dam.
- *Section 7370* prohibits taking or possessing for commercial purposes, buying or selling, or offering to buy or sell all or part of any sturgeon,

including its eggs, unless the sturgeon was cultured, taken from another state, or taken pursuant to a sport fishing license. Green sturgeon occurs in the primary and extended study areas in the Sacramento River, its tributaries, and the Delta.

California Water Commission

In November 2009, California enacted a comprehensive water package to improve the state's water supply reliability and restore the Delta ecosystem. The package included the Safe, Clean, and Reliable Drinking Water Supply Act which, if approved by voters in 2014, will direct the California Water Commission to develop tools and methods for the quantification of public benefits of water storage projects including CALFED surface storage, groundwater storage, conjunctive use and reservoir reoperation, and local and regional storage.

Delta Stewardship Council

In November 2009 the Sacramento-San Joaquin Delta Reform Act was passed by the California Legislature and signed by Governor Schwarzenegger. It established state policy of coequal goals for the Delta and created the Delta Stewardship Council as a new, independent state agency that will delineate exactly how to meet these goals through development and implementation of the Delta Plan.

The Council's principal task is to develop and implement the Delta Plan, a legally enforceable document that will include all the actions necessary to ensure the state's coequal goals for the Delta are met (Delta Stewardship Council 2013). The Delta Plan was adopted in May 2013.

Central Valley Flood Protection Board Encroachment Permit

The Central Valley Flood Protection Board (CVFPB) enforces standards for the construction, maintenance, and protection of adopted flood control plans that will protect public lands from floods. The jurisdiction of the CVFPB includes the Central Valley, including all tributaries and distributaries of the Sacramento River, the San Joaquin River, and designated floodways (Title 23, CCR Section 2). The CVFPB has all the responsibilities and authorities necessary to oversee future modifications as approved by USACE pursuant to assurance agreements with USACE and USACE's Operation and Maintenance Manuals under Title 33, CFR Section 208.10 and Title 33, USC Section 408.

The CVFPB, in cooperation with USACE, is responsible for reducing the risk of catastrophic flooding to people and property within the Central Valley. The CVPFB helps preserve the integrity of the existing flood control system and designated floodways through its regulatory authority by issuing permits for encroachments. Construction and habitat restoration projects within the jurisdiction of the CVFPB are required to meet standards for the construction, maintenance, and protection of adopted plans of flood control that will protect public lands from floods. The State, through the CVFPB, shares in the costs of construction, assumes responsibility for ensuring the operation and maintenance of the facilities, and holds the federal government harmless from liability. For the CVFPB's flood management projects, the CVFPB delegates operation and maintenance to DWR, or to local maintaining agencies.

California Water Rights

A water right is a legally granted and protected right to take possession of water and put it to beneficial use. As authorized by the California Water Code, the State Water Board allocates surface water rights and permits the diversion and use of water throughout the state. Through its Division of Water Rights, the State Water Board issues permits to divert water for new appropriations, change existing water rights, or store water for a certain length of time. The State Water Board attaches conditions to these permits to ensure that the water user prevents waste, conserves water, does not infringe on the rights of others, and puts the State's water resources to the most beneficial use in the best interest of the public.

California Public Resources Code

PRC Section 5093.542, established through enactment of the California Wild and Scenic Rivers Act, as amended (Sections 5093.50 through 5093.70), aims to preserve designated rivers that possess extraordinary scenic, recreation, fishery, or wildlife values. With the act's passage, the California system protected segments of the Smith and Klamath rivers and their tributaries, and the Scott, Salmon, Trinity, Eel, Van Duzen, and American rivers. Segments of the McCloud River, Deer Creek, and Mill Creek were subsequently protected under the act in 1989 and 1995, respectively, although these segments were not formally designated as components of the State's Wild and Scenic Rivers System.

No dam, reservoir, diversion, or other water impoundment facility may be constructed on any river segment included in the State system. No water diversion facility may be constructed on any river segment included in the State system unless the Resources Secretary determines that the facility is needed to supply domestic water to local residents and that the facility will not adversely affect the river's free-flowing condition and natural character. In reference to the McCloud River, PRC Section 5093.542(c) states the following:

> *Except for participation by the [California] Department of Water Resources in studies involving the technical and economic feasibility of enlargement of Shasta Dam, no department or agency of the state shall assist or cooperate with, whether by loan, grant, license, or otherwise, any agency of the federal, state, or local government in the planning or construction of any dam, reservoir, diversion, or other water impoundment facility that could have an adverse effect on the free-flowing condition of the McCloud River, or on its wild trout fishery.*

Designation as a wild and scenic river does not affect existing water rights and facilities. Proposed changes in existing rights and facilities or applications for new water rights and facilities on designated segments are subject to the domestic-use restriction and the nondegradation standard. Designated segments are considered fully appropriated streams by the State Water Board.

PRC Section 5093.542 shares similar criteria and definitions in regard to the purpose of protecting rivers with the Federal Wild and Scenic Rivers Act: identifying free-flowing rivers with extraordinary values suitable for protection, establishing a study process to include rivers in the system, and classifying river segments as either wild, scenic, or recreational based largely on the degree of development along each river segment included in the system. The primary purpose of both the Federal Wild and Scenic Rivers Act and the PRC is to prohibit new water impoundments on designated rivers.

The PRC also contains several other sections relevant to the project. Some examples include PRC Section 5096.225 (the California Park and Recreational Facilities Act of 1984), PRC Section 5094 (the Federal Water Project Recreation Act), and the CWA.

California Harbors and Navigation Code

The California Harbors and Navigation Code details the jurisdiction of the California Department of Boating and Waterways, which is focused on the development of public access to waterways, the safety of vessels and boating facilities, and on-the-water safety.

Porter-Cologne Water Quality Control Act

Under the Porter-Cologne Water Quality Control Act, “waters of the State” fall under the jurisdiction of the appropriate regional water quality control board (in this case, the CVRWQCB). Under the act, the regional water quality control board must prepare and periodically update basin plans. Each basin plan sets forth water quality standards for surface water and groundwater, and actions to control nonpoint and point sources of pollution to achieve and maintain these standards. Projects that affect wetlands or waters must meet the regional water quality control board’s waste discharge requirements, which may be issued in addition to a water quality certification under Section 401 of the CWA.

California Land Conservation Act of 1965 (Williamson Act)

The California Land Conservation Act of 1965, commonly known as the Williamson Act, is the principal method for encouraging preservation of agricultural lands in California. The Williamson Act enables local governments to enter into contracts with private landowners that restrict specific parcels of land to agricultural or related open-space use for 10 years. In return, landowners receive property tax assessments that are based on farming and open space uses rather than full market value. Local governments receive an annual subvention (subsidy) of forgone property tax revenues from the State via the Open Space Subvention Act of 1971.

The Williamson Act empowers local governments to establish "agricultural preserves" consisting of lands devoted to agricultural uses and other compatible uses. When establishing such preserves, the locality may offer to owners of included agricultural land the opportunity to enter into annually renewable contracts that restrict the land use for at least 10 years. In return, the landowner is guaranteed a relatively stable tax base, founded on the value of the land for agricultural/open space use only and unaffected by its development potential.

Cancelling a Williamson Act contract requires the landowner to undergo an extensive review and approval process and pay fees of up to 12.5 percent of the property value. The local jurisdiction approving the cancellation must find that the cancellation is consistent with the purpose of the California Land Conservation Act or is in the public interest. Several subfindings must be made to support either finding, as defined in Section 51282 of the California Government Code.

California Clean Air Act

The California Clean Air Act of 1988 requires nonattainment areas to achieve and maintain the State ambient air quality standards by the earliest practicable date. Local air districts must develop plans for attaining the State standards for ozone, carbon monoxide, sulfur dioxide, and nitrogen dioxide.

California Native Plant Protection Act

In addition to the CESA, the California Native Plant Protection Act provides protection to endangered and rare plant species, subspecies, and varieties of wild native plants in California. The definitions of "endangered" and "rare" in the California Native Plant Protection Act closely parallel the CESA definitions of "endangered" and "threatened" plant species.

California Surface Mining and Reclamation Act

The California Surface Mining and Reclamation Act of 1975 (SMARA) (PRC Section 2710 et seq.) addresses surface mining. Among the activities subject to SMARA are the mining of minerals, gravel, and borrow material. SMARA requires mitigation to reduce adverse impacts on public health, property, and the environment. Because the SLWRI may obtain borrow material for project construction from sites not previously permitted, Reclamation must comply with SMARA. SMARA applies to an individual or entity that would disturb more than 1 acre or remove more than 1,000 cubic yards of material through surface mining activities, including the excavation of borrow pits for soil material. SMARA is implemented through permitting ordinances developed by local government "lead agencies" that provide the regulatory framework under which local mining and reclamation activities are conducted. The State Mining and Geology Board reviews the local ordinances to ensure that they meet the procedures established by SMARA.

California Native Plant Society California Rare Plant Ranking System

The California Native Plant Society is a statewide nonprofit organization that seeks to increase understanding of California's native flora and to preserve this resource for future generations. The organization develops and maintains the California Rare Plant Ranking System (formerly known as the California Native Plant Society species lists). Species shown in this system have no formal legal protection, but the values and importance of these lists are widely recognized and these rankings provide the basis for USFS and BLM special-status species lists.

California Scenic Highway Program

The Scenic Highways Element is an optional element of the *California Highway Designs Manual* authorized by Section 65303 of the Government Code. The stated intent (Streets and Highways Code, Section 260) of the California Scenic Highway Program is to protect and enhance California's natural scenic beauty and to protect the social and economic values provided by the state's scenic resources. For a highway to receive official designation, the local jurisdiction must enact a scenic corridor protection program that protects and enhances scenic resources. A properly enforced program can do all of the following:

- Protect against inappropriate land uses
- Mitigate uses that detract from scenic values by proper siting, landscaping, or screening
- Make development more compatible with the environment by requiring building siting, height, colors, and materials that are harmonious with the surroundings
- Regulate grading to cause minimal alteration of existing contours and to preserve important vegetative features along the highway

State Lands Commission Land Use Lease

The California State Lands Commission has the authority and responsibility to manage and protect the important natural and cultural resources on certain public lands in the State and the public's rights to access these lands. Two distinct types of public lands are under the commission's jurisdiction: sovereign lands and school lands. Sovereign lands encompass approximately 4 million acres. These lands include the beds of California's naturally navigable rivers, lakes, and streams, and the state's tidal and submerged lands along the coastline, extending from the shoreline out to 3 miles offshore.

State of California General Plan Guidelines

The State of California has developed land-use compatibility guidelines for community-noise environments. The *State of California General Plan Guidelines*, published by the Governor's Office of Planning and Research (OPR

2003), provides guidance for the acceptability of projects within specific community noise equivalent level/day-night noise level (L_{dn}) contours. With regard to the SLWRI, water recreational uses are considered acceptable in areas where exterior noise levels do not exceed 75 A-weighted decibels community noise equivalent level/L_{dn}. Water recreational uses are normally unacceptable in areas exceeding 70 A-weighted decibels L_{dn} and clearly unacceptable in excess of 80 A-weighted decibels L_{dn}. The guidelines also present adjustment factors that may be used to arrive at noise-acceptability standards that reflect the particular community's noise-control goals, sensitivity to noise, and assessment of the relative importance of noise issues.

California Department of Transportation

Caltrans recommends vibration thresholds of 0.2 inch per second peak particle velocity for normal residential buildings and 0.08 inch per second peak particle velocity for old or historically significant structures (Caltrans 2002). These standards are more stringent than the Federal standard established by the Committee of Hearing, Bio Acoustics, and Bio Mechanics, presented above under "Federal Transit Administration."

Caltrans is responsible for planning, designing, construction, operating, and maintaining all State-owned roadways in California. The *Caltrans Highway Design Manual* establishes uniform policies and procedures to carry out Caltrans's highway design functions. The highway design criteria and policies in the manual provide a guide for applying standards in the design of projects and, rather than implementing enforceable regulations, present information and guidance.

3.4.3 Regional and Local

Shasta County Air Quality Management District's Authority to Construct and Permit to Operate

Facilities with equipment that may emit air pollution or would be used for controlling air pollution are subject to SCAQMD permit requirements. SCAQMD grants two types of permits: Authority to Construct and Permit to Operate. An Authority to Construct permit must be obtained before building or installing a new emissions unit or modifying an existing emissions unit that requires a permit. A Permit to Operate is issued after all construction is completed and the emission unit is ready for operation.

Other Local Permits and Requirements

Several other local permits and requirements may apply to the SLWRI. Shasta and Tehama counties and their public works departments will require compliance with local plans and ordinances, such as the county general plan, zoning ordinances, grading plan, and various use permits. Utility easements and various encroachments also may be required.

Chapter 4 Geology, Geomorphology, Minerals, and Soils

The evaluation in this chapter is based on a review of existing literature and data, along with information obtained from shoreline erosion surveys, wetland delineations, and geotechnical investigations and surveys. The information included in the technical analysis is also derived from the following sources:

- CALFED Bay-Delta Program Final Programmatic EIS/EIR (CALFED 2000a)

4.1 Affected Environment

This section describes the affected environment related to geology, seismicity, soils/erosion, mineral resources, and geomorphology for the dam and reservoir modifications proposed under SLWRI action alternatives. For a more in-depth description, see the *Geologic Technical Report.*

The environmental setting for the geology, seismicity, soils/erosion, mineral resources, and geomorphology assessment of the Shasta Lake and vicinity portion of the primary study area comprises the watersheds draining to Shasta Lake and the land area forming the shoreline of Shasta Lake. Five major drainages flow into Shasta Lake and form “arms” of the lake: Big Backbone Creek, the Sacramento River, the McCloud River, Squaw Creek, and the Pit River. This section also refers to the East and West “arms” of the Main Body of Shasta Lake as Main Body East Arm and Main Body West Arm.

4.1.1 Geology

The geology of the study area is described below for both the primary and extended study areas. The bedrock geology of the study area is described in the following paragraphs. The boundaries of geomorphic provinces referenced in Section 4.1.1 are shown in Figure 4-1.

Shasta Lake and Vicinity

The Shasta Lake and vicinity portion of the primary study area is illustrated in Figure 4-2. The drainages contributing to Shasta Lake cover a broad expanse of land with a widely diverse and complicated geology. Shasta Lake is situated geographically at the interface between the Central Valley, Klamath Mountains, and Modoc Plateau and Cascades geomorphic provinces.

The bedrock geology for the Shasta Lake and vicinity area is shown in Figure 4-3. The mapping legend that accompanies Figure 4-3 is presented in Table 4-1. Shasta Lake itself and adjacent lands (i.e., Shasta Lake and vicinity) are underlain by rocks of the Klamath Mountains and, to a much more limited extent, the Modoc Plateau and Cascades geomorphic provinces. The regional topography is highly dissected, consisting predominantly of ridges and canyons with vertical relief ranging from the surface of Shasta Lake at 1,070 feet above mean sea level (msl) to ridges and promontories more than 6,000 feet above msl. This diversity in topography is primarily a result of the structural and erosional characteristics of rock units in the Shasta Lake and vicinity area.

Klamath Mountains Geomorphic Province The Klamath Mountains Geomorphic Province is located in northwestern California between the Coast Ranges on the west and the Cascade Range on the east. The province consists of Paleozoic meta-sedimentary and meta-volcanic rocks and Mesozoic igneous rocks that make up four individual geologic terranes, also known as belts, extending to the north into southwestern Oregon: the eastern Klamath belt (also known as the eastern Paleozoic belt), central metamorphic belt, western Paleozoic and Triassic belt, and western Jurassic belt (Snoke and Barnes 2008; Hildbrande 2013). The four belts are the remnants of a chain of submarine volcanic mountains folded and faulted against the North American tectonic plate during the Mesozoic era (Heller and Ryberg 1983, Orr et al. 1992, Orr and Orr 1996). Low-angle thrust faults occur between the belts and allow the eastern blocks to be pushed westward and upward. The central metamorphic belt consists of Paleozoic hornblende, mica schists, and ultramafic rocks. The western Paleozoic and Triassic belt, and the western Jurassic belt consist of slightly metamorphosed sedimentary and volcanic rocks.

dia, , diabase dikes & small intrusive bodies
dpp, , plagioclase (+/- hornblende; quartz) porphyritic d
lake, , Shasta Lake; et al

A large portion of the Shasta Lake and vicinity area is underlain by rocks of the eastern Klamath belt. The strata of the eastern belt constitute a column 40,000–50,000 feet thick, and represent the time from the Ordovician period (about 490 million years before present) to the Jurassic period (about 145 million years before present). The stratigraphic column of formations that compose the eastern Klamath belt, including a scale of geologic time, is shown in Table 4-2 (Hackel 1966). Important eastern belt rocks that underlie Shasta Lake and vicinity include metavolcanics of Devonian age (i.e., Copley Greenstone and Balaklala Rhyolite formations), metasedimentary rocks of Mississippian age (i.e., Bragdon Formation), thin-bedded to massive sedimentary rocks of Permian age (i.e., McCloud Limestone Formation), and metasedimentary and metavolcanic rocks of Triassic age (i.e., Pit, Modin, and Bully Hill Rhyolite formations) (Reclamation 2009). Intrusive igneous rocks (e.g., localized granitic bodies) make up fewer than 5 percent of the rocks in the area but are well represented on the Shasta Lake shoreline, particularly in the south-central area of the lake. Mesozoic intrusive dikes are scattered in the western portion of the map area.

Table 4-2. Stratigraphic Column of Formations of the Eastern Klamath Belt

Period/Age Before Present (million years)	Formation	Thickness (feet)	General Features
Jurassic (145–200)	Potem Formation	1,000	Argillite and tuffaceous sandstones, with minor beds of conglomerate, pyroclastics, and limestone.
	Bagley Andesite	700	Andesitic flows and pyroclastics.
	Arvison Formation of Sanborn (1953)	5,090	Interbedded volcanic breccia, conglomerate, tuff, and minor andesitic lava flows.
Triassic (200–250)	Modin Formation	5,500	Basal member of volcanic conglomerate, breccia, tuff, and porphyry, with limestone fragments from the Hosselkus formation.
	Brock Shale	400	Dark massive argillite interlayered with tuff or tuffaceous sandstone.
	Hosselkus Limestone	0–250	Thin-bedded to massive light-gray limestone.
	Pit Formation	2,000–4,400	Predominantly dark shale and siltstone, with abundant lenses of metadacite and quartz-keratophyre tuffs.
	Bully Hill Rhyolite	100–2,500	Lava flows and pyroclastic rocks, with subordinate hypabyssal intrusive bodies.
Permian (250–300)	Dekkas Andesite	1,000–3,500	Chiefly fragmental lava and pyroclastic rocks, but includes mudstone and tuffaceous sandstone.
	Nosoni Formation	0–2,000	Mudstone and fine-grained tuff, with minor coarse mafic pyroclastic rocks and lava.
	McCloud Limestone	0–2,500	Thin-bedded to massive light-gray limestone, with local beds and nodules of chert.

Table 4-2. Stratigraphic Column of Formations of the Eastern Klamath Belt (contd.)

Period/Age Before Present (million years)	Formation	Thickness (feet)	General Features
Carboniferous (300–360)	Baird Formation	3,000–5,000	Pyroclastic rocks, mudstone, and keratophyre flows in lower part; siliceous mudstone, with minor limestone, chert, and tuff in middle part; and greenstone, quartz, keratophyre, and mafic pyroclastic rocks and flow breccia in upper part.
	Bragdon Formation	6,000±	Interbedded shale and sandstone, with grit and chert-pebble conglomerate abundant in upper part.
Devonian (360–420)	Kennett Formation	0–400	Dark, thin-bedded, siliceous mudstone and tuff.
	Balaklala Rhyolite	0–3,500	Light-colored quartz-keratophyre flows and pyroclastics.
	Copley Greenstone	3,700+	Keratophyric and spilitic pillow lavas and pyroclastic rocks.
Silurian (420–450)	Gazelle Formation	2,400+	Siliceous graywackes, mudstone, chert-pebble conglomerate, tuff, and limestone.
Ordovician (450–490)	Duzel Formation	1,250+	Thinly layered phyllitic greywacke, locally with radiolarian chert and limestone.

The McCloud Limestone is prominently exposed within the McCloud, Pit, Main Body, and Big Backbone arms of Shasta Lake. Within the lake footprint, the McCloud Arm has the largest exposure of this limestone, followed by the Pit, Main Body, and Big Backbone arms. Along the McCloud Arm, this limestone crops out on the eastern shore from the mouth at the main body of the lake to Hirz Bay. Above Hirz Bay, it is intermittently exposed on both sides of the McCloud Arm. Along the Pit Arm near the mouth of Brock Creek, the McCloud Limestone is exposed along the northern and southern banks. The McCloud Limestone is exposed near the southern shore of Allie Cove in the eastern portion of the Main Body of the lake. Along the Big Backbone Arm, the McCloud Limestone is exposed near the eastern shore between the outlets of Shoemaker and Limerock creeks. Outside the Shasta Lake footprint, an outcrop of the McCloud Limestone is exposed along the McCloud River approximately 10 miles upstream from the mouth into the McCloud Arm. The McCloud Limestone is also exposed on the north side of Bohemotash Mountain, which is approximately 2 miles from the mouth of Big Backbone Creek at the Big Backbone Arm.

“Skarn” is a geologic term that refers to metamorphic rocks formed in the contact zone of magmatic intrusions (e.g., granite) with carbonate-rich rocks (e.g., limestone). Skarn deposits are rich in lime-silicate minerals and locally contain magnetite. Permian-aged skarn deposits are present within the McCloud Arm. The deposits are located near the mouths of Marble and Potter creeks and on the peninsula at the eastern margin of the inlet of the McCloud Arm. The skarn deposits occur adjacent to the McCloud Limestone at the mouths of Marble and Potter creeks, but the McCloud Limestone is absent near skarn deposits on the peninsula.

A small area of the fossiliferous Cretaceous Chico Formation, consisting of Great Valley marine sedimentary rocks, occurs near Jones Valley Creek, a tributary to the Pit Arm. Although this rock unit occurs in the immediate vicinity, it is not exposed along the shoreline of the lake and falls outside the Shasta Lake and vicinity area. Some outcrops of McCloud Limestone, especially in the vicinity of the McCloud River Bridge, are also fossiliferous. The fossiliferous deposits exposed at these locations are invertebrates, primarily plants, corrals, and mollusks.

Modoc Plateau and Cascades Geomorphic Provinces The Cascade Range and Modoc Plateau together cover approximately 13,000 square miles in the northeast corner of California. The Cascade Range and Modoc Plateau (collectively the Modoc Plateau and Cascades Geomorphic Province) are very similar geologically and consist of young volcanic rocks that are of Miocene to Pleistocene age. Included in this province are two stratovolcanoes, Mount Shasta and Lassen Peak, and the Medicine Lake Highlands, a broad shield volcano.

The Cascade volcanics have been divided into the Western Cascade series and the High Cascade series. The Western Cascade series rocks consist of Miocene-aged basalt, andesite, and dacite flows interlayered with rocks of explosive origin, including rhyolite tuff, volcanic breccia, and agglomerate. This series is exposed at the surface in a belt 15 miles wide and 50 miles long from the Oregon border to the town of Mount Shasta. After a short period of uplift and erosion that extended into the Pliocene, volcanism resumed, creating the High Cascade volcanic series. The High Cascade volcanic series forms a belt 40 miles wide and 150 miles long just east of the Western Cascade series rocks. Early High Cascade rocks formed from very fluid basalt and andesite that extruded from fissures to form low shield volcanoes. Later eruptions during the Pleistocene contained more silica, causing more violent eruptions. Large stratovolcanoes like Mount Shasta and Lassen Peak had their origins during the Pleistocene (Norris and Webb 1990).

The Modoc Plateau consists of a high plain of irregular volcanic rocks of basaltic origin. The numerous shield volcanoes and extensive faulting on the plateau give the area more relief than otherwise may be expected for a plateau. The Modoc Plateau averages 4,500 feet in elevation and is considered a small part of the Columbia Plateau, which covers extensive areas of Oregon, Washington, and Idaho.

Volcanic rocks of the Modoc Plateau and Cascades Geomorphic Province are present adjacent to the eastern and northeastern boundaries of the Shasta Lake and vicinity area. In the vicinity of Shasta Lake they occur near the Pit Arm and along the upper reaches of the Sacramento Arm. These rocks are generally younger than 4 million years old. Volcaniclastic rocks, mudflows, and tuffs of the Tuscan Formation occur in the Pit River area, and localized volcanic deposits occur in isolated locations.

The areal extent of bedrock types within the Shasta Lake and vicinity area is presented in Table 4-3 for the portion of the area between 1,070 feet and 1,090 feet above msl (i.e., Impoundment Area), and in Table 4-4 for the portion potentially disturbed by construction activities (i.e., Relocation Areas).

Table 4-3. Areal Extent of Bedrock Types – Shasta Lake and Vicinity (Impoundment Area)

Map Unit	Formation	Bedrock Types	Acres	% of Total Impoundment Area

Cave and Karst Resources

Karst geomorphology is named after the Karst region in Slovenia, where limestone has been geologically carved into world-famous caves and other karst landforms. Caves and karst landforms are found along the Big Backbone Arm, the McCloud Arm, and the Pit Arm (Brock Creek).

Nine caves in the National Recreation Area (NRA) adjacent to Shasta Lake—Dekkas Rock Staircase Cave, Lake Level Cave, Clay Doe Cave, Jolly Time Cave, Blanchet Cave, two caves known as the McCloud Bridge Caves, and two caves known as the Town Mountain Caves—could be periodically inundated under the action alternatives (USFS 2012). The first three of these caves are registered under the Federal Cave Resource Protection Act of 1988. Dekkas Rock Staircase and the two McCloud Bridge caves are already periodically inundated under the current elevation of the dam. Field investigations performed to date have not identified any other caves that would be affected by the raising of Shasta Dam.

Upper Sacramento River (Shasta Dam to Red Bluff)

The portion of the study area along the Sacramento River downstream to the Red Bluff Pumping Plant encompasses portions of the Cascade Range, Klamath Mountains, and Central Valley Geomorphic Provinces.

Central Valley Geomorphic Province The Central Valley Geomorphic Province is a large, asymmetrical, northwest-trending, structural trough formed between the uplands of the California Coast Ranges to the west and the Sierra Nevada to the east, and is approximately 400 miles long and 50 miles wide (Page 1985). The Coast Ranges to the west consist of pre-Tertiary and Tertiary semiconsolidated to consolidated marine sedimentary rocks, volcanic rocks, and exposed uplifted oceanic rocks of the Franciscan Complex. The Coast Ranges sediments are folded and faulted and extend eastward beneath most of the Central Valley. The Sierra Nevada to the east side of the valley is composed of pre-Tertiary igneous and metamorphic rocks overlain by Tertiary volcanic and sedimentary rocks.

Along the western side of the Sacramento Valley, rocks of the Central Valley Geomorphic Province include Upper Jurassic to Cretaceous marine sedimentary rocks of the Great Valley Sequence; fluvial deposits of the Tertiary Tehama Formation; Quaternary Red Bluff, Riverbank, and Modesto Formations; and Recent alluvium.

The Great Valley Sequence was formed from sediments deposited within a trough formed between the Sierra Nevada volcanic arc and the uplifted oceanic crust now known as the Franciscan Complex in the Coast Ranges. A majority of the sediments in this trough were coalescing submarine fans. The sediment sources were the Klamath Mountains and Sierra Nevada to the north and east. These deposits include mudstones, sandstones, and conglomerates.

Tertiary and Quaternary fluvial sedimentary deposits unconformably overlie the Great Valley Sequence. The Pliocene Tehama Formation is the oldest, derived from erosion of the Coast Ranges and Klamath Mountains, and consists of pale green to tan semiconsolidated silt, clay, sand, and gravel. Along the western margin of the valley, the Tehama Formation is generally thin, discontinuous, and deeply weathered.

The Red Bluff Formation is a broad erosional surface, or pediment, of low relief formed on the Tehama Formation between 0.45 and 1.0 million years ago. Thickness varies to about 30 feet.

Recent alluvium consists of loose sedimentary deposits of clay, silt, sand, gravel, and boulders. The deposits may originate from landslides, colluvium, stream channel deposits, and floodplain deposits. Landslides occur along the project area but are generally small, shallow debris slides or debris flows.

Stream channel deposits generally consist of unconsolidated sand and gravel, with minor amounts of silt and clay. Floodplain deposits are finer grained and consist almost entirely of silt and clay (DWR 2003).

Lower Sacramento River and Delta

The study area along the lower Sacramento River and the Delta encompasses the Central Valley Geomorphic Province, as described above for the upper Sacramento River portion of the primary study area.

The Delta is a broad depression in the Franciscan Complex bedrock that resulted from an east-west expansion of the San Andreas and Hayward fault systems, filled by sediments deposited over many millions of years via the Sacramento and San Joaquin rivers and other tributary rivers and streams.

CVP/SWP Service Areas

The CVP/SWP service areas encompass portions of the Central Valley, Sierra Nevada, Coast Ranges, Cascade Range, Peninsular Ranges, Transverse Ranges, Mojave Desert, Modoc Plateau, and Klamath Mountains geomorphic provinces.

The south-of-Delta CVP/SWP service areas include two distinct, noncontiguous areas. In the north are the San Felipe Division's CVP service area and the South Bay SWP service area; to the south are the SWP service areas. The northern section of this region encompasses the Coast Ranges Geomorphic Province and the southern portion of this section includes portions of the Peninsular Ranges, Transverse Ranges, and Mojave Desert geomorphic provinces. Additional information on the geomorphic provinces is available in the *Geologic Technical Report*.

4.1.2 Geologic Hazards

Geologic hazards are described below for both the primary and extended study areas.

Shasta Lake and Vicinity

Six types of geologic hazards have the potential to occur within and near the Shasta Lake and vicinity portion of the primary study area: seismic hazards, volcanic eruptions and associated hazards, mudflows, snow avalanches, slope instability, and seiches.

Seismic Hazards Seismic hazards consist of the effects of ground shaking and surface rupture along and around the trace of an active fault. Ground shaking is the most hazardous effect of earthquakes because it is the most widespread and accompanies all earthquakes. Ground shaking can range from high to low intensity and is often responsible for structural failure, leading to the largest loss of life and property damage during an earthquake. The Modified Mercalli intensity ratings reflect the relationship between earthquake magnitudes and shaking intensity. Higher magnitude earthquakes typically produce higher shaking intensities over wider areas, which may result in greater damage.

Surface rupture occurs when an earthquake results in ground rupture, causing horizontal and/or vertical displacement. Surface rupture typically is narrow in rock and wider in saturated soils, and also typically tends to occur along previous fault lines.

An active fault is defined by the Alquist-Priolo Earthquake Fault Zoning Act (Alquist-Priolo Act) as a fault that has caused surface rupture within the last 11,000 years. According to the California Geological Survey's Alquist-Priolo Act Active Fault Maps, the nearest active fault north of the Shasta Lake and vicinity area is the Hat Creek–Mayfield–McArthur Fault Zone, located about 50 miles to the northeast of Shasta Dam (Jennings 1975). Blakeslee and Katterhorn (2013) refer to the three fault zones as the Hat Creek fault system. The Hat Creek fault system can be readily seen electronically on the California Geological Survey Web site: http://www.quake.ca.gov/gmaps/WH/ regulatorymaps.htm using "Shasta" in the search query. This fault system is composed of numerous parallel north-northwest–trending normal faults. According to the Alquist-Priolo Act maps, the Hat Creek–Mayfield–McArthur fault is capable of generating magnitude 7.0 earthquakes with a return period of 750 years (Petersen et al. 1996). The Rocky Ledge and Pittville faults appear to also be part of the Hat Creek fault system, as shown on the California Geological Survey Web site. Blakeslee and Katterhorn independently found a magnitude of 6.7 with a return interval of 667 ±167 years for the Hat Creek fault system. The U.S. Geological Survey (USGS) hazard assessment for the Hat Creek fault system ranges between a magnitude of 6.7 and 7.2 for the different faults in the fault system (http://geohazards.usgs.gov/cfusion/ hazfaults_search/disp_hf_info.cfm?cfault_id=8,%209). However, as addressed in Blakeslee and Katterhorn, there is no historic record (i.e., within the last 200 years) of movement, and they estimate the recurrence interval for the fault system to be in the range of 1,000 to 3,000 years. Therefore Blakeslee and Katterhorn assign a seismic hazard rating of "moderate," given the lack of historical earthquake events. LaForge and Hawkins (1986) identified the Hat Creek fault system as having a seismic risk rating of "potential." They associated the Holocene movement within the Modoc Geomorphic Province to be related to the extension of the high-angle block faulting in the Basin and Range Geomorphic Province located to the east on the California/Nevada border. Subsequent research, as noted by Blakeslee and Katterhorn (2013), has added credibility to this interpretation.

Northeast of the Shasta Lake and vicinity area, Quaternary-age faults (e.g., most recent movement was within the last 2 to 3 million years and therefore, the faults are potentially active under the Alquist-Priolo Act) include the Gillem-Big Crack faults near the California-Oregon border southeast of Lower Klamath Lake and the Cedar Mountain Fault southwest of Lower Klamath Lake. The faults in this zone are capable of earthquakes up to magnitude 7.0. Farther northeast, the Likely Fault is judged capable of a magnitude 6.9 earthquake. In the northeast corner of the state, the Surprise Fault is capable of a magnitude 7.0 earthquake. According to LaForge and Hawkins (1986), the nearest Quaternary-age fault is the Battle Creek fault located approximately 15 miles south-southeast of Redding. They estimate that the most recent movement on this fault occurred approximately 400,000 to 550,000 years ago. This fault has been rated by LaForge and Hawkins to not be a source of a major earthquake that may affect Shasta Dam.

Seismic activity has been reported in the area of Shasta Dam and Shasta Lake and has typically been in the 5.0 magnitude or lower range. The nearest seismic activity to Shasta Dam and Shasta Lake was a magnitude 5.2 earthquake that occurred 3 miles northwest of Redding, near Keswick Dam, in 1998 (Petersen 1999). LaForge and Hawkins (1986) found that the historical seismicity in the vicinity of the dam to be a “low level, with poorly located small magnitude events recorded.” They also found that no faults exist in and near the dam footprint and concluded that surface fault displacement in the dam foundation or reservoir is not considered to be a “credible event.”

Volcanic Eruptions and Associated Hazards Volcanic hazards include potential eruptions, and their products and associated hazards. In the Shasta Lake and vicinity area these include lava flows, pyroclastic flows, domes, tephra, and mudflows and floods triggered by eruptions. Three active centers of volcanic activity, all associated with the Modoc Plateau and Cascades Geomorphic Province, occur near enough to the Shasta Lake and vicinity area and merit discussion: the Medicine Lake Highlands, Lassen Peak, and Mount Shasta.

The Medicine Lake Highlands is located approximately 65 air miles northeast of Shasta Lake and includes a broad shield volcano that has a large caldera at its summit and more than 100 smaller lava cones and cinder cones on its flanks. The volcano developed over a period of 1 million years, mainly through lava flows. The most recent activity was approximately 500 years ago, when a large tephra eruption was followed by an extrusion of obsidian. Volcanic activity is likely to persist in the future (USFS 1994), specifically as local lava flows and tephra eruptions.

Lassen Peak lies 50 miles southeast of Shasta Lake. Lassen Peak is a cluster of dacitic domes and vents that have formed over the past 250,000 years. The most recent eruption occurred in 1914. That eruption began as a tephra eruption with steam blasts, and climaxed with a lateral blast, hot avalanches, and mudflows. Most ash from the 1914 eruption was carried to the east of the volcano.

The most prominent, active volcanic feature in the vicinity of Shasta Lake is Mount Shasta, which is located approximately 45 miles north of Shasta Lake. Mount Shasta has erupted at least once per 800 years during the last 10,000 years, and about once per 600 years during the last 4,500 years. Mount Shasta last erupted in 1786. Eruptions during the last 10,000 years produced lava flows and domes on and around the flanks of Mount Shasta. Pyroclastic flows extended up to 12 miles from the summit. Most of these eruptions also produced mudflows, many of which reached tens of miles from Mount Shasta.

Eruptions of Mount Shasta could endanger the communities of Weed, Mount Shasta, McCloud, and Dunsmuir. Such eruptions will most likely produce deposits of lithic ash, lava flows, domes, and pyroclastic flows that may affect low- and flat-lying ground almost anywhere within 12 miles of the summit. However, on the basis of its past behavior, Mount Shasta is not likely to erupt large volumes of pumiceous ash (tephra) in the future. Areas subject to the greatest risk from air-fall tephra are located mainly east and within about 30 miles of the summit (Miller 1980).

Floods commonly are produced by melting of snow and ice during eruptions of ice-clad volcanoes like Mount Shasta, or by heavy rains that may accompany eruptions. By incorporating river water as they move down valleys, mudflows may grade into slurry floods carrying unusually large amounts of rock debris. Eruption-caused floods can occur suddenly and can be of large volume. If floods caused by an eruption occur when rivers are already high, floods far larger than normal can result. Streams and valley floors around Mount Shasta could be affected by such floods as far downstream as Shasta Lake. The danger from floods caused by eruptions is similar to that from floods having other origins, but floods caused by eruptions may be more damaging because of a higher content of sediment that would increase the bulk specific gravity of the fluid (Miller 1980).

Mudflows Small mudflows not caused by eruptions are common at Mount Shasta. Relatively small but frequent mudflows have been produced historically (1924, 1926, 1931, and 1977) by melting of glaciers on Mount Shasta during warm summer months. Mudflows that occurred during the summer of 1924 entered the McCloud River and subsequently flowed into the Sacramento River (Miller 1980). In summer 2014, warm temperatures combined with accelerated glacial melt resulted in very turbid flows emanating from Mud Creek that affected the McCloud River (de la Fuente 2014).

Snow Avalanches Avalanche hazards near the Shasta Lake and vicinity area typically occur in steep, high-elevation terrane. These areas are generally above the tree line or in sparsely vegetated areas. Significant avalanche areas are limited to locations on the upper slopes outside of the Shasta Lake and vicinity area. It is noteworthy that a large snow avalanche occurred in the Sacramento River canyon near Dunsmuir, California, in the 1890s (Southern 1966).

Slope Instability (Mass Wasting) Slope instability hazards occur in areas of active and relict mass wasting features (e.g., active and relict landslides, debris flows, inner gorge landscape positions, and complexes of these features). Slope instability hazards occur throughout the Shasta Lake and vicinity area, and are most common in areas of steep topography. Locations in the Shasta Lake and vicinity area of mapped slope instability hazards are shown in Figure 4-4.

Reservoir Triggered Seismicity Shasta Lake and vicinity area could be subjected to reservoir triggered seismicity (RTS). The International Committee on Large Dams (ICOLD 2011), in their draft "Reservoirs and Seismicity – State of Knowledge" accept reservoir triggered seismicity as the most adequate term to describe the phenomena of earthquakes occurring in the vicinity of man-made water reservoirs. The two principal triggers of RTS are added weight stresses and pore pressure propagation. Lake Shasta experienced an RTS event during the initial filling. Based on the work by Packer et al. (1979) the seismic event occurred subsequent to reservoir impoundment. The largest magnitude was approximately 3.0 and occurred a few kilometers southeast of the reservoir (Packer et al. 1977).

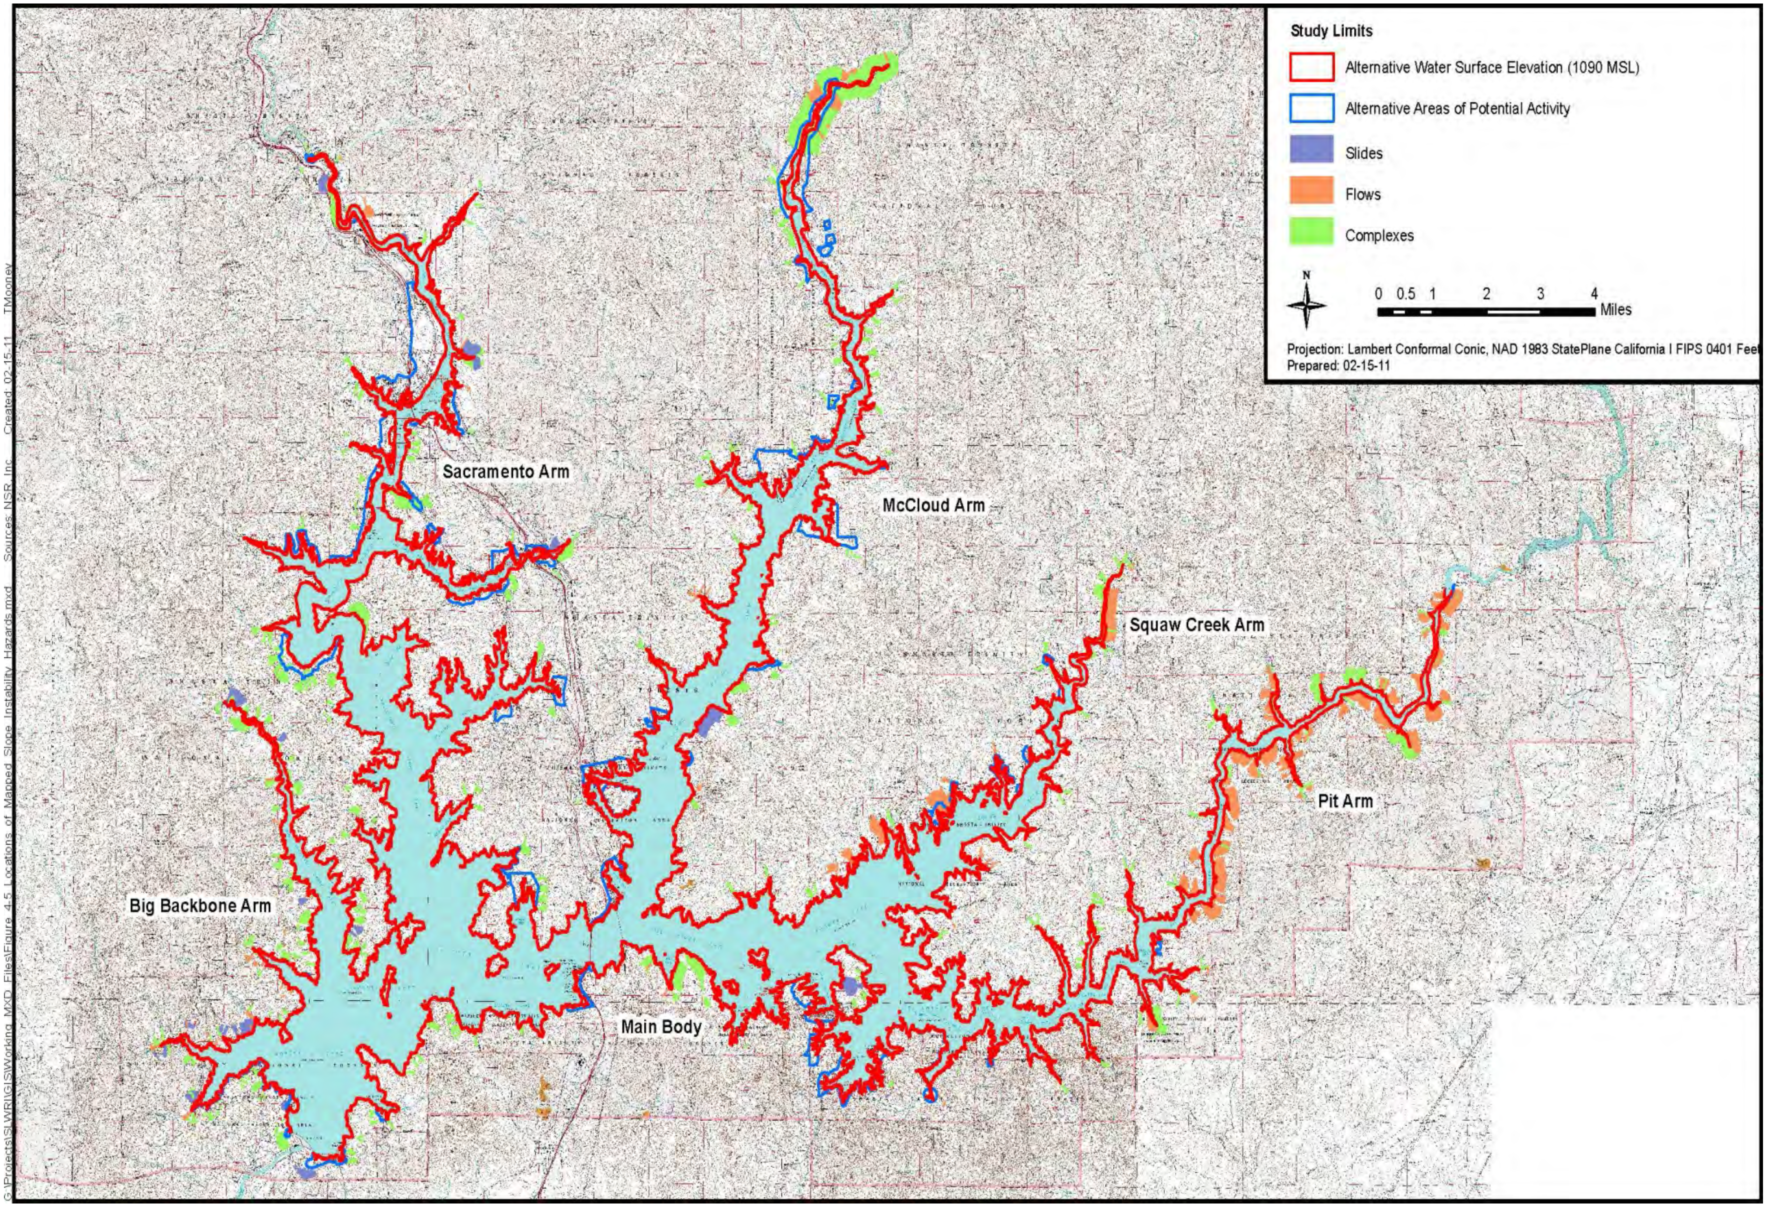

Figure 4-4. Locations of Mapped Slope Instability Hazards – Shasta Lake and Vicinity

The terrane underlying the Shasta Lake and vicinity area and the surrounding region has been influenced by a combination of tectonic uplift, mass wasting, and fluvial and surface erosion processes. The influence of these processes is ongoing, with evidence of ancient and more recent mass wasting features over the entire area, consisting of debris slides, torrents, and flows, with lesser amounts of rotational/translational landslides. The extent or distribution of mass wasting features across the region is believed not to have changed appreciably as a result of land use activities following Anglo-American settlement (USFS 1998).

Much of the topography in the general vicinity of Shasta Lake is steep, with concave swales; therefore, landslides are relatively common, ranging from small mudflows and slumps to large debris slides, debris flows, and inner gorge landslides. Small shallow debris slides associated with localized alluvial/colluvial rock units occur along the shoreline of Shasta Lake. Rockslides caused by mining activities have also occurred on the slopes surrounding Shasta Lake.

The areal extent of mapped slope instability hazards in the Shasta Lake and vicinity area is presented in Table 4-5 for the portion of the area between 1,070 feet and 1,090 feet above msl (Impoundment Area), and in Table 4-6 for the portion potentially disturbed by construction activities under the action alternatives (Relocation Areas). About 173 acres (7 percent) of the Impoundment Area is occupied by features that are potentially unstable. Potentially unstable features occupy about 232 acres (7 percent) of the Relocation Area. Most of the mapped slope instability hazards are debris flows.

Table 4-5. Areal Extent of Mapped Slope Instability Hazards – Shasta Lake and Vicinity (Impoundment Area)

Map Unit	Formation	Acres	% of Impoundment Area Acreage
1050	Slides	9.5375	0.38%
1100	Flows	66.6091	2.67%
1200	Complexes	97.1695	3.89%

Table 4-6. Areal Extent of Mapped Slope Instability Hazards – Shasta Lake and Vicinity (Relocation Areas)

Map Unit	Formation	Acres	% of Relocation Area Acreage
1050	Slides	2.9947	0.09%
1100	Flows	52.9767	1.59%
1200	Complexes	175.8020	5.26%

Seiches A seiche is an oscillation of a body of water in an enclosed or semienclosed basin that varies in period, depending on the physical dimensions of the basin, from a few minutes to several hours, and in height from a few millimeters to a few meters. Seiches arise chiefly as a result of sudden local changes in atmospheric pressure, aided by wind and occasionally tidal currents. Seiches can also be triggered by strong earthquake ground motion or large landslides entering a body of water.

If Mount Shasta were to erupt again, volcanic ash could fall in the study area, though as described previously, Mount Shasta is not likely to erupt large volumes of pumiceous ash (tephra) in the future. Minor seiches in Shasta Lake also could be generated by debris flows in the arms of the lake where its tributaries enter (City of Redding 2000). A large megathrust on the Cascadia subduction zone off the Pacific coast could generate enough ground shaking to generate a seiche in Shasta Lake. The Good Friday 1964 movement of the Cascadia subduction zone caused a seiche at Shasta Lake.

Regardless of its cause, the effects of a seiche would depend on the local conditions at the time. If the reservoir were filled to capacity, there may be some overspill by way of the dam spillways. Substantial overtopping of the dam itself is extremely unlikely, as such an event would require a seiche more than 6 meters high, even if the reservoir were filled to capacity. Excess flows into the Sacramento River triggered by a seiche in Shasta Lake would be attenuated by Keswick Reservoir (City of Redding 2000).

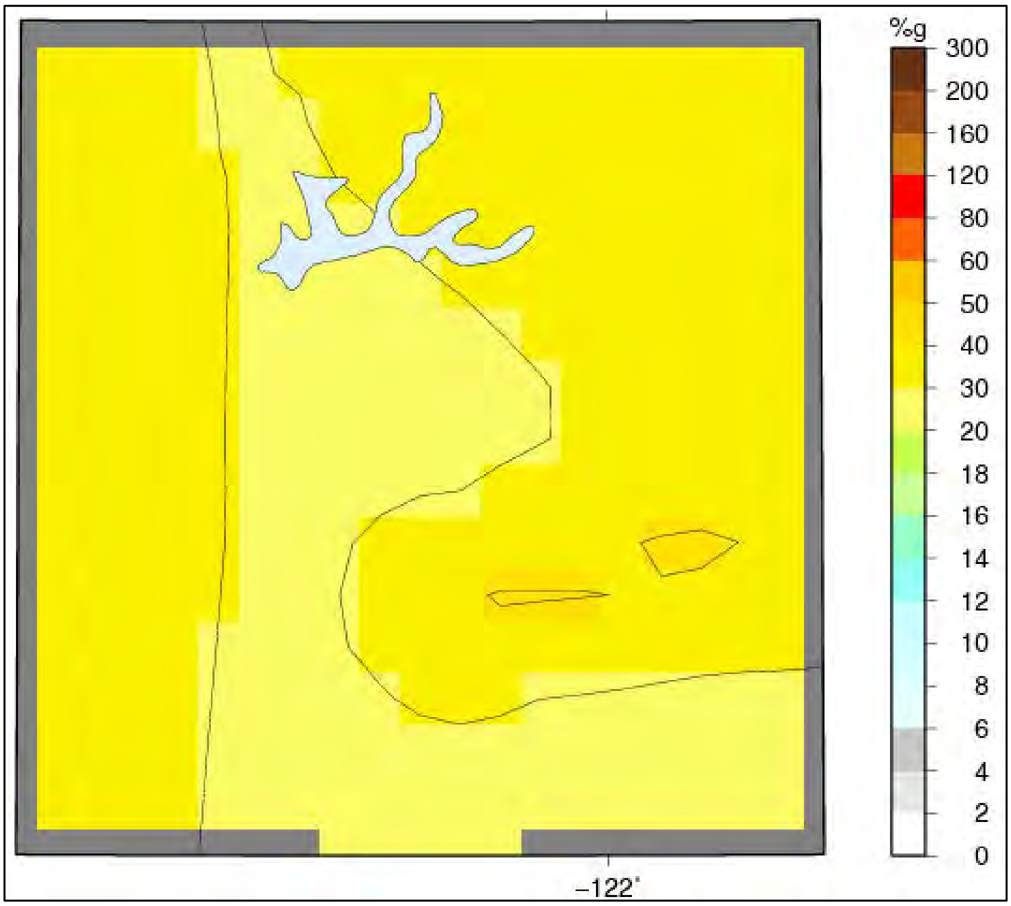
Upper Sacramento River (Shasta Dam to Red Bluff)

The upper Sacramento River portion of the primary study area could potentially be affected by geologic hazards in the region attributed to seismic hazards and volcanic eruptions and associated hazards. Mudflows, snow avalanches, slope instability, and seiches are not considered geologic hazards in this portion of the primary study area.

Seismic Hazards The northeastern area of Shasta County is part of an area between Lassen Peak and the Medicine Lake Highlands (in Siskiyou County), that is cut by a series of active normal faults that are part of the Sierra Nevada–Great Basin dextral shear zone (Shasta County 2004). These faults are likely to affect the upper watersheds northeast of the Sacramento Valley. These faults include the Mayfield–MacArthur–Hat Creek fault system (Blakeslee and Katterhorn 2013) approximately 50 miles east-northeast of Shasta Lake; the Gillem–Big Crack Faults, near the California-Oregon border southeast of Lower Klamath Lake; and the Cedar Mountain Fault, southwest of Lower Klamath Lake. The faults in this zone are capable of earthquakes up to magnitude 7.0. LaForge and Hawkins (1986) identified the Battle Creek fault approximately 15 miles south of Redding as the nearest Quaternary age fault but indicated that it is not a credible seismic hazard.

Shasta County is a seismically active region but has not experienced significant property damage or loss of life from earthquakes in the past 120 years. The City of Redding (2005) reported that maximum recorded intensities have reached Modified Mercalli VII. The majority of intense seismic activity in Shasta County has occurred in the eastern half of the county, around Lassen Peak (City of Redding 2005).

The *Shasta County General Plan* states that the maximum intensity event expected to occur in eastern Shasta County is Modified Mercalli VIII (Shasta County 2004). In the western half of Shasta County, the maximum intensity event is expected to be Modified Mercalli VII (City of Redding 2005). Shasta County is entirely within Seismic Zone 3 of the 2004 Uniform Building Code. Redding is an area of "moderate seismicity" and the Hat Creek and McArthur areas are of "moderate-to-high seismicity" (Shasta County 2004). A probabilistic seismic hazard map from the 2008 USGS conterminous data set is presented in Figure 4-5, which illustrates the peak ground acceleration (PGA) for 2 percent chance of exceedence in 50 years or a return period of 2,475 years (USGS 2014). This figure shows that in the vicinity of Shasta Lake the PGA varies from 0.3 – 0.4 g.



Source: USGS 2014

Figure 4-5. USGS 2008 Peak Ground Acceleration 2 Percent Chance of Exceedence in 50 Years in the Primary Study Area

South of Shasta County along the upper Sacramento River, potential slipping and seismic shaking could be associated with the Great Valley blind thrust fault system, which is capable of earthquakes up to magnitude 6.8 along the west side of the Sacramento Valley. This fault system is not considered active by the Alquist-Priolo Act, because blind thrust faults do not exhibit surface traces, but is identified in a database of potential earthquakes (Working Group of Northern California Earthquake Potential 1996). This fault system forms the boundary between the Coast Ranges and the Sacramento and San Joaquin valleys.

The San Andreas Fault system is located west of the Sacramento and San Joaquin valleys and is made up of a series of faults that lie along a 150-mile-long northwest-trending zone of seismicity. This zone is 10–45 miles west of the Sacramento Valley and extends from Suisun Bay past Lake Berryessa and Lake Pillsbury to near the latitude of Red Bluff. The Green Valley, Hunting Creek, Bartlett Springs, Round Valley, and Lake Mountain faults are the mapped active faults of the San Andreas Fault system most likely to affect the upper watersheds west of the Sacramento Valley. The faults in this system are capable of earthquakes up to 7.1 in magnitude.

The Indian Valley Fault, located southeast of Lake Almanor, and the Honey Lake Fault zone, located east of Lake Almanor, are likely to affect the upper watersheds east of the Sacramento Valley and are capable of a magnitude 6.9 earthquake. Surface rupture occurred in 1975 along the Cleveland Hill Fault south of Lake Oroville. The Foothills Fault system, which borders the east side of the Sacramento and San Joaquin valleys, is judged to be capable of a magnitude 6.5 earthquake.

Volcanic Eruptions and Associated Hazards Shasta County is at the southern end of the Cascade Range (as described above for the geology of the upper Sacramento River). The most recent volcanic activity in Shasta County occurred between 1914 and 1917, when Lassen Peak erupted, producing lava flows, numerous ash falls, and a large mudflow. The mudflow, a result of melting snow and ash, flowed down Lost Creek and Hat Creek (Shasta County 2004).

It is unlikely that a large mudflow from Mount Shasta would endanger Shasta County (Shasta County 2004).

Lower Sacramento River and Delta

The lower Sacramento River and Delta portion of the extended study area could potentially be affected by geologic hazards in the region attributed to seismic hazards. Volcanic eruptions and associated hazards, mudflows, snow avalanches, slope instability, and seiches are not considered geologic hazards in this portion of the extended study area.

The nearest fault to the lower Sacramento River below Red Bluff is the Dunnigan Hills Fault, which has experienced fault displacement in the Late

Quaternary and potential displacement in the Holocene along a separate segment of the fault (Jennings and Bryant 2010). The Dunnigan Hills Fault runs along the Sacramento River and is located between 6 and 10 miles west of the river near the town of Dunnigan. The Cleveland Fault is located approximately 30 miles east of the Sacramento River near the city of Oroville and is considered historic, having experienced displacement in the last 200 years (Jennings and Bryant 2010). In addition, the Great Valley blind thrust fault system (not considered active by the Alquist-Priolo Act) and San Andreas fault system extends along the Sacramento River to the west, as described above for the upper Sacramento River portion of the primary study area.

Failure of Delta levees is the primary threat to the region as a result of seismic activity. The Delta levees are located in a region of relatively low seismic activity compared to the San Francisco Bay Area (Bay Area). The major strike-slip faults in the Bay Area (the San Andreas, Hayward, and Calaveras faults) are located more than 16 miles from the Delta. The less active Green Valley and Marsh Creek–Clayton faults are more than 9 miles from the Delta. Small but significant local faults are situated in the Delta, and there is a possibility that blind thrust faults occur along the west Delta.

CVP/SWP Service Areas

The CVP/SWP service areas portion of the extended study area could potentially be affected by geologic hazards in the region attributed to seismic hazards. Volcanic eruptions and associated hazards, mudflows, snow avalanches, slope instability, and seiches are not considered geologic hazards in this portion of the extended study area. A number of active faults exist along the Sacramento and San Joaquin rivers in the CVP/SWP service areas.

Major earthquake activity has centered along the San Andreas Fault zone, including the great San Francisco earthquake of 1906 in the Bay Area. Since that earthquake, four events of magnitude 5.0 on the Richter scale or greater have occurred in the Bay Area. The San Andreas and Hayward faults remain active, with evidence of recent slippage along both faults.

In the San Joaquin River region, the Great Valley blind thrust fault system forms the boundary between the Coast Ranges and the west boundary of the San Joaquin Valley. This fault system is capable of earthquakes up to magnitude 6.7 along the west side of the San Joaquin Valley.

Active faults likely to affect the upper watersheds at the end of the San Joaquin Valley include the White Wolf Fault, which ruptured in 1952 with a magnitude 7.2 earthquake; the Garlock Fault, capable of a magnitude 7.3 earthquake; and several smaller faults 10–30 miles north of the White Wolf Fault.

A list of all of the reported faults, fault zones, and systems, according to the California Geological Survey, are presented in the Fault Activity Map of

California (Jennings and Bryant 2010) and the explanatory text to accompany the map.

4.1.3 Geomorphology

Geomorphology in the study area is described below for both the primary and extended study areas.

Shasta Lake and Vicinity

As described previously, most of the Shasta Lake and vicinity area is within the Klamath Mountains Geomorphic Province. The topography of the study area ranges from moderate to steep, and elevation ranges from approximately 1,070 feet to more than 6,000 feet above msl. The orientation and slopes of the ridges are controlled by the bedrock geology and structure. Generally speaking, the eastern slopes of the ridges are steeper than the western slopes. Hillslope gradient in the Shasta Lake and vicinity area ranges from 0 percent to more than 100 percent.

The regional stream network and boundaries of watersheds adjacent to Shasta Lake are shown in Figure 4-6. The boundaries of watersheds adjacent to Shasta Lake (shown in Figure 4-6) are the same as the boundaries of the area’s 6th Field Hydrologic Unit Code watersheds defined by USFS.

Regional-scale characteristics of the streams that are tributary to Shasta Lake are presented in Figure 4-7, where they are organized by arm. The total area of watersheds draining to the lake on a regional scale is 6,665 square miles. Of this total, watersheds that are immediately adjacent and contribute directly to Shasta Lake (i.e., 6th Field Hydrologic Unit Code watersheds) occupy about 512 square miles (Table 4-7). These immediately adjacent watersheds include small portions of the five major tributaries to Shasta Lake (Big Backbone Creek, the Sacramento and McCloud rivers, Squaw Creek, and the Pit River) and small watersheds that are adjacent and directly contributory to the Main Body of the lake.

In general, the stream networks adjacent and directly tributary to Shasta Lake are irregular and dendritic. The drainages are steep, and the drainage density ranges from 3.0 to 6.4 miles of stream per square mile of drainage area (Table 4-7). The drainage density is the lowest in the Main Body of the lake because this area has several small catchments. The density is the highest in the more well-defined arms, a function of the larger catchment areas of the tributary watersheds.

The lengths of streams within watersheds that are adjacent to Shasta Lake are also reported in Figure 4-7, where they again are aggregated by arm and further subdivided by flow regime (intermittent or perennial) and stream gradient. There are about 1,200 intermittent and perennial stream channels totaling about 2,903 miles that enter directly into Shasta Lake. These values do not include large parts of the Sacramento River, Squaw Creek, Pit River, McCloud River, and Big Backbone Creek watersheds, only the "face drainages" within the arms themselves.

Most of the stream channels that flow into Shasta Lake are intermittent and have stream slopes greater than 10 percent (mean gradient of 27 percent). Net Trace model results indicate that about 33 percent of these stream channels are perennial. About 20 percent of these channels (716) have gradients less than 10 percent and are likely to support fish and other aquatic organisms. In terms of the total number of channels, the Sacramento arm has the highest proportion (27 percent). There is approximately 707 miles of low gradient channel; 61 percent of this channel type contributes flow, sediment and organic material in the Pit (145 miles), Sacramento (150 miles) and Squaw Creek (134 miles) arms.

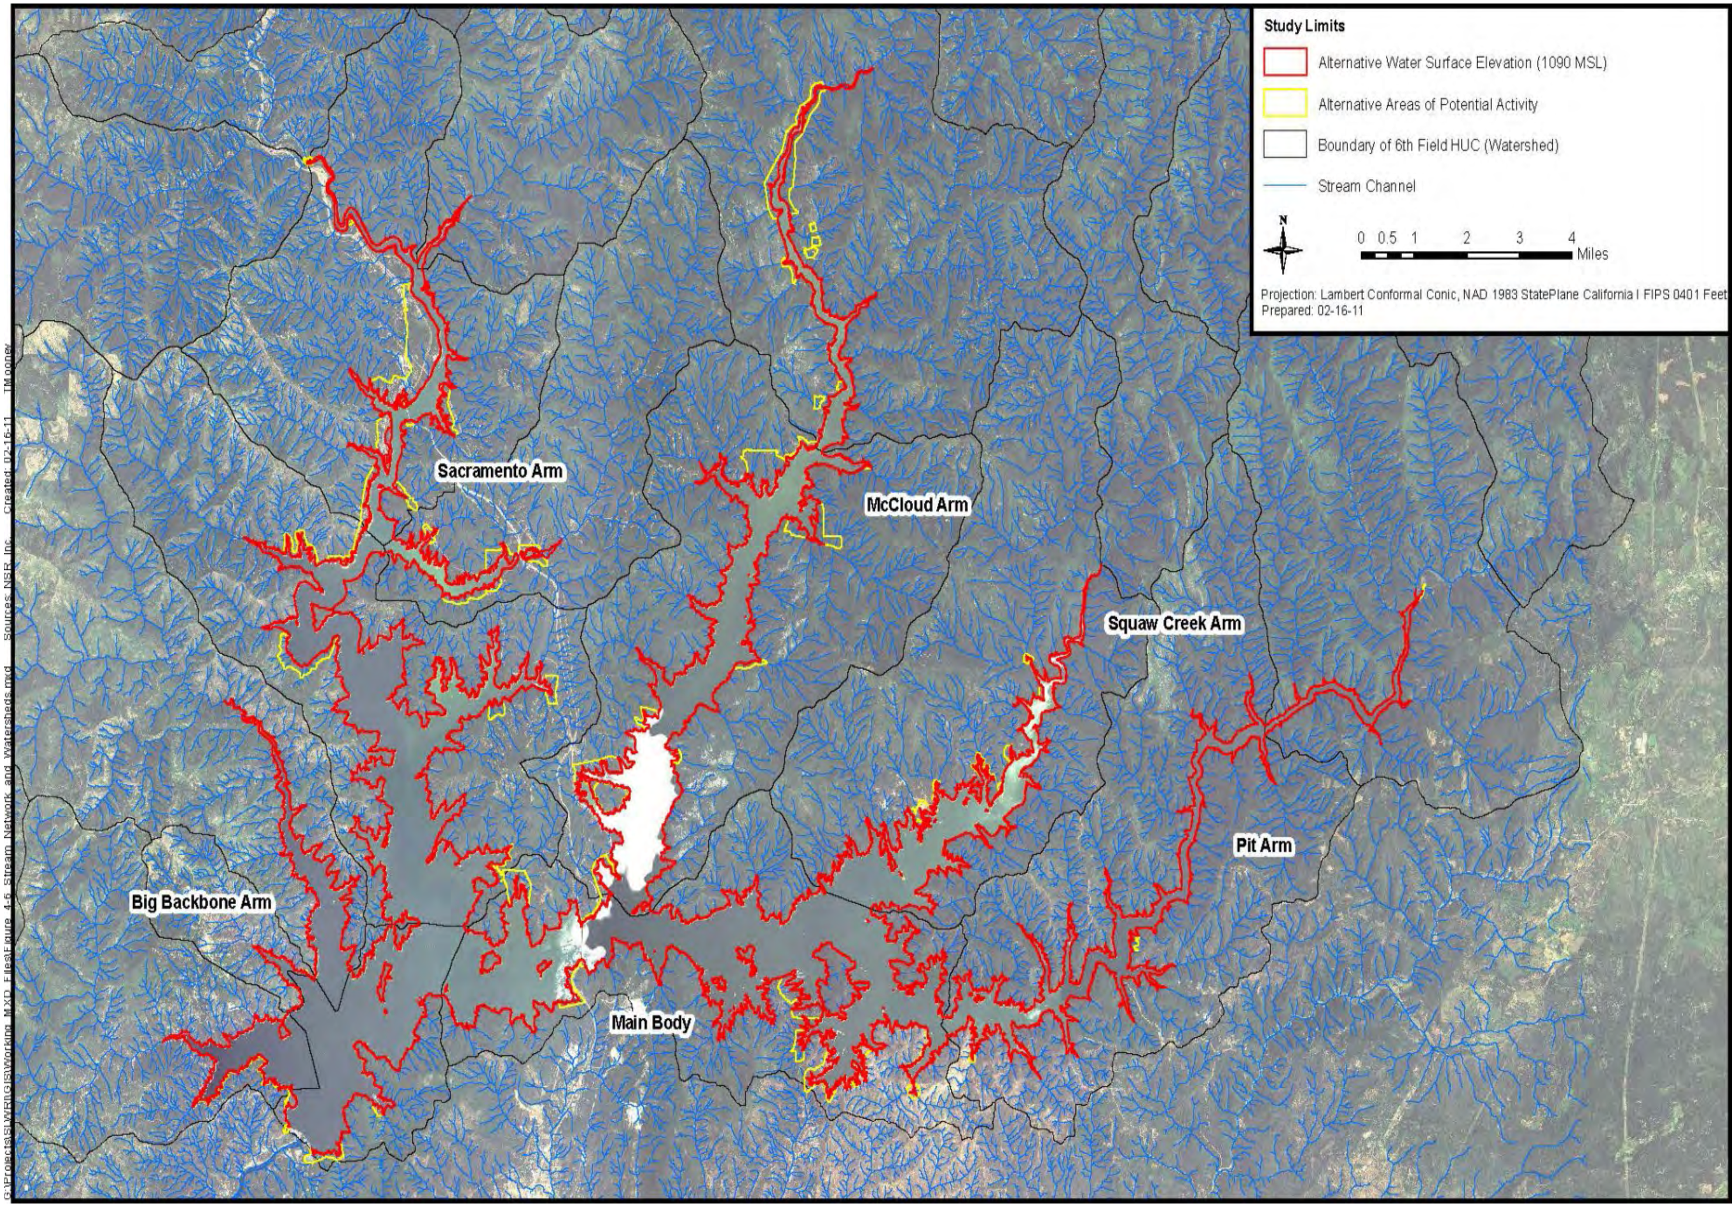


Figure 4-6. Regional Stream Network and Boundaries of Watersheds Adjacent to Shasta Lake and Vicinity

	Big Backbone Creek	Main Body	McCloud River	Pit River	Sacramento River	Squaw Creek	Total Length
Intermittent >10% Grade	214	83	297	321	597	355	1867
Perennial >10% Grade	60	6	75	51	101	71	364
Intermittent 7-10% Grade	4	10	9	31	30	24	108
Perennial 7-10% Grade	18	3	25	36	41	38	161
Intermittent <7% Grade	2	10	5	21	20	8	66
Perennial <7% Grade	30	14	38	109	109	96	396

Figure 4-7. Regional-Scale Characteristics of Streams Tributary to Shasta Lake

Table 4-7. Characteristics of Watersheds Adjacent and Directly Tributary to Shasta Lake

Lake Arm	Drainage Area (square miles)	Stream Length (miles)	Drainage Density (miles/square miles)	Average Elevation (feet)	Max Elevation (feet)	Mean Annual Precipitation (inches)
Big Backbone Creek	60	328	5.5	2,185	4,633	74
Main Body	37	126	3.4	1,260	2,723	67
McCloud River	77	449	5.8	1,911	4,669	79
Pit River	100	569	5.7	1,700	3,246	73
Sacramento River	137	898	6.5	1,825	4,589	76
Squaw Creek	100	592	5.9	2,100	5,046	83
Total	512	2,962	5.8	1,885	5,046	77

Using existing data and information (NSR 2003, Reclamation 2014), the following observations were made about the relative stability of the riverine reaches. Of the five main tributaries to Shasta Lake, all except Big Backbone Creek and the Sacramento River are underlain by shallow bedrock that limits channel incision. For this reason, Squaw Creek and the Pit and McCloud rivers have relatively stable channels that are unlikely to change significantly in response to average floods. Although they occur infrequently, debris flows have the potential to substantially affect particularly shallow bedrock reaches of smaller tributaries to Shasta Lake, as is evident in Dekkas Creek. The Sacramento River and Big Backbone Creek are relatively dynamic because the channel bed has the potential to undergo physical changes in response to a moderate floods. Although Big Backbone Creek and Squaw Creek have similar watershed areas, Squaw Creek has more bedrock reaches than Big Backbone Creek and therefore is inherently more stable.

A unique aspect of the channels that enter Shasta Lake is the fact that each one, whether large or small, is subject to periodic inundation and drawdown on an annual and often inter-annual basis. This process results in riverine aquatic habitat that is transitional in nature, with the bed and banks changing in response to reservoir operations. In 2014, Reclamation completed a study that characterized the habitat in a wide array of intermittent and perennial channels that flow into Shasta Lake (Reclamation 2014).This study documented that habitat types within these transitional reaches are dynamic; habitat values are variable and structural complexity is lacking in many of these channels.

Upper Sacramento River (Shasta Dam to Red Bluff)

The geomorphology of the Sacramento River is a product of several factors: the geology of the Sacramento Valley, hydrology, climate, vegetation, and human activity. Large flood events drive lateral channel migration and remove large flow impediments. Riparian vegetation stabilizes riverbanks and reduces water velocities, inducing deposition of eroded sediment. In the past, a balance existed between erosion and deposition along the Sacramento River. However, construction of dams, levees, and water projects has altered streamflow and other hydraulic characteristics of the Sacramento River. In some areas, human-induced changes have stabilized and contained the river, while in other reaches, the loss of riparian vegetation has reduced sediment deposition and led to increased erosion.

Human-induced changes have also affected geomorphology of downstream tributaries to the Sacramento River in the study area. Major tributaries include Clear, Cottonwood and Cow Creeks.

Cow Creek The 275,000-acre Cow Creek Watershed is a large, generally uncontrolled tributary to the Sacramento River on the eastern side. The watershed is unique in that land ownership is almost evenly divided between commercial forestland, commercial agriculture, and small rural property owners, with minimum government ownership (WSRCD and CCWMG 2005).

Copper, coal, gravel and quarry stone have been mined from the Cow Creek watershed in the past. In contrast to other tributaries, gold was not discovered on the eastside of the Sacramento River in this area. However, the available timber and grazing lands on the eastern lands became primary supply areas for the initial gold and copper mining that occurred in other parts of the region (WSRCD and CCWMG 2001).

Gravel was mined in Little Cow Creek near Bella Vista (at Dry Creek and at Salt Creek), near Palo Cedro (Graystone Court and near Bloomingdale Road), and in the lower reaches of the main stem of Cow Creek. Mining of gravel in active floodways has likely reduced available spawning gravel in Little Cow Creek and the main stem of Cow Creek. Gravel removal may also have contributed to channel incisement (WSRCD and CCWMG 2005).

Ranching is currently a dominant land use in the watershed. Diversions of water for ranching activities significantly affect instream flow on the lower reaches of Cow Creek during the summer season (WSRCD and CCWMG 2005).

Major issues in the Cow Creek watershed are water quality and quantity for agriculture uses and natural barriers to fish passage (waterfalls) located at geologic contacts which limit anadromous fish passage into four of the five tributaries to Cow Creek. Geomorphic changes in Cow Creek (i.e., knickpoints) are attributed to natural breaks in the geology of the area and not to human activities. A review of historic aerial photos and available maps show that the configuration of the channel on the main stem has not changed significantly over the last century (WSRCD and CCWMG 2005).

Cottonwood Creek Cottonwood Creek is the largest undammed watershed on the west side of the Sacramento Valley. The watershed is characterized by a flashy hydrology due to the absence of any flow regulating dams, and low intra-annual storage resulting from a combination of very little recharge to aquifers in the upper reaches of the watershed and a small amount of snow pack (CH2M HILL 2005, 2007).

Human impacts on Cottonwood Creek began in the 1850s with placer and dredge gold mining operations. Two major gravel mines currently operate on Cottonwood Creek. The Shea Mine, which is in Shasta County, is immediately downstream from Interstate 5, and the Cottonwood Creek Sand and Gravel Mine (formerly XTRA), which is in Tehama County, is approximately 0.5 mile upstream from Interstate 5 (CH2M HILL 2001).

Several reports suggest that persistent gravel mining combined with a flashy hydrology contribute to instability in channel conditions, excessive bank erosion, and bed degradation in Cottonwood Creek (DWR 1992, Matthews 2003). Cross-sectional survey locations established by the USGS in 1983 and re-surveyed in 2002 show that considerable channel incision has occurred on Cottonwood Creek; in some areas, the channel is scoured to bedrock. These changes are likely caused by instream aggregate mining in excess of annual replenishment rates (Matthews 2003).

Clear Creek To characterize existing fluvial geomorphic conditions, Clear Creek is divided into upper Clear Creek and lower Clear Creek, with the delineation occurring at Whiskeytown Dam. Upper Clear Creek (upstream from Whiskeytown Dam) is not discussed further in this section.

The lower Clear Creek watershed has been impacted by direct and indirect human activities for over a century. Widespread alterations to the watershed began in the 1800s, when the channel was placer mined and then dredged for gold, which caused extensive modifications to natural channel form and process by removing point bars, floodplains, and riparian vegetation (WSRCD 1996). In some areas, the stream is incised completely down to clay hardpan or bedrock. Clear Creek is straight and highly entrenched in some areas; in others, it has multiple, braided channels due to direct and indirect human impacts (GMA 2007). Later, timber harvesting and associated road building caused excessive erosion throughout the watershed (WSRCD 1996).

The construction of McCormick-Saeltzer Dam in 1903 (dam removed in 2000) caused further changes in streamflow and sediment transport in the stream. Alteration of the natural flow and sediment regime in Clear Creek continued with construction of Whiskeytown Dam in 1963. Whiskeytown Dam greatly reduced the volume and magnitude of historical flows and effectively blocks the downstream transport of coarse sediment to lower Clear Creek (WSRCD 1996).

More recently, instream and off-channel aggregate mining began in 1950 and continued through the mid-1980s. Several hundred thousand cubic yards of aggregate were removed from Clear Creek below the former site of McCormick-Saeltzer Dam, destroying the bankfull channel and in some areas completely removing the floodplain (WSRCD 1996).

Lower Clear Creek is the subject of several ongoing geomorphic studies, monitoring efforts, and fish habitat and channel restoration activities intended to offset past impacts on the watershed and stream channel by introducing spawning gravels into lower Clear Creek, implementing erosion control programs, and reducing fuels within the watershed (Reclamation 2012). The Lower Clear Creek Floodway Rehabilitation Project is an extensive effort to restore the natural form and function of the Clear Creek channel and floodplain in areas highly affected by gold and aggregate mining.

Two headcuts have been observed on lower Clear Creek. The upstream-most headcut was observed in 2003, upstream from the former McCormick-Saeltzer Dam location. This headcut is the result of natural channel adjustment following dam removal in 2000 combined with a large storm event that occurred in December 2002 (UC Berkeley 2003). The headcut near the former dam site was observed again during monitoring activities in 2006 (GMA 2007). As of 2011, the channel appears to have stabilized in the vicinity of the former dam, with normal patterns of aggradation and deposition occurring within the reach (UC Berkeley 2011).

A second headcut has been observed farther downstream in Clear Creek, near the location of the Lower Clear Creek Floodway Rehabilitation Project. This headcut is migrating from the upstream end of the restoration site and has been attributed to past gravel mining and reduction of coarse sediment by upstream dams. In some areas above and below the site, the channel has incised to clay hardpan. Continued gravel augmentation upstream from the restoration area may reduce the rate of channel downcutting in the future (GMA 2007).

Lower Sacramento River and Delta

Downstream from Red Bluff, the lower Sacramento River is relatively active and sinuous, meandering across alluvial deposits within a wide meander belt. The active channel consists of point bars composed of sand on the inside of meander bends, and is flanked by active floodplain and older terraces. Most of these features consist of easily eroded, unconsolidated alluvium; however, there are also outcrops of resistant, cemented alluvial units such as the Modesto and Riverbank formations. Geologic outcroppings and human-made structures, such as bridges and levees, act as local hydraulic controls and confine movement of much of the lower Sacramento River. Natural geomorphic processes in the Delta have been highly modified by changes to upstream hydrology (reservoirs and streamflow regulation) and construction of levees, channels, and other physical features.

Since construction of Shasta Dam in the early 1940s, flood volumes on the river have been reduced, which has reduced the energy available for sediment transport. Straightening and a reduced rate of meander migration of the river may be associated with flow regulation because of Shasta Dam. The reduction in active channel dynamics is compounded by the physical effects of riprap bank protection structures, which typically eliminate shaded bank habitat and associated deep pools, and halt the natural processes of channel migration.

CVP/SWP Service Areas

Geomorphology in the CVP/SWP service areas is a product of the same factors mentioned above – geology, hydrology and climate, vegetation, and human activity. Geomorphology in the CVP service areas is summarized in the descriptions of the primary study area and the lower Sacramento River and Delta portions of the extended study area.

Geomorphology in the SWP service areas extends into the southern geomorphic provinces of California and along part of the coast. The southern geomorphic provinces and coastal province include the Transverse Ranges, Peninsular Ranges, Mojave Desert, and Coast Ranges. The Transverse Ranges, composed of overlapping mountain blocks, consist of parallel and subparallel ranges and valleys. The Peninsular Ranges Geomorphic Province is composed of northwest- to southeast-trending fault blocks, extending from the Transverse Ranges into Mexico. The Peninsular Ranges are similar to the Sierra Nevada in that they have a gentle westerly slope and generally consist of steep eastern faces. The Mojave Desert Geomorphic Province's topography is controlled by two faults: the San Andreas Fault, trending northwest to southeast, and the Garlock Fault, trending east to west (Jennings 1938). Before development of the Garlock Fault, sometime during the Miocene, the Mojave Desert was part of the Basin and Range Geomorphic Province. The Mojave Desert is now dominated by alluvial basins, which are aggrading surfaces from adjacent upland continental deposits (Norris and Webb 1990). The Coast Ranges have been greatly affected by plate tectonics. The Coast Ranges Geomorphic Province consists of elongate ranges and narrow valleys that run subparallel to the coast. Some of the mountain ranges along the Coast Ranges terminate abruptly at the sea (Norris and Webb 1990).

4.1.4 Mineral Resources

This section describes the known mineral resources of commercial or otherwise documented economic value in both the primary and extended study areas. The mineral resources of concern include metals and industrial minerals (e.g., aggregate, sand, and gravel, oil and gas, and geothermal resources that would be of value to the region).

Shasta Lake and Vicinity

The following section describes mineral resources in the Shasta Lake and vicinity portion of the primary study area.

Metals The lands in the Shasta Lake and vicinity area are highly mineralized, with a history of significant mineral production. The Shasta Lake and vicinity area encompasses portions of two historic base metal mining districts, the west Shasta and east Shasta copper-zinc districts. The two districts focused on development of massive sulfide (Kuroko-type) deposits of submarine volcanogenic origin that formed contemporaneously with, and by the same process as, the host volcanic rocks. As in other areas in the Klamath Mountains, copper was by far the predominant commodity produced. Zinc, sulfur, iron, limestone, gold, and silver were produced as byproducts of copper production.

The Golinsky mine complex is located in the west Shasta district, approximately 7 miles west of Shasta Dam in the headwaters of Dry Creek and Little Backbone Creek. This inactive, abandoned mine complex is the only large historic producing mine within the Shasta Unit of the Whiskeytown-Shasta-Trinity NRA. Other mines within the NRA occur in the east Shasta district, concentrated between the McCloud and Squaw arms of Shasta Lake. The east Shasta district includes the Bully Hill, Copper City, and Rising Star mines, all of which are located in the Bully Hill area. These mines ceased operation before Shasta Dam was built.

These types of mineral deposits, in conjunction with the historic lode mining methods, have resulted in the discharge of toxic mine waste and acidic waters to Shasta Lake and some tributaries on a recurring basis (USFS 2000). The Golinsky mine complex has been subject to extensive remediation to reduce the discharge of toxic mine waste and acidic waters to Shasta Lake.

Industrial Minerals Industrial minerals occurring in the vicinity of Shasta Lake include alluvial sand and gravel, crushed stone, volcanic cinders, limestone, and diatomite. In 2002, Shasta County produced 462,000 tons of sand and gravel, 852,000 tons of crushed stone (including limestone), and 51,000 tons of volcanic cinders. Limestone (used to produce Portland cement) and diatomite are not included in these figures.

The supply of Portland cement concrete-grade alluvial sand and gravel within the region is more limited than the supply of non-Portland cement concrete-grade material. The primary sources for alluvial sand and gravel near the Shasta Lake and vicinity area are the Sacramento River (downstream from Keswick Dam), Clear Creek, Cottonwood Creek, and Hat Creek. Crushed stone has been produced at a limestone quarry in Mountain Gate, a granite quarry in Keswick, an andesite quarry in Mountain Gate, a shale quarry in Oak Run, and two basalt quarries in the Lake Britton area near Burney. Volcanic cinders are produced at sites east of the Shasta Lake and vicinity area.

Areas inundated by the reservoir have aggregate source areas available through dredging and/or excavation. Reclamation has ongoing efforts to characterize the quality and quantity of aggregate that may be used for various project-related needs.

Limestone is used in a variety of industrial applications, but the bulk of limestone is used for the production of Portland cement concrete. Most of the limestone resources found in and near the Shasta Lake and vicinity area are located in fairly remote mountainous areas where extraction is uneconomical.

However, significant mining of limestone for Portland cement concrete production occurs immediately south of Shasta Lake, in Mountain Gate. Diatomite is produced from sources near Lake Britton, east of the Shasta Lake and vicinity area.

Geothermal Resources Significant geothermal resources occur in the Medicine Lake Highlands, approximately 65 air miles northeast of Shasta Lake. The potential capacity of the Medicine Lake Highlands has been estimated at 480 megawatts (PacifiCorp 2010). Development of the Medicine Lake Highlands' geothermal resources has been the subject of extensive litigation of environmental issues and Native American concerns.

Upper Sacramento River (Shasta Dam to Red Bluff)

Economically viable minerals found within the upper Sacramento River portion of the primary study area consist of alluvial sand and gravel, crushed stone, volcanic cinders, limestone, and diatomite. Additional mineral resources are found in the surrounding regions in Shasta and Tehama counties. These mineral resources include asbestos, barium, calcium, chromium, copper, gold, iron, lead, manganese, molybdenum, silver, and zinc (USGS 2005).

Lower Sacramento River and Delta

Economically viable minerals found within the lower Sacramento River and Delta portion of the extended study area consist of alluvial sand and gravel, crushed stone, calcium, and clay. Additional mineral resources are found in the surrounding regions, including chromium, gold, granite, lithium, manganese, mercury, pumice, and silver (USGS 2005).

CVP/SWP Service Areas

The U.S. Geological Survey's mineral resources database indicates that numerous mineral resources found within the CVP/SWP service areas are or have been mined. These minerals include antimony, asbestos, barium, bismuth, boron, calcium, chromium, clay, copper, diatomite, feldspar, fluorite, gold, gypsum-anhydrite, halite, iron, lead, limestone, magnetite, manganese, marble, mercury, molybdenum, pumice, quartz, sand and gravel, silica, silver, slate, stone (crushed/broken), talc, tin, titanium, tungsten, uranium, and vanadium (USGS 2005).

4.1.5 Soils

Soils and erosion areas are described below for both the primary and extended study areas. Soils in the study area are described in the following sections in terms of their biomass productivity; susceptibility to erosion, subsidence, liquefaction, and expansion; and suitability for on-site application of waste material.

Soil biomass productivity is a measure of the capability of a site to produce biomass. The purpose of this management interpretation is to measure the site's productive capability when vegetative indicators (e.g., crop yields, site trees, and other vegetative biomass data) are not directly available. Factors that influence soil biomass productivity include soil depth, parent material, available water-holding capacity, precipitation, soil temperature regime, aspect, and reaction (i.e., pH). Soil biomass productivity is characterized using four relative rankings: high, moderate, low, and nonproductive.

The susceptibility of soil to erosion is characterized in terms of the soil's erosion hazard rating. The ratings indicate the hazards of topsoil loss in an unvegetated condition, as might occur following disturbance by construction. Ratings are based on the soil erosion factor (K), slope, and content of rock fragments. (The soil erosion factor (K) is a measure of the susceptibility of soil particles to detachment and transport by rainfall and runoff, based primarily on soil texture but also considering structure, organic matter, and permeability.) Three ratings are recognized: slight, moderate, and severe. A rating of "slight" indicates that no postdisturbance acceleration of naturally occurring erosion is likely; "moderate" indicates that some acceleration of erosion is likely, and that simple erosion-control measures are needed; and "severe" indicates that significant erosion is expected, and that extensive erosion-control measures are needed.

Land subsidence is broadly defined to mean the sudden sinking or gradual downward settling of the land surface with little or no horizontal motion. Land subsidence can arise from a number of causes: the weathering characteristics of the underlying bedrock (e.g., as occurs for certain limestone formations); decomposition of the organic matter fraction of soils that are derived from peaty or mucky parent materials; aquifer-system compaction; underground mining; and natural compaction. Three processes account for most instances of water-related subsidence: compaction of aquifer systems, drainage and subsequent oxidation of organic soils, and dissolution and collapse of susceptible rocks.

Soil liquefaction is a phenomenon in which the strength and stiffness of a soil is reduced by earthquake shaking or other rapid loading. Liquefaction occurs in saturated soils when the pore spaces between individual soil particles are completely filled with water. This water exerts a pressure on the soil particles that influences how tightly the particles themselves are pressed together. Before an earthquake, the water pressure is relatively low. However, earthquake shaking can cause the water pressure to increase to the point where the soil particles can readily move with respect to each other. When liquefaction occurs, the strength of soils decreases, and the ability of soils to support foundations for buildings and bridges is reduced.

Expansive soils are soils that contain water-absorbing minerals, mainly "active" clays (e.g., montmorillonite). Such soils may expand by 10 percent or more when wetted. The cycle of shrinking and expanding exerts continual pressure on structures, and over time can reduce structural integrity. Soil susceptibility to expansion (i.e., shrinking and swelling) is tested using Uniform Building Code Test Standard 18-1.

Soil suitability for on-site application of waste material focuses on the suitability of the soil to support the use of septic tanks or alternative wastewater disposal systems. Suitability interpretations are based on consideration of soil depth, permeability, rock content, depth to groundwater (including seasonally perched water), and slope.

Shasta Lake and Vicinity

Soils in the Shasta Lake and vicinity area derive from materials weathered from metavolcanic (e.g., basalt and greenstone) and metaigneous (e.g., granitic and serpentinite) rocks. Soils derived from the metavolcanic sources, such as greenstone, include the Goulding and Neuns families. Soils derived from metasedimentary materials include the Marpa family. Holland family soils are derived from metasedimentary and granitic rocks.

In general, metamorphosed rocks do not weather rapidly, and shallow soils are common in the area, especially on steep landscape positions. Soils from metamorphosed rocks generally contain large percentages of coarse fragments (e.g., gravels, cobbles, stones), which reduce their available water holding capacity and topsoil productivity. Granitic rocks may weather deeply, but soils derived from them may be droughty (unable to store water) because of high amounts of coarse quartz grains and low content of “active” clay. Soils derived from granitic rocks commonly are highly susceptible to erosion.

Soil map units in the Shasta Lake and vicinity area are shown in Figure 4-8; Table 4-8 presents the mapping legend that accompanies the figure. The areal extent of soil map units within the Shasta Lake and vicinity area is presented in Table 4-9 for the portion of the area between 1,070 feet and 1,090 feet above msl (Impoundment Area), and in Table 4-10 for the portion potentially disturbed by construction activities (Relocation Areas). Sixty soil map units, comprising soil families and miscellaneous land types (e.g., rock outcrop, limestone), are recognized to occur in the area. Common soil families are Marpa, Neuns, Goulding, and Holland. These are well-drained soils with fine loamy or loamy-skeletal (i.e., gravelly or cobbly) profiles.

W	Water	28.6	0.86%

Soil Biomass Productivity Soil biomass productivity in the Shasta-Trinity National Forest (STNF) ranges from nonproductive to high (USFS 1994). Using Forest Service Site Class (FSSC) as a surrogate metric for soil biomass productivity, approximately 36 percent of the Shasta Lake and vicinity area is occupied by soils of low biomass productivity, about 39 percent by soils of moderate productivity, and about 13 percent by "nonproductive" soils and miscellaneous land types (e.g., rock outcrop). Soils of high biomass productivity are unlikely to occur in the Shasta Lake and vicinity area.

Soil Susceptibility to Erosion (Uplands) Interpretations of soil susceptibility to erosion are presented in Table 4-11 for the portion of the area between 1,070 feet and 1,090 feet above msl (Impoundment Area), and in Table 4-12 for the portion potentially disturbed by construction activities. Of the approximately 4,881.36 acres in the Shasta Lake and vicinity area, 4,481 acres (92 percent of total area) are assigned a hazard rating of severe.

Table 4-11. Summary of Soil Erosion Hazard – Shasta Lake and Vicinity (Impoundment Area)

Soil Erosion Hazard	Acres	% of Total Subarea)
Moderate	38.55	1.54%
Severe	2248.81	90.03%
Not Rated	210.00	8.41%

Table 4-12. Summary of Soil Erosion Hazard – Shasta Lake and Vicinity (Relocation Areas)

Soil Erosion Hazard	Acres	% of Total Subarea
Moderate	85.59	3.59%
Severe	2232.61	93.65%
Not Rated	65.80	2.76%

Soil Susceptibility to Erosion (Shoreline) There are more than 420 miles of shoreline around Shasta Lake. As described below under "Methods and Assumptions," a conceptual model was developed to estimate current erosion rates and predict future erosion rates (see Attachment 1, Shoreline Erosion Technical Memorandum). Data for the model were collected synoptically in 2002, 2004, 2007, and 2013, providing a "snapshot" of shoreline conditions. This analysis of shoreline erosion provides an insight into the potential for erosion as the reservoir level rises. Validation of the model will come with statistically unbiased sampling and analyses that can occur during mitigation.

Based on the model output, about 18 percent of the shoreline has a low severity rating for erosion potential for the first 15 years, when most of the erosion would take place. The remaining shoreline has a moderate (58 percent) to high (23 percent) severity rating for erosion potential. Most of the shoreline that is exposed during routine drawdown periods (i.e., drawdown zone) has been subject to substantial erosion, and very little soil remains after more than 60 years of reservoir operations.

Soil Susceptibility to Subsidence Published interpretations of soil susceptibility to subsidence are generally not available for the Shasta Lake and vicinity area. The likelihood that subsidence would occur as a result of decomposition of soil organic matter is low because of the absence of soils derived from peaty or mucky parent materials. Similarly, the likelihood of subsidence caused by aquifer-system compaction is low because of the absence of significant, widespread groundwater withdrawal in the Shasta Lake and vicinity area. Land subsidence has the potential to occur in areas underlain by highly weatherable, carbonate-rich rocks (e.g., certain limestones), and in areas affected by underground construction.

Soil Susceptibility to Liquefaction Published interpretations of soil susceptibility to liquefaction are generally not available for the Shasta Lake and vicinity area. The likelihood that soil liquefaction would occur is low because of the absence of the necessary high-groundwater conditions in the Shasta Lake and vicinity area.

Soil Susceptibility to Expansion Published interpretations of soil susceptibility to expansion (i.e., shrinking and swelling) are generally not available for most of the Shasta Lake and vicinity area. The likelihood that expansive soils occur is low because the weathering products derived from the local bedrock typically contain low concentrations of “active” clays (e.g., montmorillonite).

Soil Suitability for On-site Application of Waste Material Published interpretations of soil suitability for on-site application of waste material (i.e., capability to support use of septic tanks or alternative wastewater disposal systems) are generally not available for the Shasta Lake and vicinity area. In general, soils in the Shasta Lake and vicinity area are poorly suited to these uses because of shallow soil depth, high rock content, and excessive slope.

Upper Sacramento River (Shasta Dam to Red Bluff)

The following section describes the susceptibility of soil in the upper Sacramento River portion of the primary study area to erosion (channel shoreline), erosion (wind), subsidence, liquefaction, and expansion.

Soils in the Sacramento River basin are divided into four physiographic groups: upland soils, terrace soils, valley land soils, and valley basin soils. Upland soils are prevalent in the hills and mountains of the region and are composed mainly of sedimentary sandstones, shales, and conglomerates originating from igneous rocks. Terrace and upland soils are predominant between Redding and Red Bluff; however, valley land soils border the Sacramento River through this area. Valley land and valley basin soils occupy most of the Sacramento Valley floor south of Red Bluff. Valley land soils consist of deep alluvial and aeolian soils that make up some of the best agricultural land in the state. The valley floor was once covered by an inland sea, and sediments were formed by deposits of marine silt followed by mild uplifting earth movements. After the main body of water disappeared, the Sacramento River began eroding and redepositing silt and sand in new alluvial fans.

Soil Susceptibility to Erosion (Channel Shoreline) Shasta and Keswick dams have a significant influence on sediment transport in the Sacramento River because they block sediment that would normally be transported downstream. The result has been a net loss of coarse sediment, including salmon spawning gravels, in the Sacramento River below Keswick Dam. In alluvial river sections, bank erosion and sediment deposition cause river channel migrations that are vital to maintaining instream and riparian habitats, but which can cause loss of agricultural lands and damage to roads and other structures.

Soil Susceptibility to Erosion (Wind) Soil erodibility, climatic factors, soil surface roughness, width of field, and quantity of vegetative coverage affect the susceptibility of soils to wind erosion. Wind erosion leaves the soils shallower and can remove organic matter and needed plant nutrients. In addition, blowing soil particles can damage plants, particularly young plants. Blowing soils also can cause off-site problems such as reduced visibility and increased allergic reaction to dust.

Soil Susceptibility to Subsidence Land subsidence in the Sacramento Valley is localized and concentrated in areas of overdraft from groundwater pumping. Land subsidence had exceeded 1 foot by 1973 in two main areas in the southwestern part of the valley near Davis and Zamora; however, additional subsidence since then has not been reported.

Soil Susceptibility to Expansion Most of Shasta County is characterized by moderately expansive soils with areas of low expansiveness in the South Central Region and southeastern corner of the county. Small scattered areas of highly expansive soils exist in the mountains of the Western Upland, French Gulch, and North East Shasta County planning areas. The hazard associated with expansive soils is that areas of varying moisture or soil conditions can differentially expand or shrink, causing stresses on structures that lead to cracking or settling. Effects of expansive soils on structures can be mitigated by requiring proper engineering design and standard corrective measures.

Lower Sacramento River and Delta

The following section describes the susceptibility of soil in the lower Sacramento River and Delta portion of the extended study area to erosion (channel shoreline), erosion (wind), subsidence, liquefaction, and expansion.

The soils of the Sacramento River basin are divided into four physiographic groups, as described above for the upper Sacramento River portion of the study area.

The soils of the Delta region vary primarily as a result of differences in geomorphological processes, climate, parent material, biological activity, topography, and time. The soils are divided into the following four general soil types:

- Delta organic soils and highly organic mineral soils
- Sacramento River and San Joaquin River deltaic soils
- Basin and basin rim soils
- Moderately well to well-drained valley, terrace, and upland soils

The Delta region contains soils primarily with the required physical and chemical soil characteristics, growing season, drainage, and moisture supply necessary to qualify as Prime Farmland. This includes 80–90 percent of the area of organic and highly organic mineral soils, Sacramento River and San Joaquin River deltaic soils, and basin and basin rim soils. Most of the remaining soils of the Delta region qualify as Farmland of Statewide Importance.

Soil Susceptibility to Erosion (Channel Shoreline) In the extended study area, the Sacramento River is a major alluvial river section that is active and sinuous, meandering across alluvial deposits within a wide meander belt. In alluvial river sections, bank erosion and sediment deposition cause migrations of the river channel. These migrations are extremely important in maintaining instream and riparian habitats, but also can cause loss of agricultural lands and damage to roads and other structures. Geologic outcroppings and human-made structures, such as bridges and levees, act as local hydraulic controls along the river. Bank protection, consisting primarily of rock riprap, has been placed along various sections of the Sacramento River to reduce erosion and river meandering.

The great quantities of sediment transported by the rivers into the Delta move primarily as suspended load. Of the estimated 5 million tons per year of sediment inflow into the Delta, about 80 percent originates from the Sacramento River and San Joaquin River drainages; the remainder is contributed by local streams. Approximately 15–30 percent of the sediment is deposited in the Delta; the balance moves into the San Francisco Bay system or out through CVP and SWP facilities.

Soil Susceptibility to Erosion (Wind) The Delta's organic soils and highly organic mineral soils have wind erodibility ratings of 2–4 on a scale where 1 is most erodible and 8 is least erodible. The high wind erodibility of Delta soils is caused by the organic matter content of the soil. The rate of wind erosion is estimated at 0.1 inch per year.

Soil Susceptibility to Subsidence Subsidence of the Delta's organic soils and highly organic mineral soils is attributable primarily to biochemical oxidation of organic soil material as a result of long-term drainage and flood protection. The highest rates of subsidence occur in the central Delta islands, where organic matter content in the soils is highest.

Development of the islands resulted in subsidence of the islands' interiors and greater susceptibility of the topsoil to wind erosion. Subsidence, as it relates to Delta islands, refers generally to the falling level of the land surface from primarily the oxidation of peat soil. Levee settlement may be partially caused by peat oxidation if land adjacent to levees is not protected from subsidence.

Soil Susceptibility to Expansion Soils in the lower Sacramento River and Delta portion of the extended study area vary from having low to high shrink-swell potential. In general, soils in the narrow corridor upstream along the Sacramento River have low shrink-swell potential according the U.S. Department of Agriculture's State Soil Geographic (STATSGO) Database Soil Surveys, with the exception of some soils with moderate shrink-swell potential near the Red Bluff Pumping Plant (NRCS 1995). Downstream, the shrink-swell potential of soils near the Delta is generally classified by the STATSGO Soil Surveys as "high." The hazard associated with expansive soils is that areas of varying moisture or soil conditions can differentially expand or shrink, causing stresses on structures that lead to cracking or settling. This hazard is identifiable through standard soil tests. Its effects on structures can be mitigated through the requirements of proper engineering design and standard corrective measures.

CVP/SWP Service Areas

As described above for the upper Sacramento River portion of the primary study area, soils in the CVP/SWP service areas are divided into four physiographic groups: valley land, valley basin, terrace land, and upland soils. According to the U.S. Department of Agriculture's STATSGO Database, soils within the CVP/SWP service areas consist of clay, loam, silt, and sand, some of which is gravelly. The CVP/SWP service areas also consist of unweathered and weathered bedrock that is evident through outcrops at the ground surface (NRCS 1995).

4.2 Regulatory Framework

The following section describes the Federal, State of California (State), and local regulatory setting for geological resources.

4.2.1 Federal

This section discusses the Federal regulatory setting for water quality, runoff, air quality, earthquakes, paleontological resources, and natural resources.

Clean Water Act

The Clean Water Act (CWA) includes provisions for reducing soil erosion for the protection of water quality. The CWA makes it unlawful for any person to discharge pollutants from a point source (including construction sites) into navigable waters, unless a permit has been obtained under its provisions. This pertains to construction sites where soil erosion and storm runoff and other pollutant discharges could affect downstream water quality.

National Pollutant Discharge Elimination System

The National Pollutant Discharge Elimination System process, established by the CWA, is intended to meet the goal of preventing or reducing pollutant runoff. Projects involving construction activities (e.g., clearing, grading, or excavation) with land disturbance greater than 1 acre must file a notice of intent with the applicable regional water quality control board (RWQCB) to indicate the intent to comply with the State General Permit for Storm Water Discharges Associated with Construction Activity. This permit establishes conditions to minimize sediment and pollutant loading and requires preparation and implementation of a stormwater pollution prevention plan (SWPPP) before construction.

Clean Air Act

The Clean Air Act also has provisions for reducing soil erosion relevant to air and water quality. On construction sites, exposed soil surfaces are vulnerable to wind erosion, and small soil particulates are carried into the atmosphere. Suspended particulate matter (consisting of PM_{10} and $PM_{2.5}$, as defined in Chapter 5, “Air Quality and Climate”) is one of the six criteria air pollutants of the Clean Air Act.

Earthquake Hazards Reduction Act

In October 1977, the U.S. Congress passed the Earthquake Hazards Reduction Act to “reduce the risks to life and property from future earthquakes in the United States through the establishment and maintenance of an effective earthquake hazards and reduction program.” To accomplish this, the act established the National Earthquake Hazards Reduction Program. The National Earthquake Hazards Reduction Program Act (NEHRPA) significantly amended this program in November 1990 by refining the description of agency responsibilities, program goals, and objectives. The NEHRPA designates the Federal Emergency Management Agency as the lead agency of the program and assigns it several planning, coordinating, and reporting responsibilities. Other NEHRPA agencies include the National Institute of Standards and Technology, the National Science Foundation, and U.S. Geological Survey.

Antiquities Act of 1906

Federal protection for significant paleontological resources would apply to the project if any construction or other related project impacts occurred on Federally owned or managed lands. Federal legislative protection for paleontological resources stems from the Antiquities Act of 1906 (Public Law

59-209; 16 U.S. Code 431 et seq.; 34 Stat. 225), which calls for protection of historic landmarks, historic and prehistoric structures, and other objects of historic or scientific interest on federal land.

Federal Cave Resource Protection Act of 1988

Cave and karst landform resources are provided Federal protection under the Federal Cave Resource Protection Act of 1988. Although not a legally binding agreement, the Interagency Agreement for Collaboration and Coordination in Cave and Karst Resources signed by U.S. Department of the Interior and U.S. Department of Agriculture land management agencies provides guidelines for the management, research, conservation, and protection of these resources.

Shasta-Trinity National Forest Land and Resource Management Plan

The STNF Land and Resource Management Plan (LRMP) (USFS 1995) contains forest goals, standards, and guidelines designed to guide the management of the STNF. The following goals, standards, and guidelines related to geologic and seismic hazards and soils issues associated with the study area were excerpted from the STNF LRMP.

- Goals (LRMP, p. 4-5):
  - Maintain or improve soil productivity and prevent excessive surface erosion, mass wasting, and cumulative watershed impacts.
- Standard and Guidelines (LRMP, p. 4-25):
  - Determine the sensitivity of each 2nd or 3rd order watershed using soil, geologic, and streamflow characteristics.
  - Implement Forest Soil Quality Standards and Best Management Practices for areas identified as having highly erodible soils. Specifically, apply the special practices dealing with timber harvest, site preparation, and road construction in highly erodible soils.
  - Forest Soil Quality Standards in relation to ground cover, soil organic matter, and soil porosity will be used to protect soil productivity (as referenced in Appendix O of the LRMP).

U.S. Bureau of Land Management Resource Management Plan

The U.S. Department of the Interior, Bureau of Land Management (BLM) Resource Management Plan, which is its plan for managing federal lands in Shasta County, was amended by the 1994 Record of Decision for the Northwest Forest Plan (Final Supplemental EIS for Amendments to USFS and BLM Planning Documents within the Range of the Northern Spotted Owl). This amendment required preparation of watershed analyses before initiating BLM activities. As a party to the Northwest Forest Plan, BLM, like USFS, is also required to ensure that projects are consistent with the Aquatic Conservation Strategy.

Federal Minerals Management

Mineral development is permitted on all public lands not withdrawn from mineral entry. The U.S. Mining Laws (30 U.S. Code 21–54) confer statutory right to enter upon public lands in search of minerals. Regulations found in 36 Code of Federal Regulations 228, Subpart A, set forth rules and procedures to minimize adverse environmental impacts on national forest resources. Access for mineral exploration and development is generally unrestricted, subject to the mitigation of adverse impacts on surface resources.

Access for mineral exploration on STNF land is restricted in wildernesses, the “wild” portions of wild and scenic rivers, botanical areas, Research Natural Areas, NRAs, and areas that have been withdrawn from mineral entry. Minerals in the Whiskeytown-Shasta-Trinity NRA are not locatable (minerals that may be acquired under the Mining Law of 1872, as amended), but they are leasable (USFS 1994).

Access for mineral-related activities to wilderness, the NRA, and other lands typically withdrawn from mineral entry is subject to valid existing rights. The type of access authorized must be consistent with the proposed use and of a type that would maintain the special character of the areas to the fullest extent possible.

The Federal lands within the Shasta Unit of the Whiskeytown-Shasta-Trinity NRA were withdrawn from mineral entry under the 1872 Mining Law by the NRA legislation, subject to valid existing rights. Seven claims in the NRA predate the withdrawal. Currently, there are no approved operating plans for these seven mining claims. The lands covered by these claims remain open to mineral leasing. Hard rock minerals in the NRA are available for prospecting, exploration, and development under solid mineral leasing regulations (43 Code of Federal Regulations (CFR) Subpart 3583). Authorization for this land use requires permits and leases subject to approval by the Secretary of Agriculture and terms and conditions of the USFS to protect the values of the NRA.

4.2.2 State

This section discusses the State regulatory setting for soil erosion, water quality, earthquakes, mining, air quality (related to asbestos), paleontological resources, and building design.

Porter-Cologne Act

State regulations, including the Porter-Cologne Act and California Fish and Game Code Section 1600, have provisions to reduce soil erosion. The Porter-Cologne Act established the State Water Resources Control Board and nine RWQCBs that regulate water quality. The RWQCBs carry out the National

Pollutant Discharge Elimination System permitting process for point source discharges and the CWA Section 401 certification program.

California Fish and Game Code Section 1600

California Fish and Game Code Section 1600 requires notification for projects that are planned to occur in, or in close proximity to, a river, stream, or lake, or their tributaries. Applicants are to enter into a "streambed alteration agreement" with the CDFW when a construction activity would (1) divert, obstruct, or change the natural flow or the bed, channel, or bank of any river, stream, or lake; (2) use material from a streambed; or (3) result in the disposal of debris, waste, or other material containing crumbled, flaked, or ground pavement that could pass into a river, stream, or lake. The Federal government is not required to submit a Fish and Game Code 1600 permit; however, the same impacts will be addressed under CWA Section 401 and 404 permits.

Alquist-Priolo Earthquake Fault Zoning Act

The Alquist-Priolo Act (California Public Resources Code Section 2621 et seq.) was passed by the California Legislature to mitigate the hazard of surface faulting to structures. The act's main purpose is to prevent the construction of buildings used for human occupancy on the surface trace of active faults. The act addresses only the hazard of surface fault rupture and is not directed toward other earthquake hazards. Local agencies must regulate most development in fault zones established by the State Geologist. Before a project can be permitted in a designated Alquist-Priolo Earthquake Fault Zone, cities and counties must require a geologic investigation to demonstrate that proposed buildings would not be constructed across active faults.

1990 Seismic Hazards Mapping Act

The 1990 Seismic Hazards Mapping Act (California Public Resources Code Sections 2690 through 2699.6) addresses strong ground shaking, liquefaction, landslides, or other ground failures as a result of earthquakes. This act requires statewide identification and mapping of seismic hazard zones, which would be used by cities and counties to adequately prepare the safety element of their general plans and protect public health and safety (California Geological Survey 2003). Local agencies are also required to regulate development in any seismic hazard zones, primarily through permitting. Permits for development projects are not issued until geologic investigations have been completed and mitigation measures have been developed to address identified issues.

Surface Mining and Reclamation Act of 1975

The Surface Mining and Reclamation Act of 1975 (California Public Resources Code Section 2710 et seq.) addresses surface mining and requires mitigation to reduce adverse impacts on public health, property, and the environment. The Surface Mining and Reclamation Act applies to anyone (including a government agency) that disturbs more than 1 acre or removes more than 1,000 cubic yards of material through surface mining activities, even if activities occur on Federally managed lands (CDMG 2006b). Local city and county "lead agencies" develop ordinances for permitting that provide the regulatory framework for mining and reclamation activities. The permit generally includes a permit to mine, a reclamation plan to return the land to a useable condition, and financial reports to ensure reclamation would be feasible. The State Mining and Geology Board reviews lead agency ordinances to ensure they comply with Surface Mining and Reclamation Act (CDMG 2006b).

Asbestos Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations

The Asbestos Airborne Toxic Control Measure for Construction, Grading, Quarrying, and Surface Mining Operations (Title 17, California Code of Regulations (CCR) Section 93105 (17 CCR Section 93105)) contains the requirements for construction operations that would disturb any portion of an area that is located in a geographic ultramafic rock unit or that has naturally occurring asbestos, serpentine, or ultramafic rock. Construction or grading operations on property where the area to be disturbed is greater than 1 acre require that an asbestos dust mitigation plan be submitted and approved by the air quality management district before the start of construction. The asbestos dust mitigation plan must be implemented at the beginning and must be maintained throughout the operation. To receive an exemption from this asbestos airborne toxic control measure, a State-registered professional geologist must conduct a geologic evaluation of the property and determine that no serpentine or ultramafic rock is likely to be found in the area to be disturbed. This report must be presented to the executive officer or air pollution control officer of the air pollution control or air quality management district, who may then grant or deny the exemption.

Asbestos Airborne Toxic Control Measure for Surfacing Applications

The Asbestos Airborne Toxic Control Measure for Surfacing Applications (17 CCR Section 93106) applies to any person who produces, sells, supplies, offers for sale or supply, uses, applies, or transports any aggregate material extracted from property where any portion of the property is located in a geographic ultramafic rock unit or the material has been determined to be ultramafic rock, or serpentine, or material that has an asbestos content of 0.25 percent or greater. Unless exempt, the use, sale, application, or transport of material for surfacing is restricted, unless it has been tested using an approved asbestos bulk test method and determined to have an asbestos content that is less than 0.25 percent. Any recipient of such materials may need to be provided a receipt with the quantity of materials, the date of the sale, verification that the asbestos content is less than 0.25 percent, and a warning label. Anyone involved in the transportation of the material must keep copies of all receipts with the materials at all times.

California Public Resources Code Chapter 1.7

No State or local agency requires a paleontological collecting permit to allow for the recovery of fossil remains discovered as a result of construction-related earthmoving on State or private land in a project site. California Public

Resources Code Chapter 1.7 (Archaeological, Paleontological, and Historical Sites), Section 5097.3, specifies that State agencies may undertake surveys, excavations, or other operations as necessary on State lands to preserve or record paleontological resources.

California Building Standards Code

The State of California provides minimum standards for building design through the California Building Standards Code (CBC) (see Title 24, Part 2, Table 18-1-B). Where no other building codes apply, Chapter 29 regulates excavation, foundations, and retaining walls. The CBC also applies to building design and construction in the State and is based on the Federal Uniform Building Code used widely throughout the country (generally adopted on a state-by-state or district-by-district basis). The CBC has been modified for California conditions with numerous more detailed and/or more stringent regulations.

The State's earthquake protection law (California Health and Safety Code, Section 19100 et seq.) requires that structures be designed to resist stresses produced by lateral forces caused by wind and earthquakes. Specific minimum seismic safety and structural design requirements are set forth in Chapter 16 of the CBC. The CBC identifies seismic factors that must be considered in structural design.

Chapter 18 of the CBC regulates the excavation of foundations and retaining walls, and Appendix Chapter A33 regulates grading activities, including drainage and erosion control, and construction on unstable soils such as expansive soils and liquefaction areas.

4.2.3 Regional and Local

The following section describes the regional and local regulatory setting for geological resources.

County General Plans

Section 65302(g) of the California Government Code requires that county general plans include an element that identifies and appraises seismic and geologic hazards.

Seismic hazards that must be addressed in this section include the following:

- Surface faulting
- Ground shaking
- Ground failure

Nonseismic hazards addressed include the following:

- Volcanoes

- Erosion
- Expansive soils

Local Guiding Ordinances

In addition to identifying and appraising seismic and geologic hazards, counties and municipalities in the project study area also commonly set requirements for grading and erosion control, including prevention of sedimentation or damage to off-site property. Usually these requirements are established via a grading ordinance, which is administered through issuance of grading permits. Grading permits typically require a vested map and the following information:

- Detailed grading plan
- Geological studies, if the project is located within an area prone to slippage, having highly erodible soils, or of known geologic hazards
- Detailed drainage or flood control information as required by the department of public works
- Final plan for development, if the project is located in a zone district that requires a final development plan
- Noise analysis, if the project is located in the vicinity of a high-noise-generating use

4.3 Environmental Consequences and Mitigation Measures

This section discusses environmental consequences on geology, geologic hazards, geomorphology, minerals, and soils associated with implementation of the project alternatives. It also describes potential mitigation measures associated with impacts on geology that are significant or potentially significant.

4.3.1 Methods and Assumptions

In general, the analysis presented in this section is qualitative and is based on general information on geology, geologic hazards, geomorphology, minerals, and soils, as reported in Section 4.1. Environmental consequences associated with geologic resources that could result from implementing alternatives were evaluated qualitatively based on expected construction methods; environmental commitments common to all action alternatives; and the locations, materials, and durations of project construction and related activities.

As described in following paragraphs, for the Shasta Lake and vicinity portion of the primary study area, more quantitative analyses were undertaken to address geomorphology (i.e., stream characteristics in watersheds that are adjacent and directly tributary to Shasta Lake) (also see Section 4.1.3) and shoreline erosion (also see Section 4.1.5).

Geomorphology

The analysis of fluvial characteristics of watersheds that are adjacent and directly tributary to Shasta Lake evaluated the impact of raising Shasta Dam on stream channel equilibrium, focusing on the balance between sediment transport capacity and channel stability. The average gradient and flow regime of a watercourse are often the variables that control the sediment transport capacity of a given stream channel. The flow regime of a stream is determined by the measure of the average flow of surface water. The average estimated mean annual flow among all intermittent streams calculated using Net Trace software was 0.7 cubic feet per second (cfs), ranging from 0.15 to 2.89 cfs. Any stream that has a predicted average annual flow above 3 cfs was assumed to function as a perennial stream, and any stream with a predicted flow of less than 3 cfs was assumed to function as an intermittent stream.

Typically, over time, streams reach a natural state of equilibrium based on their gradient and sediment transport capacity. Raising the water level of Shasta Lake may affect the equilibrium of watercourses that are controlled by the present reservoir level. Raising the dam may destabilize these streams by altering the length of stream that will be incorporated into the drawdown. Raising the dam will affect the gradient of adjacent watercourses by altering the length of the watercourse and the change in elevation due to seasonal fluctuations in lake water levels. This is the rationale behind analyzing the gradient and flow regime of watercourses that are adjacent and directly tributary to Shasta Lake.

The stream networks in the Shasta Lake and vicinity area were characterized using the Net Trace model generated in a geographic information system (GIS) environment. Net Trace was used because existing California and USFS stream layers lack the level of detail and necessary variables needed to assess the impact of raising the water level of Shasta Lake on stream channel equilibrium. Initially, sub-10-meter digital elevation models covering the Shasta Lake and vicinity were imported into GIS. Using the methods described in programs for digital elevation model analysis (Miller 2003), a surface stream network with user-selected attributes was created using Net Trace. The following characteristics were then calculated for each stream segment: drainage area, riparian area, length, flow direction (degrees), stream order, elevation, gradient statistics, mean precipitation, and mean annual stream flow (cfs).

To verify the accuracy of the Net Trace stream model, the measured bed gradient along surveyed transects on Squaw Creek and Big Backbone Creek was compared to the modeled gradient values calculated by Net Trace along the same transect. The combined average difference between the measured and modeled bed gradient was approximately 4.5 percent, meaning that the measured stream bed gradient is steeper than the modeled gradient. A bias in the sampling distribution is the cause of the disparity. For example, 22 segments were surveyed along the Squaw Creek transect and used to determine the measured bed gradient; however, only 5 segments were available from the Net Trace model to calculate the gradient. Simply, the surveyed transects were measured at greater level of detail than were calculated in the Net Trace model.

Although the surveyed gradient values are more accurate than the modeled values, it would be impractical to survey every watercourse within a study area as large as that of the SLWRI. A more reasonable approach to developing a systematic characterization of the stream network was to compare the surveyed water surface gradient to the modeled values. This approach eliminates the topographic details of the streambed surface and measures the surface gradient of the stream over the entire transect. The combined average difference between the measured surface gradient and modeled bed gradient was about 2 percent, meaning the measured stream bed gradient is 2 percent steeper than the modeled gradient. Although this disparity is noteworthy, the modeled stream network is considered a first-iteration representation of the hydrologic system of the study area, and the lower gradient values produce a more conservative estimate of sediment transport within the system. These results suggest that the digital elevation model-generated stream network is detailed enough to be used as a measure of the potential impacts of raising Shasta Dam on stream channel equilibrium.

Using GIS, the Net Trace stream network was intersected with polygons representative of shoreline area affected through the inundation by each alternative. These intersections were completed for each arm of Shasta Lake. The total stream length and riparian area affected by the inundation were calculated for each arm and summarized to calculate the value for the entire shoreline of Shasta Lake. The affected stream length and riparian areas were also calculated in further detail for perennial and intermittent streams by stream-gradient categories of less than or greater than 10 percent.

Soil Erosion (Shoreline)

A conceptual model was developed to predict the rate and volume of shoreline erosion. The methods and assumptions used for the model are described in Attachment 1, "Shoreline Erosion Technical Memorandum." The conceptual model represents the spatial and temporal components of shoreline erosion, and was developed as a framework for field investigations, estimating present erosion rates, and predicting future erosion rates. The process-based model characterizes the causes of shoreline erosion and uses types of erosion initiation to weight the erodibility of the shoreline. The model was developed using results from similar studies; available precipitation, wind, and lake level data; information concerning the engineering properties of the bedrock geology and soils; the shoreline and hillslope topography; measured erosion processes and rates from sequential historical aerial photographs; and field investigations. Because there were very few shoreline erosion studies for reservoirs as large as Shasta Lake to use as background and support for the analysis, readily available references were used to help characterize the process of shoreline erosion, verify the predicted shoreline erosion rates, and design mitigation measures.

The model divided the shoreline into two zones, which helped account for the episodic nature of erosional events. The nearshore zone is classified as the area above the 1,070-foot contour, and represents the “bathtub” ring around the reservoir. The drawdown zone is classified as the area between the 1,070-foot contour and the 1,020-foot contour. The latter contour was used to represent the drawdown level that typically occurs to meet USACE requirements for flood storage capacity. The nearshore zone is eroded by wave action when the reservoir is full. During drawdown periods, this zone erodes as a result of upland surface runoff, subsurface flow, and fluvial incision along stream channels and gullies.

To represent the temporal component of shoreline erosion, the model was compartmentalized so that shoreline development could be evaluated in three time steps. The first step lasts for about 15 years and is when most of the erosion occurs (Morris and Fan 1997). During this time, the inundated soils are fully saturated; as a result, they may lose cohesion and are subject to rapid erosion, transport, and deposition. Shoreline exposed in the drawdown zone is typically eroded to bedrock or to resilient soil layers, leaving an exposed surface that supports little vegetation. Within this zone, stream channels and gullies rapidly incise the underlying soil and rock.

The second time step can last between about 0 and 150 years. During this time, stable shoreline topography is developing through a sequence of slope-forming events. For modeling purposes, the types of slope-forming events were classified by lithotopo unit because several common processes initiate and control erosion. The shoreline erosion survey data suggest that stable hillslopes are typically associated with shallow soils on coherent bedrock, forming steep topography (greater than 65 percent slope gradient). Unstable hillslopes are associated with deep soils on moderately steep areas (between 30 percent and 65 percent). Around Shasta Lake, stable shoreline formed rapidly during the first 15 years of lake management. Conversely, about 60 years later, unstable hillslopes are still responding to erosional forces and, in some locations, continue to erode at a very high rate (greater than 900 cubic yards/acre/year).

The third time step is used to represent a period when the shoreline slope is stable and soil shear strength remains greater than the shear stresses acting on the slope. During this time, the erosion rate continues to decrease and eventually equals the upslope erosion rates. The analysis assumes that most of the shoreline around Shasta Lake will become stable as the reservoir ages, and the data show that about half of the shoreline is presently stable.

4.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental consequences that would be caused by, or result from, the proposed action. Under NEPA, the significance of an environmental consequence is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A “[s]ignificant effect on the environment” means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. At a minimum, impacts of an alternative on geology, geologic hazards, geomorphology, mineral resources, and soils would be significant under CEQA if project implementation would do any of the following:

- Expose people or structures to potential substantial adverse effects, including the risk of loss, or injury, or death involving the following:
    - Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault
    - Strong seismic ground shaking
    - Seismic-related ground failure, including liquefaction
    - Landslides
- Result in substantial soil erosion or loss of topsoil
- Locate project facilities on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction, or collapse
- Locate project facilities on expansive soil, as defined in Table 18-1-B of the Uniform Building Code, creating substantial risks to life or property
- Have soils incapable of adequately supporting the use of septic tanks or alternative wastewater disposal systems where sewers are not available for disposal of wastewater

- Result in the loss or availability of known mineral resources that would be of future value to the region

Significance statements are relative to both existing conditions (2005) and future conditions (2030), unless stated otherwise.

4.3.3 Topics Eliminated from Further Discussion

The topics of snow avalanches, expansive soil, and soil liquefaction are eliminated from the discussion of environmental consequences owing to the low likelihood of their occurrence as previously discussed (see Section 4.1.2 for snow avalanches and Section 4.15 for other eliminated topics).

Paleontological resources are not included in the discussion of environmental consequences. As described in Section 4.1.1, a small area of the fossiliferous Cretaceous Chico Formation occurs near Jones Valley Creek, a tributary to the Pit Arm, but this rock unit is not exposed along the shoreline of the lake and is not associated with any relocation area. Some outcrops of McCloud Limestone, especially in the vicinity of the McCloud River Bridge, also contain fossil corals and other microinvertebrates. Some areas underlain by limestone are likely to be disturbed regardless of the action alternative being considered. However, the fossils that compose the McCloud Limestone are well documented in the scientific literature, and it is unlikely that paleontological resources of scientific or cultural significance occur in this formation. In the event that an unanticipated discovery of paleontological resources occurs, the environmental commitments described in Chapter 2 will be applied.

Paleontological resources have been eliminated from further discussion in the upper Sacramento River (Shasta Dam to Red Bluff), lower Sacramento River and Delta, and CVP/SWP service areas because no impacts are anticipated to these resources as a result of reoperation of the dam.

4.3.4 Direct and Indirect Effects

The following section describes the potential environmental consequences of the project, and impacts and mitigation measures.

No-Action Alternative

This section describes potential impacts that would occur under the NEPA No-Action Alternative. Under the No-Action Alternative, no additional Federal action would be taken to address water reliability issues or increase anadromous fish survival. Shasta Dam would not be modified, and the CVP would continue operating similar to the existing condition. No new construction would occur under the No-Action Alternative and the full pool elevation of the reservoir would remain at approximately 1,070 feet above msl.

Shasta Lake and Vicinity This section describes impacts on the Shasta Lake and vicinity portion of the primary study area.

Impact Geo-1 (No-Action): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no increase in the risk of geologic hazards to people or structures. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-2 (No-Action): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Under the No-Action Alternative, the full pool level would not be increased. Therefore, the ongoing changes to aquatic habitat within the existing transitional riverine habitat would continue, specifically, periodic adjustments to the bed and banks of stream channels in response to lake level fluctuations and upstream geomorphic processes. Any habitat benefits that may occur as a result of structural changes (e.g., recruitment of large wood or coarse sediment) would be dynamic and subject to change over time. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-3 (No-Action): Loss or Diminished Availability of Known Mineral Resources that Would Be of Future Value to the Region Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no loss or diminished availability of known mineral resources that would be of future value to the region. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-4 (No-Action): Lost or Diminished Soil Biomass Productivity Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no lost or diminished soil biomass productivity. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-5 (No-Action): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under the No-Action Alternative, the full pool level would not be increased. Therefore, there would be no increase in soil erosion or loss of topsoil due to shoreline processes. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-6 (No-Action): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Under the No-Action Alternative, there would be no disturbance of upland landscape positions. Therefore, there would be no increase in soil erosion or loss of topsoil due to upland processes. No impact would occur. Mitigation is not required for the No-Action Alternative.

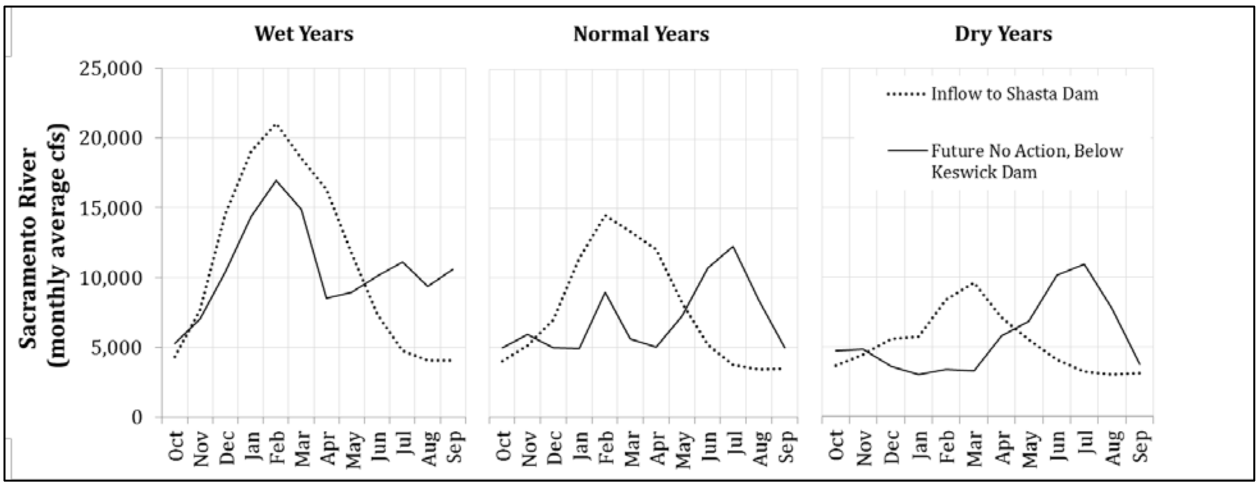
Impact Geo-7 (No-Action): Location on a Geologic Unit or Soil that Is Unstable, or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased.

Therefore, there would be no increase in the risk of land subsidence. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-8 (No-Action): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that Are Unsuited to Land Application of Waste Under the No-Action Alternative, no new construction would occur and the full pool level would not be increased. Therefore, there would be no increase in the risk of failure of septic tanks or alternative wastewater disposal systems. No impact would occur. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts on the upper Sacramento River portion of the primary study area.

Impact Geo-9 (No-Action): Substantial Increase in Channel Erosion and Meander Migration No Shasta Dam enlargement activities would be implemented, and no new water releases from the dam would occur as a result of the No-Action Alternative. As illustrated in Figure 4-9, inflow to Shasta Lake would continue to be released from Shasta and Keswick dams based on the operations for the Central Valley Project objectives and other project requirements.



Notes:
Wet Years comprised of water years (October – September) classified under State Water Board Decision 1641 as "Wet"
Normal Years comprised of years classified as "Above Normal" and "Below Normal"
Dry Years comprised of years classified as "Dry" or "Critical"

Figure 4-9. Comparison Between Inflow to Shasta Dam and No Action Alternative Releases at Keswick Dam

Figure 4-10 demonstrates how future operations of the baseline future conditions at Shasta Dam result in the capture of higher flows (generally months with inflows between 3- and 25-percent exceedence flow rates) for release during periods with more moderate inflows to Shasta Dam (generally months with inflows between 25- and 70-percent exceedence flow rates).

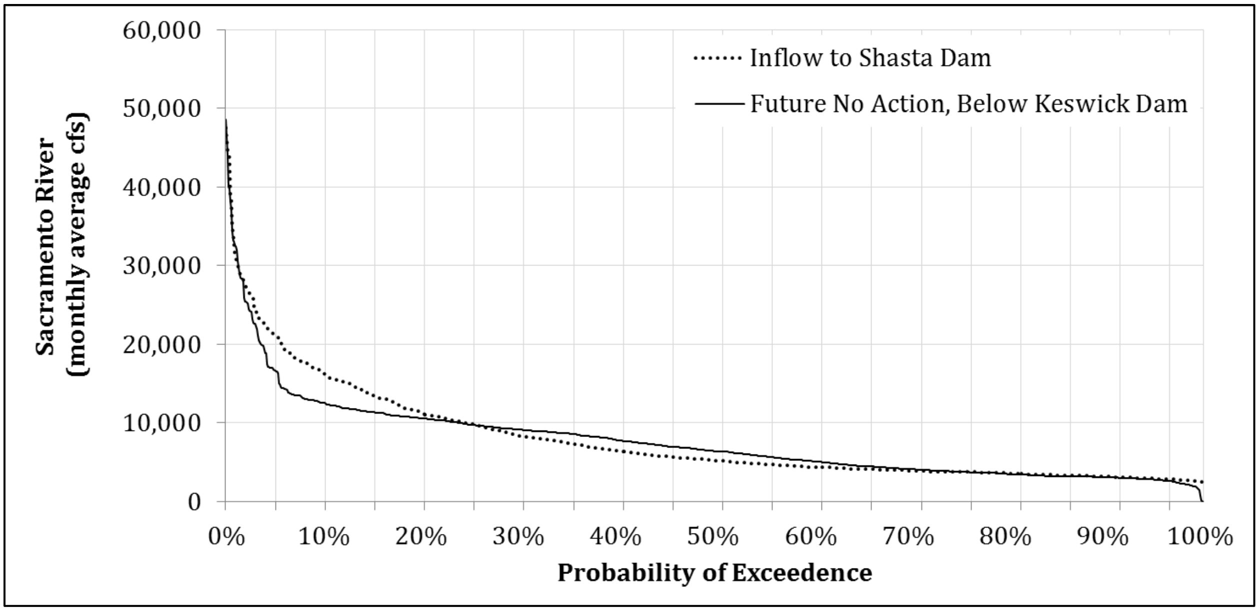


Figure 4-10. Percent Exceedence Comparison Between Inflow to Shasta Dam and Future No Action Alternative Releases from Keswick Dam

No changes would occur with implementation of the No-Action Alternative, therefore no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-10 (No-Action): Substantial Soil Erosion or Loss of Topsoil Due to Construction No Shasta Dam enlargement activities would be implemented, and no gravel augmentation activities would occur as a result of the No-Action Alternative. Therefore, no soil additional soil erosion would be anticipated on the banks along the river channel. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-11 (No-Action): Alteration of Fluvial Geomorphology Under the No-Action Alternative, Shasta Dam operations would not change. Therefore, no changes in fluvial geomorphology would be anticipated. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact Geo-12 (No-Action): Alteration of Downstream Tributary Fluvial Geomorphology Due to Shasta Dam Operations Under the No-Action Alternative, Shasta Dam operations would not change. Therefore, no changes in the fluvial geomorphology of downstream tributaries would be anticipated. No impact would occur. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta This section describes impacts on the lower Sacramento River and Delta portions of the extended study area associated with the No-Action Alternative.

Impact Geo-13 (No-Action): Substantial Increase in Channel Erosion and Meander Migration No Shasta Dam enlargement activities would be implemented, and no new water releases from the dam would occur as a result of the No-Action Alternative. The water releases from the dam would continue to vary based on time of year, water year types, and system conditions. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

CVP/SWP Service Areas This section describes the impacts associated with the No-Action Alternative on the CVP/SWP service areas within the extended study area.

Impact Geo-14 (No-Action): Substantial Increase in Channel Erosion and Meander Migration No Shasta Dam enlargement activities would be implemented, and no new water releases from the dam would occur as a result of the No-Action Alternative. No changes in operations would occur under the No-Action Alternative. The water releases from Shasta Dam, Folsom Dam, and Oroville Dam would continue to vary based on time of year, water year types, and system conditions, but would not be anticipated to be outside of normal operating conditions. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

This section describes impacts associated with CP1, which focuses on increasing water supply reliability while contributing to increased anadromous fish survival by raising Shasta Dam 6.5 feet. The dam raise would increase the reservoir's full pool by 8.5 feet, and enlarge total storage space in the reservoir by 256,000 acre-feet. Section 2.3.8 in Chapter 2, "Alternatives," describes the construction activities and potential borrow sources associated with CP1.

Shasta Lake and Vicinity This section describes impacts on the Shasta Lake and vicinity portion of the primary study area.

Impact Geo-1 (CP1): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption Implementing CP1 has the potential to increase the exposure of structures and people to geologic hazards.

No active faults are known to be present within or immediately adjacent to the Shasta Lake and vicinity area, and there is a low risk of fault rupture (CDMG 2006a). According to LaForge and Hawkins (1986), Jennings (1994), and the California Department of Conservation, Division of Mines and Geology (1997), all known faults around the Shasta Lake and vicinity area are classified as inactive. (Inactive faults show no evidence of movement in the last 10,000 years (i.e., Holocene).) Because there are few active faults in close proximity to the Shasta Lake and vicinity area, the likelihood of strong seismic ground shaking also is low. Detailed, site-specific geologic and foundation investigations will be completed to develop design criteria to withstand reasonably probable seismic events. This impact would be less than significant for CP1. Mitigation for this impact is not needed, and thus not proposed.

Under CP1, the pool level increase would inundate 78 acres of mapped slope instability hazards (i.e., active and relict landslides, debris flows, inner gorge landscape positions, and complexes of these features). Relocation of infrastructure is proposed to occur within or adjacent to several relocation areas. Subsequent to the DEIS, these relocation areas were refined using updated engineering and resource information, thereby reducing the areas subject to slope instability hazards. Inundation of bedrock and soils resulting from the increased pool elevation, and earthwork and vegetation removal associated with new construction, could reduce the stability of hillslopes prone to mass wasting. The existing relict and active mass wasting features may become less stable. The risks associated with increased slope instability due to the rise in pool elevation and relocation of infrastructure have been considered in formulating the description of CP1. Areas of known instability have been addressed via avoidance or through design measures intended to minimize the risk of increased instability. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Hazards associated with volcanic eruptions have a low probability of occurring within the Shasta Lake and vicinity area. Significant impacts resulting from eruptions in the Medicine Lake Highlands and at Lassen Peak are unlikely due to their distance from Shasta Lake and the lack of drainage connections. Eruptions of Mount Shasta are not likely to deposit lithic ash, lava flows, domes, or pyroclastic flows within the reservoir, and Mount Shasta is not likely to erupt large volumes of pumiceous ash. The danger from floods caused by eruptions is similar to that from floods having other origins, and would be mitigated via the proposed dam modifications (e.g., increased spillway capacity) and operational procedures. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Similarly, the dangers from mudflows and seiche hazards are low, and would be mitigated via the proposed dam modifications (e.g., increased spillway capacity) and operational procedures. There are few seismic hazard areas within the Shasta Lake and vicinity area that would expose structures or people to geologic hazards. However, site-specific geologic and foundation investigations will be conducted to develop design criteria to withstand reasonably probable seismic events. In addition, areas of known instability around the perimeter of the lake shore have been addressed via avoidance or through design measures to minimize exposure of structures or people to slope instability. There is a low probability of hazards associated with volcanic eruptions within the Shasta Lake and vicinity area, but any potential for floods caused by eruptions is similar to that from floods having other origins and would be mitigated via the proposed dam modifications and operational procedures. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

There is the potential for Reservoir Triggered Seismicity (RTS), seismicity resulting from the impoundment of water at or near the Lake Shasta reservoir. However, proper seismic hazard analyses will be performed and the design earthquake will be correctly defined to mitigate for any potential hazards. RTS is characterized as: seismic events that are more frequent than background levels before impoundment; an increase in both frequency and magnitude of earthquake events resulting from large oscillations of storage levels; and triggered events that tend to decrease to background levels after peaking. To identify an RTS event, an appropriate local seismic network capable of recording microseismic events would be monitored and evaluated. By following the seismic design criteria, an impact resulting from RTS would be mitigated to less than significant. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP1): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Under CP1, stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Lower gradient channels (less than 10 percent slope) with existing delta deposits would be affected more than higher gradient channels. It is likely that the delta deposits would expand both upstream and downstream as a result of this alternative. When the lake is full and regional flooding occurs, sediment transported from the uplands would be deposited as deltas at the confluence of the streams and lake. When the lake level is low during base-flow periods, stream channels within the inundation zone are likely to be channelized as they downcut into the delta deposits. In the lower gradient channels, the stream type could shift to an unstable braided channel. This impact would be significant.

Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,080 feet of elevation. CP1 could also destabilize the stream channels as a result of riparian vegetation loss on the lower and upper banks and a more mobile stream bed. Within the drawdown zone, the reintroduction of brush structures, large wood, and/or rock boulder clusters into a number of low-gradient perennial channels would provide some degree of structural complexity intended to improve habitat conditions for aquatic organisms.

Based on a stream network generated using Net Trace, the total stream length inundated as a result of CP1 is estimated to be 18.5 miles (see Figure 4-11), which equates to about 0.7 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 18.5 miles inundated, 716 stream segments totaling about 6.2 miles of streams with a gradient of less than 10 percent would be affected to some degree.

	Big Backbone Creek	Main Body	McCloud River	Pit River	Sacramento River	Squaw Creek
Intermittent >10% Grade	0.8	1.7	1.0	1.0	1.1	0.3
Perennial >10% Grade	0.1	0.2	0.2	0.1	0.2	0.0
Intermittent 7-10% Grade	0.1	0.4	0.2	0.2	0.5	0.2
Perennial 7-10% Grade	0.02	0.05	0.08	0.02	0.05	0.01
Intermittent <7% Grade	0.3	1.2	0.6	0.5	1.0	0.4
Perennial <7% Grade	0.5	0.6	1.1	1.0	2.2	0.6

Figure 4-11. Stream Lengths in Watersheds Adjacent to Shasta Lake that Would Be Periodically Inundated Under CP1

The increase in full pool would affect channels above the current full-pool elevation (1,070 msl) by altering their fluvial geomorphology and the hydrology of the aquatic habitats, as described above. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP1): Loss or Diminished Availability of Known Mineral Resources that Would Be of Future Value to the Region Significant quantities of cement, concrete sand and aggregate, and coarse aggregate would be needed under CP1. Cement Types I, II, III, and V are produced locally, but supplies are limited. Required quantities of concrete sand and aggregate are available from local commercial suppliers. The tonnage of sand anticipated to be needed is roughly more than 150 percent of the annual Shasta County production of sand and gravel. Embankment material (i.e., coarse aggregate) could be obtained from local sources, including from within Shasta Lake itself. Implementation of CP1 has the potential to diminish the availability of cement, and of concrete sand and aggregate, in the region. This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-4 (CP1): Lost or Diminished Soil Biomass Productivity Under CP1, soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction, including relocation of infrastructure. Using Equivalent FSSC as a surrogate metric for soil biomass productivity, implementation of CP1 would result in loss of the following acreages by productivity rank: moderate productivity – 1,954.6 acres; low productivity – 1,604.5 acres; nonproductive – 565 acres.

This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-5 (CP1): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP1, the area of shoreline that would be periodically inundated would be about 1,229 acres. Substantial soil erosion and loss of topsoil would result. This impact would be significant.

The inundated area would be subjected to shoreline erosional processes. For the first 15 years after the dam raise, the average rate of shoreline erosion would increase substantially, from approximately 90 cubic yards per acre per year to about 300 cubic yards per acre per year. For the first time step (i.e., 15 years), the total average annual volume of potential shoreline erosion from CP1 would be about 421,000 cubic yards per year. Within 60 years of the dam raise, the average annual volume is predicted to decrease to approximately 107,000 cubic yards per year.

Sediment delivery from shoreline erosion would likely be greatest in the Sacramento Arm, the eastern portion of the Main Body of the lake, and the

McCloud Arm. These three arms are predicted to deliver more than 66,000 cubic yards per year for the first 15 years after the dam raise. Within 60 years of the dam raise, the average rate for these arms is predicted to decrease to about 19,000 cubic yards per year. The western portion of the Main Body of Shasta Lake and the Backbone Creek Arm are predicted to have the lowest shoreline erosion rates, resulting in a 15-year average annual potential erosion volume of less than 26,000 cubic yards per year. The Pit Arm is predicted to produce about 50,000 cubic yards per year and the Squaw Creek Arm about 35,000 cubic yards per year.

Assuming the available vegetation removal prescriptions between the 1,070-foot and 1,080-foot contours, for the first time step (i.e., 15 years after the raising of Shasta Dam), there would be about 421,000 cubic yards per year of shoreline erosion. After about 15–20 years, depending on climatic variability, the new shoreline would form and would start to stabilize. Total reservoir erosion is predicted to decrease by 70 percent between 15 and 60 years after the dam raise. The wetter the climate cycle, the more rapidly the shoreline is predicted to form and stabilize.

The analysis also calculated the 15-year erosion volume using the prescribed vegetation treatments and modeled higher erosion rates for shoreline with partial and complete vegetation removal. The Big Backbone, Squaw Creek, and Pit arms would have very little vegetation removal, which would not affect the short-term rate of shoreline erosion. The Main Body and the Sacramento and McCloud arms would have substantial amounts of vegetation removal, which would result in higher short-term erosion rates. For these arms, areas treated by vegetation removal represent about half of the total predicted erosion.

Soil erosion due to shoreline processes is estimated to be 421,000 cubic yards per year, assuming the available vegetation removal prescriptions between 1,070-foot and 1,080-foot contours would occur in the first 15 years after the raising of Shasta Dam. This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-6 (CP1): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes Interpretations of soil susceptibility to erosion are presented in Table 4-12 for the portion of the area potentially disturbed by construction activities. The values in this table were updated based on refinement of the relocation areas after publication of the DEIS. Approximately 2,384 acres in the upland portion of the Shasta Lake and vicinity area could be disturbed; the likely area of disturbance is about 698 acres. The environmental commitments common to all action alternatives include implementation of best management practices, preparation and implementation of a SWPPP and development and implementation of site-specific revegetation plans. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

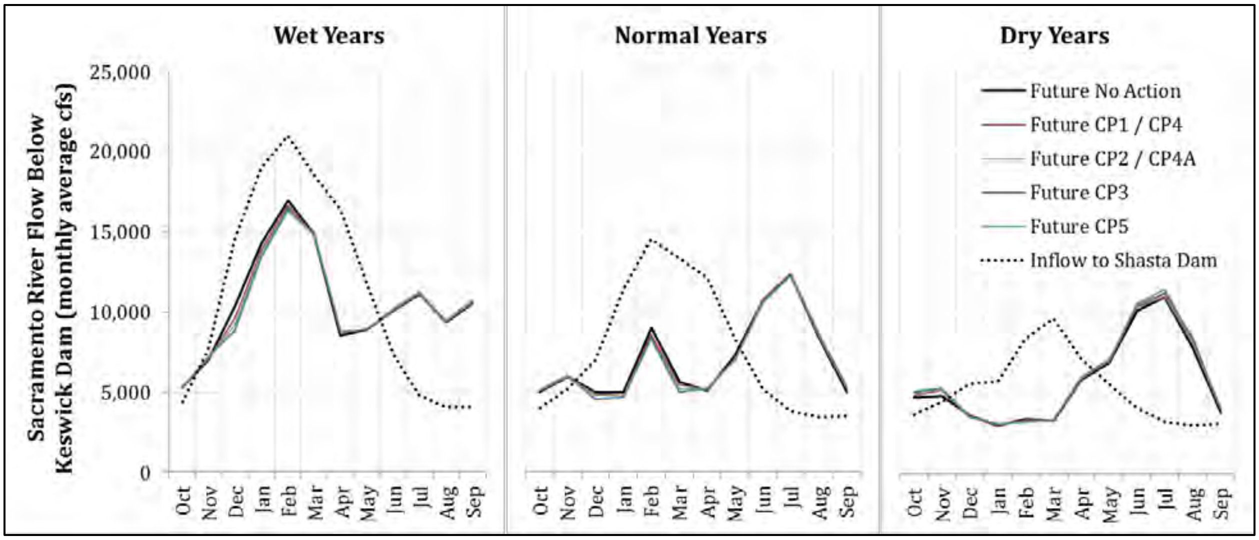
Construction-related erosion will be avoided and minimized via implementation of the SWPPP (i.e., erosion and sediment control plans, including site revegetation), which is part of the environmental commitments common to all action alternatives. These plans will address the necessary local jurisdiction requirements regarding erosion control and site revegetation, and would implement best management practices for erosion and sediment control. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP1): Location of Project Facilities on a Geologic Unit or Soil that Is Unstable or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence Of the 2,384 acres of relocation areas within the Shasta Lake and vicinity area, a small proportion (about 5 percent) occupies landscape positions underlain by limestone; these areas would be avoided during relocation activities. Land subsidence has a potential to occur in areas underlain by certain limestones and in areas affected by underground construction. Detailed, site-specific geologic and foundation investigations will be completed to inform project design concerning ways to avoid potential subsidence from these causes. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP1): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that Are Unsuited to Land Application of Waste In general, soils in the Shasta Lake and vicinity area are poorly suited to use as septic tank leach fields or for alternative waste disposal systems due to shallow soil depth, high rock content, and excessive slope. Relocated wastewater facilities would be designed and constructed to satisfy the conditions of the Shasta County Environmental Health Division Sewage Disposal System Permit. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts on the upper Sacramento River portion of the primary study area associated with CP1.

Impact Geo-9 (CP1): Substantial Increase in Channel Erosion and Meander Migration This impact would be similar to Impact Geo-9 (No-Action). Additional storage at Lake Shasta, in comparison to the No-Action Alternative, allows for greater capture of high flows and additional releases during periods when the demand for water is high and inflows to Lake Shasta are relatively low. Figure 4-12 compares average monthly releases from Keswick Dam for all alternatives. Differences between releases for the No-Action and all action alternatives are not significant. These differences are most perceptible as reductions during the winters of Wet and Normal hydrologic conditions, and increases in summer of Dry hydrologic conditions. These differences are consistent with the inter-annual storage objectives of operations at Shasta Dam and facilities.



Notes:
Wet Years comprised of water years (Oct – Sep) classified under State Water Board Decision 1641 as “Wet”
Normal Years comprised of years classified as “Above Normal” and “Below Normal”
Dry Years comprised of years classified as “Dry” or “Critical”

Figure 4-12. Comparison Between Inflow to Shasta Dam and Future Alternative Releases from Keswick Dam

Alterations to river flows have the potential to alter downstream stream erosion and change downstream geomorphologic characteristics. Specifically, the characteristics of peak flows, including magnitude, duration, and the rate at which flows change (i.e., ramping rates), govern the mechanical processes on rivers such as erosion, scour, and deposition. Figure 4-13 demonstrates the changes in average monthly flows relative to the No-Action Alternative, which are most perceptible in exceedence range between 3- and 6-percent, which indicates the potential for reductions in low- to mid-range pulse flows. The releases from Keswick Dam shown in Figure 4-13 were simulated using a reservoir operations model that operates on a monthly time-step.

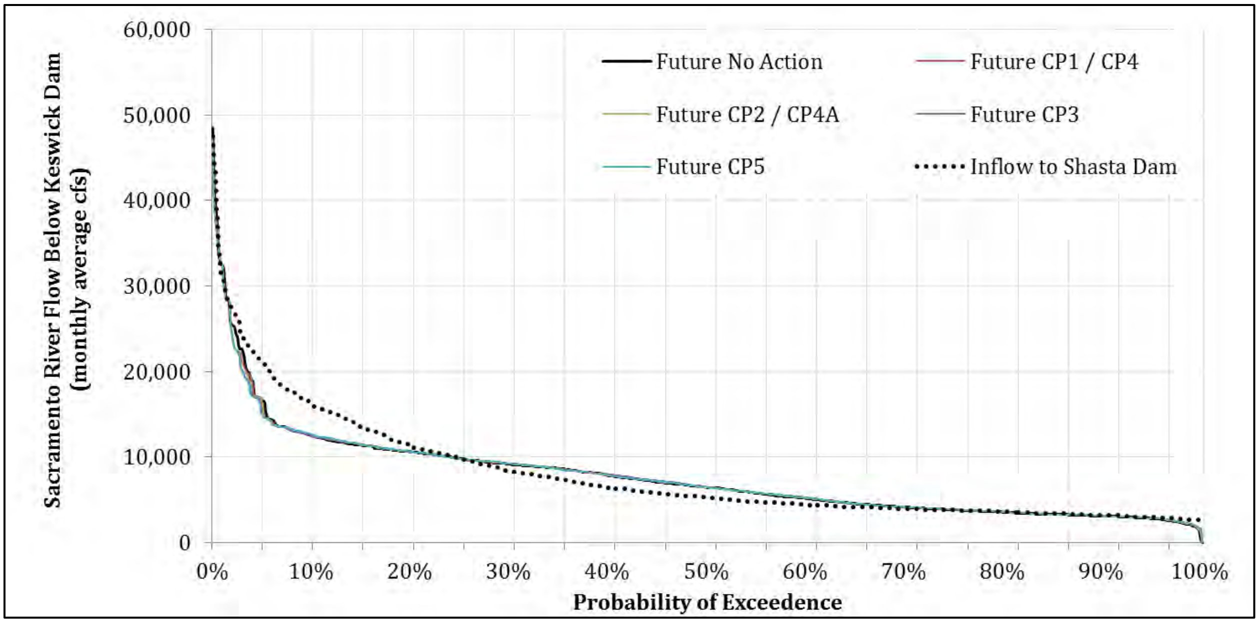


Figure 4-13. Percent Exceedence Comparison Between Inflow to Shasta Dam and Future Alternative Releases from Keswick Dam (monthly average cfs)

Geomorphic processes related to pulse flows are well correlated to daily hydrology, and only loosely correlated to monthly hydrology. Therefore, small differences in daily percent exceedence may or may not correspond to meaningful changes in geomorphology. A set of daily flows was extrapolated from the monthly model for use in temperature studies. A full description of this daily data set is described in Chapter 3, "Temporal Downsizing of CalSim-II Flows for Use in Temperature Modeling," in the EIS Modeling Appendix. This data set was used to construct daily exceedence plots, shown in Figures 4-14 and 4-15. Similar to the monthly exceedence plots, reductions in releases from Keswick Reservoir relative to the No-Action Alternative are most perceptible in exceedence range between 1- and 6-percent. These reductions are relatively small, only apply to small- to mid-sized pulse flows, and are unlikely to affect the geomorphology of the Sacramento River in a significant manner.

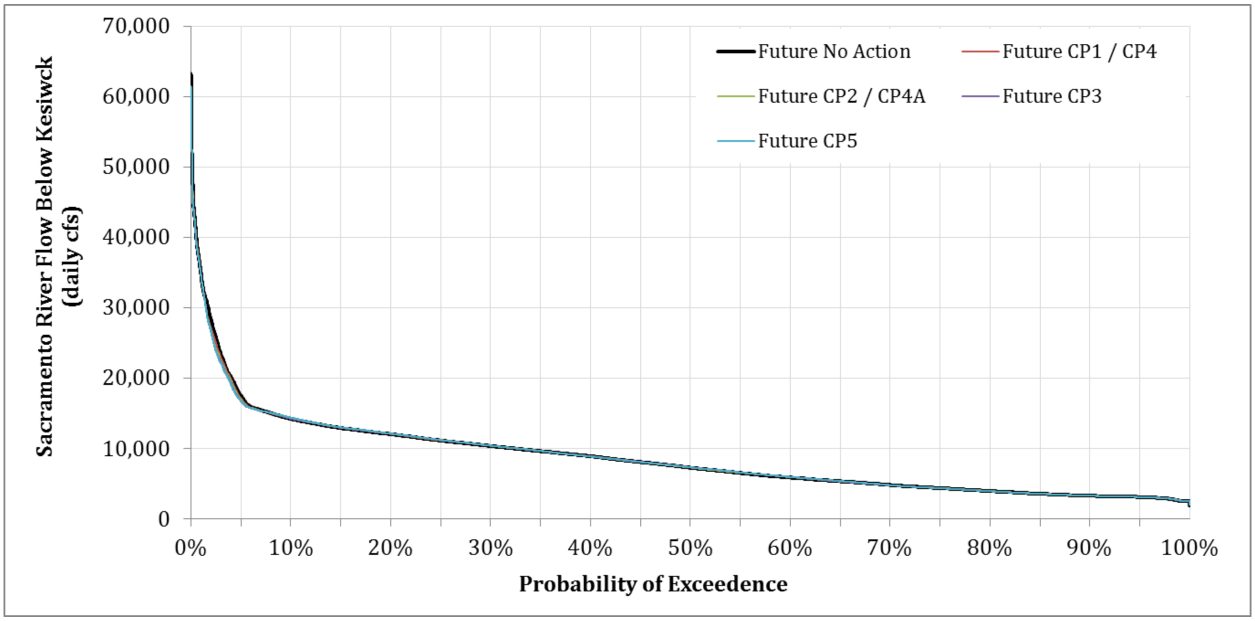

Figure 4-14. Percent Exceedence (0% to 100%) Comparison Between Future Alternative Releases from Keswick Dam (daily cfs)

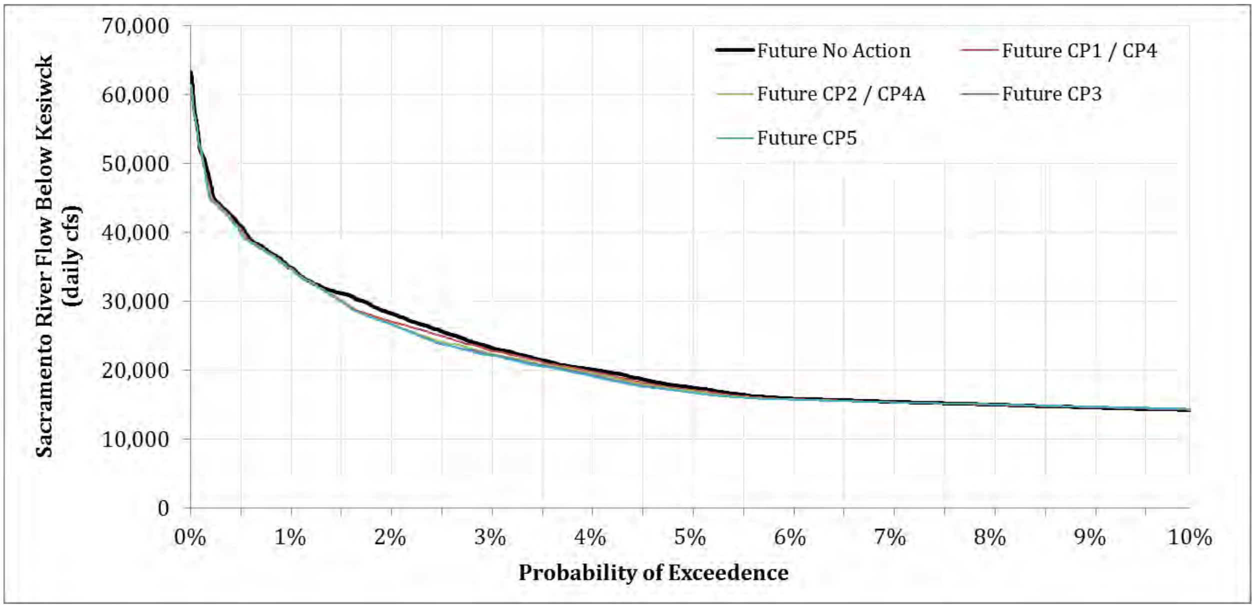

Figure 4-15. Percent Exceedence (0% to 10%) Comparison Between Future Alternative Releases from Keswick Dam (daily cfs)

The frequency and duration of high-flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion is anticipated to decrease or remain stable. This impact would be less than significant.

Reductions of stream bedload contribution are greatest during high-flow events. Bed and bank conditions in streams and rivers are created, maintained, and destroyed by natural geomorphic processes whose rates and patterns are regulated through complex interactions of flow, sediment transport, and properties of the channel and floodplain (including slope, erodibility, and morphology). Because large fluvial systems, such as the Sacramento River and its floodplain, are affected by the interaction of a wide variety of geomorphic processes, quantifying and understanding how they evolve can be complex. The legacy of land and water use in a region adds to the complexity, modulating factors such as flow, sediment supply, and floodplain erodibility, thus affecting the dynamics of riverine and floodplain characteristics.

High-flow events can mobilize and scour gravel stored in the channel bed, routing the sediment downstream. In the alluvial reaches of unregulated rivers, the sediment scoured from a local reach is generally replaced by sediment transported from upstream, supplied from tributaries, or recruited from storage in riverbanks. There may be short-term or local changes in the amount of gravel stored in a channel bed due to episodic sediment delivery (e.g., mass wasting events in the watershed) or extreme flow events. However, over a broader time span, unregulated rivers generally achieve a balance between sediment supply and routing so that in-channel sediment storage is maintained.

The first significant natural source of sediment to the Sacramento River is nearly 30 miles (48 kilometers) downstream from Keswick Dam at Cottonwood Creek (River Mile 273.5). Tributaries between Keswick Dam and Cottonwood Creek contribute little sediment to the mainstem because they drain small basins of erosion-resistant material or, as is the case for Clear Creek, are themselves regulated by dams and are affected by aggregate mining. Much of the upper Sacramento River (i.e., from River Mile 302 to approximately River Mile 273.5) is bounded by erosion-resistant bedrock and terrace deposits, such that bank erosion is not fast enough, relative to in-channel transport, to provide a significant source of coarse sediment. In other words, the rate of supply from erosion of banks due to meander migration in the upper river is minimal.

Meander migration and bank erosion occur by two processes: progressive channel migration, in which flows erode banks incrementally, and episodic meander-bend cutoff, in which the channel avulses to a completely new course. Cutoffs may be partial or complete, depending on initial meander bend geometry and the resistance of bank and floodplain materials to erosion, among other factors. Complete cutoffs are often referred to as "chute cutoffs." Partial cutoffs are sometimes also referred to as "neck cutoffs" in geomorphology texts and literature. While progressive migration and episodic cutoff can generally be thought of as distinct (i.e., mutually exclusive) processes, they are nevertheless interrelated because they simultaneously regulate and are affected by sinuosity and other channel characteristics.

An erosion and sediment control plan would be implemented, as described in Section 2.3.2, "Environmental Commitments Common to All Action Alternatives," in Chapter 2, "Alternatives," to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant. Mitigation for this impact is not needed. However, mitigation for this impact is proposed in Section 4.3.5 to further reduce the impact.

Impact Geo-10 (CP1): Substantial Soil Erosion or Loss of Topsoil Due to Construction With implementation of CP1, no gravel augmentation activities or construction activities would occur at potential upper Sacramento River restoration sites. Therefore, no additional soil erosion would be anticipated on the banks along the river channel. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP1): Alteration of Fluvial Geomorphology With implementation of CP1, no potential upper Sacramento River restoration activities would occur. Therefore, no changes in fluvial geomorphology would be anticipated. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-12 (CP1): Alteration of Downstream Tributary Fluvial Geomorphology Due to Shasta Dam Operations Under CP1, the fluvial geomorphology of downstream tributaries would not be affected by changes in Sacramento River stage attributed to Shasta Dam operations. Small increases in Sacramento River stage may occur with implementation of CP1. However, the frequency and duration of high-flow events resulting from CP1 implementation are expected to be reduced as compared to existing conditions with current operations. This impact would be less than significant.

Where they occur, geomorphic changes (headcutting, channel incisement, etc.) in major tributaries in Cow, Clear and Cottonwood creeks has been directly attributed to the presence of dams (on Clear Creek) and past and current instream gravel mining on the tributaries themselves. Future operations at Shasta Dam under CP1 are not anticipated to result in significant geomorphic changes at these major tributaries in comparison to the No-Action Alternative. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts on the lower Sacramento River and Delta portions of the extended study area associated with CP1.

Impact Geo-13 (CP1): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP1 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. With implementation of CP1, there would be a potential reduction in high-flow events. Therefore, increases in Sacramento River flow would be limited and effects on reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as flood bypasses in the extended study area. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), but would take place in the lower Sacramento River and Delta where the effects of increases in Sacramento River flow would be limited and effects on reservoirs and rivers would be attenuated and dissipated. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts on the CVP/SWP service areas within the extended study area associated with CP1.

Impact Geo-14 (CP1): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP1 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), but would be associated with the CVP/SWP service areas that extend along the Sacramento River. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

This section describes impacts associated with CP2, which focuses on enlarging Shasta Dam and Reservoir by raising Shasta Dam 12.5 feet. The dam raise would increase the reservoir's full pool by 14.5 feet, and enlarge total storage space in the reservoir by 443,000 acre-feet. Section 2.3.8 in Chapter 2, "Alternatives," describes the construction activities and potential borrow sources associated with CP2.

Shasta Lake and Vicinity This section describes impacts on the Shasta Lake portion of the primary study area.

Impact Geo-1 (CP2): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption Implementing CP2 has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to

CP1, impacts resulting from seismic conditions would be less than significant for CP2.

Under CP2, the pool level increase would inundate 110 acres of mapped slope instability hazards. Relocation of infrastructure under CP2 would occur in the vicinity of mapped slope instability hazards to a similar but greater extent than under CP1 (up to about 232 acres). For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP2.

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP2.

No active faults are known to be present within or immediately adjacent to the Shasta Lake and vicinity area, and there is a low risk of fault rupture (CDMG 2006a). According to LaForge and Hawkins (1986), Jennings (1994), and the California Department of Conservation, Division of Mines and Geology (1997), all known faults around the Shasta Lake and vicinity area are classified as inactive. (Inactive faults show no evidence of movement in the last 10,000 years (i.e., Holocene).) Because there are few active faults in close proximity to the Shasta Lake and vicinity area, the likelihood of strong seismic ground shaking also is low. Detailed, site-specific geologic and foundation investigations will be completed to develop design criteria to withstand reasonably probable seismic events. This impact would be less than significant for CP2. Mitigation for this impact is not needed, and thus not proposed.

There is the potential for Reservoir Triggered Seismicity (RTS), seismicity resulting from the impoundment of water at or near the Lake Shasta reservoir. However, proper seismic hazard analyses will be performed and the design earthquake will be correctly defined to mitigate for any potential hazards. RTS is characterized as: seismic events that are more frequent than background levels before impoundment; an increase in both frequency and magnitude of earthquake events resulting from large oscillations of storage levels; and triggered events that tend to decrease to background levels after peaking. To identify an RTS event, an appropriate local seismic network capable of recording microseismic events would be monitored and evaluated. By following the seismic design criteria, an impact resulting from RTS would be mitigated to less than significant. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP2): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Like CP1, under CP2 stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,084 feet of elevation. This impact would be significant.

Based on a stream network generated using Net Trace, the total stream length inundated as a result of CP2 would be 25.5 miles (see Figure 4-16), which equates to about 0.9 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 25.5 miles inundated, 716 stream segments totaling about 8.2 miles of streams with a gradient less than 10 percent would be affected to some degree.

Within the drawdown zone, there would be some benefit to channels with implementation of the environmental commitment to introduce brush structures, large wood, and/or boulder/rock clusters at various locations within low gradient reaches of perennial channels.

The increase in full pool would affect channels by altering fluvial geomorphology and the hydrology of aquatic habitats as described above. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP2): Loss or Diminished Availability of Known Mineral Resources that Would Be of Future Value to the Region Implementing CP2 has the same potential as CP1 to diminish the availability in the region of cement, and of concrete sand and aggregate. For the same reasons as apply to CP1, this impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

	Big Backbone Creek	Main Body	McCloud River	Pit River	Sacramento River	Squaw Creek
Intermittent >10% Grade	1.1	2.4	1.3	1.4	1.5	0.4
Perennial >10% Grade	0.1	0.2	0.3	0.1	0.3	0.0
Intermittent 7-10% Grade	0.1	0.7	0.2	0.2	0.7	0.3
Perennial 7-10% Grade	0.02	0.1	0.16	0.06	0.1	0.02
Intermittent <7% Grade	0.5	1.6	0.8	0.7	1.3	0.6
Perennial <7% Grade	0.6	0.8	1.4	1.4	3.1	0.9

Figure 4-16. Stream Lengths in Watersheds Adjacent to Shasta Lake that Would Be Periodically Inundated Under CP2

Impact Geo-4 (CP2): Lost or Diminished Soil Biomass Productivity Like CP1, under CP2 soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction, including relocation of infrastructure. Using Equivalent FSSC as a surrogate metric for soil biomass productivity, implementation of CP2 would result in loss of the following acreages by productivity rank: moderate productivity – 2,128 acres; low productivity – 1,751 acres; nonproductive – 638 acres.

This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-5 (CP2): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP2, the area of shoreline that would be inundated would be about 1,734 acres. Substantial soil erosion and loss of topsoil would result. This impact would be significant.

For the first 15 years after the dam raise, the average rate of shoreline erosion would increase substantially, from 90 cubic yards per acre per year to about 300 cubic yards per acre per year. For the first time step (i.e., 15 years), the total average annual volume of potential shoreline erosion from CP2 would be about 549,000 cubic yards per year. Within 60 years of the dam raise, the average annual volume is predicted to decrease to 150,000 cubic yards per year.

Sediment delivery from shoreline erosion would likely be greatest in the Sacramento Arm, the eastern portion of the Main Body of the lake, and the McCloud Arm. These three arms are predicted to deliver more than 90,000 cubic yards per year for the first 15 years after the dam raise. Within 60 years of the dam raise, the average rate for these arms is predicted to decrease to 27,000 cubic yards per year. The western portion of the Main Body and the Backbone Creek Arm are predicted to have the lowest shoreline erosion rates, a 15-year average annual potential erosion volume of less than 43,000 cubic yards per year. The Pit Arm is predicted to produce about 67,000 cubic yards per year and the Squaw Creek Arm about 63,000 cubic yards per year.

Assuming the available vegetation removal prescriptions between the 1,070-foot and 1,084-foot contours, for the first time step (i.e., 15 years after the raising of Shasta Dam), there would be about 549,000 cubic yards per year of shoreline erosion. After about 15–20 years, depending on climatic variability, the new shoreline would form and would start to stabilize. Total reservoir erosion is predicted to decrease by 70 percent between 15 and 60 years after the dam raise. The wetter the climate cycle, the more rapidly the shoreline is predicted to form.

The analysis also calculated the 15-year erosion volume using the prescribed vegetation treatments and modeled higher erosion rates for shoreline with partial and complete vegetation removal. The Big Backbone, Squaw Creek, and

Pit arms would have very little vegetation removal, which would not affect the short-term rate of shoreline erosion. The Main Body of Shasta Lake and the Sacramento River and McCloud arms would have substantial amounts of vegetation removal, which would result in higher short-term erosion rates. For these arms, areas treated by vegetation removal represent about half of the total predicted erosion.

This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-6 (CP2): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes CP2 is similar to CP1 with respect to its potential to cause substantial soil erosion or loss of topsoil due to upland processes. Interpretations of soil susceptibility to erosion are presented in Table 4-12 for the portion of the area that potentially would be disturbed by construction activities. The values in this table were updated based on refinement of the relocation areas after publication of the DEIS. Approximately 2,384 acres in the upland portion of the Shasta Lake and vicinity area could be disturbed, but the likely area of disturbance is about 698 acres. The environmental commitments common to all action alternatives include implementation of best management practices, preparation and implementation of a SWPPP, and development and implementation of site-specific revegetation plans. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Construction-related erosion will be avoided and minimized via implementation of the SWPPP (i.e., erosion and sediment control plans, including site revegetation) that is a part of the environmental commitments common to all action alternatives. These plans will address the local requirements regarding erosion control and site revegetation, and would implement best management practices for erosion and sediment control. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP2): Location of Project Facilities on a Geologic Unit or Soil that Is Unstable, or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence CP2 is similar to CP1 with respect to its potential to cause or be affected by subsidence. For the same reasons as apply to CP1, this impact would be less than significant for CP2, because detailed, site-specific geologic and foundation investigations will be completed to inform project design as to how to avoid potential subsidence from these causes. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP2): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste CP2 is similar to CP1 with respect to its potential to cause or be affected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste. For the same reasons as apply to

CP1, this impact would be less than significant for CP2 because relocated wastewater facilities would be designed and constructed to satisfy the conditions of the Shasta County Environmental Health Division Sewage Disposal System Permit. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes the impacts on the upper Sacramento River portion of the primary study area associated with CP2.

Impact Geo-9 (CP2): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP2 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing conditions, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows have the potential to alter downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high-flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An erosion and sediment control plan would be implemented, as described in Section 2.3.2, “Environmental Commitments Common to All Action Alternatives,” in Chapter 2, “Alternatives,” to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP2. This impact would be less than significant. Mitigation for this impact is not needed. However, mitigation for this impact is proposed in Section 4.3.5 to further reduce the impact.

Impact Geo-10 (CP2): Substantial Soil Erosion or Loss of Topsoil Due to Construction With implementation of CP2, no gravel augmentation activities would occur. Therefore, no soil additional soil erosion would be anticipated on the banks along the river channel. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP2): Alteration of Fluvial Geomorphology With implementation of CP2, no potential upper Sacramento River restoration activities would occur. Therefore, no changes in fluvial geomorphology would be anticipated. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-12 (CP2): Alteration of Downstream Tributary Fluvial Geomorphology Due to Shasta Dam Operations Under CP2, the fluvial geomorphology of downstream tributaries would not be affected by changes in Sacramento River stage attributed to Shasta Dam operations. Small increases in Sacramento River stage may occur with implementation of CP2. However, the frequency and duration of high-flow events resulting from CP2 implementation are expected to be reduced as compared to existing conditions with current operations.

Where they occur, geomorphic changes (headcutting, channel incisement, etc.) in major tributaries in Cow, Clear and Cottonwood creeks has been directly attributed to the presence of dams (on Clear Creek) and past and current instream gravel mining on the tributaries themselves. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts on the lower Sacramento River and Delta portions of the extended study area associated with CP2.

Impact Geo-13 (CP2): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP2 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. With implementation of CP2, there would be a potential reduction in high-flow events. Therefore, increases in Sacramento River flow would be limited and effects on reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP2. However, the effects of increases in Sacramento River flow in the extended study area would be limited and effects on reservoirs and rivers would be attenuated and dissipated. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts on the CVP/SWP service areas within the extended study area associated with CP2.

Impact Geo-14 (CP2): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP2 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

This section describes impacts associated with CP3, which focuses on the greatest practical enlargement of Shasta Dam and Reservoir consistent with the goals of the 2000 CALFED Bay-Delta Program Programmatic Record of Decision (CALFED 2000b). CP3 was formulated for the primary purposes of increased agricultural water supply reliability and increased anadromous fish survival by raising Shasta Dam 18.5 feet. The dam raise would raise the reservoir's full pool by 20.5 feet, and enlarge total storage space in the reservoir by 634,000 acre-feet. Section 2.3.8 in Chapter 2, "Alternatives," describes the construction activities and potential borrow sources associated with CP3.

Shasta Lake and Vicinity This section describes impacts on the Shasta Lake portion of the primary study area for CP3.

Impact Geo-1 (CP3): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption Implementing CP3 has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to CP1, impacts resulting from seismic conditions would be less than significant for CP3.

Under CP3, the pool level increase would inundate 173 acres of mapped slope instability hazards (i.e., active and relict landslides, debris slides, and inner gorge landscape positions). Relocation of infrastructure under CP3 would occur in the vicinity of mapped slope instability hazards to a similar but greater extent than under CP2 (up to about 232 acres). For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP3.

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP3.

No active faults are known to be present within or immediately adjacent to the Shasta Lake and vicinity area, and there is a low risk of fault rupture (CDMG 2006a). According to LaForge and Hawkins (1986), Jennings (1994), and the California Department of Conservation, Division of Mines and Geology (1997), all known faults around the Shasta Lake and vicinity area are classified as inactive. (Inactive faults show no evidence of movement in the last 10,000 years (i.e., Holocene).) Because there are few active faults in close proximity to the Shasta Lake and vicinity area, the likelihood of strong seismic ground shaking also is low. Detailed, site-specific geologic and foundation investigations will be completed to develop design criteria to withstand reasonably probable seismic events. This impact would be less than significant for CP3. Mitigation for this impact is not needed, and thus not proposed.

There is the potential for Reservoir Triggered Seismicity (RTS), seismicity resulting from the impoundment of water at or near the Lake Shasta reservoir. However, proper seismic hazard analyses will be performed and the design earthquake will be correctly defined to mitigate for any potential hazards. RTS is characterized as: seismic events that are more frequent than background levels before impoundment; an increase in both frequency and magnitude of earthquake events resulting from large oscillations of storage levels; and triggered events that tend to decrease to background levels after peaking. To identify an RTS event, an appropriate local seismic network capable of recording microseismic events would be monitored and evaluated. By following the seismic design criteria, an impact resulting from RTS would be mitigated to less than significant. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP3): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Similar to CP1, under CP3 stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,090 feet of elevation. This impact would be significant.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP3 would be 36.5 miles (see Figure 4-17), which equates to about 1.3 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 36.5 miles inundated, 716 stream segments totaling about 12.1 miles of streams with a gradient less than 10 percent would be affected to some degree.

Within the drawdown zone, there would be some benefit to channels with implementation of the environmental commitment to introduce brush structures, large wood, and/or boulder/rock clusters at various locations within low gradient reaches of perennial channels.

The increase in full pool would affect streams by altering fluvial geomorphology and the hydrology of aquatic habitats as described above. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

	Big Backbone Creek	Main Body	McCloud River	Pit River	Sacramento River	Squaw Creek
Intermittent >10% Grade	1.7	3.3	1.9	2.1	2.2	0.6
Perennial >10% Grade	0.2	0.2	0.5	0.1	0.4	0.1

Perennial <7% Grade	1.1	1.1	2.7	1.9	4.0	1.3

Figure 4-17. Stream Lengths in Watersheds Adjacent to Shasta Lake that Would Be Periodically Inundated Under CP3, CP4, CP4A, and CP5

Impact Geo-3 (CP3): Loss or Diminished Availability of Known Mineral Resources that Would Be of Future Value to the Region Implementing CP3 has the same potential as CP1 to diminish the availability in the region of cement, and of concrete sand and aggregate. For the same reasons as apply to CP1, this impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-4 (CP3): Loss or Diminished Soil Biomass Productivity Like CP1, under CP3 soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction, including relocation of infrastructure. Using Equivalent FSSC as a surrogate metric for soil biomass productivity, implementation of CP3 would result in loss of the following acreages by productivity rank: moderate productivity – 2,301 acres; low productivity – 2,092 acres; nonproductive – 760 acres.

This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-5 (CP3): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP3, the area of shoreline that would be inundated would be about 2,498 acres. Substantial soil erosion and loss of topsoil would result. This impact would be significant.

For the first 15 years after the dam raise, the average rate of shoreline erosion would increase substantially, from 90 cubic yards per acre per year to about 300 cubic yards per acre per year. For the first time step (i.e., 15 years), the total average annual volume of potential shoreline erosion from CP3 would be about 767,000 cubic yards per year. Within 60 years of the dam raise, the average annual volume is predicted to decrease to 216,000 cubic yards per year.

Sediment delivery from shoreline erosion would likely be greatest in the Sacramento Arm, the eastern portion of the Main Body of the lake, and the McCloud Arm. These three arms are predicted to deliver more than 140,000 cubic yards per year for the first 15 years after the dam raise. Within 60 years of the dam raise, the average rate for these arms is predicted to decrease to 39,000 cubic yards per year. The western portion of the Main Body and the Backbone Creek Arm are predicted to have the lowest shoreline erosion rates, a 15-year average annual potential erosion volume of less than 57,000 cubic yards per year. The Pit Arm is predicted to produce about 99,000 cubic yards per year and the Squaw Creek Arm about 68,000 cubic yards per year.

Assuming the available vegetation removal prescriptions between the 1,070-foot and 1,090-foot contours, for the first time step (i.e., 15 years after the raising of Shasta Dam), there would be about 767,000 cubic yards per year of shoreline erosion. After about 15–20 years, depending on climatic variability, the new shoreline would form and would start to stabilize. Total reservoir erosion is predicted to decrease by 70 percent between 15 and 60 years after the dam raise. The wetter the climate cycle, the more rapidly the shoreline is predicted to form.

The analysis also calculated the 15-year erosion volume using the prescribed vegetation treatments and modeled higher erosion rates for shoreline with partial and complete vegetation removal. The Big Backbone, Squaw Creek, and Pit arms would have very little vegetation removal, which would not affect the short-term rate of shoreline erosion. The Main Body and the Sacramento and McCloud arms would have substantial amounts of vegetation removal, which would result in higher short-term erosion rates. For these arms, areas treated by vegetation removal represent about half of the total predicted erosion.

Soil erosion due to shoreline processes is estimated to be 767,000 cubic yards per year, assuming the available vegetation removal prescriptions between 1,070-foot and 1,090-foot contours would occur in the first 15 years after the raising of Shasta Dam. This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-6 (CP3): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes CP3 is similar to CP1 with respect to its potential to cause substantial soil erosion or loss of topsoil due to upland processes.

Interpretations of soil susceptibility to erosion are presented in Table 4-12 for the portion of the area that potentially would be disturbed by construction activities. The values in this table were updated based on refinement of the relocation areas after publication of the DEIS. Approximately 2,384 acres in the upland portion of the Shasta Lake and vicinity area could be disturbed, but the likely area of disturbance is about 698 acres. The environmental commitments common to all action alternatives include implementation of best management practices, preparation and implementation of a SWPPP, and development and implementation of site-specific revegetation plans. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Construction-related erosion will be avoided and minimized via implementation of the SWPPP (i.e., erosion and sediment control plans, including site revegetation) that is a part of the environmental commitments common to all action alternatives. These plans will address the local requirements regarding erosion control and site revegetation, and would implement best management practices for erosion and sediment control. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP3): Location of Project Facilities on a Geologic Unit or Soil that Is Unstable, or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence CP3 is similar to CP1 with respect to its potential to cause or be affected by subsidence. For the same reasons as apply to CP1, this would be less than significant for CP3, because detailed, site-specific geologic and foundation investigations will be completed to inform project design as to how to avoid potential subsidence from these causes. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP3): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste CP3 is similar to CP1 with respect to its potential to cause or be affected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste. For the same reasons as apply to CP1, this would be less than significant for CP3 because relocated wastewater facilities would be designed and constructed to satisfy the conditions of the Shasta County Environmental Health Division Sewage Disposal System Permit. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts on the upper Sacramento River portion of the primary study area associated with CP3.

Impact Geo-9 (CP3): Potential Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP3 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing conditions, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows have the potential to alter downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high-flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An erosion and sediment control plan would be implemented, as described in Section 2.3.2, “Environmental Commitments Common to All Action Alternatives,” in Chapter 2, “Alternatives,” to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be greater under CP3. This impact would be less than significant. Mitigation for this impact is not needed. However, mitigation for this impact is proposed in Section 4.3.5 to further reduce the impact.

Impact Geo-10 (CP3): Substantial Soil Erosion or Loss of Topsoil Due to Construction Under CP3, no gravel augmentation activities would occur.

Therefore, no soil additional soil erosion would be anticipated on the banks along the river channel. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP3): Alteration of Fluvial Geomorphology Under CP3, no potential upper Sacramento River restoration activities would occur. Therefore, no changes in fluvial geomorphology would be anticipated. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-12 (CP3): Alteration of Downstream Tributary Fluvial Geomorphology Due to Shasta Dam Operations Under CP3, the fluvial geomorphology of downstream tributaries would not be affected by changes in Sacramento River stage attributed to Shasta Dam operations. Small increases in Sacramento River stage may occur with implementation of CP3. However, the frequency and duration of high-flow events resulting from CP3 implementation are expected to be reduced as compared to existing conditions with current operations. This impact would be less than significant.

Where they occur, geomorphic changes (headcutting, channel incisement, etc.) in major tributaries in Cow, Clear and Cottonwood creeks has been directly attributed to the presence of dams (on Clear Creek) and past and current instream gravel mining on the tributaries themselves. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts on the lower Sacramento River and Delta portions of the extended study area associated with CP3.

Impact Geo-13 (CP3): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP3 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Under CP3, there would be a potential reduction in high-flow events. Therefore, increases in Sacramento River flow would be limited and effects on reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be greater under CP3. However, the effects of increases in Sacramento River flow in the extended study area would be limited and effects on reservoirs and rivers would be attenuated and dissipated. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts on the CVP/SWP service areas within the extended study area associated with CP3.

Impact Geo-14 (CP3): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP3 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant.

This impact would be very similar to Impact Geo-9 (CP1), except the modification of flow regimes would be slightly greater under CP3. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

This section describes impacts associated with CP4 and CP4A, which focus on increasing the volume of cold water available to the Shasta Dam temperature control device through reservoir reoperations, and on raising Shasta Dam by 18.5 feet. The dam raise would increase the reservoir's full pool by 20.5 feet, and enlarge total storage space by 634,000 acre-feet.

For CP4, of the increased reservoir storage space, about 378,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as under CP1, with 70,000 acre-feet and 35,000 acre-feet reserved to specifically focus on increasing M&I deliveries during dry and critical years, respectively. Because CP4 would increase the active or useable storage in Shasta Reservoir by the same amount as under CP1, and the storage would be used under the same operational rules, releases from Shasta would be the same as under CP1. The additional storage that would be dedicated to increasing the supply of cold water, or the cold-water pool, would result in different Shasta storages and elevations, but not in any other downstream water operations.

For CP4A, of the increased reservoir storage space, about 191,000 acre-feet would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as under CP2, with 120,000 acre-feet and 60,000 acre-feet reserved to specifically focus on increasing M&I deliveries during dry and critical years, respectively. Because CP4A would increase the active or useable storage in Shasta Reservoir by the same amount as under CP2, and the storage would be used under the same operational rules, releases from Shasta would be the same as under CP2. The additional storage that would be dedicated to increasing the supply of cold water, or the cold-water pool, would result in different Shasta storages and elevations, but not in any other downstream water operations.

Construction activities for CP4 and CP4A are identical. The construction activities and potential borrow sources associated with CP4 or CP4A are described in Section 2.3.8 in Chapter 2, “Alternatives.”

Shasta Lake and Vicinity This section describes impacts on the Shasta Lake portion of the primary study area for CP4 and CP4A.

Impact Geo-1 (CP4 and CP4A): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption The implementation of CP4 or CP4A has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to CP1, impacts resulting from seismic conditions would be less than significant for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

Like CP3, under CP4 or CP4A, the pool level increase would inundate 173 acres of mapped slope instability hazards. Relocation of infrastructure under CP4 or CP4A would occur in the vicinity of mapped slope instability hazards to the same extent as under CP3 (up to about 232 acres). For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP4 or CP4A. Mitigation for this impact is not needed, and thus not proposed.

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP4 or CP4A.

No active faults are known to be present within or immediately adjacent to the Shasta Lake and vicinity area, and there is a low risk of fault rupture (CDMG 2006a). According to LaForge and Hawkins (1986), Jennings (1994), and the California Department of Conservation, Division of Mines and Geology (1997), all known faults around the Shasta Lake and vicinity area are classified as inactive. (Inactive faults show no evidence of movement in the last 10,000 years (i.e., Holocene).) Because there are few active faults in close proximity to the Shasta Lake and vicinity area, the likelihood of strong seismic ground shaking also is low. Detailed, site-specific geologic and foundation investigations will be completed to develop design criteria to withstand reasonably probable seismic events.

There is the potential for Reservoir Triggered Seismicity (RTS), seismicity resulting from the impoundment of water at or near the Lake Shasta reservoir. However, proper seismic hazard analyses will be performed and the design earthquake will be correctly defined to mitigate for any potential hazards. RTS is characterized as: seismic events that are more frequent than background levels before impoundment; an increase in both frequency and magnitude of earthquake events resulting from large oscillations of storage levels; and triggered events that tend to decrease to background levels after peaking. To identify an RTS event, an appropriate local seismic network capable of recording microseismic events would be monitored and evaluated. By following the seismic design criteria, an impact resulting from RTS would be mitigated to less than significant. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP4 and CP4A): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Like CP3, under CP4 or CP4A stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,090 feet of elevation. This impact would be significant for CP4 or CP4A.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP4 or CP4A would be the same as for CP3, about 36.5 miles (see Figure 4-17). This value equates to about 1.3 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 36.5 miles inundated, 716 stream segments totaling about 12.1 miles of streams with a gradient less than 10 percent would be affected to some degree.

Within the drawdown zone, there would be some benefit to channels with implementation of the environmental commitment to introduce brush structures, large wood, and/or boulder/rock clusters at various locations within low gradient reaches of perennial channels.

The increase in full pool would affect channels by altering fluvial geomorphology and the hydrology of aquatic habitats as described above.

This impact would be significant for CP4. Mitigation for this impact is proposed in Section 4.3.5.

This impact would be significant for CP4A. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP4 and CP4A): Loss or Diminished Availability of Known Mineral Resources that Would Be of Future Value to the Region The implementation of CP4 or CP4A has the same potential as CP1 to diminish the availability in the region of cement, and of concrete sand and aggregate.

For the same reasons as apply to CP1, this impact would be significant for CP4. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

For the same reasons as apply to CP1, this impact would be significant for CP4A. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-4 (CP4 and CP4A): Lost or Diminished Soil Biomass Productivity Like CP3, under CP4 or CP4A soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction, including relocation of infrastructure. The acreages of these losses would be the same as those reported for CP3.

This impact would be significant for CP4. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

This impact would be significant for CP4A. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-5 (CP4 and CP4A): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP4 or CP4A, the area of shoreline that would be inundated would be the same as the area reported under CP3, about 2,498 acres. Substantial soil erosion and loss of topsoil would result. The previous descriptions of the time steps and associated volumes of soil lost due to shoreline processes under CP3 also apply to CP4 or CP4A. This impact would be significant for CP4 or CP4A.

Soil erosion due to shoreline processes is estimated to be 767,000 cubic yards per year, assuming the available vegetation removal prescriptions between 1,070-foot and 1,090-foot contours would occur in the first 15 years after the raising of Shasta Dam.

This impact would be significant for CP4. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

This impact would be significant for CP4A. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-6 (CP4 and CP4A): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes CP4 and CP4A are similar to CP3 with respect to their potential to cause substantial soil erosion or loss of topsoil due to upland processes.

Interpretations of soil susceptibility to erosion are presented in Table 4-12 for the portion of the area that potentially would be disturbed by construction activities. The values in this table were updated based on refinement of the relocation areas after publication of the DEIS. Approximately 2,384 acres in the upland portion of the Shasta Lake and vicinity area could be disturbed, but the likely area of disturbance is about 698 acres. The environmental commitments common to all action alternatives include implementation of best management practices, preparation and implementation of a SWPPP, and development and implementation of site-specific revegetation plans. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Construction-related erosion will be avoided and minimized via implementation of the SWPPP (i.e., erosion and sediment control plans, including site revegetation) that is a part of the environmental commitments common to all action alternatives. These plans will address the local requirements regarding erosion control and site revegetation, and would implement best management practices for erosion and sediment control.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP4 and CP4A): Location of Project Facilities on a Geologic Unit or Soil that Is Unstable, or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence CP4 and CP4A are similar to CP1 with respect to their potential to cause or be affected by subsidence.

For the same reasons as apply to CP1, this impact would be less than significant for CP4, because detailed, site-specific geologic and foundation investigations will be completed to inform project design as to how to avoid potential subsidence from these causes. Mitigation for this impact is not needed, and thus not proposed.

For the same reasons as apply to CP1, this impact would be less than significant for CP4A, because detailed, site-specific geologic and foundation investigations will be completed to inform project design as to how to avoid potential subsidence from these causes. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP4 and CP4A): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste CP4 and CP4A are similar to CP1 with respect to their potential to cause or be affected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste.

For the same reasons as apply to CP1, this impact would be less than significant for CP4, because relocated wastewater facilities would be designed and constructed to satisfy the conditions of the Shasta County Environmental Health

Division Sewage Disposal System Permit. Mitigation for this impact is not needed, and thus not proposed.

For the same reasons as apply to CP1, this impact would be less than significant for CP4A, because relocated wastewater facilities would be designed and constructed to satisfy the conditions of the Shasta County Environmental Health Division Sewage Disposal System Permit. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts on the upper Sacramento River portion of the primary study area associated with CP4 and CP4A.

Impact Geo-9 (CP4 and CP4A): Potential Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP4 or CP4A would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing conditions, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows have the potential to alter downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high-flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An erosion and sediment control plan would be implemented, as described in Section 2.3.2, “Environmental Commitments Common to All Action Alternatives,” in Chapter 2, “Alternatives,” to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Geo-9 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed. However, mitigation for this impact is proposed in Section 4.3.5 to further reduce the impact.

This impact would be the same as Impact Geo-9 (CP1) and would be less than significant for CP4A. Mitigation for this impact is not needed. However, mitigation for this impact is proposed in Section 4.3.5 to further reduce the impact.

Impact Geo-10 (CP4 and CP4A): Substantial Soil Erosion or Loss of Topsoil Due to Construction CP4 or CP4A involve replenishing spawning gravel in the Upper Sacramento River between Keswick Dam and Red Bluff Pumping Plant. Implementation of these activities could potentially contribute to soil erosion or loss of topsoil from clearing, grading, and grubbing activities required while constructing roadways to access the new spawning gravel sites. In addition, soil erosion could also potentially occur at sites where clearing and grubbing of the river bank would be required to allow the gravel to be placed on the river bank for recruitment. An erosion and sediment control plan would be implemented, as described in Section 2.3.2, "Environmental Commitments Common to All Action Alternatives," in Chapter 2, "Alternatives," to control any short-term and long-term erosion and sedimentation effects of construction activities.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP4 and CP4A): Alteration of Fluvial Geomorphology Under CP4 or CP4A, riparian, floodplain, and side-channel habitat restoration would be constructed at one or a combination of potential locations along the upper Sacramento River. Descriptions of restoration measures for six potential sites, referred to collectively as upper Sacramento River restoration sites, are detailed in the Downstream Restoration Technical Memorandum. Stream restoration activities could potentially cause changes in fluvial geomorphology that could result in channelized or unstable braided streams, depending on the gradient of the channel and specific restoration activities. However, restoration of habitat through planting of native vegetation would stabilize channel banks.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-12 (CP4 and CP4A): Alteration of Downstream Tributary Fluvial Geomorphology Due to Shasta Dam Operations Under CP4 or CP4A, the fluvial geomorphology of downstream tributaries would not be affected by changes in Sacramento River stage attributed to Shasta Dam operations. Small increases in Sacramento River stage may occur with implementation of CP4 or CP4A. However, the frequency and duration of high-flow events resulting from CP4 or CP4A implementation are expected to be reduced as compared to existing conditions with current operations. Under CP4, there would be a potential reduction in high-flow events similar to CP1. Under CP4A, there would be a potential reduction in high-flow events similar to CP2. This impact would be less than significant.

Where they occur, geomorphic changes (headcutting, channel incisement, etc.) in major tributaries in Cow, Clear and Cottonwood creeks has been directly attributed to the presence of dams (on Clear Creek) and past and current instream gravel mining on the tributaries themselves. This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts on the lower Sacramento River and Delta portions of the extended study area associated with CP4 and CP4A.

Impact Geo-13 (CP4 and CP4A): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP4 or CP4A would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Under CP4, there would be a potential reduction in high-flow events similar to CP1. Under CP4A, there would be a potential reduction in high-flow events similar to CP2. Therefore, increases in Sacramento River flow would be limited and effects on reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact Geo-9 (CP1) and would be less than significant for CP4. Effects of increases in Sacramento River flow in the extended study area would be limited and effects on reservoirs and rivers would be attenuated and dissipated. Mitigation for this impact is not needed, and thus not proposed.

This impact would be similar to Impact Geo-9 (CP2) and would be less than significant for CP4A. Effects of increases in Sacramento River flow in the extended study area would be limited and effects on reservoirs and rivers would be attenuated and dissipated. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts on the CVP/SWP service areas within the extended study area associated with CP4 and CP4A.

Impact Geo-14 (CP4 and CP4A): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP4 or CP4A would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact Geo-9 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact Geo-9 (CP2) and would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

This section describes impacts associated with CP5, which includes raising Shasta Dam 18.5 feet. This alternative also includes (1) implementing environmental restoration features along the lower reaches of major tributaries to Shasta Lake, (2) constructing shoreline fish habitat around Shasta Lake, and (3) constructing additional and/or improved recreation features at various locations around Shasta Lake to increase the value of the recreational experience. The dam raise would increase the reservoir's full pool elevation by 20.5 feet to about 1,090 feet above msl, and enlarge total storage space by 634,000 acre-feet. Section 2.3.8 in Chapter 2, "Alternatives," describes the construction activities and potential borrow sources associated with CP5.

Shasta Lake and Vicinity This section describes impacts on the Shasta Lake portion of the primary study area for CP5.

Impact Geo-1 (CP5): Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruption Implementing CP5 has the potential to increase the exposure of structures and people to geologic hazards similar to CP1. For the same reasons as apply to CP1, impacts resulting from seismic conditions would be less than significant for CP5.

Like CP3, under CP5, the pool level increase would inundate 173 acres of mapped slope instability hazards. Relocation of infrastructure under CP5 would occur in the vicinity of mapped slope instability hazards to a similar but greater extent than under CP4 and CP4A (up to about 232 acres). For the same reasons as apply to CP1, impacts resulting from slope instability hazards would be less than significant for CP5.

For the same reasons as apply to CP1, impacts resulting from hazards associated with volcanic eruptions would be less than significant for CP5.

No active faults are known to be present within or immediately adjacent to the Shasta Lake and vicinity area, and there is a low risk of fault rupture (CDMG 2006a). According to LaForge and Hawkins (1986), Jennings (1994), and the California Department of Conservation, Division of Mines and Geology (1997), all known faults around the Shasta Lake and vicinity area are classified as inactive. (Inactive faults show no evidence of movement in the last 10,000 years (i.e., Holocene).) Because there are few active faults in close proximity to the

Shasta Lake and vicinity area, the likelihood of strong seismic ground shaking also is low. Detailed, site-specific geologic and foundation investigations will be completed to develop design criteria to withstand reasonably probable seismic events.

There is the potential for Reservoir Triggered Seismicity (RTS), seismicity resulting from the impoundment of water at or near the Lake Shasta reservoir. However, proper seismic hazard analyses will be performed and the design earthquake will be correctly defined to mitigate for any potential hazards. RTS is characterized as: seismic events that are more frequent than background levels before impoundment; an increase in both frequency and magnitude of earthquake events resulting from large oscillations of storage levels; and triggered events that tend to decrease to background levels after peaking. To identify an RTS event, an appropriate local seismic network capable of recording microseismic events would be monitored and evaluated. By following the seismic design criteria, an impact resulting from RTS would be mitigated to less than significant. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP5. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-2 (CP5): Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats Like CP3, under CP5 stream channel equilibrium and geomorphology would be affected by an increase in full pool level. Inundation of lower gradient streams draining to Shasta Lake could result in long-term changes to channel equilibrium by changing the sediment transport capacity of the stream channels between 1,070 and 1,090 feet of elevation. This impact would be significant.

Based on a GIS-generated stream network, the total stream length inundated as a result of CP5 would be the same as for CP3, about 36.5 miles (see Figure 4-17). This value equates to about 1.3 percent of the total length of the streams in watersheds that are directly adjacent and contributory to Shasta Lake. Of the 36.5 miles inundated, 716 stream segments totaling about 12.1 miles of streams with a gradient less than 10 percent would be affected to some degree.

Within the drawdown zone, channels would be benefit to some degree with implementation of the environmental commitment to introduce brush structures, large wood, and/or boulder/rock clusters at various locations within low gradient reaches of perennial channels.

The increase in full pool would affect channels by altering fluvial geomorphology and the hydrology of aquatic habitats as described above. This impact would be significant. Mitigation for this impact is proposed in Section 4.3.5.

Impact Geo-3 (CP5): Lost or Diminished Availability of Known Mineral Resources that Would Be of Future Value to the Region Implementing CP5 has the same potential as CP1 to diminish the availability in the region of cement, concrete sand, and aggregate. For the same reasons that apply to CP1, this impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-4 (CP5): Lost or Diminished Soil Biomass Productivity Like CP3, under CP5 soil productivity would be lost due to periodic inundation caused by increasing the full pool elevation and by construction including relocation of infrastructure. The acreages of these losses would be the same as those reported for CP3.

This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-5 (CP5): Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes Under CP5, the area of shoreline that would be inundated would be the same as the area reported under CP3, about 2,498 acres. Substantial soil erosion and loss of topsoil would result. The previous descriptions of the time steps and associated volumes of soil lost due to shoreline processes under CP3 also apply to CP5.

Soil erosion due to shoreline processes is estimated to be 767,000 cubic yards per year, assuming the available vegetation removal prescriptions between 1,070-foot and 1,090-foot contours would occur in the first 15 years after the raising of Shasta Dam. This impact would be significant. Mitigation for this impact is not proposed in Section 4.3.5 because no feasible mitigation is available to reduce the impact to a less-than-significant level.

Impact Geo-6 (CP5): Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes CP5 is similar to CP3 with respect to its potential to cause substantial soil erosion or loss of topsoil due to upland processes.

Interpretations of soil susceptibility to erosion are presented in Table 4-12 for the portion of the area that potentially would be disturbed by construction activities. The values in this table were updated based on refinement of the relocation areas after publication of the DEIS. Approximately 2,384 acres in the upland portion of the Shasta Lake and vicinity area could be disturbed, but the likely area of disturbance is about 698 acres. The environmental commitments common to all action alternatives include implementation of best management practices, preparation and implementation of a SWPPP, and development and implementation of site-specific revegetation plans. This impact would be less than significant.

Construction-related erosion will be avoided and minimized via implementation of the SWPPP (i.e., erosion and sediment control plans, including site revegetation) that is a part of the environmental commitments common to all action alternatives. These plans will address the local requirements regarding erosion control and site revegetation, and would implement best management practices for erosion and sediment control. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-7 (CP5): Location of Project Facilities on a Geologic Unit or Soil that Is Unstable, or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence CP5 is similar to CP1 with respect to its potential to cause or be affected by subsidence. For the same reasons as apply to CP1, this impact would be less than significant for CP5, because detailed, site-specific geologic and foundation investigations will be completed to inform project design as to how to avoid potential subsidence from these causes. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-8 (CP5): Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste CP5 is similar to CP1 with respect to its potential to cause or be affected by failure of septic tanks or alternative wastewater disposal systems due to soils that are unsuited to land application of waste. For the same reasons as apply to CP1, this impact would be less than significant for CP5, because relocated wastewater facilities would be designed and constructed to satisfy the conditions of the Shasta County Environmental Health Division Sewage Disposal System Permit. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff) This section describes impacts on the upper Sacramento River portion of the primary study area associated with CP5.

Impact Geo-9 (CP5): Potential Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP5 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. However, by altering storage and operations at Shasta Lake as compared to the No-Action Alternative and existing conditions, this alternative would change the maximum pool elevation and seasonal pool elevations at Shasta Lake and the flow regime in the Sacramento River and potentially several other reservoirs and downstream waterways. Alterations to river flows have the potential to alter downstream stream erosion and change downstream geomorphologic characteristics. However, the frequency and duration of high-flow events resulting from this action are expected to be reduced as compared to existing conditions with current operations. Therefore, downstream erosion would not be anticipated to increase. An erosion and sediment control plan would be implemented, as described in Section 2.3.2, “Environmental Commitments Common to All

Action Alternatives," in Chapter 2, "Alternatives," to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant. Mitigation for this impact is not needed. However, mitigation for this impact is proposed in Section 4.3.5 to further reduce the impact.

Impact Geo-10 (CP5): Substantial Soil Erosion or Loss of Topsoil Due to Construction CP5 involves replenishing spawning gravel in the Upper Sacramento River between Keswick Dam and Red Bluff Pumping Plant. Implementation of these activities could potentially contribute to soil erosion or loss of topsoil from clearing, grading, and grubbing activities required while constructing roadways to access the new spawning gravel sites. In addition, soil erosion could also potentially occur at sites where clearing and grubbing of the river bank would be required to allow the gravel to be placed on the river bank for recruitment. An erosion and sediment control plan would be implemented, as described in Section 2.3.2, "Environmental Commitments Common to All Action Alternatives," in Chapter 2, "Alternatives," to control any short-term and long-term erosion and sedimentation effects of construction activities. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-11 (CP5): Alteration of Fluvial Geomorphology Under CP5, riparian, floodplain, and side-channel habitat restoration would be constructed at one or a combination of potential locations along the upper Sacramento River. Descriptions of restoration measures for six potential sites, referred to collectively as upper Sacramento River restoration sites, are detailed in the Downstream Restoration Technical Memorandum. Stream restoration activities could potentially cause changes in fluvial geomorphology that could result in channelized or unstable braided streams depending on the gradient of the channel and specific restoration activities. However, restoration of habitat through planting of native vegetation would stabilize channel banks. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact Geo-12 (CP5): Alteration of Downstream Tributary Fluvial Geomorphology Due to Shasta Dam Operations Under CP5, the fluvial geomorphology of downstream tributaries would not be affected by changes in Sacramento River stage attributed to Shasta Dam operations. Small increases in Sacramento River stage may occur with implementation of CP5. However, the frequency and duration of high-flow events resulting from CP5 implementation are expected to be reduced as compared to existing conditions with current operations. This impact would be less than significant.

Where they occur, geomorphic changes (headcutting, channel incisement, etc.) in major tributaries in Cow, Clear and Cottonwood creeks has been directly attributed to the presence of dams (on Clear Creek) and past and current instream gravel mining on the tributaries themselves. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta This section describes impacts on the lower Sacramento River and Delta portions of the extended study area associated with CP5.

Impact Geo-13 (CP5): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP5 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. With implementation of CP5, there would be a potential reduction in high-flow events. Therefore, increases in Sacramento River flow would be limited and effects on reservoirs and rivers in the extended study area would be attenuated and dissipated by the large number of these water bodies, as well as by flood bypasses in the extended study area. This impact would be less than significant.

This impact would be less than significant. Effects of increases in Sacramento River flow in the extended study area would be limited and effects on reservoirs and rivers would be attenuated and dissipated. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas This section describes impacts on the CVP/SWP service areas within the extended study area associated with CP5.

Impact Geo-14 (CP5): Substantial Increase in Channel Erosion and Meander Migration It is not anticipated that implementation of CP5 would lead to increased channel erosion and meander migration as compared to the No-Action Alternative and existing conditions. Changes in water operations in the CVP/SWP service areas could potentially result in small changes in flow in the American and Feather rivers, as a result of operations at Folsom Dam and Oroville Dam. However, changes in flow affecting these reservoirs and rivers in the extended study area would be within the normal range of conditions and would not be expected to result in an increase in channel erosion or meander migration. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

4.3.5 Mitigation Measures

This section discusses mitigation measures for each significant impact described in the environmental consequences section, as presented in Table 4-13.

Table 4-13. Summary of Mitigation Measures for Geology, Geomorphology, Minerals, and Soils

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/CP4A	CP5
Impact Geo-1: Exposure of Structures and People to Geologic Hazards Resulting from Seismic Conditions, Slope Instability, and Volcanic Eruptions	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-2: Alteration of Fluvial Geomorphology and Hydrology of Aquatic Habitats	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure Geo-2: Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-3: Loss or Diminished Availability of Known Mineral Resources That Would Be of Future Value to the Region	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required.	No feasible mitigation is available to reduce impact.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Geo-4: Lost or Diminished Soil Biomass Productivity	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required	No feasible mitigation is available to reduce impact.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU
Impact Geo-5: Substantial Soil Erosion or Loss of Topsoil Due to Shoreline Processes	LOS before Mitigation	NI	S	S	S	S	S
	Mitigation Measure	None required	No feasible mitigation is available to reduce impact.				
	LOS after Mitigation	NI	SU	SU	SU	SU	SU

Table 4-13. Summary of Mitigation Measures for Geology, Geomorphology, Minerals, and Soils (contd.)

Impact		No-Action Alternative	CP1	CP2	CP3	CP4/CP4A	CP5
Impact Geo-6: Substantial Soil Erosion or Loss of Topsoil Due to Upland Processes	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-7: Be Located on a Geologic Unit or Soil that Is Unstable, or that Would Become Unstable as a Result of the Project, and Potentially Result in Subsidence	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-8: Failure of Septic Tanks or Alternative Wastewater Disposal Systems Due to Soils that are Unsuited to Land Application of Waste	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-9: Substantial Increase in Channel Erosion and Meander Migration	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	Mitigation Measure Geo-9: Modification of Flow Releases in Response to River Management and Habitat Restoration Efforts between Keswick Dam and Red Bluff.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-10: Substantial Soil Erosion or Loss of Topsoil Due to Construction	LOS before Mitigation	NI	NI	NI	NI	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	NI	NI	NI	LTS	LTS

	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS
Impact Geo-14: Substantial Increase in Channel Erosion and Meander Migration (CVP/SWP Service Areas)	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.				
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS

Key:
CP = Comprehensive Plan
CVP = Central Valley Project
LOS = level of significance
LTS = less than significant
NI = No Impact
PS = potentially significant
S = significant
SU = significant and unavoidable
SWP = State Water Project

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is required for Impact Geo-1 (CP1), Impacts Geo-6 (CP1) through Geo-8 (CP1), and Impacts Geo-10 (CP1) through Geo-14 (CP1). No feasible mitigation measures are available at the time of preparation of this EIS to reduce Impacts Geo-3 (CP1) through Geo-5 (CP1) to a less-than-significant level. Therefore, Impacts Geo-3 (CP1), Geo-4 (CP1), and Geo-5 (CP1) would be significant and unavoidable.

Mitigation is provided below for other impacts of CP1 on geology, geomorphology, minerals, and soils. No mitigation is required for Impact Geo-9 (CP1), but mitigation is provided to further reduce this less-than-significant impact.

Mitigation Measure Geo-2 (CP1): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact The loss of 18.5 miles of intermittent and perennial streams (including 6.2 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. As described in the Preliminary Environmental Commitments and Mitigation Plan Appendix to the EIS, Reclamation convened an interagency working group to enhance mitigation measures presented in the DEIS. This working group had the benefit of additional information from the recently completed Tributary Fisheries Characterization Report (Reclamation 2014). This report, summarized in Chapter 11, “Fisheries and Aquatic Ecosystems,” provides detailed information on tributaries that flow into Shasta Lake, with an emphasis on those channel reaches upstream from the current drawdown zone. The environmental commitments described in Chapter 2, “Alternatives,” and the Preliminary Environmental Commitments and Mitigation Plan of the EIS are intended to address impacts to channels within the existing drawdown zone (1070 msl).

An outcome of the interagency work group discussions was the agreement that this mitigation measure would encompass efforts within the channels actually impacted by this comprehensive plan, but would also be expanded to restore degraded aquatic habitat in channels upstream from Shasta Lake. In general, this mitigation measure would follow the approach to characterize, prioritize and identify specific restoration actions described in the *California Salmonid Stream Habitat Restoration Manual – Fourth Edition* (CDFG 2010).

For CP1, this mitigation measure would result in restoration of up to 18.5 miles of channel, with an emphasis on low gradient perennial channels to be identified by an interagency work group to be convened by Reclamation. This mitigation focuses on restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area.

This interagency working group would focus on identification of specific tributaries to Shasta Lake that may benefit from various mitigation techniques using available information. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Geo-2 (CP1) to a less-than-significant level.

Mitigation Measure Geo-9 (CP1): Modification of Flow Releases in Response to River Management and Habitat Restoration Efforts between Keswick Dam and Red Bluff No mitigation is required for Impact Geo-9 as the result of implementing any proposed alternatives (CP1, CP2, CP3, CP4, CP4A, or CP5). On an annual basis, Reclamation will coordinate with relevant river management and habitat restoration efforts between Keswick Dam and Red Bluff, including but not limited to the members of the Sacramento River Temperature Task Group. The purpose of this coordination will be to discuss how releases from Shasta and Keswick dams could be managed to best enhance downstream objectives, such as ramping rates or temperature targets, that are consistent with the CVP's capabilities and primary operating objectives. Impact Geo-9 (CP1).would be less than significant before mitigation. Implementation of this mitigation measure would further reduce Impact Geo-9 (CP1).

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply
No mitigation is required for Impact Geo-1 (CP2), Impacts Geo-6 (CP2) through Geo-8 (CP2), and Impacts Geo-10 (CP2) through Geo-14 (CP2). No feasible mitigation measures are available at the time of preparation of this EIS to reduce Impacts Geo-3 (CP2) through Geo-5 (CP2) to a less-than-significant level. Therefore, Impacts Geo-3 (CP2), Geo-4 (CP2), and Geo-5 (CP2) would be significant and unavoidable.

Mitigation is provided below for other impacts of CP2 on geology, geomorphology, minerals, and soils. No mitigation is required for Impact Geo-9 (CP2), but mitigation is provided to further reduce this less-than-significant impact.

Mitigation Measure Geo-2 (CP2): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact The loss of 25.5 miles of intermittent and perennial streams (including 8.2 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. As described in the Preliminary

Environmental Commitments and Mitigation Plan Appendix to the EIS, Reclamation convened an interagency working group to enhance mitigation measures presented in the DEIS. This working group had the benefit of additional information from the recently completed Tributary Fisheries Characterization Report (Reclamation 2014). This report, summarized in Chapter 11, "Fisheries and Aquatic Ecosystems," provides detailed information on tributaries that flow into Shasta Lake, with an emphasis on those channel reaches upstream from the current drawdown zone. The environmental commitments described in Chapter 2, "Alternatives," and the Preliminary Environmental Commitments and Mitigation Plan of the EIS are intended to address impacts to channels within the existing drawdown zone (1070 msl).

An outcome of the interagency work group discussions was the agreement that this mitigation measure would encompass efforts within the channels actually impacted by this comprehensive plan, but would also be expanded to restore degraded aquatic habitat in channels upstream from Shasta Lake. In general, this mitigation measure would follow the approach to characterize, prioritize and identify specific restoration actions described in the *California Salmonid Stream Habitat Restoration Manual – Fourth Edition* (CDFG 2010).

For CP2, this mitigation measure would result in restoration of up to 22.5 miles of channel, with an emphasis on low gradient perennial channels to be identified by an interagency work group to be convened by Reclamation. This mitigation focuses on restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area.

This interagency working group would focus on identification of specific tributaries to Shasta Lake that may benefit from various mitigation techniques using available information. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Geo-2 (CP2) to a less-than-significant level.

Mitigation Measure Geo-9 (CP2): Modification of Flow Releases in Response to River Management and Habitat Restoration Efforts between Keswick Dam and Red Bluff This mitigation measure is identical to Mitigation Measure Geo-9 (CP1). On an annual basis, Reclamation will coordinate with relevant river management and habitat restoration efforts between Keswick Dam and Red Bluff, including but not limited to the members of the Sacramento River Temperature Task Group. The purpose of this coordination will be to discuss how releases from Shasta and Keswick dams could be managed to best enhance downstream objectives, such as ramping rates or temperature targets, that are consistent with the CVP's capabilities and primary operating objectives. Impact Geo-9 (CP2).would be less than significant before mitigation. Implementation of this mitigation measure would further reduce Impact Geo-9 (CP2).

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation is required for Impact Geo-1 (CP3) and Impacts Geo-6 (CP3) through Geo-8 (CP3), and Impacts Geo-10 (CP3) through Geo-14 (CP3). No feasible mitigation measures are available at the time of preparation of this EIS to reduce Impacts Geo-3 (CP3) through Geo-5 (CP3) to a less-than-significant level. Therefore, Impacts Geo-3 (CP3), Geo-4 (CP3), and Geo-5 (CP3) would be significant and unavoidable.

Mitigation is provided below for other impacts of CP3 on geology, geomorphology, minerals, and soils. No mitigation is required for Impact Geo-9 (CP3), but mitigation is provided to further reduce this less-than-significant impact.

Mitigation Measure Geo-2 (CP3): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact The loss of 36.5 miles of intermittent and perennial streams (including 12.1 miles of streams with a gradient less than 7 percent) will be mitigated by compensating for the impact by replacing or providing substitute resources or environments. As described in the Preliminary Environmental Commitments and Mitigation Plan Appendix to the EIS, Reclamation convened an interagency working group to enhance mitigation measures presented in the DEIS. This working group had the benefit of additional information from the recently completed Tributary Fisheries Characterization Report (Reclamation 2014). This report, summarized in Chapter 11, “Fisheries and Aquatic Ecosystems,” provides detailed information on tributaries that flow into Shasta Lake, with an emphasis on those channel reaches upstream from the current drawdown zone. The environmental commitments described in Chapter 2, “Alternatives,” and the Preliminary Environmental Commitments and Mitigation Plan of the EIS are intended to address impacts to channels within the existing drawdown zone (1070 msl).

An outcome of the interagency work group discussions was the agreement that this mitigation measure would encompass efforts within the channels actually impacted by this comprehensive plan, but would also be expanded to restore degraded aquatic habitat in channels upstream from Shasta Lake. In general, this mitigation measure would follow the approach to characterize, prioritize and identify specific restoration actions described in the *California Salmonid Stream Habitat Restoration Manual – Fourth Edition* (CDFG 2010).

For CP3, this mitigation measure would result in restoration of up to 36.5 miles of channel, with an emphasis on low gradient perennial channels to be identified by an interagency work group to be convened by Reclamation. This mitigation focuses on restoring and enhancing the aquatic functions of existing, degraded aquatic habitats in or near the Shasta Lake and vicinity area.

This interagency working group would focus on identification of specific tributaries to Shasta Lake that may benefit from various mitigation techniques using available information. Examples of techniques that may be used include channel and bank stabilization, channel redirection, channel reconstruction, culvert replacement and elimination of barriers to fish passage, and enhancement of habitat physical structure (e.g., placement of woody debris, rocks). The nature and extent of the restoration and enhancement activities will be based on an assessment of the ecological functions that are lost as a consequence of implementing this alternative. Implementation of this mitigation measure would reduce Impact Geo-2 (CP3) to a less-than-significant level.

Mitigation Measure Geo-9 (CP3): Modification of Flow Releases in Response to River Management and Habitat Restoration Efforts between Keswick Dam and Red Bluff This mitigation measure is identical to Mitigation Measure Geo-9 (CP1). On an annual basis, Reclamation will coordinate with relevant river management and habitat restoration efforts between Keswick Dam and Red Bluff, including but not limited to the members of the Sacramento River Temperature Task Group. The purpose of this coordination will be to discuss how releases from Shasta and Keswick dams could be managed to best enhance downstream objectives, such as ramping rates or temperature targets, that are consistent with the CVP's capabilities and primary operating objectives. Impact Geo-9 (CP3).would be less than significant before mitigation. Implementation of this mitigation measure would further reduce Impact Geo-9 (CP3).

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

No mitigation is required for Impact Geo-1 (CP4 and CP4A), Impacts Geo-6 (CP4 and CP4A) through Geo-8 (CP4 and CP4A), and Impacts Geo-10 (CP4 and CP4A) through Geo-14 (CP4 and CP4A). No feasible mitigation measures are available at the time of preparation of this EIS to reduce Impacts Geo-3 (CP4 and CP4A) through Geo-5 (CP4 and CP4A) to a less-than-significant level. Therefore, Impacts Geo-3 (CP4 and CP4A), Geo-4 (CP4 and CP4A), and Geo-5 (CP4 and CP4A) would be significant and unavoidable.

Mitigation is provided below for other impacts of CP4 and CP4A on geology, geomorphology, minerals, and soils. No mitigation is required for Impact Geo-9 (CP4 and CP4A), but mitigation is provided to further reduce this less-than-significant impact.

Mitigation Measure Geo-2 (CP4 and CP4A): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is identical to

Mitigation Measure Geo-2 (CP3). Implementation of this mitigation measure would reduce Impact Geo-2 (CP4 and CP4A) to a less-than-significant level.

Mitigation Measure Geo-9 (CP4 and CP4A): Modification of Flow Releases in Response to River Management and Habitat Restoration Efforts between Keswick Dam and Red Bluff This mitigation measure is identical to Mitigation Measure Geo-9 (CP1). On an annual basis, Reclamation will coordinate with relevant river management and habitat restoration efforts between Keswick Dam and Red Bluff, including but not limited to the members of the Sacramento River Temperature Task Group. The purpose of this coordination will be to discuss how releases from Shasta and Keswick dams could be managed to best enhance downstream objectives, such as ramping rates or temperature targets, that are consistent with the CVP's capabilities and primary operating objectives. Impact Geo-9 (CP4 and CP4A).would be less than significant before mitigation. Implementation of this mitigation measure would further reduce Impact Geo-9 (CP4 and CP4A).

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is required for Impact Geo-1 (CP5), Impacts Geo-6 (CP5) through Geo-8 (CP5), and Impacts Geo-10 (CP5) through Geo-14 (CP5). No feasible mitigation measures are available at the time of preparation of this EIS to reduce Impacts Geo-3 (CP5) through Geo-5 (CP5) to a less-than-significant level. Therefore, Impacts Geo-3 (CP5), Geo-4 (CP5), and Geo-5 (CP5) would be significant and unavoidable.

Mitigation is provided below for other impacts of CP5 on geology, geomorphology, minerals, and soils. No mitigation is required for Impact Geo-9 (CP5), but mitigation is provided to further reduce this less-than-significant impact.

Mitigation Measure Geo-2 (CP5): Replace Lost Ecological Functions of Aquatic Habitats by Restoring Existing Degraded Aquatic Habitats in the Vicinity of the Impact This mitigation measure is identical to Mitigation Measure Geo-2 (CP3). Implementation of this mitigation measure would reduce Impact Geo-2 (CP5) to a less-than-significant level.

Mitigation Measure Geo-9 (CP5): Modification of Flow Releases in Response to River Management and Habitat Restoration Efforts between Keswick Dam and Red Bluff This mitigation measure is identical to Mitigation Measure Geo-9 (CP1). On an annual basis, Reclamation will coordinate with relevant river management and habitat restoration efforts between Keswick Dam and Red Bluff, including but not limited to the members of the Sacramento River Temperature Task Group. The purpose of this coordination will be to discuss how releases from Shasta and Keswick dams could be managed to best enhance downstream objectives, such as ramping rates or temperature targets, that are consistent with the CVP's capabilities and primary operating objectives. Impact Geo-9 (CP5).would be less than significant before mitigation. Implementation of this mitigation measure would further reduce Impact Geo-9 (CP5).

4.3.6 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," discusses overall cumulative impacts methodology related to the project alternatives, including the relationship to the CALFED Bay-Delta Program PEIS/R cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area," lists the present and reasonably foreseeable future projects that were quantitatively or qualitatively considered in this EIS. The action alternatives would not combine with any of the quantitatively assessed projects listed in Table 3-1 to have a cumulatively considerable impact on geology, geomorphology or mineral resources; therefore, this section evaluates only those projects listed in Table 3-1 that are qualitatively considered in the SLWRI.

This section provides a qualitative analysis of the overall cumulative impacts of the project alternatives combined with other past, present, and reasonably foreseeable future projects producing related impacts. For both the primary and extended study areas, a number of factors could substantially affect geology, soils and erosion, mineral resources, and geomorphology as an outcome of past, present, and future actions. Past actions that have impacted these resources include dam construction, altered flow regimes, water diversions, mining, gravel extraction, and land use impacts.

These past, present, and reasonably foreseeable actions may result in either a beneficial or adverse impact. However, there is a high level of uncertainty regarding the potential effects of the reasonably foreseeable future actions, including the Moody Flats Quarry. Therefore, geology, soils and erosion, mineral resources, and geomorphology conditions are expected to remain similar to existing conditions, with the exception of potential effects associated with future climate change and future potential development of the Moody Flats Quarry, as described below.

The effects of climate change on operations at Shasta Lake could potentially result in changes to downstream geomorphology. As described in the Climate Change Modeling Appendix, climate change could result in higher reservoir releases in the future because of an increase in winter and early-spring inflow into the lake from high-intensity storm events. The change in reservoir releases could be necessary to manage flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in downstream channel equilibrium.

The effects of increased monthly inflow into Shasta Lake in winter and early spring could also potentially result in changes to stream channel equilibrium and geomorphology upstream from the lake and at the point where the streams meet the lake.

The effects of development of the Moody Flats Quarry, a 345-acre hardrock quarry (including a 60-acre overburden fill area), a 75-acre processing area, and a 10-acre railroad cut area would result in a loss or diminished availability of mineral resources southeast of Shasta Lake.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As discussed in Section 4.3.4 above, CP1 could result in several localized project-level impacts related to (1) exposure of structures and people to geologic hazards (less than significant); (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable); (3) soil erosion from shoreline processes (significant and unavoidable); (4) soil erosion from upland processes (less than significant); (5) location of project features on unstable geologic or soil units (less than significant); and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP1 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonably foreseeable future projects in the region, CP1 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for impacts to either of these resources; therefore, CP1 would result in a cumulatively considerable incremental contribution to a significant and unavoidable cumulative impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to geomorphology. Although implementation of CP1 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP1 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River portion of the primary study area, and the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As discussed in Section 4.3.4 above, CP2 could result in several localized project-level impacts related to (1) exposure of structures and people to geologic hazards (less than significant); (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable); (3) soil erosion from shoreline processes (significant and unavoidable); (4) soil erosion from upland processes (less than significant); (5) location of project features on unstable geologic or soil units (less than significant); and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP2 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonably foreseeable future projects in the region, therefore, CP2 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for impacts to either of these resources; therefore, CP2 would result in a cumulatively considerable incremental contribution to a significant and unavoidable cumulative impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to geomorphology. Although implementation of CP2 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP2 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River portion of the primary study area, and the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

As discussed in Section 4.3.4 above, CP3 could result in several localized project-level impacts related to (1) exposure of structures and people to geologic hazards (less than significant); (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable); (3) soil erosion from shoreline processes (significant and unavoidable); (4) soil erosion from upland processes (less than significant); (5) location of project features on unstable geologic or soil units (less than significant); and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP3 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonably foreseeable future projects in the region, therefore, CP3 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for impacts to either of these resources; therefore, CP3 would result in a cumulatively considerable incremental contribution to a significant and unavoidable cumulative impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to geomorphology. Although implementation of CP3 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP3 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River portion of the primary study area, and the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

As discussed in Section 4.3.4 above, CP4 or CP4A could result in several localized project-level impacts related to (1) exposure of structures and people to geologic hazards (less than significant); (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable); (3) soil erosion from shoreline processes (significant and unavoidable); (4) soil erosion from upland processes (less than significant); (5) location of project features on unstable geologic or soil units (less than significant); and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP4 or CP4A could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonably foreseeable future projects in the region, therefore, CP4 or CP4A could contribute to significant cumulative impacts related to these mineral and soil biomass resources.   Mitigation is not available for either of these impacts; therefore, CP4 and CP4Awould result in a cumulatively considerable incremental contribution to a significant and unavoidable cumulative impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to geomorphology. Although implementation of CP4 or CP4A could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP4 or CP4A would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River portion of the primary study area, and the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

CP5 – 18.5-Foot Dam Raise, Combination Plan

As discussed in Section 4.3.4 above, CP5 could result in several localized project-level impacts related to (1) exposure of structures and people to geologic hazards (less than significant); (2) alteration of fluvial geomorphology and hydrology of aquatic habitats (significant but mitigable); (3) soil erosion from shoreline processes (significant and unavoidable); (4) soil erosion from upland processes (less than significant); (5) location of project features on unstable geologic or soil units (less than significant); and (6) the suitability of soils for wastewater disposal systems (less than significant). As with many types of geologic impacts, these project-level impacts are localized and would not contribute to any cumulative impacts.

Also discussed in Section 4.3.4 above, CP5 could result in regional impacts related to a diminished availability of cement, concrete sand, and aggregate and a loss of soil productivity. When taken together with reasonably foreseeable future projects in the region, therefore, CP5 could contribute to significant cumulative impacts related to these mineral and soil biomass resources. Mitigation is not available for impacts to either of these resources; therefore, CP5 would result in a cumulatively considerable incremental contribution to a significant and unavoidable cumulative impact.

As stated previously, effects of climate change on operations at Shasta Lake could include a higher frequency of high-flow events, potentially resulting in changes to geomorphology. Although implementation of CP5 could potentially diminish these effects through additional storage capacity of the reservoir available after construction, it is not expected to result in long-term changes to channel equilibrium downstream from Shasta Dam. In addition, potential impacts associated with channel meander and erosion under CP5 would be less than significant in the Shasta Lake and vicinity portion of the study area, the upper Sacramento River portion of the primary study area, and the extended study area. When added to the anticipated effects of climate change, raising Shasta Dam would not have a significant cumulative effect.

Chapter 5
Air Quality and Climate

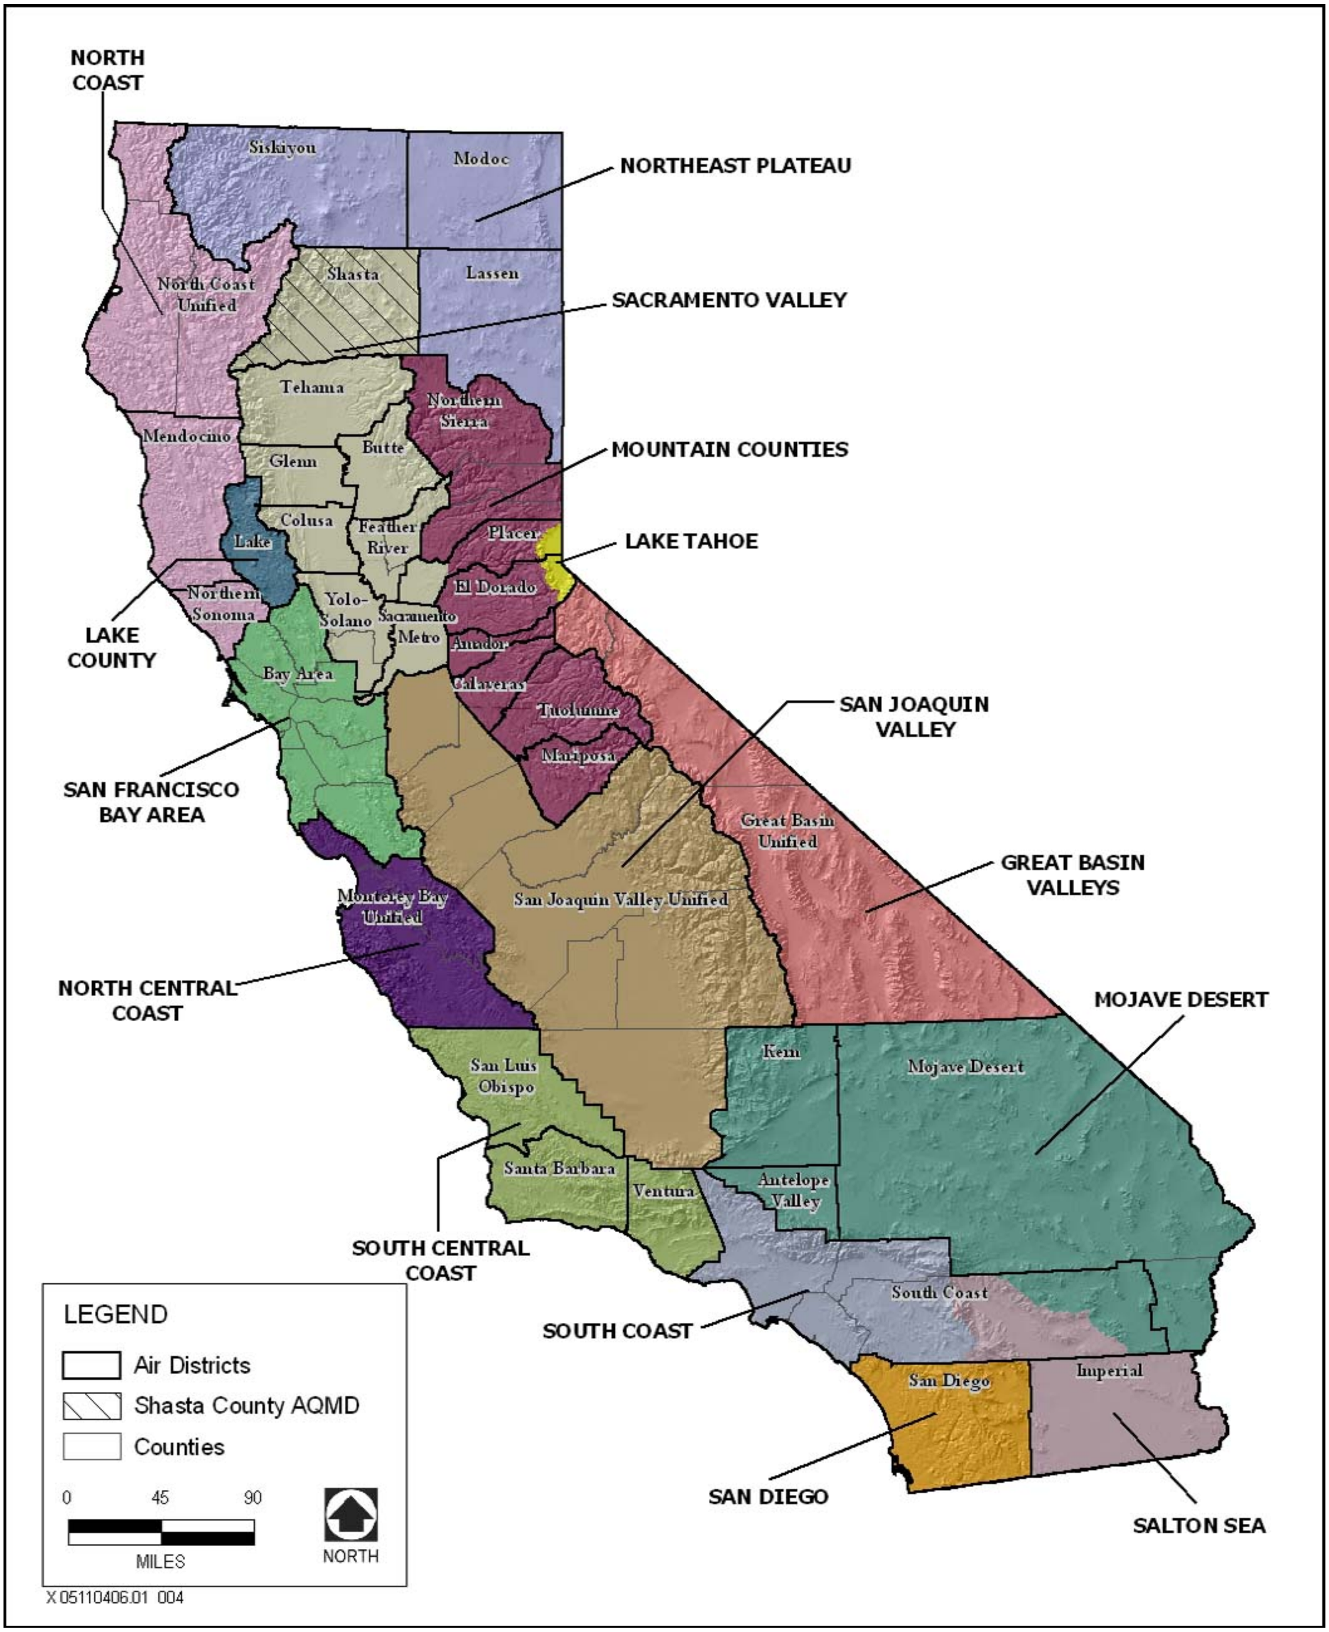
5.1 Affected Environment

This section describes existing air quality conditions in the primary study area for the dam and reservoir modifications proposed under SLWRI action alternatives. The climate and the emissions of criteria air pollutants and toxic air contaminants (TAC) at Shasta Lake and vicinity and the upper Sacramento River from Shasta Dam to Red Bluff are described. In addition, the attainment status of Shasta County relative to national and State of California (State) air quality standards is summarized.

The primary study area for air quality analysis has two components – local and regional. The local area is the area immediately surrounding Shasta Dam and Shasta Lake where project construction would occur. Regionally, Shasta and Tehama counties are located in the Northern Sacramento Valley Air Basin (NSVAB), a subarea of the Sacramento Valley Air Basin (SVAB). The SVAB also includes all of Butte, Colusa, Glenn, Sacramento, Sutter, Yolo, and Yuba counties; the western portion of Placer County; and the eastern portion of Solano County. Figure 5-1 depicts the locations of these air basins, highlighting the Shasta County Air Quality Management District (SCAQMD) area. The NSVAB includes the seven counties located in the northern portion of the Sacramento Valley: Butte, Colusa, Glenn, Shasta, Sutter, Tehama, and Yuba.

The SLWRI would not include any construction or operational activities in the extended study area (the lower Sacramento River and Delta and the CVP and SWP service areas) that would affect air quality. Therefore, this section only minimally discusses air quality conditions in the extended study area. Details about conditions in the extended study area are available in the *Air Quality and Climate Technical Report*.

This section also summarizes current climate change effects of greenhouse gas (GHG) emissions on what is referred to in this chapter as the “global study area.”



Source: ARB 2004

Figure 5-1. Air Basins in California, Including the SCAQMD Area

5.1.1 Regional Climate in the Primary Study Area

The NSVAB is bounded on the north and west sides by the Coast Ranges and on the east side by the southern portion of the Cascade Range and the northern portion of the Sierra Nevada. These mountain ranges provide a substantial physical barrier to locally created air pollution, as well as pollution transported northward on prevailing winds from the Sacramento metropolitan area (NSVPAD 2010). The valley is often subject to inversion layers that, coupled with geographic barriers and high summer temperatures, create high potential for air pollution problems.

5.1.2 Criteria Air Pollutants

Concentrations of the following air pollutants are used as indicators of ambient air quality conditions: ozone, carbon monoxide (CO), nitrogen dioxide (NO_2), sulfur dioxide (SO_2), respirable and fine particulate matter (PM_{10} and $PM_{2.5}$), and lead. Because these are the most prevalent air pollutants known to be deleterious to human health, they are commonly referred to as “criteria air pollutants.”

Each criteria air pollutant is described briefly below. A more in-depth discussion is provided in the *Air Quality and Climate Technical Report*.

Ozone

Ozone is a photochemical oxidant and the primary component of smog. Ozone is not directly emitted into the air, but is formed through complex chemical reactions between precursor emissions of reactive organic gases (ROG) and oxides of nitrogen (NO_X) in the presence of sunlight. ROG are volatile organic compounds (VOC). ROG emissions result primarily from incomplete combustion and the evaporation of chemical solvents and fuels. NO_X are a group of gaseous compounds of nitrogen and oxygen that results from the combustion of fuels.

Ozone located in the lower atmosphere is a major health and environmental concern. Meteorology and terrain play a major role in ozone formation. Low wind speeds or stagnant air coupled with warm temperatures and clear skies provide the optimum conditions for ozone formation. Therefore, summer is the peak ozone season. Ozone is a regional pollutant that often affects large areas. Ozone concentrations over or near urban and rural areas reflect an interplay of emissions of ozone precursors, transport, meteorology, and atmospheric chemistry (Godish 2004).

Carbon Monoxide

CO is a colorless, odorless, and poisonous gas produced by incomplete burning of carbon in fuels, primarily from mobile (transportation) sources. Approximately 77 percent of the nation’s CO emissions are from mobile sources. The other 23 percent consist of CO emissions from wood-burning stoves, incinerators, and industrial sources. The highest concentrations are generally associated with cold, stagnant weather conditions that occur during winter. In contrast to ozone, which is a regional pollutant, CO causes problems on a local scale.

Nitrogen Dioxide

NO_2 is a brownish, highly reactive gas that is present in all urban environments. The major human-made sources of NO_2 are combustion devices, such as boilers, gas turbines, and mobile and stationary combustion engines. NO_2 forms quickly from emissions from cars, trucks and buses, power plants, and off-road equipment. In addition to contributing to the formation of ground-level ozone and fine particle pollution, NO_2 is linked with a number of adverse effects on the respiratory system (EPA 2010a). The combined emissions of NO and NO_2 are referred to as NO_X, which are reported as equivalent NO_2. Because NO_2 is formed and depleted by reactions associated with ozone, the NO_2 concentration in a particular geographical area may not be representative of the local NO_X emission sources.

Sulfur Dioxide

SO_2 is produced by such stationary sources as coal and oil combustion, steel mills, refineries, and pulp and paper mills. SO_2 is a respiratory irritant. On contact with the moist mucous membranes, SO_2 produces sulfurous acid.

Particulate Matter

Respirable particulate matter with an aerodynamic diameter of 10 micrometers or less is referred to as PM_{10}. PM_{10} consists of particulate matter emitted directly into the air, such as fugitive dust, soot, and smoke from mobile and stationary sources, construction operations, fires, and natural windblown dust, and particulate matter formed in the atmosphere by condensation and/or transformation of SO_2 and ROG. $PM_{2.5}$ includes a subgroup of finer particles that have an aerodynamic diameter of 2.5 micrometers or less (EPA 2011a).

Lead

Lead is a metal found naturally in the environment and in manufactured products. The major sources of lead emissions have historically been mobile and industrial sources. As a result of the phase-out of leaded gasoline, metal processing is currently the primary source of lead emissions. The highest levels of lead in air are generally found near lead smelters. Other stationary sources are waste incinerators, utilities, and lead-acid battery manufacturers.

5.1.3 Monitoring Station Data and Criteria Pollutant Attainment Area Designations

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Concentrations of criteria air pollutants are measured at several monitoring stations in Shasta County. The monitoring stations in the City of Shasta Lake and at the Redding Health Department are the closest stations to the project construction area with recent data for ozone and particulate matter. In general, the ambient air quality measurements from these stations are representative of the study area's air quality. Table 5-1 summarizes the air quality data from the most recent 3 years. The data are compared with the ambient air quality standards as noted below. Refer to Table 5-2 for a full listing of all ambient all quality standards.

Table 5-1. Summary of Annual Ambient Air Quality Data (2011 – 2013)

	2011	2012	2013
Ozone			
City of Shasta Lake, Lake Boulevard			
California maximum concentration (1-hour/8-hour average, ppm)	0.083/0.076	0.078/0.068	0.078/0.071
Number of days State 1-hour/8-hour standard exceeded	0/5	0/0	0/1
Number of days national 1-hour/8-hour standard exceeded	0/1	0/0	0/0
Redding Health Department Monitoring Station			
California maximum concentration (1-hour/8-hour average, ppm)	0.073/0.064	0.082/0.061	0.078/0.052
Number of days State 1-hour/8-hour standard exceeded	0/0	0/0	0/0
Number of days national 1-hour/8-hour standard exceeded	0/0	0/0	0/0
Fine Particulate Matter ($PM_{2.5}$)			
Redding Health Department Monitoring Station			
California maximum concentration (µg/m^3)	18.8	26.4	17.6
Number of days national standard exceeded (measured[a])	0	0	0
Respirable Particulate Matter (PM_{10})			
City of Shasta Lake, La Mesa Avenue			
Maximum concentration (µg/m^3)	28.8	37.3	45.5
Number of days State standard exceeded (measured/calculated[a])	0/0.0	0/*	0/0.0
Number of days national standard exceeded (measured/calculated[a])	0/0.0	0/*	0/0.0

Table 5-1. Summary of Annual Ambient Air Quality Data (2011 – 2013) (contd.)

	2011	2012	2013
Redding Health Department Monitoring Station			
Maximum concentration ($\mu g/m^3$)	34.9	34.8	29.5
Number of days State standard exceeded (measured/calculated)[1]	0/0.0	0/*	0/*
Number of days national standard exceeded (measured/calculated)[1]	0/0.0	0/0.0	0/0.0

Source: ARB 2014

Note:
[1] Measured days are those days that an actual measurement was greater than the level of the State daily standard or the national daily standard. Measurements are typically collected every 6 days. Calculated days are the estimated number of days that a measurement would have been greater than the level of the standard had measurements been collected every day. The number of days above the standard is not necessarily the number of violations of the standard for the year.

Key:
* = insufficient data available to determine value.
$\mu g/m^3$ = micrograms per cubic meter
$PM_{2.5}$ = fine particulate matter with an aerodynamic diameter of 2.5 micrometers or less
PM_{10} = respirable particulate matter with an aerodynamic diameter of 10 micrometers or less
ppm = parts per million

Table 5-2. Ambient Air Quality Standards and Designations

Pollutant	Averaging Time	California		National Standards [1]		
		Standards [2,3]	Attainment Status (Shasta County) [4]	Primary [3,5]	Secondary [3,6]	Attainment Status (Shasta County) [7]
Ozone	1-hour	0.09 ppm (180 μg/m^3)	N (Moderate)	*Note 8*	Same as primary standard	–
	8-hour	0.070 ppm	–	0.075 ppm (147 μg/m^3)		U/A
Carbon monoxide(CO)	1-hour	20 ppm (23 mg/m^3)	U	35 ppm (40 mg/m^3)	–	U/A
	8-hour	9 ppm (10 mg/m^3)		9 ppm (10 mg/m^3)		
	8-hour (Lake Tahoe)	6 ppm (7 mg/m^3)	–	–	–	–
Nitrogen dioxide (NO_2)	Annual Arithmetic Mean	0.030 ppm (57 μg/m^3)	–	0.053 ppm (100 μg/m^3) [9]	Same as primary standard	U/A
	1-hour	0.18 ppm (339 μg/m^3)	A	0.100 ppm (188 μg/m^3) [9]		–
Sulfur dioxide (SO_2)	24-hour	0.04 ppm (105 μg/m^3)	A	–	–	U
	3-hour	–	–	–	0.5 ppm (1300 μg/m^3) [9]	
	1-hour	0.25 ppm (655 μg/m^3)	A	0.075 ppm (196 μg/m^3) [10]	–	–
Respirable particulate matter (PM_{10})	Annual Arithmetic Mean	20 μg/m^3	N	–	Same as primary standard	U/A
	24-hour	50 μg/m^3		150 μg/m^3 [6]		
Fine particulate matter ($PM_{2.5}$)	Annual Arithmetic Mean	12 μg/m^3	U	15 μg/m^3	Same as primary standard	U/A
	24-hour	–	–	35 μg/m^3		
Lead [11]	30-day Average	1.5 μg/m^3	A	–	–	–
	Calendar Quarter	–		1.5 μg/m^3	Same as primary standard	A
	Rolling 3 Month Average	–		0.15 μg/m^3		
Sulfates	24-hour	25 μg/m^3	A	No national standards		
Hydrogen sulfide	1-hour	0.03 ppm (42 μg/m^3)	U			
Vinyl chloride [11]	24-hour	0.01 ppm (26 μg/m^3)	U/A			
Visibility-reducing particle matter	8-hour	Extinction coefficient of 0.23 per kilometer—visibility of 10 mi or more	U			

Table 5-2. Ambient Air Quality Standards and Designations (contd.)

Sources: ARB 2010a, 2010b; EPA 2011b

Notes:

[1] National standards (other than ozone, particulate matter, and those based on annual averages or annual arithmetic means) are not to be exceeded more than once a year. The ozone standard is attained when the fourth highest 8-hour concentration in a year, averaged over 3 years, is equal to or less than the standard. The PM10 24-hour standard is attained when 99 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. The PM2.5 24-hour standard is attained when 98 percent of the daily concentrations, averaged over 3 years, are equal to or less than the standard. Contact the U.S. Environmental Protection Agency (EPA) for further clarification and current Federal policies.

[2] California standards for ozone, CO (except Lake Tahoe), SO_2 (1- and 24-hour), NO_2, particulate matter, and visibility-reducing particles are values that are not to be exceeded. All others are not to be equaled or exceeded. California ambient air quality standards are listed in the Table of Standards in Section 70200 of Title 17 of the California Code of Regulations.

[3] Concentration expressed first in units in which it was promulgated (i.e., parts per million (ppm) or micrograms per cubic meter ($\mu g/m^3$)). Equivalent units given in parentheses are based upon a reference temperature of 25 degrees Celsius (°C) and a reference pressure of 760 torr. Most measurements of air quality are to be corrected to a reference temperature of 25°C and a reference pressure of 760 torr; ppm in this table refers to ppm by volume, or micromoles of pollutant per mole of gas.

[4] Unclassified (U): A pollutant is designated unclassified if the data are incomplete and do not support a designation of attainment or nonattainment.

Attainment (A): A pollutant is designated attainment if the State standard for that pollutant was not violated at any site in the area during a 3-year period.

Nonattainment (N): A pollutant is designated nonattainment if there was a least one violation of a State standard for that pollutant in the area.

Nonattainment/Transitional (NT): A subcategory of the nonattainment designation. An area is designated nonattainment/transitional to signify that the area is close to attaining the standard for that pollutant.

[5] National Primary Standards: The levels of air quality necessary, with an adequate margin of safety, to protect the public health.

[6] National Secondary Standards: The levels of air quality necessary to protect the public welfare from any known or anticipated adverse effects of a pollutant.

[7] Nonattainment (N): Any area that does not meet (or that contributes to ambient air quality in a nearby area that does not meet) the national primary or secondary ambient air quality standard for the pollutant. Attainment (A): Any area that meets the national primary or secondary ambient air quality standard for the pollutant.

Unclassifiable (U): Any area that cannot be classified on the basis of available information as meeting or not meeting the national primary or secondary ambient air quality standard for the pollutant.

[8] The 1-hour ozone national ambient air quality standard was revoked on June 15, 2005, for all areas in California.

[9] To attain this standard, the 3-year average of the 98th percentile of the daily maximum 1-hour average at each monitor within an area must not exceed 0.100 part per million (ppm) (effective January 22, 2010). Note that the EPA standards are in units of parts per billion (ppb). California standards are in units of ppm. To directly compare the national standards to the California standards, the units can be converted from ppb to ppm. In this case, the national standards of 53 ppb and 100 ppb are identical to 0.053 ppm and 0.100 ppm, respectively.

[10] On June 2, 2010, EPA established a new 1-hour SO_2 standard, effective August 23, 2010, which is based on the 3-year average of the annual 99th percentile of 1-hour daily maximum concentrations. EPA also proposed a new automated Federal Reference Method (FRM) using ultraviolet technology, but will retain the older pararosaniline methods until the new FRM have adequately permeated State monitoring networks. EPA also revoked both the existing 24-hour SO_2 standard of 0.14 ppm and the annual primary SO_2 standard of 0.030 ppm, effective August 23, 2010. The secondary SO_2 standard was not revised at that time; however, the secondary standard is undergoing a separate review by EPA. Note that the new standard is in ppb. California standards are in ppm. To directly compare the new primary national standard to the California standard the units can be converted to ppm. In this case, the national standard of 75 ppb is identical to 0.075 ppm.

[11] The California Air Resources Board has identified lead and vinyl chloride as toxic air contaminants with no threshold of exposure for adverse health effects determined. These actions allow for the implementation of control measures at levels below the ambient concentrations specified for these pollutants.

Key:

$\mu g/m^3$ = micrograms per cubic meter

mg/m^3 = milligrams per cubic meter

mi = miles

ppm = parts per million

The monitoring data are used to designate areas according to their attainment status for criteria air pollutants. The purpose of these designations is to identify those areas with air quality problems and thereby initiate planning efforts for improvement. The three basic designation categories are “nonattainment,” “attainment,” and “unclassified” (see notes in Table 5-2 for full definitions). “Unclassified” is used in an area that cannot be classified on the basis of available information as meeting or not meeting the standards. In addition, the California designations include a subcategory of the nonattainment designation, “nonattainment-transitional,” that is given to nonattainment areas that are progressing and nearing attainment. The most current attainment designations for Shasta County are shown in Table 5-2 for each criteria air pollutant.

Lower Sacramento River and Delta

The lower Sacramento River and Delta areas are within the SVAB and the San Joaquin Valley Air Basin. As described in greater detail in the *Air Quality and Climate Technical Report*, these basins are Federal and State nonattainment areas for ozone, PM_{10}, and $PM_{2.5}$.

CVP/SWP Service Areas

The CVP and SWP service areas extend beyond the Central Valley into the San Francisco Bay Area, North Central Coast, South Central Coast, and Mountain Counties air basins. Federal and State ozone attainment designations for all California counties and air basins are provided in the *Air Quality and Climate Technical Report*. All counties in California south of Shasta County, with the exception of Lake, Sonoma, Tuolumne, and Mariposa counties, are State nonattainment areas for PM_{10} (ARB 2010a).

5.1.4 Toxic Air Contaminants in the Primary Study Area

TACs, or in Federal terms hazardous air pollutants (HAP), are air pollutants that may cause or contribute to an increase in mortality or in serious illness, or that may pose a hazard to human health. TACs are usually present in minute quantities in the ambient air; however, their high toxicity or health risk may pose a threat to public health even at low concentrations. Of the TACs for which data are available in California, diesel particulate matter (diesel PM), naturally occurring asbestos, benzene, 1,3-butadiene, acetaldehyde, carbon tetrachloride, hexavalent chromium, para-dichlorobenzene, formaldehyde, methylene chloride, and perchloroethylene pose the greatest known health risks. Dioxins are also considered to pose substantial health risk and diesel PM poses the greatest health risk. Current facilities permitted by SCAQMD in the project vicinity are Lehigh Southwest Cement Company, Mountain Gate Quarry, Knauf Insulation, and Sierra Pacific Industries.

5.1.5 Global Study Area

Atmospheric GHGs play a critical role in determining the earth’s surface temperature. Solar radiation enters the earth’s atmosphere from space. Prominent GHGs contributing to the greenhouse effect are carbon dioxide (CO_2), methane, nitrous oxide, hydrofluorocarbons, chlorofluorocarbons, and sulfur hexafluoride. Sources of GHG emissions associated with existing operations include vehicles used for operation and maintenance of the dam and recreation areas, vehicles used by recreational visitors, and fossil fuel-powered boats on Shasta Lake. Human-caused emissions of these GHGs that exceed natural ambient concentrations are responsible for intensifying the greenhouse effect and have led to a trend of unnatural warming of the earth's climate, known as global climate change or global warming (Ahrens 2003).

To provide a method of quantifying GHG emissions, the standard unit of CO_2e, or CO_2 equivalent, was developed. The definition of CO_2e is "The quantity of a given GHG multiplied by its total global warming potential (GWP). This is the standard unit for comparing the degree of warming that can be caused by GHGs" (CCAR 2009). The GWP of a GHG is dependent on the lifetime, or persistence, of the gas molecule in the atmosphere compared to CO_2. The GWP of methane is 23; the GWP of nitrous oxide is 296. Therefore, methane and nitrous oxide are more potent GHGs than CO_2. Expressing emissions in CO_2e takes the contributions of all GHG emissions to the greenhouse effect and converts them to a single unit equivalent to the effect that would occur if only CO_2 were being emitted. The most common quantity unit for CO_2e is million metric tons (MMT).

Climate change is a global phenomenon. GHGs are global pollutants, unlike criteria air pollutants and TACs, which are pollutants of regional and local concern. Whereas pollutants with localized air quality effects have relatively short atmospheric lifetimes (about 1 day), GHGs have long atmospheric lifetimes (1 year to several thousand years). GHGs persist in the atmosphere for long enough time periods to be dispersed around the globe. Although the exact lifetime of any particular GHG molecule is dependent on multiple variables and cannot be pinpointed, it is understood that more CO_2 is emitted into the atmosphere than is sequestered by ocean uptake, vegetation, and other forms of sequestration. Of the total annual human-caused CO_2 emissions, approximately 54 percent is sequestered through ocean uptake, uptake by Northern Hemisphere forest regrowth, and other terrestrial sinks within a year, whereas the remaining 46 percent of human-caused CO_2 emissions remains stored in the atmosphere (Seinfeld and Pandis 1998).

Effects of GHGs are borne globally, as opposed to localized air quality effects of criteria air pollutants and TACs. The quantity of GHGs that it takes to ultimately result in climate change is not precisely known; suffice it to say that the quantity is enormous, and no single project alone would be expected to measurably contribute to a noticeable incremental change in the global average temperature, or to global, local, or micro climate. From the standpoint of CEQA, GHG effects related to global climate change are inherently cumulative.

Please see the *Air Quality and Climate Technical Report* for a discussion of GHG feedback mechanisms and uncertainty.

5.1.6 Existing Sensitive Receptors

Sensitive receptors are more susceptible to the effects of air pollution than the general population. They are typically defined as "facilities that house or attract children, the elderly, people with illnesses, or others who are especially sensitive to the effects of air pollutants," such as hospitals, schools, convalescent facilities, and residential areas.

No sensitive receptors are immediately adjacent to (within 0.5 mile of) the dam. The nearest occupied residence is the horse camp located approximately 7,000 feet downstream; residences on Lake Boulevard are located approximately 4,500 feet east. Other sensitive receptors would include any residences within 0.5 mile of other construction work being done as a result of the dam raise. Bridge construction would occur at Charlie Creek, Doney Creek, McCloud River, Pit River, Fenders Ferry, Didallas Creek, and other Union Pacific Railroad bridges. Major road construction would occur on Lakeshore Drive, in the Turntable Bay Area, on Gillman Road, in Jones Valley and the Silverthorn Area, and on Salt Creek Road. The school nearest to construction activities would be the Smithson School in Lakehead (approximately 500 feet); the nearest place of worship would be Canyon Community Church, also in Lakehead (approximately 800 feet).

5.2 Regulatory Framework

Air quality in Shasta County is regulated by such agencies as the U.S. Environmental Protection Agency (EPA), the California Air Resources Board (ARB), and SCAQMD. Each of these agencies develops rules, regulations, policies, and/or goals to comply with applicable legislation. Although EPA regulations may not be superseded, both State and local regulations may be more stringent.

5.2.1 Federal

Criteria Air Pollutants

At the Federal level, EPA implements national air quality programs. EPA's air quality mandates are drawn primarily from the Federal Clean Air Act (CAA), which was enacted in 1970 and most recently amended in 1990.

The CAA required EPA to establish primary and secondary national ambient air quality standards, as shown in Table 5-2. The CAA also required each state to prepare an air quality control plan referred to as a State implementation plan (SIP). The Federal Clean Air Act Amendments of 1990 (CAAA) added requirements for states with nonattainment areas to revise their SIPs to incorporate additional control measures to reduce air pollution. The SIP is modified periodically to reflect the latest emissions inventories, planning documents, and rules and regulations of the air basins as reported by their jurisdictional agencies. EPA reviews all SIPs to determine whether they conform to the mandates of CAA and its amendments, and whether implementation will achieve air quality goals. If EPA determines a SIP to be inadequate, a Federal implementation plan that imposes additional control measures may be prepared for the nonattainment area. Failure to submit an approvable SIP or to implement the plan within the mandated time frame may result in the application of sanctions to transportation funding and stationary air pollution sources in the air basin.

Hazardous Air Pollutants

Air quality regulations also focus on TACs, or in Federal parlance, HAPs. In general, for those TACs that may cause cancer, there is no concentration that does not present some risk. In other words, there is no threshold level below which adverse health effects may not be expected to occur. This contrasts with the criteria air pollutants, for which acceptable levels of exposure can be determined and for which the ambient standards have been established (Table 5-2). Instead, EPA and ARB regulate HAPs and TACs, respectively, through statutes and regulations that generally require the use of the maximum available control technology or best available control technology for toxics to limit emissions. These statutes and regulations establish the regulatory framework for TACs.

EPA has programs for identifying and regulating HAPs. Title III of the CAAA directed EPA to promulgate national emissions standards for HAPs. National emissions standards for HAPs vary depending on the pollutant source type. The national emissions standards for HAPs for major stationary sources of HAPs could therefore be different than those for area sources. Major sources are defined as stationary sources with potential to emit more than 10 tons per year of any HAP or more than 25 tons per year of any combination of HAPs; all other sources are considered area sources. The emissions standards were to be promulgated in two phases. In the first phase (1992 to 2000), EPA developed technology-based emission standards designed to produce the maximum emission reduction achievable. These standards are generally referred to as requiring maximum available control technology. For area sources, the standards may be different, based on generally available control technology. In the second phase (2001 to 2008), EPA was required to promulgate health risk-based emissions standards, where deemed necessary, to address risks remaining after implementation of the technology-based national emission standards for HAPs.

The CAAA also required EPA to promulgate vehicle or fuel standards containing reasonable requirements that control toxic emissions of benzene and formaldehyde at a minimum. Performance criteria were established to limit mobile-source emissions of toxics, including benzene, formaldehyde, and 1,3-butadiene. In addition, Section 219 required the use of reformulated gasoline in selected areas with the most severe ozone nonattainment conditions to further reduce mobile-source emissions.

General Conformity

The 1990 amendments to CAA Section 176 require EPA to promulgate rules to ensure that Federal actions conform to the appropriate SIP. These rules are known as the General Conformity Rule (40 Code of Federal Regulations Parts 51.850–51.860 and 93.150–93.160). Any Federal agency responsible for an action in a nonattainment/maintenance area must determine whether that action conforms to the applicable SIP or is exempt from General Conformity Rule requirements.

Shasta County, where the proposed action would occur, is neither a nonattainment area nor a maintenance area for the national ambient air quality standards. Therefore, the General Conformity Rule is not applicable to the project.

Greenhouse Gases

Mandatory Greenhouse Gas Reporting Rule On September 22, 2009, EPA released its final Greenhouse Gas Reporting Rule (Reporting Rule). The Reporting Rule is a response to the fiscal year 2008 Consolidated Appropriations Act (House Bill 2764; Public Law 110-161), which required EPA to develop "…mandatory reporting of greenhouse gases above appropriate thresholds in all sectors of the economy…" The Reporting Rule applies to most entities that emit 25,000 metric tons (MT) CO_2e or more per year. Since 2010, facility owners have been required to submit an annual GHG emissions report with detailed calculations of facility GHG emissions. The Reporting Rule also mandates recordkeeping and administrative requirements for EPA to verify annual GHG emissions reports.

U.S. Environmental Protection Agency Endangerment and Cause or Contribute Findings On December 7, 2009, the EPA Administrator signed two distinct findings regarding GHGs under Section 202(a) of the CAA:

- **Endangerment Finding –** The current and projected concentrations of the six key well-mixed GHGs – CO_2, methane, nitrous oxide, hydrofluorocarbons, perfluorocarbons, and sulfur hexafluoride – in the atmosphere threaten the public health and welfare of current and future generations.

- **Cause or Contribute Finding –** The combined emissions of these well-mixed GHGs from new motor vehicles and new motor vehicle engines contribute to GHG pollution, which threatens public health and welfare.

Council on Environmental Quality Draft NEPA Guidelines Because of uneven treatment of climate change under NEPA, the International Center for Technology Assessment, Natural Resources Defense Council, and Sierra Club filed a petition with the Council on Environmental Quality (CEQ) in March 2008. The petition requested that climate change analyses be included in all

Federal environmental review documents. In October 2009, President Barack Obama signed Executive Order 13514, “Federal Leadership in Environmental, Energy, and Economic Performance.” The goal of this executive order is “to establish an integrated strategy towards sustainability in the Federal Government and to make reduction of GHGs a priority for Federal agencies” (FedCenter 2011).

In response to the petition and subsequent Executive Order 13514, CEQ issued guidance on including GHG emissions and climate change impacts in environmental review documents under NEPA. CEQ’s guidance (issued February 18, 2010) suggests that Federal agencies consider opportunities to reduce GHG emissions caused by proposed Federal actions, adapt their actions to climate change impacts throughout the NEPA process, and address these issues in the agencies’ NEPA procedures. The following are the two main factors to consider when addressing climate change in environmental documentation:

- The effects of a proposed action and alternative actions on GHG emissions
- The impacts of climate change on a proposed action or alternatives

CEQ notes that “significant” national policy decisions with “substantial” GHG impacts require analysis of their GHG effects. That is, the GHG effects of a Federal agency’s proposed action must be analyzed if the action would cause “substantial” annual direct emissions; would implement energy conservation or reduced energy use or GHG emissions; or would promote cleaner, more efficient renewable-energy technologies. Qualitative or quantitative information on GHG emissions that is useful and relevant to the decision should be used when deciding among alternatives.

CEQ states that if a proposed action would cause direct annual emissions of more than 25,000 MT CO_2e, a quantitative and qualitative assessment may be meaningful to decision makers and the public. If annual direct emissions would be less than 25,000 MT CO_2e, Federal agencies are encouraged to consider whether the action’s long-term emissions should receive similar analysis.

Greenhouse Gas Permitting Requirements on Large Industrial Facilities
New major stationary emissions sources and major modifications at existing stationary sources are required by the CAA to obtain an air pollution permit before commencing construction. On May 13, 2010, EPA issued the Prevention of Significant Deterioration and Title V Greenhouse Gas Tailor Rule (EPA 2011). This final rule sets thresholds for GHG emissions that define when permits under the New Source Review Prevention of Significant Deterioration (PSD) and Title V Operating Permit programs are required for new and existing industrial facilities.

PSD permitting requirements now cover new construction projects that emit GHG emissions of at least 100,000 tons (90,718 MT) per year even if they do not exceed the permitting thresholds for any other pollutant. Modifications at existing facilities that increase GHG emissions by at least 75,000 tons (68,039 MT) per year will be subject to permitting requirements, even if they do not significantly increase emissions of any other pollutant. Title V Operating Permit requirements apply to sources based on their GHG emissions even if they would not apply based on emissions of any other pollutant. Facilities that emit at least 100,000 tons (90,718 MT) per year of CO_2e will be subject to Title V permitting requirements.

5.2.2 State

ARB coordinates and oversees State and local air pollution control programs in California and implements the California Clean Air Act (CCAA).

Criteria Air Pollutants

The CCAA, which was adopted in 1988, required ARB to establish California ambient air quality standards (Table 5-2). The CCAA requires that all local air districts in the state endeavor to achieve and maintain California ambient air quality standards by the earliest practical date. The act specifies that local air districts should particularly focus on reducing emissions from transportation and area-wide sources, and authorizes districts to regulate indirect sources. Among ARB's other responsibilities are to oversee local air district compliance with California and Federal laws; approve local air quality plans; submit SIPs to EPA; monitor air quality; determine and update area designations and maps; and set emissions standards for new mobile sources, consumer products, small utility engines, off-road vehicles, and fuels.

Toxic Air Contaminants

TACs in California are regulated primarily through the Tanner Air Toxics Act (Assembly Bill (AB) 1807 (Statutes of 1983)) and the Air Toxics Hot Spots Information and Assessment Act (AB 2588 (Statutes of 1987)). AB 1807 sets forth a formal procedure for ARB to designate substances as TACs. Research, public participation, and scientific peer review must be completed before ARB can designate a substance as a TAC. To date, ARB has identified more than 21 TACs and has adopted EPA's list of HAPs as TACs, including diesel PM.

Once a TAC is identified, ARB adopts an airborne toxics control measure for sources that emit that particular TAC. If a safe threshold exists for a substance at which there is no toxic effect, the control measure must reduce exposure below that threshold. If there is no safe threshold, the measure must incorporate best available control technology to minimize emissions.

AB 2588 requires facilities that emit toxic substances above a specified level to do all of the following:

- Prepare a toxic emissions inventory

- Prepare a risk assessment if emissions are significant
- Notify the public of significant risk levels
- Prepare and implement risk reduction measures

Greenhouse Gases

Various statewide initiatives to reduce California's contribution to GHG emissions have raised awareness that, even though the various contributors to and consequences of global climate change are not yet fully understood, global climate change is under way, and real potential exists for severe adverse environmental, social, and economic effects in the long term. The most relevant laws and orders are discussed in more detail below.

California Environmental Quality Act and SB 97 CEQA requires lead agencies to consider the reasonably foreseeable adverse environmental effects of projects they are considering for approval. GHG emissions have the potential to adversely affect the environment because they contribute to global climate change. In turn, global climate change has the potential to raise sea levels, affect rainfall and snowfall, and affect habitat.

Senate Bill 97 Senate Bill (SB) 97 was enacted in August 2007 as part of the State budget negotiations and is codified in Section 21083.05 of the California Public Resources Code. SB 97 directs the Governor's Office of Planning and Research (OPR) to propose guidance in the State CEQA Guidelines "for the mitigation of GHG emissions or the effects of GHG emissions." SB 97 directed OPR to develop text for the State CEQA Guidelines by July 2009. This legislation also directed the State Resources Agency (now known as the California Natural Resources Agency (Resources Agency)) – the agency charged with adopting the State CEQA Guidelines – to certify and adopt such guidelines by January 2010. In April 2009, OPR prepared draft CEQA Guidelines amendments and submitted them to the Resources Agency (see below). On July 3, 2009, the Resources Agency began the rulemaking process established under the Administrative Procedure Act.

The Resources Agency recommended amendments for GHGs to fit within the existing CEQA framework for environmental analysis, which calls for lead agencies to determine baseline conditions and levels of significance and evaluate mitigation measures. The amendments to the State CEQA Guidelines do not identify a threshold of significance for GHG emissions, nor do they prescribe assessment methodologies or specific mitigation measures. The amendments encourage lead agencies to consider many factors in performing a CEQA analysis, but preserve the discretion that CEQA grants lead agencies to make their own determinations based on substantial evidence.

Section 15064.4, "Determining the Significance of Impacts from Greenhouse Gas Emissions," of the State CEQA Guidelines encourages lead agencies to consider three factors to assess the significance of GHG emissions:

1. Will the project increase or reduce GHGs as compared to the baseline?

2. Will the project's GHG emissions exceed the lead agency's threshold of significance?

3. Does the project comply with regulations or requirements to implement a statewide, regional, or local GHG reduction or mitigation plan?

These questions are addressed in Section 5.3.

Section 15064.4 also recommends that lead agencies make a good-faith effort, based on available information, to describe, calculate, or estimate the amount of GHG emissions associated with a project.

Section 15126.4, "Consideration and Discussion of Mitigation Measures Proposed to Minimize Significant Effects," of the State CEQA Guidelines lists considerations for lead agencies related to feasible mitigation measures to reduce GHG emissions. Among those considerations are the following:

- Project features, project design, or other measures that are incorporated into the project to substantially reduce energy consumption or GHG emissions

- Compliance with the requirements in a previously approved plan or mitigation program to reduce or sequester GHG emissions, when the plan or program provides specific requirements that will avoid or substantially lessen the potential impacts of the project

- Measures that sequester carbon or carbon-equivalent emissions

Section 15126.4 also specifies that where mitigation measures are proposed to reduce GHG emissions through off-site actions or purchase of carbon offsets, these mitigation measures must be part of a reasonable plan of mitigation that the relevant agency commits itself to implementing.

In addition, as part of the amendments and additions to the State CEQA Guidelines, a new set of environmental checklist questions (VII. Greenhouse Gas Emissions) was added to Appendix G of the State CEQA Guidelines. The new set asks whether a project would do either of the following:

a) Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment?

b) Conflict with any applicable plan, policy or regulation of an agency adopted for the purpose of reducing the emissions of GHGs?

Preliminary Draft Staff Proposal: Recommended Approaches for Setting Interim Significance Thresholds for Greenhouse Gases Under CEQA CEQA gives discretion to lead agencies to establish thresholds of significance based on individual circumstances. To assist in that exercise, and because OPR believes the unique nature of GHGs warrants investigation of a statewide threshold of significance for GHG emissions, OPR asked ARB technical staff to recommend a methodology for setting thresholds of significance. In October 2008, ARB released *Preliminary Draft Staff Proposal: Recommended Approaches for Setting Interim Significance Thresholds for Greenhouse Gases under the California Environmental Quality Act* (ARB 2008). This draft proposal included a conceptual approach for thresholds associated with industrial, commercial, and residential projects. For nonindustrial projects, the steps to presuming a less than significant climate change impact generally involve analyzing whether the project meets the following criteria (ARB 2008):

- Is exempt under existing statutory or categorical exemptions
- Complies with a previously approved plan or target
- Meets specified minimum performance standards
- Falls below an as-yet-unspecified annual emissions level

The performance standards focus on construction activities, energy and water consumption, generation of solid waste, and transportation. For industrial projects, the draft proposal recommends a tiered analysis procedure similar to the procedure for analyzing nonindustrial projects. However, for industrial projects a quantitative limit for less than significant impacts is established at approximately 7,000 MT CO_2e per year. These standards have not yet been adopted or finalized as a basis for evaluating the significance of a project's contribution to climate change.

Overall, as directed by SB 97, the Resources Agency adopted Amendments to the CEQA Guidelines for GHGs emissions on December 30, 2009. On February 16, 2010, the Office of Administrative Law approved the Amendments, and filed them with the Secretary of State for inclusion in the California Code of Regulations. The Amendments became effective on March 18, 2010.

Executive Order S-3-05 Executive Order S-3-05 made California the first state to formally establish GHG emissions reduction goals. Executive Order S-3-05 includes the following GHG emissions reduction targets for California:

- By 2010, reduce GHG emissions to 2000 levels.

- By 2020, reduce GHG emissions to 1990 levels.
- By 2050, reduce GHG emissions to 80 percent below 1990 levels.

The final emission target of 80 percent below 1990 levels would put the state's emissions in line with estimates of the required worldwide reductions needed to bring about long-term climate stabilization and avoidance of the most severe impacts of climate change (IPCC 2007).

Executive Order S-3-05 also dictated that the Secretary of the California Environmental Protection Agency coordinate oversight of efforts to meet these targets with all of the following:

- The Secretaries of the Business, Transportation, and Housing Agency; California Department of Food and Agriculture; and Resources Agency
- The Chairpersons of ARB and the California Energy Commission
- The President of the California Public Utilities Commission

This group was subsequently named the Climate Action Team.

As laid out in Executive Order S-3-05, the Climate Action Team has submitted biannual reports to the Governor and State legislature describing progress made toward reaching the targets. The Climate Action Team is finalizing its second biannual report on the effects of climate change on California's resources.

Assembly Bill 32 In 2006, California passed the California Global Warming Solutions Act of 2006 (AB 32; California Health and Safety Code, Sections 38500 et seq.). AB 32 further details and puts into law the midterm GHG reduction target established in Executive Order S-3-05 – reduce GHG emissions to 1990 levels by 2020. AB 32 also identifies ARB as the State agency responsible for the design and implementation of emissions limits, regulations, and other measures to meet the target.

The statute lays out the schedule for each step of the regulatory development and implementation, as follows:

- By June 30, 2007, ARB had to publish a list of early-action GHG emission reduction measures.
- Before January 1, 2008, ARB had to identify the current level of GHG emissions by requiring statewide reporting and verification of GHG emissions from emitters and identify the 1990 levels of California GHG emissions.
- By January 1, 2010, ARB had to adopt regulations to implement the early-action measures.

In December 2007, ARB approved the 2020 GHG emission limit (1990 level) of 427 MMT CO_2e. The 2020 target requires the reduction of 169 MMT CO_2e, or approximately 30 percent below California's projected "business-as-usual" 2020 emissions of 596 MMT CO_2e.

Also in December 2007, ARB adopted mandatory reporting and verification regulations pursuant to AB 32. The regulations became effective January 1, 2009, with the first reports covering 2008 emissions. The mandatory reporting regulations require reporting for major facilities, those that generate more than 25,000 MT CO_2e per year. To date ARB has met all of the statutorily mandated deadlines for promulgation and adoption of regulations.

Climate Change Scoping Plan In December 2008, ARB adopted its Climate Change Scoping Plan, which contains the main strategies California will implement to achieve reduction of approximately 118 MMT CO_2e, or approximately 22 percent from the state's projected 2020 emission level of 545 MMT CO_2e under a business-as-usual scenario (this is a reduction of 47 MMT CO_2e, or almost 10 percent, from 2008 emissions). ARB's original 2020 projection was 596 MMT CO_2e, but this revised 2020 projection takes into account the economic downturn that occurred in 2008 (ARB 2011). In August 2011, the Scoping Plan was re-approved by ARB, and includes the Final Supplement to the Scoping Plan Functional Equivalent Document, which further-examined various alternatives to Scoping Plan measures. The Scoping Plan also includes ARB-recommended GHG reductions for each emissions sector of the state's GHG inventory. ARB estimates the largest reductions in GHG emissions to be achieved by implementing the following measures and standards (ARB 2011):

- improved emissions standards for light-duty vehicles (estimated reductions of 26.1 MMT CO_2e)
- the Low-Carbon Fuel Standard (15.0 MMT CO_2e)
- energy efficiency measures in buildings and appliances (11.9 MMT CO_2e)
- a renewable portfolio and electricity standards for electricity production (23.4 MMT CO_2e)

ARB has not yet determined what amount of GHG reductions it recommends from local government operations; however, the Scoping Plan does state that land use planning and urban growth decisions will play an important role in the state's GHG reductions because local governments have primary authority to plan, zone, approve, and permit how land is developed to accommodate population growth and the changing needs of their jurisdictions. (Meanwhile, ARB is also developing an additional protocol for community emissions.) ARB further acknowledges that decisions on how land is used will have large impacts on the GHG emissions that will result from the transportation, housing, industry, forestry, water, agriculture, electricity, and natural gas emission sectors. The Scoping Plan states that the ultimate GHG reduction assignment to local government operations is to be determined (ARB 2008). With regard to land use planning, the Scoping Plan expects approximately 3.0 MMT CO_2e will be achieved associated with implementation of SB 375, which is discussed further below (ARB 2011).

Executive Order S-13-08 Executive Order S-13-08, issued November 14, 2008, directs the Resources Agency, DWR, OPR, the California Energy Commission, the State Water Resources Control Board, the California Department of Parks and Recreation, and California's coastal management agencies to participate in planning and research activities to advance California's ability to adapt to the effects of climate change. The order specifically directs agencies to work with the National Academy of Sciences to initiate the first California sea-level-rise assessment and to review and update the assessment every 2 years after completion; immediately assess the vulnerability of California's transportation system to sea level rise; and to develop a climate change adaptation strategy for California.

California Climate Change Adaptation Strategy Developed through cooperation and partnership among multiple State agencies, the 2009 *California Climate Adaptation Strategy* summarizes the best known science on climate change effects. The strategy describes effects of climate change on seven specific sectors—public health, biodiversity and habitat, ocean and coastal resources, water management, agriculture, forestry, and transportation and energy infrastructure—and recommends ways to manage against those threats.

Governor's Office of Planning and Research Technical Advisory In June 2008, OPR published a technical advisory on CEQA and climate change to provide interim advice to lead agencies regarding the analysis of GHGs in environmental documents (OPR 2008). The advisory encourages lead agencies to identify and quantify the GHGs that could result from a proposed project, analyze impacts of those emissions to determine whether they would be significant, and identify feasible mitigation measures or alternatives that would reduce adverse impacts to a less than significant level. The advisory recognized that OPR would develop, and the Resources Agency would adopt, amendments to the State CEQA Guidelines pursuant to SB 97 (see "California Environmental Quality Act and SB 97," above).

The advisory provides OPR's perspective on the emerging role of CEQA in addressing climate change and GHG emissions. It recognizes that approaches and methodologies for calculating GHG emissions and determining their significance are rapidly evolving. OPR concludes in the technical advisory that climate change is ultimately a cumulative impact, and that no individual project could have a significant impact on global climate. Thus, projects must be analyzed with respect to the incremental impact of the project when added to other past, present, and reasonably foreseeable probable future projects. OPR recommends that lead agencies undertake an analysis, consistent with available guidance and current CEQA practice, to determine cumulative significance (OPR 2008).

The technical advisory points out that neither CEQA nor the State CEQA Guidelines prescribe thresholds of significance or particular methodologies for performing an impact analysis. “This is left to lead agency judgment and discretion, based upon factual data and guidance from regulatory agencies and other sources where available and applicable” (OPR 2008). OPR states that “the global nature of climate change warrants investigation of a statewide threshold of significance for GHG emissions” (OPR 2008). Until such a standard is established, OPR advises that each lead agency should develop its own approach to performing an analysis for projects that generate GHG emissions (OPR 2008).

OPR sets out the following process for evaluating GHG emissions. First, agencies should determine whether GHG emissions may be generated by a proposed project, and if so, quantify or estimate the emissions by type or source. Calculation, modeling, or estimation of GHG emissions should include the emissions associated with vehicular traffic, energy consumption, water usage, and construction activities (OPR 2008).

Agencies should then assess whether the emissions are “cumulatively considerable” even though a project’s GHG emissions may be individually limited. OPR states: “Although climate change is ultimately a cumulative impact, not every individual project that emits GHGs must necessarily be found to contribute to a significant cumulative impact on the environment” (OPR 2008). Individual lead agencies may undertake a project-by-project analysis, consistent with available guidance and current CEQA practice (OPR 2008).

Finally, if the lead agency determines that emissions are a cumulatively considerable contribution to a significant cumulative impact, the lead agency must investigate and implement ways to mitigate the emissions (OPR 2008). OPR (2008) states:

> *Mitigation measures will vary with the type of project being contemplated, but may include alternative project designs or locations that conserve energy and water, measures that reduce vehicle miles traveled by fossil-fueled vehicles, measures that contribute to established regional or programmatic mitigation strategies, and measures that sequester carbon to offset the emissions from the project.*

OPR concludes that “A lead agency is not responsible for wholly eliminating all GHG emissions from a project; the CEQA standard is to mitigate to a level that is “less than significant” (OPR 2008). Attachment 3 to the technical advisory includes a list of GHG reduction measures that can be applied on a project-by-project basis.

California Air Pollution Officers Association In January 2008, the California Air Pollution Control Officers Association issued a "white paper" on evaluating and addressing GHGs under CEQA (CAPCOA 2008). This resource guide was prepared to support local governments as they develop their climate change programs and policies. Though not a guidance document, the paper provides information about key elements of CEQA GHG analyses, including a survey of different approaches to setting quantitative significance thresholds. The following are some of the thresholds discussed:

- Zero (all emissions are significant)
- 900 MT CO_2e per year (90 percent market capture for residential and nonresidential discretionary development)
- 10,000 MT CO_2e per year (potential ARB mandatory reporting level for cap-and-trade program)
- 25,000 MT CO_2e per year (ARB's mandatory reporting level for the statewide emissions inventory)
- Unit-based thresholds, based on identifying thresholds for each type of new development and quantifying significance by a 90 percent capture rate

5.2.3 Regional and Local

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Shasta County Air Quality Management District SCAQMD is the primary local agency regulating air quality for all of Shasta County. SCAQMD attains and maintains air quality conditions in Shasta County through a comprehensive program of planning, regulation, enforcement, technical innovation, and promotion of the understanding of air quality issues. The clean-air strategy of SCAQMD is to prepare plans and programs for the attainment of ambient air quality standards, adopt and enforce rules and regulations, and issue permits for stationary sources. SCAQMD also inspects stationary sources, responds to citizen complaints, monitors ambient air quality and meteorological conditions, and implements other programs and regulations required by the CAA, CAAA, and CCAA.

Rules and Regulations All projects in Shasta County are subject to SCAQMD rules and regulations in effect at the time of construction. Specific rules applicable to the project may include the following:

- **Rule 2:1A: Permits Required –** Any person who is building, erecting, altering, or replacing any article, machine, equipment or other contrivance, or multicomponent system including same, portable or stationary and who is not exempt under Section 42310 of the California Health and Safety Code, the use of which may cause the issuance of air contaminants, shall first obtain written authority for such construction from the Air Pollution Control Officer.

- **Rule 2:7: Conditions for Open Burning –** All material to be burned must be arranged so that it will burn with a minimum of smoke and must be reasonably free of dirt, soil, and visible surface moisture. All vegetative wastes to be burned shall be ignited only with approved ignition devices and shall be free of tires, illegal residential waste, tar paper, construction debris, and combustible and flammable waste. No burning shall cause emissions to be transported into smoke sensitive areas. No burning shall be conducted when such burns, in conjunction with present or predicted meteorology, could cause or contribute to a violation of an ambient air quality standard.

- **Rule 3:15: Cutback and Emulsified Asphalt –** A person shall not manufacture, sell, offer for sale, use, or apply for paving, construction, or maintenance of parking lots, driveways, streets, or highways any rapid- or medium-cure cutback asphalt, slow-cure cutback asphalt material that contains more than 0.5 percent by volume VOCs that boil at 500 degrees Fahrenheit (260 degrees Celsius) or less, or any emulsified asphalt material that contains more than 3.0 percent by volume of VOCs that evaporate at 500 degrees Fahrenheit (260 degrees Celsius) or less.

- **Rule 3:16: Fugitive, Indirect, or Nontraditional Sources –** The Air Pollution Control Officer may place reasonable conditions upon any source, as delineated below, that will mitigate the emissions from such sources to below a level of significance or to a point that such emissions no longer constitute a violation of Health and Safety Code Sections 41700 and/or 41701: fugitive sources, indirect sources, and nontraditional sources.

- **Rule 3:22: Asbestos –** No person shall use or apply serpentine material for surfacing in California unless the material has been tested using ARB Test Method 435 and determined to have an asbestos content of 5 percent or less. A written receipt or other record documenting the asbestos content shall be retained by any person who uses or applies serpentine material for at least 7 years from the date of use or application, and shall be provided to the Air Pollution Control Officer, or his or her designate, for review upon request.

- **Rule 3:31: Architectural Coatings** – The developer or contractor is required to use coatings that comply with the VOC content limits specified in the rule.

Criteria Pollutants SCAQMD has adopted pollutant emission thresholds and mitigation requirements that are used in the analysis of project impacts. The thresholds and mitigation requirements are discussed below in Section 5.3.2, "Criteria for Determining Significance of Effects."

Attainment Plan Air quality planning in the NSVAB has been undertaken on a joint basis by the air districts in seven counties. The current plan, the *Northern Sacramento Valley Planning Area 2012 Triennial Air Quality Attainment Plan* (AQAP), is an update of plans prepared in 1994, 1997, 2000, 2003, 2006, and 2009. The purpose of the plan is to achieve and maintain healthful air quality throughout the air basin. The 2012 AQAP addresses the progress made in implementing the 2009 plan and proposes modifications to the strategies necessary to attain the California ambient air quality standards for the 1-hour ozone standard at the earliest practicable date.

The AQAP is based on each county's projected emission inventory, which includes stationary, area-wide, and mobile sources. Emission inventories are based on general plans and anticipated development.

Toxic Air Contaminants At the local level, air pollution control or management districts may adopt and enforce ARB control measures. Under SCAQMD Rule V, "Additional Procedures For Issuing Permits To Operate For Sources Subject To Title V Of The Federal Clean Air Act Amendments Of 1990," Rule 2:1, "New Source Review," and Rule 2:1A, "Permits Required," all sources that possess the potential to emit TACs are required to obtain permits from the district. Permits may be granted to these operations if they are constructed and operated in accordance with applicable regulations, including new-source-review standards and air-toxics control measures. SCAQMD limits emissions and public exposure to TACs through a number of programs. SCAQMD prioritizes TAC-emitting stationary sources based on the quantity and toxicity of the TAC emissions and the proximity of the facilities to sensitive receptors.

Shasta County General Plan The Air Quality Element of the *Shasta County General Plan* (Shasta County 2004) contains objectives and policies aimed at protecting and improving Shasta County's air quality, meeting the requirements of the CAA and CCAA, and integrating planning efforts (e.g., transit, land use) to reduce air pollution contaminants, among others.

Tehama County Air Pollution Control District The southern portion of the primary study area is in Tehama County. The Tehama County Air Pollution Control District is the primary local agency with respect to air quality for Tehama County. The Tehama County Air Pollution Control District has rules and regulations similar to those described for SCAQMD. The Tehama County

Air Pollution Control District is in the NSVAB and is therefore a participant in NSVAB's 2003 AQAP.

Lower Sacramento River and Delta and CVP/SWP Service Areas

All areas of California are within the jurisdiction of an air pollution control district or an air quality management district. Each district has rules and regulations similar to those described above for SCAQMD. Districts that are classified as nonattainment for one or more criteria pollutants have attainment plans or similar documents as required by ARB. Most districts have guidance documents for the analysis of air quality impacts for CEQA compliance.

Global Study Area—Greenhouse Gases

There are no regional or local policies, regulations, or laws pertaining to GHG emissions.

5.3 Environmental Consequences and Mitigation Measures

5.3.1 Methods and Assumptions

Criteria Air Pollutants

The proposed SLWRI alternatives are quite complex. They consist of implementing construction activities for the dam structure; clearing the reservoir area that would be affected by the increase in pool height; relocating and modifying bridges, roads, utilities, and recreation areas; and completing other related tasks. A detailed list including each piece of heavy duty construction equipment for every construction activity to be completed under each action alternative, including proposed work hours, was available. In addition, total quantities of material hauled and imported was available. Information on daily trips for construction workers and material hauling was also available for each action alternative. Quantification of air pollutant emissions were based on a combination of methods, including the use of emission factors from the EPA's published AP-42, exhaust emission factors from the Sacramento Metropolitan Air Quality Management District's (SMAQMD) Road Construction Emissions Model, emission rates from OFFROAD 2007 and EMFAC 2011, and the California Emissions Estimator Model (CalEEMod) version 2011.1.1. The application of each methodology is described separately below.

SMAQMD's Road Construction Emissions Model, version 7.1.2 was used to obtain exhaust emission rates for ROG, NO_x, PM_{10}, CO, and CO_2 for heavy duty construction equipment that would be used for construction activities. The model uses emission rates for heavy-duty construction equipment based on OFFROAD 2007 and EMFAC 2011 (described separately below). Emission rates for 2016 (the earliest year that construction would begin) were applied to each piece of equipment based on the anticipated operation hours of equipment by construction activity and action alternative.

The off-road emissions inventory is an estimate of the population, activity, and emissions estimate of the varied types of off-road equipment within each county in California. The major categories of engines and vehicles include agricultural, construction, lawn and garden, and off-road recreation. OFFROAD was run for Shasta County in 2016 (the earliest year that construction would begin) and was used to generate emission rates for certain, specific equipment such as chippers and chainsaws that were not included in the SMAQMD Road Construction Model described above.

EMFAC 2011 is a model developed by ARB used for estimating emissions from on-road vehicles. EMFAC 2011 was run for Shasta County in 2016 (the earliest year that construction would begin) and was used to generate exhaust emission rates for worker commute trips and truck hauling trips. Emission rates were applied to daily truck trips and worker commute trips required by each action alternative.

Emission factors obtained from AP-42 were used to calculate dust emissions ($PM_{2.5}$ and PM_{10}) from construction activity (grading, earthmoving, stockpiling of material), travel on paved road for truck haul trips and for worker commute trips. For dust generated during construction activity, two primary construction activities were identified that would represent the dust emissions from all action alternatives: aggregate handling and storage piles, and grading/earth moving. AP-42 provides emission factors that estimate dust emissions from the loading of aggregate onto storage piles, equipment traffic in storage areas, wind erosion from pile surfaces, loadout of aggregate for shipment or return to the process stream (batch or continuous drop operations), and from bulldozing/grading.

Primary inputs to estimate dust from aggregate handling and storage piles included total quantities of excavated material and inputs for bulldozing/grading included total equipment hours for equipment that perform these activities (e.g., graders, bulldozers).

CalEEMod was developed in collaboration with the air districts of California. Default data (e.g., emission factors, trip lengths, meteorology, source inventory, etc.) were provided by the various California air districts to account for local requirements and conditions. CalEEMod can be used to estimate air pollutant emissions from construction activities, mobile-source emissions, and operational emissions from mobile and area sources. CalEEMod was used to estimate mobile-source emissions of criteria air pollutants (ROG, NO_x, $PM_{2.5}$, PM_{10}, and CO) from operational trips associated with visitation to the recreational sites of the project.

Toxic Air Contaminants and Odors

TACs and odors are discussed in accordance with SCAQMD, ARB, and EPA policies and rules.

Global Warming

Emissions of CO_2e from construction activities and from recreational visitors' vehicles were calculated using emission factors for heavy duty construction equipment from the SMAQMD's Road Construction Emission Model and CalEEMod 2011.1.1. Exhaust emissions from construction equipment were summed by the various construction activities under each action alternative. Mobile source GHG emissions associated with recreational visitor trips were estimated using the operational trip rates provided for each action alternative in CalEEMod. Data on emissions avoided by generation of electricity from Shasta Dam were obtained from Chapter 5 of the Shasta Lake Water Resources Investigation Plan Formulation Report (Reclamation 2007). GHG emissions from cleared and burned vegetation were estimated using the Carbon Online Estimator (COLE Development Group 2011). Indirect emissions from cement production and CO_2 absorption by water and vegetation are discussed, but not quantified.

5.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The following significance criteria were developed based on guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on air quality and climate would be significant if project implementation would do any of the following:

- Conflict with or obstruct implementation of the applicable air quality plan
- Violate any air quality standard or contribute substantially to an existing or projected air quality violation
- Result in a cumulatively considerable net increase of a criteria air pollutant for which the project region is nonattainment under any applicable Federal or State ambient air quality standard (including releasing emissions that exceed quantitative thresholds for ozone precursors)

- Expose sensitive receptors to substantial pollutant concentrations
- Create objectionable odors affecting a substantial number of people
- Generate GHG emissions, either directly or indirectly, that may have a significant impact on the environment
- Conflict with any applicable plan, policy, or regulation of an agency adopted for the purpose of reducing the emissions of GHGs

As stated in Appendix G of the State CEQA Guidelines, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the above determinations. SCAQMD has adopted air quality thresholds (Table 5-3). These thresholds are based on SCAQMD New Source Review Rule 2:1. The thresholds and policy are published in the *Shasta County General Plan*.

Table 5-3. Shasta County Air Quality Management District's Air Quality Emission Thresholds

NO_X	ROG	PM_{10}	CO
Level A Thresholds			
25 lb/day	25 lb/day	80 lb/day	500 lb/day
Level B Thresholds			
137 lb/day	137 lb/day	137 lb/day	500 lb/day

Source: Shasta County 2004

Note:
These thresholds will be applied during the Shasta County Planning Division's CEQA review process. The CO thresholds do not appear in the general plan, but are included in SCAQMD policy.

Key:
CEQA = California Environmental Quality Act
CO = carbon monoxide
lb/day = pounds per day
NO_X = oxides of nitrogen
PM_{10} = respirable particulate matter
ROG = reactive organic gases
SCAQMD = Shasta County Air Quality Management District

The policy includes standard mitigation measures (SMM) and best available mitigation measures (BAMM). Briefly, the policy for applying SMMs and BAMMs is as follows:

- Apply SMM to all projects; this effort will help contribute to reducing cumulative effects.
- Apply SMM and appropriate BAMM when a project exceeds Level A thresholds.

- Apply SMM, BAMM, and special BAMM when a project exceeds Level B thresholds.

- If application of the above procedures will reduce project emissions below Level B thresholds, the project can proceed with an environmental determination of a mitigated negative declaration, assuming that other project impacts do not require more extensive environmental review.

- If project emissions cannot be reduced to below Level B thresholds, emission offsets will be required. If, after applying the emissions offsets, the project emissions still exceed the Level B threshold, an environmental impact report will be required before the project can be considered for action by the reviewing authority.

Thus, as recommended by SCAQMD, impacts of an alternative on air quality would be significant if either of the following would occur as a result of project implementation:

- Emissions of criteria air pollutants or precursors in Shasta County during construction or long-term operations would exceed the SCAQMD Level B thresholds of 137 pounds per day (lb/day) of ROG, NO_X, or PM_{10} and 500 lb/day of CO after the application of mitigation measures.

- Emissions of criteria air pollutants or precursors in Tehama County during construction or long-term operations would exceed 137 lb/day of ROG, NO_X, or PM_{10} after the application of mitigation measures.

SCAQMD has not adopted a numeric significance criterion for GHGs generated by nonindustrial projects. (However, two California air districts, the Bay Area Air Quality Management District and the South Coast Air Quality Management District, have adopted thresholds for GHG emissions generated by development projects.) No numeric thresholds adopted by any air district or by ARB would be applicable to the action alternatives. However, by adopting AB 32, the State has established GHG reduction targets. Further, the State has determined that GHG emissions, as they relate to global climate change, are a source of adverse environmental impacts in California and should be addressed under CEQA. AB 32 did not amend CEQA, although the legislation identifies the myriad environmental problems in California caused by global warming (Health and Safety Code, Section 38501(a)). SB 97, in contrast, did amend CEQA by requiring OPR to revise the State CEQA Guidelines to address the mitigation of GHG emissions or their consequences (California Public Resources Code, Sections 21083.05 and 21097).

Based on the size, scope, and purpose of this project, the following significance criteria will be used to determine the significance of GHG emissions from this project:

- Whether the project has the potential to conflict with or is consistent with the following plans to reduce or mitigate GHG emissions:
  - The six key elements of the *Climate Change Scoping Plan* (described previously)
  - ARB's 39 recommended actions in the *Climate Change Scoping Plan*
  - Regulations or requirements adopted to implement a statewide, regional, or local plan for the reduction or mitigation of GHG emissions
- Whether the project is part of a plan that includes overall reductions in GHG emissions
- Whether the relative amounts of GHG emissions over the life of the project are small in comparison to the amount of GHG emissions for major facilities that are required to report such emissions (25,000 MT CO_2e per year)
- Whether the project has the potential to contribute to a lower carbon future, through factors such as the following:
  - The design of the proposed project is inherently energy efficient
  - All applicable best management practices that would reduce GHG emissions are incorporated into the project design
  - The project implements or funds its fair share of a mitigation strategy designed to alleviate climate change
  - There are process improvements or efficiencies gained by implementing the project

5.3.3 Topics Eliminated from Further Consideration

No topics related to air quality and climate change that are included in the significance criteria listed above were eliminated from further consideration. All relevant topics are analyzed below.

5.3.4 Direct and Indirect Effects

No-Action Alternative

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Impact AQ-1 (No-Action): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction No short-term, construction-related increases in emissions of criteria air pollutants or precursors at Shasta Lake or in the vicinity would result from implementation of the No-Action Alternative. No impact would occur.

Under the No-Action Alternative, no new facilities would be constructed at Shasta Lake or in the vicinity. No changes to Reclamation's existing facilities would occur that would directly or indirectly result in any increases in emissions of criteria air pollutants or precursors in this portion of the primary study area. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact AQ-2 (No-Action): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation No long-term operational increases in emissions of criteria air pollutants or precursors in the primary study area would result from implementation of the No-Action Alternative. However, PM_{10} emissions are expected to continue increasing through 2020 because of increased growth in the area. This impact would be less than significant.

Under the No-Action Alternative, no changes to Reclamation's existing operations in the primary study area would occur that would directly or indirectly result in any increases in emissions of criteria air pollutants or precursors in the primary study area. According to ARB, emission levels for ROG, NO_X, and CO are trending downward from 1990 to 2020 in the project area even with increased population growth (ARB 2009). More stringent mobile-source emission standards, cleaner burning fuels, and new rules have largely contributed to this decline. However, PM_{10} emissions are expected to continue increasing through 2020 because of increased growth in the area and associated emissions (e.g., from travel on paved and unpaved roads). Thus, such emissions will likely be worse in the future. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact AQ-3 (No-Action): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations The No-Action Alternative would not change existing exposure of sensitive receptors to pollutants. No impact would occur.

Sensitive receptors in the primary study area are not currently exposed to substantial pollutant concentrations. There is no indication of circumstances under the No-Action Alternative that would change exposure levels. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact AQ-4 (No-Action): Exposure of Sensitive Receptors to Odor Emissions The No-Action Alternative would not change existing exposure of sensitive receptors to odors. No impact would occur.

Sensitive receptors in the primary study area are not currently exposed to substantial concentrations of odors. There is no indication of circumstances under the No-Action Alternative that would change the exposure. Therefore, no impact would occur. Mitigation is not required for the No-Action Alternative.

Impact AQ-5 (No-Action): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction No short-term, construction-related increases in emissions of criteria air pollutants or precursors below Shasta Dam would result from implementation of the No-Action Alternative. No impact would occur.

The Gravel Augmentation Program (proposed under CP4, CP4A, and CP5, as described below) would not be implemented under the No-Action Alternative. No new facilities would be constructed below Shasta Dam. Furthermore, no changes to Reclamation’s existing facilities or operations would occur that would directly or indirectly result in any increases in emissions of criteria air pollutants in this portion of the primary study area. No impact would occur. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under the No-Action Alternative; therefore, potential effects in those geographic regions are not discussed further in this EIS.

Global Study Area

Impact AQ-6 (No-Action): Generation of Greenhouse Gases State goals to reduce project-related GHG emissions would not be implemented under this alternative; however, the No-Action Alternative would not obstruct or conflict with those goals. This impact would be less than significant.

Under the No-Action Alternative, no new facilities would be constructed. No changes to Reclamation’s existing facilities or operations would occur that would directly or indirectly result in any increases or decreases in GHG emissions. Therefore, no efforts would be made to reduce existing GHG emissions in the project vicinity under this alternative. Although the State’s goals to reduce GHG emissions would not be implemented, the No-Action Alternative would not obstruct or conflict with those goals. Therefore, this impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity

Impact AQ-1 (CP1): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction could result in short-term emissions (e.g., ROG, NO_x, and PM) that exceed applicable SCAQMD thresholds. This conclusion is based on detailed calculations of estimated emissions for project elements and the simultaneous occurrence thereof. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

Construction emissions are described as "short-term" or temporary in duration because they would cease when the dam raise and associated construction projects are completed. The emissions of ozone precursors ROG and NO_X are associated primarily with gas and diesel engine equipment exhaust from off-road equipment and on-road vehicles. Off-road equipment anticipated in the project includes construction equipment such as bulldozers, graders, water trucks, and loaders. On-road vehicles include trucks that would bring materials to the project site and haul excavated spoils and materials cleared from lands away from the project site. An additional on-road source would be the vehicles used by workers commuting to and from the project site. Engine equipment exhaust also emits CO, PM_{10}, and $PM_{2.5}$. Refer to Attachment 1 to the *Air Quality and Climate Technical Report* for all air quality modeling inputs and outputs.

The primary sources of PM_{10} and $PM_{2.5}$ emissions are fugitive dust from site preparation, vehicle travel on unpaved and paved roads, and storage piles. Emissions vary as a function of such parameters as soil silt content, soil moisture, wind speed, acreage of disturbance area, and vehicle miles traveled by construction vehicles on- and off-site. Burning of cleared vegetation would also be a source of particulate emissions. PM_{10} and $PM_{2.5}$ would also be emitted during the materials handling processes associated with operation of a concrete batch plant.

Major construction elements under CP1 would be the dam raise of 6.5 feet and the clearing of land that would be inundated by the larger full pool. Land-clearing equipment used would be based on the terrain, and would range from full-size bulldozers to smaller backhoes and hand tools. In steep terrain helicopters would be used for material removal. In addition, wing dams and reservoir dikes would be constructed; railroad and roadway bridges would be replaced; roads, structures, and utilities would be relocated; and excavation and loading would occur at borrow areas to provide materials for dam construction.

Emissions were calculated as described above in Section 5.3.1, "Methods and Assumptions." The results are shown in Table 5-4 for individual project elements. (All air quality modeling inputs and outputs for the Comprehensive Plans (CP) are presented in Attachment 1 to the *Air Quality and Climate Technical Report*.) As seen in Table 5-4, ROG, NO_X, and PM emissions for several of the individual project elements could exceed applicable Shasta County thresholds, which would result in a significant impact. As shown in Figures 5-2 to 5-8, maximum daily emissions (lb/day) for CP1 could reach 260 for ROG, 1,682 for NO_x, 107 for PM_{10} exhaust, 2,944 for PM_{10} dust, 93 for $PM_{2.5}$ exhaust, 309 for $PM_{2.5}$ dust, and 1,125 for CO based on the worst-case simultaneous construction of project elements as shown in detail in Attachment 1 to the *Air Quality and Climate Change Technical Report*.

Particulate emissions from operation of a concrete batch plant are not included in the above calculations. Batch plants must obtain operating permits from Shasta County Air Pollution Control District. The granting of a permit would assure that the impact of PM_{10} and $PM_{2.5}$ emissions from batch plant sources would not exceed applicable thresholds.

Based on the data in Table 5-4 and the preceding discussion, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. As a result, this impact would be significant.

The Shasta County standards require SMMs for all projects and additional mitigation measures when project emissions are anticipated to exceed applicable thresholds. Mitigation for this impact that incorporates these mitigation measures is proposed in Section 5.3.5.

Table 5-4. Summary of Daily Short-Term Construction-Generated Emissions by Project Element (Pounds per Day) – CP1[1]

Project Element for 6.5-Foot Raise (Activities)	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO

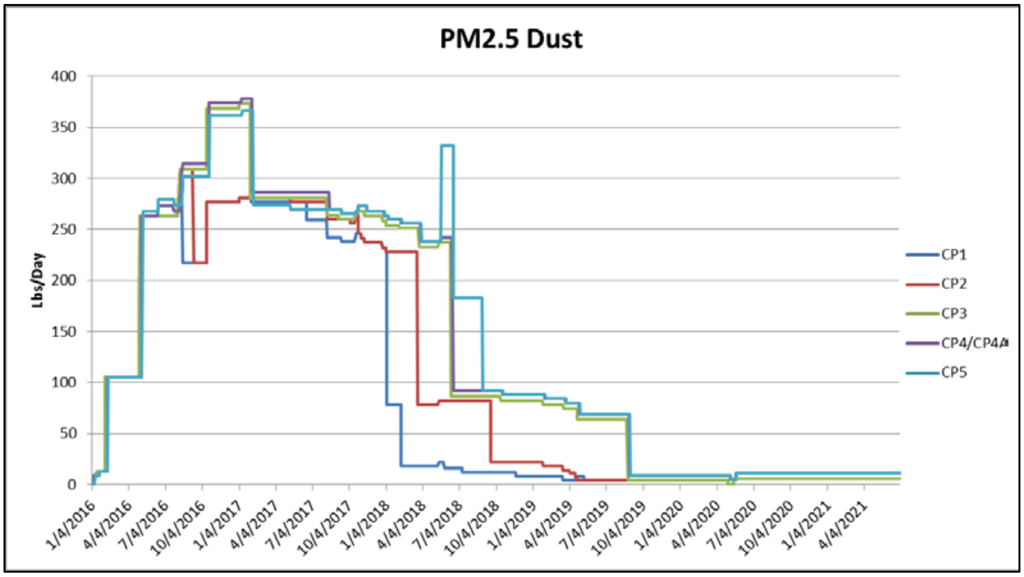

Figure 5-7. Maximum Daily Short-Term Construction-Generated Emissions of Fine Particulate Matter Dust by Action Alternative (Pounds per Day)

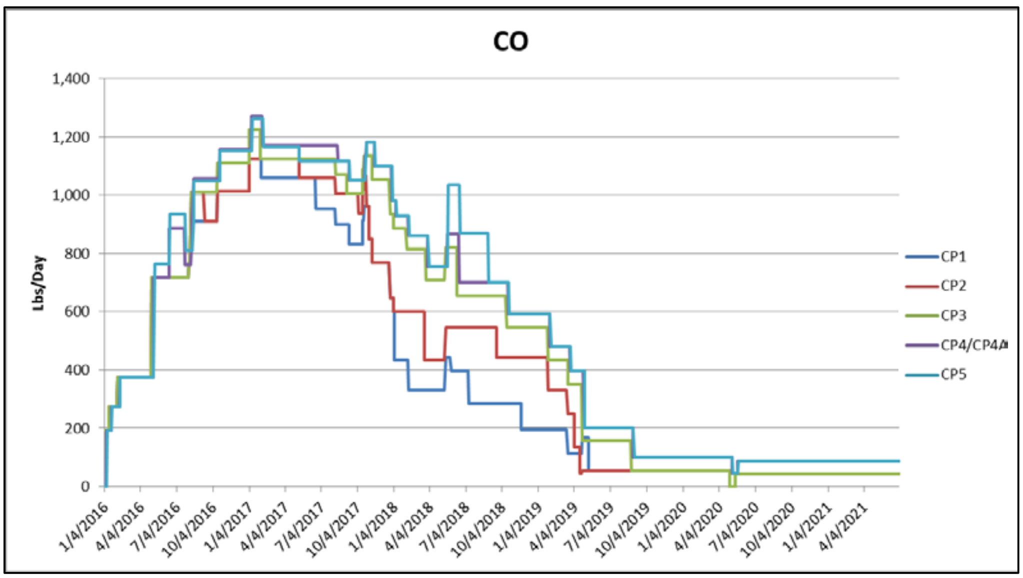

Figure 5-8. Maximum Daily Short-Term Construction-Generated Emissions of Carbon Monoxide by Action Alternative (Pounds per Day)

Impact AQ-2 (CP1): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAMQD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. Stationary sources could include emergency generators powered by diesel engines or pumps, boilers, and major kitchen equipment. No new stationary sources of note are anticipated as part of the project. Pollutant-emitting replacement equipment would be anticipated to be similar to equipment presently in operation.

Area sources include gas-fired building heating and hot water equipment, landscape maintenance equipment, and architectural coatings (paints, lacquers) used in maintenance. Area-source increases would be anticipated to be negligible.

After completion of the dam raise, the principal sources of long-term emissions would be mobile sources; an increase in vehicle trips would result from increased recreational activity at Shasta Lake and the associated recreation areas. It is assumed that maintenance activity for the dam and recreation areas would not change markedly. No new stationary sources of emissions would be anticipated as part of the project.

Enlarging Shasta Dam would include facilities to ensure that at least the existing recreation capacity is maintained. CP1would affect recreation participation by increasing the reservoir's surface area and decreasing reservoir draw-down during the peak recreation season. Table 5-5 compares user days (visitor days) for each of the CPs to existing and future conditions. The Modeling Appendix provides additional information on recreational visitation estimates.

Table 5-5. Average Annual Predicted Increase in User Days [1]

Item	CP1	CP2	CP3	CP4	CP4A	CP5
Existing Conditions						
Increase in user days per year (thousands)	78	164	216	363	308	199
Future Conditions						
Increase in user days per year (thousands)	89	134	205	370	259	175

Note:
[1] All alternatives are to include features to, at minimum, maintain existing Shasta Lake recreation capacity.

Key:
CP = Comprehensive Plan

The increase in recreational opportunities and visitor days would generate vehicle trips for the travel of visitors to and from the Shasta Lake area. Increased trip generation and vehicle emissions were calculated using CalEEMod and the following assumptions:

- The average visitor stay is 2.5 days.

- The average number of visitors per vehicle is 2.5.
- The recreation season for most visitors is 180 days.
- The average one-way trip distance for visitors is 25 miles.
- The first year of operations is expected to be 2015 or later.

With these assumptions and 78,000 increased visitor days under existing conditions from Table 5-5, there would be an increase of an average of 138 one-way trips per day for CP1 under existing conditions. With these assumptions and 89,000 increased visitor days under future conditions from Table 5-5, there would be an increase of an average of 158 one-way trips per day for CP1 under future conditions.

The results of the emissions calculations are shown in Table 5-6. Anticipated emissions would be less than the SCAQMD significance thresholds.

Table 5-6. Operations Emissions for Shasta Dam Raise, 2015 – CP1

Activity	Emissions—pounds per day						
	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
Existing Conditions							
Vehicle trips for increase in recreational visitors	1.1	3.6	0.1	1.9	0.1	-	7.8
Future Conditions							
Vehicle trips for increase in recreational visitors	1.2	4.1	0.1	2.2	0.1	-	8.9

Note:
Totals may not add due to rounding.

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh. = exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases

Based on the above analysis, operation under CP1 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD Level A thresholds. Consequently, long-term emissions during project operation under CP1 would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-3 (CP1): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

Pollutants of concern for exposure of sensitive receptors include CO, PM_{10} and $PM_{2.5}$, and TACs. Local exposure of CO may occur near severe congestion on major roadways. The project is not anticipated to generate areas of severe roadway congestion, nor would the project locate receptors near major roadways; no local CO impact would occur.

Sensitive receptors could be exposed to substantial amounts of PM_{10} and $PM_{2.5}$ if receptors were located near large areas of grading or earthmoving and dust generation was not controlled. Similarly, substantial exposure to particulates and other smoke-borne pollutants could result if receptors were near areas where cleared brush would be burned. There are no sensitive receptors near the dam raise areas; however, there may be sensitive receptors near the some of the lands that would be cleared before inundation by the expanded reservoir. Dust control measures would be required for all land clearing activities; these measures would prevent most PM_{10} and $PM_{2.5}$ from reaching sensitive receptors. Similarly, smoke control measures would be required by SCAQMD Rule 2:7. The impact of exposure of sensitive receptors to PM_{10} and $PM_{2.5}$ would be less than significant.

The principal TAC of concern for project construction is diesel PM. Diesel PM would be generated in the exhaust of diesel engine construction equipment. The largest concentration of diesel engines would be located at the dam raise site. There are no sensitive receptors within one-half mile of the dam site, and sensitive receptors would not be exposed to diesel PM from that source. Diesel equipment would be used for land clearing operations, and there may be sensitive receptors near the land clearing. The dose to which receptors are exposed is the primary factor used to determine health risk (i.e., potential exposure to TAC emission levels that exceed applicable standards). Dose is a function of the concentration of a substance or substances in the environment and the duration of exposure to the substance. Dose is positively correlated with time, meaning that a longer exposure period would result in a higher exposure level for the maximally exposed individual. Thus, the risks estimated for a maximally exposed individual are higher if a fixed exposure occurs over a longer period of time. According to the Office of Environmental Health Hazard Assessment, health risk assessments, which determine the exposure of sensitive receptors to TAC emissions, should be based on a 70-year exposure period; however, such assessments should be limited to the period/duration of activities associated with the project. Thus, because the use of off-road construction equipment would be limited to a few days near any sensitive receptor, short-term construction activities would not result in exposure of sensitive receptors to substantial TAC emissions.

Project implementation is not expected to result in the operation of any new significant sources of TAC emissions after construction is complete. Thus, short-term construction and long-term operational sources would not expose sensitive receptors to substantial TAC concentrations. As a result, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP1): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

The occurrence and severity of odor impacts depend on numerous factors: the nature, frequency, and intensity of the source; wind speed and direction; and the presence of sensitive receptors. Although offensive odors rarely cause any physical harm, they still can be very unpleasant, leading to considerable distress and often generating citizen complaints to local governments and regulatory agencies.

Diesel exhaust has some odor, but it dissipates rapidly from the source with an increase in distance. There are no sensitive receptors immediately adjacent to the project site and people would not be exposed to substantial odors in that area. At other work sites, construction equipment use would be intermittent and temporary, resulting in an odor impact that would be less than significant.

Project implementation would not develop any major sources of odor. The project does not include one of the common types of facilities that are known to produce odors such as a landfill or a coffee roaster. Thus, short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact AQ-5 (CP1): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction Gravel augmentation and habitat restoration in the upper Sacramento River proposed under CP4, CP4A, and CP5 would not be implemented under CP1. No other project construction or long-term operation activities that would affect emissions of criteria air pollutants and precursors are planned in the Shasta Dam-to-Red Bluff area under CP1. Therefore, no impact would occur.

Gravel augmentation and habitat restoration (proposed under CP4, CP4A, and CP5, as described below) would not be implemented under CP1. No new facilities would be constructed below Shasta Dam under this alternative, and no changes in Reclamation’s existing facilities or operations would occur that would directly or indirectly result in any increases in criteria air pollutant emissions in this portion of the primary study area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP1; therefore, potential effects in those geographic regions are not discussed further in this EIS.

Global Study Area

Impact AQ-6 (CP1): Generation of Greenhouse Gases Project construction and operational activities would result in emission of a less than significant quantity of GHGs. Overall, implementation of CP1 would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

There are no established quantitative criteria under CEQA for determining a significant impact related to GHG emissions. The criteria suggested by various agencies principally address long-term emissions, and not the relatively short-term emissions of construction activities. One of the more commonly suggested mass emissions thresholds is 25,000 MT CO_2e per year. This value has been selected because it is the threshold established for mandatory emissions reporting for most sources in California under AB 32. Due to a longer than usual period of construction, construction-generated emissions are amortized over the lifetime of the project and added to operational emissions to determine the overall level of GHG generation. Based on the modeling conducted, construction of CP1 would result in 3,319 MT CO_2e/year amortized over the project lifetime.

GHG emissions of sequestered carbon in removed vegetation were calculated at 3,156 MT CO_2e per year for CP1. This calculation assumes that all vegetation removal, overstory removal, and relocation acreages (370 acres total) would be covered in 70-year-old stands of forest vegetation (Ponderosa pine, Douglas-fir, montane hardwood-conifer, and montane hardwood forest) and that all above-ground vegetation would be disposed of in a manner that releases the sequestered carbon into the atmosphere. All 370 acres would not be covered with 70-year forest as used in the model (ages would vary) or release all carbon to the atmosphere. Also, most utilities would be relocated in roadways, but separate relocation (and additional disturbance) was assumed in the estimated relocation acreages. This approach was applied to ensure that underestimating would not occur.

With implementation of CP1, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated CO_2e emissions of 296 MT/year under existing conditions and 337 MT/year under future conditions based on the same assumptions described above (Table 5-5). Increasing the size of Shasta Dam and Shasta Lake would result in the ability to increase hydropower generation at Shasta generating facilities. Generation of electricity by hydropower reduces the need for fossil-fuel generation of electricity and the GHG emissions that would occur with that generation.

For existing conditions, raising Shasta Dam by 6.5 feet and implementing the operational strategy for CP1 would result in a net increase in CVP/SWP power generation of 3 gigawatt-hours (GWh) [1] per year (Table 5-7). This net generation estimate accounts for the energy required for pumping the increased water supplies. Fossil-fuel generation of 3 GWh of energy would produce an estimated 2,700 MT of CO_2e, also shown in Table 5-7. Therefore, the increased generation of electricity at Shasta Dam in the near term would reduce the need to build facilities for fossil-fueled generation of 3 GWh per year in the global study area.

For future conditions, however, raising Shasta Dam by 6.5 feet and implementing the operational strategy for CP1 would result in a net decrease in CVP/SWP power generation of 3 GWh per year (Table 5-7). Fossil-fuel generation of 3 GWh of energy would produce an estimated 2,700 MT of CO_2e, also shown in Table 5-7. Therefore, the overall net generation decrease would increase the need to build facilities for fossil-fueled generation of 3 GWh per year in the global study area.

Table 5-7. Average Annual Hydropower CVP/SWP Generation

Item	CP1	CP2	CP3	CP4	CP4A	CP5
Existing Condition (2005)						
Net increased generation (GWh/year)	3	14	66	70	48	21
CO_2e displaced (1,000 metric tons)	2.7	12.5	59.0	62.5	42.8	18.7
Future Condition (2030)						
Net increased generation (GWh/year)	(3)	1	65	64	33	1
CO_2e displaced (1,000 metric tons)	(2.7)	0.9	58.1	57.1	29.4	0.9

Key:
CO_2e = carbon dioxide equivalent
CP = Comprehensive Plan
GWh/year = gigawatt-hours per year

The results of the above analysis show that CP1 would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam for existing conditions. The results of the above analysis show that CP1 would result in short-term emissions of GHG for the years of construction, followed by a long-term effect of GHG increase for future conditions. The GHG emissions from construction activities would be temporary in duration and mitigated to the extent feasible; therefore, such emissions would not conflict with State or

[1] Net power generation values throughout this chapter account for providing in-kind power to offset reduced generation at Pit 7 Dam and related facilities. Net power generation values were rounded to the nearest gigawatt-hour in air quality evaluations.

regional planning efforts or emit GHG in excess of mandatory reporting standards. GHG emissions from long-term operations would likely have a net benefit as a result of increased hydroelectric generation and would thus also not conflict with planning efforts or mandatory reporting thresholds. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

In addition to the effects described above, the loss of vegetation presently in the area that would be inundated would likely result in a loss of CO_2 absorption by that vegetation, as well as increased emissions of decomposing material present in the lake as a result of increased volume. There may be some offset to this effect with increased surface area of Shasta Lake for absorption. These effects are speculative and infeasible to quantify at this time.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

Shasta Lake and Vicinity

Impact AQ-1 (CP2): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction could result in short-term emissions (e.g., ROG, NO_x, and PM) that exceed applicable SCAQMD thresholds. This conclusion is based on detailed calculations of estimated emissions for project elements and the simultaneous occurrence thereof. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

CP2 includes a dam raise of 12.5 feet. This impact would be similar to Impact AQ-1 (CP1) as the same type of construction equipment and activities would be involved. Emissions were calculated as described above in Section 5.3.1, “Methods and Assumptions.” The results are shown in Table 5-8 for individual project elements. (All air quality modeling inputs and outputs for the CPs are presented in Attachment 1 to the *Air Quality and Climate Technical Report*.) As shown in Table 5-8 (similar to CP1), ROG, NO_x, and PM emissions for several of the individual project elements could exceed applicable Shasta County thresholds, which would result in a significant impact. As shown in Figures 5-2 to 5-8, maximum daily emissions (lb/day) for CP2 (similar to CP1), could reach much higher levels based on the worst-case simultaneous construction of project elements as shown in detail in Attachment 1 to the *Air Quality and Climate Change Technical Report*. For the same reasons as described for CP1, this impact would be significant. Mitigation for this impact is proposed in Section 5.3.5.

Table 5-8. Summary of Daily Short-Term Construction-Generated Emissions by Project Element (Pounds per Day) – CP2 [1]

Project Element for 12.5-Foot Raise (Activities)	ROG	NOx	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
UPRR Doney Creek Bridge	20	140	8	34	7	5	82
Left Wing Dam	18	138	7	165	6	18	106
Main Concrete Dam	20	138	8	26	2	4	90
Outlet Works	13	138	5	26	5	4	53
Pit River Bridge Pier 3 and 4 Protection	15	138	6	26	5	4	66
Powerplant and Penstocks	12	138	4	26	4	4	48
Railroad Realignment	12	138	4	159	4	17	53
Right Wing Dam	11	138	3	54	3	7	45
Sacramento River UPRR 2nd Crossing	28	141	12	35	11	5	121
Spillway	27	139	11	26	10	4	113
TCD Modifications	20	138	8	26	8	4	82
Visitor Center Replacement	10	138	3	43	3	6	41
Vehicular Bridges	24	155	10	34	9	5	110
Reservoir Clearing	35	260	12	27	11	4	112
Dikes	28	138	12	902	11	91	100
Buildings/Facilities – Recreation	40	141	20	1,483	18	150	166
Roads [2]	28	138	12	588	11	60	102
Utilities	18	138	7	26	6	4	70

Notes:
[1] Totals may not add due to rounding
[2] Quantities modeled are greater than Environmental Impact Statement road quantities

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh.= exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
TCD = temperature control device
UPRR = Union Pacific Railroad

Impact AQ-2 (CP2): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be the same as Impact AQ-2 (CP1) for stationary and area sources and similar to Impact AQ-2 (CP1) for mobile sources. With CP2, there would be an annual increase of 164,000 and 134,000 visitor days under existing and future conditions, respectively, as was shown in Table 5-5, resulting in 291 and 238 average daily trips under existing and future conditions, respectively. The associated daily emissions are shown in Table 5-9.

Based on the above analysis, operation under CP2 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD Level A thresholds. Consequently, long-term emissions during project operation under CP2 would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 5-9. Operations Emissions for Shasta Dam Raise, 2015 – CP2

Activity	Emissions – pounds per day						
	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
Existing Conditions							
Vehicle trips for increase in recreational visitors	2.2	7.6	0.2	4.0	0.2	0.1	16.5
Future Conditions							
Vehicle trips for increase in recreational visitors	1.8	6.2	0.2	3.3	0.2	0.1	13.5

Note:
Totals may not add due to rounding.

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh. = exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases

Impact AQ-3 (CP2): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP2): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact AQ-5 (CP2): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction Gravel augmentation and habitat restoration in the upper Sacramento River proposed under CP4, CP4A, and CP5 would not be implemented under CP2. No other project construction or long-term operation activities that would affect emissions of criteria air pollutants and precursors are planned in the Shasta Dam-to-Red Bluff area under CP2. Therefore, no impact would occur.

This impact would be the same as Impact AQ-5 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP2; therefore, potential effects in those geographic regions are not discussed further in this EIS.

Global Study Area
Impact AQ-6 (CP2): Generation of Greenhouse Gases Project construction and operational activities would result in emission of a less than significant quantity of GHGs. Overall, implementation of CP2 would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

This impact would be similar to Impact AQ-6 (CP1) for construction and operations. Based on the modeling conducted, construction of CP2 would result in 3,807 MT CO_2e/year amortized over the project lifetime. GHG emissions of sequestered carbon in removed vegetation were calculated at 5,031 MT CO_2e per year for CP2 (590 acres total). Increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated CO_2 emissions of 622 and 507 MT CO_2e per year for existing conditions and future conditions, respectively.

For existing conditions, raising Shasta Dam by 12.5 feet and implementing the operational strategy for CP2 would result in a net increase in CVP/SWP power generation of 14 GWh per year (Table 5-7). Fossil-fuel generation of 14 GWh of energy would produce an estimated 12,500 MT CO_2e, also shown in Table 5-7. Thus, CP2 would reduce the need to build facilities for fossil-fueled generation of 14 GWh per year in the global study area.

For future conditions, raising Shasta Dam by 12.5 feet and implementing the operational strategy for CP2 would result in a net increase in CVP/SWP power generation of 1 GWh per year (Table 5-7). Fossil-fuel generation of 1 GWh of energy would produce an estimated 900 MT of CO_2e, also shown in Table 5-7.

Therefore, the overall net generation increase would reduce the need to build facilities for fossil-fueled generation of 1 GWh per year in the global study area.

Thus, the results of the above analysis show that CP2 would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam for existing conditions. The results of the above analysis show that CP2 would result in short-term emissions of GHG for the years of construction, followed by a long-term effect of GHG increase for future conditions. Considering construction emissions, the magnitude of the GHG "savings" for each year of operation would be approximately 3,040 MT CO_2e for existing conditions and a GHG "deficit" of 8,400 MT CO_2e for future conditions amortized over the project lifetime. The GHG emissions from construction activities would be temporary in duration and mitigated to the extent feasible; therefore, such emissions would not conflict with State or regional planning efforts or emit GHG in excess of mandatory reporting standards. GHG emissions from long-term operations would likely not conflict with planning efforts or mandatory reporting thresholds. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Agricultural Water Supply

Shasta Lake and Vicinity

Impact AQ-1 (CP3): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction could result in short-term emissions (e.g., ROG, NO_x, and PM) that exceed applicable SCAQMD thresholds. This conclusion is based on detailed calculations of estimated emissions for project elements and the simultaneous occurrence thereof. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

CP3 includes a dam raise of 18.5 feet. This impact would be similar to Impact AQ-1 (CP1) as the same type of construction equipment and activities would be involved. Emissions were calculated as described above in Section 5.3.1, "Methods and Assumptions." The results are shown in Table 5-6 for individual project elements. (All air quality modeling inputs and outputs for the CPs are presented in Attachment 1 to the *Air Quality and Climate Technical Report*.) As shown in Table 5-10 (similar to CP1), ROG, NO_x, and PM emissions for several of the individual project elements could exceed applicable Shasta County thresholds, which would result in a significant impact. As shown in Figures 5-2 to 5-8, maximum daily emissions (lb/day) for CP3 (similar to CP1), could reach much higher levels based on the worst-case simultaneous construction of project elements as shown in detail in Attachment 1 to the *Air Quality and Climate Change Technical Report*. For the same reasons as described for CP1, this impact would be significant. Mitigation for this impact is proposed in Section 5.3.5.

Table 5-10. Summary of Daily Short-Term Construction-Generated Emissions by Project Element (Pounds per Day) – CP3 [1]

Project Element for 18.5-Foot Raise (Activities)	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
UPRR Doney Creek Bridge	20	140	8	34	7	5	82
Left Wing Dam	18	138	7	165	6	18	106
Main Concrete Dam	20	138	8	26	2	4	90
Outlet Works	13	138	5	26	5	4	53
Pit River Bridge Pier 3 and 4 Protection	15	138	6	26	5	4	66
Powerplant and Penstocks	12	138	4	26	4	4	48
Railroad Realignment	12	138	4	159	4	17	53

Buildings/Facilities – Recreation	40	141	20	1,483	18	150	166
Roads [2]	28	138	12	588	11	60	102
Utilities	18	138	7	26	6	4	70

Notes:
[1] Totals may not add due to rounding
[2] Quantities modeled are greater than Environmental Impact Statement road quantities

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh.= exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
TCD = temperature control device
UPRR = Union Pacific Railroad

Impact AQ-2 (CP3): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be the same as Impact AQ-2 (CP1) for stationary and area sources and similar to Impact AQ-2 (CP1 and CP2) for mobile sources. With CP3, there would be an annual increase of 216,000 and 205,000 visitor days under existing and future conditions, respectively, as was shown in Table 5-5, resulting in 384 and 364 average daily trips under existing and future conditions, respectively. The associated daily emissions are shown in Table 5-11. Overall trip levels would be greater than under CP1 and CP2, but emissions would remain below significance thresholds.

Table 5-11. Operations Emissions for Shasta Dam Raise, 2015 – CP3

Activity	Emissions – pounds per day						
	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
Existing Conditions							
Vehicle trips for increase in recreational visitors	2.8	10.0	0.3	5.4	0.3	0.1	21.7
Future Conditions							
Vehicle trips for increase in recreational visitors	2.7	9.5	0.3	5.1	0.3	0.1	20.6

Note:
Totals may not add due to rounding.

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh. = exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases

Based on the above analysis, operation under CP3 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed SCAQMD Level A thresholds. Consequently, long-term emissions during operation under CP3 would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-3 (CP3): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP3): Exposure of Sensitive Receptors to Odor Emissions
Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact AQ-5 (CP3): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction Gravel augmentation and habitat restoration in the upper Sacramento River proposed under CP4, CP4A, and CP5 would not be implemented under CP3. No other project construction or long-term operation activities that would affect emissions of criteria air pollutants and precursors are planned in the Shasta Dam-to-Red Bluff area under CP3. Therefore, no impact would occur.

This impact would be the same as Impact AQ-5 (CP1). No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP3; therefore, potential effects in those geographic regions are not discussed further in this EIS.

Global Study Area
Impact AQ-6 (CP3): Generation of Greenhouse Gases Project construction and operational activities would result in emission of a less than significant quantity of GHGs. Overall, implementation of CP3 would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

This impact would be similar to Impact AQ-6 (CP1) for construction and operations. Based on the modeling conducted, construction of CP3 would result in 4,350 MT CO_2e/year amortized over the project lifetime. GHG emissions of sequestered carbon in removed vegetation were calculated at 7,164 MT CO_2e per year for CP3 (840 acres total). Increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated emissions of 819 and 776 MT CO_2e per year for existing conditions and future conditions, respectively.

For existing conditions, raising Shasta Dam by 18.5 feet and implementing the operational strategy for CP3 would result in a net increase in CVP/SWP power generation of 66 GWh per year, as was shown in Table 5-7. Fossil-fuel generation of 66 GWh of energy would produce an estimated 59,000 MT of CO_2, also shown in Table 5-7. Thus, CP3 would reduce the need to build facilities for fossil-fueled generation of 66 GWh per year in the global study area.

For future conditions, raising Shasta Dam by 18.5 feet and implementing the operational strategy for CP3 would result in a net increase in power generation of 65 GWh per year, as was shown in Table 5-7. Fossil-fuel generation of 65 GWh of energy would produce an estimated 58,100 MT of CO_2, also shown in Table 5-7. Thus, CP3 would reduce the need to build facilities for fossil-fueled generation of 65 GWh per year in the global study area.

Thus, the results of the above analysis show that CP3 would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation would be approximately 46,667 and 45,810 MT CO_2e for existing conditions and future conditions, respectively, considering construction emissions amortized over the project lifetime. The GHG emissions from construction activities would be temporary in duration and mitigated to the extent feasible; therefore, such emissions would not conflict with State or regional planning efforts or emit GHG in excess of mandatory reporting standards. GHG emissions from long-term operations would likely have a net benefit as a result of increased hydroelectric generation and would thus also not conflict with planning efforts or mandatory reporting thresholds. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

Shasta Lake and Vicinity

Impact AQ-1 (CP4 and CP4A): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction
Project construction could result in short-term emissions (e.g., ROG, NO_x, and PM) that exceed applicable SCAQMD thresholds. This conclusion is based on detailed calculations of estimated emissions for project elements and the simultaneous occurrence thereof. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant for CP4 or CP4A.

CP4 and CP4A include a dam raise of 18.5 feet. The impact for CP4 or CP4A would be similar to Impact AQ-1 (CP1) as the same type of construction equipment and activities would be involved. Emissions were calculated as described above in Section 5.3.1, "Methods and Assumptions." The results are shown in Table 5-12 for individual project elements. (All air quality modeling inputs and outputs for the CPs are presented in Attachment 1 to the *Air Quality and Climate Technical Report*.) As shown in Table 5-12 (similar to CP1), ROG, NO_x, and PM emissions for several of the individual project elements could exceed applicable Shasta County thresholds, which would result in a significant impact. As shown in Figures 5-2 to 5-8, maximum daily emissions (lb/day) for CP4 or CP4A (similar to CP1), could reach much higher levels based on the worst-case simultaneous construction of project elements as shown in detail in Attachment 1 to the *Air Quality and Climate Change Technical Report*.

For the same reasons as described for CP1, this impact would be significant for CP4. Mitigation for this impact is proposed in Section 5.3.5.

For the same reasons as described for CP1, this impact would be significant for CP4A. Mitigation for this impact is proposed in Section 5.3.5.

Table 5-12. Summary of Daily Short-Term Construction-Generated Emissions by Project Element (Pounds per Day) – CP4 and CP4A[1]

Project Element for 18.5-Foot Raise (Activities)	ROG	NOx	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
UPRR Doney Creek Bridge	20	140	8	34	7	5	82

Notes:
[1] Totals may not add due to rounding
[2] Quantities modeled are greater than Environmental Impact Statement road quantities

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh.= exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
TCD = temperature control device
UPRR = Union Pacific Railroad

Impact AQ-2 (CP4 and CP4A): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant for CP4 or CP4A.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be similar to AQ-2 (CP1) for stationary, area, and mobile sources. With CP4, there would be an annual increase of 363,000 and 370,000 visitor days under existing and future conditions, respectively, as shown in Table 5-5, resulting in 646 and 658 average daily trips under existing and future conditions, respectively. The associated daily emissions are shown in Table 5-13. Overall trip levels would be greater than under CP1 and CP2, but emissions would remain below significance thresholds.

Table 5-13. Operations Emissions for Shasta Dam Raise, 2015 – CP4 and CP4A

Activity	Emissions—pounds per day						
	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
CP4							
Existing Conditions							
Vehicle trips for increase in recreational visitors	4.8	16.8	0.5	9.0	0.5	0.1	36.5
Future Conditions							
Vehicle trips for increase in recreational visitors	4.9	17.1	0.5	9.2	0.5	0.1	37.2
CP4A							
Existing Conditions							
Vehicle trips for increase in recreational visitors	4.1	14.2	0.4	7.6	0.4	0.1	31.0
Future Conditions							
Vehicle trips for increase in recreational visitors	3.4	12.0	0.4	1.7	0.3	0.1	26.0

Note:
Totals may not add due to rounding.

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh. = exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases

Based on the above analysis, operation under CP4 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed SCAQMD Level A thresholds. Consequently, long-term emissions during operation under CP4 would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

Operation under CP4A would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed SCAQMD Level A thresholds. With CP4A, there would be an annual increase of 308,000 and 259,000 visitor days under existing and future conditions, respectively, as shown in Table 5-5, resulting in 548 and 460 average daily trips under existing and future conditions, respectively. The associated daily emissions are shown in Table 5-13. Overall trip levels would be greater than under CP1 and CP2, but emissions would remain below significance thresholds. Consequently, long-term emissions during operation under CP4A would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-3 (CP4 and CP4A): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP4 and CP4A): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant for CP4 or CP4A.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact AQ-5 (CP4 and CP4A): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction Gravel augmentation proposed for areas along the upper Sacramento River would add to emissions of ROG, NO_X, and PM_{10} from project construction. Habitat restoration activities proposed for the upper Sacramento River would also add ROG, NO_X, and PM_{10} emissions. However, these emissions separately and combined would add negligible amounts to annual emission levels. This impact would be less than significant for CP4 or CP4A.

Gravel augmentation proposed under CP4 or CP4A would add an additional 1 lb/day of ROG, 16 lb/day of NO_X, and 1 lb/day of PM_{10} to project construction emission levels. Emissions from gravel augmentation would be from gravel material hauling consisting of approximately 18 trips per day, 40 miles round trip to sites identified to the south along the Sacramento River. Gravel augmentation would only occur for 2 months out of the year; therefore, these emissions would add negligible amounts to annual emission levels.

Habitat restoration in the upper Sacramento River proposed under CP4 or CP4A would add an additional 6.7 lb/day of ROG, 50.1 lb/day of NO_X, and 12.4 lb/day of PM_{10} to project construction emission levels. During habitat restoration, emissions would be generated from potentially removing vegetation from the Sacramento River's side channel, removing noxious invasive plant species from the area, minor grading, and hauling away waste materials (approximately 25 trips per day). Restoration activities would occur for only 2 months for a total of 44 8-hour work days; therefore, these emissions would add negligible amounts to annual emission levels.

The combined emissions from gravel augmentation and habitat restoration activities for CP4 or CP4A would be 7.7 lb/day of ROG, 76 lb/day of NO_X, and 13.4 lb/day of PM_{10}. These emissions are below SCAQMD's Level A thresholds of 25 lb/day of ROG, 25 lb/day of NO_X, and 80 lb/day of PM_{10}.

This impact would be less than significant for CP4. Mitigation for this impact is not needed, and thus not proposed.

This impact would be less than significant for CP4A. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP4; therefore, potential effects in those geographic regions are not discussed further in this EIS.

Global Study Area

Impact AQ-6 (CP4 and CP4A): Generation of Greenhouse Gases Project construction and operational activities would result in emission of a less-than-significant quantity of GHGs. Overall, implementation of CP4 or CP4A would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant for CP4 or CP4A.

This impact would be similar to Impact AQ-6 (CP1) for construction and operations. Based on the modeling conducted, construction of CP4 or CP4A would result in 5,112 MT CO_2e/year amortized over the project lifetime. GHG emissions of sequestered carbon in removed vegetation were calculated at 7,164 MT CO_2e per year for CP4 and CP4A (840 acres total).

Under CP4, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated emissions of 1,376 and 1,403 MT CO_2e per year for existing conditions and future conditions, respectively. Under CP4A, increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated emissions of 1,168 and 982 MT CO_2e per year for existing conditions and future conditions, respectively.

For existing conditions under CP4, raising Shasta Dam by 18.5 feet and implementing the operational strategy would result in a net increase in CVP/SWP power generation of 70 GWh per year (Table 5-7). Fossil-fuel generation of 70 GWh of energy would produce an estimated 62,500 MT CO_2 (Table 5-7). Thus, CP4 would reduce the need to build facilities for fossil-fueled generation of 70 GWh per year in the global study area.

For future conditions under CP4, raising Shasta Dam by 18.5 feet and implementing the operational strategy would result in a net increase in CVP/SWP power generation of 64 GWh per year (Table 5-7). Fossil-fuel generation of 64 GWh of energy would produce an estimated 57,100 MT CO_2 (Table 5-7). Thus, CP4 would reduce the need to build facilities for fossil-fueled generation of 64 GWh per year in the global study area.

Thus, the results of the above analysis show that CP4 would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation would be approximately 48,848 and 43,421 MT CO_2e for existing conditions and future conditions, respectively, considering construction emissions amortized over the project lifetime.

For existing conditions under CP4A, raising Shasta Dam by 18.5 feet and implementing the operational strategy would result in a net increase in CVP/SWP power generation of 48 GWh per year (Table 5-7). Fossil-fuel generation of 48 GWh of energy would produce an estimated 42,800 MT CO_2 (Table 5-7). Thus, CP4A would reduce the need to build facilities for fossil-fueled generation of 48 GWh per year in the global study area.

For future conditions under CP4A, raising Shasta Dam by 18.5 feet and implementing the operational strategy would result in a net increase in CVP/SWP power generation of 33 GWh per year (Table 5-7). Fossil-fuel generation of 33 GWh of energy would produce an estimated 29,400 MT CO_2 (Table 5-7). Thus, CP4A would reduce the need to build facilities for fossil-fueled generation of 33 GWh per year in the global study area.

Thus, the results of the above analysis show that CP4A would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam. The magnitude of the GHG "savings" for each year of operation would be approximately 29,356 and 16,142 MT CO_2e for existing conditions and future conditions, respectively, considering construction emissions amortized over the project lifetime.

In conclusion, under both CP4 and CP4A, the GHG emissions from construction activities would be temporary in duration and mitigated to the extent feasible; therefore, such emissions would not conflict with State or regional planning efforts or emit GHG in excess of mandatory reporting standards. GHG emissions from long-term operations would likely have a net benefit as a result of increased hydroelectric generation and would thus also not conflict with planning efforts or mandatory reporting thresholds. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

Shasta Lake and Vicinity

Impact AQ-1 (CP5): Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction Project construction could result in short-term emissions (e.g., ROG, NO_x, and PM) that exceed applicable SCAQMD thresholds. This conclusion is based on detailed calculations of estimated emissions for project elements and the simultaneous occurrence thereof. Shasta County is a nonattainment area for the State ozone and PM_{10} standards. Thus, short-term emissions generated during construction could contribute substantially to an existing or projected air quality violation. This impact would be significant.

CP5 includes a dam raise of 18.5 feet. This impact would be similar to Impact AQ-1 (CP1) as the same type of construction equipment and activities would be involved. Emissions were calculated as described above in Section 5.3.1, "Methods and Assumptions." The results are shown in Table 5-14 for individual project elements. (All air quality modeling inputs and outputs for the CPs are presented in Attachment 1 to the *Air Quality and Climate Technical Report*.) As shown in Table 5-14 (similar to CP1), ROG, NO_x, and PM emissions for several of the individual project elements could exceed applicable Shasta County thresholds, which would result in a significant impact. As shown in Figures 5-2 to 5-8, maximum daily emissions (lb/day) for CP5 (similar to CP1), could reach much higher levels based on the worst-case simultaneous construction of project elements as shown in detail in Attachment 1 to the *Air Quality and Climate Change Technical Report*. For the same reasons as described for CP1, this impact would be significant. Mitigation for this impact is proposed in Section 5.3.5.

Table 5-14. Summary of Daily Short-Term Construction-Generated Emissions by Project Element (Pounds per Day) – CP5[1]

Project Element for 18.5-Foot Raise (Activities)	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO

Notes:
[1] Totals may not add due to rounding
[2] Quantities modeled are greater than Environmental Impact Statement road quantities

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh.= exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases
TCD = temperature control device
UPRR = Union Pacific Railroad

Impact AQ-2 (CP5): Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation Long-term project operation is not anticipated to result in ROG, NO_X, PM_{10}, or CO emissions that exceed applicable SCAQMD thresholds. Thus, long-term operational emissions would not be anticipated to violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant.

Long-term operational emissions would come from stationary, area, and mobile sources. This impact would be similar to AQ-2 (CP1) for stationary, area, and mobile sources. With CP5 there would be an annual increase of 199,000 and 175,000 visitor days under existing and future conditions, respectively, as shown in Table 5-5, resulting in 354 and 311 average daily trips under existing and future conditions, respectively. The associated daily emissions are shown in Table 5-15.

Table 5-15. Operations Emissions for Shasta Dam Raise, 2015 – CP5

Activity	Emissions—pounds per day						
	ROG	NO_x	PM_{10} Exh.	PM_{10} Dust	$PM_{2.5}$ Exh.	$PM_{2.5}$ Dust	CO
Existing Conditions							
Vehicle trips for increase in recreational visitors	2.6	9.2	0.3	5.0	0.3	0.1	20.0
Future Conditions							
Vehicle trips for increase in recreational visitors	2.3	8.1	0.3	4.4	0.3	0.1	17.6

Note: Totals may not add due to rounding.

Key:
CO = carbon monoxide
CP = Comprehensive Plan
Exh. = exhaust
NO_X = oxides of nitrogen
$PM_{2.5}$ = fine particulate matter
PM_{10} = respirable particulate matter
ROG = reactive organic gases

Based on the above analysis, operation under CP5 would not result in ROG, NO_X, PM_{10}, or CO emissions that exceed SCAQMD Level A thresholds. Consequently, long-term emissions during operation under CP5 would not violate an air quality standard or contribute substantially to an existing or projected air quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-3 (CP5): Exposure of Sensitive Receptors to Substantial Pollutant Concentrations Neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, or TACs. This impact would be less than significant.

This impact would be the same as Impact AQ-3 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact AQ-4 (CP5): Exposure of Sensitive Receptors to Odor Emissions Short-term construction and long-term operational sources would not expose sensitive receptors to substantial odor emissions. This impact would be less than significant.

This impact would be the same as Impact AQ-4 (CP1) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact AQ-5 (CP5): Short-Term Emissions of Criteria Air Pollutants and Precursors Below Shasta Dam During Project Construction The gravel augmentation proposed for areas along the upper Sacramento River would add to emissions of ROG, NO_X, and PM_{10} from project construction. However, these emissions would add negligible amounts to annual emission levels. This impact would be less than significant.

This impact would be the same as Impact AQ-5 (CP4) and would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta and CVP/SWP Service Areas No effects on climate and air quality are expected to occur in the lower Sacramento River and Delta and CVP/SWP service areas under CP5; therefore, potential effects in those geographic regions are not discussed further in this EIS.

Global Study Area
Impact AQ-6 (CP5): Generation of Greenhouse Gases Project construction and operational activities would result in emission of a less than significant quantity of GHGs. Overall, implementation of CP5 would result in beneficial effects on GHG emissions because generation of electricity at Shasta Dam would increase. This impact would be less than significant.

This impact would be similar to Impact AQ-6 (CP1) for construction and operations. Based on the modeling conducted, construction of CP5 would result in 5,199 MT CO_2e/year amortized over the project lifetime. GHG emissions of sequestered carbon in removed vegetation were calculated at 7,164 MT CO_2e per year for CP5 (840 acres total). Increased activity by recreational visitors to the Shasta Lake area would result in additional vehicle trips and estimated emissions of 754 MT CO_2e per year.

For existing conditions, raising Shasta Dam by 18.5 feet and implementing the operational strategy for CP5 would result in a net increase in CVP/SWP power generation of 21 GWh per year, as was shown in Table 5-7. Fossil fuel generation of 21 GWh of energy would produce an estimated 18,700 MT CO_2, also shown in Table 5-7. Thus, CP5 would reduce the need to build facilities for fossil-fueled generation of 21 GWh per year in the global study area.

For future conditions, raising Shasta Dam by 18.5 feet and implementing the operational strategy for CP5 would result in a net increase in CVP/SWP power generation of 1 GWh per year, as was shown in Table 5-7. Fossil fuel generation of 1 GWh of energy would produce an estimated 900 MT CO_2, also shown in Table 5-7. Thus, CP5 would reduce the need to build facilities for fossil-fueled generation of 1 GWh per year in the global study area.

Thus, the results of the above analysis show that CP5 would result in short-term emissions of GHG for the years of construction, followed by long-term benefits of GHG reduction through generation of electricity at Shasta Dam for existing conditions. The magnitude of the GHG "savings" for each year of operation would be approximately 5,583 MT CO_2e for existing conditions and a GHG "deficit" of 12,126 MT CO_2e for future conditions considering construction emissions amortized over the project lifetime. The GHG emissions from construction activities would be temporary in duration and mitigated to the extent feasible; therefore, such emissions would not conflict with State or regional planning efforts or emit GHG in excess of mandatory reporting standards. GHG emissions from long-term operations would likely not conflict with planning efforts or mandatory reporting thresholds. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

5.3.5 Mitigation Measures

Table 5-16 presents a summary of mitigation measures for air quality and climate.

Table 5-16. Summary of Mitigation Measures for Air Quality and Climate Change

		No-Action Alternative	CP1	CP2	CP3	CP4	CP4A	CP5
Impact AQ-1: Short-Term Emissions of Criteria Air Pollutants and Precursors at Shasta Lake and Vicinity During Project Construction	LOS before Mitigation	NI	S	S	S	S	S	S
	Mitigation Measure	None required.	Mitigation Measure AQ-1: Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels.					
	LOS after Mitigation	NI	SU	SU	SU	SU	SU	SU
Impact AQ-2: Long-Term Emissions of Criteria Air Pollutants and Precursors During Project Operation	LOS before Mitigation	LTS	LTS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.					
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS	LTS
Impact AQ-3: Exposure of Sensitive Receptors to Substantial Pollutant Concentrations	LOS before Mitigation	NI	LTS	LTS	LTS	LTS	LTS	LTS
	Mitigation Measure	None required.	None needed; thus, none proposed.					
	LOS after Mitigation	NI	LTS	LTS	LTS	LTS	LTS	LTS

	Mitigation Measure	None required.	None needed; thus, none proposed.					
	LOS after Mitigation	LTS	LTS	LTS	LTS	LTS	LTS	LTS

Key:
CP = Comprehensive Plan
LOS = level of significance
LTS = less than significant
NA = not applicable
NI = no impact
S = significant
SU = significant and unavoidable

No-Action Alternative

No mitigation measures are needed for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts AQ-2 (CP1), AQ-3 (CP1), AQ-4 (CP1), AQ-5 (CP1), and AQ-6 (CP1). Mitigation is provided below for the remaining impact of CP1 on air quality.

Mitigation Measure AQ-1 (CP1): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels Reclamation (referred to below as "the project applicant" or "the applicant") and its primary construction contractor(s) will implement the mitigation measures listed below to reduce emissions of criteria air pollutants and precursors generated during construction. In addition, any reasonable Best Management Practices recommended by SCAQMD during construction permitting would be implemented by Reclamation and its primary construction contractor(s).

Standard Mitigation Measures The following SCAQMD SMMs are applicable to all projects.

PM_{10} Controls

- Alternatives to open burning of vegetative material on the project site shall be used by the project applicant unless otherwise deemed infeasible by SCAQMD. Among suitable alternatives is chipping, mulching, or conversion to biomass fuel.

- The applicant shall be responsible for ensuring that all adequate dust control measures are implemented in a timely and effective manner during all phases of project development and construction.

- All material excavated, stockpiled, or graded shall be sufficiently watered to prevent fugitive PM_{10} dust emissions from leaving the property boundaries and causing a public nuisance or a violation of an ambient air standard. Watering shall occur at least twice daily with complete site coverage, preferably in the mid-morning and after work is completed each day.

- All areas (including unpaved roads) with vehicle traffic shall be watered periodically or dust palliatives applied for stabilization of fugitive PM_{10} dust emissions.

- All on site vehicles shall be limited to a speed of 20 miles per hour on unpaved roads developed for construction.

- All land clearing, grading, earthmoving, or excavation activities on a project shall be evaluated and suspended when winds exceed 20 miles per hour if particulate matter becomes airborne.

- All inactive portions of the development site shall be seeded and watered until a suitable grass cover is established.

- The applicant shall be responsible for applying Shasta County Department of Public Works-approved nontoxic soil stabilizers (according to manufacturers' specifications) to all inactive construction areas (previously graded areas that remain inactive for 96 hours) in accordance with the Shasta County Grading Ordinance.

- All trucks hauling dirt, sand, soil, or other loose material shall be covered or maintain at least 2 feet of freeboard (i.e., minimum vertical distance between top of the load and the trailer) in accordance with the requirements of California Vehicle Code Section 23114. This provision shall be enforced by local law enforcement agencies.

- All material transported off site shall be either sufficiently watered or securely covered to prevent a public nuisance.

- During initial grading, earthmoving, or site preparation, the project shall be required to construct a paved (or dust palliative-treated) apron, at least 100 feet in length, onto the project site from the adjacent paved road(s).

- Paved streets adjacent to the development site shall be swept or washed at the end of each day to remove excessive accumulations of silt and/or mud that may have accumulated as a result of activities on the development site.

- Adjacent paved streets shall be swept (water sweeper with reclaimed water recommended) at the end of each day if substantial volumes of soil materials have been carried onto adjacent public paved roads from the project site.

- Wheel washers shall be installed where project vehicles and/or equipment enter and/or exit onto paved streets from unpaved roads. Vehicles and/or equipment shall be washed before each trip.

- Before final occupancy, the applicant shall reestablish ground cover on the construction site through seeding and watering in accordance with the Shasta County Grading Ordinance.

Streets

- The project shall provide for temporary traffic control as appropriate during all phases of construction to improve traffic flow as deemed appropriate by the Shasta County Department of Public Works and/or the California Department of Transportation.

- Construction activities shall be scheduled that direct traffic flow to off-peak hours as much as practicable.

Energy Conservation For any new or relocated structures, the following features will be incorporated as much as practicable:

- The project shall provide for the use of energy-efficient lighting, including controls, and process systems such as water heaters, furnaces, and boiler units.

- The project shall use a central water heating system featuring the use of low-NO_X hot water heaters.

Best Available Mitigation Measures None of the SCAQMD BAMMs are appropriate for the project. Therefore, the following measures will be incorporated into the project:

- The project applicant will prepare and submit to SCAQMD for approval a plan demonstrating that the heavy-duty (equal to or greater than 50 horsepower) off-road vehicles to be used in the construction project, including owned, leased, and subcontractor vehicles, shall achieve a project-wide fleet-average 20 percent NO_X reduction and 45 percent particulate reduction compared to the most recent ARB fleet average at time of construction. Acceptable options for reducing emissions may include use of late-model engines, low-emission diesel products, alternative fuels, engine retrofit technology, after-treatment products, and/or other options as they become available.

- The project applicant will locate all construction equipment maintenance and staging areas at the farthest distance possible from nearby sensitive land uses.

- Idling of diesel-powered vehicles and equipment will not be permitted during periods of nonactive vehicle use. Diesel-powered engines will not be allowed to idle for more than 5 consecutive minutes in a 60-minute period when the equipment is not in use, occupied by an operator, or otherwise in motion, except under the following conditions:

- When equipment is forced to remain motionless because of traffic conditions or mechanical difficulties over which the operator has no control
- When it is necessary to operate auxiliary systems installed on the equipment, only when such system operation is necessary to accomplish the intended use of the equipment
- To bring the equipment to the manufacturer's recommended operating temperature
- When the ambient temperature is below 40ºF or above 85ºF
- When equipment is being repaired

Implementation of the above mitigation measure would reduce ROG, NO_X, and PM_{10} emissions from on-site heavy-duty equipment exhaust by approximately 5 percent, 20 percent, and 45 percent, respectively, and fugitive PM_{10} dust emissions by 75 percent. However, NO_X emissions generated during construction would still exceed the SCAQMD Level B threshold of 137 lb/day. Thus, this impact would be significant and unavoidable.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation is needed for Impacts AQ-2 (CP2), AQ-3 (CP2), AQ-4 (CP2), AQ-5 (CP2), and AQ-6 (CP2). Mitigation is provided below for the remaining impact of CP2 on air quality.

Mitigation Measure AQ-1 (CP2): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

No mitigation is needed for Impacts AQ-2 (CP3), AQ-3 (CP3), AQ-4 (CP3), AQ-5 (CP3), and AQ-6 (CP3). Mitigation is provided below for the remaining impact of CP3 on air quality.

Mitigation Measure AQ-1 (CP3): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation is needed for Impacts AQ-2 (CP4 and CP4A), AQ-3 (CP4 and CP4A), AQ-4 (CP4 and CP4A), AQ-5 (CP4 and CP4A), and AQ-6 (CP4 and CP4A). Mitigation is provided below for the remaining impact of CP4 and CP4A on air quality.

Mitigation Measure AQ-1 (CP4 and CP4A): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation is needed for Impacts AQ-2 (CP5), AQ-3 (CP5), AQ-4 (CP5), AQ-5 (CP5), and AQ-6 (CP5). Mitigation is provided below for the remaining impact of CP5 on air quality.

Mitigation Measure AQ-1 (CP5): Implement Standard Measures and Best Available Mitigation Measures to Reduce Emissions Levels This mitigation measure is identical to Mitigation Measure AQ-1 (CP1). For the reasons described above under Mitigation Measure AQ-1 (CP1), this impact would be significant and unavoidable.

5.3.6 Cumulative Effects

Chapter 3, “Considerations for Describing the Affected Environment and Environmental Consequences,” discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, “Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area,” lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. The action alternatives would not combine with any of the quantitatively assessed projects listed in Table 3-1 to have a cumulatively considerable impact on air quality or climate change; therefore, this section evaluates only those projects listed in Table 3-1 that are qualitatively considered in this EIS.

Past impacts on air quality and GHG include land use changes, construction, fossil fuel uses, and transportation emissions. Reasonably foreseeable future projects in the primary study that may affect air quality and GHG include the Moody Flats Quarry, the Mountain Gate at Shasta Mixed-Use Area Plan and the Antlers Bridge Replacement.

The effects of climate change on operations at Shasta Lake could potentially result in changes downstream. As described in the Climate Change Appendix, climate change could result in higher reservoir releases in the future due to an increase in winter and early spring inflow into the lake from high intensity storm events. The change in reservoir releases could be necessary to manage for flood events resulting from these potentially larger storms. The potential increase in releases from the reservoir could lead to long-term changes in downstream channel equilibrium.

Growth is likely to continue to occur throughout the primary and extended study areas and some future projects that could generate emissions are reasonably foreseeable, but emissions associated with these projects would be associated primarily with short-term construction activities that would cease once the projects are complete. In addition, emissions associated with one or a few projects would not be considered substantial such that a cumulative impact would occur to a cumulative, global issue such as climate change. Thus, increases in emissions of criteria air pollutants or precursors in the primary and extended study areas are unlikely to make a cumulatively considerable contribution to an overall cumulatively significant impact on air quality. For cumulative effects of climate change on other resource areas, please see the “Cumulative Effects” sections in other chapters of this EIS.

Shasta Lake and Vicinity and Upper Sacramento River (Shasta Dam to Red Bluff)

Under the project alternatives (CP1 – CP5), construction activities would result in short-term emissions of ROG, NO_X, and PM_{10} that without mitigation would exceed applicable SCAQMD thresholds. After implementing the best available and all feasible mitigation measures, ROG and PM_{10} emissions would not exceed applicable thresholds; and in combination with past, present, and reasonably foreseeable future projects, would not result in an overall cumulatively significant impact. Therefore, with mitigation, these emissions would not be cumulatively considerable. Emissions of NO_X, however, would still exceed the applicable SCAQMD threshold after implementation of the BAMMs. These emissions would be cumulatively considerable, and this would be a cumulatively significant and unavoidable impact.

Operation of any of the action alternatives would not result in cumulatively considerable emissions of ROG, NO_X, and PM_{10}. Also, neither short-term construction nor long-term operational sources would expose sensitive receptors to substantial concentrations of CO, PM_{10}, $PM_{2.5}$, TACs, or odors. None of these emissions would be cumulatively considerable contributions to a significant cumulative impact of ROG, NO_X, and PM_{10}.

Lower Sacramento River and Delta and CVP/SWP Service Areas

The project alternatives would not generate any short-term or long-term air pollutant emissions in the extended study area. Therefore, there would be no cumulative air quality impact.

Global Study Area—Climate Change

As discussed in Section 5.1, "Affected Environment," of this chapter, climate change is a global phenomenon. All GHG emissions are considered cumulative. The impact analyses for Impacts AQ-6 (CP1), AQ-6 (CP2), AQ-6 (CP3), AQ-6 (CP4 and CP4A), and AQ-6 (CP5), in Section 5.3.4, "Direct and Indirect Effects," of this chapter are cumulative analyses. All project alternatives (CP1–CP5) would result in short-term cumulative impacts that would be less than the suggested significance threshold for this cumulative effect, and therefore are considered to not make a cumulatively considerable incremental contribution to a significant cumulative impact, and would have beneficial long-term effects. For cumulative effects of climate change on other resource areas, please see the "Cumulative Effects" sections in other chapters of this EIS.

Chapter 6 Hydrology, Hydraulics, and Water Management

6.1 Affected Environment

This affected environment section first presents background information and then describes storage and diversion facilities, and hydrology, hydraulics, and water management (H&H), including flood management, south Delta water levels, and groundwater resources. For a more in-depth description of the affected environment, see the *Hydrology, Hydraulics, and Water Management Technical Report*.

6.1.1 Storage Facilities

Facilities described below include Shasta Dam and Powerplant, Keswick Dam and Powerplant, and Anderson-Cottonwood Irrigation District Diversion Dam.

Shasta Lake and Vicinity

This section describes storage facilities in the Shasta Lake area.

Shasta Dam and Powerplant Shasta Dam is a curved, gravity-type, concrete structure that rises 533 feet above the streambed with a total height above the foundation of 602 feet. The dam has a crest width of about 41 feet and a length of 3,460 feet. Shasta Reservoir has a storage capacity of 4,550,000 acre-feet, and water surface area at full pool of 29,600 acres. Maximum seasonal flood management storage space in Shasta Reservoir is 1.3 million acre-feet (MAF). Releases from Shasta Dam can be made through the powerplant, over the spillway, or through the river outlets. The powerplant has a maximum release capacity of nearly 20,000 cubic feet per second (cfs), the river outlets can release a maximum of 81,800 cfs at full pool, and the maximum release over the drum-gated spillway is 186,000 cfs.

Upper Sacramento River (Shasta Dam to Red Bluff)

This section describes storage facilities along the Upper Sacramento River.

Keswick Dam and Powerplant Keswick Dam is about 9 miles downstream from Shasta Dam. In addition to regulating outflow from the dam, Keswick Dam controls runoff from 45 square miles of drainage area. Keswick Dam is a concrete, gravity-type structure with a spillway over the center of the dam. The spillway has four 50- by 50-foot fixed wheel gates with a combined discharge capacity of 248,000 cfs at full or full pool elevation (587 feet). Storage capacity below the top of the spillway gates at full pool is 23,800 acre-feet. The powerplant has a nameplate generating capacity of 105,000 kilowatts and can pass about 15,000 cfs at full pool.

6.1.2 Diversion Facilities

In the Klamath Basin, the Clear Creek Tunnel diverts water from Lewiston Reservoir (below Trinity Reservoir) to Whiskeytown Reservoir. The Spring Creek Tunnel then diverts water from Whiskeytown Reservoir to Keswick Reservoir on the Sacramento River. These two diversions bring water from the Klamath Basin into the Sacramento Basin; the water is used for power generation, water temperature regulation and local water supplies.

Below Keswick Dam, two facilities divert flows from the Sacramento River, the Anderson-Cottonwood Irrigation District Diversion Dam and Red Bluff Pumping Plant (RBPP). The primary purpose of these two facilities is to divert water into canals for local agricultural use.

In the Delta, the CVP and SWP primarily make diversions through two pumping plants, the CVP C.W. “Bill” Jones Pumping Plant (Jones) and the SWP Harvey O. Banks Pumping Plant (Banks). These two pumping plants supply water to the CVP/SWP service areas south of the Delta. Although other diversion facilities are located between RBPP and the Delta, they would have less of an effect on project operations than those discussed above.

6.1.3 Hydrology and Hydraulics

The Sacramento Valley contains the Sacramento, Feather, and American river basins, covering an area of more than 24,000 square miles in the northern portion of the Central Valley. The Sacramento Valley comprises four distinct areas; the Sacramento River headwater that includes the McCloud River, Pit River, and Sacramento River in the north; the Delta in the south; the Sierra Nevada Mountains and Cascade Ranges in the east; and the Coast Range and Klamath Mountains in the west.

Shasta Lake and Vicinity

The most northern portion of the Sacramento River basin, upstream from Shasta Dam, is drained by four major tributaries (the Sacramento River, McCloud River, Pit River, and Squaw Creek) in addition to numerous minor tributary creeks and streams.

Upper Sacramento River (Shasta Dam to Red Bluff)

Flows in the Sacramento River in the 65-mile reach between Shasta Dam and Red Bluff (River Mile (RM) 244) are regulated by Shasta Dam and are reregulated downstream at Keswick Dam (RM 302). In this reach, flows are influenced by tributary inflow. Major west side tributaries to the Sacramento River in this reach of the river include Clear and Cottonwood creeks. Major east side tributaries to the Sacramento River in this reach of the river include Battle, Bear, Churn, Cow, and Paynes creeks. This section of the Sacramento River also receives water from Klamath Basin (see Section 6.1.2, “Diversion Facilities).

Lower Sacramento River and Delta

The Sacramento River enters the Sacramento Valley about 5 miles north of Red Bluff. From Red Bluff to Chico Landing (52 miles), the river receives flows from Antelope, Mill, Deer, Big Chico, Rock, and Pine creeks on the east side and Thomes, Elder, Reeds, and Red Bank creeks on the west side. From Chico Landing to Colusa (50 miles), the Sacramento River meanders through alluvial deposits between widely spaced levees. Stony Creek is the only major tributary in this segment of the river. No tributaries enter the Sacramento River between Stony Creek and its confluence with the Feather River.

Floodwaters in the Sacramento River overflow the east bank at three sites in a reach referred to by the State of California (State) as the Butte Basin Overflow Area. In this river reach, several Federal projects begin, including the Sacramento River Flood Control Project, Sacramento River Major and Minor Tributaries Project, and Sacramento River Bank Protection Project. Levees of the Sacramento River Flood Control Project begin in this reach, downstream from Ord Ferry on the west (RM 184), and downstream from RM 176 above Butte City on the east side of the river.

Shasta Reservoir also is operated to meet a flow requirement in the Sacramento River, at Wilkins Slough near Grimes (RM 125), also known as the Navigation Control Point. Downstream from Wilkins Slough, the Feather River, the largest east side tributary to the Sacramento River, enters the river just above Verona. Between Wilkins Slough and Verona, floodwater is diverted at two places in this segment of the river—Tisdale Weir into the Tisdale Bypass and Fremont Weir into the Yolo Bypass. The bypass system routes floodwater away from the mainstem Sacramento River to discharge into the Delta.

Below Verona, the Sacramento River flows 79 miles to the Delta, passing the City of Sacramento. The Yolo Bypass parallels this river reach to the west. Flows enter this river reach at various points. First, flows from the Natomas Cross Canal enter the Sacramento River approximately 1 mile downstream from the Feather River mouth. The American River flows into the Sacramento River in the City of Sacramento. When Sacramento River system flood flows are the highest, a portion of the flow is diverted into the Yolo Bypass at the Sacramento Weir, about 3 miles upstream from the American River confluence in downtown Sacramento. At the downstream end, Yolo Bypass flows reenter the Sacramento River near Rio Vista. As the river enters the Delta, Georgiana Slough branches off from the mainstem of the Sacramento River, routing a portion of the flow into the central Delta.

The hydraulics of the Delta are complicated by tidal influences, a multitude of agricultural and municipal and industrial (M&I) diversions for use within the Delta itself, and by CVP and SWP exports. The principal factors affecting Delta hydrodynamics are (1) river inflow and outflow from the Sacramento River and San Joaquin River systems, (2) daily tidal inflow and outflow through San Francisco Bay, and (3) export pumping from the south Delta, primarily through the Jones and Banks pumping plants.

The Jones Pumping Plant consists of six pumps, with a maximum export capacity of 4,600 cfs. The Jones Pumping Plant is at the end of an earth-lined intake channel about 2.5 miles long.

The Banks Pumping Plant supplies water for the South Bay Aqueduct and the California Aqueduct, with an installed capacity of 10,300 cfs. Under current operational constraints, exports from Banks Pumping Plant generally are limited to a daily average of 6,680 cfs, except between December 15 and March 15, when exports can be increased by 33 percent of San Joaquin River flow. The Banks Pumping Plant exports water from the Clifton Court Forebay, a 31,000-acre-foot reservoir that provides storage for off-peak pumping, and moderates the effect of the pumps on the fluctuation of flow and stage in adjacent Delta channels.

The Contra Costa Water District (CCWD) supplies CVP water to its users via a pumping plant at the end of Rock Slough. The Rock Slough diversion capacity of 350 cfs gradually decreases to 22 cfs at the terminus. CCWD also constructed and operates the 160,000-acre-foot Los Vaqueros Reservoir, which has intakes and pumping plants on the Old River and Victoria Canal for diverting surplus Delta flows to reservoir storage or contract water to CCWD users. Because tidal inflows are approximately equivalent to tidal outflows during each daily tidal cycle, tributary inflows and export pumping are the principal variables that define the range of hydrodynamic conditions in the Delta. Excess outflow occurs almost entirely during the winter and spring months. Average winter outflow is about 32,000 cfs, while the average summer outflow is 6,000 cfs.

CVP/SWP Service Areas

This section describes the hydrology and hydraulics of the CVP/SWP service areas, located south of the primary study area.

Downstream from the Jones Pumping Plant, CVP water flows in the Delta-Mendota Canal and can be either diverted by the O’Neill Pumping-Generating Plant into the O’Neill Forebay or can continue down the Delta-Mendota Canal for delivery to CVP contractors. The O’Neill Pumping-Generating Plant consists of six pump-generating units, with a capacity of 700 cfs each.

The O’Neill Forebay is a joint CVP/SWP facility, with a storage capacity of about 56,000 acre-feet. In addition to its interactions with the Delta-Mendota Canal via the O’Neill Pumping-Generating Plant, it is a part of the SWP California Aqueduct. The O’Neill Forebay serves as a regulatory body for San Luis Reservoir; the William R. Gianelli Pumping-Generating Plant, also a joint CVP/SWP facility, can pump flows from the O’Neill Forebay into San Luis

Reservoir and also make releases from San Luis Reservoir to the O'Neill Forebay for diversion to either the Delta-Mendota Canal or the California Aqueduct. Also, several water districts receive diversions directly from the O'Neill Forebay. The William R. Gianelli Pumping-Generating Plant consists of eight units, with 1,375 cfs of capacity each.

San Luis Reservoir provides offstream storage for excess winter and spring flows diverted from the Delta. It is sized to provide seasonal carryover storage, with a total capacity of 2,027,840 acre-feet. The CVP share of the storage is 965,660 acre-feet; the remaining 1,062,180 acre-feet are the SWP share. During spring and summer, water demands and schedules are greater than the capability of Reclamation and DWR to pump water from the Jones and Banks pumping plants; water stored in San Luis Reservoir is used to make up the difference. The CVP share of San Luis Reservoir typically is at its lowest in August and September, and at its maximum in April. The San Felipe Division of the CVP supplies water to customers in Santa Clara and San Benito counties from San Luis Reservoir. The operation of San Luis Reservoir has the potential to affect the water quality and reliability of these supplies if reservoir storage drops below 300,000 acre-feet.

South of the O'Neill Forebay, the Delta-Mendota Canal terminates in the Mendota Pool, about 30 miles west of Fresno. From the Delta-Mendota Canal, the CVP makes diversions to multiple water users and refuges. Delta-Mendota Canal capacity at the terminus is 3,211 cfs. Parallel to the Delta-Mendota Canal, the San Luis Canal-California Aqueduct is a joint-use facility for the CVP and SWP. It begins on the southeast edge of the O'Neill Forebay and extends about 101.5 miles southeasterly to a point near Kettleman City. Water from the canal serves the San Luis Federal service area, mostly for agricultural purposes and for some M&I uses. The canal has a capacity ranging from 8,350 cfs to 13,100 cfs.

South of Banks Pumping Plant, the California Aqueduct flows into Bethany Reservoir, a 5,000-acre-foot forebay for the South Bay Pumping Plant. Exiting the Bethany Forebay, the California Aqueduct flows through a series of checks to the aforementioned O'Neill Forebay, and is either pumped into San Luis Reservoir or released to the San Luis Canal, the CVP/SWP joint-use portion of the California Aqueduct. Deliveries are made from the California Aqueduct to agricultural and M&I contractors.

Downstream from the pumping plants is the Delta-Mendota Canal/California Aqueduct Intertie, a shared federal-state water system improvement project which connects the Delta-Mendota Canal (federal facility) and the California Aqueduct (state facility) and pumping station and two 108-inch-diameter pipes. The pumping station has a capacity of 467 cfs up hill and 900 cfs gravity flow from the California Aqueduct to the Delta-Mendota Canal. The Intertie is located at the closest point between the Delta-Mendota Canal and California Aqueduct which is 500 feet horizontal and 50 feet vertical. The Intertie provides redundancy in the water distribution system, allows for maintenance and repair activities that are less disruptive to water deliveries, and provides the flexibility to respond to CVP and SWP emergencies.

6.1.4 Surface Water Supply

Although water supply reliability is one of the two primary planning objectives of the SLWRI, operations for Shasta Reservoir primarily are focused on delivering water supply to CVP contractors. However, because of the interconnectivity of the CVP and SWP, water supply operations of the SWP could be affected by changes in operations of the CVP associated with the SLWRI.

CVP/SWP Service Areas

This section describes surface water supply to CVP and SWP contractors.

CVP Contractors At certain times of the year, operations of Shasta Reservoir are driven by water supply needs of the CVP contractors. The CVP provides water to settlement contractors in the Sacramento Valley, exchange contractors in the San Joaquin Valley, agricultural and M&I water service contractors in both the Sacramento and San Joaquin valleys, and wildlife refuges both north and south of the Delta. At the beginning of each year, Reclamation evaluates hydrologic conditions throughout California and uses this information to forecast CVP operations, and to estimate the amount of water to be made available to the Federal water service contractors for the year.

The majority of the Federal water service contractors have service areas located south of the Delta. In general, allocations to CVP water service contractors south of the Delta are lower than allocations to service contractors in the Sacramento Valley. Because of water rights secured before construction of the CVP, Sacramento Valley settlement contractors and San Joaquin Valley exchange contractors have a higher level of reliability for their supplies; except in extremely dry years, when the water year type, as defined by the Shasta Hydrologic Index, is classified as critical, settlement and exchange contractors receive 100 percent of their contract amounts. In Shasta critical years, settlement and exchange contractors receive 75 percent of their contract amounts. A Shasta critical year is defined as a year when the total inflow to Shasta Reservoir is below 3.2 MAF, or the average inflow for a 2-year period is below 4.0 MAF and the total 2-year deficiency for deliveries is higher than 0.8.

SWP Contractors The CVP and SWP are intrinsically linked through the Delta; shared responsibilities under their respective water rights and coordinated operations agreements mean that a change in flow from one project could result in a flow change from the other. Accordingly, SWP water supply operations are discussed below.

The SWP operates under long-term contracts with public water agencies throughout California. These agencies, in turn, deliver water to wholesalers or retailers, or deliver it directly to agricultural and M&I water users (DWR 1999). The SWP contracts between DWR and individual State water contractors define several classifications of water available for delivery under specific circumstances.

6.1.5 Flood Management

This section describes major features of the flood management system in the primary and extended study areas, including reservoirs, levees, weirs, and bypasses. Historical operation of these facilities also is described.

Shasta Lake and Vicinity

Releases from Shasta Dam often are made for flood management. Releases for flood management occur either in the fall, beginning in early October, to reach the prescribed vacant flood space, or to evacuate space during or after a storm event to maintain the prescribed vacant flood space in the reservoir. During a storm event, releases for flood management occur either over the spillway during large events or through river outlets for smaller events. Between 1950 and 2006, flows over the spillway occurred in 12 years, or in 21 percent of years. During the same time interval, releases for flood management (either for seasonal space evacuation or during a flood event, and including spills over the spillway) occurred in about 37 years, or nearly 70 percent of the years.

Upper Sacramento River (Shasta Dam to Red Bluff)

Historically, the largest flood events along the upper Sacramento River have been from heavy rainfall, with a relatively smaller component of the flows coming from snowmelt in the upper basin. Flood management operations at Shasta Dam include forecasting runoff into Shasta Lake as well as runoff of unregulated creek systems downstream from Keswick Dam. A critical component of upper Sacramento River flood operations is the forecast of local runoff entering the Sacramento River between Keswick Dam and Bend Bridge near Red Bluff.

The unregulated creeks (major tributaries include Cottonwood, Cow, and Battle creeks) discharging into the Sacramento River between Keswick Dam and Bend Bridge can produce high runoff rates into the Sacramento River in short periods of time. During large flood events, the local runoff between Keswick Dam and Bend Bridge can exceed 100,000 cfs.

Lower Sacramento River and Delta

Flood management facilities along the lower Sacramento River and in the Delta include the levees, weirs, and bypasses of upper and lower Butte basin, the Sacramento River between Colusa and Verona, and the Sacramento River between Verona and Collinsville. The levees, weirs, and bypasses are features of the Sacramento River Flood Control Project, which began operation in the 1930s and was significantly expanded in the 1950s.

When Sacramento River flows exceed between 90,000 and 100,000 cfs at Ord Ferry, water flows naturally over the banks of the river into Butte basin. In addition to the Sacramento River overbank flows at Ord Ferry, the basin receives inflow over the Colusa and Moulton weirs and from tributary streams draining from the northeast, principally Cherokee Canal and Butte Creek. Before construction of the Feather River levees, Butte basin also received overflows from the Feather River north of the Sutter Buttes. Outflows from Butte basin move through the Sutter Bypass when the Sacramento River is high or through the Butte Slough outfall gates (RM 139) into the Sacramento River when the river is low.

The Sacramento River meanders through the 64 miles between Colusa (RM 143) and Verona (RM 79). The levee system continues along both sides of this river reach. The levee spacing (or channel width), east to west, is wider between the upstream sections, from RM 176 to RM 143 at Colusa, than the levee spacing downstream from Colusa. The Feather River, the largest east side tributary to the Sacramento River, enters the river just above Verona. Flood management diversions occur at two places in this segment of the river, at the Tisdale Weir and Fremont Weir.

Below Verona, the Sacramento River flows 79 miles to Collinsville, at the mouth of the Delta, passing the City of Sacramento along the way. The Yolo Bypass parallels this river reach to the west. Flows enter this river reach at various points. First, flows from the Natomas Cross Canal enter the Sacramento River approximately 1 mile downstream from the Feather River mouth (RM 80). The American River (RM 60), the southernmost major Sacramento River tributary, enters the river at the City of Sacramento. Flows in the Yolo Bypass reenter the river near Rio Vista (RM 12). As the river enters the Delta, Georgiana Slough branches off from the mainstream Sacramento River, routing flows into the central Delta. The one diversion point for flood management is at Sacramento Weir, where floodwaters are diverted from the Sacramento River through the Sacramento Bypass to the Yolo Bypass under the highest flow conditions.

CVP/SWP Service Areas

This section describes flood management facilities in the CVP/SWP service areas by river basin, including the Feather River, American River, San Joaquin River, and east side tributaries to the Delta (i.e., Littlejohns Creek, Calaveras River, and Mokelumne River).

The primary flood management feature of the Feather River basin is Oroville Reservoir, with a flood management reservation volume of 750,000 acre-feet. Oroville Reservoir releases are used to help meet the objective flow on the Feather River of 150,000 cfs, and in conjunction with New Bullards Bar Reservoir on the Yuba River, to meet an objective flow below the Yuba River confluence of 300,000 cfs. Levees line the Feather River from its confluence with the Sacramento River to the City of Oroville (RM 63).

The lower American River is primarily protected from flooding by Folsom Dam. The Folsom Reservoir flood management reservation volume is variable, ranging from 400,000 acre-feet to 670,000 acre-feet. The objective release on the American River is 115,000 cfs; however, some damage to infrastructure along the American River occurs at flows above 20,000 cfs. The American River is leveed from its confluence with the Sacramento River to near the Carmichael Bluffs on the north bank, and to near the Sunrise Boulevard Bridge on the south bank (RM 19).

The San Joaquin River basin is protected by an extensive reservoir system, including the following:

- Friant Dam and Millerton Lake (RM 270), with a flood management reservation volume of 170,000 acre-feet
- Big Creek Dam, on Big Creek, with a flood management reservation of 30,200 acre-feet
- Hidden Dam and Hensley Lake on the Fresno River, with a flood management reservation of 65,000 acre-feet
- Buchanan Dam and H.V. Eastman Lake on the Chowchilla River, with a flood management reservation of 45,000 acre-feet
- Los Banos Detention Dam on Los Banos Creek, with a flood management reservation of 14,000 acre-feet
- Merced County Stream Group Project, consisting of five dry dams (i.e., Bear, Burns, Owens, Mariposa, and Castle) and two diversion structures, with a total flood storage capacity of 30,500 acre-feet
- New Exchequer Dam and Lake McClure on the Merced River, with a flood management reservation of 350,000 acre-feet
- Don Pedro Dam and Lake on the Tuolumne River, with a flood management reservation of 340,000 acre-feet
- New Melones Dam and Lake on the Stanislaus River, with a flood management reservation of 450,000 acre-feet

The streams in the northern portion of the San Joaquin River basin, between the American and Stanislaus rivers, commonly are referred to as the eastside tributaries to the Delta. These rivers flow into the San Joaquin River within the boundaries of the Delta. Flood management features on the eastside tributaries to the Delta include the following:

- Farmington Dam and Reservoir on Littlejohns Creek, with a flood management reservation of 52,000 acre-feet
- New Hogan Dam and Lake on the Calaveras River, with a flood management reservation of 165,000 acre-feet
- Camanche Dam and Reservoir on the Mokelumne River, with a flood management reservation of 200,000 acre-feet

6.1.6 South Delta Water Levels

This section discusses the variability of water levels in the south Delta, as part of CVP/SWP operations in the extended study area.

In the south Delta, decreases in water levels resulting from CVP and SWP export pumping are a concern for local agricultural diverters because, during periods of low water levels, sufficient pump draft cannot be maintained and irrigation can be interrupted. Historically, the highest minimum stage in the Middle River typically occurs in February and is about 0.1 foot below mean sea level (msl). The lowest minimum stage typically occurs in August and is about 0.8 foot below msl. During dry and critical years,[1] under existing conditions, the highest minimum stage in the Middle River typically occurs in April and is about 0.6 foot below msl. The lowest minimum stage typically occurs in September and is about 0.7 foot below msl (CALFED 2000a).

6.1.7 Groundwater Resources

The use and sustainable management of groundwater resources is an important component in meeting water demands in California. More than 70 percent of California’s groundwater extraction occurs in the Central Valley from Tulare Lake, San Joaquin River, and Sacramento River Hydrologic Regions (HR) combined (DWR 2003b). The South Coast, North Coast, North Lahontan, San Joaquin River, and Sacramento River HRs take between 20 and 40 percent of their supply from groundwater. Information specific to groundwater resources includes groundwater levels and budget and groundwater quality.

Shasta Lake and Vicinity

Shasta Lake and vicinity are located in the foothill area northwest of the Redding groundwater basin. Small groundwater basins underlying Shasta Lake and vicinity do not have significant groundwater availability for use as a source of supply (Shasta County Water Agency 1998). Groundwater basins underlying Shasta County include the Fall River Valley groundwater basin, Lake Britton groundwater basin, and North Fork Battle Creek. Of these three groundwater basins, the Fall River Valley groundwater basin covers the largest area (54,800 acres) and groundwater extraction for agricultural use in this basin is the highest (approximately 19,000 acre-feet). Estimated groundwater extraction for M&I

[1] Throughout this document, water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

use in these subbasins ranges from 5 acre-feet to 240 acre-feet. Deep percolation from applied water is minor, ranging from 10 acre-feet to 4,800 acre-feet. Groundwater quality in Shasta Lake and vicinity typically is good. Total dissolved solids (TDS) concentrations in the Fall River Valley groundwater basin are low, ranging from 115 to 232 milligrams per liter (mg/L) and some wells in the area have high iron concentrations (DWR 2003b).

Upper Sacramento River (Shasta Dam to Red Bluff)

The upper Sacramento River portion of the study area extends from Redding to Red Bluff and includes the Redding groundwater basin and the northern portion of the Sacramento groundwater basin.

The Redding groundwater basin underlies most of the upper Sacramento River area between Shasta Dam and Red Bluff. The basin is bordered on the north, east, and west by foothills, and on the south by the Sacramento Valley groundwater basin (Tehama 1996). The foothill areas that constitute the eastern and western portions of Shasta and Tehama counties, adjacent to the Redding groundwater basin, are designated as “highland” areas, noted for their relative scarcity of groundwater resources. DWR Bulletin 118 (2003b) subdivides the Redding groundwater basin into six subbasins: Anderson, Enterprise, Millville, Rosewood, Bowman, and South Battle Creek.

The Sacramento groundwater basin extends from the Redding groundwater basin to the San Joaquin Valley, and includes Tehama, Glenn, Butte, Yuba, Colusa, Placer, and Yolo counties.

In general, groundwater flows southeasterly on the west side of the Redding groundwater basin and southwesterly on the east side, toward the Sacramento River (Reclamation and DWR 2003). DWR conducted a review of groundwater level hydrographs in the Anderson, Enterprise, Millville, Rosewood, and Bowman subbasins where groundwater level data was available. This review illustrated the following trends associated with the 1976-1977 and 1987-1994 droughts in each subbasin, followed by a gradual recovery in levels to pre-drought conditions of the early 1970’s and 1980’s (DWR 2003b).

- Slight decline (Anderson Subbasin),
- Gradual decline of approximately 5- to 10-feet (Enterprise Subbasin),
- Slight decline of approximately 5-feet (Millville Subbasin),
- Slight decline (Rosewood Subbasin),
- Slight decline (Bowman Subbasin)

This review also illustrated generally seasonal fluctuations in groundwater levels in the Anderson, Enterprise, Millville, Rosewood, and Bowman subbasins where groundwater level data was available, within the following ranges:

- Ranges from 1- to 10-feet for normal and dry years (Anderson Subbasin),
- Ranges from 5- to 10-feet and for the semi-confined wells, between 10- to 15-feet for normal and dry years (Enterprise Subbasin),
- Range from 2- to 8-feet for normal and dry years (Millville Subbasin),
- Range from 5- to 10-feet for normal and dry years (Rosewood Subbasin),
- Approximately 5-feet for normal and dry years (Bowman Subbasin).

Historically, groundwater levels in the Redding groundwater basin have remained relatively stable, with no apparent long-term trend of declining or increasing levels. DWR has estimated the total quantity of groundwater storage in the Redding groundwater basin at approximately 6.9 MAF (Reclamation and DWR 2003).

In the northern portion of the Sacramento groundwater basin, the following three subbasins are included in upper Sacramento River portion of the primary study area: Red Bluff, Antelope, and Bend subbasins. Groundwater extraction in the Red Bluff subbasin is nearly 90,000 acre-feet. DWR reported that Red Bluff, Corning, Woodland, Davis, and Dixon are completely dependent on groundwater. Domestic use of groundwater varies, but in general, rural unincorporated areas rely completely on groundwater (DWR 2003b).

Groundwater in the Redding area is of good quality, as shown by low TDS concentrations, ranging from 70 to 360 mg/L within the six Redding Groundwater Basin subbasins (DWR 2003b). This range is below the U.S. Environmental Protection Agency and California Environmental Protection Agency secondary drinking water standard of 500 mg/L, and also below the agricultural water quality goal of 450 mg/L. Areas of high salinity and poor quality are generally found on the basin margins where groundwater is derived from marine sedimentary rock containing brackish to saline water (Reclamation and DWR 2003). The groundwater is degraded by underlying marine sediments mixing with fresh water from the younger alluvial aquifer (DWR 2003b).

Groundwater quality in the Sacramento groundwater basin is generally good and sufficient for agricultural and M&I uses, with TDS levels ranging from 200 to 500 mg/L (Reclamation and DWR 2003). Localized groundwater quality issues occur as a result of natural water quality impairments at the north end of the Sacramento Valley, where marine sedimentary rocks containing brackish to saline water are near the surface (Reclamation and DWR 2003).

Lower Sacramento River and Delta

The groundwater basins underlying the lower Sacramento River and Delta areas include the Sacramento Valley groundwater basin, and North and South San Joaquin Valley groundwater basins.

In the Sacramento groundwater basin, groundwater flows inward from the edges of the basin and south parallel to the Sacramento River. Groundwater extraction in some local areas resulted in groundwater depressions and local groundwater gradients (Reclamation and DWR 2003). Before completion of CVP facilities (1964 through 1971), pumping along the west side of the basin caused groundwater levels to decline. In the Sacramento groundwater basin, a slight decline of 2 to 12 feet was experienced in groundwater levels as a result of the 1976 through 1977 and 1987 through 1994 droughts. This was followed by a recovery to predrought conditions of the early 1970s and 1980s. Generally, groundwater level data show an average seasonal fluctuation ranging from 2 to 15 feet. Groundwater production in the basin increased from 500,000 acre-feet in the 1940s to 2 MAF annually in the mid-1990s.

As mentioned, groundwater quality in the Sacramento groundwater basin is generally good and is sufficient for agricultural and M&I uses, with TDS levels ranging from 200 to 500 mg/L (Reclamation and DWR 2003).

CVP/SWP Service Areas

The groundwater basins underlying the CVP/SWP service areas include the San Joaquin Valley, Santa Clara Valley, Antelope Valley, Fremont Valley, Coastal Plain of Los Angeles, and Coastal Plain of Orange County groundwater basins, and multiple other smaller groundwater basins underlying areas that receive water from the CVP/SWP system.

The San Joaquin Valley groundwater basin is a regional basin and is the largest in California, extending approximately from the Delta to Bakersfield. Areas within the San Joaquin Valley groundwater basin are heavily groundwater-reliant. Groundwater accounts for about 30 percent of the annual supply used for agricultural and urban purposes (Reclamation and DWR 2003). Groundwater production in the north San Joaquin Valley groundwater basin alone increased from 1.5 MAF annually in the 1920s to more than 3.5 MAF annually in 1990 (Reclamation and DWR 2003). In the south San Joaquin Valley groundwater basin, groundwater production for agriculture rose from approximately 3.0 MAF per year in the 1920s to more than 5.0 MAF per year in the 1980s (Reclamation and DWR 2003). Much of the San Joaquin groundwater basin is in overdraft conditions because of extensive groundwater pumping and irrigation, although the extent of overdraft varies widely from region to region.

Groundwater quality throughout the San Joaquin Valley is in general suitable for most urban and agricultural uses. Average TDS concentrations range from 218 to 1,190 mg/L. Areas of high TDS concentration, primarily along the west side of the San Joaquin Valley, are the result of streamflow recharge that originates from marine sediments. High TDS concentrations are also seen in the trough of the San Joaquin Valley because of concentration of salts resulting from evaporation and poor drainage (Reclamation and DWR 2003). Agricultural pesticides and herbicides have been detected in groundwater throughout the region, but primarily along the east side of the San Joaquin Valley, where soil permeability is higher and depth to groundwater is shallower. From 1994 to 2000, 523 public wells out of 689 wells sampled met the State primary maximum contamination levels for drinking water. The remaining wells have constituents that exceed one or more maximum contamination levels (Reclamation and DWR 2003).

6.2 Regulatory Framework

6.2.1 Federal

The following Federal laws, regulations, standards, and plans are discussed as part of the regulatory setting:

- The U.S. Department of the Interior, Fish and Wildlife Service (USFWS) 2008 *Formal Endangered Species Act Consultation on the Proposed Coordinated Operations of the CVP and SWP* (2008 USFWS Biological Opinion (BO)) (USFWS 2008)
- The National Marine Fisheries Service (NMFS) 2009 *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO) (NMFS 2009b)
- Central Valley Project Improvement Act (CVPIA) (Reclamation 1999)
- San Joaquin River Restoration Program (SJRRP) Programmatic Environmental Impact Statement/Environmental Impact Report (PEIS/R) (Reclamation and DWR 2012)
- CVP long-term water service contracts
- Trinity River Record of Decision (ROD) (Reclamation 2000)
- Flow objective for navigation (Wilkins Slough)
- Flood management requirements

Regulatory requirements include the 2008 USFWS BO, the 2009 NMFS BO and associated Reasonable and Prudent Alternatives (RPA), and the agreement between the United States and the State for the coordinated operation of the CVP and SWP, otherwise commonly known as the “Coordinated Operations Agreement” (COA).

Ongoing consultation for the 2008 USFWS and 2009 NMFS BOs have resulted in some uncertainty in future CVP and SWP operational constraints. In response to lawsuits challenging the 2008 and 2009 BOs, the District Court for the Eastern District of California (District Court) remanded the BOs to USFWS and NMFS in 2010 and 2011, respectively, and subsequently ordered reconsultation and preparation of new BOs. These legal challenges may result in changes to CVP and SWP operational constraints if the revised USFWS and NMFS BOs contain new or amended RPAs.

Despite this uncertainty, the 2008 and 2009 BOs issued by the fishery agencies contain the most recent estimate of potential changes in water operations that could occur in the near future. Because the RPAs contained in the 2008 and 2009 BOs have the potential to significantly impact SWP/CVP operations and potential benefits of the SLWRI, they have been implemented in this analysis.

National Marine Fisheries Service 2009 Biological Opinion

The 2009 NMFS BO addresses the effects of the continued long-term operation of the CVP and SWP on Sacramento River winter-run Chinook salmon, Central Valley spring-run Chinook salmon, and Central Valley steelhead and their critical habitat, as well as the green sturgeon and its proposed critical habitat and the killer whale (NMFS 2009). The BO includes an RPA that specifies a number of actions, including formation of operation groups, habitat improvements, monitoring requirements and fish passage as well as flow and temperature objectives. Key operational actions in the NMFS RPA that would directly affect project water operations, mainly flow and temperature objectives are listed below. Operations in the RPA that were directly modeled in CalSim II are described in Table 2-2 of the Modeling Appendix.

Shasta-Trinity Division

- Clear Creek flow and temperature objectives
- Reclamation deliverable water forecast procedures
- End-of-year (September 30) Shasta target storages
- Sacramento River temperature objectives between Keswick Dam and Bend Bridge

American River Division

- Lower American River flow objectives
- Lower American River temperature objectives

East Side Division

- Stanislaus River flow objectives
- Stanislaus River temperature objectives

Delta Division

- Delta Cross Channel gate operation
- San Joaquin River Inflow to Export Ratio objectives
- Old and Middle River (OMR) negative or reverse flow objectives

U.S. Fish and Wildlife Service 2008 Biological Opinion

The 2008 USFWS BO addresses the effects of the continued operation of the CVP and SWP on delta smelt and its critical habitat (USFWS 2008). The BO included habitat restoration, formation of the smelt working group, and monitoring requirements as well as RPA actions that would impact project operations. This section discusses the actions in the RPA that would directly affect project water operations, mainly flow and delta salinity conditions. The details on how these were implemented in the modeling and subsequent analysis are included in the Table 2-2 of the Modeling Appendix.

- OMR flow limits of no more than -1500 to -5000 cfs during periods when delta smelt could be subject to entrainment at the pumps.
- X2 location limits during the fall following above normal and wet years.

Central Valley Project Improvement Act

Reclamation's evolving mission was written into law on October 30, 1992, with the passage by Congress, and signing by President George H. W. Bush, of Public Law 102-575, the Reclamation Projects Authorization and Adjustment Act of 1992. Included in the law was Title 34, the CVPIA (Reclamation 1999). The CVPIA amended previous authorizations of the CVP to include fish and wildlife protection, restoration, and mitigation as project purposes having equal priority with irrigation and domestic water supply uses, and fish and wildlife enhancement having equal priority with power generation. Among the changes mandated by the CVPIA are the following:

- Dedicating 800,000 acre-feet annually to fish, wildlife, and habitat restoration
- Authorizing water transfers outside the CVP service area
- Implementing the Anadromous Fish Restoration Program
- Creating a restoration fund financed by water and power users
- Providing for the Shasta Dam temperature control device (TCD)
- Implementing fish passage measures at RBPP

- Planning to increase water supplies for CVP deliveries
- Mandating firm water supplies for Central Valley wildlife refuges
- Meeting Federal trust responsibility to protect fishery resources on the Trinity River

The CVPIA is being implemented on a broad front. The Final Programmatic Environmental Impact Statement (Reclamation 1999) for the CVPIA analyzes projected conditions in 2022, 30 years from the CVPIA's adoption in 1992. The Final Programmatic Environmental Impact Statement was released in October 1999, and the CVPIA ROD was signed on January 9, 2001.

Operations of the CVP reflect provisions of the CVPIA, particularly Sections 3406 (b)(1), (b)(2), and (b)(3). The U.S. Department of the Interior Final Decision on Implementation of Section 3406 (b)(2) of the CVPIA, May 9, 2003 provides the basis for implementing upstream and Delta actions with CVP delivery capability. The Vernalis Adaptive Management Program assumes that San Joaquin River water will be acquired under Section 3406 (b)(3) to support increased Vernalis flows during certain times of the year. Similarly, the Anadromous Fish Restoration Program assumes Sacramento River water will be acquired under Section 3406 (b)(3).

San Joaquin River Restoration Program

The SJRRP was established in 2006 to implement the Stipulation of Settlement in *NRDC, et al., v. Kirk Rodgers, et al.* (Settlement). Federal authorization for implementing the Settlement is provided in the San Joaquin River Restoration Settlement Act, included in Public Law 111-11. Alternatives for implementation of the Settlement and related legislation were evaluated in the SJRRP PEIS/R (Reclamation and DWR 2012).

The Settlement calls for releases of water from Friant Dam to the confluence of the Merced River, referred to as Interim and Restoration flows; a combination of channel-related and structural modifications along the San Joaquin River below Friant Dam; and reintroduction of Chinook salmon. Restoration Flows are specific volumes of water to be released from Friant Dam during different year types, according to Exhibit B of the Settlement. Interim Flows were experimental flows that were implemented from 2009 until Restoration Flows were implemented in 2014. Interim Flows allowed the SJRRP to collect relevant data about flows, temperatures, fish needs, seepage losses, recirculation, recapture, and reuse.

The release of Interim Flows began in October 2009; however, the release of Interim Flows was limited by channel capacity constraints between Friant Dam and the Merced River confluence. The release of Restoration Flows began on January 1, 2014, but is currently restricted due to capacity constraints. Full Restoration Flows are intended to include annual releases from Friant Dam of up to 840,000 acre-feet, depending on year type. In some years, peak releases from Friant Dam could reach as much as 8,000 cfs for several hours, within the constraints of channel capacity. For the SLWRI, existing conditions include Interim Flows and future conditions include full Restoration Flows.

Central Valley Project Long-Term Water Service Contracts

In accordance with CVPIA Section 3404c, Reclamation is renegotiating long-term water service contracts. As many as 113 CVP water service contracts in the Central Valley may be renewed during this process. Reclamation issued a Notice of Intent for long-term contract renewal in October 1998. Environmental documentation was prepared on a regional basis. In February 2005, Reclamation issued decisions (a ROD or Finding of No Significant Impact) for renewing contracts of the Sacramento River, San Luis, and Delta-Mendota Canal divisions, the Sacramento River settlement contracts, and several individual contracts. Preparation of environmental documents for other divisions and contracts is ongoing.

Trinity River Record of Decision

Export of Trinity River water to the Sacramento basin provides increased water supply for the CVP and is a major source of CVP power generation. The amounts and timing of the Trinity exports are determined after consideration is given to forecasted Trinity water supply available and Trinity in-basin needs, including carryover storage. Trinity exports also are a key component of water temperature control operations on the upper Sacramento River.

Based on the December 19, 2000, Trinity River Mainstem ROD (Reclamation 2000), 368,600 to 815,000 acre-feet are allocated annually for Trinity River flows. After several challenges and injunctions, on July 13, 2004, the Ninth Circuit Court upheld the ROD flows for the Trinity River.

Flow Objective for Navigation (Wilkins Slough)

Historical commerce on the Sacramento River resulted in the requirement to maintain minimum flows of 5,000 cfs at Chico Landing to support navigation. Currently, no commercial traffic exists between Sacramento and Chico Landing, and USACE has not dredged this reach to preserve channel depths since 1972. However, long-time water users diverting from the river have set their pump intakes just below this level. Therefore, the CVP is operated to meet the navigation flow requirement of 5,000 cfs to Wilkins Slough under all but the most critical water supply conditions to facilitate pumping.

At flows below 5,000 cfs at Wilkins Slough, diverters have reported increased pump cavitation as well as greater pumping head requirements. Diverters operate for extended periods at flows of 4,000 cfs at Wilkins Slough, but pumping operations are severely affected and some pumps become inoperable at flows lower than 4,000 cfs. Flows may drop as low as 3,500 cfs for short periods while changes are made in Keswick releases to reach target levels at Wilkins Slough.

No criteria have been established that specify when the navigation minimum flow should be relaxed. However, the basis for Reclamation's decision to operate at less than 5,000 cfs is the increased importance of conserving water when water supplies are not sufficient to meet full contractual deliveries and other operational requirements.

Flood Management Requirements

Shasta Dam provides flood protection to the nearby communities of Redding, Anderson, Red Bluff, and Tehama, as well as to agricultural lands, industrial developments, and communities downstream along the Sacramento River. Shasta Dam is operated for an objective release of 100,000 cfs at Bend Bridge in Red Bluff, subject to consideration of the following:

- Releases are not to be increased more than 15,000 cfs or decreased more than 4,000 cfs in any 2-hour period.

- The 2,500-square-mile uncontrolled drainage area between Keswick Dam and Bend Bridge can produce flows well in excess of the design channel capacity of 100,000 cfs. These high-magnitude flows can occur very rapidly, requiring release changes based on official flow forecasts, and are complicated by the 8- to 12-hour travel time between Keswick Dam and Bend Bridge.

- Flow gages on major east side tributaries (Cow, Battle, and Paynes creeks) between Keswick Dam and Red Bluff are helpful in coordinating operations of Shasta Dam and Reservoir with flows from uncontrolled downstream areas. Whiskeytown Dam, located on Clear Creek, provides regulation of Trinity River flows and regulates runoff to the Sacramento River from the Clear Creek drainage area. The most critical flood forecast for the Sacramento River is that of local runoff entering the Sacramento River between Keswick Dam and Bend Bridge. As the Bend Bridge flow is projected to recede, Keswick Dam releases are increased to evacuate water stored in the flood management space in Shasta Reservoir.

The following constraints are considered when making release changes at Keswick Dam:

- The maximum capacity of Shasta Powerplant is about 18,000 cfs, but this varies considerably with head. Maximum powerplant release is required when Shasta Reservoir storage encroaches on the flood management space by 25 percent or less, with actual or forecasted inflows of 40,000 cfs or less.

- The capacity of Keswick Powerplant is about 16,000 cfs, which represents a maximum release rate when no flood management space is being used. The Keswick Dam release must include discharge from

Spring Creek Powerplant, releases from Spring Creek Debris Dam, and local flows into Keswick Reservoir.

- Flows greater than 36,000 cfs begin to cause flood coordination efforts in the local Redding area to close riverfront roads and parks. These coordination efforts require some advance notice to increase Keswick releases above this rate.

All outflows from Shasta Dam flow into and through Keswick Reservoir, located about 5 miles west of Redding. Keswick Reservoir also receives inflow from the drainage area of Whiskeytown Reservoir on Clear Creek. Clear Creek flows are augmented by the interbasin transfer coming from Trinity Reservoir (see Section 6.1.2, "Diversion Facilities").

Flood Management Space Requirements Shasta Reservoir capacity is 4.552 MAF, with a maximum objective release capacity of 79,000 cfs. The end-of-September storage target for Shasta Reservoir is 1.9 MAF, except in the driest 10 percent of water years, to conserve sufficient cold water for meeting temperature criteria for the winter-run Chinook incubation period (summer to early fall). Storage levels are lowest by October to provide sufficient flood protection and capture capacity during the following wet months. The storage target gradually increases from October to full pool in May. Storage is then withdrawn for high water demand (i.e., municipal, agricultural, fishery, and water quality uses) during summer.

A storage space of up to 1.3 MAF below a full pool elevation of 1,067 feet is also kept available for flood management purposes in the reservoir in accordance with the Shasta Dam and Lake Flood Control Diagram (USACE 1977) , as prescribed by USACE (USACE 1977) (see Exhibit B in the *Hydrology, Hydraulics, and Water Management Technical Report*). Under the diagram, flood management storage space increases from zero on October 1 to 1.3 MAF (elevation 1,018.55) on December 1, and is maintained until December 23. From December 23 to June 15, the required flood management space varies according to parameters based on the accumulation of seasonal inflow. This variable space allows for the storage of water for conservation purposes, unless it is required for flood management based on basin wetness parameters and the level of seasonal inflow. Daily flood management operation consists of determining the required flood storage space reservation, and scheduling releases in accordance with flood operations criteria.

Objective Flow The current regulation of Shasta Dam for flood management requires that releases be restricted to quantities that will not cause downstream flows or stages to exceed, insofar as possible, (1) a flow of 79,000 cfs at the tailwater of Keswick Dam and (2) a stage of 39.2 feet for the Sacramento River at the Bend Bridge gaging station near Red Bluff (corresponding roughly to a flow of 100,000 cfs).

Tributary Inflows Shasta Lake collects flow in the upper Sacramento River watershed, but many uncontrolled tributaries enter the Sacramento River downstream from the dam. Stream gages have been added to major uncontrolled tributaries entering downstream from Shasta Lake (Cow, Battle, Cottonwood, and Thomes creeks). To a limited extent, operators of Shasta Dam can adjust releases containing these uncontrolled flows to try to reduce downstream peak flows. Trinity Lake, Lewiston and Whiskeytown reservoirs can also adjust releases to some extent. Accordingly, the influence of Shasta Dam and Reservoir operation on reducing peak flood flows diminishes downstream on the Sacramento River.

6.2.2 State

The following State laws, regulations, standards, and plans are discussed as part of the regulatory setting:

- State Water Resources Control Board (State Water Board) Orders 90-05 and 91-01
- 1960 CDFW-Reclamation Memorandum of Agreement (CDFG and Reclamation 1960)
- Water Quality Control Plan (WQCP) for the San Francisco Bay/San Joaquin Delta Estuary (State Water Board 1995)
- State Water Board Revised Water Right Decision 1641 (RD-1641) (State Water Board 2000)
- COA (Reclamation and DWR 1986)
- Groundwater regulations

State Water Resources Control Board Orders 90-05 and 91-1

In 1990 and 1991, the State Water Board issued Water Right Orders 90-05 and 91-01 modifying Reclamation's water rights for the Sacramento River. The orders included a narrative water temperature objective for the Sacramento River, and stated that Reclamation shall operate Keswick and Shasta dams and Spring Creek Powerplant to meet a daily average water temperature of 56°F at RBPP in the Sacramento River during periods when higher temperatures would be harmful to fisheries.

Under the orders, the water temperature compliance point may be modified when the objective cannot be met at RBPP. The Sacramento River Temperature Task Group (SRTTG), a multiagency group, develops temperature operational plans for the Shasta and Trinity divisions of the CVP pursuant to State Water Board Water Rights Orders 90-5 and 91-1. These temperature plans consider the impacts to winter-run Chinook salmon and other races of Chinook salmon from project operations. Previous plans have included releases of water from the low-level outlets at Shasta Dam and Trinity Dam, operation of the TCD, warm-water releases, and manipulating the timing of Trinity River diversions through Spring Creek Powerplant. Warm-water releases from the upper level outlets have been made to conserve cold water in Shasta Lake for temperature control in the late summer and to induce winter-run Chinook salmon to spawn as far upstream as possible. The SRTTG typically first meets in the spring once the cold-water availability in Shasta Lake is known. In almost all years since installation of the TCD on Shasta Dam in 1997, those plans have included modifying the compliance point near the RBPP to make the best use of the cold-water resources based on the location of spawning Chinook salmon (NMFS 2009).

The water right orders also recommended construction of a TCD to improve management of the limited cold-water resources. Two temperature control curtains were installed at both the Lewiston Reservoir and the Whiskeytown Reservoir to reduce temperature of water released from the Trinity Dam (Vermeyen 1995). Reclamation constructed the TCD on Shasta Dam in 1997. This device releases cool water from Shasta Lake through low-level river outlets that bypass the powerplant. These devices provide flexibility to Shasta Dam operations and allows downstream temperature goals to be consistently achieved (Reclamation 2004).

Reclamation operates the Shasta, Sacramento River, and Trinity River divisions of the CVP to meet, to the extent possible, the provisions of State Water Board Order 90-05 and 91-01 and the 2009 NMFS BO.

1960 California Department of Fish and Wildlife-Reclamation Memorandum of Agreement

An April 5, 1960, Memorandum of Agreement between CDFW and Reclamation (CDFW and Reclamation 1960) originally established flow objectives in the Sacramento River for the protection and preservation of fish and wildlife resources. The agreement provided for minimum releases into the natural channel of the Sacramento River at Keswick Dam for normal and critical years. Since October 1981, Keswick Dam has been operated based on a minimum release of 3,250 cfs for normal years from September 1 through the end of February, in accordance with an agreement between CDFW and Reclamation. This release schedule was included in Order 90-05, which maintains a minimum release of 3,250 cfs at Keswick Dam and RBPP from September through the end of February in all water years, except critical years.

Water Quality Control Plan for the San Francisco Bay/San Joaquin Delta Estuary

The 1995 San Francisco Bay/Sacramento-San Joaquin Delta (Bay-Delta) WQCP (State Water Board 1995) established water quality control objectives for the protection of beneficial uses in the Delta. The 1995 WQCP identified (1) beneficial uses of the Delta to be protected, (2) water quality objectives for the reasonable protection of beneficial uses, and (3) a program of implementation for achieving the water quality objectives. Because these new beneficial objectives and water quality standards were more protective than those of the previous State Water Board Water Right Decision 1485, the new objectives were adopted in 1995 through a water right order for operation of the CVP and SWP. Key features of the 1995 WQCP include estuarine habitat objectives for Suisun Bay and the western Delta (consisting of salinity measurements at several locations), export/inflow (E/I) ratios intended to reduce entrainment of fish at the export pumps, Delta Cross Channel gate closures, and San Joaquin River electrical conductivity (EC) and flow standards. The State Water Board adopted a new Bay-Delta WQCP on December 13, 2006. However, this new WQCP made only minor changes to the 1995 WQCP.

State Water Resources Control Board Revised Water Right Decision 1641

The 1995 Bay-Delta WQCP contains current water quality objectives. State Water Board RD-1641 (State Water Board 2000) and Water Right Order 2001-05 contain the current water right requirements to implement the 1995 WQCP. RD-1641 incorporates water right settlement agreements between Reclamation and DWR and certain water users in the Delta and upstream watersheds regarding contributions of flows to meet water quality objectives. However, the State Water Board imposed terms and conditions on water rights held by Reclamation and DWR that require these two agencies, in some circumstances, to meet many of the water quality objectives established in the 1995 WQCP. RD-1641 also authorizes the CVP and SWP to use joint points of diversion (JPOD) in the south Delta, and recognizes the CALFED Bay-Delta Program (CALFED) Operations Coordination Group process for operational flexibility in applying or relaxing certain protective standards.

Delta Outflow Requirement Delta outflow, inflow that is not exported or diverted, is the primary factor controlling water quality in the Delta. When Delta outflow is low, seawater is able to intrude further into the Delta, impacting water quality at drinking water intakes. RD-1641 specifies minimum monthly Delta outflow objectives to maintain a reasonable range of salinity in the estuarine aquatic habitat based on the Net Delta Outflow Index (NDOI). The NDOI is a measure of the freshwater outflow and is determined from a water balance that considers river inflows, precipitation, agricultural consumptive demand, and project exports. The NDOI does not take into account the semidiurnal and spring-neap tidal cycles.

The monthly minimum values of the NDOI specified in RD-1641 depend on the water year type. Minimum flows are specified for the months of January and July to December. The outflow objectives from February to June are determined based on the X2[2] objective.

Delta Salinity Objectives Salinity standards for the Delta are stated in terms of EC (for protection of agricultural and fish and wildlife beneficial uses), and

[2] X2 is the most downstream location of either the maximum daily average or the 14-day running average of 2.64 millimhos per centimeter (mmhos/cm) isohaline, as measured in river kilometers from the Golden Gate Bridge.

chloride (for protection of M&I uses). Compliance values vary with water year and month. The salinity objectives at Emmaton on the Sacramento River and at Jersey Point on the San Joaquin River often control Delta outflow requirements during the irrigation season from April through August, requiring additional releases from upstream CVP and SWP reservoirs.

X2 Objective The location of X2, the 2 parts per thousand salinity unit isohaline at 1 meter above the bottom of the Sacramento River channel, is used as a surrogate measure of ecosystem health in the Delta. The X2 objective requires specific daily surface EC criteria to be met for a certain numbers of days each month, from February through June. Compliance can also be achieved by meeting a 14-day running average salinity or 3-day average outflow equivalent. These requirements were designed to provide improved shallow water habitat for fish species in the spring. Because of the relationship between seawater intrusion and interior Delta water quality, the X2 objective also improves water quality at Delta drinking water intakes.

Maximum Export/Inflow Ratio RD-1641 includes a maximum E/I standard to limit the fraction of Delta inflows that are exported. This requirement was developed to protect fish species and to reduce entrainment losses. Delta exports are defined as the combined pumping of water at Banks and Jones pumping plants. Delta inflows are the gaged or estimated river inflows. The maximum E/I ratio is 0.35 for February through June and 0.65 for the remainder of the year. If the January eight-river runoff index is less than 1.0 MAF, the February E/I ratio is increased to 0.45. The CVP and SWP have agreed to share the allowable exports equally if the E/I ratio is limiting exports.

Joint Point of Diversion The JPOD refers to the CVP and SWP use of each other's pumping facilities in the south Delta to export water from the Delta. The CVP and SWP have historically coordinated use of Delta export pumping facilities to assist with deliveries and to aid each other during times of facility failures. In 1978, by agreement with DWR, and with authorization from the State Water Board, the CVP began using the SWP Banks Pumping Plant for replacement pumping (195,000 acre-feet per year) for pumping capacity lost at Jones Pumping Plant because of striped bass pumping restrictions in State Water Board Water Right Decision 1485. In 1986, Reclamation and DWR formally agreed that "either party may make use of its facilities available to the other party for pumping and conveyance of water by written agreement" and that the SWP would pump CVP water to make up for striped bass protection measures (Reclamation and DWR 1986).

Reclamation filed a number of temporary petitions with the State Water Board to use Banks Pumping Plant for purposes other than replacement pumping and CVP deliveries that contractually relied on SWP conveyance. Such uses included deliveries to Cross Valley Contractors, the Musco Olive Company, and the San Joaquin National Cemetery. In RD-1641, the State Water Board conditionally approved the use of the JPOD in three separate stages:

- Stage 1 is the use of the JPOD to serve Cross Valley Canal contractors, the Musco Olive Company and the San Joaquin National Cemetery; to support a recirculation study; and to recover export reductions made to benefit fish. Authorization for Stage 1 JPOD pumping to recover export reductions prohibits the CVP and SWP from annually exporting more water than each would have exported without the use of each other's pumping facilities. Stage 1 pumping is subject to State Water Board approval of a water level response plan, and a water quality response plan.

- Stage 2 is the use of the JPOD for any purpose authorized in the water rights permits up to the limitations contained in the USACE permit. In addition to the Stage 1 requirements, Stage 2 pumping is subject to State Water Board approval of an operations plan to protect aquatic resources and other legal users of water.

- Stage 3 is the use of the JPOD for any purpose authorized under the water right permits up to the physical capacity of the export pumps. Stage 3 is subject to the operation of barriers or other means to protect water levels in the south Delta, a State Water Board-approved operations plan that adequately protects aquatic resources and other legal users of water, and certification of a project-level EIR by DWR for the South Delta Improvements Program.

The State Water Board has had a policy that all water transfers must meet similar criteria and conditions, as set forth for the JPOD, and the State Water Board has mandated a "response plan" evaluation process for real-time incremental export operations to determine the effects of water transfers and JPOD operations. The State Water Board approval of the 2006 and 2007 Accord Pilot Programs included the provision that rediversion of transfer water at Banks and Jones pumping plants must be in compliance with the various plans under RD-1641 that are prerequisites for the use of the JPOD by Reclamation and DWR.

Reclamation and DWR have produced the following response plans:

- Water Level Response Plan, to address incremental effects of additional export, at the time of the export, to water levels in the south Delta environment (Reclamation and DWR 2004a)

- Water Quality Response Plan, to address incremental effects of additional export, at the time of the export, to water quality in the Delta, and south Delta specifically (Reclamation and DWR 2004b)

- Operations Plan, to protect fish and wildlife, and other legal uses of water

Vernalis Adaptive Management Plan The Vernalis Adaptive Management Plan (VAMP) was a 12-year experimental management program proposed under the 1998 San Joaquin River Agreement (SJRA), which was adopted by the State Water Resources Control Board (State Water Board) in Water Right Decision 1641 (December 1999). Although VAMP expired in 2011, VAMP requirements are included in SLWRI modeling to represent interim actions and future State Water Board objectives for San Joaquin River flows at Vernalis.

VAMP was initiated to protect juvenile Chinook salmon emigrating through the San Joaquin River and Delta, and to evaluate how Chinook salmon survival rates change in response to alterations in San Joaquin River flows and exports at CVP and SWP facilities in the south Delta when the Head of Old River Barrier is installed. A water acquisition program for in-stream flows and a monitoring program for VAMP were implemented through the SJRA, which was adopted in 2000 and twice extended, finally expiring in December 2011. Signatories to the SJRA included Reclamation, DWR, CDFW, USFWS, San Joaquin River Group Authority and member agencies, Exchange Contractors, and select CVP and SWP Contractors, San Francisco Public Utilities Commission, and several environmental interest groups.

VAMP provided guidance for flows in the lower San Joaquin River during a 31-day pulse-flow period during April and May. The predicted April 15 San Joaquin River flows at Vernalis were increased by 1 to 2 predefined “steps,” ranging from 1,200 cfs to 1,300 cfs between each step. If the average of water-year conditions for the current year and the previous year was a below-normal, dry, or critical condition, then the flows would only be increased to the next step. However, if the average of water-year conditions for the current year and the previous year was a wet, above-normal, or average (i.e., between above normal and below normal) condition, then the flows would be increased by two steps. During a multiple year drought, when the current and previous two water years were comprised of either (1) three critical years or (2) two critical years and one dry year, there would be no required flow increases under VAMP. VAMP flow requirements typically were met either through additional releases or through reductions in demands from the Merced Irrigation District, Oakdale Irrigation District, Mendota Pool Exchange Contractors, Modesto Irrigation District, and Turlock Irrigation District.

The expiration of VAMP in 2011 introduced uncertainty regarding responsibility for meeting San Joaquin River flow standards set forth in the 1995 Bay Delta Plan until new San Joaquin River flow standards are identified. In 2012 and 2013, Reclamation implemented a “single-step” VAMP, in which flows were increased by only one step in all water year types. It is anticipated that future State Water Board objectives will be as protective as the original VAMP requirements and will remain in place through 2030.

Coordinated Operations Agreement

The COA defines how Reclamation and DWR share their joint responsibility to meet Delta water quality standards and the water demands of senior water right holders, and how the two agencies share surplus flows (Reclamation and DWR 1986). The COA defines the Delta as being in either "balanced water conditions" or "excess water conditions." Balanced water conditions are periods when Delta inflows are just sufficient to meet water user demands within the Delta, outflow requirements for water quality and flow standards, and export demands. Under excess water conditions, Delta outflow exceeds the flow required to meet the water quality and flow standards. Typically, the Delta is in balanced water conditions from June to November, and in excess water conditions from December through May. However, depending on the volume and timing of winter runoff, excess or balanced water conditions may extend throughout the year.

With the goal of using coordinated management of surplus flows in the Delta to improve Delta export and conveyance capability, the COA received Congressional approval in 1986, and became Public Law 99-546. The COA, as modified by interim agreements, coordinates operations between the CVP and SWP, and provides for the equitable sharing of surplus water supply. The COA requires that the CVP and SWP operate in conjunction to meet State water quality objectives in the Bay-Delta estuary, except as specified. Under this agreement, the CVP and SWP can each contract from the other for the purchase of surplus water supplies, potentially increasing the efficiency of water operations.

Since 1986, the COA principles have been modified to reflect changes in regulatory standards, facilities, and operating conditions. At its inception, the COA water quality standards were those of the 1978 WQCP; these were subsequently modified in the 1991 WQCP. The adoption of the 1995 WQCP by the State Water Board superseded those requirements. The Environmental Water Account was established by CALFED in 2000 to protect the fish of the Bay-Delta estuary via changes in the operations of the CVP and SWP, without incurring uncompensated cost to the projects' water users. Evolution of the Clean Water Act over time has also impacted implementation of the COA.

Groundwater Regulations

Groundwater use is subject to limited statewide regulation; however, all water use in California is subject to constitutional provisions that prohibit waste and unreasonable use of water (State Water Board 1999). In general, groundwater is subject to a number of provisions in the Water Code. Assembly Bill 3030, Water Code Section 10750, commonly referred to as the Groundwater Management Act, permits local agencies to develop groundwater management plans (Reclamation and DWR 2003).

Other groundwater regulation is related primarily to water quality issues, which are addressed by several different State agencies, including the State Water

Board and nine Regional Water Quality Control Boards, the California Department of Toxic Substances Control, Department of Pesticide Regulation, and Department of Health Services.

The Supplemental Report of the 1999 Budget Act required the State Water Board to develop a comprehensive ambient groundwater monitoring plan. To meet this mandate, the State Water Board created the Groundwater Ambient Monitoring and Assessment (GAMA) Program. The primary objective of the GAMA Program is to assess water quality and relative susceptibility of groundwater resources. The GAMA Program has two sampling components: the California Aquifer Susceptibility Assessment for addressing public drinking water wells, and the Voluntary Domestic Well Assessment Project for addressing private drinking water wells.

The GAMA Program is being directed by the State Water Board Division of Water Quality, Land Disposal Section, Groundwater Special Studies Unit. The Voluntary Domestic Well Assessment Project samples domestic wells for various constituents commonly found in domestic well water, and provides that information to domestic well owners. In addition, the Voluntary Domestic Well Assessment Project includes a public education component to aid the public in understanding water quality data and water quality issues affecting domestic water wells. The Voluntary Domestic Well Assessment Project focuses on specific areas, as resources permit. The focus areas are chosen based on existing knowledge of water quality and land use, in coordination with local environmental agencies. The State Water Board incurs the costs of sampling and analysis, and results are provided to domestic well owners as quickly as possible.

6.2.3 Regional and Local

The following local laws, regulations, standards, and plans are discussed as part of the regulatory setting:

- Local surface water regulations (i.e., water supply master plans, general plans, habitat and conservation plans, land use ordinances)
- Local groundwater regulations (i.e., management plans, county ordinances)

Local Surface Water Regulations

Local surface water regulations include goals, objectives, and policies pertaining to the primary and extended study areas, including the following:

- Local water supply master plans
- County general plans
- City general plans

- Local habitat and conservation plans (e.g., Natomas Basin Habitat Conservation Plan)
- Local land-use ordinances

Local Groundwater Regulations

Local regulatory setting documents on groundwater resources in the study areas include local groundwater management plans and county ordinances. Table 6-1 lists current groundwater management plans and county ordinances that apply to agencies in the Redding Area and Sacramento Valley groundwater basins. Groundwater management plans and county ordinances in the San Joaquin Valley groundwater basins are presented in Table 6-2. These documents typically involve provisions to limit or prevent groundwater overdraft, protect groundwater quality, and regulate transfers.

6.3 Environmental Consequences and Mitigation Measures

The purpose of this section is to provide information about the environmental consequences of the SLWRI study alternatives on hydraulics and hydrology, including water management, and potential impacts on existing facilities. This section describes the methods and assumptions, criteria for determining significant impacts, and impacts and mitigation measures associated with the H&H effects of each of the SWLRI alternatives. Implementation of the action alternatives considered in the study would affect the H&H of the Sacramento River, Feather River, American River, and the CVP/SWP systems. Impacts on the H&H of the CVP/SWP systems would translate to potential impacts on related surface and groundwater supplies available for CVP/SWP water users.

6.3.1 Methods and Assumptions

A suite of modeling tools was used to evaluate the potential impacts of the No-Action Alternative and various SLWRI action alternatives on the H&H of the project, and to quantify potential benefits. The SLWRI 2012 Version CalSim-II model, developed for the SLWRI, was used to simulate CVP and SWP operations, determining the surface water flows, storages, and deliveries associated with each alternative. CalSim-II is a specific application of the Water Resources Integrated Modeling System (WRIMS) to simulate CVP and SWP water operations. A detailed description of the SLWRI 2012Version CalSim-II model, including modeling assumptions, is included in Chapter 2 of the Modeling Appendix. Delta Simulation Model 2 (DSM2), Version 8.0.6, was used to simulate Delta hydrodynamics and Delta water quality, providing the data used to discuss the water-level-related impacts of each alternative. A detailed description of DSM2 and the assumptions used in the SLWRI analysis are included in Chapter 7 of the Modeling Appendix. Analysis and modeling results are summarized below; more detailed results of the CalSim-II output can be found in Attachment 1 of the Modeling Appendix. Attachment 16 of the Modeling Appendix contains detailed results of the DSM2 modeling.

CalSim-II

CalSim-II is the application of the WRIMS software to the CVP/SWP. This application was jointly developed by Reclamation and DWR for comparative planning studies relating to CVP/SWP operations. The primary purpose of CalSim-II is to evaluate the water supply reliability of the CVP and SWP at current and/or future levels of development (e.g., 2005, 2030), with and without various assumed future facilities, and with different modes of facility operations. Geographically, the model covers the drainage basin of the Delta, and CVP/SWP exports to the San Francisco Bay Area, San Joaquin Valley, Central Coast, and Southern California.

CalSim-II simulates system operations for an 82-year period using a monthly time step. The model assumes that facilities, land use, water supply contracts, and regulatory requirements are constant over this period, representing a fixed level of development (e.g., 2005, 2030). The historical flow record of October

1921 to September 2003, adjusted for the influences of land use changes and upstream flow regulation, is used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities are represented by a network of arcs and nodes. CalSim-II uses a mass balance approach to route water through this network. Simulated flows are mean flows for the month; reservoir storage volumes correspond to end-of-month storage.

CalSim-II models a complex and extensive set of regulatory standards and operations criteria. Descriptions of both are contained in Chapter 2 of the Modeling Appendix. The hydrologic analysis conducted for this EIS used SLWRI 2012 Version CalSim-II models, which are the best available hydrological modeling tools, to approximate system-wide changes in storage, flow, salinity, and reservoir system reoperation associated with the SLWRI alternatives. Although CalSim-II is the best available tool for simulating system-wide operations, the model also contains simplifying assumptions in its representation of the real system. CalSim-II's planning capability is limited and cannot be readily applied to analyzing flood flows and hourly, daily, or weekly time steps for hydrologic conditions. The model, however, is useful for comparing the relative effects of alternative facilities and operations within the CVP/SWP system.

A general external review of the methodology, software, and applications of CalSim-II was conducted in 2003 (Close et al. 2003). An external review of the San Joaquin River Valley CalSim-II model also was conducted (Ford et al. 2006). Several limitations of the CalSim-II models were identified in these external reviews. The main limitations of the CalSim-II models are as follows:

- Model uses a monthly time step
- Accuracy of the inflow hydrology is uncertain
- Model lacks a fully explicit groundwater representation

In addition, Reclamation, DWR, and external reviewers have identified the need for a comprehensive error and uncertainty analysis for various aspects of the CalSim-II model. DWR has issued the CalSim-II Model Sensitivity Analysis Study (DWR 2005) and Reclamation has completed a similar sensitivity and uncertainty analysis for the San Joaquin River basin (Reclamation and DWR 2006a). This information will improve understanding of model results.

Despite these limitations, monthly CalSim-II model results remain useful for comparative purposes. It is important to differentiate between "absolute" or "predictive" modeling applications and "comparative" applications. In "absolute" applications, the model is run once to predict a future outcome; errors or assumptions in formulation, system representation, data, operational criteria, etc., all contribute to total error or uncertainty in model results. In "comparative" applications, the model is run twice, once to represent a base condition (no-action) and a second time with a specific change (action) to assess the change in the outcome because of the input change. In the comparative mode (the mode used for this EIS), the difference between the two simulations is of principal importance. Most potential errors or uncertainties affecting the "no-action" simulation also affect the "action" simulation in a similar manner; as a result, the effect of errors and uncertainties on the difference between the simulations is reduced. However, not all limitations are fully eliminated by the comparative analysis approach; small differences between the alternatives and the bases of comparison are not considered to be indicative of an effect of the alternative.

DSM2

DSM2 is a branched 1-dimensional model used to simulate hydrodynamics, water quality, and particle tracking in a network of riverine or estuarine channels. The hydrodynamic module can simulate channel stage, flow, and water velocity. The water quality module can simulate the movement of both conservative and nonconservative constituents. DWR uses the model to perform operational and planning studies of the Delta.

DSM2 analysis is typically performed for the period 1922 to 2003. In model simulations, EC is typically used as a surrogate for salinity. Results from CalSim-II are used to define Delta boundary inflows. CalSim-II-derived boundary inflows include the Sacramento River flow at Hood, the San Joaquin River flow at Vernalis, inflow from the Yolo Bypass, and inflow from the eastside streams. In addition, Net Delta Outflow from CalSim-II is used to calculate the salinity boundary at Martinez.

Details of the model, including source codes and model performance, are available online at the DWR Bay-Delta Office's Modeling Support Branch Web site. Documentation on model development is discussed in annual reports to the State Water Board, such as Methodology for Flow and Salinity Estimates in the Sacramento-San Joaquin Delta and Suisun Marsh, prepared by the Delta Modeling Section of DWR (DWR 2009).

6.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A significant effect on the environment means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

The significance criteria were developed based on the guidance provided by the State CEQA Guidelines, and consider the context and intensity of the environmental effects as required under NEPA. Impacts of an alternative on H&H would be significant if project implementation would cause the results in the second column of Table 6-3 to occur. Simulated stream flow and reservoir storage data, generated as part of the H&H impact assessment, were used in the impact assessments for groundwater, hydropower, flood control, water quality, fisheries, terrestrial biology, recreation, and cultural resources. Accordingly, a detailed description of changes in flow and storage expected to result from each of the SLWRI alternatives is included, in addition to the impact analysis.

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise.

Table 6-3. Impact Indicators and Significance Criteria for Water Management

Impact Indicator	Significance Criterion
Flood Management	Increase frequency or severity of damaging flood flows, as indicated by the following: • Increase frequency of daily flows above 100,000 cfs on the Sacramento River below Bend Bridge • Place housing or other structures within a 100-year flood hazard area as mapped on a Federal flood hazard boundary or Flood Insurance Rate Map or other flood hazard delineation map • Place within a 100-year flood hazard area structures that would impede or redirect flood flows
Water Supply Reliability	Reduce water supply reliability to the following CVP/SWP contractors: • North-of-Delta CVP Water Service Contractors or Refuges • South-of-Delta CVP Water Service Contractors or Refuges • SWP Table A Contractors
Water Levels in the South Delta[1]	Reduce water surface elevation, relative to the basis of comparison, with sufficient frequency and magnitude to adversely affect south Delta water users' abilities to divert water during the irrigation season.
X2 Location	Increase in X2 that adversely affects CCWD's ability to fill Los Vaqueros Reservoir: • Movement of X2 location to west of Chipps Island from February through May • Movement of X2 location to west of Collinsville during December, January, and June
Delta Excess Water Conditions	Reduction in the duration of Delta excess conditions during the November-to-June period that adversely affects CCWD's ability to fill Los Vaqueros Reservoir.
Groundwater Resources	A change in groundwater level or quality that would adversely affect users, as indicated by the following: • A change in groundwater level resulting in long-term overdraft conditions for the groundwater basins • A change groundwater quality resulting in substantially adverse effects to designated beneficial uses of groundwater.

Note:
[1] Changes in south Delta water levels are estimated using the DSM2 Model.

Key
CCWD = Contra Costa Water District
cfs = cubic feet per second
CVP = Central Valley Project
Delta = Sacramento-San Joaquín Delta
SWP = State Water Project

Flood Management

To prevent an increase in flood damages in the study area, the SLWRI must not cause a significant increase in the frequency or magnitude of flood flows on the Sacramento River. The current regulation of Shasta Dam for flood control requires that releases be restricted to quantities that will not cause downstream flows or stages to exceed, insofar as possible, (1) a flow of 79,000 cfs at the tailwater of Keswick Dam, and (2) a stage of 39.2 feet at the Sacramento River Bend Bridge gaging station near Red Bluff (corresponding roughly to a flow of 100,000 cfs). Because of the uncontrolled nature of the inflows between Keswick Dam and Bend Bridge, the 100,000 cfs flow objective at Bend Bridge is the critical objective for minimizing flood damage. It is also important to ensure that the project does not increase potential flood damages by locating any new facilities within the 100-year floodplain or in a location that could impede or redirect flood flows, thereby potentially increasing damage to other property.

Water Supply Reliability

The CVP provides water to a range of contract types; Settlement and Exchange contractors have the highest degree of reliability because of water rights senior to the CVP. Because of their high priority, these contractors are not strongly affected by any of the SLWRI alternatives. Water service contractors and refuges are subject to shortages according to water availability and their geographic location; because of conveyance constraints, south-of-Delta water service contractors and refuges have a lower degree of reliability than North-of-Delta water service contractors and refuges. Although the SWP has several contractors north of the Delta, the vast majority of recipients of SWP water supplies are south of the Delta. SWP contractors have several types of water in their contract; the Table A contracts (DWR 2003a) are most susceptible to variability of supply.

To prevent a decrease in water supply, the SLWRI must not cause a significant reduction in long term water supply reliability to CVP and SWP contractors. For this analysis a significant reduction in long term reliability is defined as a 5 percent or greater reduction in average annual or average dry and critical year reliability. This is assumed to represent a reduction that could not reliably be replaced from other sources, such as groundwater pumping or water transfers.

Some flexibility would exist to adjust for changes in surface water supply from month to month (e.g., temporarily increased ground water pumping), but long term changes in monthly supply could have a significant impact. For this analysis a significant reduction in monthly reliability is defined as a greater than 10 percent reduction in average monthly water supply. This is assumed to represent a reduction that could not reliably be replaced from other sources, such as groundwater pumping or water transfers.

South Delta Water Levels

Water levels in the south Delta are influenced to varying degrees by natural tidal fluctuations, San Joaquin River flows, barrier operations, CVP and SWP export pumping, local agricultural diversions and drainage return flows, channel capacities, siltation, and dredging. When the CVP and SWP are exporting water, water levels in local channels can be drawn down, particularly during low water years. The South Delta Water Agency and local farmers in the south and central Delta have interests in maintaining the water levels so that their siphons and pumps, which are installed at fixed locations in the Delta, can continue to be used for irrigation diversions. The SLWRI alternatives could affect the ability of the South Delta Water Agency to divert water if changes in Delta operations reduce Delta channel water levels during the irrigation season, from April to October.

The South Delta Temporary Barriers Program was initiated by DWR in 1991 to improve water conditions in the south Delta and to provide design data for permanent gates. Since 1991, DWR has seasonally installed four barriers. Three barriers, located on the Middle River, Grant Line Canal, and Old River, ensure adequate water levels and water quality for agricultural diversions. The barriers are constructed from rock fill and incorporate overflow weirs and gated culverts. These barriers are installed in spring and removed in fall. A fourth barrier is seasonally installed at the Head of the Old River for fish control. The existing seasonal barriers significantly affect water levels in the south Delta.

To determine the potential for changes in Delta CVP/SWP operations to occur as an indirect effect of Restoration flows from the San Joaquin River reaching the Delta, analyses in the EIS compared water surface elevations simulated using DSM2 to the criteria identified in the Water Level Response Plan. The criteria identified in the plan also are applied in the EIS, such that a change in water level is considered potentially significant if the following conditions are both true:

1. The simulated water level is below 0.0 feet at msl at the Old River near Tracy Boulevard Bridge and at locations above the Grant Line Canal Barrier, or 0.3 foot above msl at the Middle River near the Howard Road Bridge. A simulated water level below these thresholds would indicate a time period when Reclamation and DWR would adjust real-time operations at Jones and Banks pumping plants to maintain consistency with the provisions of the Water Level Response Plan. Typically this would include reducing diversions at Jones and Banks pumping plants.

2. The simulated water level change between the alternative and baseline is greater than a 0.1-foot decrease during the irrigation season of April through October when the simulated water levels under the baseline conditions are below the threshold values for the three locations described above. A threshold of change of 0.1-foot was selected

because it is consistent with the level of precision provided in the water level response plan standards, and it provides a conservative threshold to identify the likelihood that real-time adjustments to CVP/SWP operations would result in water recapture from the Delta that would differ from simulated operations.

X2 Location

CCWD depends almost entirely on the Delta for water supply. CCWD's raw water system consists of four Delta pumping plants (i.e., Mallard Slough, Rock Slough, Old River, and Victoria Canal), and a 160,000-acre-feet reservoir (Los Vaqueros). The intakes on Rock Slough, Old River, and Victoria Canal are the primary source for CCWD. The fourth intake at Mallard Slough is used only when water quality conditions in the western Delta permit, usually following a prolonged period of surplus Delta outflow. Water diverted at the Old River and Victoria Canal intakes is either used directly or stored in Los Vaqueros Reservoir for later use. CCWD's current operational priority is to fill Los Vaqueros Reservoir with high quality water whenever possible.

CCWD diversions to fill Los Vaqueros Reservoir are constrained by the USFWS delta smelt BOs on operations of Los Vaqueros Reservoir (USFWS 1993 and 2011), as modified by agreements among CCWD, USFWS, CDFW, and the State Water Board. From February through May, the BO precondition for filling the reservoir is that the X2 location is west of Chipps Island. In December, January, and June, the X2 location must be west of Collinsville. Filling Los Vaqueros Reservoir is unconstrained in December if no delta smelt are present at the diversion location.

For the impact analysis, it is assumed that from February to June, the X2 requirement for filling Los Vaqueros Reservoir will be met by Reclamation and DWR as part of their responsibilities under RD-1641.[3] Changes in simulated Delta conditions are considered to be potentially significant only for the months of December and January, and only when all of the following conditions are met:

- The Delta is not in balanced condition[4]
- Under the basis of comparison, X2 is west of Collinsville
- Under the SLWRI alternatives, X2 is east of Collinsville

[3] When the Eight River Index is less than 8.1 MAF, the RD-1641 X2 requirements for May and June are relaxed, potentially impacting filling of Los Vaqueros Reservoir. Model simulations show that this would occur eight times during the simulated or historical record for water years 1922 to 1994, but in these circumstances the Delta would be in balanced water conditions.

[4] Balanced water conditions are periods when it is agreed by Reclamation and DWR that releases from upstream reservoirs plus unregulated flows approximately equal the water supply needed to meet Sacramento Valley in-basin uses plus required Delta outflows and exports (Reclamation and DWR 1986).

Reclamation and DWR are not authorized to use the JPOD when the Delta is in excess conditions, and when such diversions would cause the location of X2 to shift upstream and prevent CCWD from filling Los Vaqueros Reservoir under its water right permits.

Delta Excess Water Conditions

Changes from Delta excess water conditions to balanced conditions could adversely affect CCWD's ability to fill Los Vaqueros Reservoir. Under State Water Board Water Right Decision 1629, filling Los Vaqueros Reservoir is restricted to the parts of the period from November 1 to June 30 when the Delta is in excess water conditions. Changes in simulated Delta conditions are considered to be potentially significant if during this period the following conditions are met:

- Under the basis of comparison, the Delta is in excess conditions
- Under the SLWRI alternatives, the Delta is in balanced conditions

Groundwater Resources

Impacts on groundwater resources would be considered significant if actions related to the SLWRI alternatives would cause the groundwater resources impacts described in Table 6-3. Improvements in water supply reliability under the SLWRI alternatives may affect groundwater levels, budget, and quality in the primary and extended study areas. In general, potential impacts of the SLWRI in the primary and extended study areas would result from a reduction in water extraction because of increased surface water supply reliability. Currently, CVP and SWP water users in the primary and extended study areas pump groundwater to supplement surface water supply.

Potential impacts on groundwater resources, particularly groundwater levels, budget, and water quality, are evaluated qualitatively based on changes in surface water supply. This approach is based on the assumption that the actual reduction in groundwater extraction would be proportional to the increase in surface water supply reliability that would occur in the study areas under the SLWRI alternatives. According to the 2009 update to the California Water Plan (DWR 2009), groundwater pumping is approximately 2.6, 2.7, and 5.5 MAF per year in the Sacramento (CVP north of Delta area), San Joaquin (CVP south of Delta), and Tulare Lake (SWP agricultural deliveries south of Delta, or about half of total SWP south of Delta deliveries) basins respectively. Changes in groundwater pumping in the study areas would be relatively small compared to the estimated millions of acre-feet of annual groundwater pumping. Nevertheless, the SLWRI alternatives would have a positive, albeit limited, impact by reducing reliance on groundwater in the study areas. Because effects on groundwater basins would be limited and positive, groundwater impacts are discussed qualitatively.

6.3.3 Direct and Indirect Effects

This section describes the environmental consequences of the SLWRI alternatives, and proposed mitigation measures for any impacts determined to be significant or potentially significant. All alternatives are compared to a basis of comparison. For the existing condition (2005 level of development), a CalSim-II simulation for the existing condition is used. Similarly, the future condition (2030 level of development)[5] uses a CalSim-II simulation of the No-Action/No-Project Alternative as a basis of comparison. Each of the alternatives is simulated using the same level of development so that any changes from the basis of comparison in H&H can be attributed to the alternative.

Alternatives Description

The SLWRI alternatives are described in the following subsections.

No-Action Alternative Under the No-Action Alternative, the Federal government would take reasonably foreseeable actions, including actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete. However, the Federal Government would not take additional actions toward implementing a plan to raise Shasta Dam to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water reliability issues in California. Shasta Dam would not be modified, and the CVP would continue operating similar to the existing condition. Changes in regulatory conditions and water supply demands would result in differences in flows on the Sacramento River and at the Delta between existing and future conditions. Possible changes include the following:

- Firm Level 2 Federal refuge deliveries[6]
- SWP deliveries based on full Table A amounts
- Full implementation of the Grassland Bypass Project
- Implementation of San Joaquin River flow requirements similar to the Vernalis Adaptive Management Plan

[5] The level of development used for future conditions is a composite of multiple land use scenarios developed by DWR and Reclamation. The Sacramento Valley hydrology, which includes the Sacramento and Feather River basins, is based on projected 2020 land use assumptions associated with DWR Bulletin 160-98 (1998) and the San Joaquin Valley hydrology is based on the 2030 land use assumptions developed by Reclamation. Under any 2020 to 2030 level of development scenario, the majority of the CVP and SWP unmet demand is located south of the Delta, including the San Joaquin Valley. Please see Table 2-1 in the Modeling Appendix for additional information on CalSim-II modeling assumptions.

[6] Level 2 water is the refuges' most reliable annual supply of water since Reclamation provides it to refuges from the CVP's annual water supplies. IL 4 acquisitions, however, vary from year to year, depending on annual hydrology, water availability, water market pricing, and funding. Therefore, it would be speculative to predict or assume quantities and locations of annual acquisitions from willing sellers. See Chapter 3 of the EIS for a qualitative discussion of potential effects of the action alternatives on deliveries of IL 4 water.

- Implementation of the South Bay Aqueduct Improvement and Enlargement Project
- Increased San Joaquin River diversions for water users in the Stockton Metropolitan Area after completion of the Delta Water Supply Project
- Increased Sacramento River diversions by Freeport Regional Water Project agencies
- SJRRP Full Restoration Flows

This alternative is used as a basis of comparison for future condition comparisons.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability and increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 6.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 8.5 feet and enlarge the total storage capacity in the reservoir by 256,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP1 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As with CP1, CP2 focuses on increasing water supply reliability and anadromous fish survival. CP2 primarily consists of raising Shasta Dam by 12.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 14.5 feet and enlarge the total storage capacity in the reservoir by 443,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP2 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

CP3 focuses on increasing agricultural water supply reliability while also increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 18.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Because CP3 focuses on increasing agricultural water supply reliability, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries. Operations for water supply, hydropower, and environmental and other regulatory requirements would be similar to existing operations, with the additional storage retained for water supply reliability and to expand the cold-water pool for downstream anadromous fisheries.

Simulations of CP3 did not involve any changes to the modeling logic for deliveries or flow requirements; all rules for water operations were updated to include the new storage, but were not otherwise changed.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

CP4 and CP4A focus on increasing anadromous fish survival while also increasing water supply reliability. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, both CP4 and CP4A would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. The additional storage created by the 18.5-foot dam raise would be used to improve the ability to meet temperature objectives and habitat requirements for anadromous fish during drought years and increase water supply reliability.

For CP4, about 378,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as in CP1, with 70,000 acre-feet and 35,000 acre-feet reserved specifically to focus on increasing M&I deliveries during dry and critical years, respectively. CP4 also includes augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River.

For CP4A, about 191,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as in CP2 where Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved for M&I deliveries. CP4A would help reduce future water shortages by increasing drought year and average year water supply reliability for agricultural and M&I deliveries. Like CP4, CP4A includes augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River for fisheries benefit.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily focuses on increasing water supply reliability, anadromous fish survival, Shasta Lake area environmental resources, and recreation opportunities. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP5 would increase the height of the reservoir full pool by 20.5 feet and enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD would be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 150,000 acre-feet and 75,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP5 also includes constructing additional fish habitat in and along the shoreline of Shasta Lake and along the lower reaches of its tributaries; augmenting spawning gravel and restoring riparian, floodplain, and side channel habitat in the upper Sacramento River; and increasing recreation opportunities at Shasta Lake.

CP5 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the cold-water pool in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Changes to CVP/SWP Operations

Each of the SWLRI alternatives would have similar impacts on CVP and SWP operations compared to either the existing condition or the No-Action Alternative. However, the magnitude of the impacts would vary according to the alternative. Detailed tables of the estimated monthly flows and storages associated with each alternative, in addition to changes from the bases of comparison, are included in Attachment 1 of the Modeling Appendix. Results are summarized below.

The analysis assumed that the SLWRI alternatives would not alter existing operational rules or protocols; no formal changes to CVP or SWP operating criteria are associated with the SLWRI. At a base level, each action alternative would store some additional flows behind Shasta Dam during periods when the flows would have otherwise been released downstream. The resulting increase in storage would then be used to both create an expanded cold-water pool, thus benefiting fisheries, and for subsequent release downstream when there are opportunities to put the water to beneficial use.

Reductions in Shasta releases under the various SLWRI alternatives would typically occur during winter (November through March) in relatively wet years, and increases in releases would typically occur in the late spring and summer (June through September) of drier years. Shasta Dam typically makes releases for one of six purposes:

- Flood management
- Sacramento River flow requirements both below Keswick and at Wilkins Slough
- Sacramento River water temperature requirements at Bend Bridge
- Delta water quality requirements
- Senior water rights along the Sacramento River
- CVP water supply contracts needs both north and south of the Delta

However, release for one purpose may also be sufficient for meeting another; for instance, releases for Sacramento River water temperatures may also be used to both meet Delta water quality requirements and for export to south-of-Delta contractors. Although releases for flood management purposes typically occur in winter, water temperature and water quality requirements exist year-round. Releases for water supply purposes primarily occur in late spring, summer, and early fall.

Table 6-4 summarizes monthly flows and changes below Shasta Dam. Releases from Shasta Dam would typically be increased in the summer months, corresponding with the periods of greatest agricultural demands. Similarly, releases would be reduced in the winter months, when the increased storage would be used to capture additional runoff rather than releasing to the downstream river.

Storage in Shasta Reservoir fluctuates greatly throughout a year; storage is typically highest at the end of winter, March and April, as the need for flood control reservation space in the reservoir is reduced. Storage is typically at its lowest in October and November after the irrigation season and before the winter refill begins. As a result of the increased storage capacity attributed to each alternative, and the flow reductions described above, Shasta Reservoir storage would be generally higher under the SLWRI alternatives than under the existing condition or the No-Action Alternative (future condition). This additional storage would typically be greatest in the winter (March and April), and would be lowest at the end of summer (October or November), as shown in Table 6-5. Additional runoff captured by the increased storage increment would typically remain in storage until it could be used to meet one of the purposes described above. Conversely, under either of the bases of comparison, if water in storage were insufficient to meet all of the project purposes, the first increment to be reduced would be deliveries to water service contractors. Therefore, increased releases would typically be made on a schedule providing increased reliability of deliveries to water service contractors, typically in July through October of relatively dry years.

A key indicator of water temperature benefits of the SLWRI alternatives to the Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Reservoir before the water temperature operation season, about May through October. As previously described, Shasta Reservoir generally reaches its maximum storage during late April or early May. Also, the cold-water pool volume in the lake accumulates during the winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for each dam raise alternative should also result in an incremental increase in the cold-water pool volume.

Reclamation operates the Shasta Dam TCD to manage water temperatures in the Sacramento River to: (1) improve habitat for the endangered winter-run Chinook salmon and other threatened runs, (2) withdraw warmer surface water in the winter and spring to preserve cold-water storage for release during the temperature operation season, and (3) enable power generation to continue while controlling release temperatures, which eliminates the need to bypass the powerplant penstocks via the low-level river outlets. Generally, to accomplish these temperature objectives during the temperature operation season, the TCD functions to select water temperatures in the 47 degrees Fahrenheit (°F) to 52°F range. Therefore, a good index of the temperature-related benefits of the alternative is the volume of the cold-water pool less than 52°F at the end of April. In the context of historical project operation, reservoir storage and cold-water pool conditions in mid-spring represent the available cold-water "bank" managed throughout the temperature operation season (July through October), as prescribed by the SRTTG. The simulated end-of-April volume of water less than 52°F for the two bases of comparison, and the change in cold-water pool volume for each of the SLWRI alternatives, are shown by Sacramento Valley Index in Table 6-6. As expected, the higher dam raise alternatives generally reflect a larger cold-water pool volume.

Table 6-6. Simulated Average Volume of Water Less than 52˚F in Shasta Reservoir at the End of April

Downstream from Shasta Dam, the Sacramento River combines with releases from Trinity Reservoir through Whiskeytown Reservoir and Spring Creek Tunnel above Keswick Dam. Because of the connected nature of Shasta Reservoir and Trinity Reservoir for meeting instream flow requirements and water supply demands below Keswick Dam, changes in Shasta Reservoir operations would possibly result in changes to operations of Trinity Reservoir. Table 6-7 shows changes in Trinity Reservoir storage and Trinity River flows below Lewiston that would result from SLWRI alternatives. These changes are small relative to the reservoir storage and should not result in noticeable changes at Trinity Reservoir. To limit the effect of the enlarged Shasta Reservoir on Trinity Reservoir operations, the relationship in CalSim-II between Shasta Reservoir storage and Trinity Reservoir exports to the Sacramento River was modified through interpolation to approximately maintain the export level of the basis of comparison in the action alternatives.

Below Keswick Dam, Sacramento River flows would be increasingly affected by tributary inflows rather than releases from Shasta Lake. Table 6-8 shows the input monthly average tributary inflows to the Sacramento River between Keswick Dam and RBPP. The tributary inflows are consistent between the 2005 and 2030 levels of development simulations and for each alternative. Below RBPP, flow changes associated with the SLWRI alternatives would be considerably smaller relative to total flow in the river.

Tributary influence on Sacramento River monthly average flows is apparent when existing condition and No-Action Alternative total flows are compared (see Tables 6-4 and 6-9). Total flows are greater downstream from RBPP, after several tributaries have entered the Sacramento River, than they are immediately downstream from Shasta Dam.

In addition to the multiple tributary inflows between Keswick Dam and Red Bluff, downstream flows on the Sacramento River would be affected by diversions above RBPP. Specifically, contractors off Tehama-Colusa Canal receive supplies from above the RBPP. Because contractors off Tehama-Colusa Canal are all water service contractors, and thus would be subject to delivery shortages when CVP storage is low, the SLWRI alternatives would result in increased deliveries to Tehama-Colusa Canal contractors in relatively dry years. Table 6-10 shows simulated diversions from RBPP to Tehama-Colusa Canal in dry and critical years. Agricultural diversions typically occur between April and September, with some additional diversions in March and October; accordingly, deliveries on Tehama-Colusa Canal increase in the agricultural diversion months, but see no changes in other months with little or no irrigation.

Although Tehama-Colusa Canal water users are the primary recipient of CVP water service contract deliveries north of the Delta, other north-of-the-Delta users are subject to changes in water supply, including wildlife refuges. Average monthly deliveries to CVP water service contractors and refuges north of the Delta are included in Table 6-11.

As would be expected, the change in deliveries to water service contractors increases with the greater enlargement volumes, and increases in deliveries are much greater in the dry and critical years than in average years, corresponding to the increased likelihood of shortages during drier periods. On a long-term average basis, there would be no significant change in deliveries to refuges. Minor increases and decreases in Refuge deliveries are not a true representation of real-time operations but an indication of modeling artifacts. Such reduction would not occur in real time due to efficient water allocation and management schemes that can be captured adequately in a water resources planning model such as CalSim-II. Table 6-12 shows average deliveries to water service contractors and refuges north of Delta in dry and critical years.

As described in Chapter 1 of the *Hydrology, Hydraulics, and Water Management Technical Report*, during high flow periods, Sacramento River flows below Red Bluff can be diverted into the Sutter Bypass near Ord Ferry, or from the Moulton, Colusa, or Tisdale weirs. Similarly, flows can be diverted into the Yolo Bypass from the Fremont and Sacramento weirs. Table 6-14 shows the recurrence of annual spills over the various Sacramento Valley weirs into the Sutter and Yolo bypasses.

Table 6-14. Simulated Number of Years of Sacramento Valley Weir Spill

As the Sacramento River nears the Delta, the basis-of-comparison flow would increase considerably so that flow changes associated with SLWRI alternatives would be miniscule in most months. Table 6-15 shows the simulated monthly average Sacramento River flow below Freeport. Flow changes because of each alternative are small compared to the bases of comparison; average monthly flow changes are typically between 0 percent and 2 percent. Larger flow increases are because of operations specifically for export; since conditions typically only allow for increased exports in July, August, and September, the majority of the changes are observed during those months.

Table 6-15. Simulated Monthly Average Sacramento River Flows Below Freeport

Because of the interconnected nature of CVP and SWP operations for meeting shared Sacramento River flow requirements and Delta water quality obligations, changes in Shasta Reservoir operations could potentially affect operations of both Oroville Reservoir on the Feather River and Folsom Reservoir on the American River. For example, an increase in Shasta Reservoir releases may create opportunities for increased SWP export of releases from Oroville Reservoir by improving Delta water quality. Tables 6-16 and 6-17 show simulated end-of-month storage at Oroville Reservoir and Feather River flow below the Thermalito Afterbay, respectively.

Similarly, an increase in Shasta Reservoir releases in a particular month may result in improved Delta water quality, allowing for a possible reduction in CVP releases from the American River, and a corresponding increase in Folsom Reservoir storage. Tables 6-18 and 6-19 show simulated end-of-month storage at Folsom Reservoir and on the American River near the H-Street Bridge, respectively.

Table 6-18. Simulated Average End-of-Month Folsom Reservoir Storage

The Delta is the confluence of the Sacramento, San Joaquin, Cosumnes, Calaveras, and Mokelumne rivers in addition to several other smaller streams and creeks. As the “central hub” of California’s water supplies, minor changes in operations in one region could result in other minor changes throughout the system. As previously described, changes in operations associated with the SLWRI alternatives could possibly result in minor changes in operations to other CVP and SWP facilities. New Melones Reservoir on the Stanislaus River is operated by the CVP to meet water quality requirements in the lower San Joaquin River only, not in the South Delta, and would not be expected to be affected by changes in Sacramento River flow or Delta exports. Simulations indicate the SLWRI alternatives would not result in any changes to New Melones operations. (See Attachment 1 of the Modeling Appendix for details about New Melones Reservoir and Stanislaus River operations.)

Besides potentially changing exports to south-of-Delta water users, changes in Delta inflow could also be reflected in changes in Delta outflow. Changes in Sacramento River flow, as shown above in Table 6-15, are typically reflected as a combination of Delta outflow and export. Table 6-20 shows changes in Delta outflow associated with each alternative.

Table 6-20. Simulated Monthly Average Change in Delta Outflow

SLWRI = Shasta Lake Water Resources Investigation

TAF = thousand acre-feet

The CVP and SWP divert water via the Jones Pumping Plant and the Banks Pumping Plant, respectively. The increase in water supply from the SLWRI alternatives would typically be moved through the Jones Pumping Plant. However, even under existing conditions or No-Action Alternative (the bases of comparison), pumping capacity at Jones is often already maximized in wetter years, leaving little ability to export any additional water due to physical pumping limits or regulatory pumping restrictions. Accordingly, although unmet CVP demand south of the Delta may exist in some relatively wet years, conveyance restrictions could limit opportunities to export available water south of the Delta in those years. In drier years, however, capacity is typically available to increase pumping at Jones Pumping Plant, and with the increase in Shasta storage there is an increase in water supply available for pumping. Thus, there are greater increases in average annual pumping volumes in drier years.

Tables 6-21 and 6-22 show the average annual exports through Jones Pumping Plant in all years and dry and critical years only, respectively.

Recipients of exports through the Jones Pumping Plant include San Joaquin Valley Exchange Contractors, Federal wildlife refuges, and water service contractors. Because the Exchange Contractors have substantially higher levels of reliability of delivery compared to the refuges and water service contractors, their deliveries will not change under any of the SLWRI alternatives. Deliveries to the refuges and water service contractors would increase with an enlargement of Shasta Dam.

Tables 6-23 and 6-24 show the mean monthly delivery to the CVP south-of-Delta refuges and water service contractors for all years and for dry and critical years respectively. Differences in timing between exports through the Jones and Banks pumping plants and deliveries to CVP and SWP contractors are because of the ability of both projects to store water in San Luis Reservoir during winter months and to use that storage to augment Delta exports in summer months. (Attachment 1 of the Modeling Appendix includes information about San Luis Reservoir storage.)

Source: SLWRI 2012 Version CalSim-II model 2005 and 2030 simulations (Nodes DEL_CVP_PAG_S and DEL_CVP_PRF_S)

Notes: Simulation period: 1922-2003
Dry and critical years as defined by the Sacramento Valley Index
(%) indicates percent change from either existing condition or No-Action Alternative
Key:
Alt = alternative
cfs = cubic feet per second
CP = comprehensive plan
CVP = Central Valley Project
SLWRI = Shasta Lake Water Resources Investigation
TAF = thousand acre-feet

When evaluating project effects on water supply reliability, CVP south-of-Delta allocations are a valuable indicator of benefits resulting from each alternative. Tables 6-25 and 6-26 show the simulated annual allocations to south-of-Delta agricultural and M&I refuges and water service contractors for the existing condition and the No-Action Alternative, and the simulated change in allocation for each of the SLWRI alternatives. Simulated allocations are calculated by dividing annual deliveries of each contract type by the demand. The contract period for CVP allocations is assumed to be March through February; the assumed simulated demand for each contract type is as follows:

- **Agricultural water service contractors –** 1.987 MAF/year (both 2005 and 2030 level of development)
- **M&I water service contractors –** 164,200 acre-feet/year (both 2005 and 2030 level of development)
- **Federal refuges –** 304,600 acre-feet/year (2005 level of development) and 281,100 acre-feet/year (2030 level of development)

Tables 6-25 and 6-26 show that changes in allocations would typically increase, and years with small decreases in allocations could occur. More important than the average annual change in allocation is the increase in allocation in years with low allocations under either the existing condition or No-Action Alternative, such as in 1928, 1944, and 1976. Some decreases in allocations would occur during years in the latter parts of prolonged droughts. This likely is because of changes in CalSim-II north-of-Delta reservoir storage and water supply relationships.

Table 6-25. Simulated Annual Delivery Allocations to South-of-Delta CVP Water Service Contractors and Refuges for a 2005 Level of Development

Table 6-26. Simulated Annual Delivery Allocations to South-of-Delta CVP Water Service Contractors and Refuges for a 2030 Level of Development (contd.)

Key:
% = percent
Ag = Agricultural Water Service Contractor
Alt = alternative
Avg = average
CP = Comprehensive Plan
CVP = Central Valley Project
M&I = municipal and industrial contractor
Ref = refuge
Refuge = Level 2 Federal Refuge
SLWRI = Shasta Lake Water Resources Investigation

The Banks Pumping Plant provides water supply to SWP contractors, and when capacity is available may also export CVP water to support CVP deliveries. CP1, CP2, CP4, CP4A, and CP5 all include reserving a portion of the increased storage capacity in Shasta Reservoir to specifically focus on increasing M&I deliveries. For this EIS, these operations were simulated in CalSim-II by using the reserved storage capacity to provide deliveries for previously unmet SWP demands during dry and critical years. These additional water supplies for SWP deliveries are pumped through Banks Pumping Plant. Table 6-27 shows average annual exports through Banks Pumping Plant for the various SLWRI alternatives.

Table 6-27. Simulated Monthly Average Exports Through the Banks Pumping Plant

Changes in Delta export operations could potentially result in changes in reservoir operations south of the Delta along the San Joaquin River due to changes in return flows from project deliveries. These changes, if they occur, would be expected to be very small. Any changes in operations of San Joaquin River basin reservoirs would be reflected in changes in San Joaquin River flows near its confluence with the Delta. The San Joaquin River at Vernalis is commonly used as the downstream end of the San Joaquin River. Table 6-30 shows simulated San Joaquin River flow at Vernalis. According to modeling, the SLWRI alternatives do not affect San Joaquin River flows at Vernalis.

Table 6-30. Simulated Monthly Average San Joaquin River Flows at Vernalis

No-Action Alternative

For a complete list of the differences between the No-Action Alternative and the existing conditions, see Table 2-1 in the Modeling Appendix.

As described above, modeling indicates that the No-Action Alternative would continue to meet water supply demands at levels of compliance similar to the existing conditions and would not result in any appreciable changes in water supply reliability.

Shasta Lake and Vicinity The significance criteria for H&H do not apply in the Shasta Lake and vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this EIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (No-Action): Change in Frequency of Flows above 100,000 cfs on the Sacramento River below Bend Bridge Flood management operations would not change under the No-Action Alternative as compared to the existing condition; the recurrence of flows above 100,000 cfs on the Sacramento River below Bend Bridge would remain the same as the existing condition. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact H&H-2 (No-Action): Place Housing or Other Structures within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map No new structures would be built in the floodplain under the No-Action Alternative, and flood management operations at Shasta Dam would not change under the No-Action Alternative as compared to the existing condition. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact H&H-3(No-Action): Place within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows No new structures would be built in the floodplain under the No-Action Alternative, and flood management operations at Shasta Dam would not change under the No-Action Alternative. No impact would occur. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta

Impact H&H-4 (No-Action): Change in Water Levels in the Old River near Tracy Road Bridge Water levels in the Old River near Tracy Road Bridge could be slightly lower under the No-Action Alternative than the existing condition. This impact would be less than significant.

As shown in Table 6-31, maximum monthly reductions in minimum daily water level associated with No-Action compared to the existing conditions would exceed -0.1 feet; however, the reductions would not result in water levels less than 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Table 6-31. Simulated Monthly Maximum 15-Minute Change in Water Levels at Various Locations in the South Delta at Low-Low Tide

Month	Change from Existing Condition		
	Old River near Tracy Road Bridge (feet)	Grant Line Canal near the Grant Line Canal Barrier (feet)	Middle River near the Howard Road Bridge (feet)
Apr	-0.02 (0%)	-0.02 (0%)	-0.02 (0%)
May	-0.27 (0%)	-0.37 (0%)	-0.29 (0%)
Jun	-0.42 (0%)	-0.48 (0%)	-0.45 (0%)
Jul	-0.05 (0%)	-0.04 (0%)	-0.05 (0%)
Aug	-0.05 (0%)	-0.02 (0%)	-0.05 (0%)
Sep	-0.19 (0%)	-0.08 (0%)	-0.21 (0%)
Oct	-0.08 (0%)	-0.03 (0%)	-0.08 (0%)

Source: Version8.0.6 DSM2 2005 and 2030 simulations (Node 071_3116, Node 129_5691, and Node 206_5533)

Notes:
Simulation period: 1922-2003
(%) indicates the percentage of months out of 82 years with a maximum decrease in water level exceeding 0.1 feet.

Impact H&H-5 (No-Action): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Water levels in the Grant Line Canal near the Grant Line Canal Barrier could be slightly lower under the No-Action Alternative than the existing condition. This impact would be less than significant.

As shown in Table 6-31, maximum monthly reductions in minimum daily water level associated with No-Action compared to the existing conditions would exceed -0.1 feet; however, the reductions would not result in water levels less than 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact H&H-6 (No-Action): Change in Water Levels in the Middle River near the Howard Road Bridge Water levels in the Middle River near the Howard Road Bridge could be slightly lower under the No-Action Alternative than the existing condition. This impact would be less than significant.

As shown in Table 6-31, maximum monthly reductions in minimum daily water level associated with No-Action compared to the existing conditions would exceed -0.1 feet; however, the reductions would not result in water levels less than 0.3 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact H&H-7 (No-Action): Change in X2 Position The X2 position would not change from west to east of Collinsville in December or January when the Delta would not be in balanced conditions. Examination of simulation output indicates that compared to the existing condition, in no months would the No-

Action Alternative cause the X2 position to shift from west to east of Collinsville, when the Delta would not be in balanced conditions. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact H&H-8 (No-Action): Change in Recurrence of Delta Excess Conditions Few changes would occur from excess to balanced Delta conditions under the No-Action Alternative. This impact would be less than significant.

As shown in Table 6-32, CP1 would cause the Delta to change from excess to balanced conditions 16 times in the simulation; however, no month would change more than 5 percent of the time and at most only once during the 82-year period, according to the simulation. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Table 6-32. Simulated Number of Years the Delta Changes from Excess to Balanced Condition

Number of Years the Delta Changes from Excess to Balanced Conditions Compared to Existing Condition

CVP/SWP Service Areas

Impact H&H-9 (No-Action): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to North-of-Delta CVP water service contractors would decrease under the No-Action Alternative relative to the existing condition. Average annual deliveries to north-of-Delta refuges would increase under the No-Action Alternative relative to the existing condition. The impact on North-of-Delta CVP water service contractors would be potentially significant.

As shown in Table 6-33, average annual deliveries to North-of-Delta CVP water service contractors would decrease under the No-Action Alternative. Deliveries to refuges under the No-Action Alterative would be greater than under existing conditions. This impact to water service contractors would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 6-33. Simulated Monthly Average Deliveries and Percent Change of Deliveries to North-of-Delta CVP Water Service Contractors and Refuges

Month	Change from Existing Conditions

Impact H&H-11 (No-Action): Change in Deliveries to SWP Table A Contractors Average deliveries to SWP Table A contractors would increase under the No-Action Alternative relative to the existing condition. This impact would be beneficial.

As shown in Table 6-35, average annual and monthly deliveries to SWP Table A contractors would increase under the No-Action Alternative relative to existing conditions for the average of all years, and for dry and critical years. This impact would be beneficial. Mitigation is not required for the No-Action Alternative.

Table 6-35. Simulated Monthly Average Deliveries and Percent Change of Deliveries to SWP Table A Contractors

Source: SLWRI 2012 Version CalSim-II model 2005 and 2030 simulations (Nodes DEL_SWP_PAG and DEL_SWP_PMI)

Note:

Simulation period: 1922-2003. Change as measured from either existing condition or No-Action Alternative. Dry and critical years as defined by the Sacramento Valley Index

Key:

% = percent

cfs = cubic feet per second

SLWRI = Shasta Lake Water Resources Investigation

SWP = State Water Project

TAF = thousand acre-feet

Impact H&H-12(No-Action): Change in Groundwater Changes in groundwater levels would not be measurable under the No-Action Alternative as compared to the existing condition. This impact would be less than significant.

As shown in Tables 6-33, 6-34, and 6-35, total surface water deliveries to CVP and SWP contractors increase for the No-Action Alternative as compared to the existing condition. However, these increases in deliveries are likely associated with increases in demands rather than increases in water supply. Although groundwater pumping would still be required, the volume of pumping in the CVP/SWP service area would not be expected to change noticeably. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact H&H-13 (No-Action): Change in Groundwater Quality Changes in groundwater quality under the No-Action Alternative as compared to the existing condition would not be measurable. This impact would be less than significant.

As shown in Tables 6-11, 6-12, 6-23, 6-24, 6-28, and 6-29, total surface water deliveries to CVP and SWP contractors increase for the No-Action Alternative compared to the existing condition. However, these increases in deliveries are likely associated with increases in demands rather than increases in water supply. Although groundwater pumping would still be required, the volume of pumping in the CVP/SWP service area would not be expected to change noticeably. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 primarily consists of raising Shasta Dam by 6.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 8.5 feet and enlarge the total storage capacity in the reservoir by 256,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries.

Shasta Lake and Vicinity The significance criteria for H&H do not apply in the Shasta Lake and vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this EIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP1): Change in Frequency of Flows above 100,000 cfs on the Sacramento River below Bend Bridge Although flood management operations would not change under CP1, a slight reduction could occur in the frequency of flows greater than 100,000 cfs. This impact would be beneficial.

SLWRI modeling uses a monthly time step, which is inappropriate for flood control analysis; however, flood management operations for downstream objectives would not change under CP1. Although a slight decrease in recurrence of high flows would be possible because of the increased storage capability, CP1 would not increase the frequency of flows above 100,000 cfs.

This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP1): Place Housing or Other Structures within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map No new structures would be built downstream from Shasta Dam. All project construction would be completed at the Shasta Dam site, and although the reservoir area would be expanded, any structures located within the reservoir area would be removed. Because reservoir operations for downstream objectives would not change, no additional structures downstream from the dam would be located within the 100-year flood hazard area. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP1): Place within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows No new structures would be built downstream from Shasta Dam. All project construction would be done at the Shasta Dam site, and although the reservoir area would be expanded, any structures located within the reservoir area would be removed. Because reservoir operations for downstream objectives would not change, no additional structures downstream from the dam would be located within the 100-year flood hazard area that would impede or redirect flood flows. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP1): Change in Water Levels in the Old River near Tracy Road Bridge Simulated water levels in the Old River near Tracy Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-36, maximum monthly reduction in minimum daily water level associated with CP1 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-36. Simulated Monthly Maximum 15-Minute Change in Old River Water Levels near Tracy Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP1 (2005) Change (feet)	CP1 (2030) Change (feet)

Impact H&H-5 (CP1): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Simulated water levels in the Grant Line Canal near the Grant Line Canal Barrier show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-37, maximum monthly reduction in minimum daily water level associated with CP1 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-6 (CP1): Change in Water Levels in the Middle River near the Howard Road Bridge Simulated water levels in the Middle River near the Howard Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-38, maximum monthly reduction in minimum daily water level associated with CP1 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action alternative. The water levels would remain above 0.3 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-38. Simulated Monthly Maximum 15-Minute Change in Middle River Water Levels near the Howard Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP1 (2005) Change (feet)	CP1 (2030) Change (feet)

Key:
CP = comprehensive plan

Impact H&H-7 (CP1): Change in X2 Position The X2 position would not change from west to east of Collinsville in December or January when the Delta was not in balanced conditions. Examination of simulation output indicates that compared to the existing condition, or No-Action Alternative, CP1 shows no months when the X2 position shifts from west to east of Collinsville when the Delta would not be in balanced conditions. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP1): Change in Recurrence of Delta Excess Conditions Changes from excess to balanced Delta conditions would be rare. This impact would be less than significant.

As shown in Table 6-39, CP1 would cause one April, one June, two Julys, three Augusts, one October, and one November to switch from excess to balanced Delta conditions when compared to the existing condition, and two Augusts, two Novembers, and one each of October and December when compared to the No-Action Alternative. Because of the low number of occurrences, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact H&H-9 (CP1): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to North-of-Delta water service contractors would increase under all conditions. Average annual deliveries to Refuges would not change under all conditions. This impact would be less than significant.

As shown in Table 6-40, average annual deliveries to North-of-Delta water service contractors under both existing and future conditions would increase relative to the basis of comparison. Deliveries to Refuges North-of-Delta would not significantly change under all conditions on an annual average basis. Minor increases and decreases in Refuge deliveries are not true representation of real-time operations but an indication of modeling artifacts. Such reduction would not occur in real time due to efficient water allocation and management schemes that cannot be captured adequately in a water resources planning model such as CalSim-II. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-40. Simulated Monthly Average Deliveries and Percent Change of Deliveries to North-of-Delta CVP Water Service Contractors and Refuges

Impact H&H-11 (CP1): Change in Deliveries to SWP Table A Contractors

Average annual deliveries would increase under both existing and future conditions, but some less than significant decreases could occur in monthly deliveries under future conditions. This impact would be less than significant.

As shown in Table 6-42, average annual deliveries to SWP Table A contractors would increase under CP1 in both existing and future conditions relative to the bases of comparison in both average years and in dry and critical years. Under both existing and future conditions some decreases could occur in deliveries under CP1.These decreases would be less than 1 percent. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-42. Simulated Monthly Average Deliveries and Percent Change of Deliveries to SWP Table A Contractors

TAF = thousand acre-feet

Impact H&H-12 (CP1): Change in Groundwater Levels CP1 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. This impact would be beneficial.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP1. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. With less groundwater pumping, groundwater basins that were in overdraft conditions would be anticipated to improve as a result of increasing groundwater levels. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP1): Change in Groundwater Quality CP1 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. This impact would be less than significant for groundwater quality.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP1. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. Because CP1 would have a positive, albeit limited, impact by reducing reliance on groundwater, the effects of CP1 on groundwater quality also would be limited. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP2 primarily consists of raising Shasta Dam by 12.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 14.5 feet and would enlarge the total storage capacity in the reservoir by 443,000 acre-feet. The existing TCD also would be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries.

Shasta Lake and Vicinity The significance criteria for H&H do not apply in the Shasta Lake and vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this EIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP2): Change in Frequency of Flows above 100,000 cfs on the Sacramento River below Bend Bridge Although flood management operations would not change under CP2, a slight reduction could occur in the frequency of flows greater than 100,000 cfs. This impact would be beneficial.

SLWRI modeling uses a monthly time step, which is inappropriate for flood control analysis; however, flood management operations for downstream objectives would not change under CP2. Although a slight decrease in recurrence of high flows would be possible because of the increased storage capability, CP2 would not increase the frequency of flows above 100,000 cfs. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP2): Place Housing or Other Structures within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map This impact would be the same as Impact H&H-2 (CP1); no new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP2): Place within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows This impact would be the same as Impact H&H-3 (CP1); no new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP2): Change in Water Levels in Old River near Tracy Road Bridge Simulated water levels in the Old River near Tracy Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-43, maximum monthly reduction in minimum daily water level associated with CP2 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-43. Simulated Monthly Maximum 15-Minute Change in Old River Water Levels near Tracy Road Bridge at Low-Low Tide

Impact H&H-5 (CP2): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Simulated water levels in the Grant Line Canal near the Grant Line Canal Barrier show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-44, maximum monthly changes in minimum daily water level associated with CP2 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-6 (CP2): Change in Water Levels in the Middle River near the Howard Road Bridge Simulated water levels in the Middle River near the Howard Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-45, maximum monthly changes in minimum daily water level associated with CP2 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.3 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-7 (CP2): Change in X2 Position The X2 position would change from west to east of Collinsville in one December compared to the existing conditions, when the Delta would not be in balanced conditions. This impact would be less than significant.

Examination of simulation output indicates that compared to the existing condition, only in one month, December 1979, would the X2 position change from west to east of Collinsville. Under the existing conditions, the X2 position would be at 78.25 kilometers (km), and under CP2, it would be at 81.27 km, a 3.03 km shift; however, the Delta was not in balanced conditions. When compared to the No-Action Alternative, CP2 shows no months when the No-Action Alternative would cause the X2 position to shift from west of Collinsville to east of Collinsville when the Delta is not in balanced conditions.

This single month change would not significantly limit CCWD's ability to fill Los Vaqueros Reservoir. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP2): Change in Recurrence of Delta Excess Conditions Changes from excess to balanced Delta conditions would be rare. This impact would be less than significant.

As shown in Table 6-46, CP2 would cause few changes from excess to balanced Delta conditions when compared to the existing condition and the No-Action Alternative. Because of the low number of occurrences, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-46. Simulated Number of Years the Delta Changes from Excess to Balanced Condition

	Number of Years the Delta Changes from Excess to Balanced Conditions Compared to Existing Condition or No-Action Alternative

CVP/SWP Service Areas

Impact H&H-9 (CP2): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to North-of-Delta CVP Water Service Contractors would increase under all conditions. This impact would be beneficial. Annual average deliveries to North-of-Delta refuges would not change under all conditions. This impact would be less than significant.

As shown in Table 6-47, average annual deliveries to North-of-Delta CVP Service Water Contractors under both existing and future conditions would increase relative to the basis of comparison. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed. Average annual deliveries to North-of-Delta refuges would not change under all conditions. Minor increases and decreases in Refuge deliveries are not a true representation of real-time operations but an indication of modeling artifacts. Such reduction would not occur in real time due to efficient water allocation and management schemes that cannot be captured adequately in a water resources planning model such as CalSim-II. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-10 (CP2): Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to South-of-Delta CVP Water Service Contractors would increase under all conditions. This impact would be beneficial. Annual average deliveries to South-of-Delta refuges would not change under all conditions. This impact would be less than significant.

As shown in Table 6-48, average annual deliveries to South-of-Delta CVP Water Service Contractors under both existing and future conditions would increase relative to the basis of comparison. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed. Average annual deliveries to South-of-Delta refuges would not change under all conditions. Minor increases and decreases in Refuge deliveries are not a true representation of real-time operations but an indication of modeling artifacts. Such reduction would not occur in real time due to efficient water allocation and management schemes that cannot be captured adequately in a water resources planning model such as CalSim-II. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-11 (CP2): Change in Deliveries to SWP Table A Contractors
Average annual and monthly deliveries would increase under both existing and future conditions. This impact would be less than significant.

As shown in Table 6-49, average annual deliveries to SWP Table A contractors would increase under CP2 in both existing and future conditions relative to the bases of comparison in both average years and in dry and critical years. Some decreases in monthly average deliveries could occur under CP2 relative to existing conditions and the No-Action Alternative in both average annual and dry and critical years. These decreases would be less than 1 percent. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-12 (CP2): Change in Groundwater Levels CP2 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. This impact would be beneficial.

With increased water supply deliveries to CVP and SWP water contractors, and with an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP2. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. With less groundwater pumping, groundwater basins that were in overdraft conditions would be anticipated to improve as a result of increasing groundwater levels. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP2): Change in Groundwater Quality CP2 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. This impact would be less than significant.

With increased water supply deliveries to CVP and SWP water contractors, and with an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP2. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries could result in a decrease in groundwater pumping. Because CP2 could have a positive, albeit limited, impact by reducing reliance on groundwater, the effects of CP2 on groundwater quality also would be limited. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP3 primarily consists of raising Shasta Dam by 18.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 20.5 feet and would enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD also would be extended to achieve efficient use of the expanded cold-water pool. Because CP3 would focus on increasing agricultural water supply reliability, none of the increased storage capacity in Shasta Reservoir would be reserved for increasing M&I deliveries.

Shasta Lake and Vicinity The significance criteria for H&H do not apply in the Shasta Lake and vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this EIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP3): Change in Frequency of Flows above 100,000 cfs on the Sacramento River below Bend Bridge Although flood management operations would not change under CP3, a slight reduction could occur in the frequency of flows greater than 100,000 cfs. This impact would be beneficial.

SLWRI modeling uses a monthly time step, which is inappropriate for flood control analysis; however, flood management operations for downstream objectives would not change under CP3. Although a slight decrease in recurrence of high flows would be possible because of the increased storage capability, CP3 would not increase the frequency of flows above 100,000 cfs. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP3): Place Housing or Other Structures within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map This impact would be the same as Impact H&H-2 (CP1); no new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP3): Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows This impact would be the same as Impact H&H-3 (CP1); no new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP3): Change in Water Levels in the Old River near Tracy Road Bridge Simulated water levels in the Old River near Tracy Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-50, maximum monthly reduction in minimum daily water level associated with CP3 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-50. Simulated Monthly Maximum 15-Minute Change in Old River Water Levels near Tracy Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP3 (2005) Change (feet)	CP3 (2030) Change (feet)

Notes:

Simulation period: 1922-2003

(%) indicates the percentage of months out of 82 years with a maximum decrease in water level exceeding 0.1 feet.

Key:

CP = comprehensive plan

Impact H&H-5 (CP3): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Similar to Impact H&H-5 (CP1), CP3 would have the potential to affect water levels in the Grant Line Canal above the Grant Line Canal Barrier. This impact would be less than significant.

As shown in Table 6-51, maximum monthly changes in minimum daily water level associated with CP3 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition. Similarly, when compared to the No-Action Alternative, maximum monthly changes would be less than 0.1 foot in all months during the irrigation season.

Table 6-51 also shows the percentage of months when the maximum decreases in water levels are greater than 0.1 feet when the water levels under the baseline conditions are below the identified limit of 0.3 feet in the Grant Line Canal near the Grant Line Canal Barrier. These maximum decreases in water lever would not violate the threshold and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-51. Simulated Monthly Maximum 15-Minute Change in Grant Line Canal Water Levels near the Grant Line Canal Barrier at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative
	CP3 (2005) Change (feet)	CP3 (2030) Change (feet)
Apr	0 00 (0%)	-0.02 (0%)
May	-0.02 (0%)	-0.02 (0%)
Jun	-0.04 (0%)	-0.03 (0%)
Jul	-0.02 (0%)	-0.03 (0%)

Key:
CP = comprehensive plan

Impact H&H-6 (CP3): Change in Water Levels in the Middle River near the Howard Road Bridge This impact is similar to Impact H&H-6 (CP1). During the agricultural season (April through October), the maximum change in water level at low-low tide compared to the existing condition would exceed 0.1 foot in one month, September 1986. This impact would be less than significant.

As shown in Table 6-52, when compared to the No-Action Alternative, maximum monthly changes would be less than 0.1 foot in all months during the irrigation season. Table 6-52 also shows the percentage of months when the maximum decreases in water levels would be greater than 0.1 feet when the water levels under the baseline conditions were below the identified limit of 0.3 feet in the Middle River near the Howard Road Bridge. These maximum decreases in water lever would not violate the threshold and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-7 (CP3): Change in X2 Position The X2 position would change from west to east of Collinsville in one December, compared with existing conditions and the No-Action Alternative, when the Delta would not be in balanced conditions. This impact would be less than significant.

Examination of simulation output indicates that compared to the existing condition, only in one month, December 1979, would the X2 position shift from west to east of Collinsville. Under existing conditions, the X2 position would be at 78.25 km, and under CP3, it would be at 81.37 km, a 3.12 km shift.

Compared with the No-Action Alternative, only in one month, December 1979, would the X2 position change from west to east of Collinsville. Under the No-Action Alternative, the X2 position would be at 78.63 km, and under CP3, it would be at 81.08 km, a 2.45 km shift.

This single month change would not substantially limit CCWD's ability to fill Los Vaqueros Reservoir. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP3): Change in Recurrence of Delta Excess Condition
Under CP3, changes from excess to balanced Delta conditions would be rare. This impact would be less than significant.

As shown in Table 6-53, CP3 would cause few changes from excess to balanced Delta conditions when compared to the existing condition and to the No-Action Alternative. Because of the low number of occurrences, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-53. Simulated Number of Years the Delta Changes from Excess to Balanced Condition

	Number of Years the Delta Changes from Excess to Balanced Conditions Compared to Existing Condition or No-Action Alternative											
	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec

CVP/SWP Service Areas

Impact H&H-9 (CP3): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to North-of-Delta CVP Water Service Contractors would increase under all conditions. This impact would be beneficial. Annual average deliveries to North-of-Delta refuges would not change under all conditions. This impact would be less than significant.

As shown in Table 6-54, average annual deliveries to North-of-Delta CVP Water Service Contractors under both existing and future conditions would increase relative to the basis of comparison. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed. Average annual deliveries to North-of-Delta refuges would not change under all conditions. Minor increases and decreases in Refuge deliveries are not a true representation of real-time operations but an indication of modeling artifacts. Such reduction would not occur in real time due to efficient water allocation and management schemes that cannot be captured adequately in a water resources planning model such as CalSim-II. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-10 (CP3): Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to South-of-Delta CVP Water Service Contractors would increase under all conditions. This impact would be beneficial. Annual average deliveries to South-of-Delta refuges would not change under all conditions. This impact would be less than significant.

As shown in Table 6-55, average annual deliveries to South-of-Delta Water Service Contractors under both existing and future conditions would increase relative to the basis of comparison. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed. Average annual deliveries to South-of-Delta refuges would not change under all conditions. Minor increases and decreases in Refuge deliveries are not a true representation of real-time operations but an indication of modeling artifacts. Such reduction would not occur in real time due to efficient water allocation and management schemes that cannot be captured adequately in a water resources planning model such as CalSim-II. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-11 (CP3): Change in Deliveries to SWP Table A Contractors
Average annual and monthly deliveries would decrease under both existing and future conditions. This decrease would be larger than what would occur under other action alternatives because no storage space would be reserved for increasing M&I deliveries under CP3. Accordingly, SWP deliveries were affected. This decrease would be less than 5 percent. This impact would be less than significant.

As shown in Table 6-56, average annual deliveries to SWP Table A contractors would decrease under CP3 in both existing and future conditions relative to the bases of comparison in both average years and in dry and critical years. Under both existing conditions and future conditions, the average monthly deliveries would decrease less than 5 percent in most months in both average annual and dry and critical years. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-56. Simulated Monthly Average Deliveries and Percent Change of Deliveries to SWP Table A Contractors

Key:

cfs = cubic feet per second

CP = comprehensive plan

SLWRI = Shasta Lake Water Resources Investigation

SWP = State Water Project

TAF = thousand acre-feet

Impact H&H-12 (CP3): Change in Groundwater Levels CP3 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. This impact would be beneficial.

With increased water supply deliveries to CVP and SWP water contractors, and with an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP3. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. With less groundwater pumping, groundwater basins that were in overdraft conditions would be anticipated to improve as a result of increasing groundwater levels. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP3): Change in Groundwater Quality CP3 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping could improve groundwater quality. This impact would less than significant.

With increased water supply deliveries to CVP and SWP water contractors, and with an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP3. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. Because CP3 would have a positive, albeit limited, impact by reducing reliance on groundwater, the effects of CP3 on groundwater quality also would be limited. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP4 and CP4A– 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

CP4 and CP4A focus on increasing anadromous fish survival while also increasing water supply reliability. By raising Shasta Dam 18.5 feet, in combination with spillway modifications, CP4 or CP4A would increase the height of the reservoir full pool by 20.5 feet and would enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD also would be extended to achieve efficient use of the expanded cold-water pool.

For CP4, about 378,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 256,000 acre-feet) would be the same as under CP1, with 70,000 acre-feet and 35,000 acre-feet reserved to specifically focus on increasing M&I deliveries during dry and critical years, respectively. Because CP4 would increase the active or useable storage in Shasta Reservoir by the same amount as under CP1, and the storage would be used under the same operational rules, releases from Shasta would be the same as under CP1.

For CP4A, about 191,000 acre-feet of the increased reservoir storage space would be dedicated to increasing the supply of cold water for anadromous fish survival purposes. Operations for the remaining portion of increased storage (approximately 443,000 acre-feet) would be the same as under CP2, when in dry years and critical years, 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. Because CP4A would increase the active or usable storage in Shasta Reservoir by the same amount as under CP2, and the storage would be used under the same operational rules, releases from Shasta would be the same as under CP2.

For CP4 or CP4A, the additional storage that would be dedicated to increasing the supply of cold water, or the cold-water pool, would result in different Shasta storages, elevations, and release temperatures but not in any other downstream water operations.

Shasta Lake and Vicinity The significance criteria for H&H do not apply in the Shasta Lake and vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this EIS.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact H&H-1 (CP4 and CP4A). Change in Frequency of Flows above 100,000 cfs on the Sacramento River below Bend Bridge For CP4, this impact would be the same as Impact H&H-1 (CP1). Although flood management operations would not change under CP4, a slight reduction could occur in the frequency of flows greater than 100,000 cfs. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-1 (CP2). Although flood management operations would not change under CP4A, a slight reduction could occur in the frequency of flows greater than 100,000 cfs. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP4 and CP4A). Place Housing or Other Structures within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map For CP4, this impact would be the same as Impact H&H-2 (CP1). No new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as H&H-2 (CP2), which is the same as Impact H&H-2 (CP1); no new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP4 and CP4A). Place Within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows For CP4, this impact would be the same as Impact H&H-3 (CP1). No new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-3 (CP2), which is the same as Impact H&H-3 (CP1); no new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta

Impact H&H-4 (CP4 and CP4A). Change in Water Levels in Old River near Tracy Road Bridge For CP4, this impact would be the same as Impact H&H-4 (CP1). Simulated water levels in the Old River near Tracy show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-4 (CP2). Simulated water levels in the Old River near Tracy Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-5 (CP4 and CP4A). Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier For CP4, this impact would be the same as Impact H&H-5 (CP1). Simulated water levels in the Grant Line Canal near the Grant Line Canal Barrier show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-5 (CP2). Simulated water levels in the Grant Line Canal near the Grant Line Canal Barrier show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-6 (CP4 and CP4A). Change in Water Levels in Middle River near the Howard Road Bridge For CP4, this impact would be the same as Impact H&H-6 (CP1). Simulated water levels in the Middle River near the Howard Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-6 (CP2). Simulated water levels in the Middle River near the Howard Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-7 (CP4 and CP4A): Change in X2 Position For CP4, this impact would be the same as Impact H&H-7 (CP1). The X2 position would not change from west to east of Collinsville in December or January, when the Delta would not be in balanced conditions. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-7 (CP2). The X2 position would change from west to east of Collinsville in one December compared to the existing conditions, when the Delta would not be in balanced conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP4 and CP4A): Change in Recurrence of Delta Excess Conditions For CP4, this impact would be the same as Impact H&H-8 (CP1); changes from excess to balanced Delta conditions would be rare. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-8 (CP2). Changes from excess to balanced Delta conditions would be rare. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact H&H-9 (CP4 and CP4A): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges For CP4, this impact would be the same as Impact H&H-9 (CP1). Average annual and monthly deliveries to North-of-Delta CVP water service contractors would increase under both existing and future conditions, but some small decreases could occur in monthly deliveries under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed. Average annual deliveries to North-of-Delta refuges would not change under all conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-9 (CP2). Average annual deliveries to North-of-Delta CVP water service contractors would increase under all conditions. Average monthly deliveries would generally increase but could show small decreases in October and November of less than the significance criteria. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed. Average annual deliveries to North-of-Delta refuges would not change under all conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-10 (CP4 and CP4A): Change in Deliveries to South-of-Delta CVP Water Service Contractors and Refuges For CP4, this impact would be the same as Impact H&H-10 (CP1). Average annual and monthly deliveries would increase under both existing and future conditions. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-10 (CP2), which is similar to Impact H&H-10 (CP1). Average annual and monthly deliveries would increase under both existing and future conditions, except the increase in deliveries would be greater under CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-11 (CP4 and CP4A): Change in Deliveries to SWP Table A Contractors For CP4, this impact would be the same as Impact H&H-11 (CP1). Average annual deliveries would increase under both existing and future conditions, but some less than significant decreases could occur in monthly deliveries under future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-11 (CP2). Average annual and monthly deliveries would increase under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-12 (CP4 and CP4A). Change in Groundwater Levels For CP4, this impact would be the same as Impact H&H-12 (CP1). CP4 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-12 (CP2). CP4A would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP4 and CP4A). Change in Groundwater Quality For CP4, this impact would be the same as Impact H&H-13 (CP1). CP4 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

For CP4A, this impact would be the same as Impact H&H-13 (CP2). CP4A would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP5 – 18.5-Foot Dam Raise, Combination Plan

CP5 primarily would consist of raising Shasta Dam by 18.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir’s full pool by 20.5 feet and would enlarge the total storage capacity in the reservoir by 634,000 acre-feet. The existing TCD also would be extended to achieve efficient use of the expanded cold-water pool. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 150,000 acre-feet and 75,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries.

Shasta Lake and Vicinity The significance criteria for H&H do not apply in the Shasta Lake and vicinity geographic region; therefore, potential effects in that geographic region are not discussed further in this EIS.

Upper Sacramento River (Shasta Dam to Red Bluff)
Impact H&H-1 (CP5): Change in Frequency of Flows above 100,000 cfs on the Sacramento River below Bend Bridge Although flood management operations would not change under CP5, a slight reduction could occur in the frequency of flows greater than 100,000 cfs. This impact would be beneficial.

SLWRI modeling uses a monthly time step, which is inappropriate for flood control analysis; however, flood management operations for downstream objectives would not change under CP5. Although a slight decrease in recurrence of high flows would be possible because of the increased storage capability, CP5 would not increase the frequency of flows above 100,000 cfs. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-2 (CP5): Place Housing or Other Structures within a 100-Year Flood Hazard Area as Mapped on a Federal Flood Hazard Boundary or Flood Insurance Rate Map or Other Flood Hazard Delineation Map This impact would be the same as Impact H&H-2 (CP1). No new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-3 (CP5): Place within a 100-Year Flood Hazard Area Structures that Would Impede or Redirect Flood Flows This impact would be the same as Impact H&H-3 (CP1). No new structures would be built downstream from Shasta Dam. No impact would occur. Mitigation for this impact is not needed, and thus not proposed.

Lower Sacramento River and Delta
Impact H&H-4 (CP5): Change in Water Levels in Old River near Tracy Road Bridge Simulated water levels in the Old River near Tracy Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-57, maximum monthly reduction in minimum daily water level associated with CP5 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This

impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-57. Simulated Monthly Maximum 15-Minute Change in Old River Water Levels near Tracy Road Bridge at Low-Low Tide

Month	Change from Existing Condition	Change from No-Action Alternative

Impact H&H-5 (CP5): Change in Water Levels in the Grant Line Canal near the Grant Line Canal Barrier Simulated water levels in the Old River near Tracy show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-58, maximum monthly reduction in minimum daily water level associated with CP5 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.0 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-6 (CP5): Change in Water Levels in the Middle River near the Howard Road Bridge Simulated water levels in the Middle River near the Howard Road Bridge show very small reductions that would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant.

As shown in Table 6-59, maximum monthly reduction in minimum daily water level associated with CP5 would be less than 0.1 foot in all months during the irrigation season, compared to the existing condition and the No-Action Alternative. The water levels would remain above 0.3 feet elevation and would not adversely affect agricultural users' ability to divert irrigation water. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-7 (CP5): Change in X2 Position The X2 position would change from west to east of Collinsville in one December, compared with existing conditions and the No-Action Alternative when the Delta would not be in balanced conditions. This impact would be less than significant.

Examination of simulation output indicates that compared to the existing condition, only in one month, December 1979, would the X2 position shift from west to east of Collinsville. Under existing conditions, the X2 position would be at 78.25 km, and under CP5, it would be at 81.36 km, a 3.11 km shift. Compared to the No-Action Alternative, only in one month, December 1979, would the X2 position change from west to east of Collinsville. Under the No-Action Alternative, the X2 position would be at 78.63 km, and under CP5, it would be at 81.08 km, a 2.45 km shift. This single month change would not significantly limit CCWD’s ability to fill Los Vaqueros Reservoir. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-8 (CP5): Change in Recurrence of Delta Excess Condition Under CP5, changes from excess to balanced Delta conditions would be rare. This impact would be less than significant.

As shown in Table 6-60, CP5 would cause one March, one June, one August, one October, three Novembers, and one December to change from excess to balanced Delta conditions, when compared to the existing condition, and four Julys, one August, five Octobers , and three Novembers when compared to the No-Action Alternative. Because of the low number of occurrences, this impact

would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CVP/SWP Service Areas

Impact H&H-9 (CP5): Change in Deliveries to North-of-Delta CVP Water Service Contractors and Refuges Average annual deliveries to North-of-Delta CVP Water Service Contractors would increase under all conditions. This impact would be beneficial. Annual average deliveries to North-of-Delta refuges would not change under all conditions. This impact would be less than significant.

As shown in Table 6-61, average annual deliveries to North-of-Delta Water Service Contractors under both existing and future conditions would increase relative to the basis of comparison. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed. Average annual deliveries to North-of-Delta refuges would not change under all conditions. Minor increases and decreases in Refuge deliveries are not true a representation of real-time operations but an indication of modeling artifacts. Such reduction would not occur in real time due to efficient water allocation and management schemes that cannot be captured adequately in a water resources planning model such as CalSim-II. This impact is less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-61. Simulated Monthly Average Deliveries and Percent Change of Deliveries to North-of-Delta CVP Water Service Contractors and Refuges

Month	Existing Condition (2005)				Future Condition (2030)			
	Average All Years		Dry and Critical Years		Average All Years		Dry and Critical Years

Impact H&H-11 (CP5): Change in Deliveries to SWP Table A Contractors
This impact would be similar to Impact H&H-11 (CP1), except the increase in average annual deliveries would be greater, and potential decreases in average monthly deliveries in some months could be slightly larger under CP5. This impact would be less than significant.

As shown in Table 6-63, average annual deliveries to SWP Table A contractors would increase under CP5, in both existing and future conditions relative to the bases of comparison in both average years and in dry and critical years. Some monthly average decreases around 1 percent could occur in deliveries relative to the No-Action Alternative under existing and future conditions in both average annual and dry and critical years. The average monthly deliveries would increase in all months under CP5 relative to the No-Action Alternative under future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 6-63. Simulated Monthly Average Deliveries and Percent Change of Deliveries to SWP Table A Contractors

CP = comprehensive plan

SLWRI = Shasta Lake Water Resources Investigation

SWP = State Water Project

TAF = thousand acre-feet

Impact H&H-12 (CP5): Change in Groundwater Levels CP5 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping would result in increased groundwater levels. This impact would be beneficial.

With increased water supply deliveries to CVP and SWP water contractors, and with an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP5. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. With less groundwater pumping, groundwater basins that were in overdraft conditions would be anticipated to improve as a result of increasing groundwater levels. This impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact H&H-13 (CP5): Change in Groundwater Quality CP5 would deliver additional surface water to CVP and SWP water contractors, reducing their need to pump groundwater. The reduction in groundwater pumping could improve groundwater quality. This impact would less than significant.

With increased water supply deliveries to CVP and SWP water contractors, and an associated increase in surface water supply reliability to those contractors, shortages in deliveries would decrease under CP5. Contractor responses to shortages in surface water deliveries would vary; some may elect to fallow their land, others may buy water on the transfer market, and some may pump groundwater. An increase in surface water deliveries would result in a decrease in groundwater pumping. Because CP5 would have a positive, albeit limited, impact by reducing reliance on groundwater, the effects of CP5 on groundwater quality also would be limited. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

6.3.4 Mitigation Measures

Table 6-64 presents a summary of mitigation measures for H&H. No potentially significant impacts have been identified, and therefore no mitigation measures are proposed.

No-Action Alternative

No mitigation measures are required for this alternative.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are required for this alternative.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

No mitigation measures are required for this alternative.

CP3 – 18.5-Foot Dam Raise, Agricultural Water Supply Reliability and Anadromous Fish Survival

No mitigation measures are required for this alternative.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus with Water Supply Reliability

No mitigation measures are required for CP4 or CP4A.

CP5 – 18.5-Foot Dam Raise, Combination Plan

No mitigation measures are required for this alternative.

6.3.5 Cumulative Effects

Chapter 3, "Considerations for Describing the Affected Environment and Environmental Consequences," discusses overall cumulative impacts methodology related to the action alternatives, including the relationship to the CALFED Bay-Delta Program Programmatic EIS/EIR cumulative impacts analysis, qualitative and quantitative assessment, past and future actions in the study area, and significance criteria. Table 3-1, "Present and Reasonably Foreseeable Future Actions Included in the Analysis of Cumulative Impacts, by Resource Area" lists the present and reasonably foreseeable future projects considered quantitatively and qualitatively within the cumulative impacts analysis. This cumulative impacts analysis accounts for potential project impacts combined with the impacts of existing facilities, conditions, land uses, and reasonably foreseeable actions expected to occur in the study area on a qualitative and quantitative level. Past impacts to these resources include dam construction and altered flow regimes, water diversions, flood control facilities, and land use changes.

Actions which are included quantitatively in this cumulative effects analysis are those that are reasonably foreseeable, including actions with current authorization, secured funding for design and construction, and environmental permitting and compliance activities that are substantially complete. As described in Chapter 2, "Alternatives," Section 2.2, "No-Action Alternative," the NEPA No-Action alternative includes all reasonably foreseeable actions included quantitatively in the cumulative effects analysis, but excludes effects for project actions. The future with-project conditions combine project actions with the actions included in the No-Action Alternative (2030 baseline). Therefore, quantitative impact assessments for the future with-project conditions presented in this chapter in Section 6.3.3, "Direct and Indirect Effects," also serve as the quantitative impacts assessments for the cumulative effects analysis. A list of projects included in the Final EIS No-Action Alternative and future with-project impact analyses is located in the Modeling Appendix, Chapter 2, Table 2-1.

Projects which do not meet the parameters of reasonably foreseeable for inclusion in this quantitative cumulative effects analysis but which may have past, present, or reasonably foreseeable cumulative impacts in combination with the proposed project may be included in the cumulative impacts analysis qualitatively. Projects and actions considered include, but are not limited to, North of Delta Offstream Storage Investigation, Bay-Delta Conservation Plan, SJRRP, Davis Woodland Water Supply Project and Central Valley Flood Protection Plan. This section provides an analysis of overall cumulative impacts of the project alternatives with other past, present, and reasonably foreseeable future projects producing related impacts.

The effects of climate change on operations at Shasta Lake could result in changes to H&H. As described in the Climate Change Modeling Appendix, climate change could result in higher reservoir releases in the winter and early spring because of an increase in runoff during these times. The change in winter and early spring releases could necessitate managing flood events resulting from potentially larger storms. Similarly, climate change could result in lower reservoir inflows and Sacramento tributary flows during the late spring and summer because of a decreased snow pack. This reduction in inflow and tributary flow could result in Shasta Lake storage being reduced because of both a reduced ability to capture flows and an increased need to make releases to meet downstream requirements.

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As described in Section 6.3.3, no potentially significant impacts would occur under CP1.

When combined with other past, present, and reasonably foreseeable future projects, a change in the Sacramento River flows would be likely. Because Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and the Delta, a new project or program along the Sacramento River and in the Delta could affect H&H resources under CP1. With the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume that there would not be a reduction in flow requirements or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Although regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP1 combined with other projects could result in changes to water levels during the irrigation season, at a magnitude and frequency that would affect south Delta water users. Accordingly, CP1 combined with a number of other projects and on-going actions could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and the Delta outflow are primarily products of Delta inflow and export pumping. As previously mentioned, CP1 combined with other projects could result in changes to Delta inflow and export pumping. Although CP1 would result in rare changes to either the X2 position or the Delta outflow of a magnitude affecting CCWD’s ability to fill Los Vaqueros Reservoir, and would result in a less-than-significant impact on the X2 position, CP1 combined with other projects could result in potentially significant and unavoidable impacts.

As previously described, CP1 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is unlikely that CP1, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to existing conditions or the No-Action Alternative. Accordingly, no impact on groundwater levels or groundwater quality would occur. Therefore, CP1, combined with other projects, would be likely to have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect downstream flood management. Consequently, when combined with CP1, either no cumulative impact or a beneficial impact on flood management would occur from past, present or reasonably foreseeable future projects.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP1 potentially would diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Under climate change, additional impacts from CP1 on flood management, water supply, south Delta water levels, and groundwater management would be less adverse (or beneficial) than without climate change, and would be less than significant. Therefore, under the anticipated effects of climate change, CP1 would not have a significant cumulative effect, and could be beneficial.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As described in Section 6.3.3, no potentially significant impacts would occur under CP2.

When combined with the other past, present, and reasonably foreseeable future projects, a change in the Sacramento River flows would be likely. Because Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and the Delta, a new project or program along the Sacramento River and in the Delta could affect the H&H resources under CP2. With the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume that there would not be a reduction in flow requirements or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Although regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP2 combined with other projects could result in changes to water levels during the irrigation season, at a magnitude and frequency that would affect south Delta water users. Accordingly, CP2 combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and the Delta outflow are primarily products of Delta inflow and export pumping. As previously mentioned, CP2 combined with other projects could result in changes to Delta inflow and export pumping. Although CP2 would result in rare changes to either the X2 position or the Delta outflow of a magnitude affecting CCWD's ability to fill Los Vaqueros Reservoir, and would result in a less-than-significant impact on the X2 position, CP2 combined with other projects possibly could result in potentially significant and unavoidable impacts.

As previously described, CP2 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is unlikely that CP2, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to existing conditions or the No-Action Alternative. Accordingly, no impact on groundwater levels or groundwater quality would occur. Therefore, CP2, combined with other projects, would be likely to have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect downstream flood management. Consequently, when combined with CP2, either no cumulative impact or a beneficial impact on flood management would occur from past, present or reasonably foreseeable future projects.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP2 potentially would diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Under climate change, additional impacts from CP2 on flood management, water supply, south Delta water levels, and groundwater management would be less adverse (or beneficial) than without climate change, and would be less than significant. Therefore, even under the anticipated effects of climate change, CP2 would not have a significant cumulative effect, and could be beneficial.

CP3 – 18.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply

As described in Section 6.3.3, no potentially significant impacts would occur under CP3.

When combined with the other past, present, and reasonably foreseeable future projects, a change in the Sacramento River flows would be likely. Because Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and the Delta, a new project or program along the Sacramento River and in the Delta could affect the H&H resources under CP3. With the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume that there would not be a reduction in flow requirements or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Although regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP3 combined with other projects could result in changes to water levels during the irrigation season, at a magnitude and frequency that would affect south Delta water users. Accordingly, CP3 combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and the Delta outflow are primarily products of Delta inflow and export pumping. As previously mentioned, CP3 combined with other projects could result in changes to Delta inflow and export pumping. Although CP3 would result in rare changes to either the X2 position or the Delta outflow of a magnitude affecting CCWD's ability to fill Los Vaqueros Reservoir, and would result in a less-than-significant impact on the X2 position, CP3 combined with other projects possibly could result in potentially significant and unavoidable impacts.

As previously described, CP3 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is unlikely that CP3, when combined with a number of other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to existing conditions or the No-Action Alternative. Accordingly, no impact on groundwater levels or groundwater quality would occur. Therefore, CP3, combined with a number of other projects, would be likely to have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect downstream flood management. Consequently, when combined with CP3, either no cumulative impact or a beneficial impact on flood management would occur from past, present or reasonably foreseeable future projects.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP3 potentially would diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Under climate change, additional impacts from CP3 on flood management, water supply, south Delta Water levels, and groundwater management would be less adverse (or beneficial) than without climate change, and would be less than significant. Therefore, under the anticipated effects of climate change, CP3 would not have a significant cumulative effect, and could be beneficial.

CP4 and CP4A – 18.5-Foot Dam Raise, Anadromous Fish Focus With Water Supply Reliability

As described in Section 6.3.3, no potentially significant impacts would occur under CP4 or CP4A.

When combined with the other past, present, and reasonably foreseeable future projects, a change in the Sacramento River flows would be likely. Because Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and the Delta, a new project or program along the Sacramento River and in the Delta could affect the H&H resources under CP4 or CP4A. With the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume that there would not be a reduction in flow requirements or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Although regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP4 or CP4A combined with other projects could result in changes to water levels during the irrigation season, at a magnitude and frequency that would affect south Delta water users. Accordingly, CP4 or CP4A combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and the Delta outflow are primarily products of Delta inflow and export pumping. As previously mentioned, CP4 or CP4A combined with other projects could result in changes to Delta inflow and export pumping. Although CP4 or CP4A would result in rare changes to either the X2 position or the Delta outflow of a magnitude affecting CCWD’s ability to fill Los Vaqueros Reservoir, and would result in a less-than-significant impact on the X2 position, CP4 or CP4A combined with other projects possibly could result in potentially significant and unavoidable impacts.

As previously described, CP4 or CP4A would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is unlikely that CP4 or CP4A, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative existing conditions or the No-Action Alternative. Accordingly, no impact on groundwater levels or groundwater quality would occur. Therefore, CP4 or CP4A, combined with other projects, would be likely to have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect downstream flood management. Consequently, when combined with CP4 or CP4A, either no cumulative impact or a beneficial impact on flood management would occur from past, present and reasonably foreseeable future projects.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP4 or CP4A could potentially would diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Under climate change, additional impacts from CP4 or CP4A on flood management, water supply, south Delta water levels, and groundwater management would be less adverse (or beneficial) than without climate change, and would be less than significant. Therefore, under the anticipated effects of climate change, CP4 or CP4A would not have a significant cumulative effect, and could be beneficial.

CP5 – 18.5-Foot Dam Raise, Combination Plan

As described in Section 6.3.3, no potentially significant impacts would occur under CP5.

When combined with the other past, present, and reasonably foreseeable future projects, a change in the Sacramento River flows would be likely. Because Shasta Reservoir is operated to meet flow and water quality requirements in the Sacramento River and the Delta, a new project or program along the Sacramento River and in the Delta could affect the H&H resources under CP5. With the implementation of the other past, present, and reasonably foreseeable future projects, it is reasonable to assume that there would not be a reduction in flow requirements or a reduction in the level of protection from current water quality requirements. Therefore, during periods when the CVP and SWP are operated to meet regulatory constraints, the effects of the implementation of the projects described above would be limited.

Water levels in the south Delta could be affected by changes in Delta inflow and export pumping. Although regulatory requirements restrict export pumping when water levels in the south Delta reach certain levels, CP5 combined with other projects could result in changes to water levels during the irrigation season, at a magnitude and frequency that would affect south Delta water users. Accordingly, CP5 combined with other projects could result in potentially significant and unavoidable impacts to south Delta water levels.

Both the X2 position and the Delta outflow are primarily products of Delta inflow and export pumping. As previously mentioned, CP5 combined with other projects could result in changes to Delta inflow and export pumping. Although CP5 would result in rare changes to either the X2 position or the Delta outflow of a magnitude affecting CCWD’s ability to fill Los Vaqueros Reservoir, and would result in a less-than-significant impact on the X2 position, CP5 combined with other projects could result in potentially significant and unavoidable impacts.

As previously described, CP5 would have a beneficial impact on groundwater resources in the CVP/SWP service areas. Similarly, it is unlikely that CP5, when combined with other projects, would result in a decrease in surface water deliveries and an increased reliance on groundwater pumping relative to existing conditions or the No-Action Alternative. Accordingly, no impact on groundwater levels or groundwater quality would occur. Therefore, CP5, combined with other projects, would be likely to have a beneficial effect.

None of the other past, present, and reasonably foreseeable future projects would negatively affect downstream flood management. Consequently, when combined with CP5, either no cumulative impact or a beneficial impact on flood management would occur from past, present or reasonably foreseeable future projects.

As stated previously, effects of climate change on operations of Shasta Lake could include increased inflows and releases at certain times of the year, and decreased inflows at other times. The additional storage associated with CP5 potentially would diminish these effects and allow Shasta Lake to capture some of the increased runoff in the winter and early spring for release in late spring and summer. Under climate change, additional impacts from CP5 on flood management, water supply, south Delta water levels, and groundwater management would be less adverse (or beneficial) than without climate change, and would be less than significant. Therefore, under the anticipated effects of climate change, CP5 would not have a significant cumulative effect, and could be beneficial.

Chapter 7
Water Quality

7.1 Affected Environment

This section describes the affected environment related to water quality for the dam and reservoir modifications proposed under SLWRI action alternatives. For more detail, please see the *Water Quality Technical Report*.

7.1.1 Overview of Water Quality Conditions

Surface water quality in the study area is affected by natural runoff, agricultural return flows, abandoned mines, construction, logging, grazing, and operations of flow-regulating facilities, urbanization, and recreation. This section discusses key water quality constituents of concern (i.e., temperature, sediments, and metals), the factors influencing their concentrations, and the regulatory objectives associated with maintaining beneficial uses.

The following discussion provides an overview of water quality and its relationship to beneficial uses throughout the primary and extended study areas. This section is followed by discussions of key water quality parameters that influence beneficial uses to varying degrees within the study areas: temperature, sediment, and metals.

Shasta Lake and Vicinity

This section addresses water quality in the Shasta Lake and vicinity portion of the primary study area (see Figure 7-1). It focuses on the six arms of Shasta Lake and tributaries that enter into Shasta Lake from the surrounding watersheds.

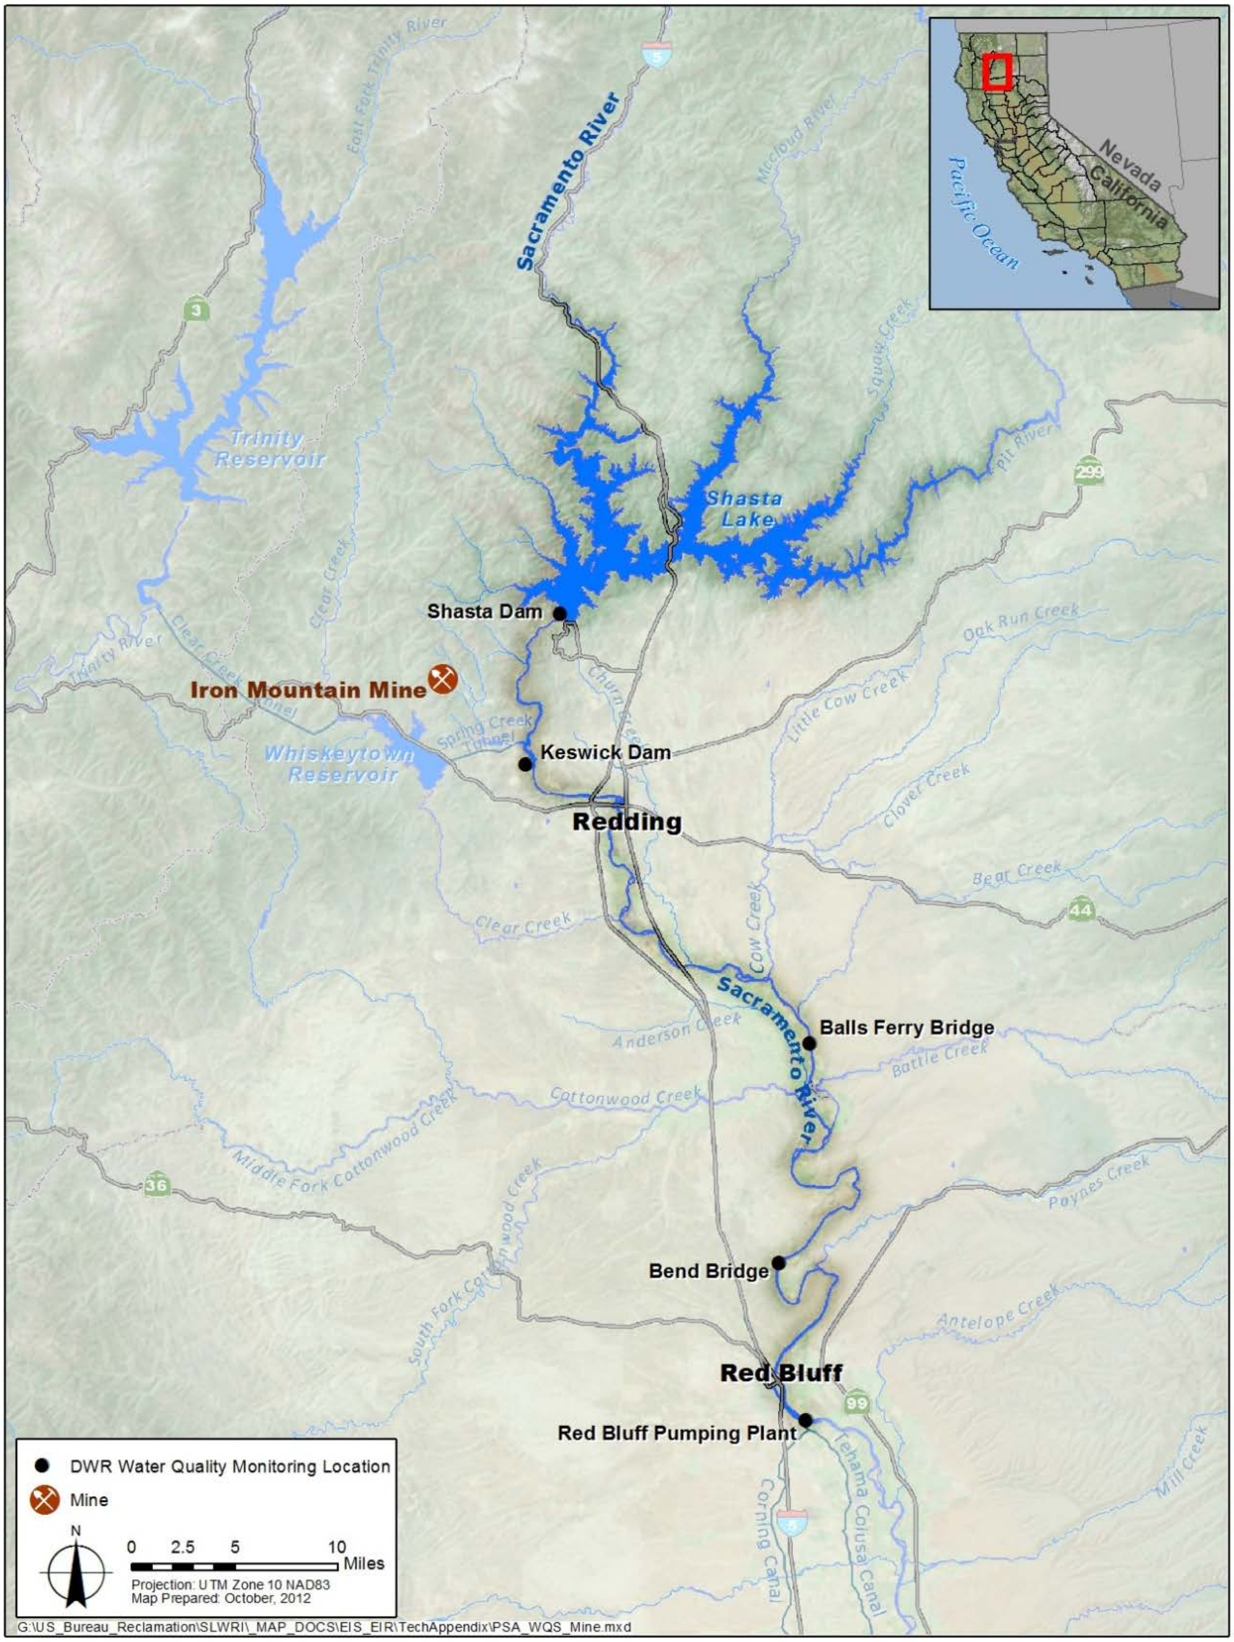

Figure 7-1. Upper Sacramento River Primary Study Area

Water quality in this portion of the primary study area generally meets the standards for beneficial uses identified in the Basin Plan (CVRWQCB 2011). However, some areas exist where the water quality does not meet the standards during periods of storm runoff because of past management activities, large wildfires, or drainage from historic mining and processing operations. All of Shasta Lake is listed by the EPA as impaired by mercury on the Federal Clean Water Act (CWA) 2008–2010 Section 303(d) list. A two-year study conducted by the State Water Resources Control Board (State Water Board) sampled mercury accumulations in fish at a number of locations throughout Shasta Lake. This study documented elevated levels of mercury in some specimens (Davis et al. 2010). In addition, West Squaw Creek below the Balakala Mine, lower Little Backbone Creek, lower Horse Creek, and Town Creek are impaired water bodies under Section 303(d) of the CWA. All of these water bodies drain into the southwestern-most edge of Shasta Lake. Within Little Backbone Creek and West Squaw Creek, the waters are locally limited by low pH and elevated concentrations of heavy metals caused by drainage from abandoned mines and are listed as impaired on the Section 303(d) list (CVRWQCB 2003a).

Nutrient inputs and bacteria are not of concern in the Sacramento and McCloud arms (USFS 1998); however, they may be an issue in the Pit Arm as a result of runoff from agricultural and range lands in the upper Pit River watershed. In addition, data suggest that sediment and turbidity locally affect beneficial uses, mainly contact recreation.

The quality of surface waters in Shasta County is generally considered good, although some water bodies are affected by nonpoint pollution sources that influence surface water quality, including high turbidity from controllable sediment discharge sources (e.g., land development and roads); high concentrations of nitrates and dissolved solids from range and agricultural runoff or septic tank failures; contaminated street and lawn runoff from urban areas, roads, and railroads; acid mine drainage and heavy metal discharges from historic mining and processing operations; and warm-water discharges into cold-water streams.

The quality of water in underground basins and water-bearing soils is also considered generally good throughout most of Shasta County and is discussed in more detail in Chapter 6, “Hydrology, Hydraulics, and Water Management.” Potential hazards to groundwater quality involve nitrates and dissolved solids from agricultural and range practices and septic tank failures. The ability of soils in Shasta County to support septic tanks and on-site wastewater treatment systems is generally severely limited, particularly on older valley terrace soils and certain loosely confined volcanic soils in the eastern portions of the county (CVRWQCB 2011).

The surface water quality of streams and lakes draining Shasta-Trinity National Forest (STNF) and adjacent private lands generally meets standards for beneficial uses defined by the Basin Plan (CVRWQCB 2011). However, some areas exist where the water quality does not meet the standards during periods of storm runoff because of past management activities, large wildfires, or as a result of drainage from historic mining and processing operations. The U.S. Environmental Protection Agency (EPA) has listed the West Squaw Creek below the Balakala Mine, the lower Little Backbone Creek, the lower Horse Creek, and the Town Creek as impaired water bodies under Section 303(d) of the Federal Clean Water Act (CWA). All of these water bodies drain into the Main Arm of Shasta Lake. In the 1995 Land and Resource Management Plan (LRMP), the STNF acknowledged the drainages that are all listed by the cumulative impacts of successive activities, such as road construction and timber harvesting on private and National Forest System (NFS) lands contribute to the degradation of water quality on NFS lands (USFS 1995). In addition to NFS and U.S. Department of the Interior, Bureau of Land Management (BLM) lands in the watersheds tributary to Shasta Lake, there have been similar types of activities on private lands. Watershed assessments and analysis conducted by the STNF, BLM, and the Sacramento River Exchange for most of the watersheds tributary to Shasta Lake acknowledge that roads and wildfires continue to have impacts to water quality in various portions of these watersheds (The River Exchange 2010).

In 2012, the Bagley fire burned large portions of the McCloud River and Squaw Creek watersheds with varying levels of intensity. High-intensity rainfall events in November and December 2012 resulted in extensive erosion throughout the fire area, including roads, upland areas, and riparian areas. Recent studies conducted by STNF staff (STNF 2014) document road-related sedimentation effects from this fire, providing a good example of the interrelationship between fire and erosional processes. Preliminary USFS results indicate that 2,200,000 tons of sediment has been eroded from upland areas in the Squaw Creek watershed. Approximately 452,000 tons are stored in channel networks, and more than 1,700,000 tons of sediment has been delivered to Shasta Lake. Putting this in perspective, volume estimates for shoreline erosion (see Chapter 4, “Geology, Geomorphology, Minerals, and Soils”) range between 187,110 and 289,170 tons[1] per year. These values are about 10 percent of the erosion associated with the Bagley fire.

Upper Sacramento River (Shasta Dam to Red Bluff)

Tributaries to the Upper Sacramento River, and place names referred to in the text are shown in Figure 7-1. The main sources of water in the Sacramento River below Keswick Dam are rain and snowmelt that collect in upstream reservoirs and are released in response to water needs or flood control. The quality of surface water downstream from Keswick Dam is also influenced by other human activities along the Sacramento River downstream from the dam, including agricultural, historical mining, and municipal and industrial (M&I) inputs.

[1] Conversion factor of 1.215 from cubic yards to tons.

The quality of water in the Sacramento River is relatively good. Only during conditions of stormwater-driven runoff are water quality objectives typically not met (Domagalski et al. 2000). Water quality issues within the primary study area of the Sacramento River include the presence of mercury, pesticides such as organochlorine pesticides, trace metals, turbidity, and toxicity from unknown origin (CALFED 2000a).

Water quality in the Sacramento River and its major tributaries above Red Bluff Pumping Plant (RBPP) is generally good (Table 7-1). Nutrients such as nitrate were found to be low throughout the Sacramento River basin (Domagalski and Dileanis 2000, as cited in Domagalski et al. 2000). Water temperature is a principal water quality issue in the upper Sacramento River between Keswick Dam and RBPP.

Table 7-1. Summary of Conventional Water Quality Constituents Collected in the Sacramento River at Red Bluff from 1996 to 1998

Constituent (unit)	Water Quality Objective	Average Measurement
Conventional Physical and Chemical Constituents		
Temperature	< 2.5ºF [1]	52.7ºF
Conductivity (µS/cm)	–	116
Dissolved Oxygen (mg/L)	7.0 [2]	10.7
Dissolved Oxygen Saturation (%)	85 [2]	99
pH (standard unit)	6.5 to 8.5 [3]	7.8
Alkalinity (mg/L $CaCO_3$)	–	48.3
Total Hardness (mg/L $CaCO_3$)	–	46.6
Suspended Sediment (mg/L)	–	38.8
Calcium (mg/L)	narrative [4]	10.3
Magnesium (mg/L)	–	5.0
Sodium (mg/L)	–	5.8
Potassium (mg/L)	–	1.1
Chloride (mg/L)	500 [5]	2.4
Conventional Physical and Chemical Constituents		
Sulfate (mg/L)	500 [5]	4.5
Silica (mg/L)	–	20.5
NO2 + NO3 (mg/L N)	NO3 < 10 [6]	0.12
Total Phosphorus (mg/L P)	–	0.0477

Table 7-1. Summary of Conventional Water Quality Constituents Collected in the Sacramento River at Red Bluff from 1996 to 1998 (contd.)

Constituent (unit)	Water Quality Objective	Average Measurement
Trace Metals		
Arsenic (µg/L)	50 [7]	1.0
Chromium (µg/L)	180 [7]	1.0
Copper (µg/L)	5.1 [7]	1.6
Mercury (µg/L)	0.050 [7]	0.0045
Nickel (µg/L)	52 [7]	1.2
Zinc (µg/L)	120 [7]	2.3
Organic Pesticides		
Molinate (ng/L)	13,000 [8]	< 60
Simazine (ng/L)	3,400 [9]	< 22
Carbofuran (mg/L)	40,000 [5], 500 [9]	< 31
Diazinon (mg/L)	51 [10]	< 28
Carbaryl (ng/L)	700 [11]	< 41
Thiobencarb (ng/L)	1,000 [1]	< 38
Chlorpyrifos (ng/L)	14 [10]	< 25
Methidathion (ng/L)	–	< 38

Although all trace metals shown in Table 7-1 were well below their established water quality objectives, one of the principal water quality issues in the upper Sacramento River portion of the primary study area is acid mine drainage and associated heavy-metal contamination from the Spring Creek drainage and other abandoned mining sites. It should be noted that the U.S. Geological Survey

(USGS) study detected mercury, but it did not exceed the criterion of ambient level specified in the California Toxics Rule; however, California Toxics Rule levels for mercury are not protective to prevent the high concentration of mercury found in fish tissue. In addition to heavy metal contamination, the Central Valley Regional Water Quality Control Board (CVRWQCB) determined that the 25-mile reach of the Sacramento River from Keswick Dam downstream to Cottonwood Creek is impaired because the water periodically contains levels of dissolved cadmium, copper, and zinc that exceed levels identified to protect aquatic organisms. The 26-mile reach from Keswick Dam to Red Bluff is listed for unknown sources of toxicity (CVRWQCB 2007a).

Lower Sacramento River and Delta

Water quality in the lower Sacramento River is affected by agricultural runoff, acid mine drainage, stormwater discharges, water releases from dams, diversions, and urban runoff. However, the flow volumes generally provide sufficient dilution to prevent excessive concentrations of contaminants in the river.

Several total maximum daily loads (TMDL) are currently proposed for the lower Sacramento River. In addition, the Sacramento River downstream from Red Bluff to Knights Landing is listed as an impaired water body under the EPA's Section 303(d) list for mercury and unknown toxicity. Elevated metals and pesticide levels have been found at some sites in the Sacramento River Valley downstream from Knights Landing. The parameters of concern in the Sacramento River from Knights Landing to the Sacramento-San Joaquin Delta (Delta) include diazinon, mercury, and unknown sources of toxicity (CVRWQCB 2007a, 2007b).

Water quality in the Delta is highly variable temporally and spatially. It is a function of complex circulation patterns that are affected by inflows, pumping for Delta agricultural operations and exports, operation of flow control structures, and tidal action. The existing water quality problems of the Delta system may be categorized as presence of toxic materials, eutrophication and associated fluctuations in dissolved oxygen, presence of suspended sediments and turbidity, salinity, and presence of bacteria (State Water Board 1999).

The Delta waterways within the area under the CVRWQCB's jurisdiction are listed as impaired on the EPA's 303(d) list for dissolved oxygen, electrical conductivity (EC), dichlorodiphenyl-trichloroethane, mercury, Group A pesticides, diazinon and chlorpyrifos, and unknown toxicity (CVRWQCB 2003b). The area of the Delta that is under the jurisdiction of the San Francisco Bay Regional Water Quality Control Board (RWQCB) is listed as impaired for mercury, chlordane, selenium, dichlorodiphenyl-trichloroethane, dioxin compounds, polychlorinated biphenyl compounds, dieldrin, nickel, exotic species, and furan compounds (SFBRWQCB 2007).

Organic carbon in the Delta originates from runoff from agricultural and urban land, drainage water pumped from Delta islands that have soils with high organic matter, runoff and drainage from wetlands, wastewater discharges, and primary production in Delta waters. Delta agricultural drainage can also contain high levels of nutrients, suspended solids, organic carbon, minerals (salinity), and trace chemicals such as organophosphate, carbamate, and organochlorine pesticides.

Salinity is also an important water quality constituent in the Delta. Salinity in the Delta is the result of tidal exchange with San Francisco Bay, variations in freshwater inflow from the San Joaquin and Sacramento rivers, agricultural and urban exports/diversions, and agricultural return flows. During dry conditions, seawater intrusion is the primary factor influencing Delta salinity and can adversely affect agricultural and municipal uses. The highest concentrations typically occur in late summer or early fall.

CVP/SWP Service Areas

The CVP and SWP service areas are affected by water quality from the Delta. Particular water quality concerns are those related to salinity and drinking-water quality. Salinity is an issue because excessive salinity may adversely affect crop yields and require more water for salt leaching, may require additional M&I treatment, may increase salinity levels in agricultural soils and groundwater, and is the primary water quality constraint to recycling wastewater (CALFED 2000b).

Constituents that affect drinking-water quality include bromide, natural organic matter, microbial pathogens, nutrients, total dissolved solids (TDS), hardness, alkalinity, pH, organic carbon, disinfection byproducts, and turbidity.

7.1.2 Sediment

Shasta Lake and Vicinity

Sediment-caused turbidity is one of the limiting water quality issues for Shasta Lake and its tributaries. It is a noticeable recurring water quality problem that affects beneficial uses, including recreation and fisheries. Within the reservoir, turbid water results from clay- and silt-sized soil particles suspended in the water column. Under certain conditions, inflow to the Pit Arm appears to be influenced by water quality conditions upstream from Shasta Lake, but monitoring data are not available to adequately document this phenomenon.

Before the construction of Shasta Dam, the widespread loss of vegetation caused by historic copper mining and smelting operations resulted in large-scale erosion, particularly in the watersheds that are tributary to the Main Body of Shasta Lake and the Squaw Creek Arm. In addition to sediment sources from upland areas, including roads and historic mining features, the construction and operation of Shasta Dam continue to influence erosional processes that introduce sediment into Shasta Lake, causing turbid conditions that are visible to the casual observer.

Nonpoint sources of fine sediment that increase turbidity in Shasta Lake include sediment discharge from tributaries, wave-related erosion below and adjacent to the fluctuating water surface, and surficial erosion of exposed surfaces as the lake levels fluctuate (USFS 2014). Erosion of the fine-textured soil and rock types that constitute much of the shoreline is a predominant factor in causing turbidity. The turbid water is noticeable along the shoreline throughout the year, but typically increases during wind and runoff events. Plumes of turbid water entering from tributaries are also visible periodically throughout the year. The fluctuation of lake levels, combined with various wave-generating processes, also influences the degree and location of erosion-related turbidity. Turbidity and, to a lesser degree, sediment suspended in the water column influence recreational uses of the lake, including fishing, swimming, and boating, by decreasing the clarity of the water along the shoreline.

Sediment discharge from tributaries to Shasta Lake (perennial and intermittent channels) is episodic in terms of magnitude and frequency. Initially, sediment discharged into Shasta Lake is stored in deltaic deposits. Subsequently, some portion of this sediment load is remobilized, dependent on site-specific conditions such as channel gradient and particle size. Over time, sediment stored in these channels and associated deltas may be transported through channels within the drawdown zone to locations deeper in the reservoir. Depending on reservoir fluctuations, these sediment deposits may remain in place for some period of time before being subjected to erosional processes, typically associated with wave erosion and streambank erosion. These erosional processes are more pronounced during periods of reservoir drawdown.

Although some amount of fine sediment is transported downstream from Shasta Dam, the size and location of the reservoir provide an efficient sediment trap for material typically mobilized as bedload. A 2011 report that summarizes 2005 USGS turbidity records indicates that some turbidity records for the Sacramento River upstream from Shasta Lake exceeded the apparent measuring capability of 1,000 nephelometric turbidity units (ntu). Turbidity readings at Shasta Dam for the same time period were much lower (Pace Engineers 2011). This report reinforces the premise that location of the discharge from Shasta Dam (at-depth) acts to buffer discharge of turbid water most of the time. Additional discussion of erosional processes is provided in Chapter 4, “Geology, Geomorphology, Minerals, and Soils.”

Upper Sacramento River (Shasta Dam to Red Bluff)

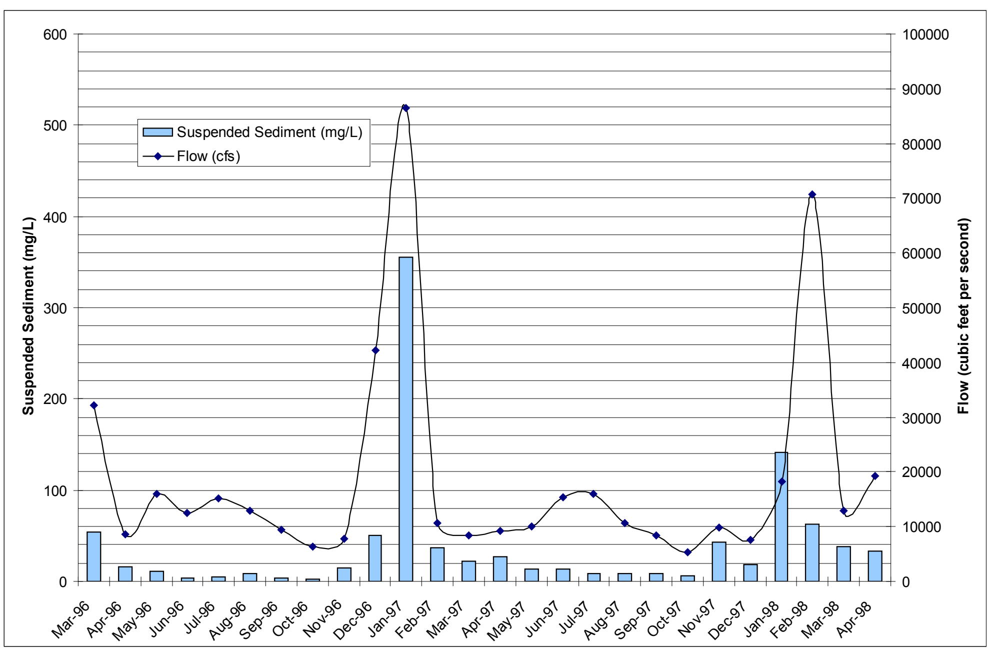
Rates of loading and discharge of suspended sediment within the upper Sacramento River watershed have been altered by activities such as mining, smelting, agriculture, urbanization, and dam construction. The storage and diversion of water within reservoirs for hydroelectric or other purposes can affect sediment yield, downstream sediment levels, and transport characteristics.

In particular, dams such as Shasta can trap sediment and result in the depletion of coarse sediments needed by fisheries. This has resulted in the creation of gravel replenishment programs on the upper Sacramento River as part of the Central Valley Project Improvement Act restoration program.

Historic hydraulic gold mining has probably had the greatest effect on sediment yield in the Sacramento River watershed (Wright and Schoellhamer 2004). During the late 1800s, such mining introduced mass quantities of silt, sand, and gravel into the Sacramento River system. Suspended sediment was washed downstream into the Delta. Current sediment transport patterns in the Sacramento River watershed are greatly affected by the trapping of sediment in reservoirs such as Shasta Lake (Wright and Schoellhamer 2004).

Characteristics of peak-flow events are fundamental regulators of sediment mobilization, bed scour, riparian recruitment, and bank erosion. However, upstream sediment supply rates and sediment load distribution also affect suspended sediment loading (CALFED 2003). The upper Sacramento River contributes little coarse sediment from erosion because it is bounded by erosion-resistant bedrock and terrace deposits (Stillwater Sciences 2006). Therefore, today a decreasing trend in suspended sediment exists in the Sacramento River (Wright and Schoellhamer 2004).

USGS assessed concentrations of suspended sediment in the Sacramento River at Big Bend above Red Bluff from February 1996 to April 1998 (USGS 2000a). Concentrations of suspended sediment ranged from 3 milligrams per liter (mg/L) to 355 mg/L, with an average of 38.8 mg/L (see Figure 7-2).



Source: USGS 2000a

Figure 7-2. Concentrations of Suspended Sediment and Associated Flows in the Sacramento River Above Big Bend near Red Bluff

Lower Sacramento River and Delta

Delivery of suspended sediment from the Sacramento River to the Delta and finally to San Francisco Bay decreased by about one-half during the period 1957 to 2001 (Wright and Schoellhamer 2004). Factors contributing to this trend in sediment yield included the depletion of erodible sediment from hydraulic mining in the late 1800s, trapping of sediment in reservoirs, riverbank protection, altered land uses, and levee construction.

Sediment supply to the Sacramento and San Joaquin river watersheds has declined over the last few decades because dams on rivers and other water management actions have resulted in less sediment transport (CALFED 2000c), although agricultural drainage in the Delta often contains high levels of suspended sediments (Reclamation and DWR 2005). Sediments that include fine sands, silts, and clays are transported by rivers and the Yolo Bypass into the Delta. Coarser materials are deposited at points higher up in the river basins. Sands typically are transported in the bed load, while clays and silts move in the suspended load. The suspended load is composed of generally finer materials moving downstream in the water column. Sediment loads from the Sacramento River are higher than those from the San Joaquin River (Reclamation and DWR 2005).

Hydraulic gold mining, particularly through the major westerly flowing tributaries such as the American, Feather, Yuba, and Bear rivers, may also affect sediment transport in the extended study area. USGS found that the Sacramento River is the primary supplier of suspended sediment to the Delta.

CVP/SWP Service Areas

Some suspended sediments are transported within the CVP and SWP service areas, but turbidity and sedimentation are not issues within the service areas (CALFED 2000c).

7.1.3 Temperature

Shasta Lake and Vicinity

Water temperature is an important water quality parameter affecting the beneficial uses of Shasta Lake and its tributaries, including contact and noncontact recreation and aquatic organisms. Within the reservoir, water temperature commonly controls the growth of algae and the rate of biochemical processes. Shasta Lake periodically stratifies and a thermocline develops on an annual basis, although turnover is incomplete and the lake has not been known to freeze over (Bartholow et al. 2001). Strong stratification of the reservoir occurs during summer at a depth of 10 to 15 meters. This stratification isolates the epilimnion from nutrients available in the deeper hypolimnion, segregating spring and fall algal blooms when water temperatures might otherwise support algal production in the euphotic zone, the zone close to the surface that provides opportunities for photosynthesis. The period of stratification generally overlaps with the peak recreation season (May to September), when surface water temperatures are comfortable for contact recreation activities. During fall, the stratification dissipates and the surface water temperature is reduced.

Shasta Dam operations greatly influence the annual and seasonal water temperature of the reservoir. The wetness of a given water year or series of years generally controls the mean annual water temperature. The current temperature regime of Shasta Lake is related to CVP operational requirements, including those necessary to optimize the water temperatures in the Sacramento River downstream from Keswick Dam. Overall, the tributaries that enter Shasta Lake meet the Basin Plan water quality objective for temperature.

Upper Sacramento River (Shasta Dam to Red Bluff)

Water temperature in the Sacramento River from Shasta Dam to Keswick Reservoir is determined primarily by the temperature of Shasta Dam release flows. At Keswick Reservoir, Shasta Dam release flows mix with flows from diverted through the Spring Creek Tunnel from Whiskeytown Reservoir, and are released back into the Sacramento River from Keswick Dam.

Water temperature for rivers within the Sacramento River basin is reportedly maintained consistent with regulatory requirements (e.g., NMFS Biological Opinion (BO)) most of the time, but temperature management can be difficult during low-flow periods (USGS 2000a). Historically, low-flow events and a lack of flexibility in dam operations can cause water temperatures to periodically approach critical levels for sustaining juvenile salmon populations. In addition to low flows, high water temperatures released from reservoirs, coupled with natural instream warming, can cause elevated river water temperatures (Vermeyen 1997).

A number of water quality objectives exist for the upper Sacramento River. The Basin Plan specifies that water temperature will not be elevated above 56 degrees Fahrenheit (°F) from Keswick Dam to Hamilton City (+9). In addition, the Basin Plan specifies that at no time or place will the temperature of cold or warm intrastate waters be increased more than 5°F above natural receiving-water temperature (CVRWQCB 2011). Keswick Dam releases are managed to meet temperature control requirements.

On December 15, 2008, USFWS issued the *Formal Endangered Species Act Consultation on the Proposed Coordinated Operations of the CVP and SWP* (2008 USFWS BO) for delta smelt and its critical habitat. On June 4, 2009, NMFS issued the *BO and Conference Opinion on the Long-Term Operations of the CVP and SWP* (2009 NMFS BO) for listed anadromous fishes and marine mammal species and their critical habitats. According to the 2009 NMFS BO, the Sacramento River water temperatures will be below 56°F at compliance locations between Balls Ferry and Bend Bridge from April 15 through September 30 to protect winter-run Chinook salmon, and when possible, not in excess of 56°F at the same compliance locations between Balls Ferry and Bend

Bridge from October 1 through October 31 to protect spring-run Chinook salmon.

Before 1997, to help meet the needs of federally listed winter-run Chinook salmon, cold water was released from low outlets at Shasta Dam. These cold-water releases bypassed hydropower facilities, causing the loss of power revenues. To achieve water temperature objectives in the Sacramento River without interrupting power generation, Reclamation constructed a temperature control device (TCD) on Shasta Dam that became operational in 1997. The TCD allows selective withdrawal of water from different reservoir depths without bypassing power generation, provides flexibility to Shasta Dam operations, and allows downstream temperature goals to be consistently achieved.

Historical Sacramento River water temperatures below Shasta Dam were analyzed from January 1991 through December 2005. The data set indicates that average temperatures vary seasonally, ranging from 47.9°F in February to 55.7°F in November. Water temperatures below Keswick Dam were analyzed for January 1990 through December 2006. Like the temperatures below Shasta Dam, average temperatures below Keswick Dam vary seasonally, ranging from 47.8°F in February to 54.9°F in November. Summer and fall temperatures typically increase by about 7°F. Water temperatures just downstream from Keswick Dam are influenced by releases from Shasta Lake and Whiskeytown Reservoir and Keswick Dam operations.

Lower Sacramento River and Delta

Water temperature in the Sacramento River at Colusa varies seasonally, ranging from 47.5°F to 67.5°F. Water temperatures gradually increase through the spring and summer and reach an average of about 65°F. Water temperature in the Sacramento River at Freeport varies seasonally, ranging from 48.7°F to 72.1°F (USGS 2000a).

Water temperature in the Delta is influenced only slightly by water management activities (i.e., dam releases) (Reclamation and DWR 2005). The 2004 and 2009 BOs for Sacramento River winter-run Chinook salmon are among the most influential factors governing Shasta releases, in terms of both quantity and timing (NMFS 2004, 2009). The BOs set temperature requirements below Keswick Dam for April through October. In years when CVP facilities cannot be operated to meet required temperature and storage objectives, Reclamation reinitiates consultation with NMFS (NMFS 2009).

CVP/SWP Service Areas

Water quality in the CVP and SWP service areas, including water temperature, is affected by fluctuations of water quality in the Delta, which in turn are influenced by water quality in the San Joaquin River, CVP and SWP export pumping rates, local agricultural diversions and drainage water, and the Sacramento River (CALFED 2000c).

7.1.4 Metals

Shasta Lake and Vicinity

Certain areas of Shasta Lake have been identified as impaired by toxic metal pollutants. For this reason, Shasta Lake is listed on the EPA's Section 303(d) list of impaired water bodies. For water bodies on the Section 303(d) list, the CWA requires the development of TMDL allocations for the pollutants of concern. A TMDL allocation must estimate the total maximum daily load, with seasonal variations and a margin of safety, for all suitable pollutants and thermal loads, at a level that would ensure protection and propagation of a balanced population of indigenous fish, shellfish, and wildlife. Table 7-2 shows the potential sources of pollution within specific areas of Shasta Lake, along with the TMDL priority and the estimated affected area of the pollutants.

Table 7-2. CWA Section 303(d) List of Water Quality Limited Segments, Shasta Lake, 2010

Pollutant	Potential Sources	TMDL Priority	Estimated Area Affected
Horse Creek, Town Creek, and Little Backbone Creek			
Cadmium	Resource extraction	Low	1.50 miles
Copper	Resource extraction	Low	1.50 miles
Lead	Resource extraction	Low	1.50 miles
Zinc	Resource extraction	Low	1.50 miles
All of Shasta Lake			
Mercury	Resource Extraction	Low	430 Miles
Area where West Squaw Creek enters Squaw Creek Arm of Shasta Lake			
Cadmium	Resource extraction	Low	20 acres
Copper	Resource extraction	Low	20 acres
Zinc	Resource extraction	Low	20 acres

Source: State Water Board 2006a

Key:
TMDL = total maximum daily load

Waters discharged by stream channels draining the areas disturbed by the mining of sulfide ore deposits are generally acidic and contain high concentrations of dissolved metals, including iron, copper, and zinc. The streams with the highest metal concentrations are Flat Creek (below Shasta Dam), Little Backbone Creek, Spring Creek (below Shasta Dam), West Squaw Creek, Horse Creek, and Zinc Creek (USGS 1978). Dissolved metals concentrations discharged by these streams violate water quality objectives and fish kills occur periodically, primarily during periods of high rainfall runoff (CVRWQCB 2003b) . The sources of the metals are surface and groundwater discharge from underground mines and waters flowing through open pits, tunnels, mine tailing deposits, waste rock, and Quaternary deposits that include modern alluvium along the shoreline. Interaction with sulfide minerals and erosion of metal-rich material commonly result in low pH readings and high metal concentrations.

The sources of the metals in the two areas identified in Table 7-2 are associated with the Bully Hill/Rising Star mining complex adjacent to West Squaw Creek. Although these mines are no longer operational and remedial action continues, these areas are a documented source of metals and continue to be subject to an abatement order issued by the CVRWQCB. A containment structure constructed sometime during the early 1900s has filled with sediment downstream from the Bully Hill Mine. No information is available on the character of the material stored behind this earth fill dam. In 2006, North State Resources, Inc., conducted a Phase 1 Site Assessment of sediment deposits at two isolated locations in a cove over a small divide from the Bully Hill Mine. This assessment documented elevated levels of sulfide minerals in these sediment deposits and extremely low pH values in surface waters draining this deposit of sediment (NSR 2007).

Tributaries to the Main Body of Shasta Lake are also a source of metals, along with acid mine drainage from a number of mines in the West Squaw Creek and Little Backbone Creek watersheds. In addition to runoff from the historic workings (i.e., adits and portals), a number of large mine tailing deposits are currently leaching various metals into tributaries to Shasta Lake (CVRWQCB 2003a).

Between 2002 and 2003, the CVRWQCB conducted an investigation intended to increase the understanding of the relationship between elevated metal concentrations (dissolved copper and zinc) in discharges from Shasta Dam and the temporal and spatial distribution of these metals within and upslope of Shasta Lake (CVRWQCB 2003a). Specifically, this investigation attempted to answer two questions:

- Why do these elevated metal concentrations appear seasonally?
- Are the concentrations somehow related to the operation of the TCD that is attached to the upstream face of Shasta Dam?

In 2003, the CVRWQCB issued an interim report that provided data and limited analysis at 17 sites upstream from Shasta Dam. The data set included 412 discrete samples and included 1,043 specific chemical analyses for various chemical constituents (CVRWQCB 2003b). The interim report offers the following conclusion: “This study shows a direct correlation between dissolved copper concentrations in the upper water column near the dam and dissolved copper concentrations immediately downstream from the dam in the winter months.” The report goes on to suggest that this correlation may somehow be related to the operation of the TCD as it relates to the seasonal thermocline that develops in Shasta Lake (CVRWQCB 2003b).

Upper Sacramento River (Shasta Dam to Red Bluff)

A major source of metals to the Sacramento River is drainage from inactive mines in the Iron Mountain area of the West Shasta mining district. During mining and smelting activities from the 1880s to the 1960s, Iron Mountain's acid mine drainage discharged directly to Spring Creek, a Sacramento River tributary upstream from Redding (USGS 2000b).

USGS conducted a water quality assessment of trace metal concentrations in the Sacramento River at Big Bend above Red Bluff from February 1996 to May 1998 (USGS 2000b). Although metals concentrations are a serious water quality concern in the project area, metals did not exceed water quality objectives during the study period.

The CVRWQCB has determined that the 25-mile segment of the upper Sacramento River between Keswick Dam and Cottonwood Creek near Balls Ferry in Shasta County is impaired because of levels of dissolved cadmium, copper, and zinc that exceed water quality standards (CVRWQCB 2002). The impairment results primarily from inactive mines in the upper Sacramento River watershed, predominantly the Iron Mountain site upstream from Keswick Dam and other mines upstream from Shasta Dam.

Water quality enhancement actions at the mines and improved coordination of the Spring Creek and Keswick Reservoirs have resulted in a notable decrease in the number of water quality targets exceeded in the past 10 years. However, metal loading remains high enough to cause periodic exceedences (CVRWQCB 2002). The sediments found in the Spring Creek Arm of Keswick Reservoir contain high levels of copper and zinc, which settled out of the contaminated stormwater runoff from the Iron Mountain Mine Superfund site. In 2009 and 2010, EPA dredged and removed contaminated sediments at this location with the goal of protecting the downstream Sacramento River ecosystem during storm events, when contaminated sediments can become mobilized and carried downstream. EPA expects that dredging the contaminated sediments will eliminate the last major threat that contamination from the Iron Mountain Mine poses to human health and the environment (EPA 2009).

High mercury concentrations in the Sacramento River correlate with concentrations of suspended sediment and high flows, because much of the mercury is transported adsorbed to suspended sediments (Domagalski et al. 2000). In May 2000, EPA adopted a water quality objective for total mercury for the Sacramento River watershed of 50 nanograms per liter (30-day average). In a USGS study of mercury levels along the Sacramento River at Big Bend above Red Bluff, conducted from February 1996 to May 1998, mercury levels were consistently below the EPA criterion of 50 nanograms per liter (USGS 2000b).

Lower Sacramento River and Delta

The downstream tributaries Cache Creek and Putah Creek are known to be substantial sources of mercury to the Sacramento River. The Sacramento River from Knights Landing to the Delta is listed as impaired on EPA's 303(d) list for mercury (CVRWQCB 2002).

The Delta waterways within the area under the CVRWQCB's jurisdiction are listed on EPA's 303(d) list as impaired for mercury from agriculture and historic mining, while the western Delta, under the jurisdiction of the San Francisco Bay RWQCB, is listed as impaired for mercury, nickel, and selenium. The primary sources of mercury are abandoned mine sites in the upper watershed that drain into the lower Sacramento River and Delta. The City of Sacramento is also the largest urban source of nitrogen, mercury, and assorted other urban waste products. Selenium concentrations are attributed to agriculture and oil refiners, while the primary source of nickel is unknown (State Water Board 2006a).

CVP/SWP Service Areas

Water quality in the CVP and SWP service areas is affected by fluctuations of water quality in the south Delta, which in turn are influenced by water quality in the San Joaquin River, CVP and SWP export pumping rates, local agricultural diversions and drainage water, and the Sacramento River (CALFED 2000c).

7.1.5 Salinity

The following discussion of the affected environment in the study area with regard to salinity is limited to a discussion of conditions in the lower Sacramento River and Delta portion of the extended study area because of the potential effects of salinity in this geographic area on beneficial uses. Salinity is particularly important in the Delta, which is influenced by tidal exchange with San Francisco Bay; during low-flow periods, seawater intrusion results in increased salinity.

Lower Sacramento River and Delta

The following are recognized water quality issues in the Delta (Reclamation and DWR 2005):

- High salinity from Suisun Bay intrudes into the Delta during periods of low Delta outflow. Salinity can adversely affect agricultural, M&I, and recreational uses.

- Delta exports contain elevated concentrations of disinfection byproduct precursors (e.g., dissolved organic carbon), and the presence of bromide increases the potential for formation of brominated compounds in treated drinking water.

- Agricultural drainage in the Delta contains high levels of nutrients, suspended solids, dissolved organic carbon and minerals (salinity), and agricultural chemicals (pesticides).
- Synthetic organic chemicals and heavy metals have bioaccumulated in Delta fish and other aquatic organisms, occasionally exceeding standards for food consumption.
- The San Joaquin River inflow to the Delta is typically lower quality than Delta inflow from other tributary sources such as the Sacramento River. Because the south Delta receives a substantial portion of water from the San Joaquin River, the influence of this relatively poor San Joaquin River water quality is greatest in the south Delta channels and in CVP and SWP exports.

Trends in Delta water quality reflect the effects of river inflows, tidal exchanges with San Francisco Bay, diversions, and pollutant releases. The north Delta tends to have better water quality primarily because of inflow from the Sacramento River. The quality of water in the west Delta is strongly influenced by tidal exchange with San Francisco Bay; during low-flow periods, seawater intrusion results in increased salinity. In the south Delta, water quality tends to be poorer because of the combination of inflows of poorer water quality from the San Joaquin River, discharges from Delta islands, export pumping, seasonal agricultural barriers, and effects of diversions that can sometimes increase seawater intrusion from San Francisco Bay.

The Sacramento and San Joaquin rivers contribute approximately 61 percent and 33 percent, respectively, to TDS concentrations within the Delta from tributary inflows. TDS concentrations are relatively low in the Sacramento River, but because of its large volumetric contribution, the river provides the majority of the TDS load supplied by tributary inflow to the Delta (DWR 2001). Although actual flow from the San Joaquin River is lower than flow from the Sacramento River, TDS concentrations in San Joaquin River water average approximately seven times the TDS concentrations in the Sacramento River.

7.2 Regulatory Framework

Several regulatory authorities at the Federal, State of California (State), and local levels control the flow, quality, and supply of water in California either directly or indirectly. This section focuses on laws related directly to the water quality aspect of the project.

Management of the Delta is partly determined by Federal and State regulations developed to protect both human and environmental beneficial uses. Primary institutional and regulatory influences on the use and management of the Delta consist of the CVP; the SWP; direct Delta diverters, including Contra Costa

Water District (CCWD), Solano County Water Agency, and the City of Stockton Metropolitan Area; San Francisco Bay water quality needs; and multiple regulations governing protection of endangered species.

At the State level, the State Water Board and the RWQCBs regulate and monitor Delta water quality. Nine regional boards oversee water quality in California. Two of these, the CVRWQCB and San Francisco Bay RWQCB, oversee Delta water quality. EPA also plays an important role under the auspices of the CWA and the Safe Drinking Water Act (SDWA). The California Department of Public Health has an interest in the Delta because the Delta is the source of drinking water for more than 23 million Californians. DWR extensively monitors Delta water quality as part of its Municipal Water Quality Investigations program; in cooperation with Reclamation, DWR monitors Delta water quality under the State Water Board's compliance monitoring requirements.

At the local level, water agencies that divert from the Delta have both strong interest in and influence on Delta water quality management. These agencies include CCWD, Solano County Water Agency, and City of Stockton Metropolitan Area.

Two agencies with key planning roles in the Delta are the California Bay-Delta Authority and the Delta Protection Commission. The California Bay-Delta Authority became a State agency in January 2003, and is responsible for implementing the CALFED Bay-Delta Program (CALFED). State legislation created the Delta Protection Commission in 1992 with the goal of developing regional policies for the Delta to protect and enhance existing land uses. In 2000, the commission was made a permanent State agency. The Delta Protection Commission comments on applications for CALFED ecosystem restoration grants that affect the Delta and participates in meetings with other CALFED agencies to provide input to CALFED management decisions.

7.2.1 Federal

Safe Drinking Water Act

The SDWA was established to protect the quality of drinking water in the United States. The SDWA authorized EPA to set national health-based standards for drinking water and requires many actions to protect drinking water and its sources, including rivers, lakes, reservoirs, springs, and groundwater wells. Furthermore, the SDWA requires all owners or operators of public water systems to comply with primary (health-related) standards. EPA has delegated to the California Department of Public Health, Division of Drinking Water and Environmental Management, the responsibility for administering California's drinking-water program. The California Department of Public Health is accountable to EPA for program implementation and for adopting standards and regulations that are at least as stringent as those developed by EPA. Contaminants of concern relevant to domestic water supply are defined as those that pose a public health threat or that alter the aesthetic acceptability of the water. These types of contaminants are regulated by EPA primary and secondary maximum contaminant levels that are applicable to treated water supplies delivered to the distribution system. Maximum contaminant levels and the process for setting these standards are reviewed triennially.

Clean Water Act

The CWA is the major Federal legislation governing the water quality aspects of the project. The objective of the act is "to restore and maintain the chemical, physical, and biological integrity of the nation's waters." The CWA establishes the basic structure for regulating discharge of pollutants into the waters of the United States and gives EPA the authority to implement pollution control programs such as setting wastewater standards for industries. In certain states such as California, EPA has delegated authority to state agencies.

Section 303 This section of the CWA requires states to adopt water quality standards for all surface waters of the United States. The three major components of water quality standards are as follows:

- **Designated uses** – Uses that society, through the Federal and State governments, determines should be attained in the water body, such as supporting communities of aquatic life, supplying water for drinking, irrigating crops and landscaping, and industrial purposes, and recreational uses (e.g., fishing, swimming, boating).

- **Water quality criteria** – Levels of individual pollutants or water quality characteristics, or descriptions of conditions of a water body that, if met, will generally protect the designated use of the water. Water quality criteria must be scientifically consistent with attainment of designated uses, which means that only scientific considerations can be taken into account when determining what water quality conditions are consistent with meeting a given designated use. Economic and social impacts are not considered when developing water quality criteria.

- **Antidegradation policy** – Designed to prevent deterioration of existing levels of good water quality (see the "Antidegradation Policy" section below for more information).

Where multiple uses exist, water quality standards must protect the most sensitive use. In California, EPA has given the State Water Board and its nine RWQCBs the authority to identify beneficial uses and adopt applicable water quality objectives.

Section 303(d) of the CWA requires states and authorized Native American tribes to develop a list of water quality-impaired segments of waterways. The list includes waters that do not meet water quality standards necessary to support the beneficial uses of that waterway, even after point sources of pollution have installed the minimum required levels of pollution control technology. Only waters impaired by "pollutants," not those impaired by other types of "pollution" (e.g., altered flow and/or channel modification), are to be included on the list. (Pollutants include clean sediments, nutrients (e.g., nitrogen and phosphorus), pathogens, acids/bases, temperature, metals, cyanide, and synthetic organic chemicals.)

Section 303(d) of the CWA also requires states to maintain a listing of impaired water bodies so that a TMDL can be established. A TMDL is a plan to restore the beneficial uses of a stream or to otherwise correct an impairment. It establishes the allowable pollutant loadings or other quantifiable parameters (e.g., pH or temperature) for a water body and thereby provides the basis for the establishment of water quality-based controls. The calculation for establishment of TMDLs for each water body must include a margin of safety to ensure that the water body can be used for the purposes the State has designated. Additionally, the calculation also must account for seasonal variation in water quality. The CVRWQCB develops TMDLs for the Sacramento River (see discussion on the Porter-Cologne Water Quality Control Act (Porter-Cologne Act) below). Sedimentation/siltation impacts are the primary water quality parameters of concern with construction projects.

Reductions in pollutant loading are achieved by implementing strategies authorized by the CWA, such as the following, which are discussed in more detail below.

- **Section 401** – This section of the CWA requires Federal agencies to obtain certification from the State or Native American tribes before issuing permits that would result in increased pollutant loads to a water body. The certification is issued only if such increased loads would not cause or contribute to exceedences of water quality standards.

- **Section 402** – This section creates the National Pollutant Discharge Elimination System (NPDES) permit program. This program covers point sources of pollution discharging into a surface water body.

- **Section 404** – This section regulates the placement of dredged or fill materials into wetlands and other waters of the United States.

Section 401 – Water Quality Certification This section of the CWA requires an applicant for any Federal license or permit (e.g., a Section 404 permit) that may result in a discharge into waters of the United States to obtain a certification from the State that the discharge would comply with provisions of the CWA. The State Water Board and RWQCBs administer this program. The State Water Board issues Section 401 certifications for projects that would take place in two or more regions. Any condition of a Section 401 certification (or water quality certification) would be incorporated into the USACE permit.

The CVRWQCB has jurisdiction over the primary study area, but the extended study area encompasses the San Francisco Bay, Central Coast, Los Angeles, Lahontan, Colorado River basin, and the Santa Ana and San Diego RWQCBs. A Section 401 certification would not be required from the RWQCBs within the extended study area because no construction would occur in the extended study area.

Section 402 – National Pollutant Discharge Elimination System All point sources that discharge into waters of the United States must obtain an NPDES permit under provisions of Section 402 of the CWA. As with Section 401, the State Water Board and RWQCBs are responsible for implementing the NPDES permitting process at the State and regional levels, respectively.

The NPDES permit process also provides a regulatory mechanism for controlling nonpoint-source pollution created by runoff from construction and industrial activities, and general and urban land use, including runoff from streets. Projects involving construction activities (e.g., clearing, grading, or excavation) involving land disturbance greater than one acre must file a notice of intent with the appropriate RWQCB(s) to indicate their intent to comply with the General Permit for Discharges of Stormwater Associated with Construction Activity (Construction General Permit Order 2009-0009-DWQ, which went into effect and replaced Order 99-08-DWQ on July 1, 2010). This general permit establishes conditions to minimize sediment and pollutant loadings and requires preparation and implementation of a Stormwater Pollution Prevention Plan (SWPPP) before construction. The SWPPP is intended to help identify the sources of sediment and other pollutants, and to establish best management practices (BMP) for stormwater and nonstormwater source control and pollutant control. A sediment monitoring plan must be included in the SWPPP if the discharges occur directly to a water body listed on the Section 303(d) TMDL list for sediment.

The CVRWQCB has jurisdiction over the primary study area. A NPDES permit would not be required from the RWQCBs within the extended study area because no construction would occur in the extended study area.

Section 404 – Discharge of Dredged or Fill Material into Waters of the United States Section 404 deals with one broad type of pollution – the placement of dredged or fill material into "waters of the United States." Jurisdictional limits of these features are typically noted by the ordinary high-water mark. Isolated ponds or seasonal depressions had been previously regulated as waters of the United States. However, in *Solid Waste Agency of Northwestern Cook County v. United States Army Corps of Engineers et al.* (January 8, 2001), the U.S. Supreme Court ruled that certain "isolated" wetlands (e.g., nonnavigable, isolated, and intrastate) do not fall under the jurisdiction of the CWA and are no longer under USACE jurisdiction. (Although isolated wetlands may not be under Federal regulation, they are regulated by the State (see Porter-Cologne Act discussion below)). Some circuit courts (e.g., *U.S. v.*

Deaton, 2003; *U.S. v. Rapanos*, 2003; *Northern California River Watch v. City of Healdsburg*, 2006), however, have ruled that Solid Waste Agency of Northwestern Cook County does not prevent CWA jurisdiction if a "significant nexus" such as a hydrologic connection exists. The hydrologic connection may be human-made (e.g., roadside ditch) or a natural tributary to navigable waters, or direct seepage from the wetland to the navigable water through a surface or underground hydraulic connection. An ecological connection (e.g., the same bird, mammal, and fish populations are supported by both the wetland and the navigable water) and changes to chemical concentrations in the navigable water caused by water from the wetland may also constitute a significant nexus.

The discharge of dredge or fill generally includes the following activities:

- Placement of fill that is necessary for the construction of any structure or infrastructure in a water of the United States
- The building of any structure, infrastructure, or impoundment requiring rock, sand, dirt, or other material for its construction
- Site-development fills for recreational, industrial, commercial, residential, or other uses
- Causeways or road fills
- Dams and dikes
- Artificial islands
- Property protection and/or reclamation devices such as riprap, groins, seawalls, breakwaters, and revetments
- Beach nourishment
- Levees
- Fill for structures such as sewage treatment facilities, intake and outfall pipes associated with powerplants, and subaqueous utility lines
- Placement of fill material for construction or maintenance of any liner, berm, or other infrastructure associated with solid waste landfills
- Placement of overburden, slurry, mine tailing deposits, or similar mining-related materials
- Artificial reefs

USACE regulations and policies mandate avoiding the filling of wetlands unless it can be demonstrated that no practicable alternatives (to filling wetlands) exist.

Four basic processes exist for obtaining Section 404 authorization from USACE. Because of its scale and potential impact, this project would require an individual permit.

USACE's Sacramento District has jurisdiction over the primary study area, but the extended study area encompasses the San Francisco and Los Angeles Districts of USACE.

Antidegradation Policy

The Antidegradation Policy, established in 1968 and revised in 2005 (Title 40, Code of Federal Regulations, Section 131.12), is designed to protect existing uses and water quality and national water resources, as authorized by Section 303(c) of the CWA. At a minimum, the policy and implementation methods must be consistent with the following:

- Existing instream water uses and the level of water quality necessary to protect the existing uses shall be maintained and protected.
- Where the quality of the waters exceeds levels necessary to support propagation of fish, shellfish, and wildlife and recreation in and on the water, that quality shall be maintained and protected unless the State finds that allowing lower water quality is necessary to accommodate important economic or social development in the area in which the waters are located. In allowing such degradation or lower water quality, the State shall assure water quality adequate to protect existing uses fully. Further, the State shall assure that there shall be achieved the highest statutory and regulatory requirements for all new and existing point sources and all cost-effective and reasonable BMPs for nonpoint source control.
- Where high-quality waters constitute an outstanding National resource, such as waters of National and State parks and wildlife refuges and waters of exceptional recreational or ecological significance, that water quality shall be maintained and protected.

Although the quality of water in the upper Sacramento River is relatively good, water quality problems do occur, including the presence of mercury, pesticides such as organochlorine pesticides, trace metals, turbidity, and toxicity from unknown origin (CALFED 2000a).

The CWA requires states to maintain a listing of impaired water bodies so that a TMDL can be established. A TMDL is a plan to restore the beneficial uses of a stream or to otherwise correct an impairment. The most prevalent contaminants in the Sacramento River basin are for organophosphate pesticides (agricultural runoff) and trace metals (acid mine drainage), for which TMDLs currently are being considered. Only during conditions of stormwater-driven runoff are water quality objectives typically not met (Domagalski et al. 2000).

Shasta-Trinity National Forest Land and Resource Management Plan

STNF is guided by various laws, regulations, and policies that provide the framework for all levels of planning. These include regional guides, the STNF LRMP, and site-specific planning documents, such as this document.

The STNF LRMP provides guidance for managing NFS lands in STNF. The development of a forest LRMP occurs within the framework of regional and national USFS planning. The LRMP includes forest goals, forest objectives (including forest-wide prescription assignment by acres, outputs, and activities), and forest standards and guidelines. Forest goals state the management philosophy of the LRMP, and the Forest objectives describe the purpose of the management prescriptions. The forest-wide management prescriptions apply a management theme to specific types of land (e.g., wilderness, roaded high-density recreation).

In essence, this LRMP requires that projects authorized by STNF be designed and implemented in a manner that maintains the existing conditions or implements actions to restore biological and physical processes within their natural range of variability.

Water Quality Goals (LRMP, p. 4-6)

- Maintain or improve water quality and quantity to meet fish habitat requirements and domestic use needs.
- Maintain water quality to meet or exceed applicable standards and regulations.

Standards and Guidelines (LRMP, p. 4-25)

- Implement BMPs for protection or improvement of water quality, as described in "USFS Soil and Water Handbook for Region 5," for applicable management activities. Determine specific practices or techniques during project-level planning using information obtained from on-site soil, water, and geology investigations.

Best Management Practices

- STNF water quality BMPs were developed in compliance with USFS National Best Management Practices for Water Quality Management on National Forest Lands.
- STNF water quality BMPs were developed in compliance with the USFS Soil and Water Handbook for Region 5 that was updated in 2011. The following BMPs are applicable to the proposed action:

Road Building and Site Construction Standards and Guidelines (LRMP, Appendix E, pp. E-2 through E-3)

- General guidelines for the location and design of roads
- Erosion control plan
- Timing of construction activities
- Road slope stabilization (preventive practice)
- Road slope stabilization (administrative practice)
- Dispersion of subsurface drainage from cut and fill slopes
- Control of road drainage
- Construction of stable embankments
- Minimization of sidecast material
- Servicing and refueling equipment
- Control of construction in riparian management zones
- Controlling in-channel excavation
- Diversion of flows around construction sites
- Bridge and culvert installation
- Disposal of right-of-way and roadside debris
- Specifying riprap composition
- Maintenance of roads
- Road surface treatment to prevent loss of materials
- Traffic control during wet periods
- Surface erosion control at facility sites

Recreation Standards and Guidelines (LRMP, Appendix E, p. E-3)

- Documentation of water quality data
- Control of sanitation facilities
- Control of refuse disposal

- Protection of water quality within developed and dispersed recreation areas

Aquatic Conservation Strategy (LRMP, p. 4-53)

- Maintain and restore the distribution, diversity, and complexity of watershed- and landscape-scale features to ensure protection of the aquatic systems to which species, populations, and communities are uniquely adapted.

- Maintain and restore spatial and temporal connectivity within and between watersheds. Lateral, longitudinal, and drainage network connections include floodplains, wetlands, upslope areas, headwater tributaries, and intact refugia. These network connections must provide chemically and physically unobstructed routes to areas critical for fulfilling life history requirements of aquatic and riparian-dependent species.

- Maintain and restore the physical integrity of the aquatic system, including shorelines, banks, and bottom configurations.

- Maintain and restore water quality necessary to support healthy riparian, aquatic, and wetland ecosystems. Water quality must remain within the range that maintains the biological, physical, and chemical integrity of the system and benefits survival, growth, reproduction, and migration of individuals composing aquatic and riparian communities.

- Maintain and restore the sediment regime under which aquatic ecosystems evolved. Elements of the sediment regime include the timing, volume, rate, and character of sediment input, storage, and transport.

- Maintain and restore instream flows sufficient to create and sustain riparian, aquatic, and wetland habitats and to retain patterns of sediment, nutrient, and wood routing. The timing, magnitude, duration, and spatial distribution of peak, high, and low flows must be protected.

- Maintain and restore the timing, variability, and duration of floodplain inundation and water table elevation in meadows and wetlands.

- Maintain and restore the species composition and structural diversity of plant communities in riparian areas and wetlands to provide adequate summer and winter thermal regulation, nutrient filtering, appropriate rates of surface erosion, bank erosion, and channel migration and to supply amounts and distributions of coarse woody debris sufficient to sustain physical complexity and stability.

- Maintain and restore habitat to support well-distributed populations of native plant, invertebrate, and vertebrate riparian-dependent species.

U.S. Bureau of Land Management

The BLM's Resource Management Plan, which is its plan for managing Federal lands in Shasta County, was amended by the 1994 Record of Decision (ROD) for the Northwest Forest Plan (Final Supplemental EIS for Amendments to Forest Service and Bureau of Land Management Planning Documents within the Range of the Northern Spotted Owl). This amendment required preparation of Watershed Analysis before initiating BLM activities. As a party to the Northwest Forest Plan, BLM, like USFS, is also required to ensure that projects are consistent with the Aquatic Conservation Strategy.

Biological Opinions on the Long-term Central Valley Project and State Water Project Operations Criteria and Plan

Since 2004, NMFS and USFWS BOs regarding effects of the proposed Operations Criteria and Plan (OCAP) have been revised twice. On October 22, 2004, NMFS issued a BO regarding effects of the proposed OCAP for the CVP in coordination with the SWP on winter-run Chinook salmon, spring-run Chinook salmon, Central Valley steelhead, Southern Oregon/Northern California Coast Coho salmon, and Central California Coast steelhead and their designated critical habitat. On February 16, 2005, USFWS issued a BO regarding effects of the proposed OCAP on delta smelt. The 2004 and 1995 BOs supersede the prior BOs issued by NMFS and USFWS, and contain reasonable and prudent measures and terms and conditions that specify fisheries monitoring actions, spawning gravel augmentation, forecasting of deliverable water, management of cold-water supply within reservoirs, temperature monitoring, adaptive management processes to analyze annual cold-water management, minimization of flow fluctuations, passage at Red Bluff Diversion Dam, operation of gates in the Delta, fish screening at pumping facilities, and numerous other effects minimization measures. In response to litigation, the 2004 and 2005 BOs were remanded to NMFS and USFWS for revision, but were not vacated.

In August 2008, Reclamation reinitiated consultation with the fishery agencies based on the 2008 *Biological Assessment on the Continued Long-Term Operations of the CVP and SWP* (2008 Long-Term Operation BA). In December 2008, the USFWS issued the 2008 USFWS BO, finding that the long-term operations of the CVP and SWP would jeopardize the continued existence of the Delta smelt. In July 2009, NMFS issued the 2009 NMFS BO, finding that the same operations would jeopardize populations of listed salmonids, steelhead, green sturgeon and killer whales. Because both agencies made jeopardy determinations, both agencies included a Reasonable and Prudent Alternative (RPA) in their BOs.

In response to lawsuits challenging the 2008 and 2009 BOs, the District Court for the Eastern District of California (District Court) remanded the BOs to

USFWS and NMFS in 2010 and 2011, respectively. The District Court ordered USFWS and Reclamation to prepare a final BO and associated final NEPA document by December 1, 2013. Similarly, the District Court ordered NMFS and Reclamation to prepare a final BO and associated final NEPA document by February 1, 2016. These legal challenges may result in changes in CVP and SWP operational constraints, if the revised USFWS and NMFS BOs contain new or amended RPAs. Despite this uncertainty, the 2008 Long-Term Operation BA and the 2008 and 2009 BOs issued by the fishery agencies contain the current estimate of potential changes in water operations that could occur in the near future. Furthermore, it is anticipated that the final BOs issued by the resource agencies will contain similar RPAs.

7.2.2 State

Porter-Cologne Water Quality Control Act

The Porter-Cologne Act is California's statutory authority for the protection of water quality. Under the act, the State must adopt water quality policies, plans, and objectives protecting the State's waters for the use and enjoyment of the people. Obligations of the State Water Board and RWQCBs to adopt and periodically update their basin plans are set forth in the act. A basin plan identifies the designated beneficial uses for specific surface water and groundwater resources, applicable water quality objectives necessary to support the beneficial uses, and implementation programs that are established to maintain and protect water quality from degradation for each of the RWQCBs. The act also requires waste dischargers to notify the RWQCBs of their activities through the filing of reports of waste discharge and authorizes the State Water Board and RWQCBs to issue and enforce waste discharge requirements (WDR), NPDES permits, Section 401 water quality certifications, or other approvals. The RWQCBs also have authority to issue waivers to reports of waste discharge/WDRs for broad categories of "low threat" discharge activities that have minimal potential for adverse water quality effects when implemented according to prescribed terms and conditions.

The Basin Plan (originally published in 1998, last revised in October 2011) (CVRWQCB 2011) regulates waters of the State located within the primary study area. The Basin Plan covers an area including the Sacramento and San Joaquin river basins, involving an area bounded by the crests of the Sierra Nevada on the east and the Coast Ranges and Klamath Mountains on the west. The area covered in the Basin Plan extends some 400 miles, from the California/Oregon border southward to the headwaters of the San Joaquin River, encompassing a substantial portion of the extended study area. The beneficial uses of the Sacramento River are as follows (CVRWQCB 2011):

- Municipal and domestic supply
- Irrigation and stock watering

- Service supply
- Power
- Contact recreation and canoeing and rafting
- Other noncontact recreation
- Freshwater habitat (warm and cold)
- Migration habitat (warm and cold)
- Spawning habitat (warm and cold)
- Wildlife habitat
- Navigation

The Basin Plan recognizes Shasta Reservoir (i.e., Shasta Lake) as a discrete water body and identifies a number of specific beneficial uses:

- Municipal and domestic supply
- Agricultural supply
- Hydropower generation
- Water contact recreation
- Noncontact recreation
- Freshwater habitat (warm and cold)
- Spawning, reproduction, and/or early development
- Wildlife habitat

The CVRWQCB has also promulgated water quality objectives for all surface waters in the Sacramento and San Joaquin River basins (CVRWQCB 2011) for the following:

- Bacteria levels
- Biostimulatory substances
- Chemical constituents
- Color
- Dissolved oxygen
- Floating material
- Methylmercury
- Oil and grease
- pH
- Pesticides
- Radioactivity
- Salinity
- Sediment
- Settleable material
- Suspended material
- Tastes and odors
- Temperature
- Toxicity
- Turbidity

Primary Study Area The CVRWQCB determined that the 25-mile reach of the Sacramento River from Keswick Dam downstream to Cottonwood Creek is impaired because the water periodically contains levels of dissolved cadmium, copper, and zinc that exceed levels identified to protect aquatic organisms. Consequently, the CVRWQCB developed a TMDL program for dissolved cadmium, copper, and zinc loading into the upper Sacramento River because of these exceedences of water quality standards (CVRWQCB 2002) and has proposed implementing the water quality objectives listed in Table 7-3 as numeric targets for this TMDL. No other TMDLs have been finalized for this area (CVRWQCB 2007a).

Table 7-3. Proposed TMDL Numeric Targets for Dissolved Cadmium, Copper, and Zinc for a 25-Mile Segment of the Upper Sacramento River between Keswick Dam and Cottonwood Creek near Balls Ferry in Shasta County

Metals	Acute Numeric Target (µg/L)	Chronic Numeric Target (µg/L)
Cadmium	0.22	0.22
Copper	5.6	4.1
Zinc	16	16

Source: CVRWQCB 2002

Key:
µg/L = micrograms per liter
TMDL = total maximum daily load

Extended Study Area The Sacramento River downstream from RBPP was listed as an impaired water body under Section 303(d) of the CWA. The parameters of concern in this reach included diazinon, mercury, and unknown sources of toxicity (CVRWQCB 2003b). TMDLs under development for the Sacramento River are for diazinon, methylmercury, and chlorpyrifos (CVRWQCB 2007b). The extended study area encompasses the San Francisco, Central Coast, Los Angeles, Lahontan, Colorado River basin, and the Santa Ana and San Diego RWQCBs.

Clean Water Act Section 401 Water Quality Certification

The CVRWQCB, under the auspices of the State Water Board, requires that a project proponent obtain a CWA Section 401 water quality certification in conjunction with the Section 404 permits granted by USACE. Because the project would have the potential to affect water quality in Shasta Lake, the CVRWQCB is likely to impose water quality limitations on the project through WDRs. Reclamation will prepare and submit to the CVRWQCB a request for water quality certification before development of the project. A likely condition of the water quality certification is preparation of an erosion and sedimentation control plan and a spill prevention and containment plan.

Waste Discharge Permit

The CVRWQCB controls the discharge of wastes to surface waters from industrial processes or construction activities through the NPDES permit process. WDRs are established in the permit to protect beneficial uses. The CVRWQCB will require an application for a waste discharge permit for the project.

Industrial Stormwater General Permit

The Industrial Stormwater General Permit (General Industrial Permit) is an NPDES permit that regulates discharges associated with 10 broad categories of industrial activities. This permit requires implementation of management measures that will achieve the performance standard of best available technology economically achievable and best conventional pollutant control technology. This permit also requires development of a SWPPP and a monitoring plan. Through the SWPPP, sources of pollutants are to be identified and the means to manage the sources to reduce stormwater pollution are described.

Stormwater Pollution Prevention Plan

The General Industrial Permit includes provisions for developing a SWPPP to maximize the potential benefits of pollution prevention and sediment- and erosion-control measures at construction sites. Developing and implementing a SWPPP would provide Reclamation with the framework for reducing soil erosion and minimizing pollutants in stormwater during project construction.

Water Quality Control Plan for the Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California

The Water Quality Control Plan for the Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California (Thermal Plan) sets limits for "thermal waste" and "elevated temperature waste" discharged into coastal and interstate waters and enclosed bays and estuaries of California (State Water Board no date). Estuarine waters are considered to extend from "…a bay or the open ocean to the upstream limit of tidal action" (State Water Board no date). This definition includes the Delta as defined by Section 12220 of the California Water Code, as well as portions of the Sacramento River that are subject to tidal action. Generally, the Basin Plan defines temperature objectives in two parts (CVRWQCB 2011):

> *At no time or place shall the temperature of COLD or WARM intrastate waters be increased more than 5°F above natural receiving water temperature.*
>
> *The temperature shall not be elevated above 56°F in the reach from Keswick Dam to Hamilton City nor above 68°F in the reach from Hamilton City to the I Street Bridge during periods when temperature increases will be detrimental to the fishery.*

The first water quality standards for the Delta were adopted in May 1967, when the State Water Rights Board (predecessor to the State Water Board) released State Water Board Water Right Decision 1275 (D-1275), approving water rights for the SWP while setting agricultural salinity standards as terms and conditions. Since then, these requirements were changed in 1971 under State Water Board Water Right Decision 1379 (D-1379), and again in 1978 under State Water Board Water Right Decision 1485 and the Water Quality Control Plan (WQCP) for the Delta and Suisun Marsh (1978 WQCP). In May 1995, State Water Board adopted a new Bay-Delta WQCP, and it was implemented through State Water Board Revised Water Right Decision 1641 (RD-1641) in March 2000.

2006 Water Quality Control Plan[2]

The 2006 WQCP for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary (State Water Board 2006b) established water quality control measures that contribute to the protection of beneficial uses in the Delta. The 2006 WQCP identified (1) beneficial uses of the Delta to be protected, (2) water quality objectives for the reasonable protection of beneficial uses, and (3) a program of implementation for achieving the water quality objectives. The 2006 WQCP superseded the WQCP for the San Francisco Bay/Sacramento-San Joaquin Delta Estuary adopted in May 1995 (1995 Bay-Delta Plan or 1995 Plan) as well as the preceding plans that the 1995 WQCP superseded (including the original 1978 WQCP and 1991 amended WQCP). Amendments made as part of the December 15, 1994, Bay-Delta Accord committed the CVP and SWP to new Delta habitat objectives. Because these new beneficial objectives and water quality standards were more protective than those of the previous Water Right Decision 1485, the new objectives were adopted by amendment in 1995 through a Water Rights Order for operation of the CVP and SWP. One key feature of the 1995 WQCP was the estuarine habitat (X2) objectives for Suisun Bay and the western Delta. The X2 objective required specific daily or 14-day surface EC criteria, or 3-day averaged outflow requirements to be met for a certain number of days each month, February through June. These requirements were designed to provide improved shallow water habitat for fish species in spring. Because of the relationship between seawater intrusion and interior Delta water quality, the X2 criteria also improved water quality at Delta drinking water intakes. Other new elements of the 1995 WQCP included export-to-inflow ratios intended to reduce entrainment of fish at the export pumps, Delta Cross Channel gate closures, and San Joaquin River EC and flow standards. Further amendments in 2006 updated the program of implementation in the 1995 WQCP, including adding direction and recommendations to other agencies regarding activities that the agencies should take to assist in achieving the objectives; and included several commitments and recommendations for studies and other activities.

[2] The 2006 WQCP was updated in 2013 to reflect the plan amendments adopted up through July 2013. The 2006 WQCP was used to support the analysis included in this EIS; the 2013 WQCP updates do not change this analysis.

Water Right Decision 1641

RD-1641 and Water Rights Order 2001-05 contain the water right requirements to implement the 2006 WQCP. RD-1641 incorporates water right settlement agreements between Reclamation and DWR and certain water users in the Delta and upstream watersheds regarding contributions of flows to meet water quality objectives. However, Reclamation and/or DWR are responsible for ensuring that objectives are met in the Delta. RD-1641 also authorizes the CVP and SWP to use joint points of diversion (JPOD) in the south Delta, and recognizes the CALFED Operations Coordination Group process for operational flexibility in applying or relaxing certain protective standards. The additional exports allowed under the JPOD could result in additional degradation of water quality for water users in the south and central Delta. The JPOD also could affect water levels in the south Delta and endangered fish species.

In February 2006, the State Water Board issued notice to Reclamation and DWR that each agency is responsible for meeting the objectives in the interior south Delta, as described in RD-1641. The State Water Board order requires Reclamation and DWR to comply with a detailed plan and time schedule that will bring them into compliance with their respective permit and license requirements for meeting interior south Delta salinity objectives by July 1, 2009. The State Water Board order also revised the previously issued (July 1, 2005) Water Quality Response Plan approval governing Reclamation's and DWR's use of each other's respective point of diversion in the south Delta. Additionally, the order specifies that JPOD operations are authorized pursuant to the 1995 WQCP, and that Reclamation and DWR may conduct JPOD diversions, provided that both agencies are in compliance with all conditions of their respective water right permits and licenses at the time the JPOD diversions would occur (State Water Board 2006a).

Municipal and Industrial Water Quality Objectives

In the 1978 WQCP, the State Water Board set two objectives that it believed would provide reasonable protection for M&I beneficial uses of Delta waters from the effects of salinity intrusion. The first objective established a year-round maximum mean daily chloride concentration measured at five Delta intake facilities, including CCWD's Pumping Plant Number 1, of 250 mg/L for the reasonable protection of municipal beneficial uses. This objective was consistent with the EPA secondary maximum contaminant level for chloride of 250 mg/L, and is based only on aesthetic (taste) considerations. The second objective established a maximum mean daily chloride concentration of 150 mg/L (measured at either CCWD Pumping Plant No. 1 or the San Joaquin River at the Antioch water works intake) for the reasonable protection of industrial beneficial uses (specifically manufacture of cardboard boxes by Gaylord Container Corporation in Antioch). This requirement is in effect for a minimum of between 155 and 240 days each calendar year, depending on the water year type.

In the 1991 WQCP, the State Water Board reviewed the water quality objectives for M&I use contained in the 1978 WQCP, and reviewed potential new objectives for trihalomethanes and other disinfection byproducts, including bromides. The State Water Board concluded that technical information regarding trihalomethanes and other disinfection byproducts was not sufficient to set a scientifically sound objective. Accordingly, the State Water Board continued the existing objectives for chloride concentration, and until development of more information about these constituents, set a water quality "goal" for bromides of 0.15 mg/L (150 micrograms per liter). The State Water Board also noted that the 150 mg/L chloride objective was maintained in part because it provides ancillary protection for other M&I uses in the absence of objectives for trihalomethanes and other disinfection byproducts.

These objectives remained unchanged in the 1995 and 2006 WQCPs. The State Water Board and CVRWQCB basin plans specify water quality objectives to protect designated beneficial uses, including municipal drinking-water supply. The CVRWQCB is also currently developing a Central Valley drinking-water policy that may lead to regulations limiting the discharge of bromide, organic carbon, pathogens, and other drinking water constituents of concern. The CVRWQCB took the important step of adopting resolutions in July 2004 (Resolution No. R5-2004-0091) and July 2010 (Resolution No. R5-2010-0079), supporting development of the policy. Resolution No. R5-2010-0079 directed CVRWQCB staff to develop and bring a comprehensive drinking water policy to the board within 3 years (i.e., by 2013).

Coordinated Operations Agreement

The Coordinated Operations Agreement defines how Reclamation and DWR share their joint responsibility to meet Delta water quality standards and meet the water demands of senior water right holders. The Coordinated Operations Agreement defines the Delta as being in either "balanced water conditions" or "excess water conditions." Balanced conditions are periods when Delta inflows are just sufficient to meet water user demands within the Delta, outflow requirements for water quality and flow standards, and export demands. Under excess conditions, Delta outflow exceeds the flow required to meet the water quality and flow standards. Typically, the Delta is in balanced water conditions from June to November, and in excess water conditions from December through May. However, depending on the volume and timing of winter runoff, excess or balanced conditions may extend throughout the year.

7.2.3 Local

The primary study area is located within both Shasta and Tehama counties, while the extended study area includes the following counties: Glenn, Butte, Colusa, Sutter, Yolo, Yuba, Sacramento, Napa, Solano, San Francisco, Contra Costa, San Joaquin, Alameda, Santa Clara, Stanislaus, Santa Cruz, San Benito, Merced, Madera, Fresno, Tulare, King, Kern, Santa Barbara, Ventura, Los Angeles, San Bernardino, Orange, Riverside, San Diego, and Imperial. Each of these counties has a general plan that includes general policies to protect water quality, water supply, water resources, and watersheds. No specific local requirements are pertinent to this analysis.

Water quality protection measures are included in the *Shasta County General Plan*. The county's goal is to protect all aspects of water quality in the county. The county defines erosion and downstream sedimentation as geologic hazards that must be prevented as part of grading and site development. The Shasta County Grading Ordinance sets requirements for grading and erosion control, including prevention of sedimentation or damage to off-site property. Grading permits require a vested map and the following information:

- A detailed grading plan
- Geological studies, if the project is located within an area that is prone to mass-movement, or has highly erodible soils or other known geologic hazards
- Detailed drainage or flood control information as required by the Department of Public Works
- A final development plan, if the project is located in a zone or district that requires a final development plan
- A noise analysis, if the project is located in the vicinity of a high-noise-generating use

The water quality protection goal included in the Open Space and Conservation Element of the Tehama County General Plan (Tehama County 2009) is to ensure that water supplies are of sufficient quality and quality, now and into the future, to serve the needs of Tehama County (Goal OS-1). Policies in support of this goal include sound watershed management, protection of surface water quality and streamflows, and protection of groundwater quality through the minimization of erosion and prevention of intrusion of wastes into water supplies.

7.3 Environmental Consequences and Mitigation Measures

7.3.1 Methods and Assumptions

A combination of water quality monitoring data and computer modeling was used to aid in the evaluation of potential impacts of the alternatives on water quality. Anticipated construction practices and materials, location, and duration of construction were also evaluated.

To evaluate potential Delta water quality impacts, the analysis relied on quantitative modeling tools to simulate conditions that would be expected to occur under the SLWRI alternatives compared to the bases of comparison (i.e., existing conditions without project and future conditions without project). The analysis of potential impacts on water quality in the Delta includes an analysis of potential impacts on water quality for all in-Delta water users. Delta parameters used in the evaluation include simulated changes in X2 location, Delta outflow, export-to-inflow ratio, salinity, and chloride ion concentrations.

The water quality impact assessment focuses on EC, measured in millimhos per centimeter (mmhos/cm), and chloride ion concentration in mg/L, as indicators of Delta water quality because they are the primary water quality constituents most likely to be affected by changes in Delta outflow and pumping operations. EC also is the parameter for which considerable monitoring data are available, and which has been used to calibrate the modeling tools used to simulate Delta water quality conditions.

A suite of modeling tools was used to evaluate the potential impacts of existing conditions, and the No-Action and other SLWRI alternatives, on the Delta water quality of the project and to quantify potential benefits. The SLWRI 2012 Version CalSim-II model, which was developed in 2012 for SLWRI, was used to simulate CVP and SWP operations, determining the surface water flows, storages, and deliveries associated with each alternative. CalSim-II is a specific application of the Water Resources Integrated Modeling System (WRIMS) to simulate CVP and SWP water operations. A detailed description of CalSim-II is included in Chapter 2 of the Modeling Appendix. Delta Simulation Model 2 (DSM2) was used to simulate the hydrodynamics of the Delta, providing the data used in discussion of the water-quality-related impacts of each alternative. (A detailed description of DSM2 and the assumptions used in the SLWRI analysis are included in Chapter 7 of the Modeling Appendix.) Summaries of the analysis and modeling results are provided below. (More detailed results of the CalSim-II output can be found in Attachment 1 of the Modeling Appendix.) Attachment 17 of the Modeling Appendix contains more detailed DSM2 output.

To understand the effects of the alternatives under both existing and future conditions, each alternative was modeled using two different assumptions about level of development (i.e., 2005 and 2030) and compared to the appropriate baseline modeling results to determine the character and extent of impacts.

CalSim-II

CalSim-II is the application of the WRIMS software to the CVP/SWP. This application was jointly developed by Reclamation and DWR for planning studies relating to CVP/SWP operations. The primary purpose of CalSim-II is to evaluate the water supply reliability of the CVP and SWP at current or future levels of development (e.g., 2005, 2030), with and without various assumed future facilities, and with different modes of facility operations. Geographically, the model covers the drainage basin of the Delta, and CVP/SWP exports to the Bay Area, San Joaquin Valley, Central Coast, and Southern California.

CalSim-II typically simulates system operations for an 82-year period using a monthly time step. The model assumes that facilities, land use, water supply contracts, and regulatory requirements are constant over this period, representing a fixed level of development (e.g., 2005, 2030). The historical flow record of October 1921 to September 2003, adjusted for the influences of land use changes and upstream flow regulation, is used to represent the possible range of water supply conditions. Major Central Valley rivers, reservoirs, and CVP/SWP facilities are represented by a network of arcs and nodes. CalSim-II uses a mass balance approach to route water through this network. Simulated flows are mean flows for the month; reservoir storage volumes correspond to end-of-month storage.

CalSim-II models a complex and extensive set of regulatory standards and operations criteria. (Descriptions of both are contained in Chapter 2 of the Modeling Appendix.) The hydrologic analysis for this EIS used SLWRI 2012 Version CalSim-II model, which is the best available hydrological modeling tool, to approximate the changes in storage, flow, salinity, and reservoir system reoperation associated with the SLWRI alternatives. Although CalSim-II is the best available tool for simulating system-wide operations, the model also contains simplifying assumptions in its representation of the real system.

A general external review of the methodology, software, and applications of CalSim-II was conducted in 2003 (Close et al. 2003). An external review of the San Joaquin River Valley CalSim-II model was also conducted (Ford et al. 2006). Several limitations of the CalSim-II model were identified in these external reviews. The main limitations of the CalSim-II model are as follows:

- Model uses a monthly time step
- Accuracy of the inflow hydrology is uncertain:
  - Model lacks a fully explicit groundwater representation

Reclamation, DWR, and the external reviewers have identified the need for a comprehensive error and uncertainty analysis for various aspects of the CalSim-II model. DWR has issued a CalSim-II Model Sensitivity Analysis Study (DWR 2005), and Reclamation is currently embarking on a similar sensitivity and uncertainty analysis for the San Joaquin River basin. This information will improve understanding of the model results.

Despite these limitations, the monthly CalSim-II model results remain useful for comparative purposes. It is important to differentiate between “absolute” or “predictive” modeling applications and “comparative” applications. In “absolute” applications, the model is run once to predict a future outcome and errors or assumptions in formulation, system representation, data, operational criteria, etc., all contribute to total error or uncertainty in model results. In “comparative” applications, the model is run twice, once to represent a base condition (No-Action Alternative) and a second time with a specific change (project) to assess the change in the outcome because of the input change. In this mode (the mode used for this EIS), the difference between the two simulations is of principal importance. Potential errors or uncertainties that exist in the "no-project" simulation are also present in the "project" simulation such that their impacts are reduced when assessing the change in outcomes. The SLWRI analysis is a comparative analysis.

DSM2

DSM2 is a branched 1-dimensional model for simulation of hydrodynamics, water quality, and particle tracking in a network of riverine or estuarine channels (DWR 2002). The hydrodynamic module can simulate channel stage, flow, and water velocity. The water quality module can simulate the movement of both conservative and nonconservative constituents. The model is used by DWR to perform operational and planning studies of the Delta.

Impact analyses for planning studies of the Delta are typically performed for an 82-year period (1922 to 2003). In model simulations, EC is typically used as a surrogate for salinity. Results from CalSim-II are used to define Delta boundary inflows. CalSim-II-derived boundary inflows include the Sacramento River flow at Hood, San Joaquin River flow at Vernalis, inflow from the Yolo Bypass, and inflow from the eastside streams. In addition, Net Delta Outflow from CalSim-II is used to calculate the salinity boundary at Martinez.

Details of the model, including source codes and model performance, are available from the DWR Bay-Delta Office, Modeling Support Branch Web site (http://modeling.water.ca.gov/delta/models/dsm2/index.html). Documentation on model development is discussed in annual reports on Methodology for Flow and Salinity Estimates in the Sacramento-San Joaquin Delta and Suisun Marsh submitted to the State Water Board by the DWR Delta Modeling Section.

Sediment

The potential impacts from sediment in terms of erosion and geomorphology are analyzed in Chapter 4, "Geology, Geomorphology, Minerals, and Soils."

The Watershed Erosion Prediction Project (WEPP) developed for the USFS is a model that is physically-based and applies fundamentals of erosion mechanics including hydrology, hydraulics and plant science. WEPP was developed by several land grant universities and federal resource agencies to replace the Modified Universal Soil Loss Equation and the earlier Universal Soil Loss Equation. Completed work has been documented in several hundred graduate degree theses and dissertations, government technical reports and peer-review professional journals. Climate, topography, soil and vegetation management are the four input values in WEPP. Possible outputs include soil detachment and deposition for roads and hillslopes under a variety of vegetation management scenarios.

First-iteration WEPP simulations were completed to support the development of feasible mitigation measures related to erosion and water quality. Road and Disturbed WEPP simulate erosion under several scenarios for roads and hillslopes. These models predicted sediment transport and delivery for disturbed ground related to conceptual mitigation measures (e.g., road sediment reduction, fuels reduction) that would be implemented within the primary study area. Alternatives for mitigating erosion were developed using a simplified sediment budget approach to demonstrate the feasibility and relative value of various types of mitigation activities described in the "Preliminary Environmental Commitments and Mitigation Plan Appendix."

Temperature

The analysis presented in Chapter 6, "Hydrology, Hydraulics, and Water Management," assumed that the SLWRI alternatives would not alter existing operational rules or protocols and that there would be no formal changes to CVP or SWP operating criteria. Each action alternative would include storing some additional flows behind Shasta Dam during periods when the flows would have otherwise been released downstream. The resulting increase in storage would be used both to create an expanded cold-water pool (CWP), thus benefiting fisheries, and for subsequent release downstream when opportunities would exist to put the water to beneficial use.

HEC-5Q temperature modeling was used to simulate flow and temperature for the Sacramento River system above Red Bluff. This model was updated to better represent the upper Sacramento River system with an emphasis on operation of the Shasta TCD. CalSim-II results were used as flow inputs to the HEC-5Q model. Temperature results are presented in Chapter 11, "Fisheries and Aquatic Resources." The water quality impacts analysis for temperature based on those results is summarized below.

Metals

Water quality data available for Shasta Lake and its tributaries were used to assess the impacts related to the discharge of metals into Shasta Lake. Available monitoring data for the Sacramento River were used to assess the impacts of metals in Keswick Reservoir and the Sacramento River downstream.

7.3.2 Criteria for Determining Significance of Effects

An environmental document prepared to comply with NEPA must consider the context and intensity of the environmental effects that would be caused by, or result from, the proposed action. Under NEPA, the significance of an effect is used solely to determine whether an EIS must be prepared. An environmental document prepared to comply with CEQA must identify the potentially significant environmental effects of a proposed project. A "[s]ignificant effect on the environment" means a substantial, or potentially substantial, adverse change in any of the physical conditions within the area affected by the project" (State CEQA Guidelines, Section 15382). CEQA also requires that the environmental document propose feasible measures to avoid or substantially reduce significant environmental effects (State CEQA Guidelines, Section 15126.4(a)).

Overall Impact Indicators for Water Quality

The significance criteria described below were developed based on guidance provided by the State CEQA Guidelines for use in assessing potential impacts on water quality; they also consider the context and intensity of the environmental effects as required under NEPA. These significance criteria were applied to the qualitative assessment and quantitative modeling results and used to determine impact significance. The analysis of water quality impacts and benefits focuses on temperature, metals, and sediment, because they are important water quality constituents in the both the primary and extended study areas.

The impact significance criteria for Delta water quality variables that have regulatory objectives or numerical standards, such as those contained in the 2006 WQCP, are developed from the general considerations listed below.

Impacts of an alternative on water quality would be significant if project implementation would do any of the following:

- Violate existing water quality standards or otherwise substantially degrade water quality
- Result in substantial water quality changes that would adversely affect beneficial uses
- Result in substantive undesirable impacts on public health or environmental receptors

Significance statements are relative to both existing conditions (2005) and future conditions (2030) unless stated otherwise.

Impact Indicators for Delta Salinity

If changes in salinity within the Delta during months of increased pumping would result in an increase in salinity, relative to the basis of comparison, of sufficient frequency and magnitude over the long term to adversely affect designated beneficial uses, to increase the frequency that existing regulatory standards are exceeded, or to substantially degrade water quality at the locations below, then the impact would be considered significant:

- Sacramento River at Collinsville
- San Joaquin River at Jersey Point
- Sacramento River at Emmaton
- Old River at Rock Slough

- Delta-Mendota Canal at Jones Pumping Plant
- West Canal at mouth of the Clifton Court Forebay
- San Joaquin River at Vernalis
- Old River near Tracy Road Bridge
- Old River at Middle River
- San Joaquin River at Brandt Bridge

Figure 7-3 shows the major Delta islands, waterways, water quality control stations, and M&I intakes within the Delta.

Salinity Salinity-related water quality impacts associated with the operational component of the SLWRI alternatives were assessed at several locations in the Delta. EC was used as a surrogate for salinity. Using the assumptions discussed above, and detailed in Chapter 7 of the Modeling Appendix, the DSM2 model calculated changes in monthly mean EC values for the alternatives, relative to the bases of comparison. Monthly EC results were derived for an 82-year simulation period, extending from 1922 through 2003.

DSM2 model output was used to evaluate potential changes in salinity under the SWLRI alternatives, relative to the bases of comparison: changes equal to or greater than 5 percent in long-term monthly average EC values and average monthly EC values by water year type, and compliance with water quality standards, including the number of occurrences during which an EC compliance standard was met or exceeded.

Node ID	Description
1	Sacramento River at Rio Vista
2	Sacramento River at Emmaton
3	Sacramento River at Collinsville
4	Sacramento River at Chipps Island
5	Sacramento River at Port Chicago (Roe Island)
6	Old River near Middle River
7	Old River at Tracy Road Bridge
8	Delta Mendota Canal at Tracy Pumping Plant
9	West Canal at mouth of Clifton Court Forebay Intake
10	Old River at CCWD Los Vaqueros Intake
11	CCWD Proposed Alternative Intake
12	Middle River east of Victoria Island
13	Woodward Canal
14	Old River at Rock Slough
15	Contra Costa Canal at Pumping Plant #1
16	San Joaquin River near Vernalis
17	San Joaquin River at Brandt Bridge
18	San Joaquin River downstream of Calaveras River
19	Stockton Proposed Intake
20	San Joaquin River at Prisoners Point
21	San Joaquin River at San Andreas Landing
22	San Joaquin River at Jersey Point
23	San Joaquin River at Antioch Ship Channel
24	Mokelumne River at Terminous
25	Barker Slough at North Bay Aqueduct Intake
26	Head of Old River Barrier
27	Middle River Barrier
28	Grant Line Canal Barrier
29	Old River Barrier at Tracy Road Bridge

Figure 7-3. Major Delta Islands, Waterways, Water Quality Control Stations, and Municipal and Industrial Intakes

Changes in salinity were evaluated in the Delta during months of increased pumping under the alternatives, relative to the bases of comparison. Potential significant impacts could occur if salinity increases were of sufficient frequency and magnitude over the long term to adversely affect designated beneficial uses, to exceed existing regulatory standards, or to substantially degrade water quality.

Delta water quality is directly controlled by existing Delta water quality objectives (State Water Board 1995) for M&I, agricultural, and fish and wildlife uses that are incorporated in State Water Board RD-1641 (State Water Board 2000). The 2006 WQCP objectives vary with month and water year type. Also, the 2006 WQCP objectives may only apply for some months and at some locations.

Applicable EC objectives were evaluated for the agricultural diversion season of April through August at Emmaton and Jersey Point, and during the entire year at each of the CVP/SWP export locations and three south Delta locations. Increases in EC values that result in exceedence of the objective at specified locations in the Delta were considered to be significant water quality impacts. Monthly changes in EC values are also considered to be significant if they exceeded 10 percent of the applicable objective.

Impact Indicators for X2 Position

If a change in mean monthly position of X2, relative to the bases of comparison, would be of sufficient frequency and magnitude to adversely affect water quality, then it will be considered a significant impact.

The X2 parameter represents the geographical location of the 2 parts per thousand near-bottom salinity isohaline in the Delta, which is measured in distance upstream from the Golden Gate Bridge in Suisun Bay (Jassby et al. 1995). The location of the estuarine salinity gradient is regulated during the months of February through June by the location of the X2 objective in the 2006 WQCP. During this time period, the X2 location must remain downstream from the confluence of the Sacramento and San Joaquin rivers at Collinsville for the entire 5-month period. The X2 objective also specifies the number of days each month that that location of X2 must be downstream from Chipps Island or downstream from Roe Island (also referred to as the Port Chicago EC monitoring station).

Estuarine EC objectives (i.e., X2) specified in the 2006 WQCP are applicable at Chipps Island during February through June for most years. The maximum EC objective at Chipps Island is 2.640 mmhos/cm (corresponding to a 2 parts per thousand salinity at Chipps Island) and must be satisfied for a specified number of days each month, depending on the previous month's Eight River Index (a measure of runoff in the Sacramento and San Joaquin valleys).

7.3.3 Topics Eliminated from Further Consideration

The action alternatives include measures to remove or abandon on-site wastewater treatment facilities (e.g., septic tanks and/or drain fields) in conjunction with relocation activities. Several wastewater treatment packages will be developed to ensure that management of effluent from lakeshore developments is consistent with requirements of Federal, State, and local agencies. Only minor project-related effects on nutrients are expected to occur in either the primary study area or the extended study area; therefore, potential effects on the study areas related to nutrients are not discussed further in this EIS.

7.3.4 Direct and Indirect Effects

No-Action Alternative

Under the No-Action Alternative, the Federal Government would take reasonably foreseeable actions, as defined above, but would take no additional action toward implementing a specific plan to help increase anadromous fish survival in the upper Sacramento River, nor help address the growing water reliability issues in California. Shasta Dam would not be modified, and the CVP would continue operating similar to the existing condition. Changes in regulatory conditions and water supply demands would result in differences in flows on the Sacramento River and at the Delta between existing and future conditions.

Shasta Lake and Vicinity

Impact WQ-1 (No-Action): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no construction activities would occur. Therefore, there would be no short-term increases in turbidity and suspended sediment in Shasta Lake and tributary streams that would cause violations of water quality standards or adversely affect beneficial uses. Ongoing impacts of sediment on beneficial uses would remain consistent with those that occur periodically under baseline conditions. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-2 (No-Action): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no new facilities associated with raising Shasta Dam would be constructed; therefore, no short-term changes in the temperature regime of waters within Shasta Lake or its tributaries would occur. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-3 (No-Action): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action

Alternative, no new facilities associated with raising Shasta Dam would be constructed in the vicinity of Shasta Lake; therefore, no construction-related metal effects would occur in Shasta Lake or tributary streams that would cause violations of water quality standards or adversely affect beneficial uses. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-4 (No-Action): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Under the No-Action Alternative, the operation of Shasta Dam would continue to influence the amount and duration of exposed shoreline below the maximum elevation of the reservoir, and sediment would continue to periodically be transported into Shasta Lake from tributaries and subsequently remobilized to other locations within the water column. Therefore, sediment and turbidity would remain consistent with baseline conditions. No impact would occur. Mitigation is not required for the No-Action Alternative.

As described in Chapter 4, "Geology, Geomorphology, Minerals, and Soils," the shoreline would continue to erode, and impacts to beneficial uses, namely recreation and to some extent, the warm-water fishery along the shoreline of Shasta Lake, would be ongoing. In addition to active areas of shoreline erosion, sediment would continue to periodically be transported into Shasta Lake from tributaries as a result of other ongoing actions within the project area. Wave action and nearshore currents would continue to remobilize sediment that is typically visible as turbid plumes of water along portions of the shoreline. Sediment and turbidity would remain consistent with baseline conditions. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-5 (No-Action): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Under the No-Action Alternative, Shasta Dam would continue to be operated consistent with current regulatory requirements with respect to storage and release of water to the upper Sacramento River. Therefore, there would be no change in the temperature regime of waters within Shasta Lake or its tributaries. Periodic changes in water temperature on a seasonal or interannual basis would be consistent with those that occur under baseline conditions. No impact would occur. Mitigation is not required for the No-Action Alternative.

Reclamation operates the Shasta Dam TCD to manage water temperatures in the upper Sacramento River to (1) improve habitat for the endangered winter-run Chinook salmon and other threatened runs; (2) withdraw warmer surface water in the winter and spring to preserve cold-water storage for release during the temperature operation season; and (3) enable power generation to continue while controlling release temperatures, thereby eliminating the need to bypass the power plant penstocks via the low-level river outlets. Generally, to accomplish these temperature objectives during the temperature operation season, the TCD functions to select water temperatures in the 47°F to 52°F range. Therefore, a good index of the temperature-related benefits of the alternative is the volume of the CWP with a water temperature lower than 52°F at the end of April.

Under the No-Action Alternative, Shasta Dam would continue to be operated consistent with current regulatory requirements with respect to storage and release of water to the upper Sacramento River. As described in Chapter 6, “Hydrology, Hydraulics, and Water Management,” the temperature profile within Shasta Lake would not be changed under the No-Action Alternative. Therefore, there would be no change in the temperature regime of waters within Shasta Lake or its tributaries. Periodic changes in water temperature on a seasonal or interannual basis would be consistent with those that occur under baseline conditions. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-6 (No-Action): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Under the No-Action Alternative, metal concentrations in the Main Body and the Squaw Creek Arm of Shasta Lake would continue to be within the range of variability that currently exists with respect to the ongoing discharge and potential storage of heavy metals associated with historic mining and smelting operations. Concentrations of metals, specifically copper and zinc that may persist within the water column of Shasta Lake would continue to remain in suspension at locations and levels similar to baseline conditions. Ongoing remediation of historic mining properties at locations in the Dry Creek, Little Backbone, Squaw Creek, and Horse Creek watersheds are anticipated to reduce the amount of acid mine drainage into Shasta Lake over time, thereby reducing metal concentrations in the water column. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (No-Action): Temporary Construction-Related Sediment Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no new facilities would be constructed at Shasta Lake; thus there would be no construction-related sediment effects on the upper Sacramento River that would cause violations of water quality standards or adversely affect beneficial uses. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-8 (No-Action): Temporary Construction-Related Temperature Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no new facilities associated with raising Shasta Dam would be constructed; therefore, no short-term changes in the temperature regime of waters within the upper Sacramento River would occur. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-9 (No-Action): Temporary Construction-Related Metal Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no new facilities associated with raising Shasta Dam would be constructed; therefore, no construction-related metal effects would occur in the upper Sacramento River that would cause violations of water quality standards or adversely affect beneficial uses. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-10 (No-Action): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Under the No-Action Alternative, the operation of Shasta Dam would continue to influence the amount and duration of sediment transported from Shasta Lake into the upper Sacramento River. Analysis of flow modeling results indicates little change in flows on the upper Sacramento River between existing conditions and the future No-Action Alternative conditions. Therefore, sediment and turbidity would remain similar to baseline conditions. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact WQ-11 (No-Action): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Under the No-Action Alternative, ongoing operations to meet existing regulatory requirements would be continued. The ability to comply with existing temperature requirements would not be improved. Analysis of temperature modeling results indicates little change in compliance with temperature objectives on the upper Sacramento River between existing conditions and the future No-Action Alternative conditions. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact WQ-12 (No-Action): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Under the No-Action Alternative, ongoing remediation of historic mining properties at locations in the Dry Creek, Little Backbone, Squaw Creek, and Horse Creek watersheds are anticipated to reduce the amount of acid mine drainage into Shasta Lake over time, thereby reducing metal concentrations in the water column. Therefore, no long-term metals effects would occur that would cause violations of water quality standards or adversely affect beneficial uses in the upper Sacramento River. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact WQ-13 (No-Action): Temporary Construction-Related Sediment Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no construction activities would occur. Therefore, there would be no short-term increases in turbidity and suspended sediment in the extended study area that would cause violations of water quality standards or adversely affect beneficial uses. Ongoing impacts of sediment on beneficial uses would remain consistent with those that occur periodically under baseline conditions. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-14 (No-Action): Temporary Construction-Related Temperature Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no new facilities associated with raising Shasta Dam would be constructed; therefore, no short-term changes in the temperature regime of waters within the extended study area would occur. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-15 (No-Action): Temporary Construction-Related Metal Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under the No-Action Alternative, no new facilities associated with raising Shasta Dam would be constructed; therefore, no construction-related metal effects would occur in the extended study area that would cause violations of water quality standards or adversely affect beneficial uses. No impact would occur. Mitigation is not required for the No-Action Alternative.

Impact WQ-16 (No-Action): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Modeling results have indicated that flows in the Sacramento River would change little between existing conditions and the future No-Action Alternative conditions. Therefore, under the No-Action Alternative, sediment and turbidity would remain similar to baseline conditions. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact WQ-17 (No-Action): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Analysis of temperature modeling shows little to no change in compliance with temperature objectives on the upper Sacramento River. This suggests that there would be little or no changes in temperature in the extended study area as a result of the No-Action Alternative. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact WQ-18 (No-Action): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Under the No-Action Alternative, ongoing remediation of historic mining properties at locations in the Dry Creek, Little Backbone, Squaw Creek, and Horse Creek watersheds are anticipated to reduce the amount of acid mine drainage into Shasta Lake over time, thereby reducing metal concentrations in the water column. Therefore, no long-term metals effects would occur that would cause violations of water quality standards or adversely affect beneficial uses in the extended study area. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Salinity The No-Action Alternative would differ from the existing conditions primarily through changes in regulatory conditions and water supply demands. Potential impacts, which are evaluated below, include changes in the following:

- Delta salinity on the Sacramento River at Collinsville
- Delta salinity on the San Joaquin River at Jersey Point
- Delta salinity on the Sacramento River at Emmaton
- Delta salinity on the Old River at Rock Slough
- Delta water quality on the Delta-Mendota Canal at Jones Pumping Plant
- Delta water quality on the West Canal at the mouth of the Clifton Court Forebay
- Delta salinity on the San Joaquin River at Vernalis
- Delta salinity on the San Joaquin River at Brandt Bridge
- Delta salinity on the Old River near the Middle River
- Delta salinity on the Old River at Tracy Road Bridge
- X2 position

Impact WQ-19a (No-Action): Delta Salinity on the Sacramento River at Collinsville The No-Action Alternative would result in both increases and decreases in salinity in comparison with baseline conditions; however, none of the increases would be sufficient to result in any violations of the salinity standards for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 6 percent. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

The water quality requirement on the Sacramento River at Collinsville is specified in RD-1641, and is defined for all year types,[3] from October through April. The RD-1641 objectives for the Sacramento River at Collinsville are defined in Table 7-4.

Table 7-4. RD-1641 Water Quality Objectives for the Sacramento River at Collinsville

Months	Year-Type	Value (mmhos/cm)
October	All	19.0
November–December	All	15.5
January	All	12.5
February–March	All	8.0
April–May	All	11.0

Source: State Water Board 2000

Notes:
Year types defined by Sacramento Valley Index.
The requirement is the maximum monthly average of daily high tide EC values or demonstration that equivalent or better protection will be provided at the location.

Key:
EC = electrical conductivity
mmhos/cm = millimhos per centimeter (unit of EC)
RD-1641 = Revised Water Right Decision 1641

As shown in Table 7-5, the No-Action Alternative would result in both increases and decreases in salinity as compared with baseline conditions; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 6 percent. Table 7-6 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The No-Action Alternative would not result in any violations of the salinity standards for the Sacramento River at Collinsville. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

[3] Water year types are defined according to the Sacramento Valley Index Water Year Hydrologic Classification unless specified otherwise.

Source: Version 8.0.6, DSM2 Existing and Future simulations (Node RSAC081)

Note:

Simulation period: 1922–2003. Change as measured from Existing Condition. Dry and critical years as defined by the Sacramento Valley Index.

Key:

% = percent

Impact WQ-19b (No-Action): Delta Salinity on the San Joaquin River at Jersey Point The No-Action Alternative would result in both increases and decreases in salinity in comparison with baseline conditions; however, none of the increases would be sufficient to change compliance for the San Joaquin River at Jersey Point on a long-term basis. On a percentage basis, all increases in salinity would be less than 4 percent. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

The water quality requirement on the San Joaquin River at Jersey Point is specified in RD-1641 as two components. The first component of the requirement begins on April 1, and extends through a year-type-dependent date. The second component of the Jersey Point requirement begins at the end of the first component, and ends on August 15. The numerical requirement of the second component is dependent on the year type. Objectives for the San Joaquin River at Jersey Point are defined in Table 7-7.

Table 7-7. RD-1641 Water Quality Objectives for the San Joaquin River at Jersey Point

Year Type	0.45 EC April 1 to the Date Shown	EC from Date Shown to August 15 (mmhos/cm)
Wet	August 15	0.45
Above Normal	August 15	0.45
Below Normal	June 20	0.74
Dry	June 15	1.35
Critical	April 1	2.20

Source: State Water Board 2000

Note:
Year types defined by Sacramento Valley Index. Although requirement in RD-1641 is the maximum 14-day running average of mean daily EC, modeling uses a monthly average.

Key:
EC = electrical conductivity
mmhos/cm = millimhos per centimeter
RD-1641 = Revised Water Right Decision 1641

Table 7-8 shows simulated monthly average salinity and percent change for the San Joaquin River at Jersey Point. On an average monthly basis EC requirements would be satisfied in all months in an average year under the No-Action Alternative. Furthermore, all increases in EC during April through August would be less than 4 percent. Table 7-9 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Jersey Point in the period of simulation. The No-Action Alternative would result in an increase in the frequency of violations under existing conditions. Violations occur during June, July, and August and are greatest in August, when violations would be approximately 30 percent for all years and 38 percent during dry and critical years. The long-term and dry-year average EC values in April and May are found to be below the standards, which indicate the violation is marginal and does not show any significant changes in water quality. In June, the long-term average dry-year values would increase from 0.4 mmhos/cm to 0.5 mmhos/cm. In June of critical years and July of both dry and critical years, the long-term average would remain above the standards and would not change from the existing condition. In August and September of dry years, EC would decrease on a long-term average, and remain above the standards and unchanged in critical years.

Overall, the frequency of exceedence of salinity standards for the San Joaquin River at Jersey Point under the No-Action Alternative would be similar to those under existing and future conditions. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Table 7-8. Simulated Monthly Average Salinity and Percent Change for the San Joaquin River at Jersey Point Under the Existing Condition and No-Action Alternative

Month	Average All Years		Dry and Critical Years	
	Existing Condition (mmhos/cm)	No-Action Alternative Change (mmhos/cm (%))	Existing Condition (mmhos/cm)	No-Action Alternative Change (mmhos/cm (%))

Impact WQ-19c (No-Action): Delta Salinity on the Sacramento River at Emmaton The No-Action Alternative would result in both increases and decreases in salinity in comparison to baseline conditions; however, changes in salinity would not affect compliance with the standard as the Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Similar to the water quality requirement on the San Joaquin River at Jersey Point, the water quality requirement on the Sacramento River at Emmaton is specified in RD-1641 as two components. The first component of the requirement begins on April 1, and extends through a year-type-dependent date. The second component of the Emmaton requirement begins at the end of the first component, and ends on August 15. The numerical requirement of the second component is dependent on the year type. Objectives for the Sacramento River at Emmaton are defined in Table 7-10.

Table 7-10. RD-1641 Water Quality Objective for the Sacramento River at Emmaton

Year Type	0.45 EC April 1 to the Date Shown	EC from Date Shown to August 15 (mmhos/cm)
Wet	August 15	0.45
Above Normal	July 1	0.63
Below Normal	June 20	1.14
Dry	June 15	1.67
Critical	April 1	2.78

Source: State Water Board 2000

Note:
Year types defined by Sacramento Valley Index. Although requirement in RD-1641 is the maximum 14-day running average of mean daily EC, modeling uses a monthly average.

Key:
EC = electrical conductivity
mmhos/cm = millimhos per centimeter
RD-1641 = Revised Water Right Decision 1641

Although Table 7-11 shows the EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, no change in the ability to meet EC requirements would occur in all months in an average year under the No-Action Alternative. Maximum change in monthly EC would not be greater than 6.8 percent. Table 7-12 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. The No-Action Alternative would result in an increase in the frequency of violations under during April, May, and July of dry and critical years, and in July and August on average for all year types. The modeled potential violations shown in Table 7-12 are most likely caused by a mismatch between the CalSim-II operations model and the DSM2 Delta hydrodynamics and mixing model, and are not caused by water operations in the Delta. Modeled standards violations caused by mismatches between DSM2 and CalSim-II occur because CalSim-II's monthly time step is not well-suited to handling daily or 14-day standards, or running average standards that span more than 1 month, such as those evaluated here. Furthermore, CalSim-II uses empirical approximations for estimating Delta salinities that may not match the physically-based salinity calculations done in DSM2.The apparent violations in the model results are referred to as "potential violations" because they occur in the model but would not occur in actual operations. The Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative.

Table 7-11. Simulated Monthly Average Salinity and Percent Change for the Sacramento River at Emmaton Under the Existing Condition and No-Action Alternative

Month	Average All Years		Dry and Critical Years	
	Existing Condition (mmhos/cm)	No-Action Alternative Change (mmhos/cm (%))	Existing Condition (mmhos/cm)	No-Action Alternative Change (mmhos/cm (%))

Key:
% = percent

Overall, the compliance of standards for the Sacramento River at Emmaton would be similar to the baseline levels under the No-Action Alternative. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19d (No-Action): Delta Salinity on the Old River at Rock Slough
Under the No-Action Alternative, changes in chloride concentrations would not affect compliance with the standard as the Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Rock Slough is the location of the CCWD diversion for the Contra Costa Canal, but compliance with the salinity objectives is measured at Contra Costa Canal Pumping Plant No. 1. However, simulating water quality at Contra Costa Canal Pumping Plant No. 1 is difficult, and DSM2 does not explicitly simulate water quality at that location. Instead, a transfer function is applied to estimate the water quality at Contra Costa Canal Pumping Plant No. 1 based on the simulated water quality at Old River at Rock Slough from DSM2. The requirements, as defined in RD-1641, specify a minimum number of days during the calendar year that the maximum mean daily chloride concentration of

150 mg/L must be maintained. Objectives for the Contra Costa Canal Pumping Plant No. 1 are defined in Table 7-13.

Table 7-13. RD-1641 Water Quality Objective for Contra Costa Canal Pumping Plant No. 1

Year Type	Number of Days Each Calendar Year Chlorides Less Than or Equal to 150 mg/L
Wet	240
Above Normal	190
Below Normal	175
Dry	165
Critical	155

Source: State Water Board 2000

Note:
Year-types defined by Sacramento Valley Index.
Maximum mean daily 150 mg/L Cl- for at least the number of days shown.

Key:
RD-1641 = Revised Water Right Decision 1641
mg/L = milligram per liter

Table 7-14 shows simulated monthly average chloride concentrations and percent change for Contra Costa Canal Pumping Plant No. 1. On an average annual basis, the No-Action Alternative would not increase chloride concentrations by more than 10 percent. Maximum changes in chloride concentrations under the No-Action Alternative are less than 6.6 percent for dry and critical years.

Table 7-15 shows the average number of days in a year simulated chloride values exceeded the standard of 150 mg/L for Contra Costa Canal Pumping Plant No. 1. An increase in the number of potential daily violations of the chloride standard would occur under the No-Action Alternative as compared with the existing condition during the months of December through March, and July through September. As described for Impact WQ-19c (No-Action) for Table 7-12, the apparent violations shown in Table 7-15 are referred to as “potential violations” because they occur in the model but would not occur in actual operations. The Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative. Overall, the No-Action Alternative would not alter the compliance level for Contra Costa Canal Pumping Plant No. 1. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Table 7-14. Simulated Monthly Average Chlorides and Percent Change for Contra Costa Canal Pumping Plant No. 1 Under the Existing Condition and No-Action Alternative

Month	Average All Years		Dry and Critical Years

Impact WQ-19e (No-Action): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. Both requirements would continue to be met under the No-Action Alternative. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Table 7-16 shows both the chloride and EC thresholds that must be met at Jones Pumping Plant. Tables 7-17 and 7-18 show that the No-Action Alternative would not exceed chloride thresholds. Chloride concentrations decrease in the Delta-Mendota Canal at Jones Pumping Plant under the No-Action Alternative. Tables 7-19 and 7-20 show that EC would decrease under the No-Action Alternative and would not exceed the EC threshold. The No-Action Alternative would not change the baseline compliance levels under both existing and future conditions. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Percentage values reported in parenthesis are reported as zero if the change is less than one day.
Key:
% = percent

Impact WQ-19f (No-Action): Delta Water Quality on the West Canal at the Mouth of the Clifton Court Forebay The 250 mg/L chloride concentration standard at the West Canal would not be exceeded on an average annual or dry and critical year basis under the No-Action Alternative. The No-Action Alternative would result in both increases and decreases in EC in comparison to baseline conditions; however, changes in EC would not affect compliance with the standard as the Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Clifton Court Forebay is the source of water supply for the Banks Pumping Plant and SWP exports south of the Delta. Similar to the Delta-Mendota Canal at Jones Pumping Plant, the water quality requirement on the West Canal at the mouth of the Clifton Court Forebay has two components, a chloride requirement and an EC requirement. Table 7-21 shows both the chloride and EC concentration requirements.

Table 7-21. RD-1641 Water Quality Objective for the West Canal at the Mouth of the Clifton Court Forebay

Year Type	Month	Chloride Concentration (mg/L)	Electrical conductivity (mmhos/cm)
All	October–September	250	1.0

Source: State Water Board 2000

Note:
Year types defined by Sacramento Valley Index.

Key:
RD-1641 = Revised Water Right Decision 1641
mg/L = milligrams per liter
mmhos/cm = millimhos per centimeter

Table 7-22 shows that maximum chloride concentrations would be lower under the No-Action Alternative than the 250 mg/L threshold. Maximum increases under the No-Action Alternative would be less than 1.1 percent. As shown in Table 7-23, the maximum increase in EC values under the No-Action Alternative would be less than 1 percent, and would decrease in most months.

Table 7-24 shows the average number of days simulated chloride values exceeded the standards of 250 mg/L for the West Canal at the Clifton Court Forebay in a year. There would be no additional violations throughout the year for average annual or dry and critical years under the No-Action Alternative. The No-Action Alternative would not change the baseline compliance levels.

Table 7-24. Simulated Number of Days by Month of Exceedence of the Chloride Standard for the West Canal at the Clifton Court Forebay Under the Existing Condition and No-Action Alternative

As shown in Table 7-25, the No-Action Alternative would result in potential additional violations of the salinity standards in November and December, and would result in decreases in EC violations during January. As described under Impact WQ-19c (No-Action) for Table 7-12, the apparent violations shown in Table 7-25 are referred to as "potential violations" because they occur in the model but would not occur in actual operations. The Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative. Overall, the No-Action Alternative would not alter the compliance level for the West Canal at the Clifton Court Forebay. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Table 7-25. Simulated Number of Months of Exceedence of the Salinity Standard for the West Canal at the Clifton Court Forebay Under the Existing Condition and No-Action Alternative

Note:
Simulation period: 1922-2003. Change as measured from Existing Condition. Dry and critical years as defined by the Sacramento Valley Index.

Key:
% = percent

Impact WQ-19g (No-Action): Delta Salinity on the San Joaquin River at Vernalis Under the No-Action Alternative, on an average monthly basis, EC would meet requirements in all months, in both average years and in dry and critical years. The No-Action Alternative would exceed EC thresholds on the San Joaquin River at Vernalis in some months; however, changes in EC would not affect compliance with the standard as the Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

To protect water quality in the south Delta, RD-1641 includes a salinity objective at several locations on the San Joaquin River and on the Old River. The objective is the same for all four locations: the San Joaquin River at Airport Way Bridge in Vernalis, the San Joaquin River at Brandt Bridge, the Old River near the Middle River, and the Old River at Tracy Road Bridge. The water quality requirement is a maximum 30-day average of mean daily EC. Table 7-26 shows the south Delta water quality requirement.

Table 7-26. RD-1641 South Delta Water Quality Objective

Year Type	Months	EC Standard (mmhos/cm)
All	April–August	0.7
All	September–March	1.0

Source: State Water Board 2000

Note:
Year types defined by Sacramento Valley Index. Although requirement in RD-1641 is the maximum 30-day running average of mean daily EC, modeling uses a monthly average. San Joaquin River at Vernalis measured at the Airport Way Bridge.

Key:
RD-1641 = Revised Water Right Decision 1641
EC = electrical conductivity
mmhos/cm = millimhos per centimeter

Under the No-Action Alternative, on an average monthly basis, EC would meet requirements in most months in both average years and in dry and critical years. As shown in Tables 7-27 and 7-28, the No-Action Alternative would exceed EC thresholds on the San Joaquin River at Vernalis more frequently in July and August; however, EC would decrease under the No-Action Alternative in May and June. As described under Impact WQ-19c (No-Action) for Table 7-12, the apparent violations shown in Table 7-25 are referred to as “potential violations” because they occur in the model but would not occur in actual operations. The Delta is operated to meet water quality standards and would continue being operated to meet standards under the No-Action Alternative. Overall, the No-Action Alternative would not change the baseline compliance levels. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact WQ-19h (No-Action): Delta Salinity on the San Joaquin River at Brandt Bridge On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years under the No-Action Alternative. The No-Action Alternative would not change EC on the San Joaquin River at Brandt Bridge. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

As previously mentioned, RD-1641 contains a south Delta water quality requirement applicable at several locations, including on the San Joaquin River at Brandt Bridge. Table 7-26 details water quality requirement standards for salinity.

On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years, as shown in Table 7-29. Table 7-30 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Brandt Bridge in the period of simulation. The No-Action Alternative would decrease occurrence of EC values exceeding the standards in April, May, June, and August. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact WQ-19i (No-Action): Delta Salinity on the Old River near the Middle River Under the No-Action Alternative, on an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. The No-Action Alternative would decrease EC on the Old River near the Middle River. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

As previously mentioned, RD-1641 contains a south Delta water quality requirement applicable at several locations, including on the Old River near the Middle River. Table 7-26 details water quality requirement standards for salinity.

On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years, as shown in Table 7-31. Table 7-32 shows the number of months simulated EC values exceeded the standards for the Old River near the Middle River in the period of simulation. The No-Action Alternative would decrease occurrence of EC values exceeding the standards in April, May, June, and August. This impact would be less than significant. Mitigation is not required for the No-Action Alternative.

Impact WQ-20 (No-Action): X2 Position The No-Action Alternative would change average monthly X2 in some months by more than 0.1 kilometer (km). This impact would be potentially significant.

Table 7-35 shows the simulated monthly average X2 position for the No-Action Alternative compared to the existing condition. As previously described, the X2 parameter is measured in distance upstream from the Golden Gate Bridge in Suisun Bay, and is required to be maintained at not more than 75 km during the months of February through June. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month. As shown in Table 7-35, the No-Action Alternative would shift X2 upstream by up to 0.2 km in May and June on an average annual basis, and by as much as 0.4 km in May of dry and critical years. This impact would be potentially significant. Mitigation is not required for the No-Action Alternative.

Table 7-35. Simulated Monthly Average X2 Position Under the Existing Condition and No-Action Alternative

CP1 – 6.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

CP1 focuses on increasing water supply reliability and increasing anadromous fish survival. This plan primarily consists of raising Shasta Dam by 6.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 8.5 feet and enlarge the total storage capacity in the reservoir by 256,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded CWP. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 70,000 acre-feet and 35,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP1 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the CWP in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact WQ-1 (CP1): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses The construction-related activities described in Chapter 2, "Alternatives," would result in short-term changes in the amount of exposed area that would be subject to erosion. In addition to the clearing of vegetation in various areas to accommodate relocation activities, about 500 acres of vegetation in various arms of Shasta Lake would be cleared before inundation. Removal of vegetation would reduce the amount of effective ground cover (e.g., duff, large woody debris), thereby increasing the potential for short-term erosion and sedimentation along the shoreline. This impact would be potentially significant.

The relocation activities would result in exposing about 698 acres to some amount of soil disturbance. These effects are described in more detail in Chapter 4, "Geology, Geomorphology, Minerals, and Soils." The disturbed sites would have the potential to contribute sediments to nearby water bodies.

Although the environmental commitments, including BMPs described in Chapter 2, "Alternatives," are intended to reduce the potential effects of introducing sediment into Shasta Lake and its tributaries, CP1 would affect water quality by increasing the levels of turbidity and suspended sediment in the receiving waters at levels that could be inconsistent with the Basin Plan. These increased levels of turbidity and suspended sediment could affect the beneficial uses of Shasta Lake and/or its tributaries. Therefore, the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP1): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Because of the large water surface area of Shasta Lake, coupled with the isolated and discrete nature of the relocation activities on the tributaries, temporary construction-related effects are not expected to modify water temperature in a manner that would have a negative effect on beneficial uses or result in a water quality violation. Therefore, this impact would be less than significant.

Under CP1, construction activities associated with enlarging Shasta Dam as well as the relocation actions would result in sizeable areas that would be subject to surface disturbance, including jurisdictional waters within the influence zone associated with CP1. Efforts to document jurisdictional waters associated with relocation areas are described in Chapter 12 "Botanical Resources and Wetlands." This information has been updated since the DEIS was circulated for public review. If the SLWRI is authorized, Reclamation will work closely with its cooperating agencies to ensure compliance with the CWA (e.g., Section 401 and 404) consistent with the development of the least environmentally damaging preferred alternative (LEDPA).

Environmental commitments and BMPs for the various construction and relocation activities (e.g., bridge replacement, boat ramp construction, demolition of facilities) have been incorporated into CP1. These activities could include removal of riparian vegetation, thereby exposing water bodies to increased solar radiation for various time periods. As described in Chapter 2, “Alternatives,” and the “Preliminary Environmental Commitments and Mitigation Plan Appendix,” riparian revegetation would be implemented at all construction and relocation sites as applicable to ensure that shade is quickly reestablished after construction is completed.

As described in Chapter 2, “Alternatives,” although the TCD may not be operational for some period of time during construction, project sequencing would ensure that changes to water temperature in Shasta Lake and downstream in the upper Sacramento River, as well as associated limnological conditions in Shasta Lake, would be consistent with those that occur periodically under the No-Action Alternative typically associated with maintenance and outage periods.

Because of the large water surface area of Shasta Lake, coupled with the isolated and discrete nature of the relocation activities on the tributaries, temporary construction-related effects are not expected to modify water temperature in a manner that would have a negative effect on beneficial uses or result in a water quality violation. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP1): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Under CP1, no construction activities would occur that would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP1): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Under CP1, the exposure of an additional 1,227 acres of shoreline surrounding Shasta Lake would result in a potential for increased wave-related shoreline erosion (see Chapter 4, “Geology, Geomorphology, Minerals, and Soils”). As the reservoir is lowered during summer and fall, the exposed surface area would also be subject to surficial erosion processes that could mobilize and transport sediment to the newly expanded Shasta Lake. Although environmental commitments and BMPs are incorporated into the project description, the project would result in an incremental increase in the delivery of suspended sediment and turbidity to the receiving waters. The amount of sediment that could be delivered is not entirely quantifiable because of the size of the lake and the number of variables that influence sediment transport and delivery. Chapter 4, “Geology, Geomorphology, Minerals, and

Soils," does provide information on the estimated volume of sediment that may be introduced into Shasta Lake as a result of increases in shoreline erosion. Under CP1, it's estimated that about 421,000 cubic yards per year would be delivered to Shasta Lake as a result of shoreline erosion. This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP1): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries CP1 would store some additional flows behind Shasta Dam during periods when the flows would have otherwise been released downstream. The resulting increase in storage would then be used both to create an expanded CWP available for carryover storage, thus benefiting fisheries, and for subsequent release to support beneficial uses downstream. On average, CP1 would provide approximately a 5 percent increase in annual storage.

Table 7-36 shows the simulated monthly change in storage for CP1 as a percent increase above the existing condition.

Table 7-36. Simulated Average Increased End-of-Month Shasta Lake Storage – CP1

Month	Existing Conditions (TAF)	CP1 Change (TAF)	CP1 % Increase
October	2,592	148	5.7%

TAF = thousand acre-feet

Under CP1, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-36 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

As shown in Table 7-36, the increase in storage provided by CP1 fluctuates greatly throughout a year; storage is typically highest at the end of winter, in April and May, as the need for flood control reservation space in the reservoir is reduced. Storage is typically at its lowest in September, October, and November, after summer irrigation concludes and before winter refill begins. Additional runoff captured by the increased storage increment would typically remain in storage and available to support beneficial uses downstream. Conversely, if insufficient water in storage existed to meet downstream demands, the first increment to be reduced would be deliveries to water service contractors. As such, increased releases would typically be made on a schedule providing increased reliability of deliveries to water service contractors, typically in July through October of relatively dry years.

A key indicator of the water temperature benefits of CP1 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake before the water temperature operation season, about May through October. As previously described, Shasta Lake generally reaches its maximum storage during late April or early May. Also, the CWP volume in the lake accumulates during winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP1 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52°F for the existing condition and the change in CWP volume for CP1 is shown, by Sacramento Valley Index (SVI) year type, in Table 7-37.

In addition to illustrating the average change in available CWP, Table 7-37 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall, would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. Although an increase in the active storage and carryover storage of the CWP would occur, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-37. Simulated Average Volume of Water Less than 52°F in Shasta Lake at the End of April – CP1

SVI Year Type	Existing Conditions (TAF)	CP1 Change (TAF)	% Increase
Average of All Years	2,609	142	5%
Wet	2,916	194	7%
Above Normal	2,972	163	5%
Below Normal	2,699	129	5%
Dry	2,542	130	5%
Critical	1,601	49	3%

Impact WQ-6 (CP1): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries The increase in storage associated with CP1 would result in modifying the depth and thickness of the thermocline in Shasta Lake. The level of change would be correlated to a number of parameters, including carryover storage, climatic conditions, and the timing and duration of stratification (Bartholow et al. 2001). A study conducted by the CVRWQCB in 2002 and 2003 suggests that a direct correlation exists between dissolved copper concentrations in the upper levels of Shasta Lake near the dam and dissolved copper concentrations in the waters immediately downstream from the power plant (CVRWQCB 2003a). This study concluded that there appears to be a correlation between operation of the TCD and concentration of dissolved metals within the thermocline; an increase in available storage, however, would increase the opportunity to dilute metals concentrations below current levels.

Within the Squaw Creek Arm, two depositional features associated with historic copper mining and smelting operations are immediately adjacent to the shoreline of Shasta Lake in the general vicinity of the Bully Hill Mine. As mapped, these two sites appear to have about 7,300 cubic yards of material that could be subjected to shoreline and surficial erosional processes, with a high potential for delivery to Shasta Lake. This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (CP1): Temporary Construction-Related Sediment Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

As described in Impact WQ-1 (CP1), ground-disturbing activities associated with construction could cause soil erosion and sedimentation of local drainages and eventually the Sacramento River. Construction activities could also discharge waste petroleum products or other construction-related substances that could enter these waterways/facilities in runoff. The environmental protection measures and BMPs described in Chapter 2, "Alternatives," are intended to reduce the potential effects of introducing sediment into Shasta Lake and into downstream releases to the upper Sacramento River; however, CP1 would affect water quality by increasing the levels of turbidity and suspended sediment in the receiving waters at levels that could be inconsistent with the Basin Plan. These increased levels of turbidity and suspended sediment could affect the beneficial uses of the upper Sacramento River. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP1): Temporary Construction-Related Temperature Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

As described for Impact WQ-2 (CP1), changes to water temperature and associated limnological conditions in Shasta Lake would be consistent with those that occur periodically under the No-Action Alternative associated with maintenance and outage periods. Therefore, water temperatures in the upper Sacramento River, which are related to releases from Shasta Lake, would not be expected to be modified during construction in a manner that would negatively affect beneficial uses or result in a water quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP1): Temporary Construction-Related Metal Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

As described in Impact WQ-3 (CP1), there would be no construction activities that would disturb locations known to contain elevated metal concentrations in either sediments or the water column of Shasta Lake. Because water quality in the upper Sacramento River is related to the quality of releases from Shasta Lake, metals concentrations would not be expected to be modified during construction in a manner that would negatively affect beneficial uses or result in a water quality violation. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP1): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment, because modeling results have indicated that CP1 would cause little change in average mean monthly flow, and could cause a decrease in peak flows that are associated with increased sediment transport. This impact would be less than significant.

Long-term effects on water quality could be caused by changes in the size and timing of releases from the reservoir associated with CP1. The analysis used flow data from hydrologic modeling as an indicator of effects on sediment and metals.

For CP1, fall and winter flows on the upper Sacramento River would be reduced in some years, and summer flows would increase in many years. In addition, retention of winter flows would reduce or eliminate some overbank flood events in the upper Sacramento River. Because the reservoir would be able to store additional water during high-flow periods, in some years wintertime peak flows would be reduced as a result of the project. High-flow events transport sediments and can produce bank erosion and meander.

The Basin Plan specifies that changes to suspended sediment loading and discharge rates cannot cause nuisance or adversely affect beneficial uses (CVRWQCB 2007b). Under both existing and future conditions, analysis of modeling results indicates that the generally small changes in average mean monthly flow from CP1 are unlikely to have a significant effect on sediment transport within the upper Sacramento River. In addition, it appears that CP1 would reduce wintertime peak flow events, which may reduce sediment loading and discharge rates. Beneficial uses that may be beneficially affected include municipal and domestic supply, irrigation and stock watering, service supply, power, contact recreation and canoeing and rafting, other noncontact recreation, and navigation. However, there could be varying effects on beneficial uses concerning habitat, such as freshwater and spawning habitat. These impacts are explored further in Chapter 11, “Fisheries and Aquatic Resources.” Because the project would cause little change in average mean monthly flow, and a potential decrease in peak flows, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP1): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP1 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the CWP in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact of CP1 on water quality measured as temperature would be beneficial.

CP1 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critical years. This would be accomplished by raising Shasta Dam 6.5 feet, thus increasing the depth of the CWP in Shasta Lake and resulting in an increase in seasonal cold-water volume below the thermocline (i.e., layer of greatest water temperature and density change). Cold water released from Shasta Dam influences water temperature conditions in the Sacramento River between Keswick Dam and RBPP, with effects diminishing downstream.

This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, "Fisheries and Aquatic Resources."

Analysis of temperature modeling results indicates that CP1 would improve compliance with the temperature requirements on the Sacramento River. The 2009 BO for CVP and SWP operations and their effects on the Sacramento River winter-run Chinook salmon require that Sacramento River water temperatures be below 56°F at compliance locations between Balls Ferry and Bend Bridge from April 15 through September 30, and not in excess of 60°F at the same compliance locations in during October. Currently, this standard is not always met, particularly in dry and critical years. CP1 would reduce the amount of daily exceedences of the 2009 BO standards under both existing and future conditions. Table 7-38 provides a summary of modeled reductions in exceedences over the 82-year modeling period under each of the alternatives.

Based on this analysis, the impact of CP1 on water quality measured as temperature would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Table 7-38. Modeled Reduction in Daily Exceedences of Sacramento River Temperature Requirements (as Defined by the 2009 Biological Opinion for CVP and SWP Operations and Their Effects on the Sacramento River Winter-Run Chinook Salmon) for April 15 – October 31

Comprehensive Plan	Existing Conditions (2005)		Future Conditions (2030)	
	Balls Ferry	Bend Bridge	Balls Ferry	Bend Bridge
CP1	7%	5%	11%	4%
CP2	13%	7%	14%	7%
CP3	17%	10%	19%	11%
CP4	29%	13%	32%	13%
CP4A	25%	11%	25%	11%
CP5	15%	10%	16%	11%

Impact WQ-12 (CP1): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

The analysis used flow data from hydrologic modeling as an indicator of effects on sediment and metals. The Sacramento River and its tributaries upstream from Keswick Dam are the primary source of metals to the lower Sacramento River (USGS 2000b). Shasta Lake is also listed as impaired for metals. As described in Impact WQ-6 (CP1), a study conducted by the CVRWQCB in 2002 and 2003 suggests that a direct correlation exists between dissolved copper concentrations in the upper levels of Shasta Lake near the dam and dissolved copper concentrations in the waters immediately downstream from the power plant (CVRWQCB 2003a).

The 25-mile reach of the Sacramento River from Keswick Dam downstream to Cottonwood Creek is impaired for cadmium, copper, and zinc. The CVRWQCB developed a TMDL program for these constituents in the upper Sacramento River because of exceedences of water quality standards. Heavy metals such as copper, zinc, mercury, lead, and cadmium are water quality parameters that are impairing beneficial uses. Natural mineral deposits and historical mining practices are a source of metals, including mercury, within Shasta Lake and the upper Sacramento River. High metals concentrations in the Sacramento River correlate with concentrations of suspended sediment and high flows because metals are transported adsorbed to suspended sediments (USGS 2000b; Domagalski et al. 2000).

Under both existing and future conditions, the generally small changes in average mean monthly flow from the project predicted by modeling are unlikely to have a significant effect on metals within the upper Sacramento River and would not be expected to result in exceedences of the dissolved metals numeric targets established in the TMDL (as shown in Table 7-3). Remediation activities at Iron Mountain Mine and other mine sites over the last several years, as well as dredging of contaminated sediment in the Spring Creek Arm of Keswick Reservoir in 2009 and 2010, are also expected to reduce the likelihood of future exceedences of the TMDL numeric targets below Keswick Dam.

However, as described in Impact WQ-6 (CP1), two depositional features associated with historic copper mining and smelting operation within the Squaw Creek Arm of Shasta Lake could be subjected to shoreline and surficial erosional processes, with a high potential for delivery to Shasta Lake and subsequent delivery to the upper Sacramento River. Therefore, the water quality impact of CP1 related to metals in the upper Sacramento River would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas

Impact WQ-13 (CP1): Temporary Construction-Related Sediment Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

Construction would only temporarily influence water quality in the primary study area. Construction effects are anticipated to be localized and would be further minimized with appropriate BMPs. Therefore, construction is not anticipated to affect water quality conditions downstream in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP1): Temporary Construction-Related Temperature Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses As described in Impact WQ-13 (CP1), construction is not anticipated to affect water temperature in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP1): Temporary Construction-Related Metal Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses As described in Impact WQ-13 (CP1), construction is not anticipated to affect metals in the extended study area. This

impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP1): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Water quality effects of CP1 could influence the extended study area, but effects would diminish with distance into the study area. Water quality effects are attenuated by multiple factors including flow from tributaries, stormwater runoff, and municipal and agricultural discharges, as described below.

Because the Sacramento River is the primary supplier of suspended sediment to the Delta, sediment loading and discharge rates from the upper Sacramento River could affect water quality and beneficial uses in the extended study area. However, changes in sediment loading in the upper Sacramento River would be less than significant and changes in the extended study area would be even smaller. Therefore, the impact on sediment would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP1): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Analysis of temperature modeling shows little to no change in temperature at RBPP caused by CP1. This suggests that there would be no changes in temperature beyond RBPP as a result of CP1. This conclusion is further supported by the operational experience of the CVP, which indicates that the 60-mile stretch of river between Keswick Dam and Red Bluff is the extent to which the Shasta-Trinity Division can control temperatures through normal operations of the CVP. Therefore, no temperature effects are anticipated in the extended study area. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP1): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area CP1 would alter the operations of Shasta Lake. Increases in metals concentrations can result from changes in flows that cause increases in concentrations of suspended sediments during high-flow periods. The reduction in frequency and magnitude of peak flow events resulting from CP1 would suggest a beneficial impact for metals; however, as described in Impact WQ-6 (CP1), two depositional features associated with historic copper mining and smelting operation within the Squaw Creek Arm of Shasta Lake could be subjected to shoreline and surficial erosional processes, with the potential for delivery to Shasta Lake and subsequent delivery to the Sacramento River. Therefore, the effects of CP1 related to metals in the lower Sacramento River could be potentially significant because operation of the project could add substantial additional amounts of metal to the river system. Thus, the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Salinity CP1 would differ from the No-Action Alternative primarily through a 256,000 acre-feet enlargement of Shasta Lake. Potential impacts, which are evaluated below, include changes in the following:

- Delta salinity on the Sacramento River at Collinsville
- Delta salinity on the San Joaquin River at Jersey Point
- Delta salinity on the Sacramento River at Emmaton
- Delta salinity on the Old River at Rock Slough
- Delta water quality on the Delta-Mendota Canal at Jones Pumping Plant
- Delta water quality on the West Canal at the mouth of the Clifton Court Forebay
- Delta salinity on the San Joaquin River at Vernalis
- Delta salinity on the San Joaquin River at Brandt Bridge
- Delta salinity on the Old River near the Middle River
- Delta salinity on the Old River at Tracy Road Bridge
- X2 position

Impact WQ-19a (CP1): Delta Salinity on the Sacramento River at Collinsville Operations for CP1 would result in both increases and decreases in salinity in comparison with baseline conditions; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 5 percent. This impact would be less than significant.

The water quality requirement on the Sacramento River at Collinsville is specified in RD-1641, and is defined for all year types, from October through April. The RD-1641 objectives for the Sacramento River at Collinsville are defined in Table 7-4.

As shown in Table 7-39, operations for CP1 would result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 5 percent. Table 7-40 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The operation of CP1 would not result in any violations of the salinity standards for the Sacramento River at Collinsville under both existing and future conditions. This

impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19b (CP1): Delta Salinity on the San Joaquin River at Jersey Point
Operations for CP1 would result in both increases and decreases in salinity in comparison with baseline conditions; however, none of the increases would be sufficient to change compliance for the San Joaquin River at Jersey Point. On a percentage basis, all increases in salinity would be less than 5 percent. This impact would be less than significant.

The water quality requirement on the San Joaquin River at Jersey Point is specified in RD-1641 as two components. The first component of the requirement begins on April 1, and extends through a year-type-dependent date. The second component of the Jersey Point requirement begins at the end of the first component, and ends on August 15. The numerical requirement of the second component is dependent on the year type. Objectives for the San Joaquin River at Jersey Point are defined in Table 7-7.

Table 7-41 shows simulated monthly average salinity and percent change for the San Joaquin River at Jersey Point. On an average monthly basis EC requirements would be satisfied in all months in an average year under CP1 operations. Furthermore, all changes during April through August would be less than 2 percent. Table 7-42 shows the number of months simulated EC values exceeded the standards for the San Joaquin River at Jersey Point in the period of simulation. CP1 would result in an increase in the frequency of violations under existing conditions. Violations occur during June and are 10 percent for all years and 12.5 percent during dry and critical years. The long-term and dry- and critical-year average EC values in June are found to be below the standards, which indicate the violation is marginal and does not show any significant changes in water quality in June. Overall, the frequency of exceedence of salinity standards for the San Joaquin River at Jersey Point under CP1 would be similar to those under existing and future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP1): Delta Salinity on the Sacramento River at Emmaton
Operations for CP1 would result in both increases and decreases in salinity in comparison to baseline conditions; however, none of the increases would be sufficient to change compliance for the Sacramento River at Emmaton. On a percentage basis, all increases in salinity would be less than 5 percent. This impact would be less than significant.

Similar to the water quality requirement on the San Joaquin River at Jersey Point, the water quality requirement on the Sacramento River at Emmaton is specified in RD-1641 as two components. The first component of the requirement begins on April 1, and extends through a year-type-dependent date. The second component of the Emmaton requirement begins at the end of the first component, and ends on August 15. The numerical requirement of the second component is dependent on the year type. Objectives for the Sacramento River at Emmaton are defined in Table 7-10.

Although Table 7-43 shows the EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, no change in the ability to meet EC requirements would occur in all months in an average year under CP1 operations. Maximum change in monthly EC would not be greater than 2.1 percent under both existing and future conditions. Table 7-44 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. Operations of CP1 would not result in any additional violation of salinity standards between October and March. CP1 would result in an increase in the frequency of violations under existing and future conditions during May, by up to 100 percent in all years and dry and critical years. However, CP1 would result in a decrease in the frequency of violations under existing and future conditions during August and April, by up to 11.5 percent in all years and up to 50 percent during dry and critical years. Overall, the compliance of standards for the Sacramento River at Emmaton would be similar to the baseline levels under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19d (CP1): Delta Salinity on the Old River at Rock Slough On an average annual basis, all months except September through January under both the existing condition and future condition would be less than 150 mg/L. Change in chloride concentration would not affect compliance with the standard as it would already be exceeded under the basis of comparison. This impact would be less than significant.

Rock Slough is the location of the CCWD diversion for the Contra Costa Canal, but compliance with the salinity objectives is measured at Contra Costa Canal Pumping Plant No. 1. However, simulating water quality at Contra Costa Canal Pumping Plant No. 1 is difficult, and DSM2 does not explicitly simulate water quality at that location. Instead, a transfer function is applied to estimate the water quality at Contra Costa Canal Pumping Plant No. 1 based on the simulated water quality at Old River at Rock Slough from DSM2. The requirements, as defined in RD-1641, specify a minimum number of days during the calendar year that the maximum mean daily chloride concentration of 150 mg/L must be maintained. Objectives for the Contra Costa Canal Pumping Plant No. 1 are defined in Table 7-13.

Table 7-45 shows simulated monthly average chloride concentrations and percent change for Contra Costa Canal Pumping Plant No. 1. On an average annual basis, CP1 would not increase chloride concentrations by more than 1.1 percent. Maximum changes in chloride concentrations under the CP1 are less than 2.1 percent for dry and critical years.

Table 7-46 shows the average number of days in a year simulated chloride values exceeded the standard of 150 mg/L for Contra Costa Canal Pumping Plant No. 1. No additional daily violations of the chloride standards are shown to occur under both existing and future conditions for CP1, as compared with baseline conditions. Overall, CP1 would not alter the compliance level for Contra Costa Canal Pumping Plant No. 1 observed under both existing and future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19e (CP1): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. Both requirements would continue to be met under CP1 under both existing and future conditions. This impact would be less than significant.

Table 7-16 shows both the chloride and EC thresholds that must be met at Jones Pumping Plant. Tables 7-47 and 7-48 show that CP1 would not exceed chloride thresholds. All increases in chloride concentrations would be less than 5 percent under CP1. Tables 7-49 and 7-50 show that increases in EC would be less than 1.0 percent under CP1 and would not exceed the EC threshold. CP1 would not change the baseline compliance levels under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP = Comprehensive Plan

Impact WQ-19f (CP1): Delta Water Quality on the West Canal at the Mouth of the Clifton Court Forebay The 250 mg/L chloride concentration standard at the West Canal would not be exceeded on an average annual or dry and critical year basis under CP1. CP1 would also not exceed EC thresholds. This impact would be less than significant.

Clifton Court Forebay is the source of water supply for the Banks Pumping Plant and SWP exports south of the Delta. Similar to the Delta-Mendota Canal at Jones Pumping Plant, the water quality requirement on the West Canal at the mouth of the Clifton Court Forebay has two components, a chloride requirement and an EC requirement. Table 7-21 shows both the chloride and EC concentration requirements.

Table 7-51 shows that maximum chloride concentrations under both existing and future project conditions are lower for CP1 than the 250 mg/L threshold. Maximum changes under both existing and future projection conditions are less than 1.5 percent. As shown in Table 7-52, CP1 the maximum change in EC values under existing and future project conditions would be less than 1.5 percent.

mmhos/cm = millimhos per centimeter

Table 7-53 shows the average number of days simulated chloride values exceeded the standards of 250 mg/L for the West Canal at the Clifton Court Forebay in a year. There would be no additional violations throughout the year for average annual or dry and critical years, under both existing and future project conditions. CP1 would not change the baseline compliance levels under both existing and future conditions.

As shown in Table 7-54, CP1 would not result in any additional violations of the salinity standards. CP1 would actually result in decreases in EC during several months of the year. CP1 would not change the baseline compliance levels under both existing and future conditions.

The impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19g (CP1): Delta Salinity on the San Joaquin River at Vernalis On an average monthly basis, EC would meet requirements in all months, in both average years and in dry and critical years. Moreover, CP1 would not exceed EC thresholds on the San Joaquin River at Vernalis. This impact would be less than significant.

To protect water quality in the south Delta, RD-1641 includes a salinity objective at several locations on the San Joaquin River and on the Old River. The objective is the same for all four locations: the San Joaquin River at Airport Way Bridge in Vernalis, the San Joaquin River at Brandt Bridge, the Old River near the Middle River, and the Old River at Tracy Road Bridge. The water quality requirement is a maximum 30-day average of mean daily EC. Table 7-26 shows the south Delta water quality requirement.

On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP1 would not exceed EC thresholds on the San Joaquin River at Vernalis, as shown in Tables 7-55 and 7-56. CP1 would not change the baseline compliance levels under both existing and future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19i (CP1): Delta Salinity on the Old River near the Middle River
On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years. CP1 would not measurably change EC on the Old River near the Middle River. This impact would be less than significant.

As previously mentioned, RD-1641 contains a south Delta water quality requirement applicable at several locations, including on the Old River near the Middle River. Table 7-26 details water quality requirement standards for salinity.

On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years, as shown in Table 7-59. Table 7-60 shows the number of months simulated EC values exceeded the standards for the Old River near the Middle River in the period of simulation. Compliance with salinity standards for the Old River near the Middle River would not change under CP1. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19j (CP1): Delta Salinity on the Old River at Tracy Road Bridge
On an average monthly basis, EC would meet requirements in all months in both average years and in dry and critical years under CP1. CP1 would not measurably change EC on the Old River at Tracy Road Bridge. This impact would be less than significant.

As previously mentioned, RD-1641 contains a south Delta water quality requirement applicable at several locations, including on the Old River at Tracy Road Bridge. Table 7-26 details water quality requirement standards for salinity.

CP1 would not measurably change EC on the Old River at Tracy Road Bridge, as shown in Table 7-61. Table 7-62 shows the number of months simulated EC values exceeded the standards for the Old River near Tracy Road Bridge in the period of simulation. Although exceedence would occur during August, under future conditions, on an annual average basis, the compliance of salinity standards under CP1 would not change from the existing conditions. CP1 would not alter the compliance level for the Old River near Tracy Road Bridge observed under both existing and future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-20 (CP1): X2 Position CP1 would not change average monthly X2, in either average years or in dry and critical years, by more than 0.1 km under either the existing condition or future condition. Although several months may be out of compliance individually under the bases of comparison, the impact would be less than significant.

Table 7-63 shows the simulated monthly average X2 position for CP1 compared to the existing condition and future condition baselines. CalSim-II calculates the X2 position on a 1-month delay; the values shown have been corrected to accurately reflect the X2 position for the specified month.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

CP2 – 12.5-Foot Dam Raise, Anadromous Fish Survival and Water Supply Reliability

As with CP1, CP2 focuses on increasing water supply reliability and increasing anadromous fish survival. CP2 primarily consists of raising Shasta Dam by 12.5 feet, which, in combination with spillway modifications, would increase the height of the reservoir's full pool by 14.5 feet and enlarge the total storage capacity in the reservoir by 443,000 acre-feet. The existing TCD would also be extended to achieve efficient use of the expanded CWP. Shasta Dam operational guidelines would continue essentially unchanged, except during dry years and critical years, when 120,000 acre-feet and 60,000 acre-feet, respectively, of the increased storage capacity in Shasta Reservoir would be reserved to specifically focus on increasing M&I deliveries. CP2 would help reduce future water shortages through increasing drought year and average year water supply reliability for agricultural and M&I deliveries. In addition, the increased depth and volume of the CWP in Shasta Reservoir would contribute to improving seasonal water temperatures for anadromous fish in the upper Sacramento River.

Shasta Lake and Vicinity

Impact WQ-1 (CP2): Temporary Construction-Related Sediment Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-1 (CP1). However, the construction-related activities described in Chapter 2, "Alternatives," would result in about 500 more acres of exposed shoreline than CP1. Relocation activities under CP2 would expose a similar but greater acreage to erosion than would CP1 (up to 698 acres). This alternative is similar to, but somewhat larger than CP1. Therefore, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-2 (CP2): Temporary Construction-Related Temperature Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses Similar to CP1, construction activities associated with enlarging Shasta Dam as well as the relocation actions would result in sizeable areas that would be subject to surface disturbance, including jurisdictional waters within the influence zone of CP2. Efforts to document jurisdictional waters associated with relocation areas are described in Chapter 12, "Botanical Resources and Wetlands." This information has been updated since the DEIS was circulated for public review. If the SLWRI is authorized, Reclamation will work closely with its cooperating agencies to ensure compliance with the CWA (e.g., Section 401 and 404) consistent with the development of the LEDPA.

Environmental commitments and BMPs for the various construction and relocation activities (e.g., bridge replacement, boat ramp construction, demolition of facilities) have been incorporated into CP2. These activities could include removal of riparian vegetation, thereby exposing water bodies to increased solar radiation for various time periods. As described in Chapter 2, "Alternatives," and the "Preliminary Environmental Commitments and Mitigation Plan Appendix," riparian revegetation would be implemented at all construction and relocation sites as applicable to ensure that shade is quickly reestablished after construction is completed.

As described in Chapter 2, "Alternatives," although the TCD may not be operational for some period of time during construction, project sequencing would ensure that changes to water temperature in Shasta Lake and downstream in the upper Sacramento River, as well as associated limnological conditions in Shasta Lake, would be consistent with those that occur periodically under the No-Action Alternative typically associated with maintenance and outage periods.

Because of the large water surface area of Shasta Lake, coupled with the isolated and discrete nature of the relocation activities on the tributaries, temporary construction-related effects are not expected to modify water temperature in a manner that would have a negative effect on beneficial uses or result in a water quality violation. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-3 (CP2): Temporary Construction-Related Metal Effects on Shasta Lake and Its Tributaries that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses This impact is similar to WQ-3 (CP1). There would be no construction activities that would disturb locations known to contain elevated metal concentrations in either sediments or the water column. Therefore, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-4 (CP2): Long-Term Sediment Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries This impact is similar to WQ-4 (CP1), except that the exposure of an additional 1,735 acres of shoreline surrounding Shasta Lake would result in a potential for increased wave-related shoreline erosion (see Chapter 4, "Geology, Geomorphology, Minerals, and Soils"). As the reservoir is lowered during summer and fall, the exposed surface area would also be subject to surficial erosion processes that could mobilize and transport sediment to the newly expanded Shasta Lake. Although environmental commitments and BMPs are incorporated into the project description, the project would result in an incremental increase in the delivery of suspended sediment and turbidity to the receiving waters. The amount of sediment that could be delivered is not entirely quantifiable because of the size of the lake and the number of variables that influence sediment transport and delivery. Chapter 4 does provide information on the estimated volume of sediment that may be introduced into Shasta Lake as a result of increases in shoreline erosion. Under CP2, its estimated that about 549,000 cubic yards per year would be delivered to Shasta Lake as a result of shoreline erosion. This would be a potentially significant impact. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-5 (CP2): Long-Term Temperature Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, this alternative would increase storage on a monthly basis although it would vary by water year. This impact would be less than significant.

Table 7-64 shows the simulated monthly change in storage for CP2 as a percent increase above the existing condition. On average, CP2 would provide an approximately 10 percent increase in the end-of-month storage on an annual basis.

Table 7-64. Simulated Average Increased End-of-Month Shasta Lake Storage – CP2

Month	Existing Conditions (TAF)	CP2 Change (TAF)	CP2 % Increase
October	2,592	282	10.9%
November	2,568	271	10.6%
December	2,722	295	10.8%
January	2,995	310	10.3%

CP = Comprehensive Plan
TAF = thousand acre-feet

Under CP2, existing water temperature requirements would typically be met in most years; therefore, the additional increase in water storage shown in Table 7-64 would primarily be released for water supply purposes. Accordingly, minimal increases in releases from Shasta Dam would be expected in months when Delta exports are constrained, or when flow is not usable for water supply purposes.

Similar to CP1, the increase in storage provided by CP2 fluctuates greatly throughout a year. A key indicator of water temperature benefits of CP2 to the upper Sacramento River between Keswick Dam and Red Bluff is the amount of cold water available in Shasta Lake before the water temperature operation season, about May through October. Similar to CP1, the CWP volume in the lake accumulates during the winter and early spring and is not likely to increase after April. Therefore, the expected increase in spring storage for CP2 should also result in an incremental increase in the CWP volume.

The simulated end-of-April volume of water with a temperature lower than 52°F for the existing condition and the change in CWP volume for CP2 is shown, by SVI year type, in Table 7-65.

Table 7-65. Simulated Average Volume of Water Less than 52°F in Shasta Lake at the End of April – CP2

SVI Year Type	Existing Conditions (TAF)	CP2 Change (TAF)	% Increase
Average of All Years	2,609	267	10%
Wet	2,916	345	12%
Above Normal	2,972	296	10%
Below Normal	2,699	263	10%
Dry	2,542	231	9%
Critical	1,601	134	8%

Year types as defined by the Sacramento Valley Index

Key:
°F = degrees Farenheit
% = percent
CP = Comprehensive Plan
SVI = Sacramento Valley Index
TAF = thousand acre-feet

In addition to illustrating the average change in available CWP, Table 7-65 also shows the influence of climatic conditions on these values. The diversity between water year types, coupled with unique combinations of storage and rainfall would continue to influence the ability to manage storage in Shasta Lake to maximize carryover capacity. An increase in active storage and carryover storage of the CWP would occur. However, the impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-6 (CP2): Long-Term Metals Effects that Would Violate Water Quality Standards or Adversely Affect Beneficial Uses in Shasta Lake or Its Tributaries Similar to CP1, the increase in storage associated with this alternative would not result in modifying the depth and thickness of the thermocline that persists in Shasta Lake. This impact would be less than significant.

Within the Squaw Creek Arm, two depositional features associated with historic copper mining and smelting operations are immediately adjacent to the shoreline of Shasta Lake in the general vicinity of the Bully Hill Mine. As mapped, these two sites appear to have about 7,300 cubic yards of material that could be subjected to shoreline and surficial erosional processes at slightly higher elevations on the features than CP1 with a high potential for delivery to Shasta Lake. This impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Upper Sacramento River (Shasta Dam to Red Bluff)

Impact WQ-7 (CP2): Temporary Construction-Related Sediment Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction would include ground-disturbing activities that could result in soil erosion and sediment effects on the upper Sacramento River. This impact would be potentially significant.

Similar to Impact WQ-7 (CP1), the impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-8 (CP2): Temporary Construction-Related Temperature Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in temperature effects on the upper Sacramento River because changes to water temperature in Shasta Lake and subsequent releases to the Sacramento River would be consistent with typical periodic fluctuations. This impact would be less than significant.

This impact would be identical to Impact WQ-8 (CP1). For the same reasons as described for Impact WQ-8 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-9 (CP2): Temporary Construction-Related Metal Effects on the Upper Sacramento River that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses Construction activities are not anticipated to result in water quality effects on the upper Sacramento River related to metals because construction would not disturb locations of known elevated metal concentrations. This impact would be less than significant.

This impact would be identical to Impact WQ-9 (CP1). For the same reasons described for Impact WQ-9 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-10 (CP2): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River No long-term water quality impacts are anticipated in the upper Sacramento River in regard to sediment, because modeling results have indicated that CP2 would cause little change in average mean monthly winter flows during some years, which could slightly reduce sediment transport. This impact would be less than significant.

This impact would be similar to Impact WQ-10 (CP1) because the extent of the effect of CP2 on sediment would be similar to but slightly greater than that for CP1 (i.e., CP2 would have greater potential to reduce erosional processes and sediment transport in the upper Sacramento River). For the same reasons as described for Impact WQ-10 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-11 (CP2): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Analysis of temperature modeling results indicates that CP2 would improve compliance with the temperature requirements on the Sacramento River because of the increased depth of the CWP in Shasta Lake and the associated enhanced ability to regulate water temperature releases to the upper Sacramento River. Therefore, the impact of CP2 on water quality measured as temperature would be beneficial.

CP2 would increase the ability of Shasta Dam to release cold water and regulate water temperature in the upper Sacramento River, primarily in dry and critical years. Raising Shasta Dam 12.5 feet would increase the CWP and benefit seasonal water temperatures along the upper Sacramento River. This section focuses on compliance with water quality standards for temperature. For an analysis of temperature effects on fisheries and aquatic habitat, see Chapter 11, "Fisheries and Aquatic Resources."

Analysis of temperature modeling results indicates that under both existing and future conditions, CP2 would have a beneficial effect on temperature within the upper Sacramento River, with a slight decrease in average monthly water temperature during summer. Decreased temperatures would improve compliance with the temperature objectives for the upper Sacramento River in the 2004 and 2009 NFMS BOs (NMFS 2004, 2009). CP2 would reduce temperature exceedences at Balls Ferry by 15 percent under existing conditions and 19 percent under future conditions. At the Bend Bridge compliance station, CP2 would reduce temperature exceedences by 6 percent under existing conditions and 8 percent under future conditions. Table 7-38 summarizes the temperature modeling results.

Based on this analysis, the impact would be beneficial. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-12 (CP2): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Upper Sacramento River Long-term operation of the project could result in water quality effects on the upper Sacramento River in regard to metals as a result of erosional processes to historic mining and smelting operation features. This impact would be potentially significant.

This impact would be similar to Impact WQ-12 (CP1) because the extent of the effect of CP2 on metals would be similar to but slightly greater than that for CP1. For the same reasons as described for CP1, this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Lower Sacramento River and Delta and CVP/SWP Service Areas CP2 would differ from the No-Action Alternative primarily through a 443,000 acre-feet enlargement of Shasta Lake. The impacts described below are the same as described for CP1.

Impact WQ-13 (CP2): Temporary Construction-Related Sediment Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards Construction is not anticipated to affect water quality conditions in the extended study area. This impact would be less than significant.

This impact would be similar to Impact WQ-13 (CP1). For the same reasons as described for Impact WQ-13 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-14 (CP2): Temporary Construction-Related Temperature Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-14 (CP1). For the same reasons as described for Impact WQ-14 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-15 (CP2): Temporary Construction-Related Metal Effects on the Extended Study Area that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses This impact would be similar to Impact WQ-15 (CP1). For the same reasons as described for Impact WQ-15 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-16 (CP2): Long-Term Sediment Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area Project implementation could affect water quality in the extended study area, but effects would diminish with distance. This impact would be less than significant.

This impact would be similar to Impact WQ-16 (CP1). For the same reasons as described for Impact WQ-16 (CP1), this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-17 (CP2): Long-Term Temperature Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in *the Extended Study Area* This impact would be similar to Impact WQ-17 (CP1). Analysis of temperature modeling shows little to no change in temperature at RBPP caused by CP2. This suggests that there would be no changes in temperature beyond RBPP as a result of CP2. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-18 (CP2): Long-Term Metals Effects that Would Cause Violations of Water Quality Standards or Adversely Affect Beneficial Uses in the Extended Study Area This impact would be similar to Impact WQ-18 (CP1). For the same reasons as described for Impact WQ-18 (CP1), this impact would be potentially significant. Mitigation for this impact is proposed in Section 7.3.5.

Impact WQ-19a (CP2): Delta Salinity on the Sacramento River at Collinsville This impact would be similar to Impact WQ-19a (CP1). As shown in Table 7-66, operations for CP2 result in both increases and decreases in salinity; however, none of the increases would be sufficient to change compliance for the Sacramento River at Collinsville. On a percentage basis, all increases in salinity would be less than 5 percent. This impact would be less than significant.

Table 7-67 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Collinsville in the period of simulation. The operation of CP2 would not result in any violation of the salinity standards under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-66. Simulated Monthly Average Salinity and Percent Change for the Sacramento River at Collinsville Under Baseline Conditions and CP2

Month	Existing Condition (2005)				Future Conditions (2030)			
	Average All Years		Dry and Critical Years		Average All Years		Dry and Critical Years

Impact WQ-19b (CP2): Delta Salinity on the San Joaquin River at Jersey Point

Impact WQ-19b (CP2) would be similar to Impact WQ-19b (CP1). As shown in Table 7-68, the basis of comparison would meet the requirement on an average basis in both average years and in dry and critical years. Furthermore, all changes during April through August would be less than 2 percent. This impact would be less than significant.

Table 7-69 shows the number of months simulated EC values exceeded the standards for San Joaquin River at Jersey Point in the period of simulation. CP2 would result in an increase in the frequency of violations under existing conditions during June, by 10 percent in all years and 12.5 percent during dry and critical years. However, the EC standards are not violated on an average monthly basis. Overall, frequency of violation of salinity standards for the San Joaquin River at Jersey Point under CP2 would be similar to those under existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19c (CP2): Delta Salinity on the Sacramento River at Emmaton
Impact WQ-19c (CP2) would be similar to Impact WQ-19c (CP1). Operations for CP2 would result in both increases and decreases in salinity in comparison to baseline conditions; however, none of the increases would be sufficient to change compliance for the Sacramento River at Emmaton. On a percentage basis, all increases in salinity would be less than 5 percent. This impact would be less than significant.

Although Table 7-70 shows EC for all months, the Emmaton water quality requirement is only defined for April 1 through August 15. On an average monthly basis, EC requirements would be satisfied in all months in an average year under CP2 operations. Maximum change in monthly EC would not be greater than 5 percent under both existing and future conditions. Table 7-71 shows the number of months simulated EC values exceeded the standards for the Sacramento River at Emmaton in the period of simulation. Operations of CP2 would not result in any violation of salinity standards between October and March. CP2 would result in an increase in the frequency of violations under existing and future Conditions during May, by up to 100 percent in all years and dry and critical years. However, CP2 would result in a decrease in the frequency of violations under existing and future conditions during August and April, by up to 50 percent in all years and dry and critical years.

On an average monthly basis, the standards are not violated. Overall, the compliance of salinity standards for the Sacramento River at Emmaton would be very similar to the baseline levels under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-70. Simulated Monthly Average Salinity and Percent Change for the Sacramento River at Emmaton Under Baseline Conditions and CP2

Impact WQ-19d (CP2): Delta Salinity on the Old River at Rock Slough Impact WQ-19d (CP2) would be similar to Impact WQ-19d (CP1). On an average annual basis, chloride levels under both the existing condition and future condition would be less than 150 mg/L from February through July. This impact would be less than significant.

As shown in Table 7-72, in average annual years, CP2 would not increase chlorides by more than 1.3 percent. For dry and critical years, a maximum change of 2.3 percent in chloride concentration would occur. Change in chloride concentration would not affect compliance with the standard as it would already be exceeded under the basis of comparison. This impact would be less than significant.

Table 7-73 shows the number of days simulated chloride values exceeded the standards of 150 mg/L for Contra Costa Canal Pumping Plant No. 1 in the period of simulation. CP2 would result in no daily violations of the chloride standards under both existing and future conditions for CP2. Overall, CP2 would not alter the compliance level observed under the existing and future conditions.

This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

EC = electrical conductivity

Impact WQ-19e (CP2): Delta Water Quality on the Delta-Mendota Canal at Jones Pumping Plant Impact WQ-19e (CP2) would be similar to Impact WQ-19e (CP1). The water quality requirement on the Delta-Mendota Canal at Jones Pumping Plant has two components, a chloride requirement and an EC requirement. This impact would be less than significant.

Tables 7-74 and 7-75 show that CP2 would not exceed chloride thresholds. All increases in chloride concentrations would be less than 5 percent. Chloride values under CP2 would be similar to the baseline values under both existing and future conditions. Tables 7-76 and 7-77 show that increases in EC would be less than 5 percent under CP2 and would not exceed the EC threshold. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19f (CP2): Delta Water Quality in the West Canal at the Mouth of the Clifton Court Forebay Impact WQ-19f (CP2) would be similar to Impact WQ-19f (CP1). The 250-mg/L chloride concentration standard at the West Canal would not be exceeded on an average annual or dry and critical year basis under CP2. CP2 would also not exceed EC thresholds. This impact would be less than significant.

Table 7-78 shows that maximum chloride concentrations under both existing and future project conditions are lower for CP2 than the 250 mg/L threshold. Maximum changes under both existing and future projection conditions are less than 1.5 percent. As shown in Table 7-79, CP2 the maximum change in EC values under existing and future project conditions would be less than 1.5 percent.

Table 7-80 shows the average number of days simulated chloride values exceeded the standards of 250 mg/L for the West Canal at the Clifton Court Forebay in a year. There would be no additional violations throughout the year under both existing and future project conditions. CP2 would not change the baseline compliance levels under both existing and future conditions.

As shown in Table 7-81, CP2 would not result in any additional violations of the salinity standards. CP2 would actually result in decreases in EC during several months of the year. CP2 would not change the baseline compliance levels under both existing and future conditions.

Overall, this impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Impact WQ-19g (CP2): Delta Salinity on the San Joaquin River at Vernalis

This impact would be similar to Impact WQ-19g (CP1). On an average monthly basis, EC would meet requirements in all months, in both average years and in dry and critical years. CP2 would not exceed EC thresholds on the San Joaquin River at Vernalis as shown in Tables 7-82 and 7-83. CP2 would not change the baseline compliance levels under both existing and future conditions. This impact would be less than significant. Mitigation for this impact is not needed, and thus not proposed.

Table 7-82. Simulated Monthly Average Salinity and Percent Change for the San Joaquin River at Vernalis Under Baseline Conditions and CP2

Month	Existing Condition (2005)				Future Conditions (2030)			
	Average All Years		Dry and Critical Years		Average All Years		Dry and Critical Years
