Samantha Olson
Matt St. John
Ben Zabinsky

This TMDL is dedicated in loving memory to Elmer Dudik and Dr. Ranjit Gill who worked tirelessly in their duties to improve water quality in the Klamath River basin and throughout the North Coast to ensure that California's water resources were pollutant free, and beneficial uses were protected for all to enjoy. Their work to protect and restore water quality is a lasting testament to their dedication to the environment and to the people of California. They are sorely missed.

Acknowledgments

Working in collaboration with Oregon Department of Environmental Quality, US Environmental Protection Agency Regions 9 and 10, and Tetra Tech, Inc., the TMDL Development Team of the North Coast Regional Water Quality Control Board was responsible for data collection, data interpretation, modeling, and preparation of the report. This report would not have been possible without the efforts and contributions of many people and organizations including:

- Regional Water Board Staff – Bruce Gwynne and William Hart (GIS)
- US EPA Region 9 – Susan Keydel, Gail Louis, and Maria Rea
- US EPA Region 10 – Ben Cope and Mark Filippini
- Oregon Department of Environmental Quality – Steve Kirk, Eric Nigg, Dan Turner
- Tetra Tech, Inc. – Jon Butcher, Mustafa Faizullabhoy, Andrew Parker, and Rui Zou
- US Geological Survey – Debra Curry, Alan Flint, Laurie Flint
- The multiple agencies, Tribes, companies, and private individuals who collected data in the basin

Our thanks and appreciation to you all.

CHAPTER 1. INTRODUCTION

1.1 Overview

The purpose of this report is to present the Total Maximum Daily Loads (TMDLs) calculated by California to protect and restore beneficial uses of water in the Klamath River downstream of the Oregon border and in portions of the Klamath River watershed in California. The purpose is also to present the recalculated Site Specific Objectives (SSOs) for dissolved oxygen (DO) for the mainstem Klamath River in California (see Appendix 1). The California Klamath TMDLs are comprised of two distinct parts: the Staff Report and the Action Plan. This document is the Staff Report that contains information and findings to support the recommended Action Plan to the North Coast Regional Water Quality Control Board (Regional Water Board). It also contains, in Appendix 1, the staff report for the proposed Basin Plan Amendment to incorporate into the Water Quality Control Plan for the North Coast Region (Basin Plan) the recalculated SSOs for DO.

The Klamath River basin[1] is 12,680 square miles in area. The Klamath River originates in southern Oregon and flows through northern California to meet the Pacific Ocean at Requa in Del Norte County, California. Forty-four percent of the watershed lies within the boundaries of Oregon, while the remaining 56% of the basin lies within the boundaries of California. Figure 1.1 is a map of the Klamath River basin.

The Klamath River basin is of vital economic and cultural importance to the states of Oregon and California, as well as the Klamath Tribes in Oregon; the Hoopa, Karuk, and Yurok Tribes in California; the Quartz Valley Indian Reservation in California, and the Resighini Rancheria in California. It provides fertile lands for a rich agricultural economy in the upper basin. Irrigation facilities known as the Klamath Project owned by the U.S. Bureau of Reclamation support this economy as does hydroelectric power provided via a system of five dams operated by PacifiCorp. The basin is the home spawning grounds of a once vast Tribal, sport, and commercial fishery and provides other aquatic resources of cultural significance to the local Indian Tribes. The watershed supports an active recreational industry, including activities that are specific to the Wild and Scenic portions of the river designated by both the state and federal governments in both Oregon and California. Finally, the watershed continues to support what were once more significant mining and timber industries.

A decline in the fisheries has signaled deep impacts on the ecology of the basin. Congress passed Public Law 99-552 (Klamath Act) in 1986 to establish the Klamath River Basin Conservation Area Restoration Program with the intention of rebuilding the river's dwindling fish resources. Since that time, however, several of the fish species endemic to the basin have been listed by federal and state agencies as threatened or endangered. Impairments to water quality have been identified as one of the factors

---

1 For the purposes of this report, the terms "basin" and "watershed" are synonymous and will be used to refer to the area that drains flows to the Pacific Ocean at Requa.

contributing to the continued decline of native fish populations. This has led to water quality assessments by the States of Oregon and California and the listing of the Klamath

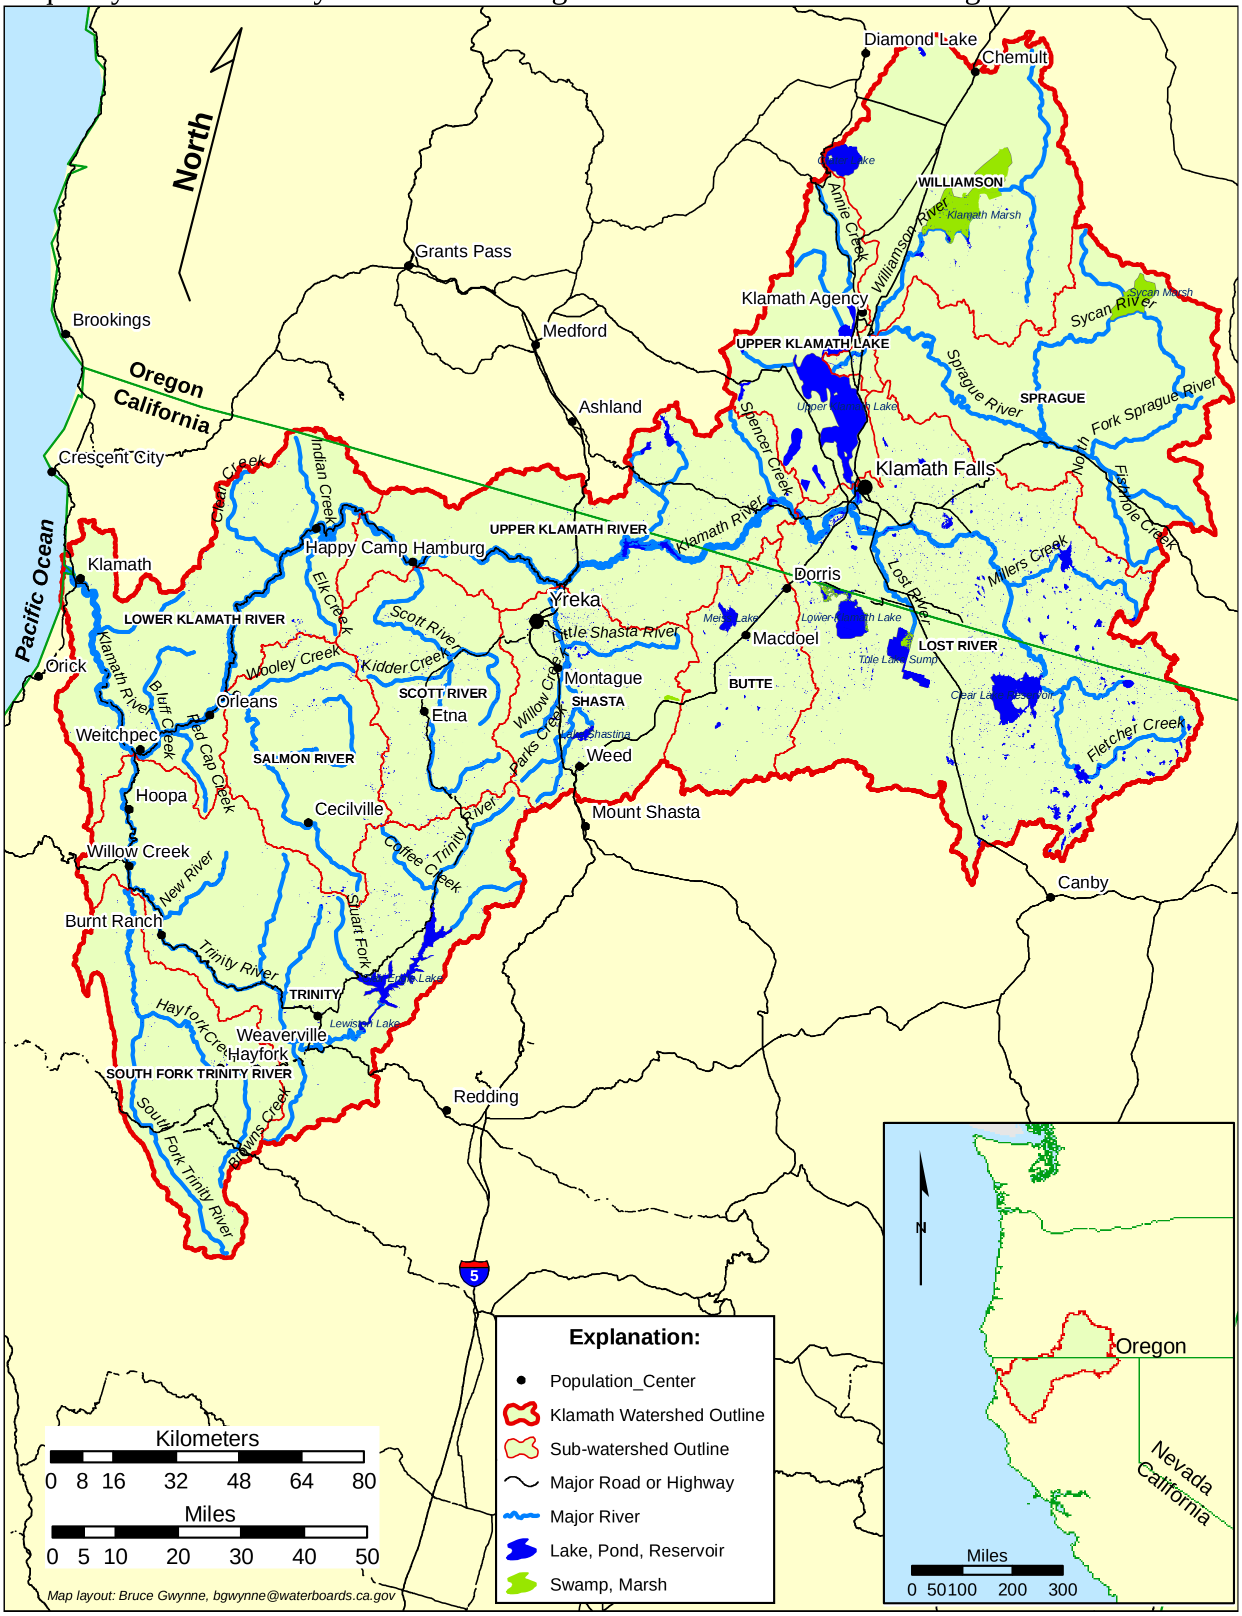

Figure 1.1: Klamath River basin showing rivers, lakes and reservoirs, population centers, and major roads

River as impaired under section 303(d) of the federal Clean Water Act (CWA). It has also led to the recalculation of the SSOs for DO in the mainstem Klamath River as contained in the Basin Plan.

The Oregon Department of Environmental Quality (ODEQ) and the Regional Water Board are working cooperatively to develop TMDLs for the water quality impaired waterbodies in the Klamath Basin, including the Lost River and the Klamath Straits Drain, and the Klamath River from Link River to the Pacific Ocean. The States of Oregon and California are responsible for calculating the TMDL of each of the pollutants of concern that can be discharged to the river while still protecting the fisheries and other beneficial uses of the waters within their respective jurisdictions. California has recalculated the SSOs for DO using data generated by the TMDL development team.

California has listed the portions of the Klamath River within its jurisdiction (from the CA/OR Stateline to the mouth) for impairments due to elevated water temperatures, elevated nutrients, and organic enrichment/low dissolved oxygen. In addition, the portion of the Klamath River watershed downstream of the Trinity River, partially within the Yurok Reservation, is listed for sedimentation/siltation impairment. Finally, in March 2008, the U.S. Environmental Protection Agency (USEPA) added the reach of the Klamath River that incorporates Copco 1 and 2 and Iron Gate Reservoirs to the 303(d) List for the blue-green algae toxin microcystin. Table 1.1 and Figure 1.2 summarize the waterbody-pollutant combinations for the Klamath River in California as identified on the current (2006) section 303(d) List[2]. The Klamath River TMDLs reported here address the water quality impairments and geographic areas summarized in Table 1.1, with the exception of sedimentation/siltation in the Klamath Glen HSA. Table 1.2 summarizes the status of the TMDLs for the entire Klamath River basin in California.

A consent decree entered into by the USEPA in March 1997 (*Pacific Coast Federation of Fishermen's Associations et al. v. Marcus*) establishes the date by which TMDLs for 17 California northcoast watersheds must be completed. The Klamath River TMDLs for the listed temperature and nutrient impairments were scheduled for completion by 2007. Negotiations between USEPA and the plaintiffs resulted in an extension of that deadline to 2010.

The current TMDLs for the Klamath River in California reported here, address temperature, dissolved oxygen, nutrient, and microcystin water quality impairments for the Klamath River Hydrologic Unit, Middle HA (Oregon to Trinity River) and Lower HA, Klamath Glen HSA (Trinity River to Pacific Ocean). These TMDLs do not explicitly address the sedimentation/siltation impairments in the Lower HA, Klamath Glen HSA. Addressing DO in the mainstem Klamath River required not only the development of a TMDL but, the recalculation of the SSOs for DO, as well. The SSOs for DO in the mainstem Klamath River have been recalculated because conditions of barometric pressure, salinity and natural receiving water temperatures at equilibrium

---

[2] Figure 1.2 identifies the water quality impairments for the entire Klamath River basin in California, as depicted in the 2006 Clean Water Act Section 303(d) List.

(e.g., 100% DO saturation) do not consistently allow for attainment of the existing SSOs for DO. Further, the *Klamath TMDL model*, as described in detail throughout the rest of this report, indicates that under natural conditions, the DO concentrations achieved in the mainstem Klamath are periodically less than the existing SSOs for DO, particularly during the summer months. For a detailed analysis of DO conditions in the mainstem Klamath River, including the recalculation of the SSOs, please see Appendix 1.

Subwatershed	**TMDL(s)**	**Year**	**Agency**
Upper Lost River	Temperature, nutrients	Delisted, 2006	-
Lower Lost River	Nutrients	Technical TMDL, 2008	USEPA
	Temperature	Delisted, 2006	-
Shasta River	Temperature, dissolved oxygen	Final Technical TMDL and Implementation Plan, 2007	Regional Water Board
Scott River	Temperature, sediment	Final Technical TMDL and Implementation Plan, 2006	Regional Water Board
Salmon River	Temperature	Final Technical TMDL, 2005	Regional Water Board
	Nutrients	Delisted, 2006	-
Trinity River	Sediment	Final Technical TMDL, 2001	USEPA
South Fork Trinity River	Sediment	Final Technical TMDL, 1998	USEPA
Klamath River	Nutrients, temperature, organic enrichment/low dissolved oxygen, microcystin	TMDL in progress	Regional Water Board

Oregon and California have formed a technical team in conjunction with USEPA and its contractor Tetra Tech, Inc. to develop a uniform water quality model of the basin and conduct joint analyses to ensure compatible TMDLs. However, the states will establish

[3] Hydrologic Area (HA) is the terminology used in the CalWater watershed delineation system to identify a sub-unit of a watershed. Similarly, Hydrologic Sub Area (HSA) identifies a smaller hydrologic unit within a HA.

independently the TMDLs for those portions of the basin within their respective jurisdiction. Oregon is not bound by the deadlines associated with the above referenced consent decree. Further, California proposes the recalculation of the SSOs for DO as contained in the Basin Plan, as an additional action not applicable in Oregon.

California has listed separately several of the major tributaries to the Klamath River as impaired; these are identified in Table 1.2. Each tributary watershed is listed for its own site-specific list of pollutants but generally include: elevated water temperature, elevated nutrients, depressed dissolved oxygen levels and excess sediment. Either technical TMDLs or TMDLs with Action Plans have been developed and approved for each of the major tributary watersheds.

1.2 Report Organization

As noted above, this document is the Staff Report supporting the Action Plan. Appendix 1 includes a separate staff report for the recalculation of the SSOs for DO in the mainstem Klamath River. This report contains several standard elements (summarized below) including:

- Chapter 1 – Introduction
- Chapter 2 – Problem Statement
- Chapter 3 – Analytic Approach
- Chapter 4 – Pollutant Source Analysis
- Chapter 5 – Klamath River TMDLs - Allocations and Numeric Targets
- Chapter 6 – Implementation Plan
- Chapter 7 – Reassessment Monitoring Program
- Chapter 8 – Antidegradation Analysis
- Chapter 9 – California Environmental Quality Act (CEQA) Environmental Analysis
- Chapter 10 – Economic Analysis
- Chapter 11 – Public Participation

Chapter 1 describes the regulatory framework for the Klamath River TMDLs and recalculation of the SSOs for DO in the mainstem Klamath River, and presents an overview of the Klamath River basin. Chapter 2 provides the assessment framework for the TMDL and recalculation of the SSOs for DO; assesses water quality conditions in the basin; and documents impairments. Chapter 3 describes the TMDL model and its use in developing the source analysis and allocations for the TMDL as well as its use in the recalculation of the SSOs for DO. Chapter 4 assesses the sources of water quality impairment in the basin and their relative contribution to the overall load of pollutants. Chapter 5 assigns pollutant load and waste load allocations and establishes numeric targets consistent with water quality standards. Chapter 6 describes a program of implementation and includes measures necessary to achieve the Klamath River TMDLs and recalculation of SSOs for DO in California. Chapter 7 describes the monitoring necessary to assess the degree of success associated with the TMDLs, the recalculation of the SSOs for DO and their implementation. Chapter 8 briefly describes the state and federal antidegradation policies and how they apply to the Action Plan. Chapter 9 describes the steps Regional Water Board staff have taken to comply with CEQA, and presents the findings of the CEQA analysis. Chapter 10 analyzes the potential economic benefits and costs that may result from the adoption and implementation of the proposed Action Plan. Chapter 11 describes some of the opportunities that have been made available to the public for comment on and participation in the development of the Klamath River TMDL Staff Report and Action Plan. See Appendix 1 for a discussion of the opportunities for public review associated with the Proposed Site Specific Dissolved Oxygen Objectives for the Klamath River in California (Klamath River DO Staff Report).

1.3 TMDL Development and Adoption Process

Regional Water Board staff submitted a Peer Review Draft Staff Report to outside scientific peer reviewers for review of the technical elements associated with the TMDL. (See Appendix 1 for discussion of the peer review process associated with the Klamath River DO Staff Report). Staff prepared a response to the peer review comment document and revised the Staff Report accordingly. Staff released a Public Review Draft Staff Report for public review and comment in June 2009. The Staff Report accompanied a TMDL Action Plan that summarizes the findings of the TMDLs and describes in detail the proposed plans for implementation, monitoring, and adaptive management. During the summer 2009 public review period, staff conducted public and Board Workshops to present the TMDL and receive oral comments. In December 2009, a revised Staff Report and TMDL Action Plan was released, incorporating revisions based on public comments. Finally, the Staff Report and Action Plan are presented before the Regional Water Board at a public hearing for the purpose of adopting the Action Plan as an amendment to the Basin Plan. Once the Regional Water Board has adopted the TMDL Action Plan, the State Water Resources Control Board (State Water Board) holds a workshop and hearing to confirm the decision of the Regional Water Board. California's Office of Administrative Law provides a final legal review before the TMDL Staff Report and Action Plan are forwarded to USEPA. USEPA approves only the technical TMDL, not the implementation plan components.

1.4 Regulatory Framework and Purpose of the TMDL

The quality of surface and ground waters in the North Coast Region of California is governed by the Water Quality Control Plan for the North Coast Region (Basin Plan) as developed and implemented by the Regional Water Board. The North Coast Region is defined as those waters draining into the Pacific Ocean from the California-Oregon state line to the southern boundary of the watershed of the Estero de San Antonio and Stemple Creek in Marin and Sonoma Counties. The Basin Plan identifies the existing and potential beneficial uses of water within the North Coast Region and the water quality objectives necessary to protect those uses. Together water quality objectives, beneficial uses, and the anti-degradation policy are known as water quality standards. The Basin Plan also prohibits certain activities and requires certain other activities as necessary to achieve water quality standards.

With respect to the Klamath River basin, the Basin Plan prohibits point source waste discharges to surface waters. Point sources are sources of pollutants discharged through a known conveyance, such as an outfall pipe. This prohibition does not apply to point source waste discharges to land, such as discharges to evaporation or percolation ponds. Similarly, the prohibition does not apply to nonpoint source discharges which are the more dispersed flow of pollutants through stormwater runoff.

Under section 303(d) of the CWA, states are required to develop a list of water bodies where legally required pollution control mechanisms are not sufficient or stringent enough to meet water quality standards applicable to such waters. The 303(d) List also includes the pollutant/stressor causing the impairment and a time schedule for addressing the water quality impairment. Placement of a water body on the 303(d) List triggers the development of a TMDL, for each water body-pollutant/stressor combination. The specific requirements for TMDLs are described in the United States Code of Federal Regulations (CFR) Title 40, sections 130.2 and 130.7 (40 CFR § 130.2 and 130.7), and section 303(d) of the federal CWA.

A TMDL is in essence a planning and management tool intended to identify, quantify, and control the sources of pollution within a given watershed such that water quality objectives are achieved and the beneficial uses of water are fully protected. A TMDL is defined as the sum of individual waste loads allocated to point sources, load allocations assigned to non-point sources, and loads assigned to natural background conditions. Loading from all pollutant sources must not exceed the loading or assimilative capacity (TMDL) of a water body. To account for uncertainty, CWA section 303(d) requires that TMDLs are established with a margin of safety.

The USEPA has federal oversight authority for the CWA section 303(d) program and may approve or disapprove TMDLs developed by the states. Under the terms of the consent decree (*Pacific Coast Federation of Fishermen's Association, et. al. v. Marcus*), if USEPA disapproves the Klamath River TMDLs as developed by the Regional Water Board, then USEPA must itself establish the TMDLs by the date specified in the decree.

The Regional Water Board, under the state's Porter-Cologne Water Quality Control Act, has the obligation to establish an Action Plan by which TMDLs are implemented. Action Plans are adopted by the Regional Water Board and incorporated as an amendment into the Basin Plan. USEPA, on the other hand, does not have this obligation. TMDLs developed by USEPA include the technical analysis only, and are then forwarded to the Regional Water Board for implementation. The States of Oregon and California utilize their authority to implement TMDLs by different methods. See <http://www.oregon.gov/DEQ/WQ/index.shtml> for information on Oregon's TMDLs and implementation planning methods.

The purpose of the Klamath River TMDLs is to estimate the assimilative capacity of the system with respect to the total loads of nutrients and organic matter that can be delivered to the Klamath River without causing an exceedance of the water quality objectives for nutrients and dissolved oxygen. The TMDLs must also establish the amount of protection from solar radiation and cold water withdrawals necessary to meet water quality objectives for water temperature.

Assessing the assimilative capacity of the system begins with an estimate of water quality under natural baseline conditions. Having simulated the natural baseline conditions, anthropogenic sources of nutrient and organic matter loads are incrementally added back into the models until that point at which water quality objectives are just being met. A somewhat different but similar approach is used for temperature to assess the assimilative capacity of the river for solar radiation and cold water withdrawals. This then forms the basis for the TMDLs. The geographic scope of these TMDLs includes the entire Klamath River hydrologic area[4] (HA) in California, not including those reaches of the Klamath River that lie within the Hoopa Valley Indian Reservation and Yurok Reservation.

1.5 Other Ongoing Regulatory Processes in the Klamath River Basin

TMDLs must consider other ongoing regulatory processes in the basin. Already described is the recalculation of the SSOs for DO in the mainstem Klamath River. Of additional relevance to water quality are:

- The Tribal Trust responsibilities of the United States government to Tribes and individual Indians.
- The need for consultation under the federal Endangered Species Act with the National Oceanic and Atmospheric Administration Fisheries (NOAA Fisheries) and U.S. Fish and Wildlife Service on projects affecting listed species occurring in the Klamath River and its watershed, and
- The relationship between the TMDL process and the water quality certification process under section 401 of the CWA associated with the relicensing application submitted by PacifiCorp to FERC for the operation of hydroelectric facilities on the Klamath River mainstem.

1.5.1 Tribal Trust Responsibilities

The United States has a trust responsibility to protect and maintain rights reserved by, or granted to, federally recognized Tribes and individual Indians, by treaties, statutes, and executive orders. The trust responsibility requires that federal agencies take all actions reasonably necessary to protect trust assets, including the fishery resources of the Indian Tribes in the Klamath River basin. The Regional Water Board must consider federal Tribal Trust responsibilities in the Klamath River basin since TMDLs are subject to the approval of the USEPA. The Regional Water Board will assist USEPA in fulfilling Tribal Trust responsibilities by adopting an Action Plan that restores and maintains pollutant levels that are protective of anadromous fish and other beneficial uses related to

---

[4] Hydrologic Area is the terminology used in the CalWater watershed delineation system to identify a sub unit of a watershed, involving a major river.

the Tribes of the Klamath River in California, including the Hoopa, Karuk, Quartz Valley, and Yurok Tribes and the Resighini Rancheria to the degree that natural conditions allow.

1.5.2 ESA Consultation

The USEPA and Regional Water Board initiated an informal consultation process with the United States Fish and Wildlife Service (USFWS) and NOAA Fisheries on the Klamath River basin TMDLs in California. USEPA and Regional Water Board staff have used this process to provide information and updates on the TMDLs in the Klamath River basin (e.g., the Salmon, Scott, Shasta, Lower Lost, and Klamath River TMDLs). USEPA has an obligation to consult with federal wildlife agencies on any action that may affect the wildlife trust responsibilities of these agencies. The Regional Water Board must consider the federal wildlife trust responsibility in the Klamath River basin since TMDLs are subject to USEPA approval. The Regional Water Board will assist USEPA in fulfilling wildlife trust responsibilities by adopting an Action Plan that restores and maintains pollutant levels that are protective of threatened or endangered species including anadromous fish, and other cold water species, and their habitat.

1.5.3 Water Quality Certification

PacifiCorp currently operates hydroelectric facilities on the Klamath River in southern Oregon and northern California. On February 23, 2004, PacifiCorp transmitted its application for a new 50-year license for the Klamath Hydroelectric Project to the Federal Energy Regulatory Commission (FERC). Associated with its application for a new license is the obligation to submit documentation under section 401 of the CWA to the State Water Board and ODEQ that demonstrates compliance of the proposed project with state water quality standards. The State Water Board then reviews the documentation and issues its water quality certification (401Certification) if the information indicates that water quality standards will be met. The certification can include conditions in order to ensure that water quality standards are met. A certification is denied if water quality standards will not be met by the project as proposed.

As a result of its review of the submitted documents, the State Water Board issued a letter on February 26, 2007 indicating that PacifiCorp had not adequately documented its assertion that water quality will be protected by the relicensing of the hydroelectric facilities. Additional studies of several areas of concern are required before 401 Certification can be issued. In addition, an environmental impact review under the CEQA is required before a certification can be issued. A key question under consideration in the certification review process is whether or not the proposed project will meet the TMDLs.

1.5.4 Klamath Basin Restoration Agreement, Agreement in Principal, and Klamath Hydroelectric Settlement Agreement

The Klamath Basin Restoration Agreement (KBRA) is a negotiated settlement agreement between as many as 26 different parties designed to settle long-standing disputes in the Klamath River basin. It focuses on water allocations in the upper basin, provides for fisheries restoration and is structured around the central assumption that an agreement to remove the lower four Klamath River Dams will be reached. On November 13, 2008, an Agreement in Principle (AIP) to remove four Klamath River dams was announced after negotiations between the federal government, representatives from the state of California, the state of Oregon, and PacifiCorp. Regional Water Board staff were not a party to the KBRA or AIP negotiations. On September 30, 2009, a draft Klamath Hydroelectric Settlement Agreement (KHSA) was released. The final KBRA and KHSA agreements may affect the TMDL implementation schedule, which relies on the FERC relicensing process and subsequent water quality certification by the State Water Board. As currently drafted, the KHSA contemplates federal legislation that would allow PacifiCorp to remain on annual licenses from FERC, thereby indefinitely delaying the 401 certification and Clean Water Act compliance. See Chapter 6 for additional discussion.

1.6 Physical Setting

It is useful to orient the reader to the physical setting within which the TMDLs for the Klamath River basin are developed as a way of establishing the background conditions influencing pollutant levels in the system. The topography of the basin, the bedrock geology, soils, vegetation and climate each play a role in shaping the particular surface water and ground water hydrology of the basin. Similarly, these factors play a role in the fate and transport of instream pollutants. More detailed descriptions of the physical setting of the Klamath River basin have been reported extensively in numerous available publications including:

- Federal Energy Regulatory Commission. 2007. Final Environmental Impact Statement for the Klamath Hydroelectric Project. Docket No. P-2082-027. November 18, 2007. U.S. DOE, FERC, Washington D.C.
- National Research Council of the National Academies (NRC). 2004. Endangered and Threatened Fishes in the Klamath River Basin. Washington, D.C. National Academies Press.

1.6.1 Population and Land Ownership

The human population in the Klamath River basin was estimated in the 2000 US Census to be about 114,000 (United States Census Bureau [USCB] 2000). The largest population concentrations lie in the upper Klamath agricultural area, the Shasta River Valley, and Scott Valley. The largest population center is Klamath Falls in Oregon (19,462 people in 2000) followed by Yreka, California (7,290 people). The Klamath River basin can generally be characterized as a rural watershed with limited population-related water quality issues.

More than two thirds of the Klamath River watershed is in federal ownership. Figure 1.3 shows, among other things, federal lands managed as National Forests, National Wildlife Refuges, and National Parks, in addition to Bureau of Land Management (BLM) land. The largest blocks of private ownership are agricultural areas in the upper Klamath watershed and agricultural and timber properties in the Shasta and Scott Valleys and adjacent areas of the mainstem. Also, much of the Klamath River Valley near the mouth of the river is privately owned.

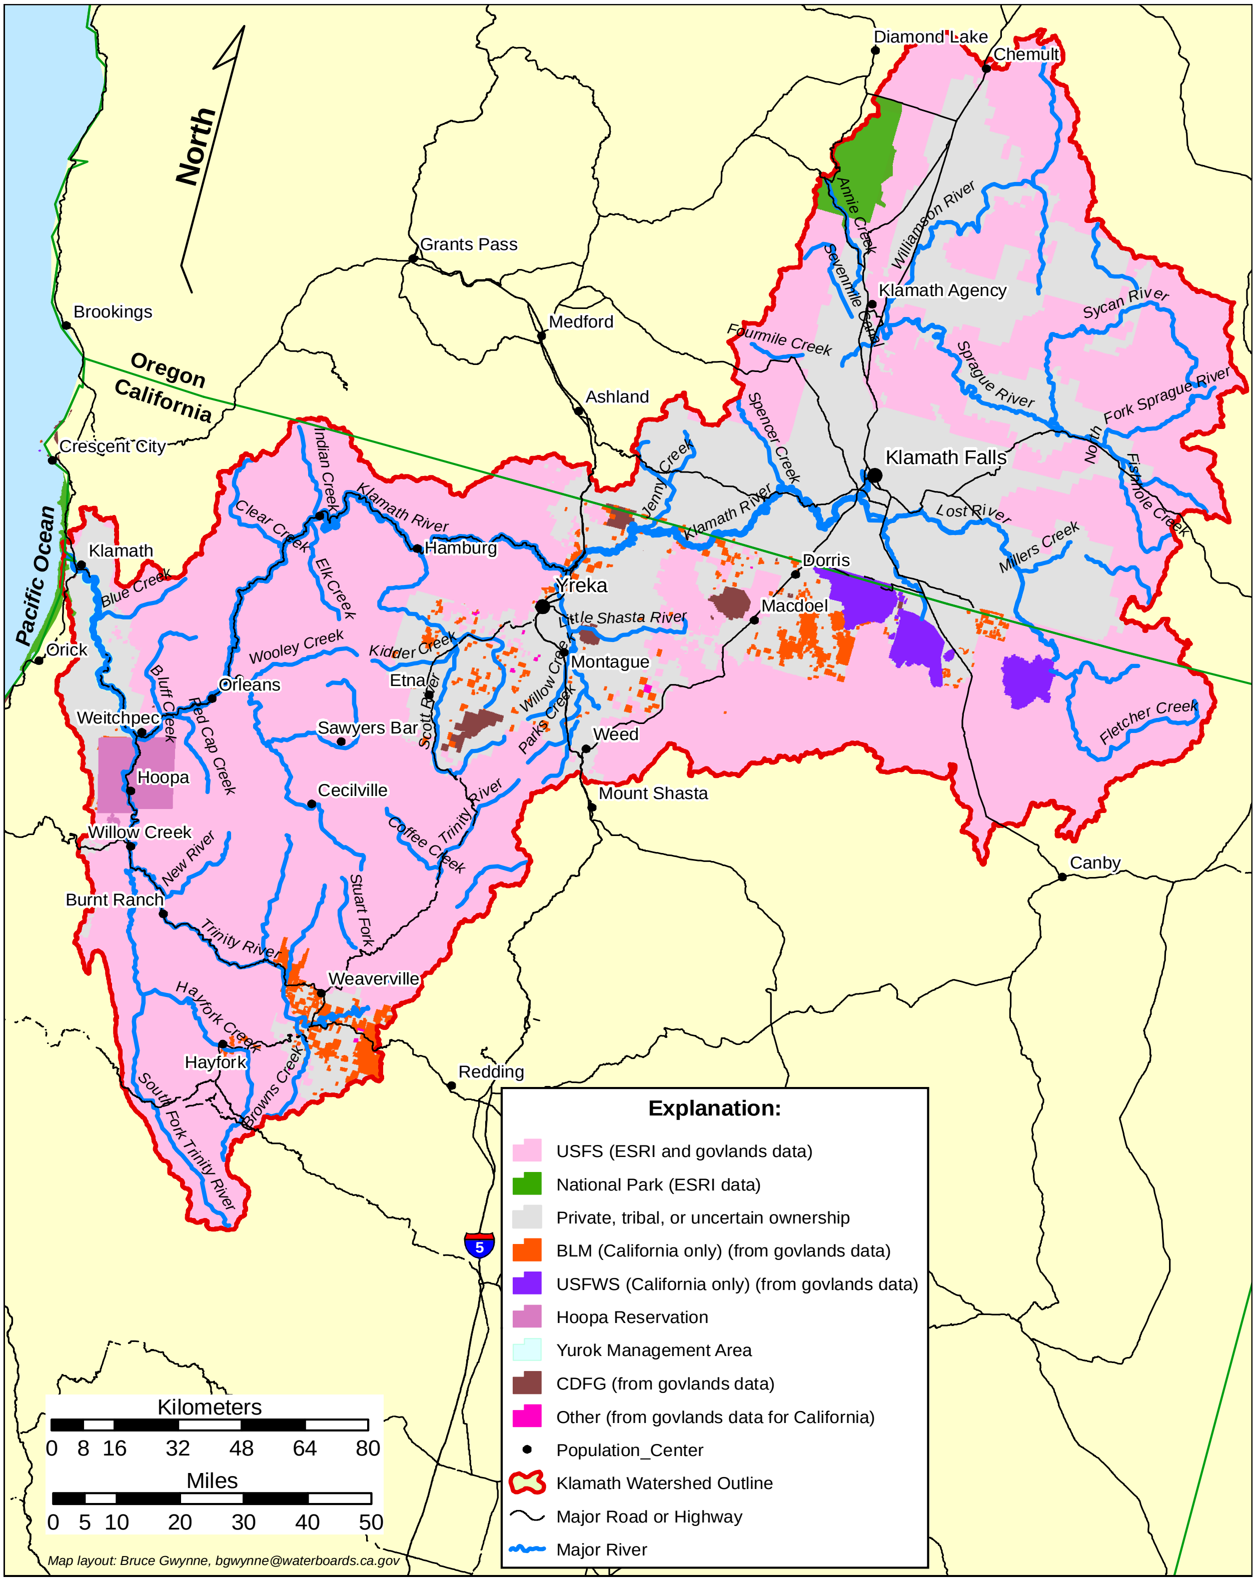

Figure 1.3: Land ownership in the Klamath River basin

The Hoopa Valley Tribe owns land, 12 miles by 12 miles, primarily in the Trinity River watershed but intersecting the Klamath River at Saints Rest Bar upstream of the confluence with the Trinity. The Yurok Reservation's lands extend from 1 mile on each side from the mouth of the Klamath River and upriver for a distance of 44 miles. The Karuk Tribe owns 800 acres of tribal trust land along the Klamath River between Orleans and Happy Camp, and in Yreka, California. The Quartz Valley Indian Reservation is located near Fort Jones and encompasses 174 acres along the Scott River. The Resighini Rancheria spans 228 acres along the south shore of the mouth of the Klamath River.

1.6.2 Topography, Geology and Soils

Topography in the Klamath River watershed varies between steep mountains and flat and rolling valley bottoms with little in between (Figure 1.4). Elevations range from sea level at the river mouth to 14,179 feet (4,322 meters) feet at the summit of Mount Shasta. The Klamath River watershed crosses four recognized geomorphic provinces, each of which is defined and shaped by its unique geologic history. From east (upstream) to west (downstream) these provinces are the Modoc Plateau, Cascade Range, Klamath Mountains, and Coast Ranges (Figure 1.5). These geomorphic provinces, defined by Oakshott (1978), are the result of the different structure and composition of the underlying rocks and different times of uplift and volcanism.

Headwaters of the Klamath gather in the Modoc Plateau, an area of geologically young lava flows (Pliocene and Pleistocene – less than fifteen million years) and flat valleys punctuated by volcanic cones. The rolling valley bottoms are at about 4000 to 5000 feet (1219 to 1524 meters) elevation and the volcanic cones rise a thousand feet higher. While drainage in this young landscape is through-flowing, many depressions contain shallow lakes, most of which have been augmented by dams. Although rainfall is low, the flat and rolling valley bottoms of rich volcanic and organic soils combine with abundance of water entering from higher surrounding country to create historically vast freshwater wetlands. Much of these have been converted to farmland. The volcanic soils are naturally rich in phosphorus, a nutrient of concern in these TMDLs. Similarly, the conversion of wetlands to farmland and other land uses has exposed the nutrient and organic rich soils to oxidation, resulting in the release to the water column of nitrogen and phosphorus previously stored in the soil and wetland vegetation (Snyder and Morace, 1997).

The transition between the Modoc Plateau and Cascade Range provinces is not sharp, so that a line on a map is by necessity a bit arbitrary (Figures 1.5, 1.6). The Cascade Range province is a belt of mainly volcanic rocks that are younger than rocks of most of the Modoc Plateau and form higher relief. The Cascade Range is defined by a chain of active and potentially active volcanoes that stretches from Mount Lassen, east of Redding, northward through Oregon and Washington into Canada. The most prominent mountain in the Klamath region is Mount Shasta, a composite volcano that rises at the head of Shasta Valley, and which last erupted about 1786. Crater Lake, in the northeast, fills the collapse crater of a volcano that erupted cataclysmically about 7,000 years ago.

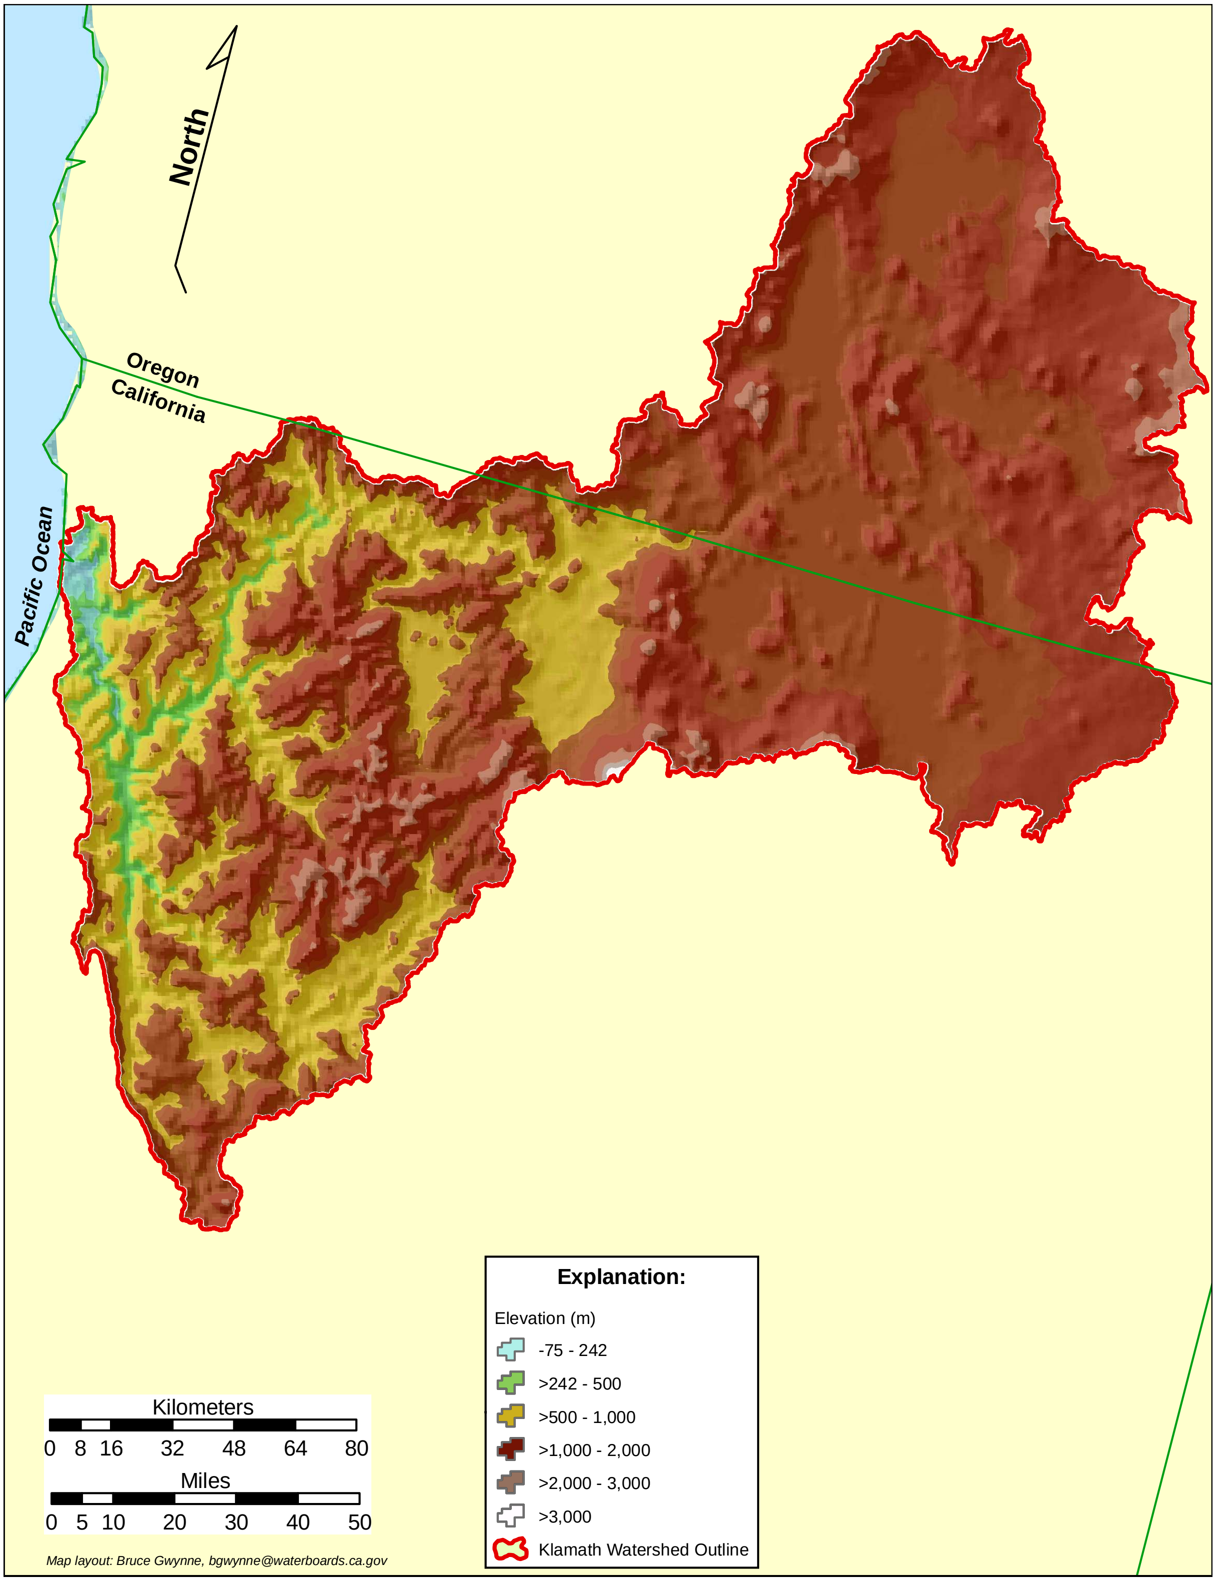

Figure 1.4: Land elevation in the Klamath River basin

Figure 1.5: Geomorphic provinces in the Klamath River basin - Source: Oakshott 1978

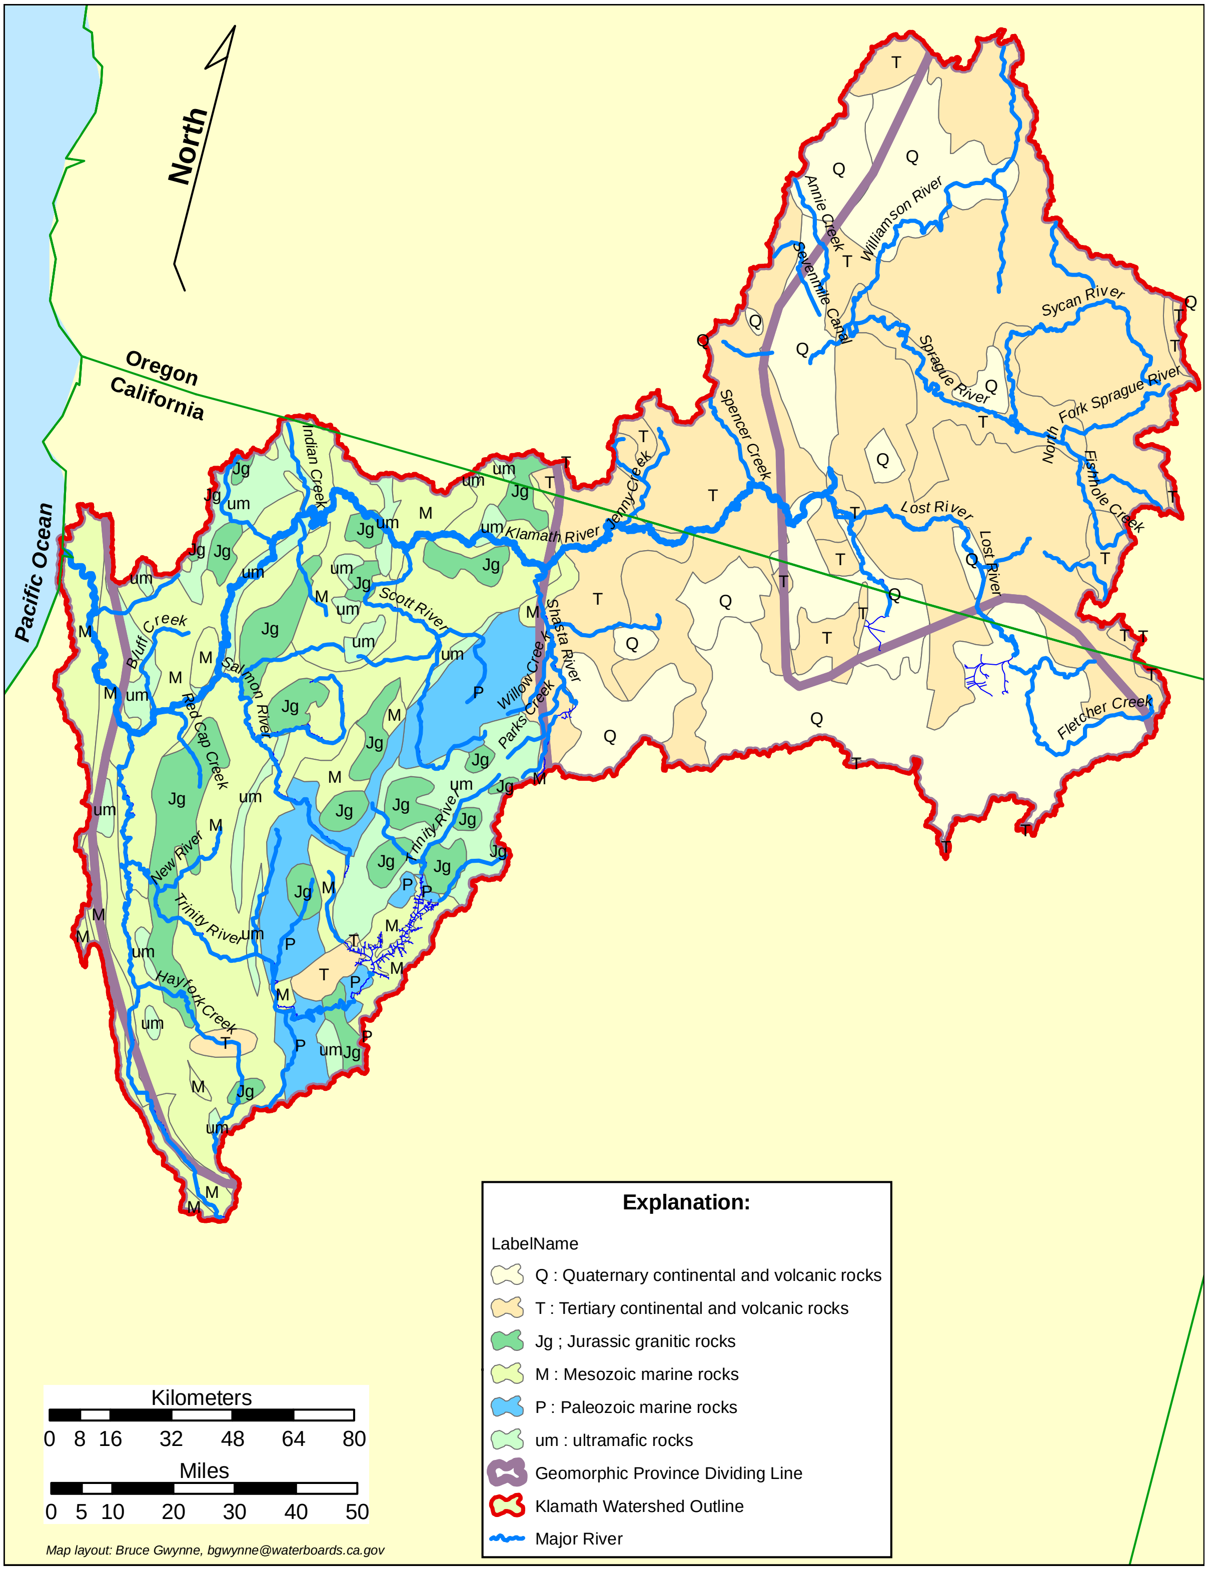

Figure 1.6: Geologic map of the Klamath River basin
Source: Modified from Schruben et al. (1997)

The border between the Cascade province and the Klamath Mountains province is spanned by Shasta Valley and covered by a unique deposit. Most of the floor of this valley is disrupted rolling topography of small hillocks and closed depressions. Crandell (1989) recognized this landscape as the deposits formed by a huge avalanche and debris flow, or series of such events, shed off the north flank of Mount Shasta more than 300,000 years ago.

The Klamath Mountains province is very steep and rugged for the most part and in the Klamath River watershed consists of several irregularly oriented ranges – the Trinity Alps, Scott Bar Mountains, Siskiyou Mountains, and Marble Mountains. Shasta and Scott Valleys have broad flat valley bottoms that support agriculture, but other valleys are narrower and steeper and therefore less developed. Most of the land in the Klamath Mountains province is in federal ownership (Figure 1.3), and this rugged landscape lends itself more to timber harvest and cattle grazing than to crops.

The bedrock geology of the Klamath Mountains province is extremely varied and complex (Figure 1.6) and largely made up of ocean-floor igneous and sedimentary rocks of a large range in ages. Most of the igneous rocks in this province are dark colored mafic and ultramafic rocks of both intrusive and extrusive origin, most of which have been partly or wholly altered to serpentine and otherwise metamorphosed. Younger, light colored granitic rocks have been intruded in some places. Recent uplift has created a landscape of rapidly downcutting streams and steep slopes that are subject to rapid erosion and landsliding. The granitic rocks in particular weather to form loosely consolidated material that sloughs and ravels easily when disturbed.

The Coast Ranges province, the westernmost province (Figure 1.5), forms about 20 miles of the lower Klamath River valley and part of the west side of the valley of the lower Trinity River and South Fork Trinity River. These rivers have exploited the fault zone that forms the geologic boundary between the Klamath Mountains province and the Coast Ranges province. The Coast Ranges are steep, but are generally more rounded and not as high as the mountains of the Klamath Mountains province. Bedrock is the Franciscan Complex, which is structurally deformed and highly varied. The mix of sedimentary rocks includes sandstone, siltstone, shale, conglomerate, greywacke, and chert. Parts of the complex have been metamorphosed and include blueschist and greenschist as well as low grade mica schist. Some areas are mélange, which is geologic terrain that has been deformed and mixed by prolonged and complex tectonic movement, and lacks continuity of structure, rock type, or age.

The gradient profile of the Klamath River is anomalous for a large river in that it is generally low gradient in the headwaters in the Modoc Plateau and steeper farther downstream (Figure 1.4). This unusual gradient is largely the result of geologic uplift in the upstream portion of the river basin in recent geologic time.

1.6.3 Vegetation

Vegetation in the Klamath varies greatly with elevation, precipitation, and degree of disturbance. Figure 1.7 shows the major classifications of vegetation (Thematic Mapper

GIS database). Conifers dominate in the steep mountains and the higher elevations. Hardwood forest and shrubs are more abundant in the lower country, which tends to be warmer and dryer. In many parts of the region a transition zone of mixed conifer and hardwood separates areas classified as conifer forest and hardwood.

1.6.4 Climate

The great geographic extent and topographic relief of the Klamath River watershed combine to produce a wide variety of climate conditions (Figure 1.8). On average, the climate is characterized by dry summers with high daytime temperatures and wet winters with moderate to low temperatures. About three quarters of the annual precipitation falls between October and March, producing a snowpack in the higher mountain ranges that feeds streamflow in many lower areas through the summer. As major storms move in from the Pacific Ocean, the moisture-laden air rises over the coastal mountain ranges and condenses as rain and snow (California Department of Water Resources [CDWR] 1986). Further inland, in the valleys of major tributaries and over the lower terrain of the upper Klamath basin, a rain shadow effect is created, and less moisture falls (Figure 1.8).

This space intentionally left blank

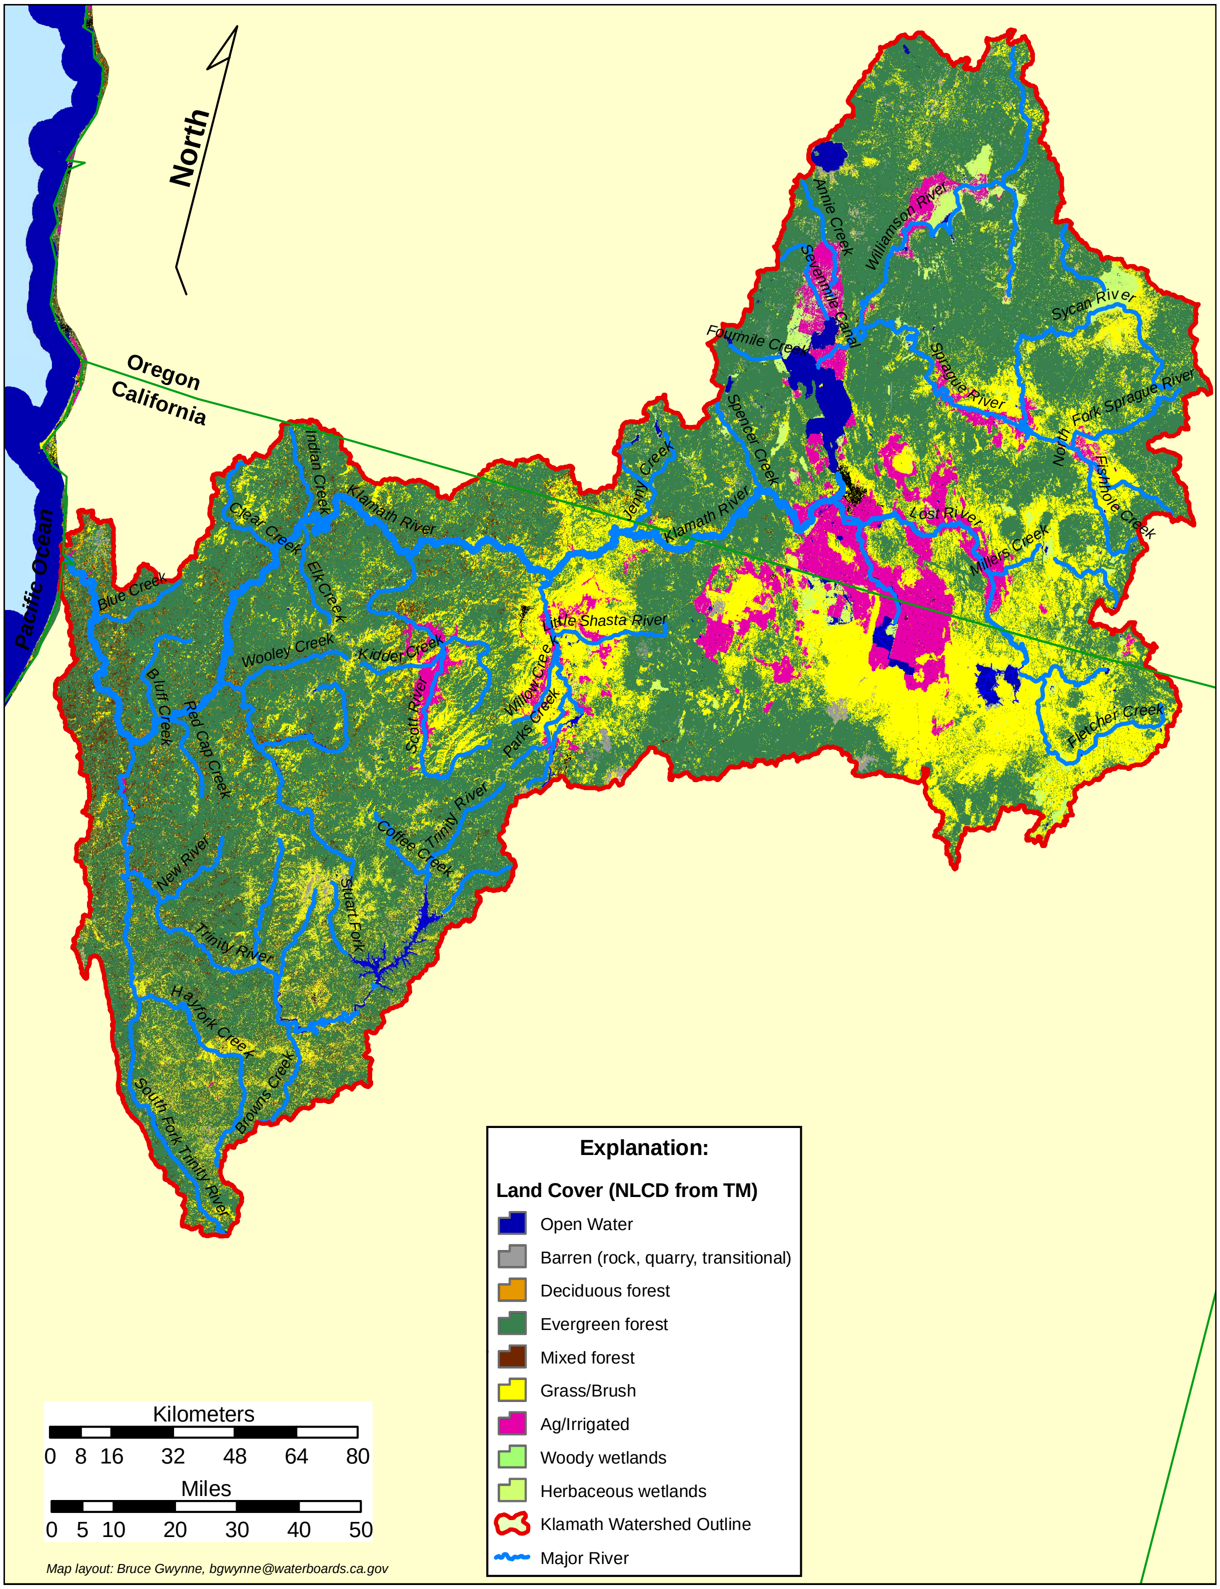

Figure 1.7: Vegetation and land cover of the Klamath River basin

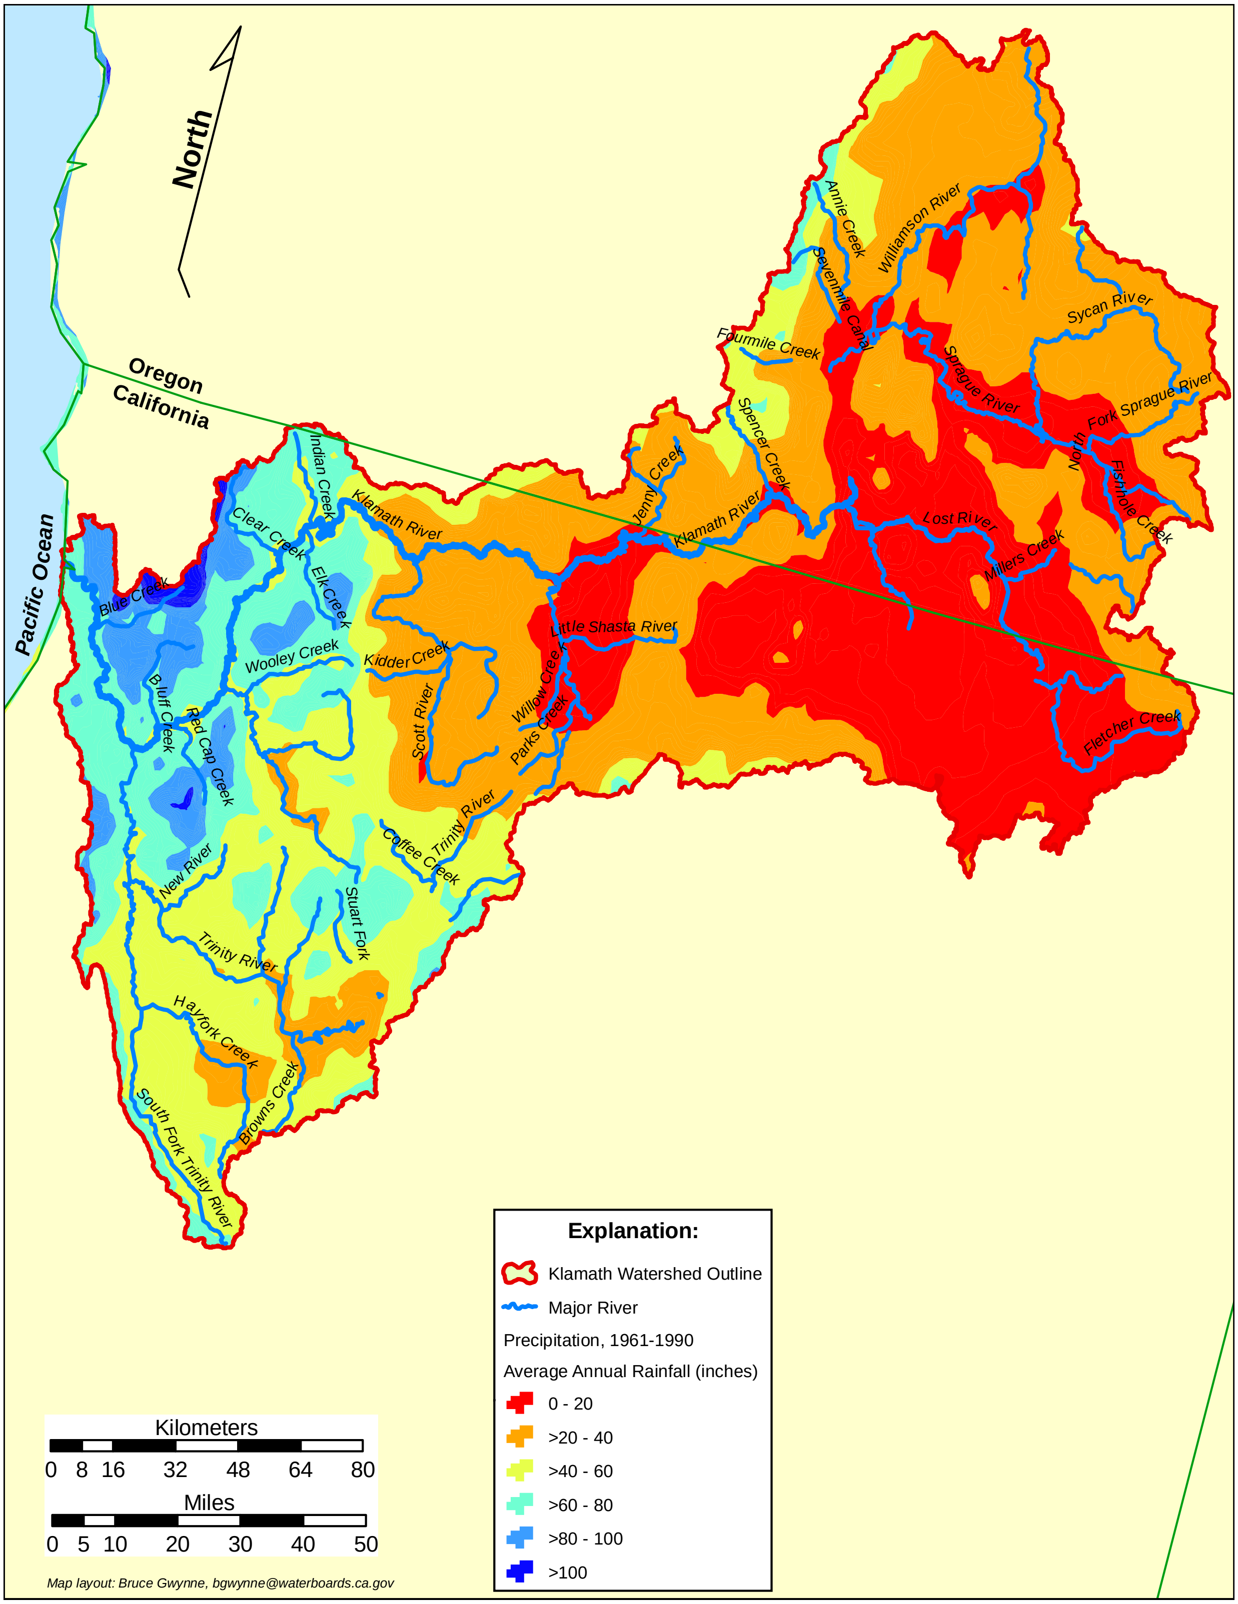

Figure 1.8: Average annual rainfall in the Klamath River basin
Source: United States Department of Agriculture (USDA) Undated

Figure 1.9 provides a comparison of monthly precipitation values from Orleans, California in the mountainous country of the lower Klamath basin and Klamath Falls, Oregon in the broad valley of the upper Klamath basin as an illustration of rainshadow effect. The mean annual precipitation in the Klamath River watershed is about 32 inches (CDWR 1986); but, local averages range from more than 80 inches in the high elevations to 10 inches in the broad inland valleys (CDWR 1986; United States Forest Service [USFS] 1996).

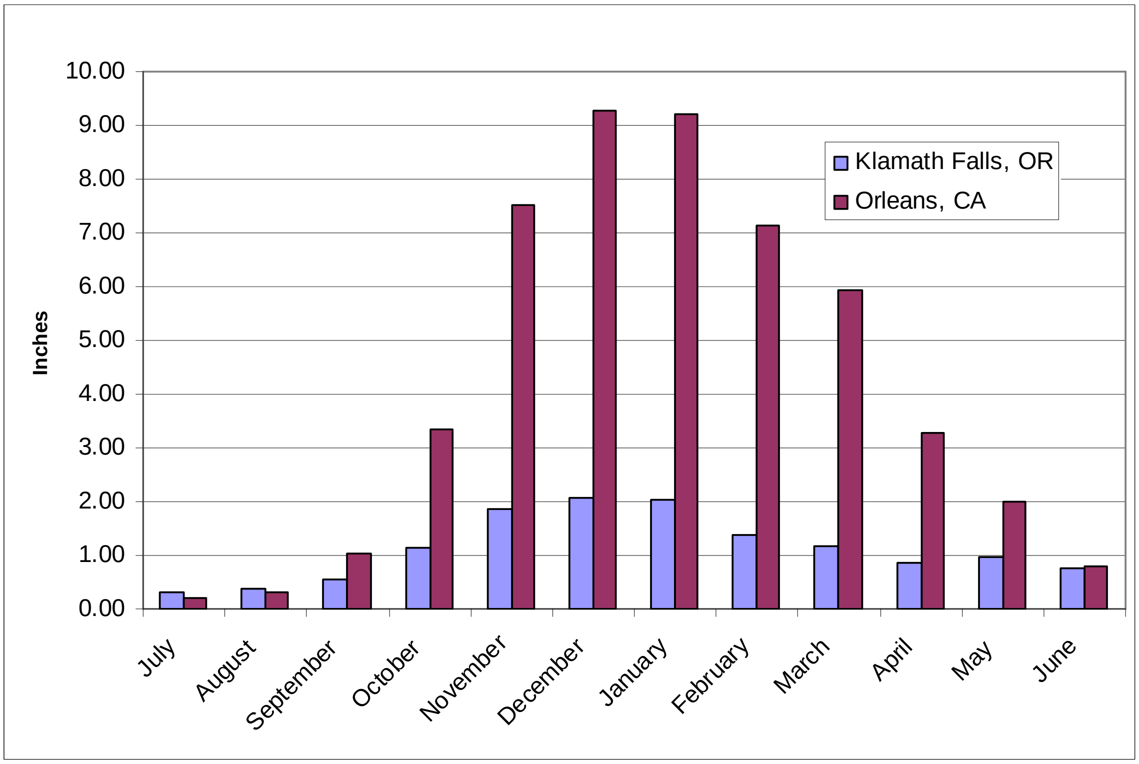

Figure 1.9: Average Monthly Precipitation, 1905-2003, in Klamath Falls, Oregon and Orleans, California
Source: California Data Exchange Center [CDEC] 2006; Oregon Climate Service [OCS] 2006

In the 20th century the Klamath River watershed was characterized by a pattern of floods and droughts. This pattern is discussed by The Klamath River Basin Fisheries Task Force [KRBFTF] (1991, p. 2-3 to 2-7). During a drought in 1976-77, precipitation was only 20 percent of normal in the Scott River watershed and 40 percent of normal in the upper Klamath River basin. The largest floods occurred when relatively warm storm systems melted a pre-existing snow pack such as occurred in 1861, 1955, 1964, 1974 and 1997 (USFS 2000, p.3-3). Many areas of the Klamath River watershed, mostly in the middle third of the basin, are susceptible to these rain-on-snow events.

Klamath Basin air and water temperature data indicate that air and water temperatures have been steadily increasing since at least the 1960s. Bartholow (2005) analyzed air and water temperature records distributed throughout the Klamath basin and evaluated water temperatures simulated using a computer-based water temperature model. The results of Bartholow's analysis strongly suggest a trend of water temperature increases of approximately 0.5 ^{o}C per decade since the 1960s.

1.6.5 Hydrology

Drainage density in the Klamath River watershed is affected by infiltration capacity, tectonics, and underlying bedrock. Figure 1.10 shows dense drainage networks in the steep, recently uplifted ranges to the west and in the volcanic mountains to the east. The lower, flatter country in the upper Klamath, in the region of Klamath Falls, has a much lower drainage density and is punctuated by lakes and wetlands associated with local tectonic subsidence.

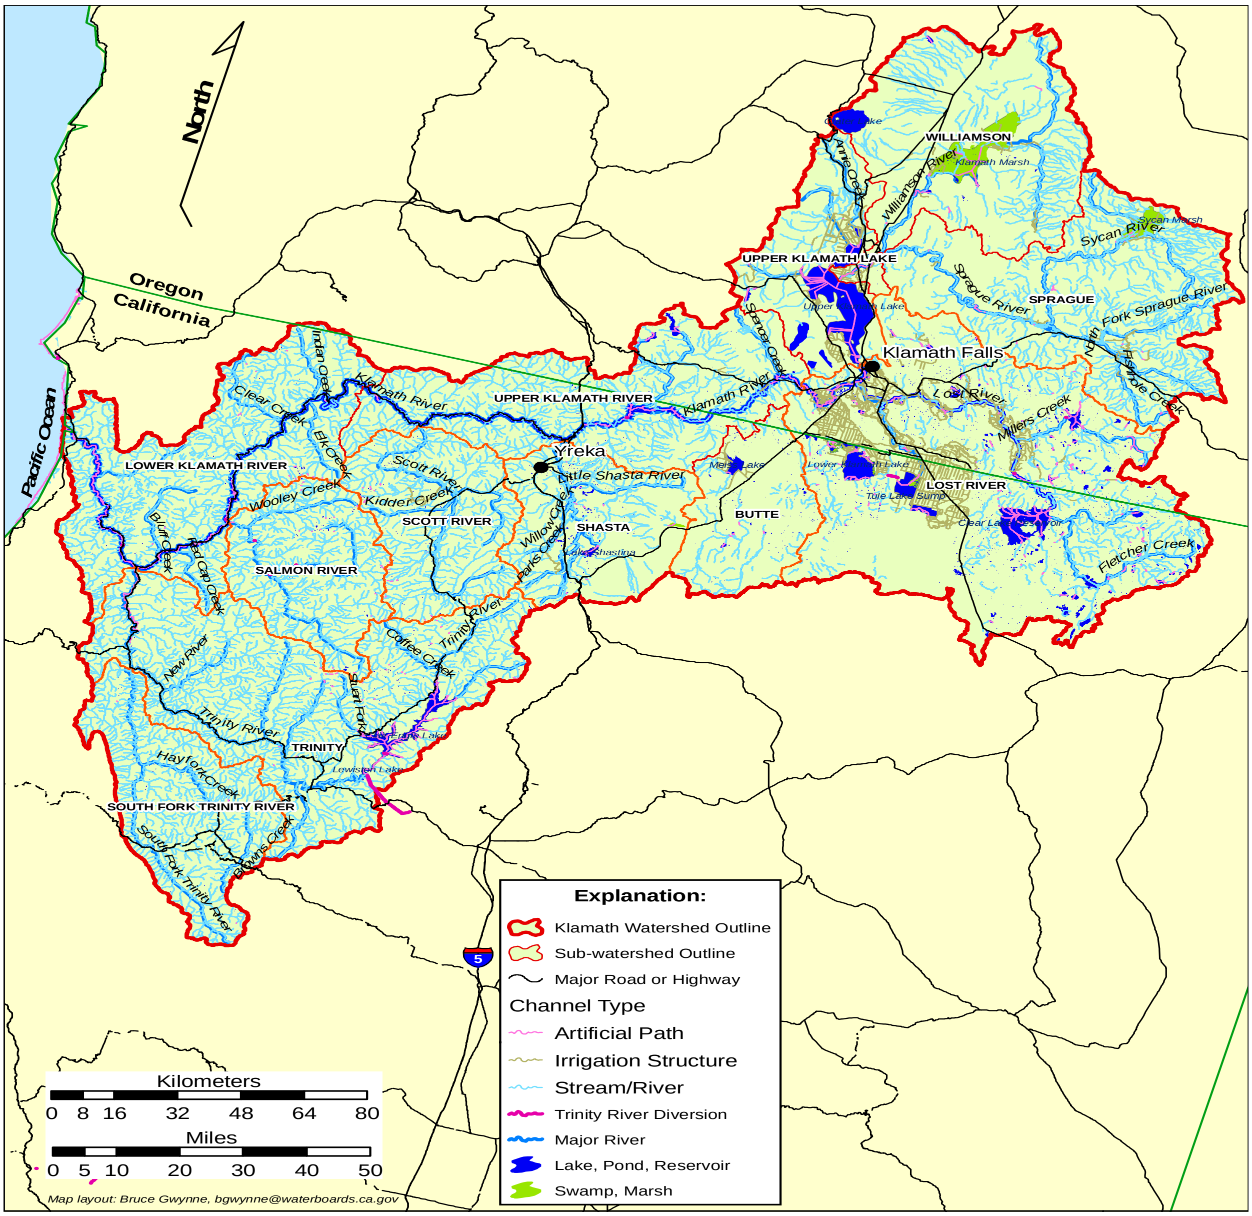

Figure 1.10: Map of Klamath River basin emphasizing subbasins and surface drainage

Water yield in the Klamath basin varies by watershed setting. As illustrated in Figure 1.11, approximately half of the February flow measured in the lower watershed at Klamath, California is drained from that portion of the basin from Orleans, California to Klamath, California, representing about a third of the basin's area. Conversely, only 7 percent of the flow originates in the upper one third of the basin. This pattern is not as dramatic in the summer months when water yield is more generally proportional to drainage area. It is important to recognize that the data presented in Figure 1.11 shows the pattern of flow associated with a history of consumptive use (e.g., Klamath Project in the upper basin) and altered flow timing (e.g., controlled releases from Upper Klamath Lake). However, these factors do not affect the above observations with respect to winter flows.

Source: United States Geological Survey [USGS] 2006

1.6.6 Water Use

There exist in the Klamath River basin numerous dams and diversions associated with power generation and irrigation. The histories of many of these are well documented and the effects on water yield quantified. The effects of diversions granted under riparian rights and groundwater withdrawals, however, are not well understood. Beginning around 1850, small dams and diversion ditches were built on smaller tributaries for use in mining and irrigation. Starting out small and temporary in nature, some became more fixed as established use persisted. As early as 1930, these more permanent diversion structures were creating barriers to fish migration (KRBFTF 1991, p.2-40, 2-62). Among the mining dams, some were left in place after cessation of mining, creating additional barriers (KRBFTF 1991, p.2-62).

Beginning in the 1890s, hydroelectric power facilities were installed, first on the Shasta River, then on the Link River. California Oregon Power Company (COPCO) built Copco Number 1 Dam and Copco Number 2 Dam between 1917 and 1925. These comprise the first major hydroelectric facilities built on the mainstem of the Klamath River (KRBFTF 1991, 2-62 to 2-64).

Prohibitions on the construction of any obstructions in the Klamath River downstream from the mouth of the Shasta River were enacted as a result of Proposition 11 passed in a statewide election of 1924 (KRBFTF 1991, p. 2-64). This effectively ended the prospective efforts to build major hydroelectric and diversion projects in the Klamath River below the mouth of the Shasta River; though no such protections were afforded the flows above the confluence with the Shasta. In 1958, J.C. Boyle (Big Bend) Dam went online just upstream of the California state line.

In 1962 Iron Gate Dam was built below Copco 1 and 2 at river mile 190. From this point to the ocean the river is protected as free flowing under the National Wild and Scenic Rivers System. Iron Gate Dam was originally built to attenuate flow variations caused by the operations of Copco 1 and 2 Dams. These dams are operated as peak demand generation facilities.

Most of the Klamath River water is used in the Klamath River basin, including the use of water for crop and pasture irrigation within the Williamson River, Sprague River, Lost River, Shasta River, Scott River, and South Fork Trinity River. Facilities built to support consumptive uses in California include the U.S. Bureau of Reclamation Klamath Project (construction began in 1906, first water delivered in 1907) and Lake Shastina (created by the construction of Dwinnell Dam on the Shasta River in 1928). A total of 240,412 acres of irrigable lands, including 235,667 acres of farmland, and 4,745 acres of residential, commercial, and industrial lands, are served by Klamath Project infrastructure.

In addition to in-basin use, however, there are also significant diversions out of the basin maintained for agriculture and power generation: The Lewiston and Trinity Dams were completed in 1964 on the Trinity River to enable a significant transfer of flow out of the Klamath watershed and into the Sacramento River system. An additional, smaller, out-of-basin diversion occurs from the upper tributaries in the Jenny Creek watershed in Oregon and into the Rogue River watershed in Oregon.

The pattern of water use, on the other hand, is nearly the opposite of the pattern in drainage density and water yield. That is, the majority of the diversions in the basin are upstream of Seiad Valley where the least amount of the water is produced. As demonstrated by Figure 1.12, some of the effects of this pattern of water use are to:

- Move the timing of the peak spring flows from mid-April to mid-March;
- Make steeper the decline in the spring hydrograph, thus reducing flows by roughly 65-70% in June and July, 45% in May, 20-25% in April, and 35-40% in August;
- Lower the minimum summer flows; and
- Move the timing of the minimum summer flow from mid-September to mid-July

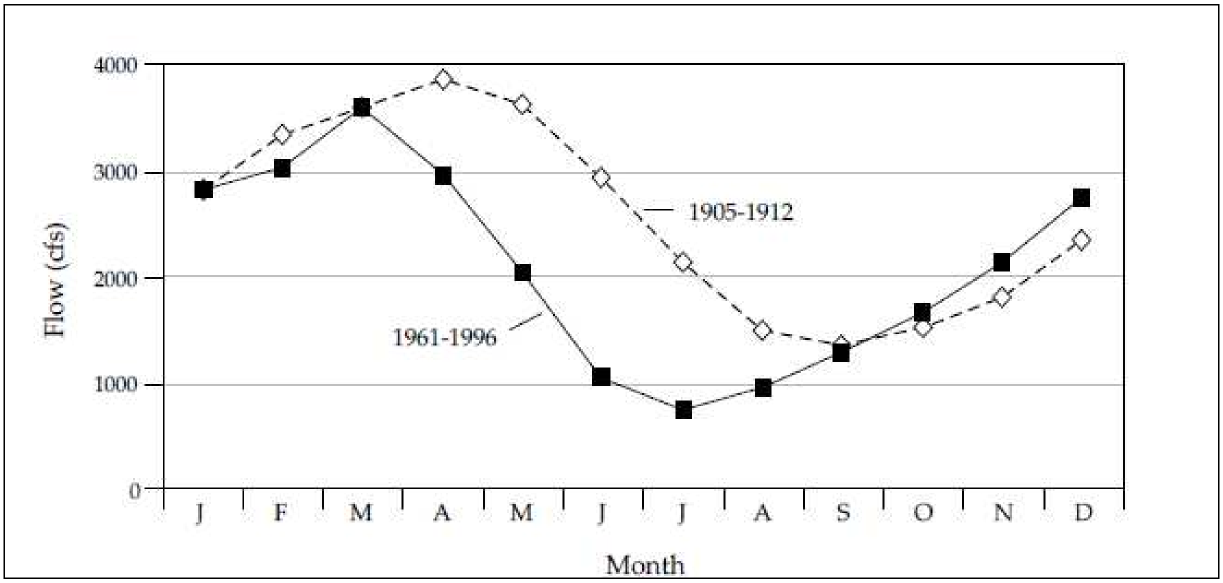

Figure 1.12: Mean monthly flows at Iron Gate Dam in 1961-1996 compared with reconstructed flows for 1905-1912
Source: NRC 2004

The estimated unimpaired flows represented in Figure 1.12 illustrate the magnitude and pattern of flows that would be expected without diversions upstream of Keno, Oregon.

<u>1.6.6.1 Water Rights of the Klamath River Basin, California</u>
Water rights within the State of California are administered by the State Water Resources Control Board, Division of Water Rights (Division of Water Rights) based on three general principles:

- All water belongs to the people of the state;
- Water rights are a right to the use of water;
- Water use must be reasonable and beneficial.

Generally, the appropriative use of surface water after 1914 requires a permit through the Division of Water Rights. Permits identify the maximum amount of water allowed to the user, the timing of permitted use, and the place and purposes of the use. In times of water shortage users with the oldest permits have the first priority to use. Permitting of water rights within the Klamath River basin in California began in June 1916. For the Klamath Basin within California, there are a total of 1614 permitted water rights listed with the Division of Water Rights.

Once all the water within a stream or river has been permitted by the Division of Water Rights for withdrawal, the stream is declared fully appropriated either year-round or during specified months. Table 1.3 lists all the fully appropriated tributaries to the Klamath River in California and below Iron Gate dam, as well as the season during which they are determined fully appropriated. Additionally, the Klamath River itself is determined to be fully appropriated during the entire year.

Table 1.3: Fully appropriated Klamath River reaches and tributaries to the Klamath River in California below Iron Gate Dam

Stream	Tributary	Season Begin-End	Critical Reach
Klamath River	Pacific Ocean	01/01-12/31	From the mainstem about 100 yards below Iron Gate Dam to the Pacific Ocean.
Trinity River	Klamath River	01/01-12/31	The mainstem from 100 yards below Lewiston Dam to the river mouth at Weitchpec.
Salmon River	Klamath River	01/01-12/31	The Salmon River from Cecilville Bridge to the river mouth near Somes Bar.
Scott River	Klamath River	01/01-12/31	The Scott River from the mouth of Shackleford Creek west of Fort Jones to the river mouth near Hamburg.
Shasta River	Klamath River	05/01-10/31	From the confluence of the Shasta River and the Klamath River upstream.
Willow Creek	Klamath River	04/01-11/30	From the York Road Bridge located within Section 8, T46N, R5W, MDB&M upstream.
Seiad Creek	Klamath River	07/01-10/31	From the confluence of Seiad Creek and the Klamath River upstream.
McKinney Creek	Klamath River	03/01-11/30	About 1 ½ miles downstream from the point of diversion on McKinney Creek upstream.
Douglas Creek	Klamath River	06/01-10/31	From a point on Douglas Creek located within the NE 1/4, Section 19, T15N, R7E, MDB&M upstream.

Source: State Water Board 1998, p.8, 13, 56, 57, 58, 64.

The right to use water can under some circumstances be legal without a permit from the Division of Water Rights. Land owners with property adjacent to a waterbody have what is known as a “riparian right” by which they can use water on their river front parcel, so long as the use is reasonable with respect to other users of the waterbody. Groundwater use is also allowed without a permit from the Division of Water Rights if not within the underflow of the river. All water use in California is subject to a constitutional prohibition against waste and unreasonable use or method of diversion.

Table 1.4 summarizes permitted water rights within the Klamath River basin in California, based on the Division of Water Rights, Water Right Information Management System (WRIMS). Table 1.4 groups water rights into reaches of the Klamath River in California including all tributaries. The Shasta, Scott, Salmon, and Trinity Rivers are summarized individually. Summer season (May through August) and winter season (September through April) water rights are summarized and the primary summer season water use is identified. Diversions for the purpose of storage are included in Table 1.4. Uses for stored water include domestic, fire protection, fish culture, irrigation, industrial, incidental power, municipal, power, recreation, stockwatering, and fish and wildlife protection and/or enhancement. The season that water is diverted for the purpose of storage varies from permit to permit. Months of diversion for storage generally occur during the period of November through June. A small portion of permits include the right to divert water throughout the year and only a few allow diversion for storage during the summer months. All values represent the maximum permitted water use.

Table 1.4: Summary of water rights in the Klamath River basin in California below Iron Gate Dam

Reach	Number of Permits	Primary Summer Use	Summer Totals (cfs)	Winter Totals (cfs)	Storage Totals (af)
Klamath River					
Iron Gate to Shasta River	50	Fish Culture	65	49	81
Shasta River to Scott River	76	Domestic	9.6	8.6	0
Scott River to Salmon River	143	Power	25	17	10
Salmon River to Trinity River	66	Domestic	0.006	0.006	160
Trinity River to Pacific Ocean	40	Power	2	2	0
Tributaries					
Tributaries to Iron Gate & Copco	34	Irrigation	72	16	0
Shasta River Watershed	121	Irrigation	982	82	9406
Scott River Watershed	272	Irrigation	255	157	387
Salmon River Watershed	86	Domestic	44	39	6
Trinity River Watershed	726	Municipal	818	593	4442

Source: WRIMS 2006
Note: Summer season is May through August and winter season is September through April.

Dates of permitted water use vary from permit to permit. Table 1.4 groups permitted water rights into summer and winter seasons. Water use permitted during the months of May through August are grouped into the summer totals. Water use permitted during the months of September through April is grouped into the winter totals. Water uses permitted for the entire year are accounted for once in the summer total and again in the winter total.

CHAPTER 2. PROBLEM STATEMENT

2.1 Introduction

In the Klamath River in California increased water temperatures, elevated nutrient levels, low dissolved oxygen concentrations, elevated pH, potential ammonia toxicity, increased incidence of fish disease, an abundance of aquatic plant growth, high chlorophyll-a levels (both planktonic and periphytic algae), and high concentrations of potentially toxinogenic blue-green algae, particularly in the impounded reaches, decrease the quality and quantity of suitable habitat for fish and aquatic life, and have disrupted traditional cultural uses of the river by resident Tribes. These conditions contribute to the non-attainment of beneficial uses, including the most sensitive beneficial uses: those associated with cold water fish and fisheries (including in particular the salmonid fishery) in California, those related to cultural uses and practices, and those related to recreation.

The purposes of the California Klamath River basin TMDL problem statement are to:

- Provide an overarching assessment framework for the TMDL;
- Present a summary assessment of current water quality conditions; and
- Document beneficial use impairments.

The Klamath River numeric and narrative water quality objectives and beneficial uses that are the comparative benchmarks for the problem statement assessment are described in the Regional Water Board's *Water Quality Control Plan for the North Coast Region* **(**Basin Plan). Section 2.2 of the problem statement, Water Quality Standards, consists of a summary description of the Basin Plan and Tribal water quality standards, objectives, and beneficial uses addressed in the TMDL. The Basin Plan and Tribal water quality standards provide the regulatory context for the assessment that follows. Section 2.3, Numeric Targets, presents the numeric water quality targets that represent attainment of applicable water quality objectives used in this TMDL.

Section 2.4, Water Quality Conceptual Models Overview, describes the technical approach used in the problem statement assessment. To ensure a comprehensive assessment and decision framework, the Regional Water Board has adopted the technical approach from the California Nutrient Numeric Endpoints (CA NNE) framework (Tetra Tech 2006). The CA NNE is used to assess and describe the water quality impacts associated with nutrient and organic enrichment and temperature alteration. The approach involves the development of conceptual models that illustrate how key factors and processes link the primary stressors (nutrients and organic enrichment, and altered temperature regime) with impacts on beneficial uses. In addition, the conceptual models can be used to identify key uncertainties and data gaps, provide lines of evidence for numeric targets and allocations, and are useful tools for adaptive management. The conceptual models for the Klamath River focus on water quality related impacts and provide perspective on other factors that contribute to impairment of beneficial uses within the Klamath River basin.

Section 2.5, Evidence of Water Quality Objective and Numeric Target Exceedances, as the title suggests, presents evidence of exceedances of water quality objectives. The Regional Water Board has compiled water quality monitoring data from several sources to support this analysis (e.g., dissolved oxygen, temperature, pH, nutrient enrichment) and CA NNE indicators (e.g., benthic algal biomass, chlorophyll-a, diurnal dissolved oxygen [DO] and pH patterns). The purpose of the analysis of water quality objectives and CA NNE indicators is to evaluate the risk of impairment to beneficial uses. The Section 2.5 analysis uses data from eleven stations along the length of the Klamath River from the Oregon border to its mouth at the Pacific Ocean. (See Appendix 1 for the Klamath River DO Staff report and a discussion of the recalculation of the SSOs for DO in the mainstem Klamath River as currently contained in the Basin Plan).

As detailed in Section 2.6, Evidence of Beneficial Use Impairment, many designated beneficial uses are not being supported in the Klamath River. The purpose of Section 2.6 is to describe how poor water quality conditions are impairing beneficial uses in the Klamath River. The focus is on the status of the elements that are essential to each beneficial use. For example, to evaluate the Cold Freshwater Habitat (COLD) beneficial use, the historical and current status of cold-water fish populations and the associated fishery is compared to demonstrate a significant degradation of cold water fish and fishery related beneficial uses.

Section 2.7, Problem Statement Synthesis, presents the problem statement conclusions regarding the status of Klamath River beneficial uses and the necessity for fully implementing the TMDL in a timely manner. The problem statement conclusions provide the focus for the TMDL pollutant allocations and implementation.

2.1.1 Non-TMDL Factors and Other Regulatory Processes

It is important to recognize that in the Klamath River basin there are factors that affect the condition of beneficial uses that are not directly addressed through the TMDL process. Klamath River beneficial uses are also impacted by other factors including but not limited to:

- The presence of dams which impede passage of anadromous fish;
- Altered flow conditions that affect habitat conditions;
- The presence of hatchery raised fish with the potential for disease and genetic effects;
- Ocean and in-river fisheries harvest rates; and
- Global climate change.

The problem statement description is a required component of any TMDL, but in this case it takes on added importance because of other ongoing regulatory processes and collaborative settlement discussions (i.e., Klamath Hydroelectric Settlement Agreement and Klamath Basin Restoration Agreement) occurring within the Klamath Basin that must be kept clearly distinct from the TMDL process. The other ongoing regulatory processes include:

- The 50-year Federal Energy Regulatory Commission (FERC) relicense for the four mainstem dams included in the Klamath Hydroelectric Project; and
- Endangered Species Act (ESA) consultation for several native species that have special federal and or state status, including but not limited to Coho salmon, shortnose sucker, Lost River sucker, and Bull trout.
- Tribal Trust responsibilities of the USEPA to Tribes and individual Indians.

The mention of these other non-TMDL factors affecting water quality and other ongoing regulatory processes that will address some of these factors is meant to underscore the need for a comprehensive solution to restore ecosystem integrity to the Klamath River basin. The TMDL process described in this document is only one component of a restoration and management program that must be implemented in the next few years to preserve and restore Klamath River water resource related uses.

2.2 Water Quality Standards

The USEPA describes a water quality standard as consisting of four basic elements: 1) designated uses of the water body, 2) water quality criteria to protect designated uses, 3) an antidegradation policy to maintain and protect existing uses and high quality waters, and 4) general policies addressing implementation issues. More information is available at <http://www.epa.gov/waterscience/standards/about/>.

The Porter Cologne Water Quality Control Act (Porter Cologne)[1] modifies USEPA's language to refer to designated uses as "beneficial uses" and water quality criteria as "water quality objectives", which includes the state anti-degradation policy (Resolution 68-16). Porter Cologne also requires a "program of implementation" (Water Code section 13050(i)) for water quality protection in California. A "program of implementation" includes actions necessary to achieve objectives, a time schedule for the actions to be taken, and surveillance to determine compliance with objectives (see Water Code section 13242).

The Regional Water Board has adopted the Basin Plan in which it establishes the region's water quality standards, including the standards that apply to that portion of the Klamath River basin that falls under the jurisdiction of the state of California. The Basin Plan has been approved by the State Water Board and by USEPA and is in full force and effect. Appendix 1 of this staff report includes the Proposed Site Specific Dissolved Oxygen Objectives for the Klamath River in California, a staff report supporting the recalculation of the existing SSOs for DO in the mainstem Klamath River.

Similarly, the Hoopa Valley Tribe has adopted the *Water Quality Control Plan for the Hoopa Valley Indian Reservation* that has been approved by USEPA and is in full effect.

---

[1] The Porter-Cologne Water Quality Control Act (Water Code §§ 13000 et seq.) is the act governing the water quality protection activities of the State Water Resources Control Board (State Board) and the nine regional boards within the state of California.

The Hoopa's standards apply to those portions of the Trinity and Klamath Rivers under the jurisdiction of the Hoopa Valley Tribe[2].

The Yurok and Karuk Tribes have also adopted water quality standards, as has the Resighini Rancheria. These water quality plans and standards have not yet been approved by USEPA, however, and the Regional Water Board will consider their content and use for guidance, as appropriate.

The Quartz Valley Tribe, located along the Scott River, is in the process of developing a document on water quality standards for approval by its Tribal government.

2.2.1 Water Quality Control Plan for the North Coast Region

The Basin Plan (Regional Water Board 2007) is divided into 6 chapters. Of concern to this discussion are Chapter 2 (Beneficial Uses), Chapter 3 (Water Quality Objectives), Chapter 4 (Implementation Plans), and Chapter 5 (Plans and Policies).

2.2.1.1 Beneficial Uses

Chapter 2 of the Basin Plan identifies 28 beneficial uses of water within the North Coast region. Within the Klamath River basin, the following beneficial uses are identified as existing uses:

- MUN—Municipal and domestic supply
- AGR—Agricultural supply
- IND—Industrial service supply
- PRO—Industrial process supply
- GWR—Groundwater recharge
- FRSH—Freshwater replenishment
- NAV—Navigation
- POW—Hydropower generation
- REC1—Water contact recreation
- REC2—Non-contact water recreation
- COMM—Commercial and sport fishing
- CUL—Native American Culture
- WARM—Warm freshwater habitat
- COLD—Cold freshwater habitat
- WILD—Wildlife habitat
- RARE—Rare, threatened, or endangered species
- MAR—Marine habitat
- MIGR—Migration of aquatic organisms
- SPWN—Spawning, reproduction, and/or early development
- SHELL—Shellfish harvesting
- EST—Estuarine habitat
- AQUA—Aquaculture

Of particular importance are those uses that are currently not fully supported due in part to degraded water quality. As detailed in Section 2.5, 17 of the 23 designated beneficial uses for the Klamath River are impaired including: Native American Culture; Subsistence Fishing; Cold Freshwater Habitat; Warm Freshwater Habitat; Rare, Threatened, or Endangered Species; Migration of Aquatic Organisms; Spawning, Reproduction, and/or Early Development; Water Contact Recreation; Non-Contact Water Recreation;

---

[2] The Hoopa Valley Tribe is a sovereign nation with land, 12 miles by 12 miles, primarily in the Trinity River watershed but intersecting with the Klamath River at Saints Rest Bar upstream of the confluence with the Trinity (www.Hoopa-nsn.gov).

Municipal & Domestic Supply; Shellfish Harvesting; Estuary Habitat; Marine Habitat; Aquaculture; Agricultural Supply; Commercial and Sport Fishing; and Wildlife Habitat. Subsistence fishing (FISH) is also listed in the Basin Plan as a beneficial use of the waters in the region. Although the specific areas in which this use exists have not yet been designated in the Basin Plan, this does not alter the need to protect this existing beneficial use.

2.2.1.2 Water Quality Objectives

Chapter 3 of the Basin Plan identifies the water quality objectives deemed necessary to protect beneficial uses. Of concern to this TMDL are the water quality objectives concerning temperature, dissolved oxygen and nutrients. These are the parameters for which instream water quality data indicate exceedances and for which the Klamath River is listed on the 303(d) list as impaired[3]. Additionally, pH is discussed because high pH can be directly stressful to salmonids and it also influences nutrient related parameters such as ammonia toxicity. Toxicity is also discussed as nutrient and temperature impairment contributes to the presence of blue-green algae blooms and associated presence of algal toxins.

Temperature

The Basin Plan contains two separate water quality objectives for temperature. The first objective is the intrastate temperature objective. This objective applies to all waters of the state.

The intrastate temperature objective is a narrative objective with associated numeric criteria and reads:

> The natural receiving water temperature of intrastate waters shall not be altered unless it can be demonstrated to the satisfaction of the Regional Water Board that such alteration in temperature does not adversely affect beneficial uses.
>
> At no time or place shall the temperature of any COLD water be increased by more than 5°F above natural receiving water temperature.
>
> At no time or place shall the temperature of WARM intrastate waters be increased more than 5°F above natural receiving water temperatures.

The second water quality objective for temperature is the interstate temperature objective contained in the state wide *Water Quality Control Plan for Control of Temperature In the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California* (Thermal Plan). The Thermal Plan, as adopted by the State Water Board, is incorporated by reference in the Basin Plan (see Appendix 3 of the Basin Plan). The plan designates the

---

[3] The Klamath River downstream of the Trinity River is also on the 303(d) list for Sedimentation/Siltation, and Copco and Iron Gate Reservoirs are on the 303(d) list for the microcystin toxin.

Klamath River as a “Cold Interstate Water”. The “Cold Interstate Waters” objective is as follows:

> Elevated temperature waste discharges into cold interstate waters are prohibited.

“Elevated Temperature Waste” is defined as:

> Liquid, solid, or gaseous material including thermal waste discharged at a temperature higher than the natural temperature of receiving water. Irrigation return water is not considered elevated temperature waste for the purpose of this plan.

The interstate objective applies to waters that cross or define the state border. The interstate temperature objective augments, but does not supersede, the intrastate temperature objective.

The federal Clean Water Act (CWA) imposes a criterion for setting loads in addition to the water quality standards defined by the State. For waters impaired by temperature, CWA section 303(d)(1)(D) requires that states estimate “the total maximum daily thermal load required to assure protection and propagation of a balanced, indigenous population of shellfish, fish, and wildlife.”

<u>Dissolved Oxygen</u>

The Basin Plan includes two sets of DO objectives. The first set of objectives included on page 3-4.00 are minimum DO levels for various beneficial uses. These DO objectives are based on the life cycle requirements of aquatic species occupying warm water and marine habitat, as well as habitat of inland saline seas, and the life cycle requirements of aquatic species occupying cold water habitat, as well as the spawning and incubation requirements of cold water species. These are given as ambient water quality objectives applicable as instantaneous minimum requirements.

The second set of objectives is included in Basin Plan Table 3-1 of the Basin Plan and describes the background conditions in individual waterbodies as defined by grab sampling studies conducted in the 1950s and 1960s. In the existing Basin Plan (Regional Water Board 2007) the Site Specific Objectives (SSOs) contained in Table 3-1 supersede the life cycle requirements for those waterbodies listed in Table 3-1 with SSOs DO.

For the Klamath River, numeric objectives are assigned in Table 3-1 of the Basin Plan for the following hydrologic areas: 1) upstream of the Iron Gate Dam, 2) downstream of Iron Gate Dam, 3) on tributaries of the Middle Klamath River, and 4) on tributaries of the Lower Klamath River. The Klamath River DO impairment applies only to the mainstem of the Klamath River.

Upstream of the Iron Gate Dam, the instantaneous minimum concentration of DO required is 7.0 mg/L. Half of the monthly mean DO values for the year must be 10.0 mg/L or greater.

Downstream of the Iron Gate Dam, the instantaneous minimum concentration of DO required is 8.0 mg/L. Half of the monthly mean DO values for the year must also be 10.0 mg/L or greater.

Staff has assessed the Basin Plan Table 3-1 DO objectives for the Klamath River, and determines that revised SSOs DO for the Klamath River are warranted and appropriate. Staff proposes the adoption of Basin Plan language in which the Table 3-1 DO objectives for the mainstem Klamath River are eliminated and replaced by percent DO saturation criteria based on natural receiving water temperatures.

Proposed Basin Plan language is as follows:

Table 3.1a[1]

Location[2]	**Percent DO saturation based on natural receiving water temperatures3**	**Time period**
Stateline to the Scott River	90%	October 1 through March 31
	85%	April 1 through September 30
Scott River to Hoopa	90%	Year round
Downstream of Hoopa-California boundary to Turwar	85%	June 1 through August 31
	90%	September 1 through May 31
Upper and Middle Estuary	80%	August 1 through August 31
	85%	September 1 through October 31 and June 1 through July 31
	90%	November 1 through May 31
Lower Estuary	For the protection of estuarine habitat (EST), the dissolved oxygen content of the lower estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors.	

[1] States may establish site specific objectives equal to natural background (USEPA, 1986. Ambient Water Quality Criteria for Dissolved Oxygen, EPA 440/5-86-033; USEPA Memo from Tudor T. Davies, Director of Office of Science and Technology, USEPA Washington, D.C. dated November 5, 1997). For aquatic life uses, where the natural background condition for a specific parameter is documented, by definition that condition is sufficient to support the level of aquatic life expected to occur naturally at the site absent any interference by humans (Davies, 1997). These DO objectives are derived from the natural conditions baseline scenario (T1BSR) run of the Klamath TMDL model and described in Appendix 7 - *Modeling Scenarios: Klamath River Model for TMDL Development.*

[2] These objectives apply to the maximum extent allowed by law. To the extent that the State lacks jurisdiction, the Site Specific Dissolved Oxygen Objectives for the Mainstem Klamath River are extended as a recommendation to the applicable regulatory authority.

[3] Corresponding DO concentrations are calculated as daily minima, based on site-specific barometric pressure, site-specific salinity, and natural receiving water temperatures as estimated by the natural conditions baseline scenario of the Klamath TMDL model and described in Appendix 7 - Modeling Scenarios: Klamath River Model for TMDL Development. The estimates of natural receiving water temperatures used in these calculations may be updated as new data or method(s) become available. After opportunity for public comment, any update or improvements to the estimate of natural receiving water temperature must be reviewed and approved by Executive Officer before being used for this purpose.

Appendix 1 (*Proposed Site-Specific Dissolved Oxygen Objectives for the Klamath River in California* [Mangelsdorf 2009]) presents Regional Water Board staff's scientific justification for the selection of this proposed site-specific DO objective for the Klamath River in California.

Nutrients

The nutrient objective is a narrative objective for controlling biostimulatory substances. Biostimulatory substances include nitrogen and phosphorus. The objective reads:

> Waters shall not contain biostimulatory substances in concentrations that promote aquatic growths to the extent that such growths cause nuisance or adversely affect beneficial uses.

Nutrient-Related Water Quality Objectives

The cycling of nutrients in an aquatic environment is strongly influenced by several factors. Depending on these factors, there is the potential for impacts to beneficial uses from secondary indicators of biostimulation such as algal biomass, chlorophyll-a, DO, and pH.

The Basin Plan does not contain numeric water quality objectives for algal biomass or chlorophyll-a. The Basin Plan does contain a set of numeric objectives for pH in the

Klamath River. Minimum pH levels shall not drop below 7.0 and maximum pH shall not be raised above 8.5.

Other impacts closely related to excessive nutrient inputs, but qualitatively different are ammonia toxicity and microcystin[4] toxicity. The Basin Plan does not include numeric objectives for ammonia toxicity or microcystin.

The Basin Plan includes a narrative objective for toxicity that reads:

> All waters shall be maintained free of toxic substances in concentrations that are toxic to, or that produce detrimental physiological responses in human, plant, animal, or aquatic life.

2.2.1.3 Antidegradation Policies

There are two applicable antidegradation policies pertinent to water quality in the North Coast Region – a state policy and a federal policy. The state antidegradation policy is titled the *Statement of Policy with Respect to Maintaining High Quality Waters in California* and is commonly known as "Resolution 68-16." The federal antidegradation policy is found at 40 CFR section 131.12. Both policies are incorporated in the Basin Plan for the North Coast Region. Although there are some differences in the state and federal policies, both require that whenever surface waters are of higher quality than

[4] Microcystin is a toxin produced by a species of blue-green algae.

necessary to protect the designated beneficial uses, such existing quality shall be maintained unless otherwise provided by the policies.

The state antidegradation policy applies to groundwater and surface water whose quality meets or exceeds water quality objectives, which may limit its direct applicability in impaired waterbodies. The state policy establishes a two-step process to determine if discharges that will degrade water quality are allowed. The federal antidegradation policy applies to both surface waters that meet or exceed water quality objectives, and those that do not meet the applicable water quality objectives (i.e., impaired waters). Under the federal policy, an activity or discharge would be prohibited if the activity would lower the quality of surface water including where that surface water currently does not meet water quality standards (i.e., the water quality is not sufficient to support designated beneficial uses) with limited exceptions set forth in federal regulations.

2.2.1.4 <u>Program of Implementation</u>
Chapter 4 of the Basin Plan describes the program of implementation by which the beneficial uses and water quality objectives are applied and enforced. This chapter includes all the prohibitions, schedules of compliance, action plans, policies, and guidelines adopted by the Regional Water Board for that purpose.

Chapter 6 of this TMDL staff report describes the proposed Implementation Plan for the TMDL, and will serve as the basis for the for the Klamath River TMDL Action Plan to be considered by the Regional Water Board as an amendment to Chapter 4 of the Basin Plan.

2.2.2 Tribal Water Quality Standards
The four Tribes in California with land along the mainstem Klamath River are the Hoopa Valley Tribe, the Karuk Tribe, the Resighini Rancheria, and the Yurok Tribe. As stated earlier, only the Hoopa Valley Tribe's water quality standards have been approved by the USEPA at this time. The water quality standards developed by the Yurok and Karuk Tribes and Resighini Rancheria will be used as guidance in developing the TMDL as appropriate.

2.2.2.1 <u>Hoopa Valley Tribe Beneficial Uses</u>
The *Water Quality Control Plan for the Hoopa Valley Indian Reservation* (Hoopa Valley Tribal Environmental Protection Agency [HVTEPA] 2008) identifies nine existing (E), four potential (P), and one historical (H) beneficial uses of water within their jurisdictional reach of the Klamath River. Figure 1.2 identifies the location and boundaries of the Hoopa Valley Indian Reservation, as well as the Yurok Indian Reservation.

- AGR—Agricultural supply(P)
- COLD—Cold freshwater habitat(E)
- CUL—Ceremonial and Cultural Water Use(H)
- GWR—Groundwater recharge(E)
- IND—Industrial service supply(P)
- MGR—Fish Migration(E)
- MUN—Municipal and domestic supply(P)
- PROC—Industrial process supply(P)

- REC1—Water contact recreation(E)
- REC2—Non-contact water recreation(E)
- SPWN—Spawning, reproduction,
- and/or early development(E)
- T&E— Preservation of Threatened and Endangered Species(E)
- W&S—Wild and Scenic(E)
- WILD—Wildlife habitat
- and Endangered Species(E)

2.2.2.2 Hoopa Valley Tribe Water Quality Criteria
The Hoopa Valley Tribe has established DO and nutrients criteria for the Klamath River as described below. The Tribe has not developed temperature criteria for the Klamath River.

Dissolved Oxygen
The existing dissolved oxygen (DO) criterion consists of a 7-day moving average of the daily minimum DO concentrations.

In areas of the Klamath River designated as COLD (year-round), the 7-day moving average of the daily minimum DO concentration required in the water column must be 8.0 mg/L or greater. Areas of the Klamath River designated as SPWN (whenever spawning occurs, has occurred in the past or has potential to occur) must have a 7-day moving average of the daily minimum DO concentration in the water column of the Klamath River of 11.0 mg/L or greater. The intragravel 7-day moving average of the daily minimum DO concentration required in the Klamath River areas designated as SPWN (whenever spawning occurs, has occurred in the past or has potential to occur) must be 8.0 mg/L or greater. In the event that these 7-day moving averages of the daily minimum DO standards "are not achievable due to natural conditions, then the COLD and SPWN standard shall instead be DO concentrations equivalent to 90% saturation under natural receiving water temperatures." This later element is contained in the Hoopa Water Quality Control Plan but has not been approved by USEPA. USEPA requires that a method for determining that the DO objectives are not achievable due to natural conditions be developed and presented. Staff believe the *Klamath TMDL model* as described in this staff report provides the tool necessary to establish natural conditions for comparison to DO objectives.

Nutrients
Nutrient criteria consist of several narrative criteria for controlling biostimulatory substances, nitrate and nitrite levels, and phosphate levels. Additionally, there are numeric objectives for nitrate, total nitrogen, ammonia, and total phosphorus.

The narrative criteria for biostimulatory substances reads:

> Waters shall not contain bio-stimulatory substances in concentrations that promote aquatic growths to the extent that such growths cause nuisance or adversely affect beneficial uses.

The narrative criteria for nitrates applies to all waterbodies except those designated as municipal or domestic supply (which have their own numeric criteria) and reads:

> …levels of nitrate shall not be increased by human related activity above the levels consistent with preservation of the specified beneficial uses.

The narrative criteria for nitrites reads:

> Levels of nitrites shall not be increased, in any body of water, by human related activity above the levels consistent with preservation of the specified beneficial use corresponding to that water body.

The narrative criteria for phosphates reads:

> In order to preserve the existing quality of water within the reservation boundaries from existing and to avoid potential eutrophication of phosphorous in any water body shall not be increased by human related activity above levels consistent with preservation of the specified beneficial uses. <sic>

Numeric nutrient criteria for the Hoopa Valley Tribe reaches of the Klamath River are displayed below in Table 2.1. "If total nitrogen and total phosphorus standards are not achievable due to natural conditions, then the standards shall instead be the natural conditions for total nitrogen and total phosphorus (HVTEPA 2008, p.53)." As stated in a footnote within the Hoopa's Basin Plan, "Through consultation, the ongoing TMDL process for the Klamath River is expected to further define these natural conditions (HVTEPA 2008, p.53)."

[2] Maximum one-hour and 30-day average concentrations linked to pH by a formula. Formula can be found in HVTEPA 2008.

Nutrient-Related Water Quality Criteria

In addition to the above narrative and numeric criteria for nutrients, the *Water Quality Control Plan for the Hoopa Valley Indian Reservation* contains narrative criteria for toxicity and Cyanobacterial scums, as well as numeric criteria for parameters which are closely related to excessive nutrient inputs and influence toxicity.

The toxicity narrative reads:

> All waters shall be maintained free of toxic substances in concentrations that produce detrimental physiological responses in human, plant, animal or aquatic life.

The Cyanobacterial scums narrative reads:

> There shall be no presence of cyanobacterial scums.

Table 2.2 displays numeric criteria for algal biomass, pH, blue-green algae, and Microcystin.

2.2.2.3 Karuk Tribe, Resighini Rancheria, and Yurok Tribe Beneficial Uses

The Karuk Tribe[5], Resighini Rancheria[6], and Yurok Tribe[7], have identified the following existing, potential, and historical beneficial uses within their respective reaches of the Klamath River:

- AGR—Agricultural Supply [6, 7, 8]
- ASQ—Aesthetic Quality [6]
- BIOL—Preservation of Areas of Special Biological Significance[6, 7]
- COL/COLD—Cold Freshwater Habitat [6, 7, 8]
- COMM—Commercial and Sport Fishing [8]
- CUL—Cultural [7,8]
- CUL-1—Cultural Contact Water [6]
- CUL-2—Cultural Non-Contact Water [6]
- EST—Estuarine Habitat [8]
- FC—Fish Consumption [6]
- FRSH—Freshwater Replenishment [6, 8]
- GW—Groundwater Recharge [6, 7, 8]
- IND—Industrial Service Supply[7]
- LIV—Livestock Watering [6]
- MGR/MIGR—Migration of Aquatic Organisms [6, 8]
- MGR—Fish Migration [7]
- MUN—Municipal and Domestic Supply [7, 8]
- NAV—Navigation [6, 8]
- PROC—Industrial Process Supply [7]
- PWR/POW—Hydropower Generation [7, 8]
- RARE/T&E—Rare, Threatened, or Endangered Species [6, 7, 8]
- REC-1—Water Contact Recreation [6, 7, 8]
- REC-2—Non-Contact Water Recreation [6, 7, 8]
- SPAWN—Fish Spawning [7]
- SPN/SPWN—Spawning, Reproduction, and/or Early Development [6, 8]
- WARM—Warm Freshwater Habitat[8]
- WLD/WILD—Wildlife [6, 7, 8]

---

5 Beneficial Uses designated by the Karuk Tribe
6 Beneficial Uses designated by the Resighini Rancheria
7 Beneficial Uses Designated by the Yurok Tribe

2.2.2.4 Karuk Tribe, Resighini Rancheria, and Yurok Tribe, Water Quality Objectives and Criteria

The Karuk and Yurok Tribes have established narrative water quality objectives for temperature, DO and nutrients. Additionally, the Tribes have created narrative objectives for toxicity and pH. The Resighini Rancheria has established narrative water quality criteria for temperature and nutrients, as well as toxicity. These narrative water quality standards are quoted in Table 2.3.

Table 2.3: Karuk Tribe, Resighini Rancheria, and Yurok Tribe narrative objectives and criteria for the Klamath River in California

KARUK	
Objective	**Description**
Temperature	The natural receiving water temperature of intratribal waters shall not be altered unless it can be demonstrated to the satisfaction of the Department of Natural Resources that such alteration in temperature does not adversely affect beneficial uses. At no time or place shall the temperature of any cold freshwater habitat (COLD) water be increased by more than 5 degrees F above natural receiving water temperature.
Dissolved Oxygen	Dissolved Oxygen Concentrations shall not at any time be depressed more than 10 percent from that which occurs naturally.
Nutrients	Biostimulatory Substances: Waters shall not contain biostimulatory substances in concentrations that promote aquatic growths to the extent that such growths cause nuisance or adversely affect beneficial uses.
Toxicity	All waters shall be maintained free of toxic substances in concentrations that are toxic to, or that produce detrimental physiological responses in human, plant, animal or aquatic life. Where appropriate, additional numerical receiving water standards for specific toxicants will be established as sufficient data become available, and source control of toxic substances will be encouraged.
pH	Changes in normal ambient pH levels shall not exceed 0.5 units within the range specified in fresh waters with designated COLD or WARM beneficial uses.
RESIGHINI RANCHERIA	
Objective	**Description**
Temperature	The natural receiving water temperature of intrastate waters shall not be altered unless it can be demonstrated to the satisfaction of the Business Council that such alteration in temperature does not adversely affect beneficial uses. At no time or place shall the temperature of any water be increased by more than 5 degrees F above natural receiving water temperature.
Nutrients	Biostimulatory Substances: Waters shall not contain biostimulatory substances in concentrations that promote aquatic growths to the extent that such growths cause nuisance or adversely affect beneficial uses.
Toxicity	All waters shall be maintained free of toxic substances in concentrations that are toxic to, or that produce detrimental physiological responses in human, plant, animal or aquatic life.
YUROK	
Objective	**Description**
Temperature	The temperature of waters within the Yurok Indian Reservation shall not be increased by human caused activity by more than 5 degrees Fahrenheit above the background level at any time or place. If a background level has not been determined, the temperature upstream of a project impacting the receiving water will be considered the background level.

Table 2.3 (cont.): Karuk Tribe, Resighini Rancheria, and Yurok Tribe narrative objectives and criteria for the Klamath River in California

YUROK (cont.)	
Objective	**Description**
Dissolved Oxygen	Dissolved oxygen concentrations shall not be altered by human caused activities that could cause a barrier to salmonid fish migration or adversely affect the water to support specified beneficial uses.
Nutrients	Ammonia: Levels of ammonia shall not be increased, in any body of water, by human related activity that could cause a nuisance or adversely affect the water to support specified beneficial uses. Biostimulatory Substances: Waters shall not contain biostimulatory substances in concentrations that promote aquatic growths to the extent that such growths cause nuisance or adversely affect beneficial uses. Nitrites: Levels of nitrites shall not be increased, in any body of water, by human related activity that could cause a nuisance, or adversely affect the water to support specified beneficial uses. Phosphates: Levels of phosphorous in any water body shall not be increased by human related activity above the levels that could cause a nuisance, or adversely affect the water to support specified beneficial uses.
Toxicity	All waters shall be maintained free of toxic substances in concentrations that are toxic to, or that produce detrimental physiological responses in human, plant, animal, or aquatic life.
pH	Changes related to human caused activities in normal pH levels shall not exceed 0.5 pH units.

Sources: Karuk Tribe of California 2002, Resighini Rancheria Environmental Department 2006, and Yurok Tribe Environmental Program (YTEP) 2004

In addition to the narrative criteria, the Karuk Tribe, Resighini Rancheria, and Yurok Tribe have established numeric criteria for water quality parameters including temperature, DO, nutrients, and other criteria related to nutrients and toxicity as displayed in Table 2.4, Table 2.5, and Table 2.6.

[1] MWAT is the maximum 7-day average temperature within a given time period.
[2] 50% lower limits represent the 50 percentile values of the monthly means for a calendar year. 50% or more of the monthly means must be greater than or equal to the lower limit.
[3] Maximum one-hour and 30-day average concentrations linked to pH by a formula. Formula can be found in YTEP 2004.

2.3 Numeric Targets for the Klamath River basin TMDLs

Numeric targets are the numeric water quality conditions that represent attainment of the applicable water quality objectives for a TMDL. In some cases numeric targets can equal a numeric water quality objective. In other cases, numeric targets are a numeric interpretation of the conditions that meet a narrative water quality objective. In all cases numeric targets are used in the calculation of a TMDL. Presented here are the numeric targets applied in the development of these Klamath River TMDLs.

The Regional Water Board considers several factors in selecting the appropriate numeric target values for the selected indicators. The most important factor is to select indicator values that will provide supporting conditions for the most sensitive beneficial uses. Another consideration is ensuring that the target values for the selected indicator(s) are consistent with the desired trophic status of the waterbody, and that the desired trophic status is appropriate for the waterbody. Although trophic classification is a tool to simply characterize the factors that define the productivity of a waterbody, often values defining thresholds between various trophic states (e.g., mesotrophic, eutrophic, or hypereutrophic) are based on ranges. Moreover, systems can be either more or less productive even within a trophic state. Thus, the Regional Water Board considered the following information regarding the trophic status conditions within the Klamath basin in selecting numeric values for selected indicators.

In the case of Upper Klamath Lake (UKL), the transition from a naturally productive condition to its current productivity condition dominated by near-monocultures of *Aphanizomenon* (Eilers et al. 2004) has had profound water quality implications and has resulted in impairment of beneficial uses within the UKL and in downstream waters. As described by Eilers et al. (2004), there have been clear shifts in UKL sediment and nutrient accumulation and species composition in the past 100 years, consistent with large scale land disturbance activities. In addition, this issue has been previously addressed in the technical report from the Upper Klamath Lake TMDL (ODEQ 2002):

> The term eutrophic is often associated with adverse water quality condition (pollution), whereas in reality, a body of water may be both ecologically "healthy" and eutrophic. Historically UKL [Upper Klamath Lake] was a productive (eutrophic) and diverse ecosystem. It is presently a hypereutrophic system that frequently experiences such poor water quality as to be lethal to its native species (Saiki and Monda 1993). Thus statements such as UKL [Upper Klamath Lake] has always been a eutrophic system" should not be used as an excuse for inaction nor construed to mean that the system was polluted or unhealthy. The argument that it is useless to reduce nutrient loading because the lake will still be eutrophic indicates a misunderstanding of trophic level classifications. - Gearheart et al. 1995

Given that UKL is the source water for the Klamath River downstream of UKL, river productivity was also likely to be historically productive with a change to even more productive conditions as UKL began to export massive biomass of blue-green algae. That is, productivity is not fixed and can change based on environmental conditions. Reducing pollutant loading in the upper basin is critical to restoring conditions in the upper Klamath River, currently eutrophic and hypereutrophic, to a range more consistent with pre-disturbance conditions of lower productivity. In addition to the risk co-factor of excessive loading of nutrients and organic matter, another contributing factor (significant risk co-factor – see section 2.4.1) affecting the trophic balance in the Klamath River is the Klamath Hydropower Project (KHP) dams. KHP dams in California have created environmental conditions that have further shifted the trophic status of these portions of the river. The TMDL numeric targets are intended to set restoration goals that are consistent with the formerly supporting trophic status for the reaches now occupied by the reservoirs.

2.3.1 Temperature

The Klamath TMDL water temperature allocations and targets are consistent with water quality standards, which are set to protect all beneficial uses of water. Establishing load allocations and targets based on natural conditions is the best possible means of achieving a balanced indigenous population and fully complies with both state water quality standards and the Clean Water Act's requirement for thermal TMDLs. The protection of all beneficial uses ensures a balanced indigenous population of aquatic life.

The numeric temperature targets are expressed as monthly average temperatures and are calculated from the estimated natural temperature regime of the Klamath River. The approach and assumptions applied in estimating the natural temperatures and calculating the numeric targets at select compliance locations are detailed in Chapter 3. The specific numeric temperature targets for select TMDL compliance locations are presented in Chapter 5.

2.3.2 Dissolved Oxygen and Nutrient-Related

The numeric DO targets are expressed as monthly average and monthly minimum DO concentrations calculated at 85% DO saturation under natural temperatures for most of the river; 90% DO saturation from October through April upstream of the Hoopa-California boundary; and 80% DO saturation during the month of August in the Middle and Upper Estuary. The approach and assumptions applied to estimating the natural temperatures and associated DO concentrations are detailed in Chapter 3. The specific numeric DO targets for select TMDL compliance locations are presented in Chapter 5.

The DO targets are the primary target associated with the nutrient and organic matter TMDLs and associated load allocations. However, additional numeric targets are associated with these TMDLs, and are used to reflect compliance with the narrative biostimulatory substances and toxicity objectives. These additional numeric targets are set for benthic algae biomass, suspended algae chlorophyll-a, *Microcystis aeruginosa* cell density and microsystin concentration. Because the Klamath River alternates between free-flowing reaches and impounded conditions it is necessary to have algal indicators appropriate to both environments: for free-flowing reaches – benthic algal biomass; and for quiescent reaches chlorophyll-a.

2.3.2.1 <u>Benthic Algae Biomass</u>

The benthic algae biomass numeric target is 150 mg chlorophyll-a/m^2. During the summer season, dense mats of attached algae form on the rocky substrate of many reaches of the Klamath River. This vegetative mass is referred to variously in the literature as periphyton, macroalgae, macrophytes, and attached benthic algal biomass. For this assessment we have adopted the term benthic algal biomass. Because of the limited amount of benthic algae data that has been collected in the Klamath River, Regional Water Board staff used various lines of evidence to develop a numeric target for this assessment. The lines of evidence include:

- The California Nutrient Numeric Endpoints (CA NNE) framework (Tetra Tech 2006) sets a benthic algal biomass target for the boundary between Beneficial Use Risk Category II (potentially impaired) and III (presumptively impaired) for streams with a cold-water fishery use (COLD) at 150 mg chlorophyll-a/m^2, interpreted as a maximum biomass in time averaged over a reach (i.e., it does not apply to single point measurements). The CA NNE boundary target is based on a review of both regional and international studies and the recommendation of university and regional experts. The CA NNE also recommends the evaluation of other lines of evidence for each waterbody to ensure the appropriateness of this boundary condition. Because of the natural continuum of conditions from the Klamath headwaters (eutrophic) to its mouth (mesotrophic), the Regional Water Board considered other information for benthic algae biomass target determination. In addition, the analysis of diurnal water chemistry impacts, within reaches of the Klamath River where the benthic algal biomass likely exceeds the proposed target, indicates extreme DO and pH conditions that present stressful conditions to resident fish.

- A recent study sponsored by the U.S. Fish and Wildlife Service -Arcata Office on an assessment of community metabolism and associated kinetic parameters in the Klamath River (Ward and Armstrong 2009 in press) concludes that the Klamath River below Iron Gate dam is mesotrophic. The target of 150 mg chlorophyll-a/m^2, interpreted as a maximum biomass in time averaged over a reach, is consistent with mesotrophic conditions.
- The Regional Water Board and EPA Region IX sponsored a *Nutrient Numeric Endpoint Analysis for the Klamath River, CA* (Appendix 2) in 2008. The study made use of the CA NNE scoping tools (described in Chapter 3) to assess benthic algal biomass targets under both existing conditions and the natural conditions baseline scenarios (described in Chapter 3 and Appendix 7). The scoping tool predicted benthic algal biomass levels very similar to those measured in the field using average current nutrient concentrations and information about other factors (e.g., accrual period). When estimates of natural background nutrient concentrations were applied at four locations along the mainstem Klamath River below Iron Gate Dam, the scoping tool estimated reach-averaged maximum benthic algal biomass densities of 109 to 157 mg chlorophyll-a/m^2, with a mean across the four stations of 141 mg chlorophyll-a/m^2.
- The Hoopa Valley Tribe Basin Plan includes a criterion of 150 mg chlorophyll-a/m^2 for the reach of the Klamath River within the Hoopa Valley Indian Reservation.

Based on these considerations, a benthic algal biomass numeric target of 150 mg chlorophyll-a/m^2 is set for this TMDL. This is a growing season (June – September) reach-average benthic algal biomass target.

The reach average is for the summer growing season and should be measured at a minimum of three points during the growing season (e.g., June, August, September) using the protocols described in: *Standard Operating Procedures for Collecting Stream Algae Samples and Associated Physical Habitat and Chemical Data for Ambient Bioassessments in California* (Fetscher et al. 2009). Sampling locations should be in close proximity to TMDL compliance points.

2.3.2.2 Suspended Algae Chlorophyll-a, *Microcystis aeruginosa*, and Microcystin Toxin

In addition to the benthic algae biomass target, the following nutrient-related numeric targets are set for the Klamath River TMDLs:

- Suspended algae chlorophyll-a = 10 μg/L (as a growing season mean -May to October)
- *Microcystis aeruginosa* cell density = 20,000 cells/mL; and
- Microcystin = 4 μg/L.

Monitoring requirements to assess these targets for each reservoir with recreational uses are: a minimum of one sample per month at each of 3 near shore reservoir entry areas and 1 open water reservoir sample, collected in accordance with *Standard Operating Procedures, Environmental Sampling of Cyanobacteria for Cell Enumeration, Identification and Toxin Analysis* (June 2099) or other protocol as approved by the Regional Water Board. Interpretation of monitoring data for these targets will conform to World Health Organization guidance for low probability of adverse health effects, from the *Guidelines for Safe Recreational Water Environments* (Table 8.3), or superseding guidance. (WHO guidelines are also summarized in *Cyanobacteria in California Recreational Water Bodies*, *Blue-Green Algae Work Group of the State Water Resources Control Board, Department of Public Health, and Office of Environmental Health and Hazard Assessment* (Sept 2008).

The selection of each of these targets is discussed below.

As an indicator for the Klamath River reservoirs, chlorophyll-a is a surrogate measure of suspended algal (phytoplankton) biomass. Chlorophyll-a is a response variable to both water quality stressors (e.g., nutrients) and to impoundment conditions. High levels of suspended algae (chlorophyll-a) indicate an aquatic ecosystem subject to biostimulatory effects due to physical conditions and/or high concentrations of nutrients. Consistently high or episodic chlorophyll-a concentrations indicate the potential occurrence of algal blooms, which can be harmful to aquatic organisms (Welch and Jacoby 2004) and negatively impact several beneficial uses. Prolonged conditions of high levels of chlorophyll-a are typical of eutrophic to hyper-eutrophic water bodies.

Water quality impacts associated with high chlorophyll-a concentrations in the Klamath River reservoirs include:

- Extreme diurnal variation in DO and pH;
- Low DO conditions due to the decay of organic matter resulting from algal blooms;
- Aesthetic impacts, both visual and aroma (olfactory), due to nuisance algal blooms; and
- Increasing likelihood of dominance of toxigenic blue-green algal species at higher concentrations of chlorophyll-a.

The CA NNE framework sets a suspended algae growing season mean chlorophyll-a target of 10 μg/L as the boundary between Beneficial Use Risk Category II (potentially impaired) and Beneficial Use Risk Category III (presumptively impaired) for support of the COLD beneficial use (Tetra Tech 2006). This concentration target was selected in part due to the rapidly increasing likelihood of nuisance algal blooms when chlorophyll-a concentrations are above this concentration (Walker 1985). In addition, as chlorophyll-a levels increase above 10 µg/L, blue-green algal species tend to begin to dominate the algal species assemblage (Downing et al. 2001). That is, the likelihood of blue-green algal biomass dominance rapidly increases as chlorophyll-a concentrations move above the target threshold. With blue-green algal dominance there is an increased probability of algal toxin production under elevated biomass of various toxicogenic blue-green algae, creating a potential public risk hazard for people, livestock, and wildlife.

The chlorophyll-*a* target is primarily for the reservoir environments but also applies to quiescent waters (backwater eddies and the estuary) of the Klamath River. For reasons stated above (increased likelihood of nuisance blooms and associated toxin production), a value of 10 µg/L of chlorophyll-a provides an appropriate target for the quiescent waters of the Klamath River. Under background free-flowing conditions the target value of 10 µg/L of chlorophyll-a would be inappropriately high and unnecessary. However the presence of the reservoirs requires the development of this numeric target due to its effect on increasing suspended algal concentrations. The river upstream rarely exceeds 10 µg/L of chlorophyll- a, despite the currently eutrophic condition of the system. Monitoring data show that mean chlorophyll-a was below 10 µg/L at Shovel Creek above the reservoirs, but above 10 ug/L below the reservoirs at the Hatchery Bridge. This has most recently been illustrated for 2008 in (Table 6 and Figure 6 in Raymond 2009: *Phytoplankton Species and Abundance Observed During 2008 in the vicinity of the Klamath Hydroelectric Project.*) These results are consistent with earlier 2005-2007 data analyzed by Asarian et al (2009); see Figures 2.22, 2.23, and 2.25 below. The reservoirs as controllable factors have created conditions more susceptible to nuisance algal blooms dominated by blue-green algal species.

The CA NNE impairment boundary value of 10 µg/L of chlorophyll-a was developed from studies that included information from a large number of reservoirs from temperate climate locations (Walker 1985). Because a large amount of data has been collected at several stations along the Klamath River including Iron Gate and Copco Reservoirs, it is possible to evaluate the site-specific relationship between high concentrations of chlorophyll-a and blue-green algal dominance (Kann and Corum 2009).

Klamath River monitoring since 2005 has documented elevated levels of the blue-green algae (a.k.a. cyanobacteria) *Microcystis aeruginosa* (MSAE) and the blue-green algae toxin microcystin. Microcystins are a class of toxic chemicals produced by some strains of the blue-green algae *Microcystis aeruginosa.* Microcystins can be found associated with algal cells and are also released into waters when blue-green algal cells die or cell membranes degrade. These chemicals are a human health risk, capable of inducing skin rashes, sore throat, oral blistering, nausea, gastroenteritis, fever, and liver toxicity (World Health Organization [WHO] 2003). Microcystin toxins have also been shown to produce effects on animals including acute livestock poisoning and tumor production in fish guts and liver (de Figueiredo et al. 2004, Lehman et al. 2005, and Xie et al. 2005). Microcystin can thus potentially impair a number of beneficial uses of a waterbody.

The targets for low risk exposure to *Microcystis aeruginosa* and microsystin come from the World Health Organization (WHO) and are 20,000 cells/mL and 4 µg/L respectively (WHO 2003).

When health advisories are issued by agencies concerned that cyanotoxins are present in waterbodies at levels that may pose a health risk, they are often issued based on "guidelines" or "risk levels." These guidelines are derived from analytic thresholds and field observations, and are established by the WHO. The WHO guidelines are largely accepted by nations and territories world-wide (WHO 1999, p. 171-175; WHO 2003, pp. 149-154). The presence of extensive blue-green algal water discolorations and scum accumulations are often used as triggers to assess the relative health risk to humans and other organisms from possible cyanotoxin exposures.

The Regional Water Board has not established numeric water quality objectives for microcystin toxins. However, the Basin Plan narrative objective for toxicity does apply. There are numeric translators for the narrative criteria for both *Microcystis aeruginosa* and microcystin that can be used as the basis for an impairment assessment and to develop numeric targets for the TMDL. The primary source for numeric assessment endpoints comes from the Blue Green Algae Work Group of the State Water Board, Department of Public Health (DPH), and Office of Environmental Health and Hazard Assessment (OEHHA) (Blue Green Algae Work Group), who developed guidance that is described in *Cyanobacteria in California Recreational Water Bodies: Providing Voluntary Guidance about Harmful Algal Blooms, Their Monitoring, and Public Notification* (State Water Board 2008). From this guidance the Regional Water Board has developed the following 303(d) impaired waters listing criteria:

Tissue Listing Criteria:

For the protection of human health from tissue contaminated with microsystin:

- Composite of three or more individual samples with microcystin edible tissue concentration $\geq$ 26 ng/g wet weight (OEHHA 2008)

Water Column Impairment Listing Criteria:

The following values are not the TMDL target values. TMDL target values are set to protect against beneficial use impacts and were therefore set at the level of low probability of health effects. The values below are used to take action (public health posting or listing) when impairment is occurring and represent a moderate level of health effects. From grab sample or fixed station trend monitoring sites, three or more samples that exceed any of the following numeric listing criteria for the protection of human health and aquatic life:

- Microsystin concentrations ≥ 8 µg/L
- *Microcystis aeruginosa* cell densities ≥ 40,000 cells/mL
- **Or** if a waterbody is posted based on photographic documentation of surface scums containing *Microcystis aeruginosa*. The photographic record must be compiled as part of a monitoring program that has an approved Quality Assurance Program and staff that have been trained in recognizing *Microcystis aeruginosa* scums, as per the posting guidelines established by the Blue Green Algae Work Group (State Water Board 2008).

The data illustrated in Figures 2.1 through 2.6 were collected by the Yurok Environmental Program, Karuk Tribe of California, and PacifiCorp in 2005, 2006, and 2007 (Kann and Corum 2009). The relationships depicted in the figures use chlorophyll-a, which indicates total algal biomass, as a means of assessing potential health effects. Using chlorophyll-a as a public health guidance value for toxic cyanobacteria is common throughout the world and in the literature. For example, the World Health Organization (WHO) uses chlorophyll-a to assess the probability of health effects; and indicates that chlorophyll-a values of 10 µg/L or greater are associated with a moderate probability of acute health effects (Graham et al. 2009). Similarly, Lindon and Heiskary (2009) combined microcystin and chlorophyll-a classes to provide a basis for describing the risk of encountering microcystin as a function of bloom intensity (chlorophyll-a). Bingham et al. (2009) reported on a survey of toxic algal [microcystin] distribution in Florida lakes. This study also provides an analysis of the probability that microcystin concentrations will exceed WHO guidance values as a function of chlorophyll, and conclude that as chlorophyll increases the probability of encountering elevated microcystin concentrations increases. Thus, chlorophyll-a provides a reasonable and robust variable to estimate the potential risk of encountering microcystin or *Microcystis* levels that pose a risk with respect to public health. The relationships depicted in the figures are consistent with these results, and show that when chlorophyll-a is elevated in the Copco/Iron Gate systems during the months presented, the probability for chlorophyll-a to be comprised of *Microcystis* increases.

The relationship illustrated in Figure 2.1 indicates that as chlorophyll-a concentrations reach 10 µg/L and above, there is a sharp increase in *Microcystis aeruginosa* cell density above 20,000 cells/mL. That is, within the Klamath River and Iron Gate and Copco Reservoirs the dominance of toxigenic blue-green algal species rapidly increases above the CA NNE target of 10 µg/L. Figure 2.2, which uses the same data as 2.1, demonstrates that the same relationship exists between chlorophyll-a and microcystin. As chlorophyll-a concentrations exceed 10 µg/L concentrations of microcystin rapidly increase above 4 µg/L. Taken together these relationships provide site-specific support for the use of the CA NNE impairment boundary target of 10 µg/L of chlorophyll-a.

The probability of exceeding three critical *Microcystis aeruginosa* cell density levels at the chlorophyll-a target of 10 µg/L can be computed from nonparametric cross-tabulation probability models developed for Iron Gate and Copco Reservoirs (Kann and Corum 2009 – the computational methodology is explained in Kann and Smith 1999). The probability plots from this analysis are illustrated in Figure 2.3 using *Microcystis aeruginosa* cell density critical values of 20,000 cells/mL (red), 40,000 cells/mL (blue), and 100,000 cells/mL (green). The probability of *Microcystis aeruginosa* cell density exceeding 20,000 cells/mL (red), 40,000 cells/mL (blue), and 100,000 cells/mL (green) at a chlorophyll-a concentration of 10 µg/L (dashed line) are approximately 32%, 13%, and 10% respectively. The exceedance probabilities for the critical values increases rapidly above 10 µg/L. For Iron Gate and Copco Reservoirs the chlorophyll-a target of 10 µg/L is a reasonable threshold to protect against conditions predisposing growth of unacceptable *Microcystis aeruginosa* cell densities.

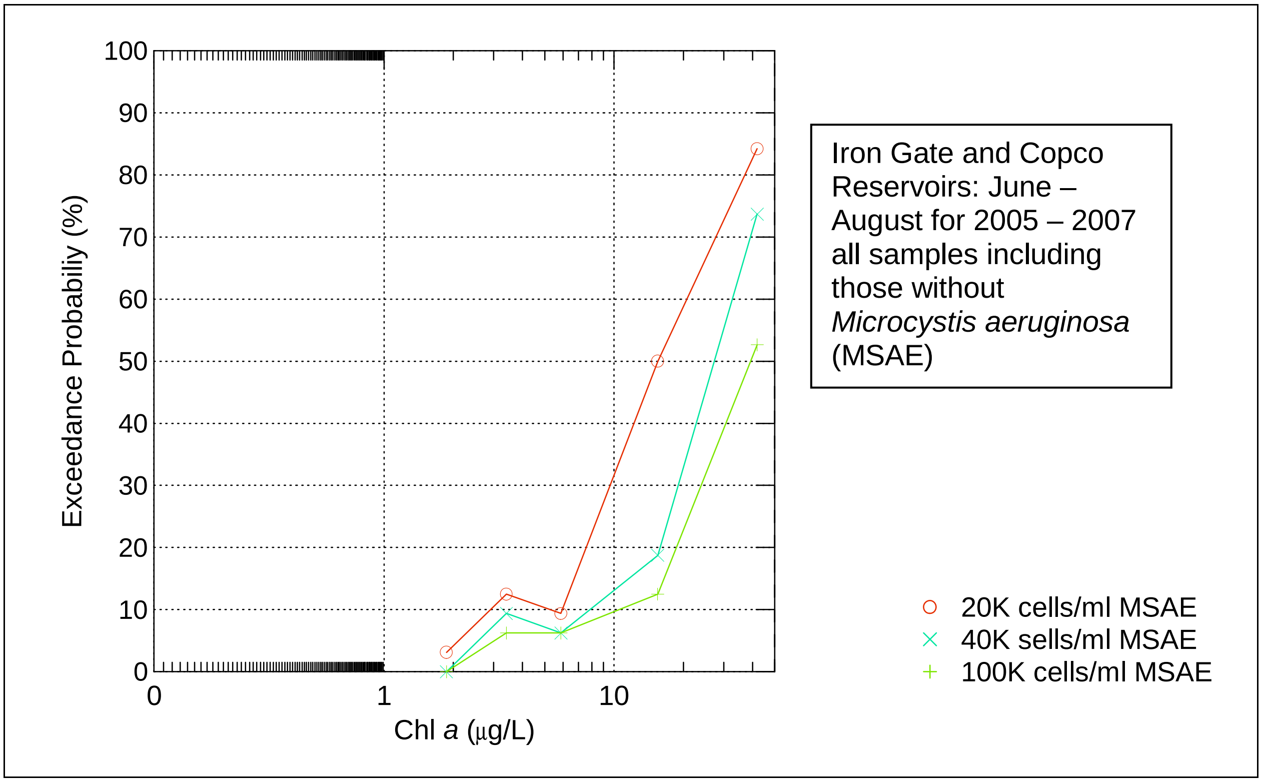

Figure 2.3: *Microcystis aeruginosa* (MSAE) cell density exceedance probability plotted as a function of chlorophyll-a concentration (10 µg/L) for Iron Gate and Copco Reservoirs using data collected by the Karuk Tribe of California for the years 2005, 2006, and 2007 during peak growing season (June – August). The probability plot includes all samples, including those with no *Microcystis aeruginosa* present.
Note: 20K = 20,000, 40K = 40,000, and 100K = 100,000
Source: Kann and Corum 2009

The same plots can be generated for the growing season (June – September) relationship between surface and/or 1 m chlorophyll-a and microcystin for Iron Gate and Copco Reservoirs for the period 2005-2007 with data collected by the Karuk Tribe of California Natural Resources Department. The probability plots from this analysis are illustrated in Figure 2.4 using microcystin concentrations critical values of 4 µg/L (red), 8 µg/L (blue), and 20 µg/L (green). The probabilities of microcystin concentrations exceeding the critical values of 4 µg/L (red), 8 µg/L (blue), and 20 µg/L (green) at a chlorophyll-a concentration of 10 µg/L (dashed line) are approximately 24%, 15%, and 10% respectively. The exceedance probabilities for the critical values increase rapidly above 10 µg/L. For Iron Gate and Copco Reservoirs the chlorophyll-a target of 10 µg/L is a reasonable threshold to protect against conditions with unacceptable microcystin concentrations.

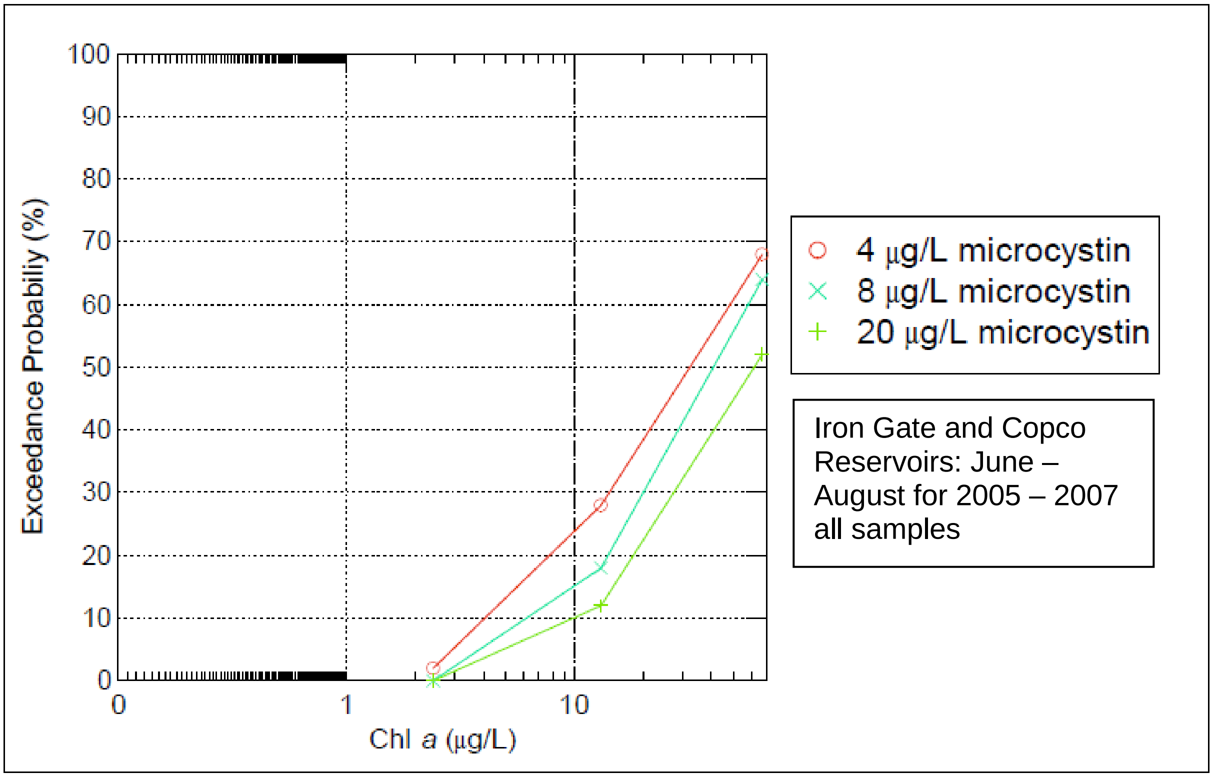

Figure 2.4: Probability of exceeding various WHO public health *Microcystis aeruginosa* (MSAE) cell density levels at varying Chl-a concentration (a), and probability of exceeding various WHO public health microcystin toxin levels at varying Chl-a concentration (b) in Copco and Iron Gate Reservoirs and the Klamath River, 2005-2007. Exceedance probability is computed using nonparametric cross-tabulation method described in Kann and Smith (1999).
Source: Kann and Corum 2009

Figure 2.5 illustrates *Microcystis aeruginosa* cell density during 2006-2007 for all stations from upper Copco through the lower estuary on the X axis with their associated microcystin concentrations on the Y axis. The measurements in the upper right hand quadrant in the chart are those measurements where cell count exceeds 20,000 cells/mL and the microcystin concentration exceeds 4 µg/L of microcystin. In regards to the relationship being evaluated, measurements in this quadrant of the graph are often referred to as true positives. The lower right hand quadrant includes those measurements that would be labeled false positives. For false positives microcystin concentrations are expected to be higher than the threshold criteria of 4 µg/L because they are associated with observed *Microcystis aeruginosa* cell densities above the threshold criteria of 20,000 cells/mL. False positives (samples in the lower right hand quadrant) with concentrations below 4 µg/L **do not** represent a risk to public health.

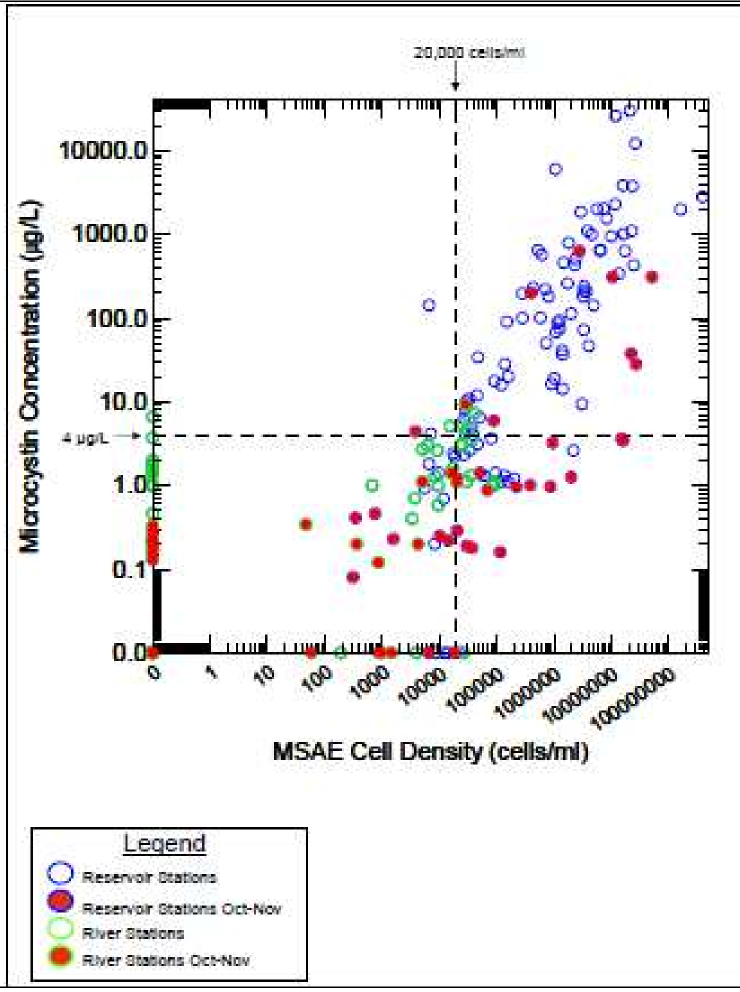

Figure 2.5: Relationship of *Microcystis aeruginosa* (MSAE) cell density and microcystin concentrations for stations along the Klamath River from above Copco Reservoir to the lower Klamath River estuary for the years 2006 and 2007 (Kann and Corum 2009). Data from Yurok Environmental Program, Karuk Natural Resources, and PacifiCorp.
Source: Kann and Corum 2009

The lower left hand quadrant represents the true negative results. That is, the true negative observations in the lower left quadrant have *Microcystis aeruginosa* cell densities less than 20,000 cells/mL and microcystin concentrations less than 4 µg/L. Measurements in the upper left hand quadrant are the false negative measurements. This is the quadrant that would represent the risk to public health with adoption of a numeric target of 4 µg/L of microcystin and a cell density of 20,000 cells/mL of *Microcystis aeruginosa.* False negative observations have concentrations of microcystin that exceed the threshold criteria of 4 µg/L, which is higher than would expected with a *Microcystis aeruginosa* cell density of less than 20,000 cells/mL. Because 4 µg/L of microcystin represents a WHO low effects level and given the few number of measurements in the false negative quadrant, the proposed numeric target represents a reasonable level of protection. The high level of correlation between cell count and microcystin concentration makes it possible to calculate the percent probability that a desired level of microcystin concentration will be exceeded at a particular cell density.

The probability of exceeding three critical level microcystin concentrations at a *Microcystis aeruginosa* cell density level of 20,000 cells/mL can be computed from nonparametric cross-tabulation probability models developed for Iron Gate and Copco Reservoirs (Kann and Corum 2009). The probability plots from this analysis are illustrated in Figure 2.6 using microcystin concentrations of 4, 8, and 20 µg/L as critical values. These concentrations represent WHO health effects levels of low, moderate, and high respectively. The probability of microcystin exceeding the critical values of 4 µg/L (red), 8 µg/L (light blue), and 20 µg/L (green) at a *Microcystis aeruginosa* cell density of 20,000 cells/mL (dashed line) are approximately 47%, 8%, and 0% respectively. Therefore at a cell density target of 20,000 cells/mL there is less than a 50% probability that microcystin concentrations will exceed the low health effects threshold of 4 µg/L.

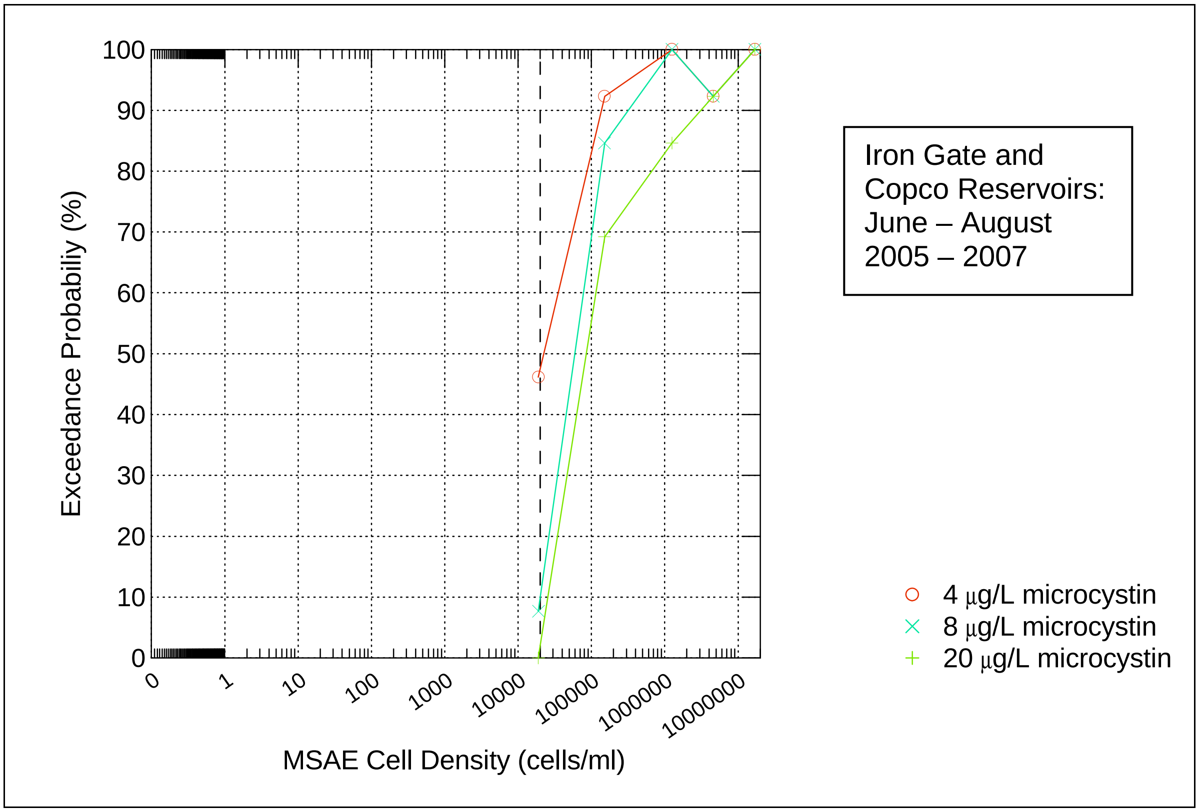

Figure 2.6: Microcystin exceedance probability plotted as a function of *Microcystis aeruginosa* cell density for Iron Gate and Copco Reservoirs using data collected by the Karuk Tribe of California Natural Resources Department and PacifiCorp for the years 2005, 2006, and 2007 during peak growing season (June – August).
Source: Kann and Corum 2009

In addition to these numeric water quality targets, monitoring targets are also identified and included in the Monitoring Plan (Chapter 7) and in Chapter 5.

The probability plots provided in Figures 2.3, 2.4, and 2.6 illustrate an increase in response variable probabilities at the recommended numeric target concentration and cell density for chlorophyll-a concentrations and Microcystis *aeruginosa* respectively. However, the probability models show exceedances of guideline levels below either the

TMDL targets or the State Water Board (2008) guidance on cyanobacteria in public recreational waters for public health. However, as noted by Kann and Corum (2009), this is because the plotted probabilities represent an interval around the median of the independent variable and thus includes values above and below any chosen value.

The probability plots are a good tool for illustrating the relationship between the independent variables (i.e., chlorophyll-a concentrations and Microcystis *aeruginosa* cell densities) and the dependent variable (microcystin concentration). However the plots require an averaging algorithm that limits an evaluation of the probability of exceedance at a specific threshold. It is possible to calculate the exceedance probability at a specific level for the independent variables. The exceedance probability for the microcystin thresholds for several specific values of the independent variables are presented in Table 2.7. The point specific evaluation demonstrates that when chlorophyll-a was less than 10 µg/L that the exceedance frequencies of the public health thresholds for *Microcystis aeruginosa* density or microcystin concentration were less than 10%.

Table 2.7: Percent exceedance for MSAE cell densities and microcystin toxin concentrations at threshold chlorophyll-a of 10 µg/L, and percent exceedance for microcystin toxin concentrations at threshold MSAE cell density of 20,000 cells/ml; Klamath River, California 2005-2007.

Likewise, when *Microcystis aeruginosa* cell density was less than 20,000 cells/ml, maximum exceedance frequencies were 14.3% and 7,1% for 4 µg/L and 8 µg/L microcystin. Frequency of exceedance for 8 µg/L microcystin when MSAE cell density was below 40,000 cells per ml was 16.7% (June-September) and 7.7% June-August (Table 2.7). The higher frequency for the computation period that includes September may be due to a tendency towards increased aqueous versus cell-bound toxin during the fall months.

The threshold analysis presented in Table 2.7 supports the numeric targets proposed by the Regional Water Board for chlorophyll-a (10 μg/L), *Microcystis aeruginosa* cell density (20,000 cells / mL), and microcystin (4 μg/L).

2.4 Water Quality Conceptual Models Overview

There are numerous overlapping physical, chemical, and biological factors that are currently contributing to impairment of water quality standards in the Klamath River. The purpose of this section is to describe these factors and discuss how they are contributing to impairment.

The challenge associated with the Klamath River TMDL problem statement is to develop a clear roadmap between the TMDL listing parameters of nutrients, temperature, and DO and their impacts on beneficial uses. There are several issues that must be addressed as part of this challenge. Nutrients and temperature often interact together and with other watershed factors to influence processes within the aquatic ecosystem that then impact ecological elements associated with Klamath River beneficial uses. With multiple factors impacting multiple ecosystem components, impacts on beneficial uses can be cumulative and involve effects from several different pathways. The Klamath River problem statement is based on a process that clearly identifies and evaluates impacts on beneficial uses from multiple concurrent stressors.

This process evaluates the likelihood that adverse ecological impacts may occur in response to one or more stressors by identifying (1) the pathways by which stressors cause ecological effects and (2) informative and representative assessment endpoints. Assessment endpoints are the link between scientifically measurable endpoints and the objectives of stakeholders and resource managers (Suter 1993). Endpoints should be ecologically relevant, related to environmental management objectives, and susceptible to stressors (USEPA 1998). For the Klamath River problem statement evaluation, nutrients and temperature are the primary stressors and separate conceptual models have been developed for each. Assessment endpoints in the conceptual models are comprised of A – Driver/Stressor, B – Environmental Conditions, D – Response/Outcome, and E – Beneficial Use (BU) Impairment. There are a total of thirty-nine assessment endpoints included in the Klamath River nutrient conceptual model, and thirty-five assessment endpoints in the temperature conceptual model. The Klamath River problem statement evaluation includes DO as a secondary indicator in the pathway analysis. The management objective for the Klamath River conceptual models is to assess conditions that are contributing to the impairment of beneficial uses designated to the Klamath River in the Basin Plan.

A conceptual model is a graphical and narrative description of the physical, chemical and biological stressors within a system, their sources, and the pathways by which they are likely to impact multiple ecological resources (Suter 1999) and contribute to beneficial use impairment. The conceptual model is important because it links exposure characteristics such as water quality conditions with the ecological endpoints important for describing the beneficial uses.

Conceptual models consist of two general components (USEPA 1998): (1) a description of the hypothesized pathways between human activities (sources of stressors), stressors, and assessment endpoints; and (2) a diagram that illustrates the relationships between human activities, stressors, and direct and indirect ecological effects on assessment endpoints. The conceptual model consolidates available information on ecological resources, stressors, and effects, and describes, in narrative and graphical form, relationships among human activities, stressors, and the effects on valued ecological resources (Suter 1999). A conceptual model provides a visual representation for the cases where multiple stressors contribute to water quality problems. With the conceptual model, some attribute or related surrogate (termed an "indicator" in both the watershed approach [USEPA 1995] and the TMDL program) provides a measurable quantity that can be used to evaluate the relationship between pollutant sources and their impact on water quality (USEPA 1999a).

2.4.1 Klamath River Nutrient and Temperature Conceptual Models

Figure 2.7 and Figure 2.8 present the nutrient and temperature conceptual models developed for the Klamath River TMDL problem statement. The components of the Klamath River nutrient and temperature conceptual models are described below.

- Driver/Stressor (A) – The primary risk element being evaluated (nutrients and temperature). There is one element, increased nutrient loading, included in this category for the nutrient conceptual model, and five elements in this category for the temperature conceptual model.

- Environmental Conditions (B) – Water quality processes directly impacted by the stressor. These conceptual model “elements” are linked to response/outcome ecosystem elements (e.g., fish populations) that are more directly linked to aspects of the beneficial use. Environmental Condition elements are secondary indicators, providing an intermediate measure (prior to primary impact) of beneficial use condition. There are 12 elements in this category for both the nutrient and the temperature conceptual models respectively.

- Risk Cofactors (C) – In the nutrient conceptual model, these are related conditions or stressors that affect how nutrients are processed in the ecosystem. The nutrient risk cofactors listed in category C can magnify or mitigate the negative impacts linked to nutrients as biostimulatory substances. In the temperature conceptual model, the risk cofactors are processes or factors which are affected by the environmental conditions (category B) caused by an altered

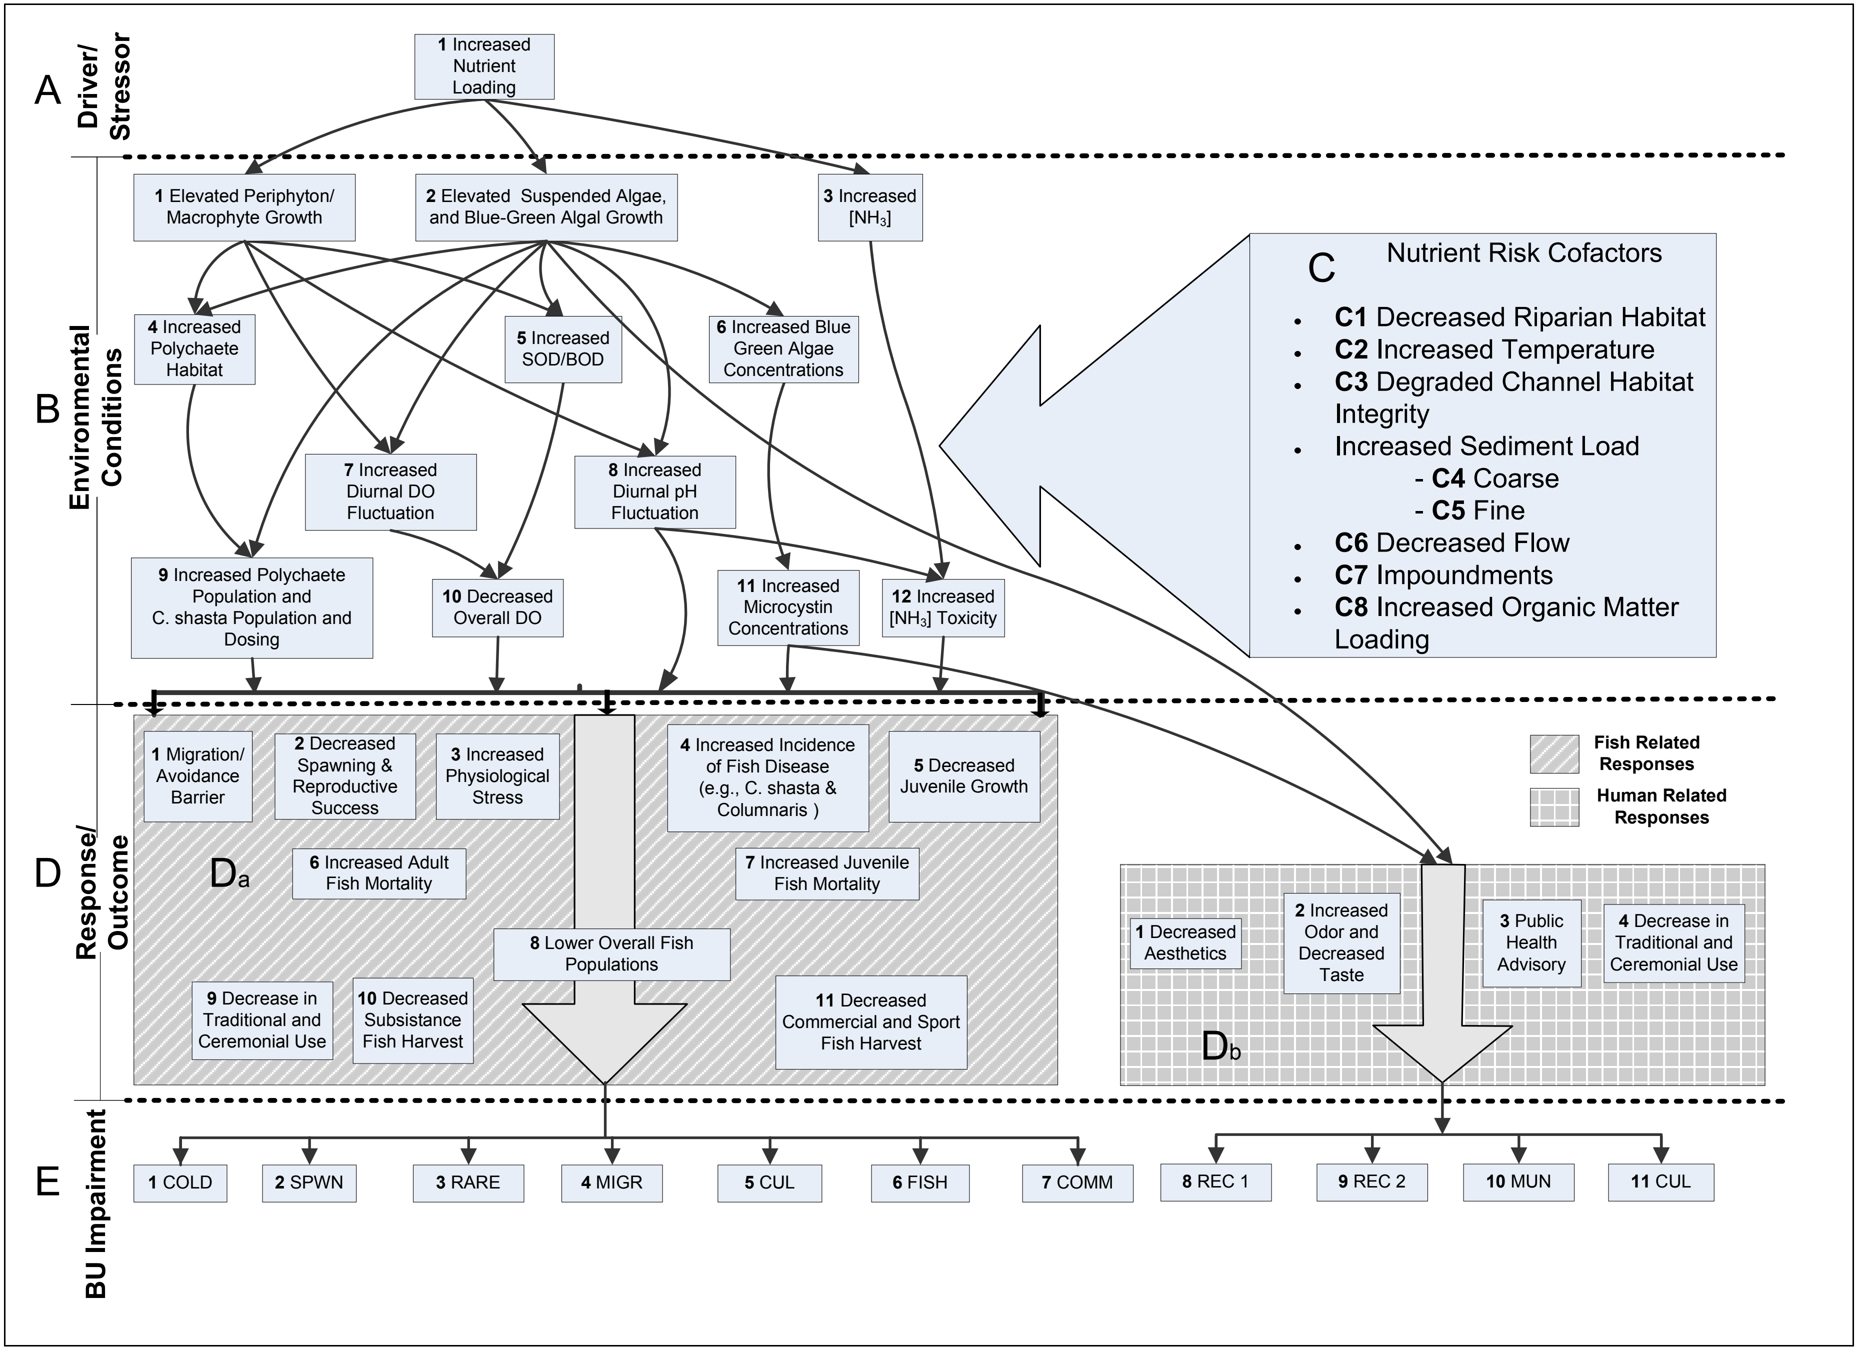

Figure 2.7: Nutrient conceptual model for the Klamath River in California

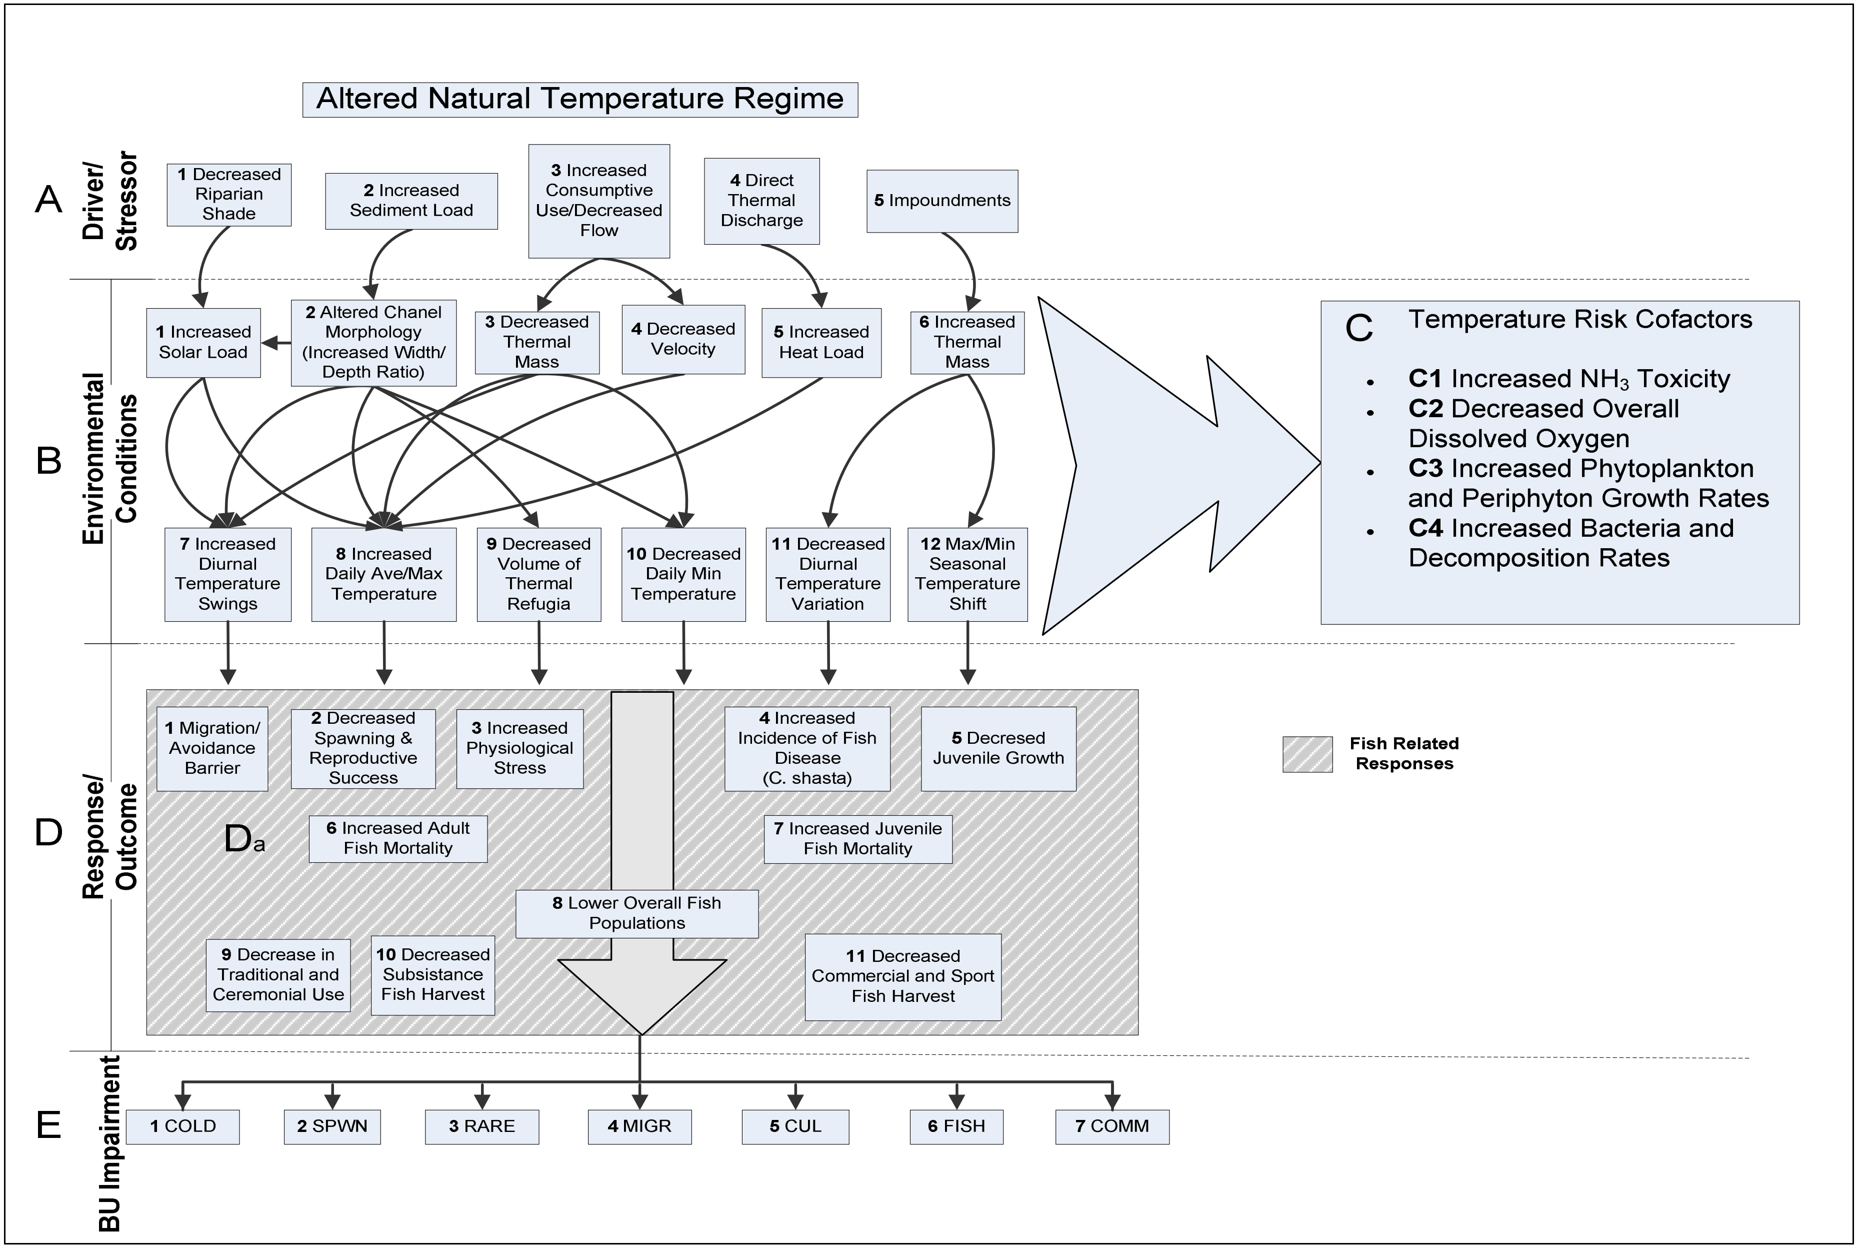

Figure 2.8: Temperature conceptual model for the Klamath River in California

natural temperature regime. There are eight nutrient risk cofactors and four temperature risk cofactors identified.

- Response/Outcome Fish and Aquatic Life (D_a) – The elements included in Category D_a involve some measure of the health of the Klamath River cold water fish populations and associated impacts to Native American culture and commercial and sport fishing. Other forms of aquatic life could be included in this category, but the cold water fish are considered most sensitive to water quality conditions resulting from increased nutrient loading and altered temperature regimes. There are 11 elements in this category for both the nutrient conceptual model and temperature conceptual models.

- Response/Outcome - Human Health and Aesthetics (D_b) – Beneficial uses linked to the human related assessment endpoints are included in category D_b. Risk related to close human contact or conditions that prohibit contact are potentially impacting long standing ceremonial practices of Tribes along the Klamath River and disruption of recreational activities. There are four assessment endpoints for this category.

- Beneficial Use Impairment (E) – Category E includes the beneficial uses that the Regional Water Board has determined to be impacted by water quality conditions in the Klamath River basin, and whose restoration will be the primary focus of the TMDL implementation plan. There are 11 beneficial uses identified as impacted in the nutrient model and seven beneficial uses identified in the temperature conceptual model.

It is not the purpose of the conceptual models developed for the Klamath River TMDL to provide a comprehensive description of all ecosystem elements and pathways. Rather the focus is on identifying assessment endpoints that either should be managed or measured as indicators of water quality condition for attaining and maintaining water quality standards in the Klamath River. The following sections describe the assessment endpoints and the linkages between the assessment endpoints that contribute to impairment of water quality standards in the Klamath River.

In the following sections, components of the nutrient conceptual model will be referenced with the letter "N", and components of the temperature conceptual model will be referenced with the letter "T". For example, a discussion related to the environmental condition of increased SOD/BOD from the nutrient conceptual model is referenced as "NB5", and a discussion of the environmental condition of increased solar loading in the temperature conceptual model is referenced as "TB1".

2.4.2 Nutrient Conceptual Model Environmental Conditions and Cofactors

The Klamath River prior to anthropogenic impacts was a highly productive ecosystem, in part driven by relatively high background loading of nutrients. More recently, anthropogenic impacts have resulted in increased levels of nutrient and organic loading and altered nutrient dynamics that have amplified the risk associated with **increased nutrient loading (NA1)** throughout the basin.

2.4.2.1 Nutrient Related Effects on Productivity

Increased nutrient loading (NA1) can result in increased primary productivity in waterbodies. Ecologically, an increase in primary production can increase the production of invertebrates and fish in streams (MacDonald et al. 1991). However, **elevated periphyton[8] and suspended algae growth (NB1, NB2)** result in high levels of algal biomass, and through algal respiration and photosynthesis can significantly **increase diurnal DO and pH swings (NB7, NB8)** and result in **decreased overall DO (NB10)** (Welch and Jacoby 2004). In their investigation of water quality conditions on the North Umpqua River, Anderson and Carpenter (1998, p.12) describe the process that occurs in rivers that have significant periphyton communities:

> Photosynthesis, a light driven process (Graham et al., 1982; Wooton and Power, 1993), consumes carbon dioxide (CO_2) and produces oxygen (Equation 1). Respiration by aquatic plants and animals, which occurs at all times, consumes oxygen and produces CO_2. Diel changes in pH are caused by shifts in the carbonate equilibrium (equation 2) as the algae utilize CO_2. (or bicarbonate, HCO3-) during photosynthesis (Wetzel 2001) faster than atmosphere inputs can equilibrate. Streams with significant periphyton communities often have supersaturated DO concentrations and high pH values late in the day and minimum DO and pH values in the early morning (for examples see Kuwabara, 1992 or Tanner and Anderson, 1996). However the solubility of DO is inversely proportional to the water temperature, which rises in response to solar radiation and thereby decreases DO solubility during daylight hours, and is also impacted by physical reaeration. In effect, stream temperature, reaeration, photosynthesis and respiration compete for control of DO and pH in streams.

Equation 1: $$6CO_2 + 6H_2O \underset{\textit{Respiration}}{\overset{\textit{Photosynthesis}}{\rightleftharpoons}} C_6H_{12}O_6 + 6O_2$$

Equation 2: $$CO_2 + H_2O \longleftrightarrow HCO_3^- + H^+ \longleftrightarrow CO_3^{2-} + 2H^+$$

The Klamath River has relatively low alkalinity (<100 mg/L) which means that it is a weakly buffered system that is susceptible to photosynthesis driven changes in pH. DO is incorporated into the Klamath River nutrient conceptual model as an assessment endpoint, and not included as a driver/stressor, because DO is an intermediate parameter that responds to the stressors. The actual concentration of DO in water depends not only

8 For the purposes of the Klamath River TMDL Problem statement the term periphyton refers primarily to plants that are attached to the substrate (mainly benthic algae). However also included are heterotrophic organisms that are also attached to stream substrate such as bacteria and other benthic macroinvertebrates.

on saturation concentration (temperature and barometric pressure dependent) but also on oxygen sinks and sources. Two of the primary oxygen sinks are **sediment oxygen demand (SOD) and biochemical oxygen demand (BOD) ($_N$B5)** of substances in the water. When organic matter, such as periphyton and suspended algae, are broken down by microorganisms in the stream this process consumes oxygen and results in **decreased DO concentrations ($_N$B10)**.

The pathways that have resulted in major documented fish mortalities in the Klamath River in the last several years are illustrated as follows: **increased nutrient loading ($_N$A1) → elevated periphyton/macrophyte growth ($_N$B1)** and **elevated suspended algae and blue-green algal growth ($_N$B2) → increased polychaete habitat ($_N$B4) → increased polychaete population and *Ceratomyxa shasta (C. shasta)* population and dosing ($_N$B9)**. This pathway is not complete without consideration of the combination of increased parasite densities with stressful water quality conditions (e.g., high temperatures, low DO) which results in an increased incidence of disease and mortality.

Ceratomyxa shasta (*C. shasta*) is thought to be indigenous to the Klamath River, and is the primary fish health issue in the Klamath River (Bartholomew et al. 2007). The lifecycle of *C. shasta* is complex because the parasite changes form and the lifecycle involves two hosts, a freshwater polychaete (worm) and a salmonid (Figure 2.9).

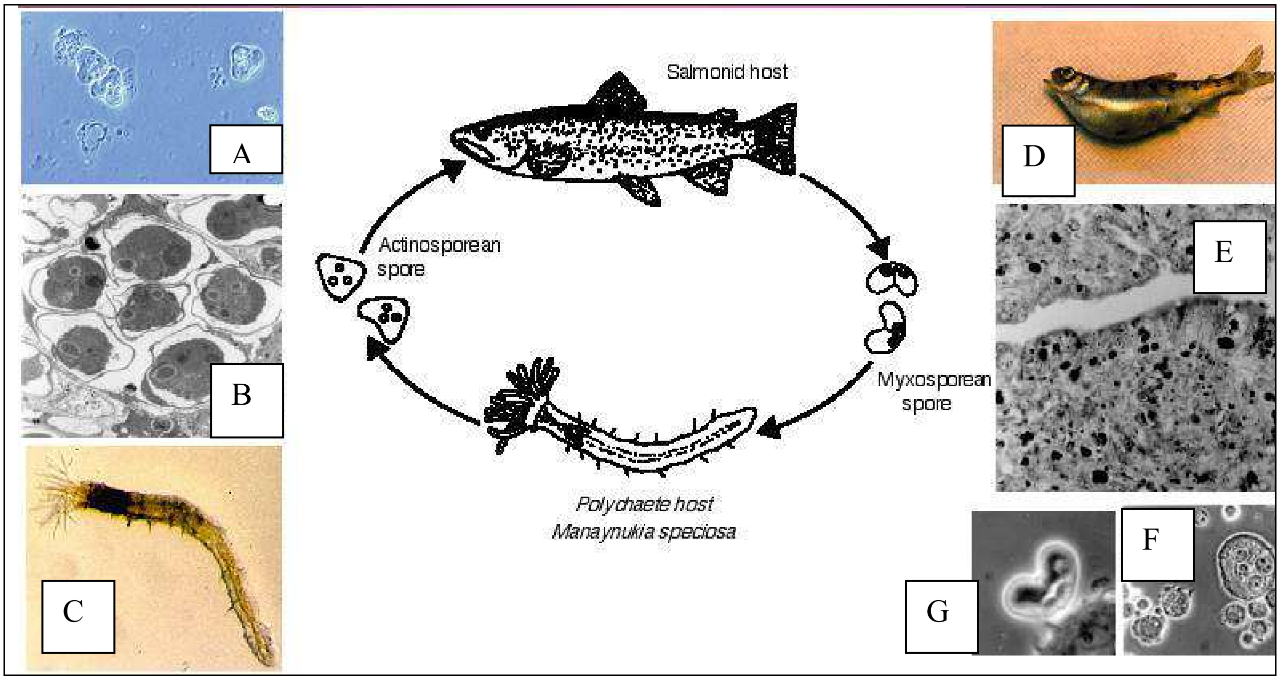

Figure 2.9: Life cycle of *C. shasta* showing release of the myxospore stage from the infected fish, the polychaete alternate host, and release of the alternate actinospore stage from the polychaete. A: released actinospores, B: electron micrograph of actinospores in the polychaete, C: polychaete, D: infected fish, E: histological section of infected intestine, F: trophozoite stages, G: myxospore
Source: Bartholomew et al. 1997 as cited by Stocking and Bartholomew 2004

One of the limiting factors for the presence of *C. shasta* appears to be the presence and abundance of the polychaete in the Klamath River (Bartholomew and Bjork 2007).

In 2003 a study by Stocking and Bartholomew (2004) found the highest densities of the polychaete living in periphyton (commonly made up of *Cladophora*). Study results from 2006 at sites located between Iron Gate Dam and Interstate-5 in California revealed that polychaete populations at habitat locations identified in 2004 and 2005 were not present in 2006, or were present in numbers too low to be considered significant (Stocking and Bartholomew 2007). According to Stocking and Bartholomew (2007), the substrate at these locations was new in 2006 and devoid of periphyton (*Cladophora)*, most likely due to scour caused by winter flushing flows. It appears that the lack of available habitat for the polychaete in 2006 led to their absence from these locations in the Klamath River.

Studies have found that the primary habitat of the polychaete also includes sand and periphyton embedded with fine particulate organic matter (FPOM) (Stocking 2006). FPOM is derived from the breakdown products of particulate organic matter, including periphyton and suspended algae.

Regional Water Board staff have consulted with Dr. Jerri Bartholomew and Mr. Richard Stocking, the principal investigators in the following studies - Bartholomew and Bjork (2007), Stocking and Bartholomew (2004), Stocking and Bartholomew (2007), and Stocking (2006) - to evaluate the presence and abundance of the polychaete that is the intermediate host for *C. Shasta* and the linkage to elevated nutrient concentrations. The conceptual model linkage is initiated with the high levels of FPOM released from the reservoirs (from upstream and within-reservoir sources) during the summer months. The FPOM is retained quite well by *Cladophora*, which grows in high densities in the river reaches below I-5, where the average river gradient decreases along with channel substrate characteristics (PacifiCorp 2004c) which are then more favorable for periphyton colonization. These high levels of FPOM appear to be a critical factor determining distribution and abundance of *M. speciosa*. According to Stocking and Bartholomew the large populations of polychaetes have been identified in the fine sediment rich inflow areas of the reservoirs, but the highest densities occur in their river samples. While the habitat is an important factor it is also likely that the populations are food limited. Published research indicates that FPOM makes up a significant portion of the Fabriciinae diet and personal observations (Stocking and Bartholomew 2007) show that *M. speciosa* (Sabellidae: Fabriciinae) is no exception. Based on discussions with Mr. Stocking the following observations support the following conceptual model linkage:

> Sparse amounts of Cladophora found near Saints Rest Bar (above the confluence with the Trinity River) possessed almost no organic matter and very low polychaete densities. Cladophora found near I-5 was saturated with FPOM and polychaetes (Stocking, 2009). Data results of numerous polychaete populations between these two locations indicate a solid trend. To the extent that project reservoirs have altered the distribution and abundance of organic matter in the Klamath River, there can be no doubt that it has also altered the abundance of C. shasta's polychaete host. (Stocking, 2009)

Based on the above information, there may be a linkage between the proliferation of *C. shasta* in the mainstem Klamath River and elevated nutrient concentrations. **Elevated nutrient concentrations (NA)** result in **increased periphyton ($_{N}$B1) and increased suspended algae and blue-green algal growth ($_{N}$B2)** in the river, which have been identified as prime habitat for the polychaete. **Increased habitat ($_{N}$B4)** leads to an **increased abundance of the polychaete ($_{N}$B9)**, which in turn leads to a high infectious spore load in the river. This results in a high probability that adult and juvenile salmonids migrating and rearing in the river will be infected by *C. shasta*.

An additional factor that is potentially shifting the balance toward increased parasite concentrations is the **elevated suspended algae and blue-green algal growth ($_{N}$B2)** in Iron Gate Reservoir, which contributes to **increased polychaete populations ($_{N}$B9)** in the mainstem Klamath River below the reservoir. The polychaetes are filter feeders and feed on fine organic detritus, as well as various forms of suspended algae. **Elevated nutrient loading ($_{N}$A)** leads to prolific amounts of phytoplankton growth in the reservoir. The phytoplankton are released into the Klamath River as water flows out of Iron Gate Dam, thus creating an abundant food source for the polychaete, which may contribute to increasing their numbers (USFWS 2006).

Figure 2.10 was presented at the 2008 Klamath River Fish Health Conference to illustrate how the balance between parasite, hosts, and the environment has shifted to favor the increased abundance of parasites. There is an emerging consensus among those conducting research on these relationships in the Klamath River basin that the changes in the environmental conditions identified in the nutrient conceptual model, in association with other risk cofactors, provides a reasonable explanation of the shift to an increasing abundance of parasites (and spores) and higher levels of infection among salmonids in the Klamath River.

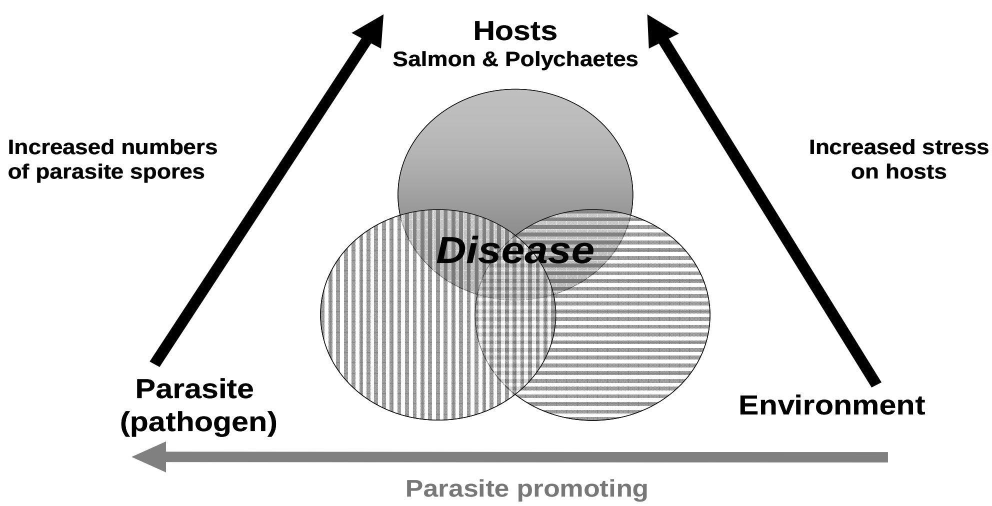

Figure 2.10: Severity of *Ceratomyxosis* in Klamath River suggests a shift in the host/parasite balance towards *C. shasta*
Source: Bartholomew personal communication 2008

The increase in the prevalence of parasite infection and related mortality is a very complex issue and it is likely that other environmental factors are also contributing to the proliferation of *C. shasta*. For example, the existing near-constant summer flow regime has eliminated extreme low flows which could cause the desiccation of the periphyton and resident polychaete populations. In addition, reduced peak flows and the elimination of small gravel from the sediment load has reduced impingement on attached periphyton reducing the amount of scouring that would normally occur, also contributing to increased periphyton densities. An example of the parasite promoting factors included in the conceptual model above is that high densities of salmonids trapped in the reach below Iron Gate lead to increased shedding of the myxosporean spore which then infects the polychaete population in the dense periphyton present downstream of the dam in the reach between Shasta and Scott Rivers. While these potential factors are not addressed explicitly in the conceptual model, they should be included in any comprehensive assessment and mitigation plan to address this issue.

In addition, the prevalence of parasite infection within the lower Klamath River downstream of Iron Gate may be due in part to the presence of the dam, which concentrates the numbers of spawners in this reach. Dense spawning redds and salmon carcasses can be found below Iron Gate Dam (Toz Soto, Karuk Tribal Fisheries Biologist, Personal Communication 2009). This observation is reinforced by U.S. Fish and Wildlife Service data (Grove 2002, as cited in FERC 2007) indicating that ~40% of the fall chinook redds observed within the 82-mile mainstem survey reach (Iron Gate Dam to Indian Creek) in 1993-2002 were located in the first 3.3 miles below Iron Gate Dam (Iron Gate to Cape Horne Creek) and another ~10% in the next 10.2 miles (Cape Horne Creek to Shasta River). There are also dense populations of the polychaete host in this same reach (Stocking and Bartholomew 2007). According to Stocking (Stocking, 2009), it appears that the prevalence of C. *shasta* in the lower Klamath River below Iron Gate may be explained by an emerging understanding of the biology of these animals (both hosts and parasite). As salmon near their spawning grounds, their immune system begins to shut down and all energy is directed towards reproduction. The parasite, *C. shasta*, takes advantage of its hosts weakened immune response and begins to proliferate within the hosts tissues in preparation for the next step in its life-cycle: infecting the polychaete host. The parasite is released from a decomposing salmon carcass, swept up in passing currents, and is deposited within a downstream population of polychaetes.

The Klamath River basin has also been subject to **excessive suspended algae and blue-green algae growth (NB2**). Blue-green algae grow and thrive in slow-moving to stagnant waterbodies such as ponds, lakes, and low gradient river reaches that usually have high nutrient loads accompanied by adequate sunlight (Hudnell 2009, and Paerl 2008). These conditions are found in Copco and Iron Gate Reservoirs, coupled with elevated nutrient concentrations, which promote nuisance **blooms of blue-green algae (NB6)**; the most common are *Microcystis aeruginosa*, *Anabaena flos-aquae, Anabaena flos-aquae,* and *Gleotricia echinulata*.

All four of these species are capable of producing cyanotoxins; however, the strain of *Aphanizomenon flos-aquae* found in Upper Klamath Lake, and subsequently transported downstream to the Klamath River, has not yet been shown to produce any toxins (Carmichael et al. 2000; Li et al. 2000). Cyanotoxins produced by these blue-green algae include dermatotoxins (cause contact dermatitis and stomach-intestinal disorders), neurotoxins (cause nervous system poisoning), and hepatotoxins (cause liver poisoning) (WHO 1999, p. 57). **Microcystin (NB11)** is a hepatotoxin produced by *Microcystis aeruginosa*, which has been measured in Copco and Iron Gate and detected in slow moving portions of the river downstream of Iron Gate dam, as well as in Klamath River fish tissue (Fetcho 2006, Kann 2006).

2.4.2.2 Nutrient Related Effects on Ammonia Toxicity

Nutrient loading to a waterbody can contribute directly to **increased ammonia concentrations (NB12)** through the addition of nitrogen to the system. The pH of the water column influences the concentration of un-ionized ammonia (NH_3) and ammonium ion (NH_4^+). As pH increases, un-ionized ammonia concentrations increase and ammonium ion concentrations decrease. These speciation relationships are important to ammonia toxicity because un-ionized ammonia is much more toxic to aquatic species than ammonium ions (USEPA 1999b). The **increased diurnal pH (NB8)** swings result in higher pH levels in the water column, and can result in **increased ammonia toxicity (NB12)**. The analysis of the potential for ammonia toxicity in the Klamath River is described below in Section 2.5.7.

2.4.2.3 Nutrient Risk Cofactors

Generally, nutrient concentrations alone do not impair beneficial uses. Rather, in combination with other factors nutrients cause indirect impacts through aquatic plant growth, low DO, high pH, and other related impacts. Nutrients are one factor in the impairment equation that must be present with other risk cofactors to express an impairment. Each of these risk cofactors contributes to the degraded conditions that exist in the Klamath River basin today. Any watershed scale recovery plan must address the potential effect of the following nutrient risk cofactors:

- **Reduced riparian habitat (NC1)** and associated reductions in shading by vegetation increases the amount of sunlight that reaches the stream and that can, in turn, drive photosynthesis of both suspended algae and periphyton. The increased solar radiation also causes **increased temperature (NC2)** of the water column which reduces oxygen saturation potential, and accelerates SOD and BOD processes. Also, reduced riparian habitat can impede riparian functions such as filtering and uptake of pollutants in runoff. These conditions are often associated with **degraded stream bank and stream channel conditions (NC3).**

- **Degraded Channel Habitat Integrity (NC3)** through sediment filling, incidental anthropogenic channel disturbance (e.g. grazing), channelization, or diking repairs can impair natural river processes that retain or remove permanently from the water column nutrients through denitrification, growth of attached algae, and the settling of organic matter. The result of these types of impacts in the upper Klamath River basin is higher downstream nutrient loading than would have occurred historically. Bernot and Dodds (2005) describe several restoration techniques for reversion to historical channel sinuosity, channel complexity, and connectivity to riparian wetlands with the objective of restoring nitrogen retention and removal characteristics.

- **<u>Increased sediment load (NC4, NC5)</u>** includes both the fine and coarse components that can originate from different sources (e.g. roads, mass wasting debris flows), but both have similar impacts on the stream ecosystem. Increased sediment load can result in stream channel aggradation, filling in pools and deeper portions of the stream channel (i.e. thalweg), creating a shallow concave channel cross-section that facilitates accelerated growth rates of periphyton and suspended algae. The transport of sediment into the water column is also a primary mechanism for nutrient loading.

- **<u>Altered flow conditions (NC6)</u>** covers a wide range of potential flow-related impacts, including: reduced flow that is more susceptible to high temperature drivers; persistent flow during normally dry conditions reducing the effect of desiccation and thus promoting excessive macrophyte and algal growth and accrual; and, for the Klamath River below Iron Gate Dam, altered sediment transport leading to reduced impingement (impact from small gravel) on periphyton due to reduced gravel transport downstream, which can increase periphyton accrual time.

- **<u>Impoundments (NC7)</u>** are a significant nutrient risk cofactor. The effect of impoundments on nutrient dynamics in the Klamath River are discussed in Section 4.2.2.2. The Klamath River impoundments are a risk cofactor for nutrients because of multiple factors:

  - Empirical data and model predictions indicate that the Copco 1 and 2 and Iron Gate Reservoirs (impoundments) have a net annual retention of nutrients (PacifiCorp 2006; PacifiCorp 2008; PacifiCorp 2009; Appendix 2 of Staff Report, Asarian et al. 2009).
  - Impoundments spread out event-driven spikes in upstream nutrient loads (PacifiCorp 2006).
  - Iron Gate and Copco Reservoirs are capable of generating their own pulses of nutrients downstream of Iron Gate Dam during intense algae blooms (see for example September 2007 conditions in Figure 14 in Asarian et al. 2009).
  - The effect of reservoir nutrient retention on downstream water quality likely varies by reach.
  - Impoundments create an environment that is more favorable to nuisance blooms of both green and blue-green algae (Kann and Corum 2009, Paerl 2008, Welch and Jacoby 2004, Kann and Asarian 2005, Wetzel 2001).

    As described in more detail in section 2.4.2.1, the Klamath River impoundments alter habitat conditions and increase fine particulate organic matter concentrations downstream of Iron Gate Dam, which may contribute to the high density of the polychaetes below Iron Gate Reservoir (which in turn supports high densities of the parasite *C. shasta*) (Stocking and Bartholomew 2007).

  - Dams typically halt the downstream transport of gravel, resulting in more coarse substrates (Biggs 2000). FERC (2007) concluded that the Klamath Hydroelectric Project reservoirs cause streambed armoring and reduce the frequency of bed-mobilizing flows. below Iron Gate Dam.. Larger substrates like cobble and boulder require higher flows to scour them than smaller substrates like gravel and sand. These coarse substrates are more stable, increasing the amount of periphyton and aquatic macrophytes that can grow (Biggs, 2000; Anderson and Carpenter 1998). In addition, the effect of reduced gravel transport and altered flows reduces the amount of impingement which is an important element contributing to dislodging attached algae (also discussed above in altered flows).

- **Increased Organic Matter Loading (NC8)** is a risk cofactor in a direct manner by contributing additional nutrients to the Klamath system and by exacerbating stressful DO conditions through SOD and BOD. The increased loading of organic matter is also a risk cofactor in a less direct manner due to its contribution to the formation of anoxic conditions that will alter nutrient dynamics increasing the abundance of dissolved inorganic nutrients contributing to increased algal productivity.

2.4.3 Temperature Conceptual Model Environmental Conditions and Cofactors

2.4.3.1 Thermal Processes Related to Solar Loading

Direct solar radiation is the primary factor influencing stream temperatures in summer months. The energy added to a stream from solar radiation far outweighs the energy lost or gained from evaporation or convection (Beschta et al. 1987; Johnson 2004; Sinokrot and Stefan 1993). At a given location, incoming solar radiation is a function of position of the sun, which in turn is determined by latitude, day of the year, and time of day. During the summer months, when solar radiation levels are highest and streamflows are low, shade from streamside forests and vegetation can be a significant control on direct solar radiation reaching streams (Beschta et al. 1987). Because shade limits the amount of direct solar radiation reaching the water, it provides a direct control on the amount of heat energy the water receives. At a workshop convened by the state of Oregon's Independent Multidisciplinary Science Team, 21 scientists reached consensus that solar radiation is the principal energy source that causes stream heating (Independent Multidisciplinary Science Team 2000).

Shade is created by vegetation and topography; however, vegetation typically provides more shade to rivers and streams than topography. The shade provided to a water body by vegetation, especially riparian vegetation, has a dramatic, beneficial effect on stream temperatures. The removal of vegetation **decreases shade (TA1)**, which **increases solar radiation levels (TB1)**, which, in turn, **increases both average and maximum stream temperatures (TB8)**, and leads to **large daily temperature variations (TB7)**. Additionally, the removal of vegetation increases ambient air temperatures, can result in bank erosion, and can result in changes to the channel geometry to a wider and shallower stream channel, all of which also increase water temperatures.

2.4.3.2 Thermal Processes Related to Sediment Load

Increased sediment loads (TA2) and associated changes in channel morphology can affect stream temperature conditions in multiple ways. These effects can manifest at both large (watershed-wide) and small (individual reach) scales. Sediment is defined as any inorganic or organic earthen material, including but not limited to: soil, silt, sand, clay, and rock (Regional Water Board 2007). The sizes of sediment that present a temperature concern are those that may result in pool filling, increased width, decreased depth, and/or a reduction of intergravel flow.

Increases in sediment loads may **alter channel morphology (TB2)**, leading to a wider and shallower wetted channel. In a study of stream channel geometry at twelve gauging stations throughout northwest California, Lisle (1982) described channel widths increasing by as much as one hundred percent, bars becoming smaller, and pools filling in response to increases in sediment supply. Channel widening associated with increased sediment loads can also result in the destruction of riparian canopy and consequent **increases in solar loading (TB1)** by increasing shear forces on channel margins (Lisle 1982). Riparian vegetation may also be removed or buried by sediment, trees, and other debris transported in debris flows. A US Forest Service report documenting the effects of the 1997 flood on Klamath National Forest resources identified the following:

> Riparian vegetation was damaged or removed from some stream segments. Temperature increases in the summer of 1997 were documented at Elk Creek, and may have occurred in the Walker, Indian, Tompkins, Portuguese, and Ukonom Creeks, as well as the South Fork of the Salmon River. Large logs were mobilized in many streams, and re-positioned within the channels. Many of the accumulations are above the bank-full channel. Additionally, channel widening undermined large trees in lower stream reaches, causing them to topple into the channel where many remain at the present time. (De la Fuente and Elder 1998, p.6, Appendix E)

Increased Width-to-Depth Ratios

A wider and shallower channel gains and loses heat more readily than a narrow and deep channel. This principal is true for any stream. A stream's width-to-depth ratio influences stream heating processes by determining the relative proportion of the wetted perimeter in contact with the atmosphere versus the streambed. Water in contact with the streambed exchanges heat via conduction. Conductive heat exchange with the streambed has a moderating influence, reducing daily temperature fluctuations. However, wide and shallow channels have a greater surface area per unit of volume in contact with the atmosphere than a narrower, deeper channel. Water in contact with the atmosphere exchanges heat via evaporation, convection, solar radiation, and long-wave radiation. Heat exchange from solar radiation far outweighs heat exchange from evaporation, convection, and long-wave radiation, unless the stream is significantly shaded. The net effect of changes in width-to-depth ratios is that streams that are wide and shallow heat and cool faster than streams that are narrow and deep (Poole and Berman 2001).

The effects of a wider and shallower channel are similar to the effects of increased solar loading. Both changes lead **to increases in daily average and maximum temperatures (TB8)**, **increased diurnal fluctuations (TB7)**, **and may lead to decreased daily minimum temperatures (TB10).**

Decreased Hyporheic Exchange

Increased sediment loads may also reduce heat exchange associated with hyporheic processes through simplification of the bed topography and reduced permeability due to increases in fine sediment deposition. Hyporheic exchange occurs when surface waters infiltrate into the interstitial spaces of stream beds. As surface water passes through the porous sediment, heat is lost (or gained) through conduction with the sediments. In some settings, streambed conduction can be a significant heat sink that buffers daily maximum temperatures in the summer season (Loheide and Gorelick 2006).

Several published studies describe mechanisms of heat transfer dependent on permeability of bed sediments, effects of sediment on stream channel morphology, and stream channel characteristics related to thermal refugia. Vaux (1968) demonstrated that hyporheic exchange is dependent on the topographic complexity of the bed surface and permeability of the sediments. Lisle (1982) reported a simplification of streambed complexity associated with aggradation at stream gauge sites following the 1964 flood. He observed that gauging sites went from a pool-like form prior to aggradation, to a riffle-like form with flat cross-sectional profiles following aggradation. Wondzell and Swanson (1999) similarly evaluated the effects of large events on channel form. They specifically evaluated changes in the hyporheic zone resulting from large flood events and demonstrated that simplification of stream channel geometry decreases intra-gravel exchange rates. Furthermore, they suggested that loss of pool-step sequences related to channel disturbances could result in decreased intra-gravel exchange.

More recently, researchers have quantified the reduction in surface stream temperatures attributable to hyporheic exchange. In a study of Deer Creek in northern California, Tompkins (2006) found that reduced daily maximum water temperatures in hyporheic seeps on the order of 3.5 ^{o}C (6.3 ^{o}F) created thermal refugia for salmonids. In a study similar to Tomkins', Loheide and Gorelick (2006) documented daily maximum temperature reductions on the order of 2 ^{o}C (3.8 ^{o}F) in study of a 1.7 km (1.1. mi) stream reach of Cottonwood Creek in Plumas County, California.

Morphological changes associated with increased sediment loads can also eliminate or result in a **decreased volume of thermal refugia (TB9)** in a stream or river and impede access to thermal refugia provided by tributaries. Refugial volume can be reduced or eliminated when deep pools fill with sediment, when side channels are buried, or when cold tributary flows percolate into aggraded tributary deltas or gravel bars before entering the river. Similarly, access to refugial tributaries can be reduced or eliminated when sediment loads result in aggradation and cause a tributary to percolate before entering the mainstem and thus become disconnected from the mainstem or become too shallow for fish to swim. Aggradation has impacted the mouths of Hunter, Turwar, Independence, Walker, Oneil, Portuguese and Grider Creeks, as well as 14 of 17 small Lower Klamath tributaries surveyed by the Yurok Tribe (De La Fuente and Elder 1998; Kier Associates 1999). Finally, refugia can be eliminated when tributary temperatures increase beyond salmonid thresholds due to the other effects of increased sediment loads discussed above.

2.4.3.3 Thermal Processes Related to Flow

Surface water diversions (TA3) decrease the volume of water in the stream, and thereby decrease a stream's capacity to assimilate heat. When water is removed from a stream the **thermal mass (TB3)** and **velocity (TB4)** of the water is decreased. Thermal mass refers to the ability of a body to resist changes in temperature. Basically, less water heats or cools faster than more water. Decreases in velocity increase the time required to travel a given distance, and thus increases the time heating and cooling processes can act on the water. These principles are true for any stream, and work in concert with other heat exchange processes to determine the overall temperature of a stream.

The increase in the rate of heating that accompanies a decrease in the volume of flow in a stream can have significant temperature effects. A decrease in thermal mass results in **higher daily high and lower daily low temperatures (TB7, TB8, TB10)**, as well as **higher daily average temperatures (TB8)**. Reduced velocities also result in **higher daily average temperatures (TB8)**.

2.4.3.4 Thermal Processes Related to Direct Thermal Discharges

Direct thermal discharge (TA4) is the discrete addition of heat to a waterbody. Direct thermal discharges occur when water is used in a cooling process, such as in power generation or industrial settings, or when warm materials are placed in a waterbody. In the Klamath basin the main source of direct thermal discharges is related to irrigation tailwater return flows.

Flood irrigation is a common irrigation practice in parts of the Klamath basin, including the Klamath Project area and the Shasta River watershed. When irrigation water is applied to a field in this manner, it generally flows across the field as a thin sheet or in shallow rivulets. As the irrigation water runs across the ground it absorbs heat. When irrigation flows return to a stream, they carry with them the **increased heat load (TB5)** added as they pass through the irrigated lands. Regional Water Board staff deployed temperature monitoring devices at several Shasta Valley locations with irrigation return flows. Upon review of the monitoring results, it was very difficult to determine when the temperature monitoring probes were exposed to irrigation return flow versus when they were exposed to the air, indicating that the temperature of the tailwater return flows was generally at equilibrium with the air temperature. The net effect of direct thermal discharges is an **increase in both daily average and maximum temperatures (TB8)**.

2.4.3.5 Thermal Processes Related to Impoundments

The water stored behind a **dam (TA5)** functions as **thermal mass (TB6)**, storing heat. Because larger volumes of water heat and cool slower than smaller volumes, the large volume of water behind an impoundment acts as a temperature buffer, **reducing daily**

temperature variations downstream (TB11). Similarly, large volumes of water resist **seasonal changes in temperature (TB12)**, and thus delay seasonal temperature changes, resulting in colder temperatures in the spring and warmer temperatures in the fall. In the Klamath River, these effects may extend downstream to the Pacific Ocean under certain conditions (Bartholow et al. 2005). The effects are most pronounced immediately downstream of Iron Gate Dam, diminishing in the downstream direction.

The expected biological implications of the changes in diurnal temperature patterns caused by dams are mixed. The **decreased diurnal temperature variation (TB11)** associated with dams lead to reduced peak temperatures, thereby reducing the most acutely harmful temperatures. Conversely, the increased daily low temperatures associated with dams could reduce the time available for fish to leave thermal refugia to feed. Also, higher daily low temperatures may lead to higher temperatures at the bottom of thermally stratified pools (Nielsen et al. 1994).

The **seasonal temperature changes (TB12)** caused by the dams may also have biological implications. Bartholow et al. (2005) evaluated the thermal effects of the Klamath River dams on downstream reaches and determined that the dams delay the seasonal temperature patterns by approximately 18 days on an annual basis. The physical implication of an 18 day shift in the seasonal temperature pattern is that the river is cooler in the springtime when juvenile salmonids are migrating to the ocean, and warmer in the fall when adults are migrating upstream and spawning, and eggs are incubating in the gravels. Cooler temperatures are known to reduce juvenile salmonid growth rates; however this effect may be mitigated by the benefit gained by reduced incidence of stressfully high temperatures during outmigration. Warmer temperatures in the summer period may reduce the nocturnal feeding opportunities of juvenile salmonids that persist at thermal refugia, thereby reducing their ability to withstand stressfully high daytime temperatures (National Research Council of the National Academies [NRC] 2004). Warmer temperatures in the fall may delay adult migration or lead to stressfully high temperatures when adults are present or eggs are incubating in gravels. More discussion of this topic can be found in Section 2.5.2.1.

2.4.3.6 Temperature Risk Cofactors

Adverse temperature conditions may combine with other factors to further impair beneficial uses beyond the primary effects of high temperatures. Temperature is a physical factor that affects chemical concentrations and biological growth rates of other factors that affect habitat and water quality. These factors are described below. Each of these risk cofactors contribute to the degraded conditions that exist in the Klamath River basin today. Any watershed scale recovery plan must address the potential effect of the following temperature risk cofactors:

- **Increased NH_3 Toxicity (TC1)** – The concentration of un-ionized ammonia (NH_3) in water increases with higher temperature, higher pH, and higher concentration of ionized ammonia (NH_4^+). In waterbodies that have high concentrations of ionized ammonia and frequent excursions of high pH an increase in temperature can result in the formation of un-ionized ammonia, which is toxic to fish and other organisms.

- **Decreased Overall Dissolved Oxygen (TC2)** – The concentration of DO in water is partly a function of the temperature of the water. Colder water can absorb more DO than warm water, if all other factors are equal. Higher temperatures reduce the DO saturation concentration, increasing the risk that other factors that cause a decrease in DO will result in concentrations less than the criteria concentrations needed to support beneficial uses.

- **Increased Suspended Algae and Periphyton Growth Rates (TC3) –** Algal growth rate is partially dependent on the temperature at which they grow. Generally, higher temperatures result in higher rates of growth (up to a limiting temperature), if all other factors are equal.

- **Increased Bacteria and Decomposition Rates (TC4)** – The rate at which bacteria grow and decay is partially dependent on the temperature of the water they are in. Higher temperatures result in higher rates of growth and decay, if all other factors are equal, resulting in greater oxygen demand within the surrounding water column.

2.4.4 Responses/Outcomes

The driver/stressors and environmental conditions discussed in the previous sections have resulted in the response/outcomes identified in Section D of the Nutrient and Temperature Conceptual Models. Many of these have been well documented and are discussed in the following sections, which describes impacts to Klamath River beneficial uses. The current conditions of many of the indicators described in this section will be presented in Section 2.5 to better assess their actual impact on beneficial uses within the Klamath River basin. Additional information on the effects of an altered natural temperature regime and the secondary effects of elevated nutrient levels on salmonids is available in Appendix 4, *Effects of Temperature, Dissolved Oxygen/Total Dissolved Gas, Ammonia, and pH on Salmonids.*

2.4.4.1 Migration/Avoidance Barrier (D_a1)

High water temperatures can inhibit or block upstream migration of adult salmonids. One study specific to the Klamath River was conducted by Strange (2007) and evaluated the association between water temperature in the mainstem Klamath River and adult fall Chinook migration. Utilizing radio telemetry to track the movements and monitor the internal body temperatures of adult fall Chinook salmon during their upriver spawning migration in the Klamath basin, Strange (2007) found that fall Chinook will not migrate upstream when mean daily temperatures are ≥22°C. Strange also noted that adult fall Chinook in the Klamath basin will not migrate upstream if temperatures are 21°C or above and rising, but will migrate at temperatures as high as 23°C if temperatures are rapidly falling.

The upstream migration by adult salmonids is typically a stressful endeavor. Sustained swimming over long distances requires high expenditures of energy and therefore requires adequate levels of DO. Migrating adult Chinook salmon in the San Joaquin River exhibited an avoidance response when DO was below 4.2 mg/L, and most Chinook waited to migrate until DO levels were at 5 mg/L or higher (Hallock et al. 1970). The swimming performance of migrating salmonids is also impacted by reduced concentrations of DO (Bjornn and Reiser 1991).

2.4.4.2 Decreased Spawning and Reproductive Success (D_a2)

There is evidence that fish that over-summer in stressfully high temperatures and low DO concentrations experience reduced reproductive success (Coutant 1987). A study by Coutant (1987) demonstrates that fish experiencing the combination of high temperatures and low DO are subject to physiological harm that persists well after the fish are exposed to these water quality conditions. Persistent effects of high temperature and low DO include a reduction in female spawning success and poor embryo survival.

2.4.4.3 Increased Physiological Stress (D_a3)

Increased temperature and the secondary effects of nutrient loading can result in physiological stress on salmonids. The metabolic processes of salmonids are directly related to temperature. When water temperatures are above the optimal metabolic range for salmonids, the resting metabolic rate increases dramatically. This results in reduced feeding rates, swimming speed, growth, reproduction, and resistance to environmental extremes (USEPA 2001, p.39). Also, if temperatures are high, much of the energy assimilated from food is lost as excessive metabolism (USEPA 2001, p.85). High incubation temperatures may create a metabolic energy deficit for pre-emergent salmon that increases mortality (Heming 1982, as cited by USEPA 2001, p.31). Further, the stressful impacts of water temperatures on salmonids are cumulative and positively correlated to the duration and severity of exposure. The longer the salmonid is exposed to thermal stress, the less chance it has for long-term survival (Ligon et al. 1999).

As the metabolic rates of salmonids increase there is an increased physiologic demand for oxygen. Low DO concentrations (<4-5 mg/L) result in decreased size of newly hatched salmonids (WDOE 2002a, p.14), as well as decreased juvenile salmonid growth and food consumption (Bjornn and Reiser 1999, p.118; Herrmann et al. 1962; and USEPA 1986, p.5-8), and decreased food conversion efficiency (ODEQ 1995, p.A-6). When DO levels are extremely low (2-3 mg/L) weight loss can occur due to decreased food consumption (Herrmann et al. 1962). Low DO concentrations also adversely affect swimming performance in both adult and juvenile salmonids (Bjornn and Reiser 1999, pp.85, 118, 119; WDOE 2002a, p.46).

Concentrations of ammonia acutely toxic to fishes may cause loss of equilibrium, hyperexcitability, increased breathing, cardiac output and oxygen uptake, and, in extreme cases, convulsions, coma, and death. At sub-acute concentrations, ammonia has many effects on fishes, including a reduction in hatching success, reduction in growth rate and morphological development, and pathologic changes in tissues of gills, livers, and kidneys (USEPA 1986, p.17).

The pH of freshwater streams, lakes, and reservoirs is also important for adult and juvenile salmonid development, and is influenced by the respiration of benthic algae and suspended algae. Chronic effects from low pH can occur at levels that are not toxic to adult fish but that impair reproduction including altered spawning behavior, reduced egg viability, decreased hatchability, and reduced survival during early life stages when salmonid development is most vulnerable to low pH (Jordahl and Benson 1987). Chronic high pH levels in freshwater streams can decrease activity levels of salmonids, create stress responses, decrease or cease feeding, and lead to a loss of equilibrium (Murray and Ziebell 1984; Wagner et al. 1997). Additionally, high temperatures can exacerbate the effects of high pH levels on salmonids, and if pH reaches extremely low or high levels, death can occur (Wagner et al. 1997).

2.4.4.4 Increased Incidence of Fish Disease (*Ceratomyxa shasta* and Columnaris) (D_a4)

The USFWS California-Nevada Fish Health Center has identified *C. shasta* as the primary fish health issue in the Klamath River, and Columnaris is the second biggest fish health threat (Foott 2005). Disease has been cited as the ultimate cause of death in most of the adult and juvenile fish kills which have occurred in the Klamath River from Iron Gate Dam to the mouth (CDFG 2000; CDFG 2004; Deas 2000; Engbring 2004; Foott 2000; Foott et al. 2002; Hannum 1997; Hendrickson 1997; KFHAT 2005; Klamt and Carter 2004; USFWS 1997; USFWS 2003a; USFWS 2003b; Williamson and Foott 1998). On more than one occasion the outbreak of disease was termed an "epizootic" (the equivalent of an epidemic in humans), and in all cases the disease outbreaks were exacerbated by a combination of poor water quality conditions including high water temperatures, low DO levels, sediment deposition, and high ammonia concentrations (CDFG 2000; CDFG 2004; Deas 2000; Engbring 2004; Foott 2000; Foott et al. 2002; Foott 2005; Hannum 1997; Hendrickson 1997; KFHAT 2005; Klamt and Carter 2004; USFWS 1997; USFWS 2003a; USFWS 2003b; Williamson and Foott 1998).

The USEPA (2003) and Washington Department of Ecology (WDOE 2002b, p.115) report that as water temperatures increase, the risk and severity of a disease outbreak increases. The infectivity of *C. shasta* and Columnaris increases with increasing temperature, and the lifecycle of these diseases shorten with increasing temperature, making outbreaks more likely. WDOE (2002b) expresses the temperature thresholds that are likely to prevent or exacerbate disease outbreaks as a Maximum Weekly Maximum Temperature (MWMT), which is the maximum seasonal or yearly value of the daily maximum temperatures over a running seven-day consecutive period. The Washington Department of Ecology (WDOE 2002b, p.115) conducted a review of studies on disease outbreak in salmonids and estimated that an MWMT of less than or equal to 14.4°C (midpoint of 12.6-16.2 range) will virtually prevent warm water disease effects. According to WDOE (2002b, p.115), to avoid serious rates of infection and mortality the MWMT should not exceed 17.4°C (midpoint of 15.6-19.2 range), and that severe infections and catastrophic outbreaks become a serious concern when the MWMTs exceed 21.0°C (midpoint of 18.6-23.2 range). In a summary of temperature considerations, USEPA (2003) states that disease risks for juvenile rearing and adult migration are minimized at temperatures from 12°C to13°C, elevated from 14°C to 17°C, and high at temperatures from 18°C to 20°C. Additionally, the crowding of salmonids in thermal refugia increases the likelihood of fish-to-fish transmission of Columnaris.

When the infectious spore load of *C. shasta* in the Klamath River is low, or juvenile salmonids are exposed for less than 24 hours, they can successfully rear at temperatures as high as 21°C (Foott 2006). However, if the infectious spore load in the river is high, or juvenile salmonids are exposed for long periods of time (2-4 days), mortality occurs at temperatures as low as 16°C (Foott 2006).

As discussed in Section 2.4.2.1 there may be a linkage between the proliferation of *C. shasta* in the mainstem Klamath River and elevated nutrient concentrations. Elevated levels of nutrients and organic matter allow for the proliferation of prime polychaete habitat (periphyton and pockets of fine benthic organic matter) and thus large numbers of polychaetes and high infectious spore load in the river. This can lead to an increased probability of *C. shasta* infections.

2.4.4.5 Decreased Juvenile Growth (D_a5)
Low dissolved oxygen levels and elevated temperatures can result in decreased juvenile fish growth, including growth of salmonids.

> Hutchins (1973 [as cited by WDOE 2002a]) reported that at 15°C, growth of juvenile coho salmon fed to repletion and held at velocities between 1.2 and 3.6 l/sec (lengths per second) at an oxygen level of 3 mg/L for 10 to 12 days was reduced by 20 and 65 percent from that of a control salmon held at respective velocities in air-saturated water (9.5 mg/L). At the intermediate oxygen concentration of 5 mg/L, growth rates of salmon were reportedly reduced by 0 and 15 percent over controls, respectively.
>
> Herrmann et al. (1962 [as cited by WDOE 2002a]) found that juvenile coho salmon (age class 0) held at 20°C and fed to repletion twice daily experienced declines in growth with reduction of oxygen from a mean of about 8.3 to 6 and 5 mg/L, and declined more sharply with further reduction of oxygen concentration, suggesting further that concentrations near 4 or 5 mg/L can be exceedingly detrimental. The authors estimated a reduction of both percent weight gain and the rate of food consumption by about 11 percent with reduction of oxygen concentration from 8.3 to 5.0 mg/L, and by at least twice as much with reduction of oxygen concentration to 4 mg/L.

Elevated water temperature has a detrimental effect on juvenile salmonid growth. Banks et al. (1971 as cited by WDOE 2002b) found that growth was similar at 15.6°C and 18.3°C, however temperatures above 19°C were associated with reduced feeding and growth, as well as increased problems with disease. Marine and Cech (2004) found that growth was substantially reduced at 21-24°C when compared to 13-16°C.

2.4.4.6 Increased Fish Mortality and Lower Overall Populations (D_a6, D_a7, D_a8)
The effects of altered temperature, decreased DO, and increased nutrient loading can have a significant impact on salmonids. In the Klamath River basin, the impacts of high water temperature directly, and in combination with other factors, has likely resulted in both adult and juvenile fish mortality and contributed to lower overall fish populations.

Bartholow (1995, p.19) states, "…water temperatures in the Klamath basin are marginal at best for anadromous salmonids, squeezing their thermal resources in both space and time." The National Research Council of the National Academies (NRC) state that various factors including decreased flows and increased water temperatures in the Klamath River basin have contributed to declining salmonid populations during the 20th century (NRC 2004, p.284). Salmonid populations in the Klamath River basin have declined sharply since the early 1900's. In 1931, Snyder (1931, p.9, 121) wrote that the fishery of the Klamath River basin is very important because with proper management it can be maintained, although he also states that depletion of the Klamath salmon is apparent and occurring at an "alarming rate" which artificial propagation alone may not remedy. The NRC (2004, p.284) reports that virtually all Klamath River basin populations of salmonids have declined considerably from their historical abundances, and note the significant link between the decline in coho, spring Chinook, and summer steelhead to the "verge of extinction" and their dependence on cool summer water temperatures. The NRC also notes that the Klamath River has become inhospitable to juvenile coho due to high water temperatures, and although the Klamath River is still important for rearing Chinook and steelhead, further increases in temperatures may make it unsuitable even for those species (NRC 2004, p.284). NRC (2004, p.268) state that in some respects, "…it is remarkable that fall-run Chinook salmon in the Klamath River are doing as well as they seem to be. Both adults migrating upstream and juveniles moving downstream face water temperatures that are bioenergetically unsuitable or even lethal." In 1991, the Klamath River Basin Fisheries Task Force (KRBFTF) identified increased stream temperatures in the lower Klamath River as impeding the recovery and posing threats to coho, winter steelhead, and late run fall Chinook (KRBFTF 1991, p.4-29). A discussion of how temperature and other water quality factors are contributing to fish mortality and salmonid population decline can be found in Section 2.6.1.

2.4.4.7 Impacts to Cultural and Harvest-Related Activities (D_a9, D_a10, D_a11)
The reduction of overall salmonid populations impacts the availability of fish for commercial, sport, and subsistence fish harvesting, as well as traditional and ceremonial uses. All of these activities require robust fish populations for long-term sustainable use of the resource. Thus, water temperatures, DO, pH, and ammonia toxicity outside the range of salmonid suitability can significantly impact these activities. Evidence of temperature and nutrient related impairment to harvest related activities is presented in Sections 2.6.2 and 2.6.4.

2.4.4.8 Impacts to Municipal Supply, Recreation, and Traditional/Cultural Use (D_b1, D_b2, D_b3, D_b4)
Elevated nutrient concentrations in the Klamath River basin have contributed to nuisance blooms of the blue-green algae *Microcystis aeruginosa*, which produces the cyanotoxin

microcystin. Exposure routes of cyanotoxin poisoning can be via direct water contact, ingestion of contaminated water, breathing of aerosolized toxin bearing water, and possibly secondarily through the ingestion of infected fish or other vertebrates, invertebrates, and plant matter. As detailed in Section 2.5.4 this toxin has been detected in Copco and Iron Gate Reservoirs at levels which are considered dangerous for contact or consumption, leading to the posting of public health warnings at the reservoirs and various locations along the river.

The Klamath River Tribes utilize the river for traditional and ceremonial uses including bathing, plant gathering, ingestion, and other activities discussed in Section 2.6.2. The presence of microcystin in the lower river presents a potential human health risk for the Tribes. Further, mats of suspended algae in the reservoirs and river are an aesthetic nuisance impacting the public's ability to enjoy the natural beauty of these waters leading to impacts on the Rec-1 and Rec-2 uses. Additionally, taste and odor problems are associated with high densities of blue-green algae, and these compounds are difficult and costly to remove from water supplies (Welch and Jacoby 2004, p.172).

2.5 Evidence of Water Quality Objective and Numeric Target Exceedances

This section presents observed water quality conditions and evaluates the data with respect to the relevant water quality objectives or surrogate thresholds.

2.5.1 Temperature and Nutrient Data Sources

Stream temperature data used for this analysis were provided by the US Forest Service, Yurok Tribe, Karuk Tribe, Forest Science Project, US Fish and Wildlife Service, Salmon River Restoration Council, and PacifiCorp. In addition, Regional Water Board staff collected temperature data.

For the DO and nutrient analyses, Regional Water Board staff compiled monitoring data from several sources including the US Fish and Wildlife Service, US Geological Survey, PacifiCorp, Karuk Tribe, Yurok Tribe, Regional Water Board, and the US Environmental Protection Agency Environmental Monitoring and Assessment Program.

2.5.2 Temperature

Regional Water Board staff conducted a literature review to evaluate stream temperature requirements for the various life stages of steelhead trout (*Oncorhynchus mykiss*), coho salmon (*Oncorhynchus kisutch*), and Chinook salmon (*Oncorhynchus tschawytscha)* as a means for interpreting the narrative temperature objective in the Basin Plan (Regional Water Board 2007). As a result of this literature review, Regional Water Board staff selected chronic and acute temperature thresholds for evaluating Klamath River basin temperatures. These temperature thresholds are used for assessing the suitability of current Klamath River basin temperatures for fully supporting salmonids. These thresholds are *not* numeric water quality targets used for calculating the Klamath River temperature TMDL. The numeric temperature targets are discussed in Section 2.3.1 and the specific temperature targets are presented in Chapter 5.

Chronic temperature thresholds were selected from the USEPA document *EPA Region 10 Guidance for Pacific Northwest State and Tribal Temperature Water Quality Standards* (2003), and are presented in Table 2.8. The Region 10 guidance is the product of a three-year interagency effort, and has been reviewed by both independent science review panels and the public. Lethal temperature thresholds were selected based upon best professional judgment of the literature, and are presented in Table 2.9. Although some studies of southern California steelhead suggest the possibility of higher temperature tolerances of salmonids occupying the southern end of the species range (Spina 2007), available studies from northern California indicate that the thresholds expressed in USEPA's guidance (2003) are appropriate for the north coast region (Welsh et al. 2001; Hines and Ambrose undated).

Table 2.8: MWMT chronic effects temperature thresholds

Life Stage	**MWMT (°C)**
Adult Migration	20
Adult Migration plus Non-Core Juvenile Rearing [1]	18
Core Juvenile Rearing [2]	16
Spawning, Egg Incubation, and Fry Emergence	13

Source: USEPA 2003

[1] The Adult Migration plus Non-Core Juvenile Rearing designation is recommended by USEPA (2003) for the "protection of migrating adult and juvenile salmonids and moderate to low density salmon and trout juvenile rearing during the period of summer maximum temperatures," usually occurring in the mid to lower part of the basin. The phrase "moderate to low density" is not specifically defined.

[2] The Core Juvenile Rearing designation is recommended by USEPA (2003) for the "protection of moderate to high density summertime salmon and trout juvenile rearing" locations, usually occurring in the mid to upper reaches of the basin. The phrase "moderate to high density" is not specifically defined.

Table 2.9: Lethal temperature thresholds

Lethal Threshold[1] (°C)			
Life Stage	**Steelhead**	**Chinook**	**Coho**
Adult Migration and Holding	24	25	25
Juvenile Growth and Rearing	24	25	25
Spawning, Egg Incubation, and Fry Emergence	20	20	20

Source: Appendix 4

[1] The lethal thresholds selected in this table are generally for chronic exposure (greater than seven days). Although salmonids may survive brief periods at these temperatures, they are good benchmarks from the literature for lethal conditions. See Appendix 4 for further discussion.

These freshwater temperature thresholds are applicable during the time of year when the life stage of each species is present in the Klamath River basin. Where life history, timing, and/or species needs overlap, the lowest of each temperature metric applies. A discussion of the distribution and periodicity of salmonids in the Klamath River basin is available in Appendix 5, *Fish and Fishery Resources of the Klamath River Basin*. Additional information on the effect of temperature on salmonids and a brief discussion of temperature metrics are available in Appendix 4.

2.5.2.1 <u>Mainstem Klamath River</u>

Temperature data from the Klamath River mainstem indicate that seasonal maximum temperatures are not supportive of beneficial uses. Figure 2.11 shows that MWMT values at all sites from the Oregon-California state line to the estuary are well above the suitable temperature range for full support of salmonids as described by USEPA (2003). These data clearly demonstrate that the river has no capacity to assimilate increased heat loads during the hottest critical periods without adversely affecting the beneficial uses COLD, RARE, and MIGR.

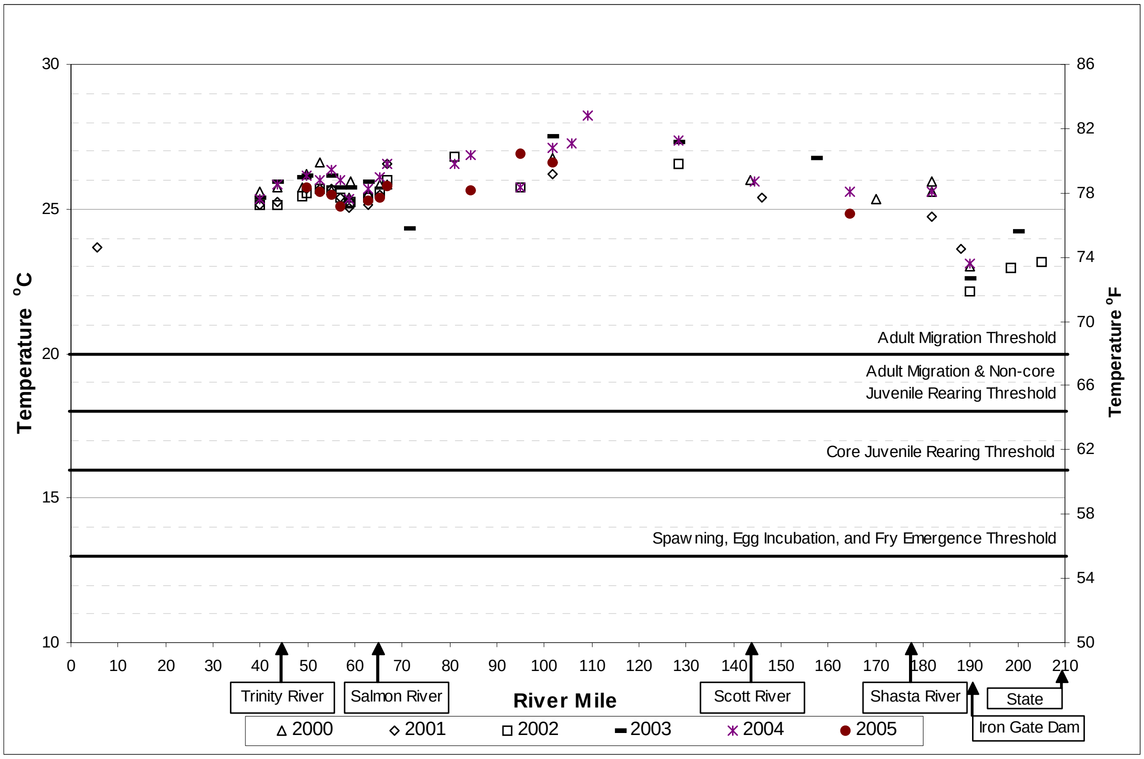

Figure 2.11: Measured Klamath River MWMTs, 2000-2005.
Note: MWMTs typically occur in late July.

The reduced diurnal temperature variation associated with the impoundments seen in Figure 2.12 also results in adverse impacts to coho salmon. The National Research Council report clearly summarizes the effects of elevated daily low mainstem temperatures on coho salmon:

> Overall, it appears that the bioenergetic demands of juvenile coho prevent them from occupying the main stem. Even with abundant food, the thermal refugia (the pools at mouths of tributaries) are inadequate: nighttime temperatures stay too high for them, and the energy costs of interactions with Chinook and steelhead, both of which are much more abundant in the pools, are probably high. Coho juveniles in the pools during June and July may die by late summer. (NRC 2004, p.220).

The results of water quality modeling completed for this TMDL process indicate that human activities have significantly altered the temperature regime of the mainstem Klamath River. The application of the water quality models is described in Chapter 3. These results indicate that the combined effects of human activities in the basin commonly result in temperature alterations in excess of 5 °F, and these alterations can be as much as 18 °F. Figure 2.12 presents simulated natural and current Klamath River temperatures, and the calculated difference, at the site of maximum temperature alteration in California.

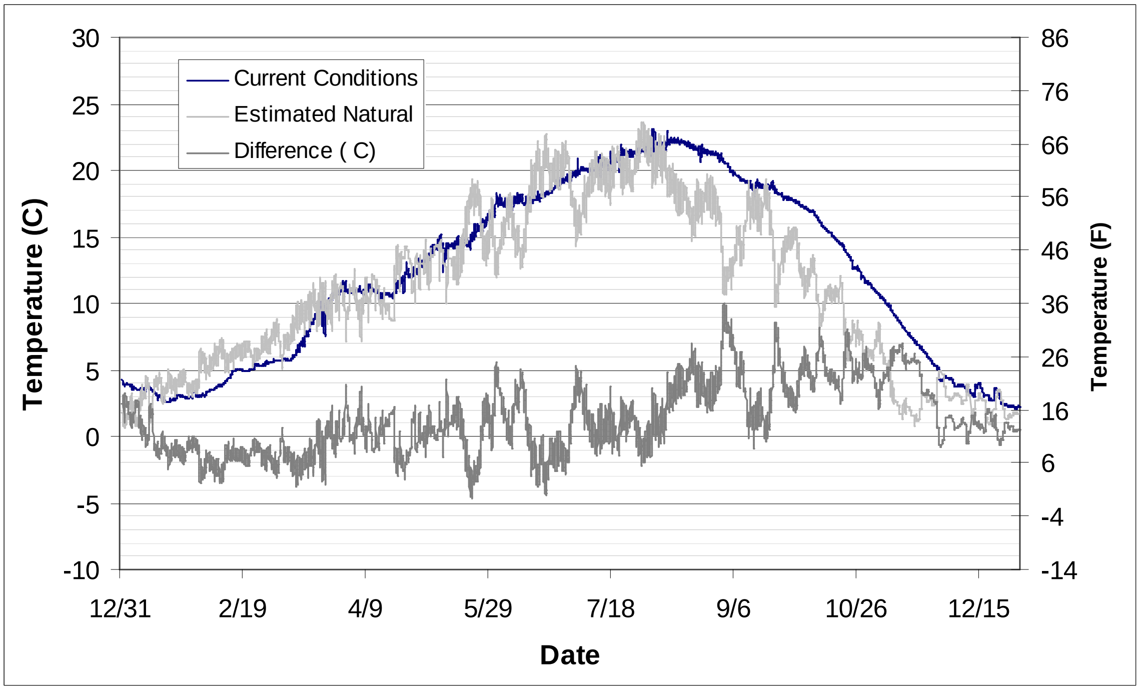

Figure 2.12: Current and estimated natural temperatures downstream of Iron Gate Dam, with difference in temperature, 2000
Note: Model results presented at 1-hour time step.

The results of the water quality modeling completed for this TMDL process are consistent with results of an analysis of temperature effects caused by the Klamath Hydroelectric Project in the 5 years from 2000-2004 (Dunsmoor and Huntington 2006). The results of that analysis are presented in Figure 2.13 and were developed using an earlier version of the modeling system used in this analysis.

This space intentionally left blank.

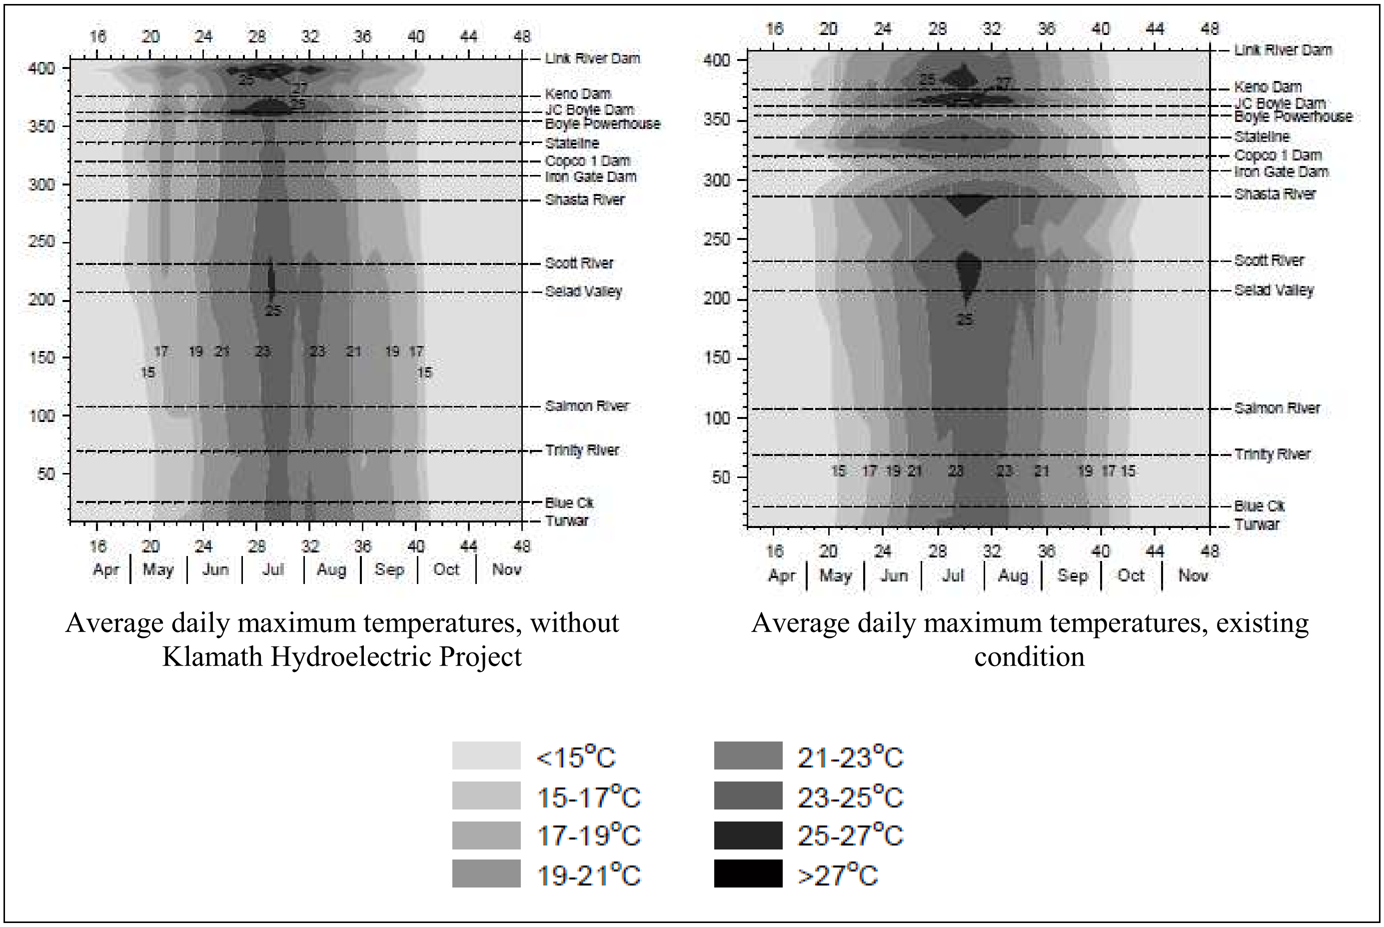

Figure 2.13: Simulated Klamath River temperatures, by week, 2000-2004.
Source: Dunsmoor and Huntington 2006

The temperature modeling indicates human impacts are responsible for the elevated temperatures that are above biological temperature thresholds for rearing juvenile salmonids and reproductive success of adult salmonids. Under current conditions, the seasonal increase in temperatures during the winter and spring months is delayed in comparison to estimated natural temperatures. Similarly, the seasonal decline in temperatures during the fall months is also delayed in comparison to estimated natural temperatures. Dunsmoor and Huntington (2006) evaluated the effects of the delay in the seasonal fall temperature decline on salmonids due to the Klamath Hydropower Project. They evaluated Pacificorp's model output data for the years 2000-2004. Their analysis of temperature alteration during the fall months indicates impaired spawning conditions resulting from the presence of the Klamath Hydropower Project, and is summarized in Table 2.10, below.

This space intentionally left blank.

Table 2.10: Summary of fall temperature effects resulting from human alteration at Iron Gate Dam.

	Pacificorp Model, 2000-2004 (Dunsmoor and Huntington, 2006)		**Klamath TMDL Model, 2000**	
Time Period	**Existing Condition**	**Without Project Condition**	**Existing Condition, MWMT (C)**	**Natural Conditions, MWMT (C)**
Sept. 10-23	Stressful or worse 90% of days	Stressful 9% of days	19.2	18.7
Sept. 24 – Oct. 7	Suboptimal or worse 100% of days	Suboptimal 37 % of days	18.1	15.5
Oct. 8 – Oct. 21	Suboptimal 70% of days	Suboptimal 1% of days	16.1	11.4
Oct. 22 – Nov. 4	Optimal 100% of days	Optimal 100% of days	12.9	8.2

Bartholow et al. (2005) concluded that in comparison to the expected temperatures resulting from a natural flow regime, the Klamath River dams create temperature conditions more favorable to migrating juveniles in the spring and less favorable to adults migrating and spawning in the fall. They suggested that the increased temperatures occurring later in the spring may increase growth rates. However, juvenile fish migrating down the Klamath River in the spring suffer high mortality rates due to C. Shasta, which is more virulent at temperatures that typically occur that time of year (see section 2.4.4.4 and Appendix A). Bartholow et al. (2005) further speculated that the changes in seasonal temperature patterns may have affected the timing of the Chinook salmon run since the dams were constructed.

The growth of juvenile salmonids is partially dependent on temperature (USEPA 2003). The optimal temperature range for juvenile salmonids is 10-15 ^{o}C, with a lower limit of 4 ^{o}C (USEPA 2003). The ability of salmonids to survive the ocean phase of their life cycle is partially dependent on their size upon entering the ocean. Thus, the delay in warming that occurs in the late winter may reduce the growth rates of salmonids rearing in the Klamath River, and may ultimately reduce the survival rate of salmonids in the ocean.

USEPA (2001) reviewed multiple literature sources and concluded that optimal protection of salmonids from fertilization through initial fry development requires that temperatures be maintained below 9-10°C, and that daily maximum temperatures should not exceed 13.5-14.5°C. Under current conditions, these temperatures are not reached until late October or November. However, the current Chinook spawning season begins in mid-September and peaks in late October (see Appendix 5 for more details).

In summary, the temperature alterations presented in Figure 2.12 result in adverse effects to salmonids. The comparison of estimated natural and current temperatures for the year 2000 at the location downstream of Iron Gate Dam clearly shows that the water quality objective for temperature is regularly exceeded. This conclusion is based on the observation that current temperatures are regularly more than 5^{o}F above the estimated natural temperatures, and the fact that there is no capacity to assimilate increased heat loads during the hottest critical periods without adversely affecting the beneficial uses.

2.5.2.2 Tributaries to the Klamath River

Tributaries are important habitat for Klamath River salmonids. Tributaries provide the majority of available rearing habitat for juvenile salmonids (NRC, 2004). In addition, many tributary mouth pools provide a refuge from higher mainstem temperatures for chinook salmon and steelhead (*Ibid*). Temperature data from the mouths of Klamath tributaries indicate that the seasonal maximum temperatures of the majority of the tributaries are not supportive of beneficial uses. The MWMT values at most of these sites are well above the non-core (low density rearing habitat) juvenile rearing threshold for salmonids suggested by USEPA (2003), as illustrated in Figure 2.14.

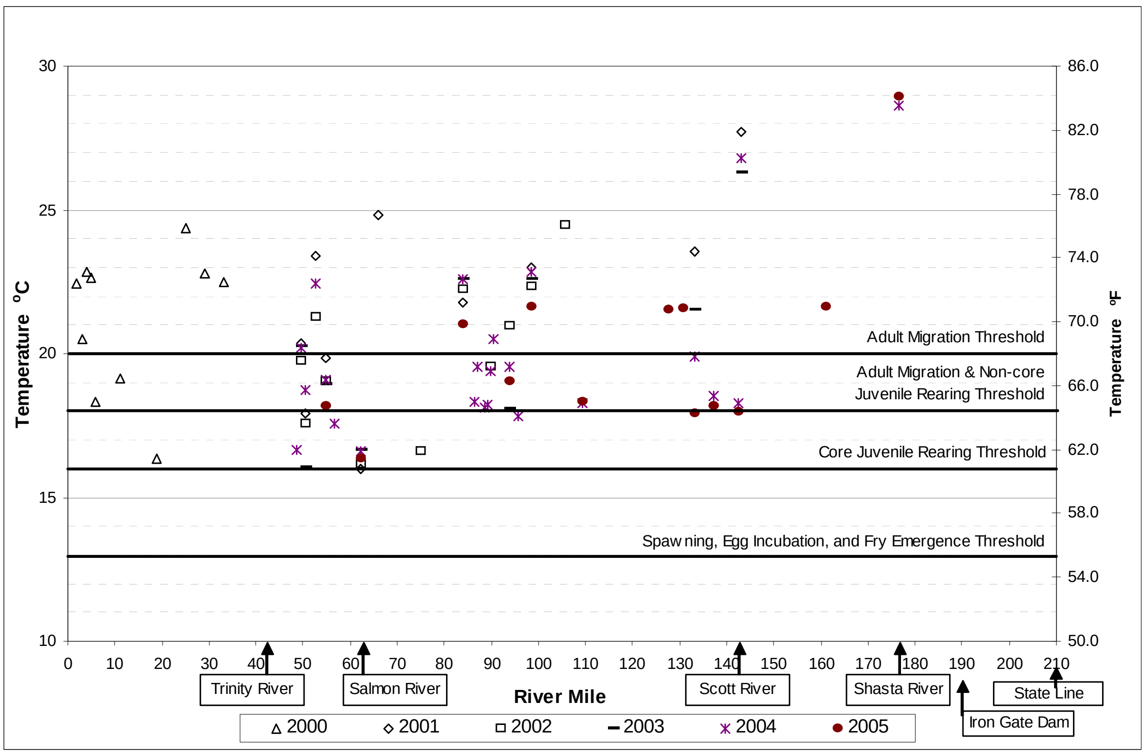

Figure 2.14: Klamath River tributary mouth MWMTs stream temperatures 2000-2005
Note: MWMTs typically occur in late July.

Of the twenty-two tributaries monitored in 2004 (the year with the most tributaries monitored), eighteen had MWMT values in excess of the adult migration and non-core juvenile rearing thresholds for salmonids suggested by USEPA (2003). These data clearly demonstrate that these tributaries have no capacity to assimilate increased heat loads during the hottest critical periods without adversely affecting beneficial uses.

The Shasta, Scott, and Salmon Rivers, three of the largest Klamath River tributaries, have been listed on the 303(d) list for temperature impairment separately. TMDL analyses developed for these tributaries have confirmed the temperature impairments, as well as the human contribution to elevated temperatures in these basins.

Although the temperatures are high relative to the temperature requirements of salmonids (USEPA 2003), the high temperatures do not exceed the water quality objective for temperature unless they are elevated due to human activities, such as riparian vegetation removal and altered channel morphology. However, it is well documented that the erosion associated with the 1997 flood in the Klamath River basin resulted in widespread stream channel alteration, loss of riparian vegetation, and shade reductions (further discussed in Section 2.5.8) and that a significant amount of the erosion was caused or exacerbated by human activities (De La Fuente and Elder 1998). Similarly, it is well known that historic mining, road building, and silvicultural practices have resulted in riparian disturbances and consequent reductions of stream shade in many tributaries (Elder et al. 2002; KNF 1999; KNF 2002). Therefore, Regional Water Board staff conclude that enough information exists to confirm impairment and justify TMDL development and implementation.

2.5.2.3 Reservoirs

The available Iron Gate and Copco Reservoir temperature and DO profile data indicate that during summer stratified conditions, temperatures are only suitable for cold water species, including salmonids, rearing at depths where the DO concentrations are near lethal levels. Redband/rainbow trout are currently present in both Copco and Iron Gate Reservoir (PacifiCorp 2004b, p.4-53 - 4-55, 4-58). A representative example of typical summer conditions is illustrated in the vertical profiles of DO concentration and temperature that are presented in Figure 2.15 for Iron Gate Reservoir.

This space intentionally left blank.

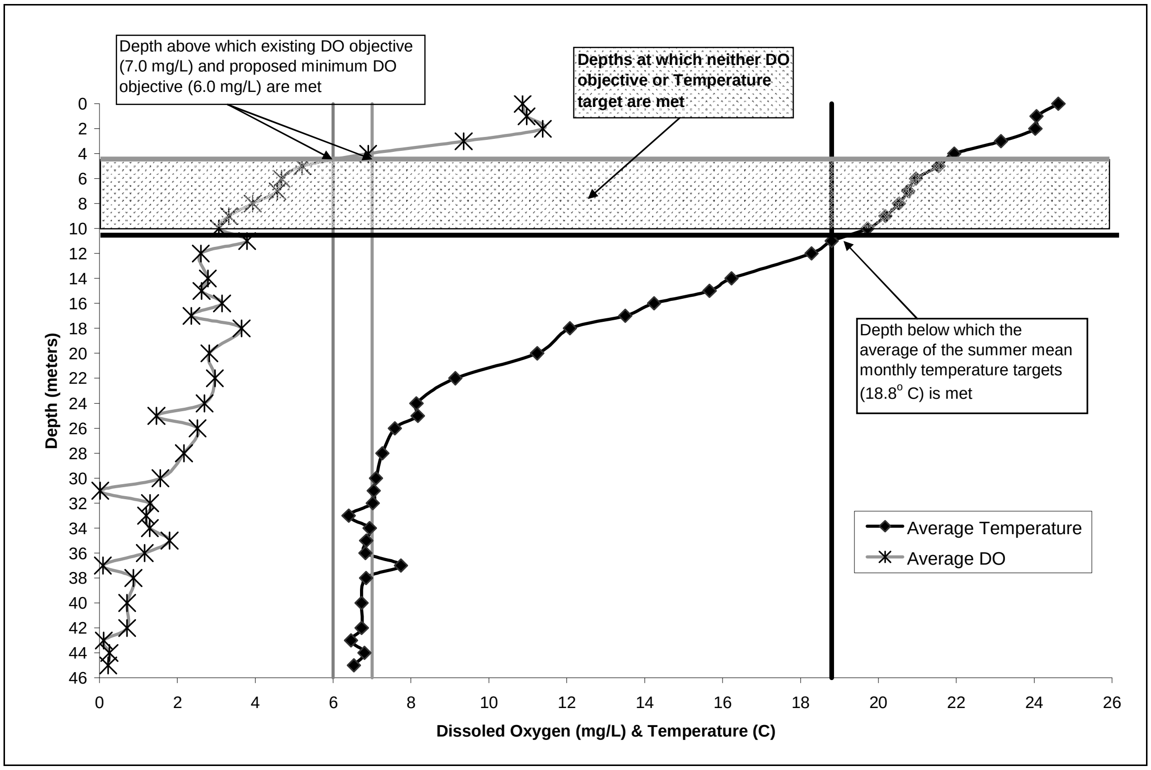

Figure 2.15: Dissolved oxygen and temperature depth profiles in Iron Gate Reservoir – average for July and August 2000 – 2005

The same pattern exists for Copco and for other years. The reservoirs become thermally stratified in the summer months. The stratification of the reservoirs prevents mixing of the low temperature/low DO waters with the high temperature/high DO waters, and thus there are no depths in the reservoirs at which the most sensitive beneficial uses are supported. Given that the stratification and the absence of suitable habitat is due to the presence of the reservoirs, Regional Water Board staff have concluded that the reservoirs contribute to exceedances of the temperature and DO water quality objectives.

2.5.3 Nutrients and Indicators of Nutrient-Related Impairment

Except in extreme cases, nutrients alone do not impair beneficial uses. Rather, they cause indirect impacts through their biostimulatory effect on algal growth, low DO, and extreme pH conditions among others that can impair uses. The water quality objectives with distinct numeric limits include DO and pH. The California Nutrient Numeric Endpoints (CA NNE) framework (Tetra Tech 2006) indentifies indicators for biostimulatory effects that can impair beneficial uses, including benthic algal biomass, planktonic chlorophyll-a concentrations, and diurnal DO and pH fluctuations. Other indicators included here are toxic blue-green algae (*Microcystis*) concentrations, and un-ionized ammonia.

2.5.3.1 <u>Nutrient Concentrations</u>

The primary driver for the nutrient conceptual model is the increased loading of nutrients to the Klamath River ecosystem. High levels of nutrient loading and elevated water column concentrations do not alone result in biostimulatory conditions, but excess nutrients are an essential precondition to this finding. Therefore the first step in evaluating impairment due to biostimulatory conditions is to determine whether existing nutrient loading and water column concentrations exceed natural baseline conditions. If it is determined that nutrient levels above natural baseline concentrations are present in the system, then the CA NNE secondary endpoints are evaluated to determine whether they have exceeded the Beneficial Use Risk Category Level III boundary for impaired waters. It is when both natural baseline nutrient levels and CA NNE Level III indicator boundaries have been exceeded that a finding of impairment due to biostimulatory conditions can be supported.

Several sources within the Klamath and Lost River watersheds contribute nutrient loads. Some of the key sources include irrigated agriculture return flows, internal nutrient cycling from nutrient enriched sediments (especially within UKL), nutrients released as a result of wetland conversion, sediments from external sources derived from land disturbance activities, and to a much lesser extent, point sources. The analysis of Klamath River nutrients involves a comparison of estimated natural baseline water column concentrations of several nutrient species to existing conditions concentrations. Natural baseline conditions are estimated based on TMDL model simulations (described in Chapter 3). These estimates are not interpreted literally but only as approximations of conditions that may have existed under natural conditions. The natural baseline conditions modeling scenario provides an estimate of nutrient loads and concentrations generated from a landscape with minimal anthropogenic disturbance. The existing conditions values come from the mean concentration of composite grab samples taken during the summer (June 1 to September 30) at twelve stations by various organizations from 1996 to 2007. Each station has at least three samples for each summer season over five years. Several stations have a much greater sampling density. The assumption for this analysis is that the annual and daily variability converges to an average over the course of a large number of samples that represent typical conditions during the summer growing season.

The purpose of the comparison is to evaluate whether nutrients have been increased by human related activities above the levels that could cause a nuisance, or adversely affect the ability of water to support specified beneficial uses. This approach does not allow for a complete mass balance comparison for the river since winter flows and concentrations have not been monitored. Rather, the information serves to provide a relative comparison of the mean summer concentrations of total nitrogen and total phosphorus to which aquatic life respond under current and natural baseline conditions (Figures 2.16 and 2.17). The left side of Figures 2.16 and 2.17 present existing conditions from stateline to the estuary, while the right side of the figure presents concentrations under natural baseline conditions. At most stations the existing summer mean concentrations for both total phosphorous and total nitrogen exceed the natural baseline conditions. Frequently the existing summer mean concentrations are more than double the natural background summer mean concentrations and can be up to five times higher than concentrations under the natural conditions baseline scenario. It is important to note that the summer mean for natural baseline conditions is based on two years of model runs versus 12 for existing (current) and that this may underestimate variability in natural conditions. These results suggest that human activities have increased nutrient loads to the Klamath River.

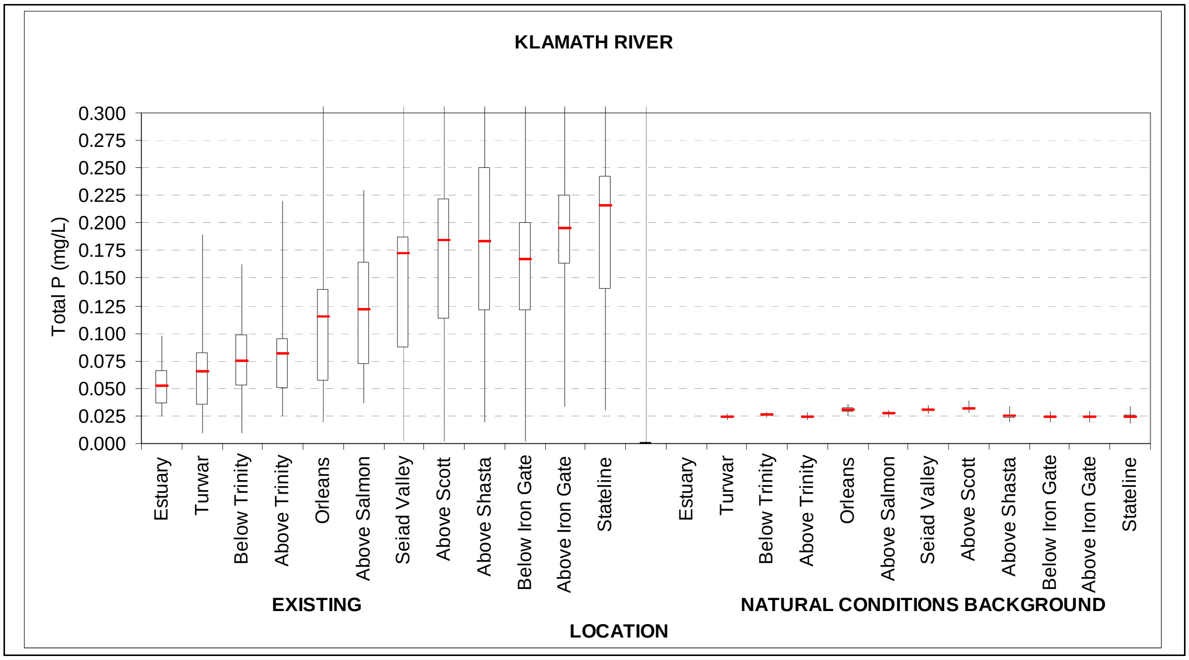

Figure 2.16: Comparison of total phosphorous concentrations for existing conditions (consolidated monitoring data 1996-2007) with estimated (TMDL model) natural baseline conditions at Klamath River monitoring stations in California.

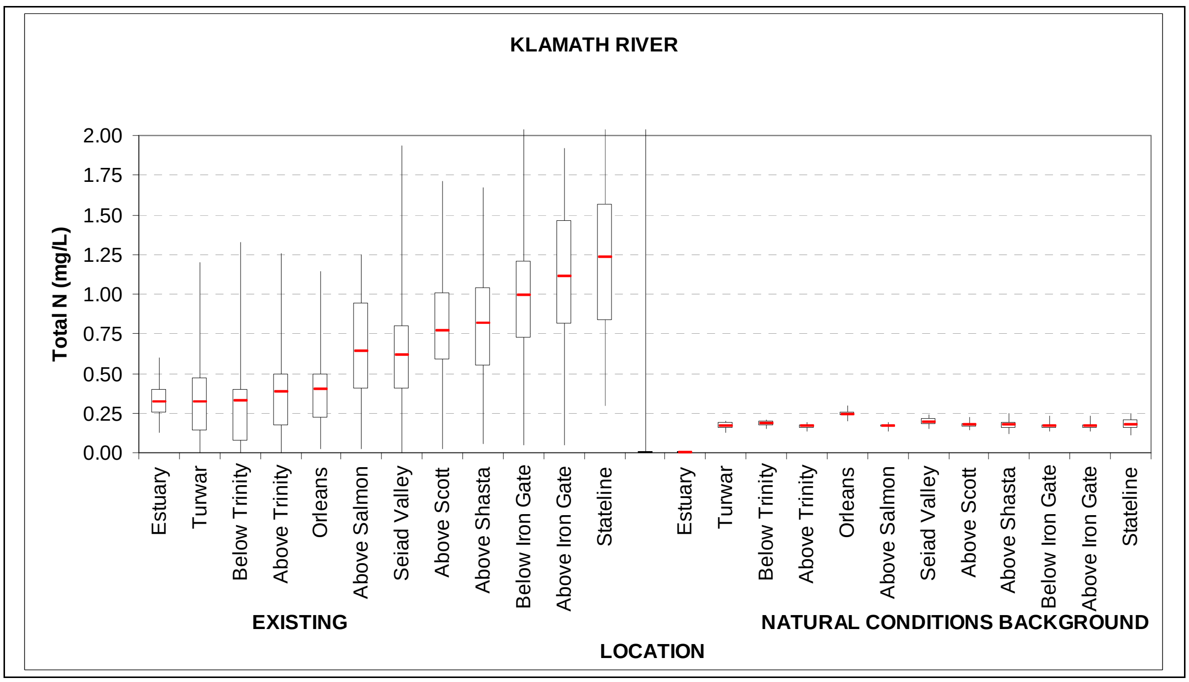

Figure 2.17: Comparison of total nitrogen concentrations for existing conditions (consolidated monitoring data 1996-2007) with estimated (TMDL model) natural baseline conditions at Klamath River monitoring stations in California.

2.5.3.2 Benthic Algal Biomass

Figure 2.18 presents the results of composited benthic algae biomass monitoring samples collected during summer months in 2003, 2004, 2006, and 2007.

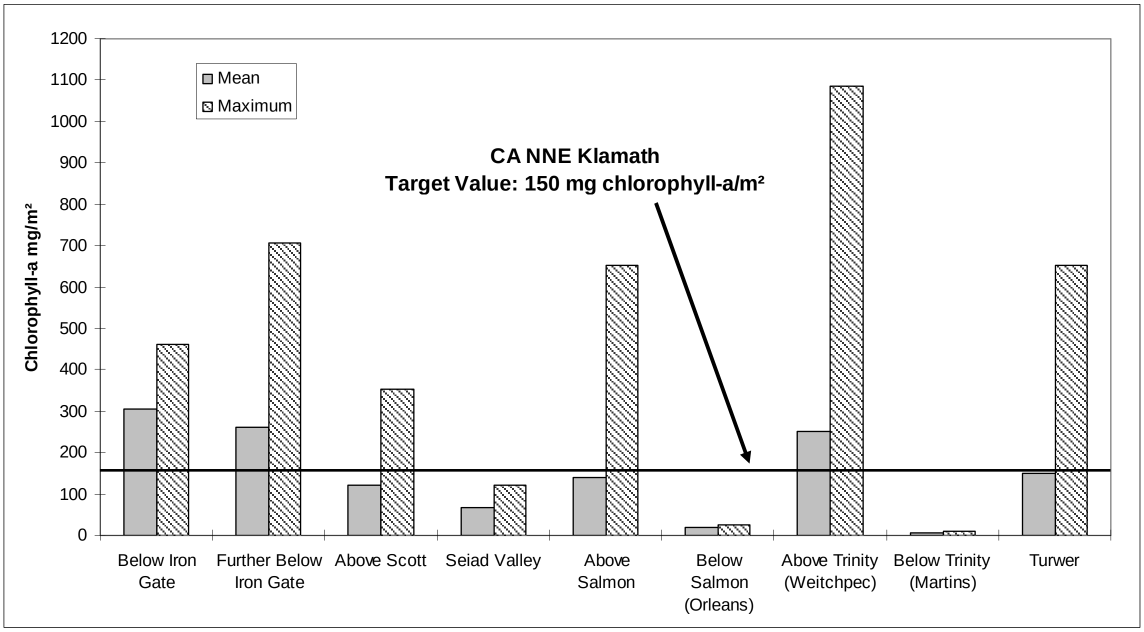

Figure 2.18: Consolidated benthic algal biomass monitoring results (summer mean and maximum) for 2003-2007 with CA NNE/TMDL numeric target.

There are a total of fifty samples for nine stations. The spatial and temporal sampling density is not ideal, but does indicate that during the summer months Klamath River benthic algae biomass in California exceed the CA NNE and TMDL numeric target of 150 mg chl-a/m^2 at several stations.

As demonstrated in the following sections, these benthic algae conditions have a direct impact on water quality via algal photosynthesis and respiration. In addition, the benthic algal biomass densities also provide habitat for polychaetes that serve as a host and source for the fish parasite *C. shasta.* In summary, existing benthic algal biomass conditions strongly suggest impairment.

2.5.3.3 Diurnal DO and pH

For several stations along the Klamath River the diurnal photosynthesis and respiration cycle is strongly influenced by dense colonies of benthic algal biomass which result in extreme diurnal cycles for DO and pH. The water quality conditions of frequent and chronic low DO and high pH illustrated in Figures 2.19 through 2.21 create chronic stressful conditions for fish populations.

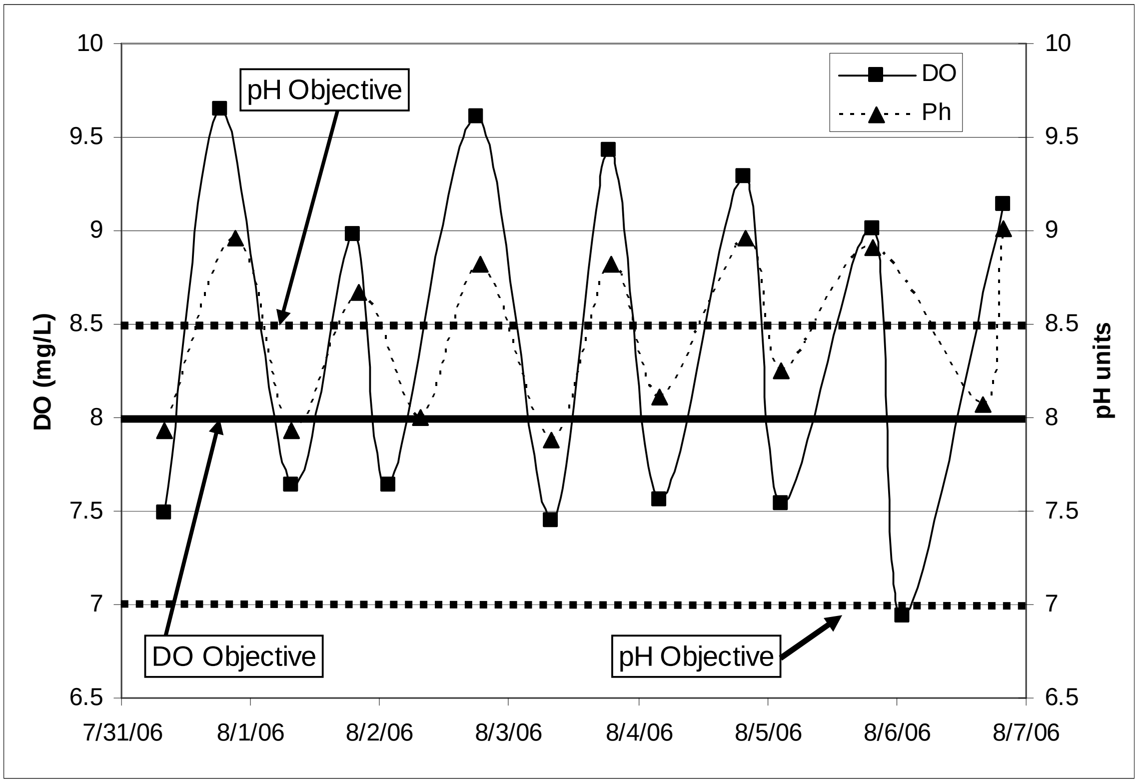

Figure 2.19: Example diurnal DO and pH cycle below Iron Gate Dam, summer 2006

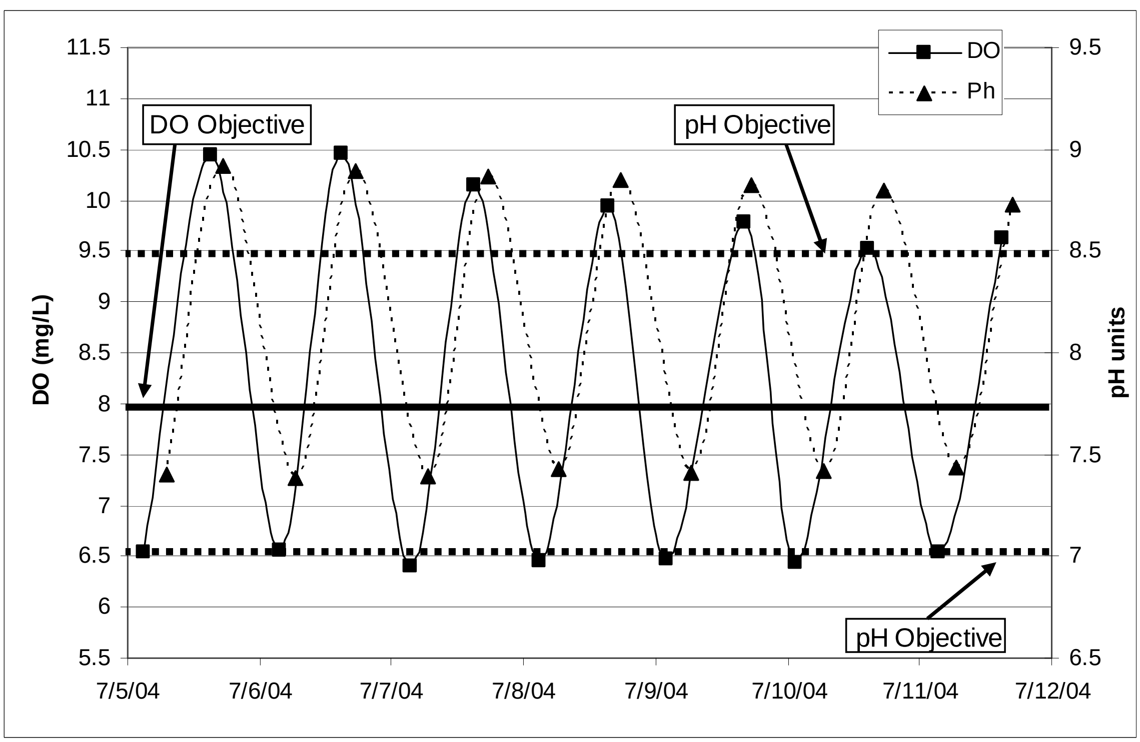

Figure 2.20: Example diurnal DO and pH cycle above the Shasta River, summer 2004

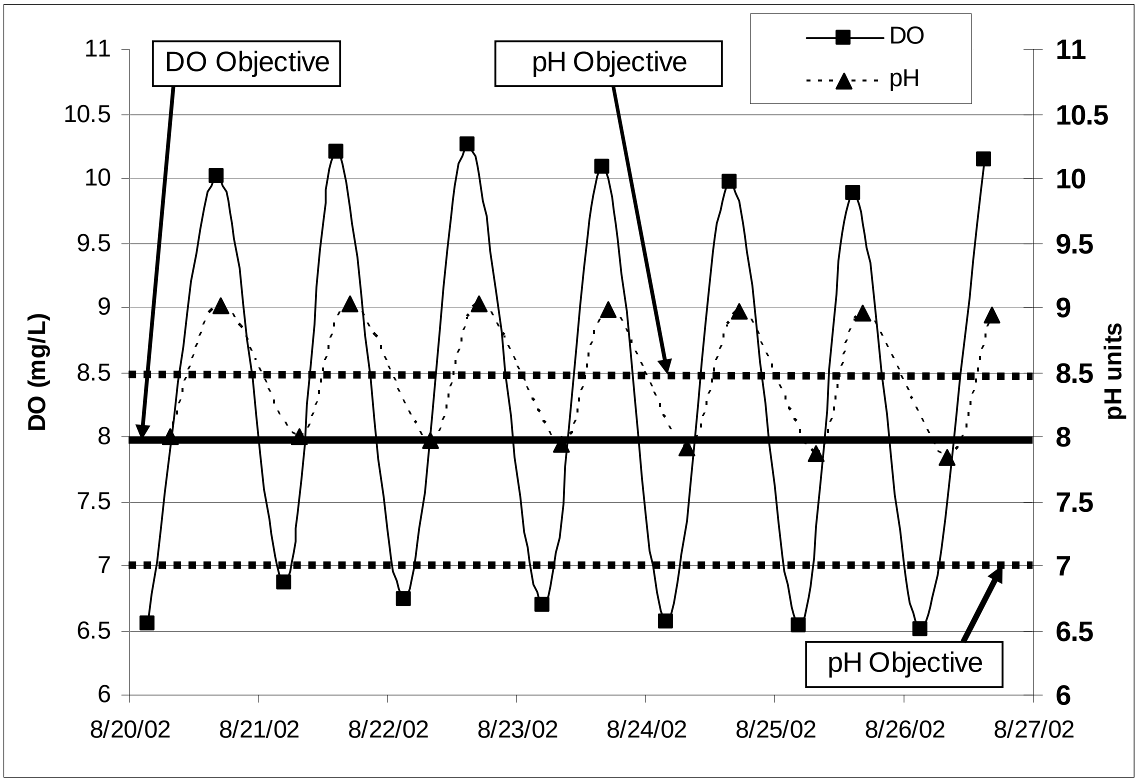

Figure 2.21: Example diurnal DO and pH cycle at Seiad Valley, summer 2002

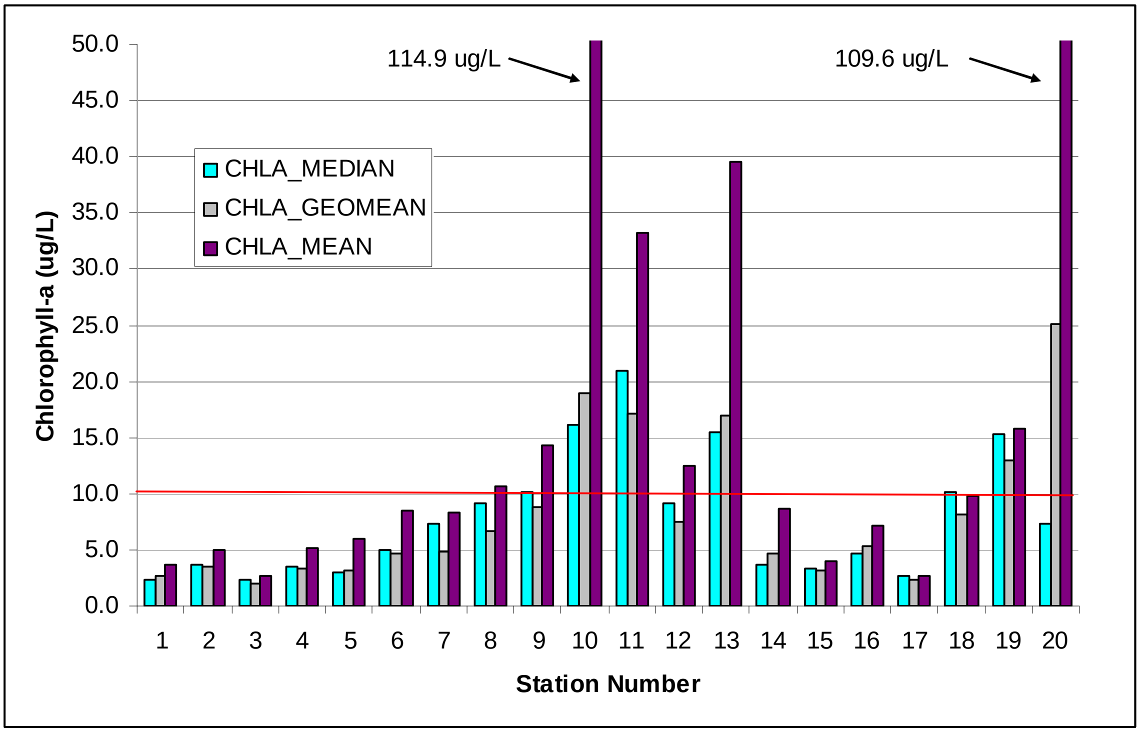
While the three plots present monitoring data from single stations, the observed pattern is consistent with summer months for other years when diurnal data has been collected and for other stations along the Klamath River. Both the existing DO objective (>8 mg/L) and pH objective (not greater than 8.5 and not less than 7.0) for the Klamath River downstream of Iron Gate Dam are exceeded on a regular basis. The extreme magnitude and regular frequency of these excursions indicate impairment from biostimulatory substances (i.e., nutrients).

2.5.3.4 Chlorophyll-a – Reservoirs

Figure 2.22 compares various measures of central tendency (mean, geometric mean, and median) of the chlorophyll-a data from samples collected during the summer period (May – September) of 2005, 2006, and 2007 by the Yurok Environmental Program, Karuk Tribe of California Natural Resources Department, and PacifiCorp at twenty stations along the Klamath River.



Station List:

1 - Lower Estuary (n=11)
2 - Turwar (n=19)
3 - Below Weitchpec (n=17)
4 - Weitchpec (n=19)
5 - Orleans (n=19)
6 - Seiad Valley (n=26)
7 - Walker Bridge (n=13)
8 - I-5 (n=16)
9 - Below Iron Gate Dam (n=61)
10 - Iron Gate Res. Lower (n=49)
11- Iron Gate Res. Upper (12)
12 - Copco Res. outflow (n=37)
13 - Copco Res. Lower (n=49)
14 - Copco Res. Upper (n=11)
15 - Above Shovel Creek (n=40)
16 - Below JC Boyle Dam (n=9)
17 - JC Boyle Res.(n=3)
18 - Above JC Boyle Res.(n=17
19 - Keno Dam (n=20)
20 - Link Mouth (n=7)

Figure 2.22: Comparison of central tendencies of summer (May – September) chlorophyll-a measurements for 2005, 2006, and 2007 at twenty monitoring stations along the Klamath River. Data from Yurok Tribe Environmental Program, Karuk Tribe of California Natural Resources Department, Regional Water Board, and PacifiCorp.

It is important to note that the data presented are from samples collected by different entities using similar but not identical protocols and the number and timing of samples vary from station to station. Presentation of the mean, geometric mean, and median values of a data set provides a useful way to assess the spread of the data. A close similarity between median and mean values is an indication that the data set is normally distributed. The geometric mean[9] is a useful measure of central tendencies when the data is log normally distributed. All three measures of central tendencies for each station are illustrated in Figure 2.22 allowing a station by station comparison of the three measures. Figure 2.23 presents the same data in box and whisker diagrams. The shoulders of the

---

9 To calculate a geometric mean of the distribution values (i.e., chlorophyll-a concentrations) the following steps are taken: 1) log transform the data; 2) calculate the mean of the logged values; and 3) then antilog (raise to 10th power) the mean.

box and whisker diagram represent the 75th and 25th percentile of the distribution of measurements; the median (50th percentile) is the solid line across the box.

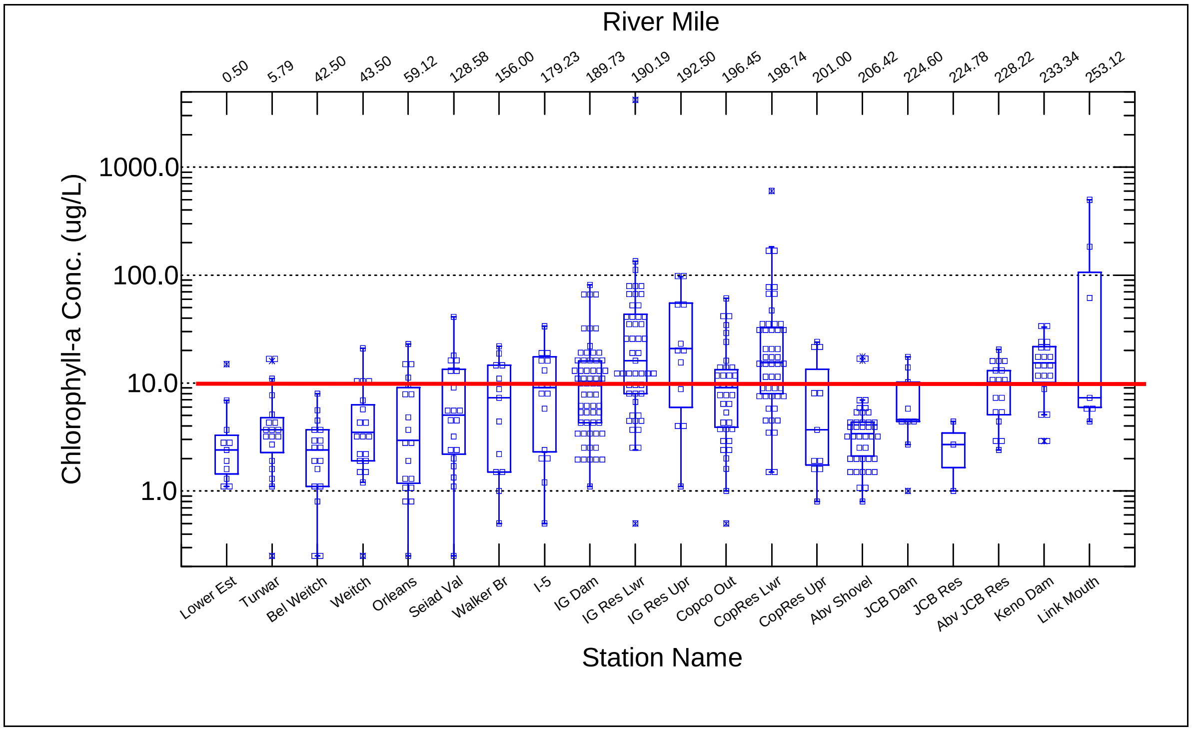


Figure 2.23: Longitudinal analysis of summer (May through September) chlorophyll-a concentrations from 2005 – 2007 along the Klamath River.
Data from Yurok Tribe Environmental Program, Karuk Tribe of California Natural Resources Department, Regional Water Board, and PacifiCorp

Each of the central tendency measures of chlorophyll-a for the Klamath River reservoir stations in California (Copco and Iron Gate) exceed the numeric target of 10 µg/L. There are also high concentrations of chlorophyll-a at Link Mouth, and at Keno Dam and above JC Boyle Reservoir. The high concentrations at these three stations are due in large part to residual algal biomass from Upper Klamath Lake. At most stations the median and the geometric mean are relatively similar, and the mean is higher than both the median and geometric mean. At the California reservoir stations (stations 10-14) however, the mean is significantly higher than either the median or the geometric mean. The very high means can be attributed to the nuisance algae bloom events during the late summer months.

The longitudinal analysis illustrated in Figures 2.22 and 2.23 demonstrates the effect of quiescent waters and the susceptibility of reservoirs on the Klamath River to nuisance algal blooms. Within Upper Klamath Lake and within the reservoirs summer mean and median chlorophyll-a concentrations are substantially higher than at the stations located in the free-flowing sections of the river. Chlorophyll-a concentrations rapidly attenuate downstream of Upper Klamath Lake and the reservoirs.

Nuisance algal blooms within Iron Gate and Copco Reservoirs are well documented in the regular blue-green algae monitoring program reports by the Karuk Tribe of California Natural Resources Department and PacifiCorp. As illustrated in Figure 2.24 the summer (May – September) mean concentrations of chlorophyll-a at all of the reporting stations for the reservoirs are at or above the summer mean numeric target of 10 µg/L. The summer mean concentrations at three of the four stations are more than double the target and the maximum concentrations are generally an order of magnitude higher.

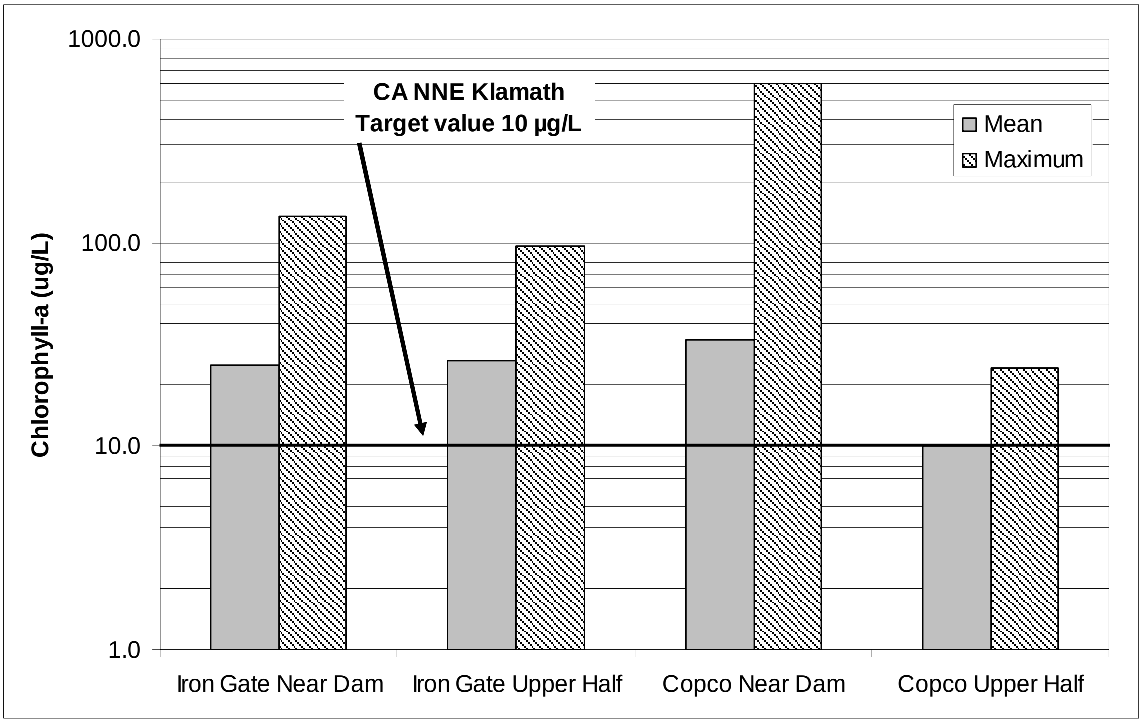

Figure 2.24: Summer (May – September) mean and maximum concentrations of chlorophyll-a (2000 – 2007) at four stations within the Iron Gate and Copco Reservoirs.

Figure 2.25 presents Regional Water Board staffs' seasonal analysis of PacifiCorp 2007 and 2008 data. The data shows an increase in total phytoplankton biovolume below Iron Gate Dam (Station KRBI) compared with above Copco Reservoir (Station KRAC). Normality tests performed on stations above and below the reservoirs showed non-normal distribution. Normality notwithstanding, the Figure 2.25 time series graphs show a distinct seasonal (June -September) increase in total algal biomass (biovolume) below the reservoirs in 2007 and 2008. Two nonparametric tests of the June - September 2007-2008 data show that the distribution of total algal biovolume is significantly greater below the reservoirs than above (Kolmogorov-Smirnov Two-Sample Test [p=0.034] and Kruskal-Wallis Mann-Whitney U Test [p=0.08]).

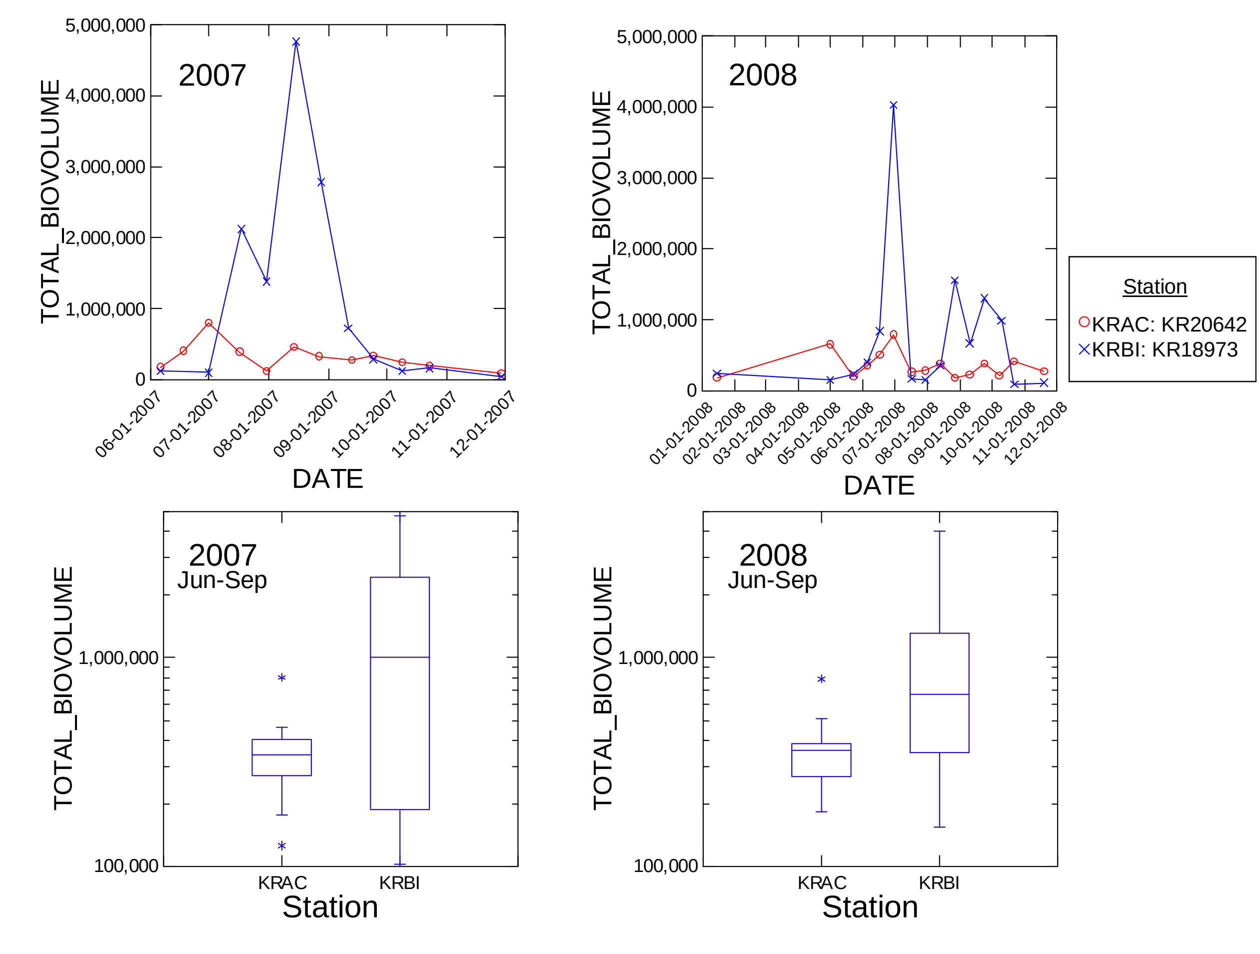

Figure 2.25. Comparison of above Copco Reservoir (Station KRAC; KR20642) and below Iron Gate Dam (Station KRBI; KR18973) biovolume for the summer 2007 and 2008. Data collected by PacifiCorp (http://www.pacificorp.com/es/hydro/hl/kr.html#).

The high concentrations of chlorophyll-a in the reservoirs have water quality impacts downstream. Suspended algae (and their breakdown products) entrained in water released from Iron Gate Reservoir may become available as a food source for polychaetes in the river reaches below the dam. In addition, these algal biomass can be deposited in the river bottom sediments, enhancing habitat conditions for polychaetes which contribute to higher levels of *C. shasta* parasite spores, and therefore contribute to higher rates of infection (Bartholomew et al. 2007; Bartholomew and Bjork 2007). The available data is insufficient to determine how the reservoirs alter the amount and form of particulate organic matter. Therefore, the net effect of fine particulate organic matter exported from the reservoirs on polychaete populations in the river downstream is unclear.

As discussed in more detail in Section 2.5.4, the reservoirs do impact the river below Iron Gate by serving as a source of blue-green algae to downstream water that can continue to grow in backwater and slower sections within the river reaches below the dams (Kann and Corum 2009, Kann and Asarian 2005). The export of algal biomass (including blue-green algae) has been documented by monitoring data showing that both *Microcystis* and microcystin are substantially higher within and below the reservoirs than they are directly upstream. For example, see Raymond (2009; *Phytoplankton Species and Abundance Observed During 2008 in the vicinity of the Klamath Hydroelectric Project* (Report prepared for CH2MHILL and PacifiCorp) which clearly illustrates (Figures 13 and 15) an increase of both *Microcystis* and microcystin toxin within the reservoirs and downstream.

In summary, the available chlorophyll-a and biovolume data suggest that the Iron Gate/Copco Reservoir complex significantly increases the quantity of algal biomass supplied to the river below Iron Gate Dam **and are a net sources of live algae to the river during the algae growing season.** Included in this algal biomass is blue-green algae **that** potentially serves as an in**n**oculant contributing to **nuisance conditions** in downstream backwater habitats. **However, the available data is insufficient to determine the net downstream effect of the reservoirs as a source of dead and decaying particulate organic matter.**

2.5.4 Blue-Green Algae and Microcystin Toxin

An important aspect of the nuisance algae conditions within Copco and Iron Gate Reservoirs is the periodic dominance of toxic blue-green algal species during the summer season. There are many forms of blue-green algae, both toxic and non-toxic. This discussion focuses primarily on *Microcystis aeruginosa* since it has become the dominant species of concern on the Klamath River in California. The frequent documented occurrence of seasonally high concentrations of *Microcystis aeruginosa* and microcystin in reaches of the Klamath River within California in each of the last several years has resulted in the documented impairment of beneficial uses including Native American Culture (CUL), Subsistence Fishing (FISH), Water Contact Recreation (REC-1), Non-Contact Water Recreation (REC-2), Municipal & Domestic Supply (MUN), Shellfish Harvesting (SHELL), Aquaculture (AQUA), Agricultural Supply (AGR), and Commercial and Sport Fishing (COMM), as discussed below. Ongoing research may also demonstrate a direct effect on the health of aquatic organisms from exposure to high levels of microcystin which would lead to the addition of other beneficial uses to this list (de Figueiredo et al. 2004).

Routine public health monitoring of blue-green algae in the Klamath River basin began in 2005. Every year since 2004 *Microcystis aeruginosa* counts and microcystin concentrations on the Klamath River have exceeded the Blue Green Algae Work Group action levels for harmful algal blooms. Table 2.11 summarizes the blue-green algal monitoring data for the years 2006, 2007, and 2008 with respect to the Blue Green Algae Work Group action levels. Data presented in the table is summarized by reach: *Reach 1*) Oregon to Iron Gate Dam; *Reach 2*) Iron Gate Dam to Scott River; *Reach 3*) Scott River to Trinity River; and *Reach 4*) Trinity River to Estuary. The blue-green algae listing criteria are most frequently exceeded in Reach 1, which is primarily composed of sample sites within Copco and Iron Gate Reservoirs. Late summer conditions are typically characterized by dense blue-green algae blooms that form thick viscous scums in parts of the reservoirs. The bloom conditions at times span much of the open water areas within the reservoirs. The reservoirs have been posted with public health advisory signs as a result of these summer blooms in 2006, 2007, and 2008.

Table 2.11: Summary of blue-green algae and microcystin monitoring data for 2006, 2007, and 2008

Reach Name	Reach #	Year	# of monitoring samples that exceed thresholds and targets		
			MSAE Cells ≥ 40,000 ml/L	microcystin ≥ 8 ug/L	Tissue ≥ 26 ng/g
Oregon to Iron Gate Dam	1	2006	27	29	*
Iron Gate Dam to Scott River	2	2006	1	1	*
Scott River to Trinity River	3	2006	2	0	*
Trinity River to Estuary	4	2006	0	0	*
Oregon to Iron Gate Dam	1	2007	47	35	41

Trinity River to Estuary	4	2008	1	1	*

* Data not collected during this period

** Not all data from monitoring programs available at time of report publication.

*** Tissue samples taken prior to bloom to determine baseline conditions, samples were not taken during bloom.

Data sources: Yurok Environmental Monitoring Program Blue-Green Algae Annual Reports: 2006, 2007, and 2008; Karuk Tribe of California Natural Resources Department Blue Green Algae Monitoring Annual Reports: 2006, 2007, and 2008; and PacifiCorp Blue-Green Algae Monitoring Program annual Reports: 2006, 2007, and 2008.

Table 2.11 also shows high concentrations of *Microcystis aeruginosa* downstream of the Iron Gate Dam in reaches 2, 3, and 4. Some reaches of the Klamath River mainstem were posted with public health advisory signs during the summers of 2008 and 2009. Algae related sampling protocols in the Klamath River have evolved since routine sampling began in 2004. Before 2008 most samples on the Klamath River mainstem were taken from the river at higher velocity areas near the channel mid-point. Until 2008 few samples had been taken in near shore backwater areas where scums have been frequently reported and photographed. Data collected in 2008 showed frequent exceedance of both 8 µg/L microcystin and 40,000 cells/ml *Microcystis aeruginosa* in various river-edge habitats between Iron Gate Dam and Seiad Valley (Figure 6: Kann and Corum 2009). The revised September 2008 Blue Green Algae Work Group report recommends that monitoring for public health should include samples of the Reasonable Maximum Exposure (RME) conditions in areas in which people and animals are most likely to contact water (State Water Board 2008).

2.5.5 Dissolved Oxygen

This section evaluates observed DO conditions relative to the existing and proposed Basin Plan water quality objectives for DO.

The US Fish and Wildlife Service (USFWS), in cooperation with the Karuk and Yurok Tribes, monitored DO conditions with datasondes at several stations along the Klamath River from 2001 to 2006. For the purposes of this assessment measured DO concentrations from the three most recent years (2004 – 2006) are evaluated in comparison to the existing and proposed DO objective. USFWS conducted an in-depth quality control review of the DO data (Ward and Armstrong 2006). Final data- sonde results have been summarized by station by evaluating the percent of total measurements during the summer season that fall below the current Basin Plan DO Objective of 8.0 mg/L. The datasondes recorded water quality conditions at 30-minute increments, for a total of forty-eight daily measurements.

In 2005 greater than ten percent of the DO measurements were less than 8.0 mg/L at six of the nine stations along the Klamath River (Table 2.12 and Figure 2.26). For the period 2004, 2005, and 2006 several of the Klamath mainstem stations (below Iron Gate, above Shasta River, above Scott River, and at Seiad Valley) had conditions where more than 40% of the measurements are less than the current Basin Plan objective indicating serious dissolved oxygen impairment for large sections of the river.

Table 2.12: Percent of DO measurements below Basin Plan water quality objective of 8.0 mg/L for 2004 – 2006 at nine stations along the Klamath River

	2004		**2005**		**2006**	
% Measurements below 8 mg/L	**n**	**%**	**n**	**%**	**n**	**%**
At Iron Gate	2706	64	4498	45	5391	61
Above Shasta River	5478	50	5533	49	-	-
Above Scott River	2966	58	4457	47	-	-
At Seiad Valley	3381	57	4713	45	5526	40

Below Weitchpec	5500	16	3529	11	5293	4
At/above Turwar	5066	30	5543	6	-	-

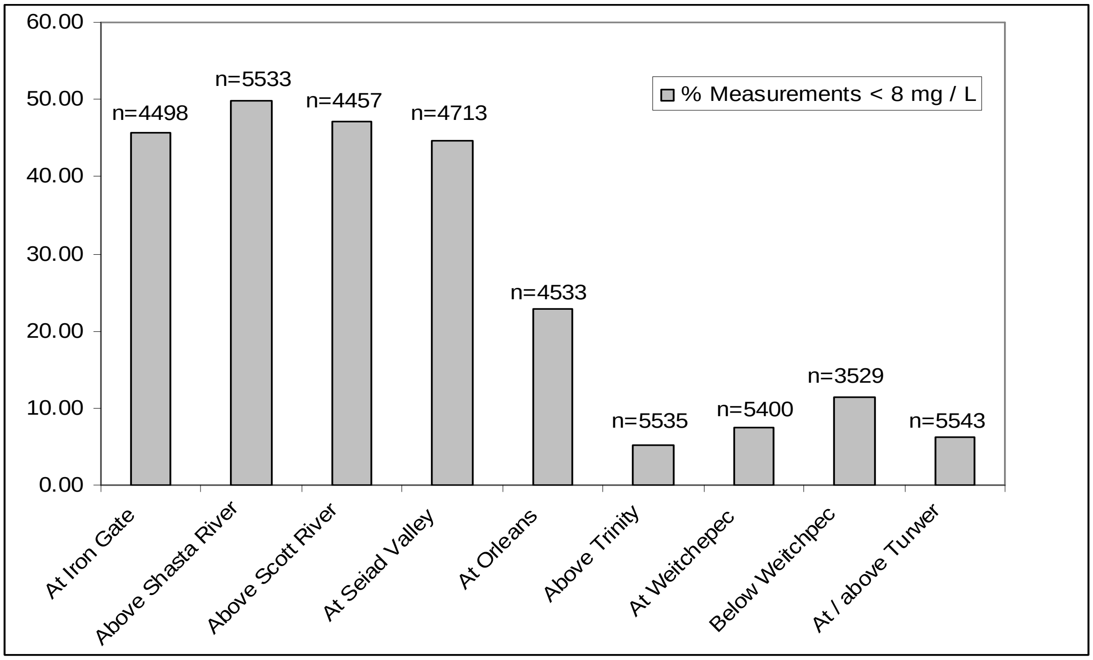

Figure 2.26: Percent of DO measurements below the Basin Plan water quality objective of 8.0 mg/L for 2005 at nine stations along the Klamath River

The analysis presented below addresses the revised DO objective being proposed (see Section 2.2.1.2. and Appendix 1). The revised objective requires that in those waterbodies identified as COLD but unable to meet the salmonid life cycle requirements (instantaneous minimum of 7.0 mg/L upstream of Iron Gate dam and 8.0 mg/L downstream of the dam, with half the monthly mean DO values for the year 10 mg/L or greater) due to natural conditions, a minimum 85% DO saturation limit throughout the mainstem, 90% DO saturation limit from October through April upstream of the Hoopa-California boundary and 80% DO saturation during August in the Middle and Upper Estuary be applied. These percent DO saturation criteria are to be calculated based on natural water temperatures.

In order to compare the USFWS measured DO data to the proposed DO objective assumptions related to temperature and barometric pressure were made. Percent DO saturation was calculated based on measured water temperatures and using a seasonal average barometric pressure. These assumptions make for a very conservative estimate of the percent of measurements below the proposed objective of 85% DO saturation at natural water temperatures. For simplicity, the analysis looks only at the 85% criteria. Estimates of natural water temperatures have not been predicted for the years 2004-2006 using the TMDL model. The results of the analysis are presented in Table 2.13 and Figure 2.27. In 2004, six of the nine stations had more than 10% of the DO measurements below 85% DO saturation.

Table 2.13: Percent of calculated percent DO saturation estimates below the proposed Basin Plan water quality objective of 85% saturation for 2004 – 2006 at nine stations along the Klamath River

% Measurements below 85% saturation at median of pressure range	**2004**		**2005**		**2006**	
	n	**%**	**n**	**%**	**n**	**%**

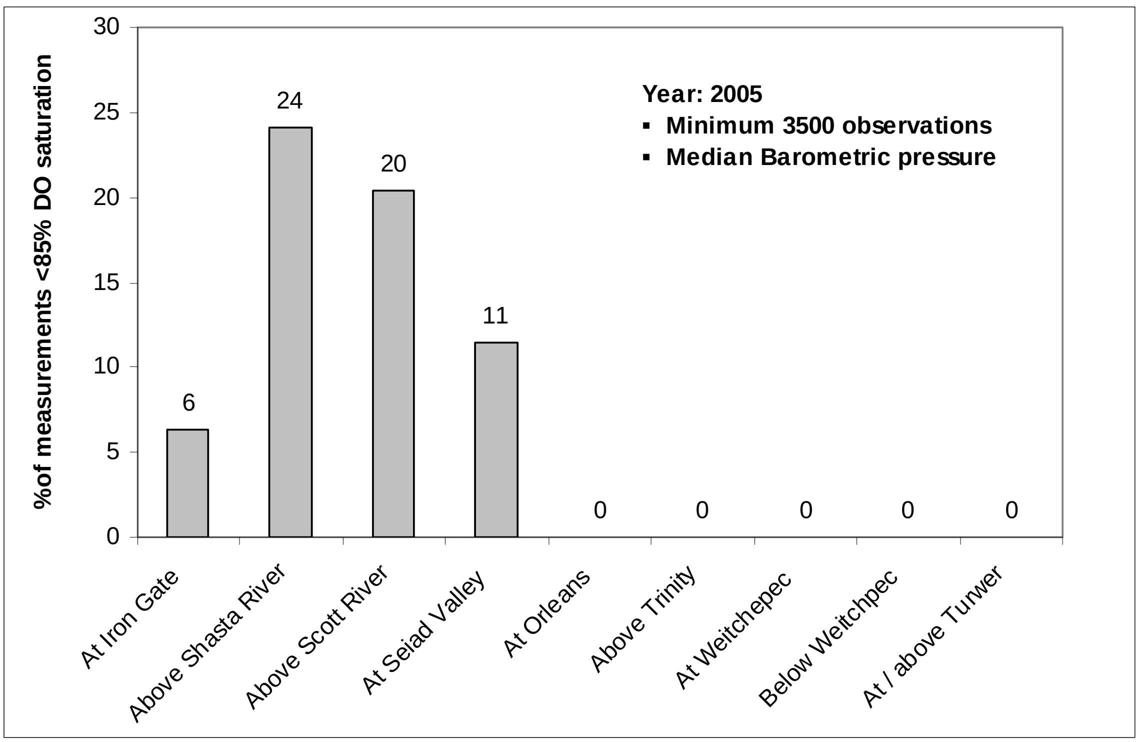

Figure 2.27: Calculated percent DO saturation at nine stations on the Klamath River for 2005 based on data sonde measurements made by U.S. Fish and Wildlife Service, Yurok Tribal Environmental Program, and Karuk Tribe Department of Natural Resources

2.5.6 pH

This assessment includes an evaluation of pH conditions along the Klamath River independent of the diurnal variation driven by photosynthesis that was addressed in Section 2.5.3.3. The data for this analysis also comes from the USFWS, Karuk and Yurok Tribes datasonde measurements. The same years (2004 – 2006) used in the DO analysis were also selected for the pH assessment. The Basin Plan water quality objective for pH is a maximum of 8.5 and a minimum of 7.0.

Five of the stations have more than 20% noncompliant measurements. The highest rate of noncompliant measurements is 48% recorded at Orleans in 2006 (Table 2.14). In the three year sample all nine stations exceeded a noncompliant measurement rate of greater than 10 percent at least once. The rate of noncompliance for the minimum pH of 7.0 is less than 0.05% at all stations. Therefore a sampling station summary table and plot have not been prepared for minimum pH.

Table 2.14: Percent of pH measurements above 8.5 for 2004 – 2006 at nine stations along the Klamath River.

Percent of Measurements above 8.5	2004		2005		2006	
	n	%	n	%	n	%
At Iron Gate	5192	32	4680	3	5486	30
Above Shasta River	5762	37	5847	40	-	-
Above Scott River	3834	28	3821	19	-	-
At Seiad Valley	3808	1	5838	1	5576	32
At Orleans	4844	0	5608	0	5442	48
Above Trinity	-	-	5826	23	5746	18
At Weitchpec	4449	33	5765	29	5823	27
Below Weitchpec	5823	1	5469	23	5125	42
At/above Turwar	4712	16	5835	23	-	-

For 2005 (Figure 2.28) at six of the nine Klamath River stations the Basin Plan objective of 8.5 is exceeded in more than 15% of the samples taken.

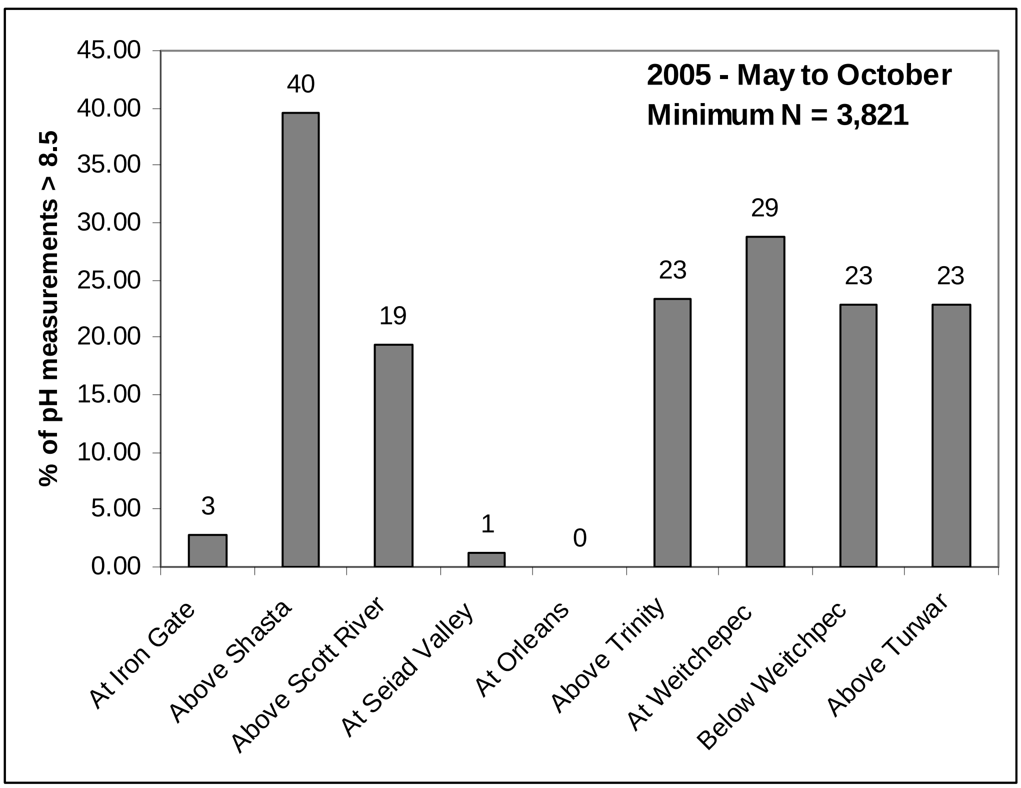

Figure 2.28: Percent of 2005 pH measurements in the Klamath River that exceed 8.5

2.5.7 Ammonia Toxicity

Regional Water Board staff evaluated all the data within our compiled Klamath River datasets in which all 3 parameters (pH, NH3, and temperature) were collected at the same time. Based upon the evaluation, there were no documented times in which acute or chronic aquatic life criteria for ammonia toxicity was exceeded.

To take this one step further, staff evaluated all the available pH and temperature data to determine what the concentration of ammonia would need to be in order for toxicity (acute or chronic) to be present. The results of that effort showed that acute toxicity probably does not occur on the Klamath River in California. However, the results showed that there are probably times when the chronic criteria are exceeded, but only for short durations of perhaps a few hours in a day a few days in a year. EPA guidance suggests that chronic criteria for the protection of aquatic life should be addressed over an averaging period of 4 days. Regional Water Board staff concludes that based on the available data, acute ammonia toxicity has not occurred in the times/years when data is available, and excursions of the chronic ammonia criterion probably only occur for short durations on a few days in a year and, if so, do not constitute an impairment of beneficial uses.

2.5.8 Sediment

The New Years Day flood of 1997 provided an example of some of the ways in which increased sediment loads affect stream temperatures in the Klamath River basin. A report by Klamath National Forest personnel (De La Fuente and Elder 1998) documenting the flood impacts within the Klamath National Forest reported 446 miles (20%) of channels that were significantly altered (i.e. with significant scouring, excessive sediment deposition, or riparian vegetation removal) by the flooding and associated sediment pulses of the 1997 flood. The report stated that “there appeared to be a considerable reduction in size, volume, and depth of pools in Elk, Indian, Beaver, Grider, Tompkins, South Fork Salmon, and Walker Creeks, and there is a larger proportion of fine sediment in the substrate. Alluvial reaches were made shallower and wider due to the sedimentation”. The report found that approximately 30% to 60% of riparian vegetation was lost in the alluvial reaches of the most affected tributaries. These effects of increased sediment loads were observed in Elk, Indian, Ukonom, Independence, Grider, Oneil, Portuguese, Beaver, Horse, and Walker Creeks, as well as numerous other streams throughout the Klamath basin after the flood of 1997 (Figure 2.29) (De La Fuente and Elder 1998; Kier Associates 1999). The conclusions of the Klamath National Forest assessment are consistent with Regional Water Board staff observations.

This space intentionally left blank

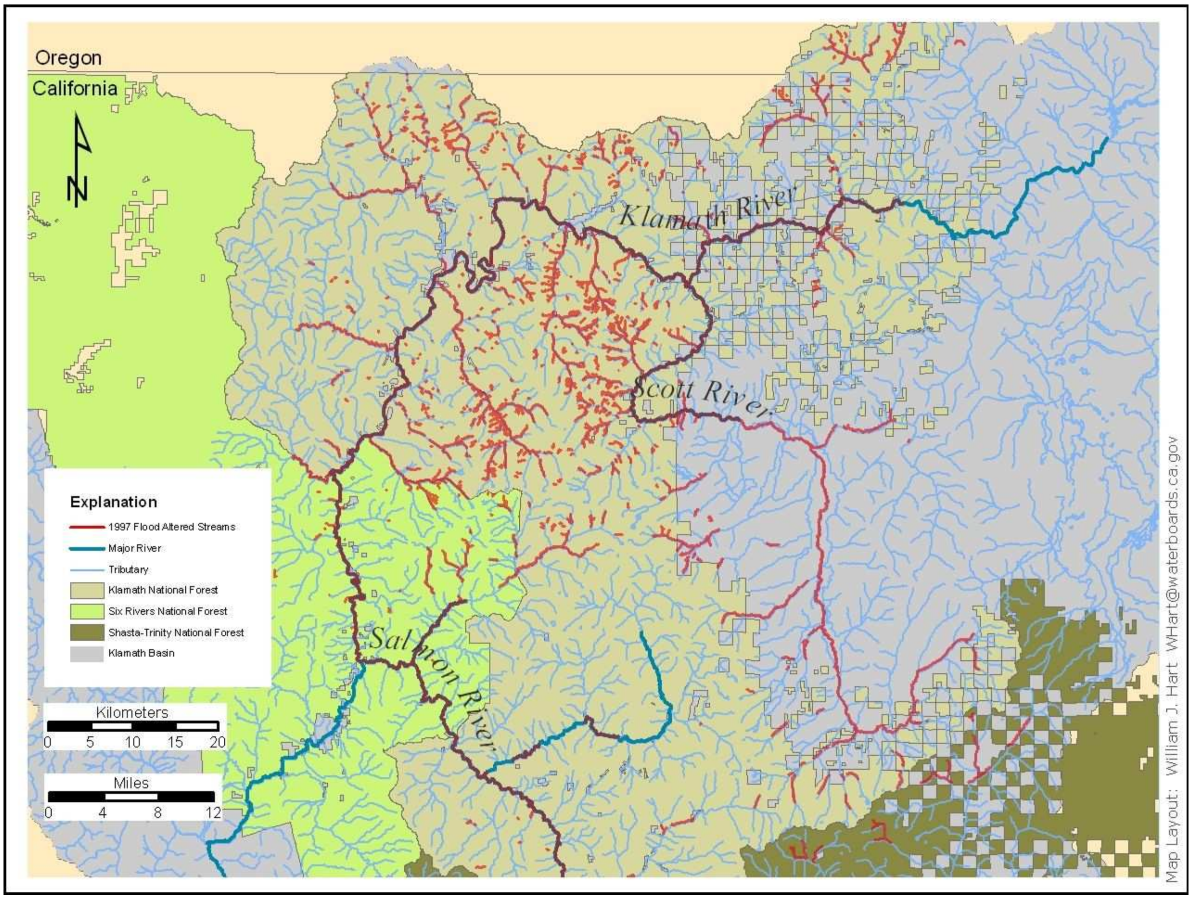

Figure 2.29: Mapped extent of stream channels substantially altered by sediment loads associated with the 1997 flood.
Source: De la Fuente and Elder 1998

The substantial changes in stream shade and channel dimensions that occurred as a result of the 1997 storm are believed to have significantly affected Klamath River tributary temperatures where they occurred. Unfortunately, little pre- and post-flood temperature comparisons are available to evaluate the changes in temperatures that resulted from the flood effects. However, a pre- and post-flood data set exists for one tributary, Elk Creek. De la Fuente and Elder presented a comparison of Elk Creek temperature data before and after the flood. The data showed that in the summer after the flood, the peak temperature was the highest of seven years of record, and was 3.8°F higher than the average from 1990-1995. Likewise, the diurnal variation increased to12.5°F, 4.9°F higher than the 1990-1995 average. Furthermore, comparison of average air temperatures for the seven years show that 1997 was warmer (74.6 °F) than all years except 1994 (76.0 °F). The recorded low flow for 1994 was 16.1 cfs, whereas 1997 had the highest low flow of all the years measured (49.3 cfs). Despite higher air temperatures and lower flows in 1994, the instantaneous maximum temperature, 7-day maximum average, 31-day maximum average, and 31-day average diurnal variation were all lower compared to 1997 temperature data, as they were in all other years between 1990 and 1995 (no data are available for 1996). The fact that the season following the major changes in morphology and effective shade associated with the

1997 flood had higher temperatures, expressed in a variety of metrics, than the six years monitored prior to the flood, including a year with higher air temperatures and a fraction of the flow, strongly suggest that the temperature increase was a result of the effects of the flood.

The Final *Staff Report for the 2008 Integrated Report for the Clean Water Act Section 305(b) Surface Water Quality Assessment and the 303(d) List of Impaired Waters* (Regional Water Board 2009) was adopted by the Regional Water Board on June 3, 2009 and includes listings for sediment in 11 tributaries to the Klamath River in the area downstream of Iron Gate Dam to the confluence of the Trinity River. The portion of the Klamath River watershed from the Trinity River to the mouth of the Klamath is currently on the 2006 303(d) List for sedimentation/siltation impairment.

2.6 Evidence of Beneficial Use Impairment

Section 2.5 demonstrates that temperature, DO, biostimulatory substances, and related water quality objectives are not met at many locations at some times of the year in the Klamath River in California. Exceedance of these water quality objectives contributes to the impairment of a number of existing beneficial uses in the Klamath River. Evidence of impairment of the COLD, RARE, MIGR, SPWN, CUL, FISH, REC-1, REC-2, and MUN beneficial uses is presented in this section. This evidence of beneficial use impairment compels the need to develop TMDLs to address the temperature, DO, and nutrient water quality problems in the Klamath River.

2.6.1 Evidence of Impairment to Cold Freshwater Habitat (COLD), Rare, Threatened, or Endangered Species (RARE), Migration of Aquatic Organisms (MIGR), and Spawning, Reproduction, and/or Early Development (SPWN)

The COLD, RARE, MIGR, and SPWN beneficial uses are currently not fully supported in the Klamath River in California, as demonstrated by the decline of salmonid populations, adult and juvenile fish kills caused by disease outbreaks, migration barriers for adult and juvenile salmonids, and degradation of spawning habitat.

2.6.1.1 <u>Salmonid Population Decline</u>

Although historically there were large runs of salmonids in the Klamath River basin, current data indicate that populations have declined sharply since the early 1900's. Utilizing information from Snyder (1931), the NRC estimated that the annual total catch in the Klamath River during the period from 1916-1927 were probably 120,000 to 250,000 fish, and thus the number of potential spawners and total population numbers was considerably higher (NRC 2004, p.267, 268). In 2007, fall and spring Chinook population estimates were 132,167 and 12,628 respectively (CDFG 2008). No current estimate of steelhead and coho populations has been made, however, it is presumed that populations have declined dramatically from historic numbers (Brown and Moyle 1991, p.8; Brown et al. 1994; Busby et al. 1994 as cited by NRC 2004, p.274; CDFG 2002, p.1; NRC 2004, p.273). More detailed information on the decline of salmonid populations in the Klamath River basin can be found in Appendix 5, and brief summaries are presented below.

Fall Chinook Salmon

Fall Chinook numbers in the Klamath River basin have dramatically declined during the past century (Hardy et al. 2006, p.7). The Klamath River fall Chinook run once totaled as many as 500,000 fish annually (Moyle 2002, p.258). Fall Chinook numbers in the Shasta River basin alone historically numbered 20,000-80,000 fish per year (Regional Water Board 2006, p.1-25). Basin-wide fall Chinook population estimates for the period from 1978-2007 ranged from a high of 239,559 fish in 1987 to fewer than 35,000 fish in 1991 (CDFG 2008).

Spring Chinook Salmon

A population of more than 100,000 spring-run Chinook was once present in the basin, although this estimate is probably low because spring-run fish were the main run of Chinook in the Klamath mainstem in the 1800's (Moyle 2002, p.259). Historic run size estimates in each of the Sprague River, Williamson River, Shasta River, and Scott River alone were at least 5,000 fish (CDFG 1990 as cited by Moyle 2002, p.259). Population estimates for spring Chinook during the period from 1980-2006 ranged from a high of 69,004 fish in 1988 to fewer than 1,945 in 1983 (CDFG 2006).

Steelhead Trout

Hardy et al (2006, p.6) report that historical run sizes for steelhead trout in the Klamath River basin were estimated at "400,000 fish in 1960 (USFWS 1960 as cited by Leidy and Leidy 1984), 250,000 in 1967 (Coots 1967), 241,000 in 1972 (Coots 1972) and 135,000 in 1977 (Boydston 1977)." More recent run sizes are summarized below.

Spring/Summer Steelhead Trout

Annual counts of spring/summer steelhead in holding areas throughout the Klamath River basin ranged from 500 to 3,000 fish (Roeloffs 1983, as cited by Hopelain 1998, p.1). In the 1990's it was estimated that there were 1000-1500 spring/summer steelhead adults divided among eight populations in the basin (Barnhart 1994; Moyle et al. 1995; Moyle 2002 as cited by NRC 2004, p.274). NMFS considers spring/summer steelhead stocks depressed and in danger of extinction (Busby et al. 1994 as cited by NRC 2004, p.274).

Fall Steelhead Trout

The fall steelhead represent the largest of the three steelhead runs, and were estimated to include 55,000-75,000 spawning adults and 150,000-225,000 half-pounders during the period from 1980-1982 (D.P. Lee, CDFG, pers. comm. as cited by Hopelain 1998, p.1).

Winter Steelhead Trout

Run size estimates for Klamath River winter steelhead were 170,000 in the 1960s, 129,000 in the 1970s, and 100,000 in the 1980s (Busby et al. 1994 as cited by NRC 2004, p.273). Current population estimates for winter steelhead have not been conducted, although Hopelain (1998, p.1) estimated a run-size of about 5,000 to 25,000 during 1980-1982. It is presumed that winter steelhead abundance is still declining although estimates, both past and present, are not very reliable (NRC 2004, p.273).

Coho Salmon
It is clear from the information available that coho salmon populations statewide have undergone a dramatic decline from historic levels (Brown and Moyle 1991, p.8; Brown et al. 1994; CDFG 2002, p.1). Maximum estimates for coho spawners in California during the 1940's range from 200,000-500,000 fish (Sagar and Glova 1988 as cited by Moyle 2002, p.250). Brown et al. (1994) state that California coho populations are probably less than 6% of what they were in the 1940s, and there has been at least a 70% decline since the 1960s. In 1994, Brown et al. estimated the coho salmon population in California to be 30,000 fish, with natural spawners comprising 43% of the total population or 13,240 fish.

The Southern Oregon/Northern California Coast Evolutionary Significant Unit (SONCC ESU), which encompasses Klamath River stocks, has been listed as threatened by the State of California and the Federal government. Coho salmon occupy only 61% of the SONCC ESU streams previously identified as historical coho salmon streams (CDFG 2002, p.2).

Historical spawning escapement estimates for the Klamath River basin approximate 15,400-20,000 coho, with 8,000 of these fish originating in the Trinity River (USFWS 1979, App. as cited by Brown et al. 1994). In 1965, CDFG estimated 15,400 coho spawners per year in the basin (CDFG 1965, p.369). In 1994, Brown et al. estimated a total abundance of 18,125 coho in the Klamath River, including 1,860 native and naturalized fish. Current population estimates for coho in the Klamath River basin have not been conducted, although adult coho return numbers to the Iron Gate Hatchery, Trinity River Hatchery, and Shasta River Fish Counting Facility during the last 42 years averaged 5949 fish (Hampton 2004, p.1; Hampton 2005a, p.1; Hampton 2005b; KRIS 2006; Marshall 2005; and Rushton 2005).

2.6.1.2 Juvenile and Adult Fish Kills
Poor water quality conditions in the Klamath River have resulted in both adult and juvenile fish kills reflecting an impairment of the COLD and RARE beneficial uses. Figure 2.30 identifies the mainstem Klamath River reaches in California where adult and juvenile fish kills have been documented.

It is believed that juvenile fish kills are very common in the Klamath River from Iron Gate Dam to the mouth of the river but often go undetected. Direct observation of juvenile fish kills is not common due to the small size of the juvenile fish within the large river system and the generally small number of outmigrant traps that operate in the river (Klamath Fish Health Assessment Team [KFHAT] 2005, p.5, 6).

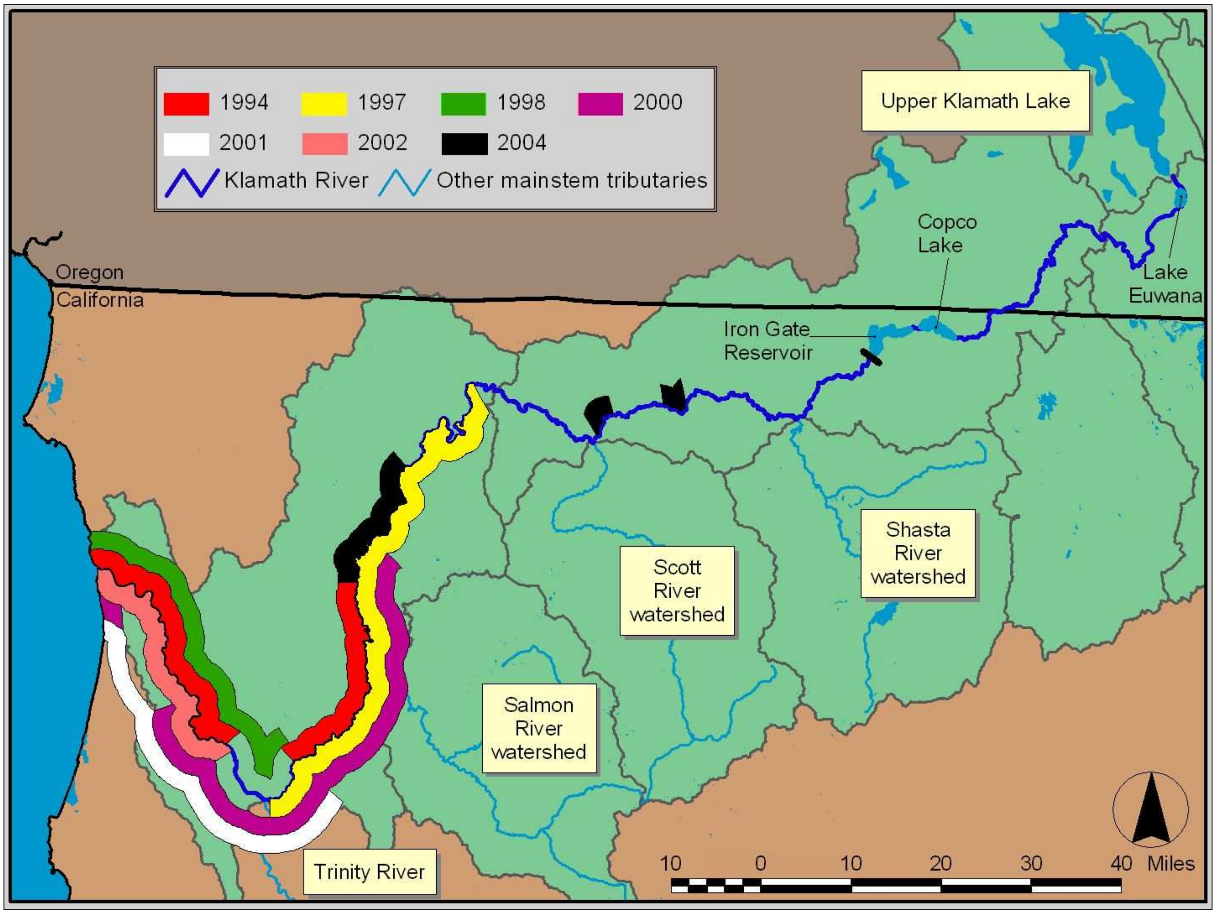

Figure 2.30: Fish kill years and locations in the Klamath River in California

Juvenile fish kills in the Klamath River in California have been documented for the years 1994, 1997, 1998, 2000, 2001, and 2004 (Table 2.15). Estimates of the number of dead fish range from 269-300,000 juvenile salmonids and non-salmonids. Disease was the ultimate cause of death in all juvenile fish kills documented. The effects of disease were exacerbated by poor water quality conditions, including low DO, high water temperature, extreme pH fluctuations, and low flow. Temperatures documented during these fish kills were as high as 25 ^{o}C, well above the lethal threshold for juvenile salmonids. Additionally, DO levels as low as 3.1 mg/L were recorded during these fish kills, which is well below the current Basin Plan objective of 8 mg/L.

This space intentionally left blank.

Table 2.15: Juvenile fish kill locations and causes in the Klamath River in California

Year	River Location	Fish	Cause of Death	Exacerbating Factors				Citations
				D.O.	Temp	NH_3	Flow	
1994	middle/ lower	~300 Chinook	None stated		X			Foott (2005) USFWS (1997)
1997	Middle	non-salmonids salmonids	Disease	X	X	X	X	Hannum (1997) Hendrickson (1997) USFWS (1997)
1998	Various	~240,000 Chinook	Disease	X	X		X	Williamson and Foott (1998)
2000	middle/ lower	10,000-300,000 Chinook & steelhead	Disease	X	X			CDFG (2000, p.1, 10, 11), Deas (2000), Foott (2000), USFWS (2003a)
2001		269 Chinook[1]	Disease					Foott et al. (2002)
2004	upper/ middle	>250,000 Chinook	Disease		X			Engbring (2004) KFHAT (2005) Klamt and Carter (2004)

[1] It is likely that the peak of the disease epizootic and associated mortalities of juvenile Chinook likely occurred prior to when KFHAT conducted their reconnaissance surveys, and thus the actual number of dead fish was much higher (KFHAT 2005).

Documentation of adult fish kills in the Klamath River in California is available for 1997 and 2002 (Table 2.16). The 1997 fish kill was determined to be caused by Columnaris and other diseases and was exacerbated by maximum water temperatures around 26°C, low DO levels of 3.1 mg/L, and low flows (Hannum 1997; Hendrickson 1997).

Table 2.16: Adult fish kill locations and Causes in the Klamath River in California

Year	River Location	Fish	Cause of Death	Exacerbating Factors					Citations
				D.O.	Temp	NH_3	Flow	Sediment	
1997	middle	>50/day non-salmonids	Disease	X	X	X	X		Hannum (1997) Hendrickson (1997) USFWS (1997)
2002	lower	>34,000 (including >33,500 salmonids)	Disease		X		X	X	USFWS (2003a) USFWS (2003b) CDFG (2004)

In mid to late September 2002 at least 34,000 fish died in the lower 36 miles of the Klamath River, although actual losses may have been more than double this number (CDFG 2004, p.III). Approximately 98.4% (33,527) of the fish killed were anadromous salmonids, representing 19.2% of the total 169,297 Klamath-Trinity run for 2002 (USFWS 2003b p.ii).

Multiple compounding factors likely contributed to the 2002 fish kill, including an early large run of fall Chinook, low river discharge which did not provide suitable attraction flows to trigger upstream migration, and warm water temperatures which were optimal for disease proliferation (CDFG 2004, p.III, 33, 124; USFWS 2003a, p.ii). Additionally, fish passage through the lower Klamath River may have been impeded by the shallow depth of the water flowing over some riffles, which were created by sediment deposition during high discharge events in the winters of 1997 and 1998 (CDFG 2004, p.III; USFWS 2003a, p.37). The majority of the dead fish examined were infected with the fish diseases *Ichthyophthiriasis* (Ich) and Columnaris, which was identified as the principal cause of death (CDFG 2004, p.III; USFWS 2003a, p.ii). Maximum daily water temperatures recorded at Turwar (RM 7) during September ranged from 18-23°C (CDFG 2004, p.70). Seven-day running averages of the weekly maximum temperature (MWMT) during this period ranged from 19-22.5°C (CDFG 2004, p.70), which exceeds the USEPA (2003) MWMT threshold values of 16°C (adult migration/core juvenile rearing), 18°C (adult migration/non-core juvenile rearing), and 20°C (adult migration). Although these high water temperatures are not unusual for the Klamath River, they are ideal for disease proliferation and thus contributed to a disease epizootic (the equivalent of an epidemic in humans) (CDFG 2004, p.III, 124; USFWS 2003a, p.ii).

2.6.1.3 Adult and Juvenile Salmonid Migration Barriers and Spawning and Rearing Habitat Degradation

Unless otherwise specified, the following information is from CDFG 2004 (p.III, 83), Hardy et al 2006 (p.10, 15, 20), and USFWS 2003a (p.ii, 36).

Poor water quality conditions are contributing to the impairment of migration (MIGR) of aquatic organisms, particularly salmonids. Section 2.4.4.1 summarized findings by Strange (2007) that adult fall Chinook salmon migration is dependent on stream temperature. As shown in Section 2.5.2, Klamath River mainstem and tributary water temperatures during the period of fall Chinook migration are often over the temperatures noted by Strange (2007) that inhibit upstream migration. Thus elevated water temperatures contribute to the impairment of MIGR.

Alterations in flow in the Klamath River basin have contributed to the degradation of salmonid spawning and rearing habitat (SPWN). Principal factors affecting anadromous fish production in the Klamath River from Iron Gate Dam to Weitchpec include impaired flow in some tributaries (particularly the Shasta and Scott Rivers), impaired flows in the mainstem, and alterations to the timing and magnitude of mainstem flows. One of the primary limiting factors for anadromous fish production in the Klamath River from Weitchpec to the mouth is the cumulative effect of impaired flow and alterations in the seasonal hydrograph. These impacts have contributed to the degradation of available spawning gravel from sedimentation (Hardy et al 2006, p.20).

Cumulative impacts resulting in sediment delivery to many tributaries of the Klamath River in California have contributed to the formation and persistence of large delta fans at many tributary confluences, impeding adult and juvenile migration (MIGR). In low flow years, this accumulation of sediment can inhibit or block access to these tributaries, thereby restricting access to habitat and thermal refugia for migrating adult and juvenile salmonids. Salmonids that are unable to enter the tributaries are forced to seek space in the limited areas of thermal refugia in the mainstem Klamath River. Overcrowding of salmonids in mainstem thermal refugia areas, combined with the high water temperatures can exacerbate disease proliferation.

As mentioned in the previous section, there is evidence that conditions inhibiting adult migration may have contributed to the 2002 adult fish kill in the Klamath River. USFWS reported that in 2002 Klamath River flows were too low to trigger upstream migration, causing adults to congregate in the lower river. After the fish kill was underway the U.S. Bureau of Reclamation increased flows, and salmonids responded by migrating out of the lower river. CDFG hypothesized that fish passage may have been impeded by shallow water depth over certain riffles.

> CDFG…reported that in 1997 and 1998 high discharge events occurred in northern California that could have altered the channel of the Klamath River. They suggested that the input of high sediment loads during high discharge events could have resulted in the filling of pools and increased the elevation of riffles in the lower Klamath River. Furthermore, they speculated that discharges that may have been sufficient for fish passage in low discharge years prior to 1997 were inadequate for passage in September 2002 (CDFG 2003b, as cited by USFWS 2003a, p.37).

Additionally,

> USFWS biologists working on the lower Klamath River [in September of 2002] observed low-flow conditions, making it more difficult to traverse shallow riffles in a jet boat than in previous years (Shaw 2002, personal communication). They observed that water depth at Pecwan and Ah Pah riffles appeared shallow enough to be an impediment to adult fish passage. Yurok biologists also observed that fish passage over some riffles was confined to multiple small channels, in which their jet boat with a six-inch draft, would occasionally touch bottom (Belchik 2003, personal communication). A former NMFS fisheries biologist (Gilroy 2003, personal communication) with experience working on the Klamath river suggested when flows are low, fish passage over certain riffles is confined to smaller channels, representing the main thalweg and much of the riffle is too shallow to pass fish. The DFG Fisheries Biologist, who has participated in angler surveys on the Klamath River since 1985, described water levels during September 2002 in the fish-kill area as the lowest she has observed in over 20 years of experience (Borok 2003, personal communication). These anecdotal observations raised concern that shallow water depth over certain riffles might have impaired the ability of salmon and steelhead to migrate upstream (CDFG 2004, p. 87).

Thus, alterations in flow and changes in channel conditions resulting from sedimentation in the mainstem Klamath River in California have contributed to the impairment of MIGR and SPWN.

2.6.2 Impairment of Native American Culture (CUL) and Subsistence Fishing (FISH) Beneficial Uses

The Water Quality Control Plan for the North Coast Region (Basin Plan) includes two Native American Cultural beneficial uses; Native American Culture (CUL) and Subsistence Fishing (FISH). The CUL beneficial use covers "uses of water that support the cultural and/or traditional rights of indigenous people such as subsistence fishing and shellfish gathering, basket weaving and jewelry material collection, navigation to traditional ceremonial locations, and ceremonial uses"; FISH encompasses "uses of water that support subsistence fishing" (Regional Water Board 2007). CUL is designated as an "Existing" use in the Ukonom, Happy Camp, Seiad Valley, Klamath Glen, and Orleans Hydrologic Subareas of the Klamath River. Due to a lack of available information at the time of the last update of the Basin Plan, no waterbodies in the North Coast have been designated as "Existing" or "Potential" use for FISH. Based on the available information, however, Regional Water Board staff consider FISH an existing use within the same Hydrologic Subareas of the Klamath River as those designated CUL.

Given the scope of the CUL and FISH uses within the Klamath River basin in California, support of these uses is closely interrelated with the uses associated with the cold freshwater salmonid fishery (i.e. COMM, COLD, RARE, MIGR, and SPWN), as well as with the water contact and drinking water uses (REC-1 and MUN). The CUL and FISH beneficial uses in the Klamath River in California is currently impaired due to the decline of salmonid populations and degraded water quality resulting in changes to or the elimination of ceremonies and ceremonial practices and risk of exposure to degraded water quality conditions during ceremonial bathing and traditional daily activities. The FISH beneficial use is currently impaired in the Klamath River basin in California due to the decline of salmonid populations and other Tribal Trust fish populations resulting in decreased use, abundance, and value of subsistence fishing locations, altered diet and associated physical and mental health issues, and increased poverty. Additionally, the presence of the toxin microcystin in fish and mussels in the Klamath River has the potential to impair both the CUL and FISH beneficial uses. It is important to note that other beneficial uses, such as COLD and MUN, are linked to the support of the CUL and FISH beneficial uses throughout the year.

2.6.2.1 <u>Decline in Salmonid and Other Fish Populations</u>

The decline of salmon populations, as well as the decline of other Tribal Trust fish species of the Klamath River basin in California including sturgeon, eulachon (candlefish), lamprey (eel) and some species of suckers, has impaired the CUL and FISH beneficial uses. The elimination of the spring Chinook run above the Salmon River has resulted in the elimination of cultural ceremonies associated with the migration of this species through the length of the Klamath River. Declines in fish populations, especially salmonids, has also resulted in decreased use, abundance, and value of subsistence fishing locations, an altered daily diet that has been linked to health issues for Tribal Members, and increased poverty.

An elaborate ceremony, called the First Salmon Ceremony, marks the passing of the first spring Chinook salmon up the Klamath River. This migrating salmon was allowed to pass all the way up the Klamath River to its spawning ground. It was believed that the first spring Chinook migrating upstream would leave its scales at each spawning location for the rest of the salmon run to follow (Roberts 1932 as cited by Sloan 2003, p. 25). This first migrating salmon of the year was considered taboo, and if eaten would cause convulsions and death. Thus, the First Salmon Ceremony allowed this fish to pass safely upstream, thereby lifting the taboo, and allowing the Native People to fish for salmon in the river (Waterman and Kroeber 1938 as cited by Sloan 2003, p.25). The dramatic decline in the spring Chinook run has made it impossible for the Klamath River Tribes to conduct the First Salmon Ceremony. "And how do you perform the Spring Salmon Ceremony, how do you perform the First Salmon Ceremony, when the physical act of going out and harvesting that first fish won't happen?"(Leaf Hillman 2004 as cited by Norgaard 2005, p.35).

The Karuk Tribe historically depended on the abundant populations of fish found in the mainstem Klamath River for subsistence. However, as fish populations have declined the Karuk have shifted their diets to other food sources (Reed 2007a). Ron Reed (2005), traditional dipnet fisherman and cultural biologist for the Karuk Tribe, states that there is only one remaining Tribal fishery location that provides any level of subsistence fishing to the Karuk Tribe, Ishi Pishi Falls. According to Reed (2005), in 2002, about 1,500 fish were caught at Ishi Pishi falls, in 2003 approximately 1,000 fish were caught, and in 2004 only 100 fish were harvested at this location. The limited harvest of fish at Ishi Pishi Falls has meant that even ceremonial salmon consumption is limited (Ron Reed Pers. Comm. as cited by Norgaard 2005, p.4). According to Norgaard (2006), in addition to declining salmonid numbers, the fishery at Ishi Pishi Falls is negatively affected by low flows. When flows are too low the ability to perform dip net fishing is limited and fewer fish are caught (Norgaard 2006).

The importance of fishing to Tribal Members is reflected by the fact that fishing locations are a form of real property (Pierce 2002, p.7-2; Sloan 2003, p.17). They can be owned by individuals, families, or a group of individuals, and can be borrowed, leased, inherited, and bought and sold (Sloan 2003, p.17, 18). The quality, use, and value of these fishing locations has been reduced as changes including increased siltation and decreased salmonid abundance have occurred in the Klamath River and its tributaries (Sloan 2003, p.18, 28).

Historically, the Karuk Tribe had a platform fishery associated with each of their 100 Tribal village sites (Reed 2006). These fisheries were located near the tops of riffles, where eddies were created along the margins of the Klamath River. These areas of low velocity were where the salmon would hold and/or utilize this microhabitat as a migration corridor. According to Reed (2006) these 100 platform fishery locations are no longer as productive as they once were, or are gone. Tribal elders convey that the riffles near these fishing areas have been filled in and flattened out by sediment, contributing to the decline in overall fish populations (Reed 2006), as well as contributing to the loss of a culturally significant way of life.

The decline of salmonids and other Tribal Trust fish populations in the Klamath River basin has altered the diet of each of the Tribes along the river and its tributaries. Historically, traditional consumption of fish by the Karuk Tribe was estimated at 450 pounds per person per year, while in 2003 the Karuk People consumed less than 5 pounds of salmon per person per year, and in 2004 less than ½ pound per person per year was consumed (Norgaard 2005, p.13). In 2005 over 80% of Karuk households surveyed reported that they were unable to harvest adequate amounts of lamprey (eel), salmon or sturgeon to fulfill their family needs (Norgaard 2005, p.4). Furthermore, 40% of Karuk households reported that there are fish species that their family historically caught, which are no longer harvested (Norgaard 2005, p.7).

The decrease in abundance and availability of traditional foods, including salmon, trout, eel, shellfish, sturgeon and riparian plants, is responsible for many diet related illnesses among Native Americans including diabetes, obesity, heart disease, tuberculosis, hypertension, kidney troubles and strokes (Joe and Young 1993 as cited by Norgaard 2005, p.9, 39). These conditions result from the lack of nutrient content in foods consumed in place of the traditional foods such as salmon, as well as from the decrease in exercise associated with fishing and gathering food (Norgaard 2005, p.40). The estimated diabetes rate for the Karuk Tribe is 21%, nearly four times the U.S. average, and the estimated rate of heart disease for the Karuk Tribe is 39.6%, three times the U.S. average (Norgaard 2005, p.40).

In addition to altered diet and increased health issues, declines in fish populations have resulted in a documented increase in poverty rates for some Klamath River Tribes.

> The destruction of the Klamath River fishery has led to both poverty and hunger. Prior to contact with Europeans and the destruction of the fisheries, the Karuk, Hupa and Yurok tribes were the wealthiest people in what is now known as California. Today they are amongst the poorest. This dramatic reversal is directly linked to the destruction of the fisheries resource base.
>
> The devastation of the resource base, especially the fisheries, is also directly linked to the disproportionate unemployment and low socio-economic status of Karuk people today. Before the impacts of dams, mining and over fishing the Karuk people subsisted off salmon year round for tens of thousands of years. Now poverty and hunger rates for the Karuk Tribe are amongst the highest in the State and Nation. The poverty rate of the Karuk Tribe is between 80 and 85% (Norgaard 2005 Exec Summary).

2.6.2.2 Degraded Water Quality

Degraded water quality in the Klamath River basin in California, including the seasonal presence of blue-green algae and algal toxins in the Klamath River and reservoirs (see Section 2.5.4), has impaired the CUL and FISH beneficial use. Known and/or perceived health risks associated with degraded water quality have resulted in the alteration of cultural ceremonies to exclude or limit ingestion of river water. Additionally, known or perceived risk of exposure to degraded water quality conditions during ceremonial bathing and traditional cultural activities such as bathing, gathering and preparing basket materials, and collecting and using plants has resulted in an impairment of CUL.

The presence of blue-green algae and algal toxins in the Klamath River and reservoirs has impaired the cultural practice of subsistence fishing. The Karuk Tribe has only one fishing location available to them and it is flow dependent. Thus, when fish are in the river and the flow is suitable for fishing, Tribal Members must fish even if blue-green algae and algal toxins are present in the river. Susan Corum, Water Resources Coordinator for the Karuk Tribe, states: "It is really not a choice to fish. It is part of their culture which they need to maintain (Corum 2007)."

Microcystin has been identified in the waters of Klamath River, as well as in the liver of salmonids and in mussels from the river. Laboratory analyses detected a trace of microcystin in the liver of an adult steelhead, and 0.54 µg/kg in the liver of a half-pounder steelhead landed in the Klamath River at Weitchpec on October 3, 2005. Although these levels are not above the 250 µg/kg threshold which is advised by Van Buynder et al. (2001) to protect human health, the Yurok Tribe has expressed concern that the mid to late summer blooms of *Microcystis* in the Klamath River generally coincides with increased salmonid upstream migrations and subsequent usage of salmonid meat for recreational, cultural, and sport purposes. Mussels in the Klamath River have also had detectable levels of microcystin found in them. In 2007, a mussel was found in the Klamath River containing >1500 µg/kg microcystin, over the threshold to protect human health advised by Van Buynder et al. (2001). Additionally, upon review of the 2007 data, OEHHA recommended against consuming mussels from the affected sections of the Klamath River and yellow perch from Iron Gate and Copco Reservoirs due to their high concentrations of microcystin (OEHHA 2008). The presence of microcystin in salmonids and mussels of the Klamath River has resulted in an impairment of the cultural practice of subsistence fishing.

The Klamath River Tribes practice their culture through their "World Renewal" ceremonial cycle, such as the "First Salmon Ceremony" and Jump Dance, the Boat Dance, the War Dance, and the White Deerskin Dance (Reed 2007b). Other Tribal ceremonies and rituals include the Brush Dance and the Flower Dance, as wells as other rituals that require a spiritual cleansing process such as for fishing and hunting, funerals, and good luck (Reed 2007b). All of these ceremonies and rituals require Tribal members to be in close proximity to the Klamath River and they are integrally linked to the river and its health (Sloan 2003 p.18).

According to Karuk Cultural Biologist Ron Reed (2006, 2007b), the "World Renewal" ceremonial cycle is held on the Klamath River at Amerikirum (approximately 2 miles below Somes Bar), Clear Creek (Inam), Somes Bar (Katimin), and Orleans (Panamnik) starting in April and continuing through September of each year. The Medicine Man, who leads the ceremony at Clear Creek, walks 14 miles through the ridges and hills along the Klamath River and is joined halfway through his journey by children and adults of the

Tribe who follow him the rest of the way for good luck. Upon reaching the Klamath River at the end of this walk, it was historically tradition to drink water from the river to complete the ceremony. This is no longer done due to health concerns about drinking water directly from the river, though children are still known to jump in and drink the water (Reed 2006).

Ceremonial bathing in the river is an important part of most ceremonies (Curtis 1924 as cited by Sloan 2003, p.28). For example, bathing in the Klamath River and its tributaries is a requirement for participants in the Brush Ceremony (Sloan 2003, P.16). "During the Fish Dam Ceremonies at *Kepel*, young girls were selected by the Medicine Man to participate in the ceremonies. Once selected, they were sent to the river to bathe and then were dressed in full regalia which they would wear during the ceremonies. Then they were sent home to their families, and were required to fast and bathe in the river every day" (Van Stranlen 1942 as cited by Sloan 2003, p. 28). During the World Renewal Ceremonies, the Medicine Man and other participants bathe in the Klamath River for up to 10 days (Reed 2006).

Bathing is also associated with funeral services, subsistence practices, recreational swimming, courtship, and for individual hygiene (Reed 2007a). Bathing associated with funeral rituals occurs year round and includes preparation for burial, and purification after burial (Curtis 1924 as cited by Sloan 2003, p.28). The Karuk Tribe historically bathed freely in the Klamath River, however in more recent years degraded water quality conditions during the summer have forced them to take precautionary steps while bathing in the river (Reed 2007a). The Yurok Tribe has reported that detached algae have been present in the Klamath River in amounts high enough to prevent access and negatively affect the spirituality associated with bathing areas (McKernan 2006).

Willow roots, wild grape, Cottonwood, and Oregon Grape are collected by Tribal Members in the riparian zone of the Klamath River and used to make baskets (Reed 2007a). Traditional collection of these basketry materials often involved wading in the water (Sloan 2007a), and further contact occurs when the material is washed and cleaned in the water (Reed 2007a). Additionally, willow roots are peeled by mouth following cleaning with river water (Reed 2006). In addition, plants are collected for food, medicine, materials, and other cultural functions (Reed 2007a). Gathering plants or plant materials involves wading and contact with the Klamath River (Sloan 2007a; Reed 2007a). Ingestion of water can occur because plants are often cleaned in the river water and water is consumed with medicinal plants (Sloan 2007a). Given degraded water quality conditions, ingestion of water may pose a potential health risk.

Table 2.17 provides a summary of the activities that are encompassed by the CUL and FISH beneficial uses. Table 2.17 also denotes when those activities occur during the year, and the footnotes identify the amount of physical contact with the water associated with each of these activities. This table is not comprehensive, but conveys the magnitude and diversity of activities that are covered under these uses. Based on the information presented, Regional Water Board staff find that the CUL and FISH beneficial uses of the Klamath River in California are not being fully supported.

■ Indicates time of use.

1-Wading, 2-Full submersion, 3-Ingestion of water

4-Tributaries utilized by the Tribes of the Klamath River for cultural purposes include many of those from the Scott River down to the mouth of the Klamath river. Additionally, the Quartz Valley Tribe utilized all tributaries which flow into the Scott and Shasta Rivers. Tributaries considered as having cultural beneficial uses include any tributary that provides spawning or rearing, or provides a migration pathway for Tribal Trust species.

Note: This table is not an exhaustive list of all activities covered under the CUL and FISH beneficial uses.

2.6.3 Impairment of Water Contact Recreation (REC-1), Non-Contact Water Recreation (REC-2), and Municipal and Domestic Supply (MUN)

Toxigenic blue-green algae blooms and their associated toxins measured in Copco and Iron Gate Reservoirs and in select reaches of the Klamath River downstream from the reservoirs are periodically impairing the Water Contact Recreation (REC-1) and Non-Contact Water Recreation (REC-2) beneficial uses. Additionally, the toxins have the potential to impair Municipal and Domestic Supply (MUN) beneficial use in the Klamath River.

2.6.3.1 Recreational Impacts

The available data on blue-green algae and toxin concentrations in the Klamath River and reservoirs are presented in Section 2.5.4. Water contact recreation (REC-1) during swimming, diving, and other direct water contact presents a high risk of exposure to inhalation or ingestion of cyanotoxins in waters contaminated with *Microcystis aeruginosa* (or other toxigenic species). Blooms of *Microcystis* and the presence of its cyanotoxin, microcystin, have prompted health advisories by the California Department of Health Services as well as the posting of on-site warnings for the public to avoid contact or use caution during water contact recreational activities in Iron Gate and Copco Reservoirs and some reaches of the river since 2005.

The presence of elevated *Microcystis* and microcystin concentrations in Iron Gate and Copco Reservoirs during August 2005 prompted the Regional Water Board cooperating with the State Water Board, USEPA, and Karuk Tribe to issue a joint press release (State Water Board 2005) warning of the potential adverse health effects to persons recreating in waterbodies of the Klamath River system contaminated with noticeably excessive algal concentrations. The Siskiyou County Health Department also issued a health advisory warning people about elevated toxin levels in Copco Reservoir. Additionally, warning signs were posted at key recreational access facilities around Iron Gate and Copco Reservoirs by the Regional Water Board.

During mid-August 2006, large blooms of *Microcystis aeruginosa* and high concentrations of microcystin led the Regional Water Board, Karuk Tribe, State Water Board, and USEPA to issue another press release, again warning recreational water users and other area residents to use caution when near the reservoirs, or avoid water contact recreation altogether in locations with noticeable blue-green algal blooms in Copco and Iron Gate Reservoirs (State Water Board 2006). The Siskiyou County Health Department also issued a public health advisory for Iron Gate and Copco Reservoirs in 2006 (Siskiyou County Public Health Department 2006). In early September 2006 the Regional Water Board posted warning signs at prominent recreational access points in both reservoirs reiterating the cautionary advisories contained in the earlier press release. In addition to these postings at the reservoirs, the Yurok Tribe posted health advisory signs along the mainstem Klamath River within the reservation borders (Fetcho 2006).

Microcystis scums were present in Iron Gate and Copco Reservoir beginning in mid- to late-June 2007 at concentrations that prompted the Regional Water Board to post precautionary health advisory signs at boat launches, campgrounds, swimming areas, and other high traffic, recreational use access points along the shorelines of the reservoirs. Shortly after the posting of the two reservoirs the USEPA as lead agency, with a number of state agencies, and the Yurok and Karuk Tribes issued a joint press release on July 5, 2007 advising the public to use caution when recreating at the two reservoirs (USEPA 2007). In August 2007, Microcystis cell counts in the mainstem Klamath River exceeded the Blue Green Algae Work Group's guidelines for posting health advisories. Consequently, Regional Water Board staff posted precautionary health advisory signs at 24 locations along the mainstem Klamath River from the sport fishing access point at Iron Gate Hatchery to the Aikens Creek Campground.

2.6.3.2. Health Impacts

Blooms of *Microcystis aeruginosa*, and subsequent releases of its cyanotoxin, microcystin, during the summer and early fall in the mainstem Klamath River have the potential to impair the municipal and domestic supply (MUN) beneficial use. The State Water Board's Department of Water Rights Information Management System (WRIMS 2006) shows numerous existing water rights that utilize in-river water withdrawals for sources of domestic drinking water and other uses. Nearly all of the water rights are located downstream from Iron Gate dam. The location, engineering, and timing of water withdrawals, as well as the magnitude and velocity of streamflow are factors that affect the possibility of entraining blue-green algae and their toxins in water supplies.

There have been no documented human health impacts due to drinking or recreating in Klamath River water during *Microcystis* blooms. However, the presence of the toxin during periods when water withdrawls are occurring and when people are recreating, presents the possibility that human health impacts could occur.

In August of 2007, a dog became very ill a few hours after swimming in Copco Reservoir and drinking the water during a *Microcystis* bloom (Tobler 2007). The sick dog was taken to the vet and tests showed elevated levels of several enzymes indicative of liver disease. Microcystin is a liver toxin, and is capable of producing this type of an enzymatic response.

2.6.3.3. Aesthetic Impacts

Visible scums formed by the presence of *Microcystis aeruginosa* and other blue-green algae in Copco and Iron Gate Reservoirs present an aesthetic nuisance, potentially impacting the aesthetic enjoyment (REC-2) of these reservoirs. A study conducted by CH2M Hill for PacifCorp compiled interviews and survey responses of recreational water users about their experiences at locations along the Klamath River, including Copco and Iron Gate Reservoirs (PacifiCorp 2004a). Interviewees' responses showed that water condition during the summer to early fall seasons has affected the quality and enjoyment of their experiences. The survey did not link responses to a specific time period; however, nearly all of the concerns expressed by respondents pertained to the summer and early fall recreational seasons of 2001 and 2002.

Approximately 70% (n = 89), of the responses to the interview questions stated water quality either detracted a lot or a little from their aesthetic enjoyment of the Klamath River within the geographical boundaries of the survey. By far, the most common complaint related to large amounts of "algae" and odors related to "algae." The survey data show that of the 70% of water uses reporting unfavorable recreational experiences with "algae," approximately 42% (n = 37) of those negative responses directly involved Iron Gate and Copco Reservoirs. Though not stated, presumably the "algae" in question were blue-green algal species that tend to accumulate along shorelines, forming scums and surface films during blooms.

2.6.4 Impairment of Commercial and Sport Fishing (COMM)

The Commercial and Sport Fishing (COMM) beneficial use is currently impaired in the Klamath River in California, as demonstrated by restrictions and closures on the sport and commercial fishing industries in the basin and beyond. Salmonid population decline has resulted in severe reductions in available Chinook salmon for both the in-river and ocean troll commercial fishing communities, and sport fishing community. Additionally, federal regulations have eliminated the right to harvest coho salmon stocks due to their dwindling numbers. Evidence documenting declining numbers of salmonids returning to spawn in the Klamath River basin is discussed in detail in section 2.6.1 and Appendix 5. The apparent disappearance of eulachon (*Thaleicthys pacificus,* also known as candlefish) spawning activity in the Klamath River (Belchik and Larson 1998) has resulted in the cessation of a historically important, commercially valuable non-salmonid fishery that was primarily utilized by Yurok Tribal members.

2.6.4.1 <u>In-River Sport Fishing Impairment</u>

Decreased salmon populations in the Klamath River have resulted in the alteration of fishing regulations further restricting the number of in-river fish harvested recreationally and the length of the recreational salmon in-river fishing season. For the 2006 season, the California Fish and Game Commission (Commission) decreased the number of days that recreational salmon fishing could occur by 11 days in the Klamath River below the Highway 96 bridge at Weitchpec (CFGC 2006). This was done in an attempt to ensure that the quota for in-river recreational harvest would not be met before Labor Day, allowing fishing during the holiday weekend (CFGC 2006).

The documentation of microcystin toxin concentrations in fish tissue of yellow perch from Copco Reservoir above human health thresholds represents an impairment of in-river sport fishing. Table 2.18 presents data from 2005 and 2007 when salmonids were collected in the Klamath River and yellow perch were collected in the reservoirs to test for the presence of microcystin. As the table reflects, microcystin was detected in the liver of a salmonid collected at Iron Gate Hatchery at a level >250 µg/kg, which is over the threshold recommended by Van Buynder et al. (2001) to protect human health. Additionally, four of the yellow perch fish tissue samples and one of the liver samples collected in Copco Reservoir were >250 ug/kg. Yellow perch are commonly harvested from Copco and Iron Gate Reservoirs for consumption.

Table 2.18: Detection of microcystin in fish tissue and liver samples from the Klamath River and reservoirs

Location Fish Collected	Year	# of fish tissue samples where Microcystin Detected	# of fish tissue samples with Microcystin total >250 µg/kg	# of fish liver samples where Microcystin Detected	# of fish liver samples with Microcystin total >250 µg/kg

** yellow perch

2.6.4.2 Ocean Sport Fishing Impairment

During the period from 1960 through 1965 there was no closed season for ocean salmon sport fishing north of Tomales Point (CDFG 1967). The catch limit during this period remained constant at 3 salmon per day. In 1960 and 1961 the minimum size limit for salmon was 22 inches, and in 1962 one fish of any size was allowed with the remainder to be over 22 inches. From 1963 through 1965 the minimum size limit was one salmon over 20 inches and two over 22 inches.

In contrast, the currently depressed state of the fall Chinook run in the Klamath Management Zone (KMZ), and the listing of coho as threatened on both the federal (1997 listing) and California (2005 listing) Endangered Species lists, has resulted in increased restrictions on the ocean sport fishery. The 2007 ocean sport fishing season in the Klamath Management Zone (KMZ), extending from Humbug Mountain, OR to Point Arena, CA, was open from May 5 to September 4 (Pacific Fishery Management Council [PFMC] 2007). However, the Klamath Control Zone, extending 6 miles north and south of the Klamath River and 12 miles off-shore, was closed in August. The catching of coho was prohibited and the Chinook catch was limited to two fish per day (PFMC 2007). Chinook were required to be a minimum of 24 inches in total length to be legal to keep (PFMC 2007). These greater restrictions have contributed to the impairment of the sport fishery in the Klamath River basin.

2.6.4.3 In-River Commercial Fishery Impairment

Between 1912 and 1934 approximately 957,000 pounds of Chinook salmon, representing close to 55,000 fish, were harvested and preserved during a single fishing season in the Klamath River (Snyder 1931, p. 7, 8, 88, and 89). Daily salmonid catches by the Tribal commercial fishery commonly ranged from 7,000 to 10,000 fish per day, with a one-day high that was reportedly approximately17,000 fish. Catch totals were mostly Chinook, but coho salmon, steelhead trout, lamprey, and green sturgeon were also caught and preserved (Snyder 1931, p. 7, 8, 88, and 89). Due to precipitous declines in salmonid populations attributed to over harvesting by the in-river commercial salmon fishery, the fishery was declared illegal and closed by court order in 1934. It was subsequently reopened by another court order in 1977; however, the Bureau of Indian Affairs closed the Tribal in-river commercial fishery the following year under a "conservation moratorium." It remained closed until 1987, when it was again reopened (Pierce 1998; Yurok Perspectives 2001, p. 7.1-7.13).

In 1993 the Department of Interior modified catch limits for the Klamath River basin Tribes, allotting 50% of the available Klamath River basin salmon harvest to the Hoopa and Yurok Tribes, or an amount sufficient to support a moderate standard of living, which ever is less. Given the depressed condition of the Klamath River basin salmon stocks in 1993, the Department of Interior concluded that 50% of the salmon harvest during that year would be allocated to the Tribes because there weren't enough fish to allow them to catch enough to support a moderate standard of living (50 CFR Part 661, NOAA 1993). Of the 50% allocated to the Tribes, 80% and 20% of that allocation, referred to as Tribal shares, are allotted to the Yurok and Hoopa Tribes, respectively. Currently, the Yurok and Hoopa Tribes are the only Tribes with Federally-recognized commercial fishing rights in the Klamath River (Pierce 1998; Yurok Perspectives 2001, p. 7.1-7.13)

From 1990 through 1998 the in-river Tribal fishery was closed to commercial gillnetting due to depressed salmon runs. In recent years, harvest rates for the Tribal gillnet fishery have varied and are currently so low that it is hard to support an in-river commercial fishery. For the 2006 salmon season the Pacific Fishery Management Council (PFMC), working with the Klamath Fisheries Management Council, determined that the allowable Tribal share of the Klamath-Trinity River basin salmon harvest is 10,000 fish (PFMC 2006a). This would allocate 8,000 salmon to the Yurok Tribe and 2,000 salmon to the Hoopa Tribe from the in-river salmon fishery.

2.6.4.4 Ocean Commercial Fishery Impairment

Salmon sold to fish buyers and processors within the Klamath Management Zone (KMZ) have dwindled significantly since 1976 through 1980 when an average of 143,900 Chinook and 72,100 coho salmon were delivered per season to the port of Crescent City alone (PFMC 2003, 2006b). From 1993 through the present, concerns about the plummeting coho salmon populations have led to the closure of the entire California ocean commercial troll for coho. In order to more rigorously protect all salmonid stocks within the KMZ, regulations on the ocean commercial fishery (consisting mostly of Chinook salmon) has been progressively more restrictive.

The economic impacts to the fishermen and on-shore industries that support the ocean commercial salmon industry have been, and continue to be significant. The maximum dollar values for the ex-vessel price (the price received by fishermen for fish landed at the dock) adjusted to 2005 dollar values are presented in Table 2.19 for the four major ports in the KMZ. The seasons when regulatory closures prohibited commercial ocean salmon fishing are not shown in the table, and correspond to no income for fishermen.

Table 2.19: Estimates of maximum dollars for the ex-vessel price of the commercial ocean salmon fishery for the four major ports within the KMZ from 1976-1990 and 1991-2001.

Port	Year(s)[1] / Maximum Dollars	Year(s)[1] / Maximum Dollars
Brookings, OR	1976-1980 / 7,355,000	1991-1995 / 126,000
Crescent City, CA	1976-1980 / 5,931,000	1991-1995 / 9,000
Eureka, CA	1976-1980 / 8,884,650	1991 / 43,640
Fort Bragg, CA	1986-1990 / 14,902,000	2001 / 663,000

Source: PFMC 2006b
[1]Multiple year's values represent the average income per year

The 2006 ocean commercial troll non-Tribal salmon fishery was severely curtailed along much of the west coast by the PFMC. The potential offspring of the 2002 Chinook stocks, the four year age class, is that cohort of fish that were predicted to have subsequently returned to the Klamath River as spawners in 2006. The loss of over 33,000 salmonids in 2002, mostly fall Chinook (USFWS 2003b p.ii), was a contributing factor to the low return and resulting fishery restrictions in 2006. In particular, within the KMZ, extending from Humbug Mountain north of Brookings, OR to Horse Mountain just south of Shelter Cove, CA, the 2006 season was closed (NOAA 2006). South of Horse Mountain to Point Arena the season was open only from September 1 through September 15, or when a Chinook salmon quota of 4,000 fish was reached. The extreme seasonal and take restrictions were deemed necessary by the PFMC to assure an adequate numbers of spawners returned to the Klamath River.

During 2007 the PFMC (2008) considered Chinook salmon stocks within the KMZ somewhat healthier than 2006 but only opened the ocean commercial Chinook season from September 10 - September 30, imposing a fleet quota of 6,000 fish. Chinook stocks south of the KMZ to Point Arena were deemed depressed to the point that the PFMC only allowed fishing during the periods from April 9-April 27 (fleet quota of 2,000 fish) and August 29-September 30 (no quota set). The ocean coho salmon fishery remained closed along the California coast for the entire fishing season.

2.7 Problem Statement Synthesis

Based on the analysis presented in this chapter, there is little doubt that the Klamath River is an impaired waterbody. The Klamath River TMDL problem statement has identified numerous water quality related factors that must be addressed in the TMDL allocations and the implementation plan. The following is a summary of the water quality conditions and impacts that are addressed in the TMDL.

- Temperature conditions that exceed natural levels exist throughout the Klamath River basin and contribute to: chronic stress and sometimes acute lethal conditions for cold water fish, migration barriers, proliferation of fish diseases such as Columnaris, lower reproductive success, increased juvenile and adult mortality, and lower overall fish populations.
- Nutrient concentrations in much of the Klamath River watershed are well above natural background levels and contribute to excess periphyton and suspended algae growth, which in turn contributes to poor DO and pH conditions, and also

contributes to increased abundance and exposure of fish to parasites (e.g., *C. shasta*).

- High levels of nutrients and the presence of impoundments have contributed to the development of nuisance levels of blue-green algae that have created potential health hazards for people exposed to reservoir and downstream river waters. This health hazard has negatively impacted both recreational and ceremonial use of the reservoirs and the river.
- Conditions of low DO and high pH are persistent in much of the Klamath River and contribute to multiple impacts on cold water fish including: migration barriers, decreased growth and fecundity, decreased reproductive success, increased juvenile fish mortality, increased adult mortality, and lower overall fish populations.
- Excess sediment delivery to the Klamath River and tributary streams has contributed to habitat impairment, increased levels of nutrients, and to the development of water column temperatures that exceed Basin Plan water quality objectives.
- Reduced flows contribute to increased water column temperatures, the accumulation of organic matter, and low DO conditions which have contributed to impacts on aquatic life.
- Water quality objectives for temperature, DO, pH, biostimulatory substances, and toxicity are regularly exceeded in the Klamath River basin in California.
- Seventeen of the twenty-three designated beneficial uses for the Klamath River are not supported due to existing water quality impairments and related factors.

This space intentionally left blank.

CHAPTER 3. ANALYTIC APPROACH

3.1 Introduction

This chapter describes the analytic approach for developing the Klamath River TMDLs for California and the development of the proposed recalculated SSO for DO in the mainstem Klamath River. The analysis incorporated empirical data analysis of the best quality assured water quality data available, review of available reports, and application of water quality models. The water quality models applied were the primary analytic tools used to establish the relationships between pollutant loadings and instream water quality response. In turn, the models were used to quantify the loading capacity of the Klamath River, establish appropriate numeric targets, and calculate load and waste load allocations necessary to achieve the loading capacity and meet water quality standards. Section 3.2 describes these water quality models applied to the Klamath River, and describes the model testing process. Appendix 6 *Model Configuration and Results – Klamath River Model for TMDL Development*, presents the model configuration and testing results in detail. Section 3.3 describes the application of these models for Klamath River TMDL development. Appendix 7 *Modeling Scenarios – Klamath River Model for TMDL Development* (details how each of these scenarios was configured, associated assumptions, and presents the results. Results of these scenarios are also summarized in Chapters 4 and 5.

3.2 Modeling Approach

3.2.1 Hydrologic Models Applied

To support TMDL development for the Klamath River system, the need for an integrated receiving water hydrodynamic and water quality modeling system was identified. A model for the Klamath River had already been developed by PacifiCorp to support studies for the Federal Energy Regulatory Commission hydropower relicensing process (Watercourse Engineering, Inc. 2004) when this project commenced. The version of the model available in 2004 is hereafter referred to as the PacifiCorp Model. Regional Water Board, ODEQ, and EPA determined that this existing PacifiCorp Model would provide the optimal basis, after making some enhancements, for TMDL model development. The PacifiCorp Model uses hydrodynamic and water quality models with a proven track record in the environmental arena and has already been reviewed by most stakeholders in the watershed. Additionally, model results can be directly compared to ODEQ, Regional Water Board and Tribal water quality criteria.

The original PacifiCorp Model consisted of several model components used in series, including the Resource Management Associates (RMA) RMA-2 and RMA-11 models and the U.S. Army Corps of Engineers' CE-QUAL-W2 model. The RMA-2 and RMA-11 models were applied for Link River (which is the stretch of the Klamath River from Upper Klamath Lake to Lake Ewauna), Keno Dam to J.C. Boyle Reservoir, Bypass/ Peaking Reach, and Iron Gate Dam to Turwar. RMA-2 simulates hydrodynamics while

RMA-11 represents water quality processes. The CE-QUAL-W2 model was applied for Lake Ewauna-Keno Dam, J.C. Boyle Reservoir, Copco Reservoir, and Iron Gate Reservoir. CE-QUAL-W2 is a two-dimensional, longitudinal/vertical (laterally averaged), hydrodynamic and water quality model (Cole and Wells 2003).

Since the estuarine portion of the Klamath River (Turwar to the Pacific Ocean) was not included in the original PacifiCorp Model, one of the first updates made was to include an estuarine model. From a review of available data for the estuary, it was apparent that hydrodynamics and water quality within the estuary are highly variable spatially and throughout the year and are greatly influenced by time of year, river flow, tidal cycle, and location of the estuary mouth (which changes due to sand bar movement). Additionally, transect temperature and salinity data in the lower estuary showed significant lateral variability, as did DO to a lesser extent. Therefore, EPA's Environmental Fluid Dynamics Code (EFDC), which is a full 3-D hydrodynamic and water quality model, was selected to model the complex estuarine environment.

EFDC is capable of predicting hydrodynamics, nutrient cycles, DO, temperature, and other parameters and processes pertinent to the TMDL development effort for the estuarine section. It is capable of representing the highly variable flow and water quality conditions within years and between years for the estuary. As with RMA-2, RMA-11, and CE-QUAL-W2, EFDC has a proven record in the environmental arena and model results can be directly compared to ODEQ, Regional Water Board and Tribal water quality criteria. EFDC is EPA-endorsed and supported and available freely in the public domain.

The combination of the PacifiCorp Model (RMA and CE-QUAL-W2), with enhancements discussed below, and the EFDC model for the estuary resulted in the Klamath River model used for TMDL development. Table 3.1 identifies the modeling elements applied to each river segment. These segments are depicted graphically in Figures 3.1 and 3.2. Linkages between the different modeling segments were made by transferring time-variable flow and water quality results from one model to the next (e.g., output from the Link River model became input for the Lake Ewauna-Keno Dam model).

Table 3.1: Models applied to each Klamath River and estuary segment

Modeling Segment #	Modeling Segment	Segment Type	Model(s)	Dimensions
1	Link River	River	RMA-2/RMA-11	1-D
2	Lake Ewauna-Keno Dam	Reservoir	CE-QUAL-W2	2-D
3	Keno Dam to J.C. Boyle Reservoir	River	RMA-2/RMA-11	1-D
4	J.C. Boyle Reservoir	Reservoir	CE-QUAL-W2	2-D
5	Bypass/Full Flow Reach	River	RMA-2/RMA-11	1-D
6	Copco Reservoir	Reservoir	CE-QUAL-W2	2-D
7	Iron Gate Reservoir	Reservoir	CE-QUAL-W2	2-D
8	Iron Gate Dam to Turwar	River	RMA-2/RMA-11	1-D
9	Turwar to Pacific Ocean	Estuary	EFDC	3-D

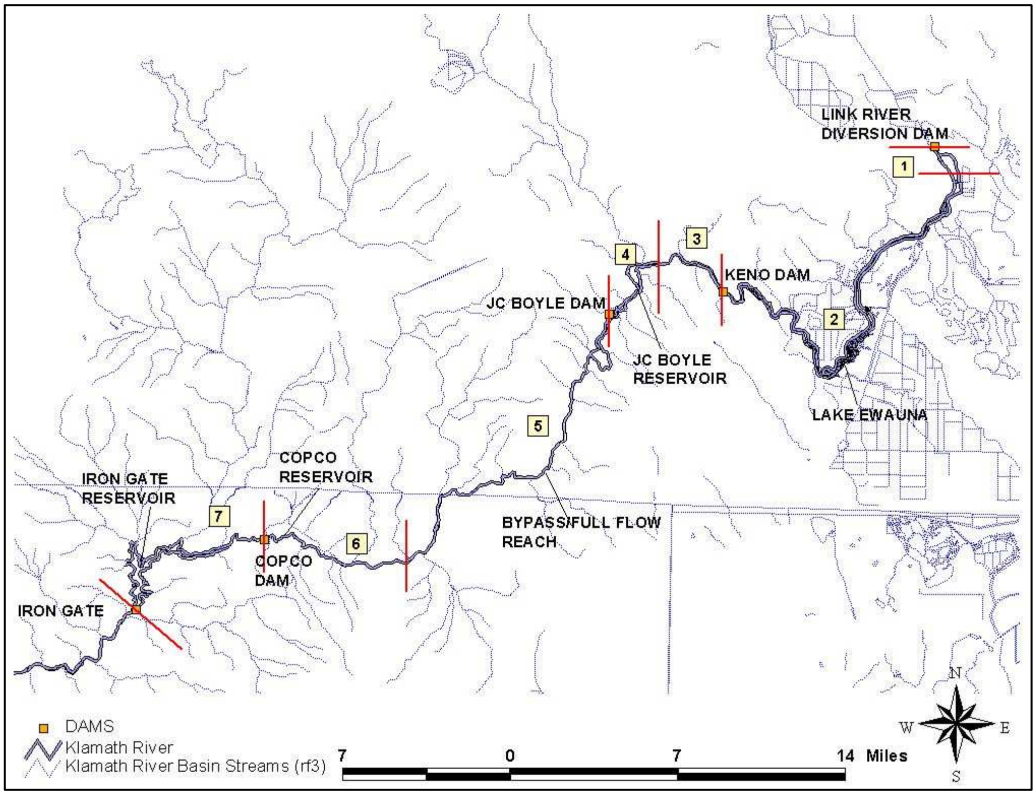

Figure 3.1: Model segments in Oregon and Northern California

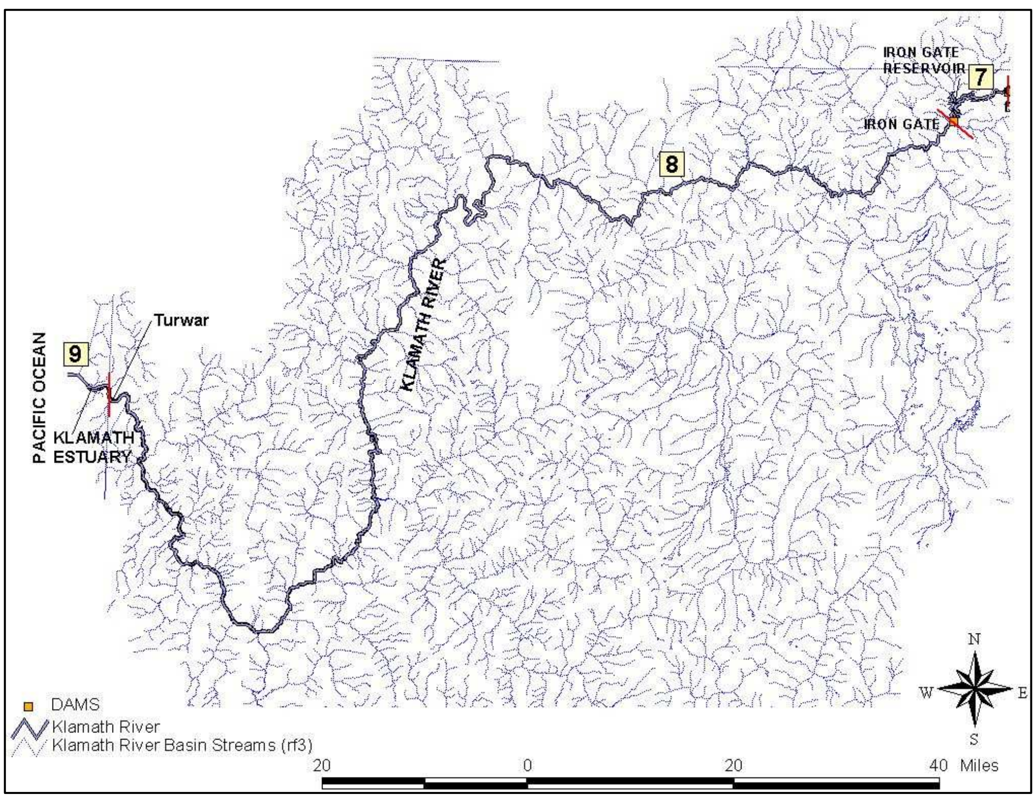

Figure 3.2: Model segments in California

Although the original PacifiCorp Model is capable of addressing the identified water quality issues, a number of adaptations to the model were identified to expedite and strengthen the model for the rigors of TMDL development for the Klamath River. Enhancements were made in the following areas: BOD/organic matter (OM) unification, algae representation in Lake Ewauna, Monod-type continuous SOD and OM decay, pH simulation in RMA, OM-dependent light extinction simulation in RMA, reaeration formulations, and dynamic OM partitioning, and are detailed in Appendix 6. In combination, the RMA/CE-QUAL-W2 and EFDC models as applied for Klamath River TMDL development, are referred to as the Klamath River TMDL models.

The Klamath River TMDL models were also used to develop the proposed recalculated SSO for DO in the mainstem Klamath River (included in this report as Appendix 1), which is a separate Basin Plan amendment that has been closely coordinated with the Klamath River TMDL. The Klamath River SSO for DO will be submitted for Board approval independent of the Klamath River TMDL. The Klamath River SSO for DO is derived from natural background conditions as estimated using percent DO saturation and natural receiving water temperatures. DO concentrations derived from the applicable DO percent saturation criteria are calculated using natural receiving water temperatures. The Klamath River TMDL model was used to create the necessary natural background conditions scenarios.

3.2.1.1 Model Configuration and Testing

The Klamath River TMDL model was configured by designating a set of variables used in the model to define the "state" of a dynamic system (i.e. state variables), preparing the computational grid, and preparing boundary conditions. Once configuration was complete, the model was tested through a rigorous calibration and corroboration process. A summary of these steps is described below, however, a more detailed discussion is included in Appendix 6.

State variables were designated to most accurately predict TMDL impairments, with particular attention paid to temperature, DO, pH, and ammonia toxicity, as well as related physical, chemical, and biological processes. State variables varied for each model type in the Klamath River model (RMA, CE-QUAL-W2, and EFDC). The following state variables were configured for the riverine segments of the Klamath River model (for the RMA portions of the model):

1) Arbitrary Constituent (configured as a tracer to evaluate the mass balance)
2) DO
3) Organic matter (OM)
4) Orthophosphorus (PO_4)
5) Ammonium (NH_4)
6) Nitrite (NO_2)
7) Nitrate (NO_3)
8) Suspended algae

9) Temperature
10) Periphyton
11) Total inorganic carbon (TIC)
12) Alkalinity (Alk)

The reservoir segments of the Klamath River, where the CE-QUAL-W2 model was applied, were configured using the following active state variables:

1) Labile dissolved organic matter (LDOM)
2) Refractory dissolved organic matter (RDOM)
3) Labile particulate organic matter (LPOM)
4) Refractory particulate organic matter (RPOM)
5) Inorganic Suspended Solids (ISS)
6) PO_4
7) NH_4
8) NO_2/NO_3
9) DO
10) Suspended algae
11) Alk
12) TIC
13) Temperature
14) Tracer
15) TDS
16) Age (to track detention time at different locations)
17) Coliform bacteria

The estuarine portion of the Klamath River, which was modeled using EFDC, was configured with the following constituents as state variables:

1) Phytoplankton
2) Periphyton
3) Labile particulate organic carbon (LPOC)
4) Labile dissolved organic carbon (LDOC)
5) Labile particulate organic phosphorous (LPOP)
6) Labile dissolved organic phosphorous (LDOP)
7) PO_4
8) Labile particulate organic nitrogen (LPON)
9) Labile dissolved organic nitrogen (LDON)
10) NH_4
11) NO_2/NO_3
12) DO
13) Temperature
14) Salinity

Note that pH is not included as a state variable in the lists above. It is computed from alkalinity and total inorganic carbon for the riverine and reservoir segments. Alkalinity and total inorganic carbon are transported by the model and are thus included as state variables.

Preparation of the computational grid consisted of segmenting the entire Klamath River into smaller computational segments for application of the various models. In general, bathymetry is the most critical component in developing the grid for the system. Within each of the model segments described above (excluding the Klamath Estuary), the primary waterbody (either a Klamath River section or a reservoir) was subdivided into higher resolution elements for greater detail in modeling. The TMDL modeling framework components were segmented similarly to the PacifiCorp Model. Only the main-stem Klamath River and its reservoirs were simulated with the Klamath River TMDL model. All tributaries to the river were represented as boundary conditions (i.e., they were not explicitly modeled). For the tidal portion of the Klamath River from Turwar to the Pacific Ocean, which was not included in the PacifiCorp Model, a boundary-fit curvilinear grid was developed to accurately represent the shape of the estuary. In the modeling domain, each cell is represented by up to 4 vertical layers.

To run the model, external forcing factors known as boundary conditions were specified for each model segment in the system. These forcing factors are a critical component in the modeling process and have direct implications on the quality of the model's predictions. External forcing factors include a wide range of dynamic information:

- Upstream Inflow Conditions: flows, temperature, and constituent values;
- Tributary (or Lateral) Inflow Conditions: Tributary inflows, temperature, and constituent boundary conditions;
- Withdrawal Boundary Conditions;
- Surface Conditions: Atmospheric conditions (including wind, air temperature, and solar radiation).

Once the Klamath River TMDL model was configured, the model was tested through a calibration and corroboration process at multiple locations. Calibration refers to the adjustment or fine-tuning of modeling parameters to produce the best fit of the simulated output to the field observations. The sequence of calibration for the Klamath River TMDL model involved calibrating flow and water surface elevation first and then calibrating water quality using available monitoring data. Since the original PacifiCorp Model was already calibrated for hydrodynamics, the focus of efforts was on hydrodynamic calibration of the EFDC portion of the model (estuary) and the water quality calibration of the entire model. The corroboration process involved testing calibrated model parameters versus field observations for a separate time period to ensure their appropriateness (qualitative and/or quantitative evaluation of a model's accuracy and predictive capabilities).

The Klamath River TMDL model above the estuary (Model Segments 1 through 8 Link Dam to Turwar) was calibrated using data from the year 2000. This year was selected for calibration because relatively good boundary condition data and in-stream data were available in the upper portion of the system. Data were available, but not to the same extent, for the lower portion of the system (particularly downstream of Iron Gate Dam). Selection of this year was deemed appropriate because water quality conditions in the upper portion of the system drive the response downstream. Although this was an average hydrologic year in terms of flow, simulating the entire year inherently tests the model's ability to represent a range of hydrologic regimes and associated water quality impacts. The model was also corroborated using data from the year 2002, which was a relatively low hydrologic year in terms of flow, for Model Segments 1 through 5, Link Dam to slightly downstream of Stateline. Again, considerably more data were available for the upper portion of the system in 2002 than for other years. The model was not run downstream (Segments 6 through 9) for 2002 primarily due to limited boundary data, but also due to cost considerations. In general, boundary condition data are limited in terms of representing the full range of temporal, spatial, and parameter variability. Thus, it is very likely that evaluation of additional calibration would be more tied to data limitations/ uncertainty than model performance. The estuarine portion (Model Segment 9) was calibrated using data from the year 2004, using bathymetric data and data for key water quality parameters collected as part of an intensive monitoring effort in 2004. Insufficient data were available to calibrate for the year 2000 or 2002 in the estuarine portion of the Klamath River. Calibration and corroboration results are presented in Appendix 6.

3.2.1.2 Assumptions, Limitations, and Uncertainty

Like any dynamic water quality model, the Klamath River TMDL models have inherent limitations and uncertainty. Development and application of the Klamath River TMDL model has focused on key best practices identified in EPA's March 2009 "Guidance on the Development, Evaluation, and Application of Environmental Models," including peer review of models; QA project planning, including data quality assessment; and model corroboration. In addition to the key practices noted above, model sensitivity and uncertainty analysis have also been considered. Appendix 6 details model assumptions, limitations, and uncertainty. The Klamath TMDL development team (US EPA Regions 9 and 10, ODEQ, Regional Water Board, and Tetra Tech) finds that the Klamath River TMDL models are suitable tools for establishing Klamath River TMDL allocations and targets.

3.2.2 Nutrient Numeric Endpoint Analysis

An additional line of evidence for establishing TMDLs in the Klamath River system was provided by an application of the California Nutrient Numeric Endpoint (CA NNE) approach (Tetra Tech 2006) to the Klamath River ([*Nutrient Numeric Endpoint Analysis for the Klamath River, CA* included as Appendix 2 of this report]). The CA NNE approach (Tetra Tech 2006) is a risk-based approach in which algae and nutrient targets can be evaluated based on multiple lines of evidence. The CA NNE approach (Tetra

Tech 2006) also includes a set of relatively simple, but effective, spreadsheet scoping tools for application in lake/reservoir or riverine systems to assist in evaluating the translation between response indicators (e.g. algal biomass) and nutrient concentrations or loads. These response indicators can be incorporated as targets, which can then be translated into site-specific nutrient targets. Nutrient targets established in this way are supplemental to those established to meet specific numeric criteria, such as water quality criteria for dissolved oxygen.

The CA NNE approach recognizes that there is no clear scientific consensus on precise levels of nutrient concentrations or response variables that result in impairment of a designated use. To address this problem, waterbodies are classified in three categories, termed Beneficial Use Risk Categories (BURCs). BURC I waterbodies are not expected to exhibit impairment due to nutrients, while BURC III waterbodies have a high probability of impairment due to nutrients. BURC II waterbodies are in an intermediate range, where additional information and analysis may be needed to determine if a use is supported, threatened, or impaired. Tetra Tech (2006) lists consensus targets for response indicators defining the boundaries between BURC I/II and BURC II/III. The BURC II/III boundary provides an initial scoping point to establish minimum requirements for a TMDL.

As part of the Klamath River CA NNE analysis, multiple lines of evidence including the use of the scoping tools were used to develop numeric targets for maximum reach-averaged density of benthic chlorophyll-a in the Klamath River below Iron Gate Dam, and planktonic chlorophyll-a and blue-green algae (e.g. *Microcystis aeruginosa* and microcystin) numeric targets for Copco and Iron Gate Reservoirs (Appendix 2 of this report). Application of the CA NNE spreadsheet scoping tool for reservoirs successfully predicts observed average concentrations of TN, TP, and chlorophyll-a in Copco and Iron Gate reservoirs, as well as the observed blue-green algal dominance.

Another important tenet of the CA NNE approach (Tetra Tech 2006) is that targets should not be set lower than the value expected under natural conditions. The hydrodynamic model natural conditions baselines scenario (T1BS) predicts TN concentrations in the Klamath River below Iron Gate that are somewhat above the targets estimated by the CA NNE benthic biomass scoping tool; however, the model results are tempered by the fact that the frequency of scouring events that limit periphyton biomass development would also increase in a dams-out scenario. The CA NNE benthic biomass scoping tool suggests that maximum periphyton chlorophyll-a densities in the river under natural conditions would likely be very close to the 150 mg/m^2 target (see section 2.3.2.1).

3.3 Model Application for TMDL Determination

After the Klamath River TMDL Model was fully tested, it was applied to evaluate a series of scenarios to support TMDL development. The scenarios simulated include:

- Natural condition baseline scenario (T1BSR)
- Oregon allocation scenario (TOD2RN)
- California allocation scenario (TCD2RN)
- With-dam TMDL scenario (T4BSRN)

The natural conditions baseline scenario (T1BSR) was run in order to estimate water quality conditions under natural conditions, because some water quality standards for both Oregon Department of Environmental Quality (ODEQ) and California North Coast Regional Water Quality Control Board (RWQCB) are based on natural conditions. The natural conditions baseline scenario (T1BSR) was also used to assess DO percent saturation potential under natural conditions, which became the basis for the proposed DO SSO. The Oregon and California allocation scenarios TOD2RN and TCD2RN, respectively represent compliance with water quality criteria in Oregon and California, respectively. The Oregon and California with-dam TMDL scenario was run in order to quantify the impacts of the dams on water quality and determining appropriate allocations.

Appendix 7 details how each of these scenarios was configured, associated assumptions, and presents the results. Results of these scenarios are also summarized in Chapters 4 and 5.

CHAPTER 4. POLLUTANT SOURCE ANALYSIS

4.1 Introduction

The purpose of a TMDL pollutant source analysis is to inventory and describe all sources of pollutants that are impacting the water quality standards of the impaired waterbody. In addition, this chapter describes the processes for delivery of the pollutants and quantifies the pollutant sources within the watershed. The water quality parameters (or pollutants) considered in this Klamath River TMDL source analysis include:

- Temperature;
- Dissolved Oxygen (DO);
- Organic matter – measured as Carbonaceous Biochemical Oxygen Demand (CBOD)[1];
- Total Phosphorus (TP);
- Total Nitrogen (TN); and
- Microcystin.

This analysis draws upon several sources of information and analytic tools to evaluate the various pollutant sources contributing to impairments within the Klamath River. It also draws upon the most current quality assured data available from ongoing monitoring programs conducted by various entities throughout the Klamath Basin. Application of the Klamath River TMDL models (described in Chapter 3) serves as the primary analytic tool for analyzing the water quality impacts of pollutant source loads. In addition, the source analysis incorporates information from published reports, including the approved TMDLs for the Klamath River tributaries listed below:

- Upper Klamath Lake Drainage TMDL and Water Quality Management Plan – Upper Klamath Lakes and Agency Lakes. Oregon Department of Environmental Quality – May 2002;
- Lost River, California Total Maximum Daily Loads: Nitrogen and Biochemical Oxygen Demand to address Dissolved Oxygen and pH Impairments. United States Environmental Protection Agency Region 9. December 2008;
- Staff Report for the Action Plan for the Shasta River Watershed Temperature and Dissolved Oxygen Total Maximum Daily Loads. State of California North Coast Regional Water Quality Control Board. June 2006;
- Staff Report for the Action Plan for the Scott River Watershed Sediment and Temperature Total Maximum Daily Loads. State of California North Coast Regional Water Quality Control Board. December 2005;
- Salmon River, Siskiyou County, California: Total Maximum Daily Load for Temperature and Implementation Plan. State of California North Coast Regional Water Quality Control Board. June 2005; and

---

[1] In this TMDL CBOD refers to CBOD- ultimate. The water quality models represent CBOD as organic matter; it is converted to CBOD-ultimate for TMDL calculations.

- Trinity River Total Maximum Daily Load for Sediment. U.S. Environmental Protection Agency Region IX. December 2001.

Pollutant loads for the year 2000 (the model calibration year) are quantified from fourteen geographic areas or entities (called 'source areas') within the California portion of the Klamath River basin. Each source area has a different combination of source categories / processes at work which contribute to the load from that area. The geographic source areas can be more generally grouped as follows:

- Stateline – waters entering California from Oregon at stateline, which includes the Williamson and Sprague River watersheds, Upper Klamath Lake, the Lost River watershed that drains the Klamath Project area and includes one municipal point source in California, municipal and industrial point sources to the Klamath River in Oregon, and Klamath River waters passing through Keno and JC Boyle Reservoirs. ODEQ's Klamath River TMDL source analysis evaluates the contributions from these discrete sources on the water quality of the Klamath River in Oregon;
- PacifiCorp hydroelectric facilities in California: Copco 1 and 2 and Iron Gate Reservoirs – Copco 1 and 2 Reservoirs are treated as a single source for the purposes of this TMDL;
- Iron Gate Hatchery; and
- Tributaries – Four individual rivers (Shasta, Scott, Salmon, and Trinity Rivers) are included as discrete source areas, while groups of smaller creeks are combined into six additional source areas (stateline to Iron Gate reach tributaries, Iron Gate to Shasta, Shasta to Scott, Scott to Salmon, Salmon to Trinity, and Trinity to Turwar) for this analysis.

The Klamath River is unusual in that it has its origins in a naturally shallow, eutrophic lake, Upper Klamath Lake, which delivers warm water with high levels of nutrients and organic matter to the Klamath River. Due to an increasing stream gradient and inputs from tributaries with water that is both cooler and generally lower in nutrient concentrations, the Klamath River is generally less eutrophic as the river approaches the Pacific Ocean, creating conditions that historically made it one of the most productive cold-water fisheries on the Pacific coast. Because of this unique attribute, traditional (i.e., Tribal) sources have referred to the Klamath River as a "river of renewal." However, despite this unique attribute, current source loads have overwhelmed the historic renewal capabilities of the Klamath River, leading to its impaired status. The intent of the source analysis is to identify and quantify current pollutant source loads, in order to determine the source loads necessary to allow the river once again to be restored through its own unique renewal capabilities.

4.1.1 Pollutant Source Categories

Both point and nonpoint sources of pollution contribute to the water quality impairments in the Klamath River. Land use pollutant source categories impacting Klamath River water quality are identified in Table 4.1. Though difficult to quantify exactly, and sometimes not reflected specifically by watershed models, these land use related nonpoint source categories contribute to water quality impairments in most of the Klamath River source areas. In a basin as large as the Klamath River, where nonpoint sources dominate pollutant loading, it is difficult to precisely quantify loading within source areas from each individual source category. Precise quantification of individual source categories within source areas is not critical because the primary mitigation for nonpoint source loads is not a specific permit limit; rather mitigation is generally based on the use of best management practices that have demonstrated effectiveness to reduce pollutant loads through their application. Therefore the quantitative estimates for the source analysis rely on source area contribution estimates. The source category assessment is a qualitative analysis intended to provide general direction for the implementation strategy. The TMDL load and waste load allocations and targets (Chapter 5) are set for source areas at the levels necessary to meet water quality standards in California. The implementation plan (Chapter 6) presents the regulatory mechanisms necessary to control the major source categories within the source areas and addresses the other source contributions, including the PacifiCorp hydroelectric facilities in California, Iron Gate Hatchery, and suction dredging.

Often, loading from one source category contributes to multiple impairments, as shown in Table 4.1. For example, sediment delivered to the Klamath River from timber harvest related activities and roads can contribute to temperature impairments, but also may contain nutrients that can contribute to DO impairment through biostimulatory effects. Another example of a combined effect is the alteration of riparian functions, such as the degradation of vegetation that provides shade to a waterbody. Not only can this lead to an increase in the temperature load to the water column, it also increases light levels that can increase biostimulatory activity, and reduces the capacity of the riparian zone to filter sediment and nutrients.

Table 4.1: Klamath River anthropogenic pollutant source categories impacting water quality parameters of concern.

Land Use Source Categories Affecting	Temperature	DO	Nutrients	Organic Matter
Wetland conversion		X	X	X
Grazing	X	X	X	X
Irrigated agriculture	X	X	X	X
Timber harvest and sediment	X	X	X	X
Roads	X	X	X	

4.1.2 Natural Conditions Baseline - Background Loads

The starting point for the Klamath River pollutant source analysis involved quantifying natural conditions baseline water quality conditions of the river. The amount of temperature, nutrient, and organic matter loading from natural background sources varies dramatically from one geographic region to another. The TMDL source analysis and allocations recognize and account for the naturally higher background levels of nutrients and organic matter within the upper Klamath River basin in comparison to other ecoregions in California. This higher natural background loading translates into a smaller loading capacity of the river, and less available assimilative capacity to avoid excess heat load, oxygen-consuming substances, and biostimulatory conditions.

As outlined in Chapter 3 and detailed in Appendix 7, the Klamath River TMDL models were applied to characterize natural conditions baseline water quality of the Klamath River. In estimating the natural conditions baseline water quality of the Klamath River, the following characteristics about the Klamath River watershed were incorporated.

The underlying geology in much of the Upper Klamath basin is of volcanic origin. Soils derived from this rock type are naturally high in phosphorus (Walker 2001). Through natural erosion and leaching processes, these soils contribute a high background phosphorous load to Upper Klamath basin waters. In a nutrient loading study conducted by Rykbost and Charlton (2001), monitoring of several natural artesian springs in the upper Klamath basin was characterized by high levels of nitrogen and phosphorus, demonstrating the high natural background loading of nutrients. Upper Klamath Lake has long been noted for its eutrophic condition and demonstrated presence of high levels of organic matter (algae), including nitrogen fixing blue-green algae (Kann and Walker 2001). This nutrient and organic-matter rich Upper Klamath Lake (UKL) water is the headwaters source of the Klamath River.

As described in Section 2.3, Eilers et al. (2004) have identified a clear shift in UKL productivity and species composition in the past 100 years, consistent with large scale land disturbance activities, which can be strongly implicated as the cause of the lake's current hypereutrophic character. These changes also include increased export of nutrients and organic matter from UKL to the downstream waters of Klamath River, contributing to the pollutant loading and water quality conditions that are present today. In addition, this issue has been previously addressed in the technical report for the Upper Klamath Lake Drainage TMDL (ODEQ 2002). This report includes a basin nutrient mass balance model that represents both existing conditions and an approximation of pre-disturbance natural conditions baseline. Pre-disturbance conditions account for the full nutrient retention / loss capabilities of the former extent of wetlands in the upper basin, and landscape export of nutrients prior to increased delivery of nutrients to UKL from silvicultural and agricultural operations. The Upper Klamath Lake Drainage TMDL was based on a number of model years and scenario assumptions providing a range of TMDL compliant conditions. The Klamath River TMDL natural conditions baseline model scenario uses the median of this range of compliance conditions as the boundary condition for source loading to Link River from UKL. A more detailed description of the modeling and assumptions that went into developing these natural condition baseline boundary conditions is available in the Upper Klamath Lake Drainage TMDL (ODEQ 2002), in ODEQ's Klamath River TMDL technical report, and in Appendix 7.

Within the Klamath Mountains Province of the mid- and lower-Klamath River (Figure 1.4), the underlying geology is not volcanic, and therefore does not tend to have the high levels of nitrogen and phosphorus characteristic of the Upper Klamath basin. Consequently, the tributaries that drain to the Klamath River within this province have considerably lower nutrient concentrations. As a result, the eutrophic condition of the Klamath River generally improves as it flows from the Upper Klamath basin to the Pacific Ocean.

Alkalinity is a measure of the ability of water to neutralize acids. In the natural environment, alkalinity comes primarily from the dissolution of carbonate rocks. Carbonate rock sources are rare in much of the Klamath basin due to its volcanic origin. As a result, the Klamath River has a relatively low alkalinity (<100 mg/L). The low alkalinity provides for a weak buffering capacity of Klamath River water. Photosynthetic activity removes carbon dioxide in the water (in the form of carbonic acid) which increases the water pH (see Section 2.4.2.1 for a discussion of impacts). Natural alkalinity serves as a buffer to minimize the photosynthetically induced increase in pH. In low alkalinity waters such as the Klamath River, this buffering capacity is frequently exceeded and high pH values are observed during daytime hours when photosynthesis is occurring. The large daily variation of pH observed in the Klamath River is caused by photosynthetic activity in the low alkalinity water.

Further exacerbating the effect of the naturally productive and weakly buffered system is the presence of regionally high ambient summer air temperatures, and the resulting high heat load to the shallow and predominantly un-shaded Upper Klamath Lake. These naturally warm waters are the source of the Klamath River. In addition, the east-west aspect of much of the Klamath River also makes it prone to heating, even within the steep gorges of some reaches of the river.

In summary, the solar exposure and seasonally high ambient air temperatures, coupled with the high levels of biological productivity and respiration that are enhanced by the high levels of biostimulatory nutrients, yield large volumes of organic matter, seasonally high water temperatures, daily low dissolved oxygen, and high pH levels. All of these water quality conditions can be extremely stressful to many forms of aquatic life. These natural background heat, nutrient, and organic matter loads to the Klamath River underscore the very limited capacity of the river to assimilate anthropogenic pollutant sources, and the necessity for establishing load allocations that will result in attainment of water quality standards.

4.1.3 Pollutant Source Loads - Overview

The Klamath River TMDL models were used to calculate loads for the year 2000, and for purposes of the Klamath TMDL, year 2000 loads represent current loading conditions. The cumulative pollutant loads to the Klamath River for the year 2000 are identified in the schematic diagrams below (Figures 4.1, 4.2, and 4.3). These figures provide an illustration or graphical representation of the current cumulative loading to the Klamath

River for total phosphorus, total nitrogen, and organic matter (CBOD[2]) from the source areas included in the Klamath River TMDL analysis (including source loads from the upper basin above stateline). Cumulative loads used in this analysis include the total annual mass generated from upstream sources that pass through the assessment location (assessment locations along the Klamath River were chosen to be just upstream of major tributary input locations). The loads identified at the assessment locations do not necessarily represent the load contribution from any one source area. Rather the load identified at the assessment location is the cumulative load passing through that location and represents both sources and sinks upstream.

This space intentionally left blank

[2] CBOD is a quantitative measure of the amount of dissolved oxygen required for the biochemical oxidation of carbon-containing compounds.

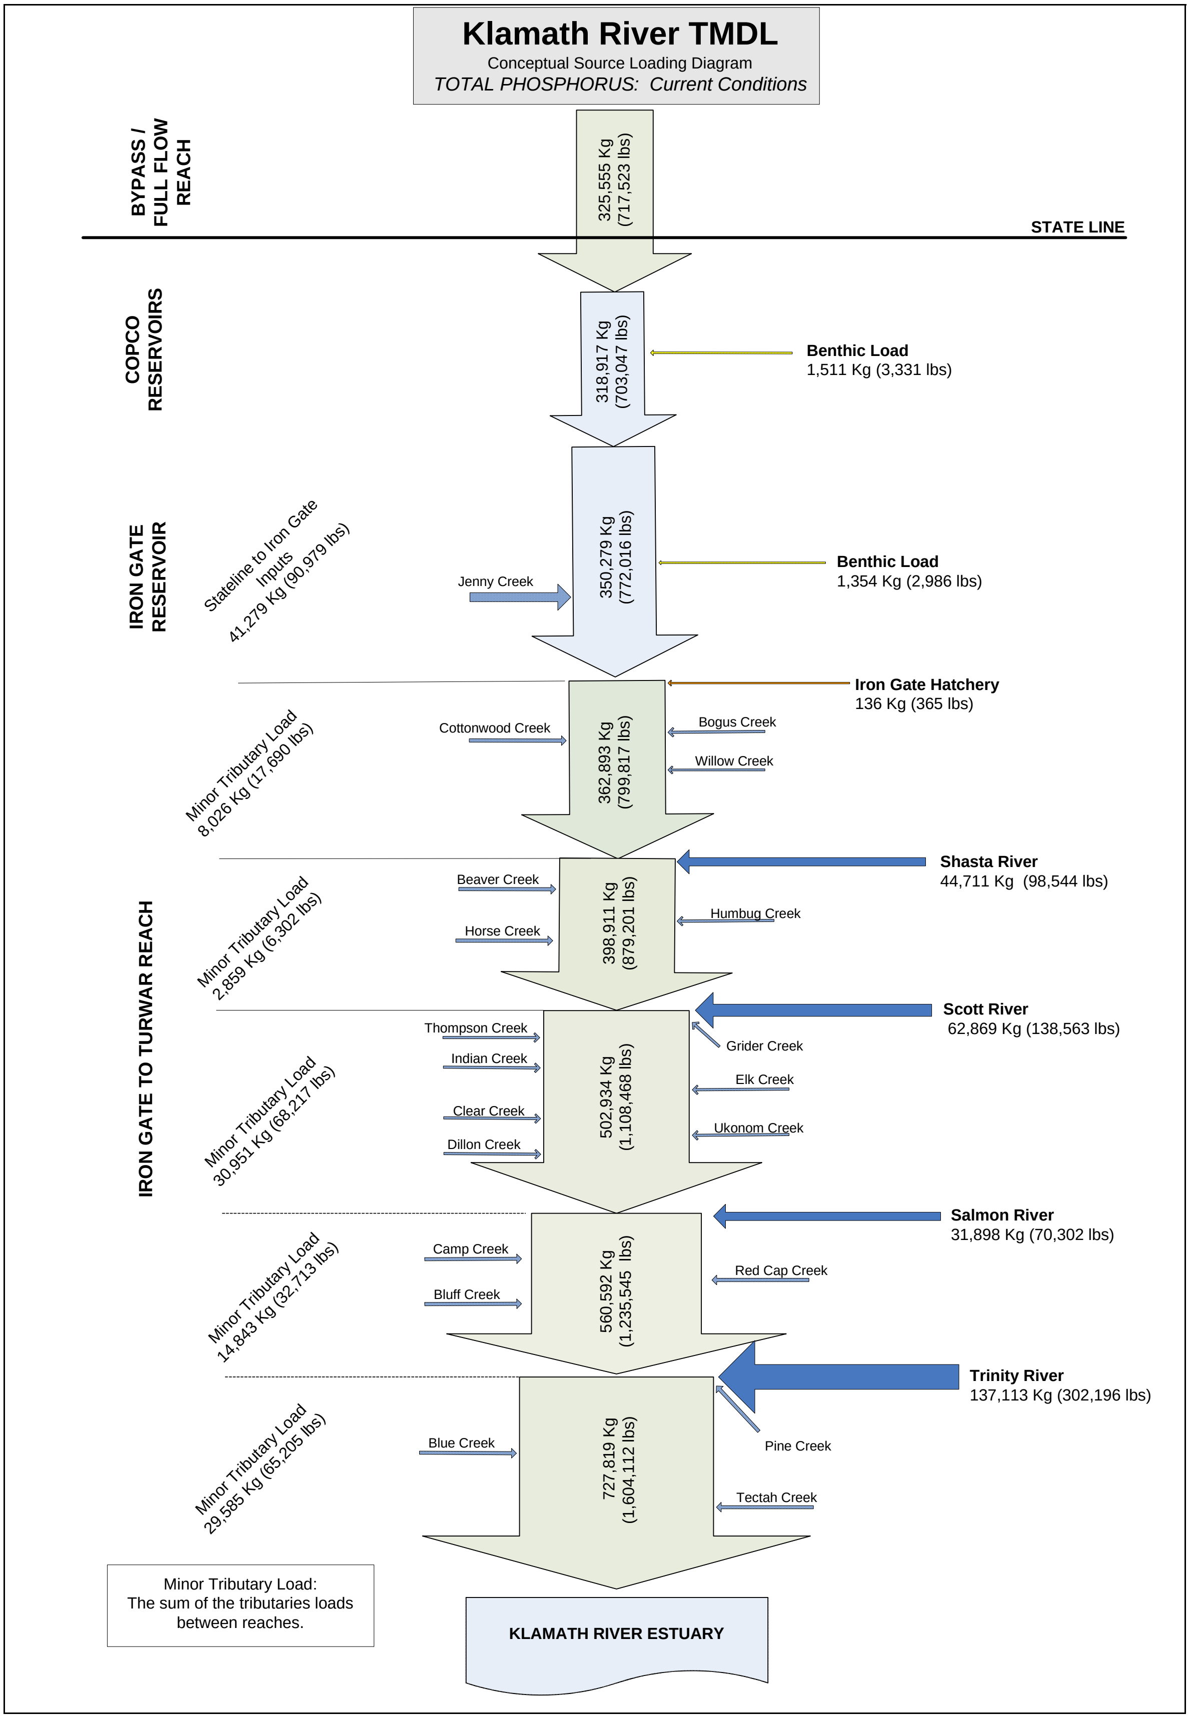

Figure 4.1: Current total phosphorus annual loading diagram

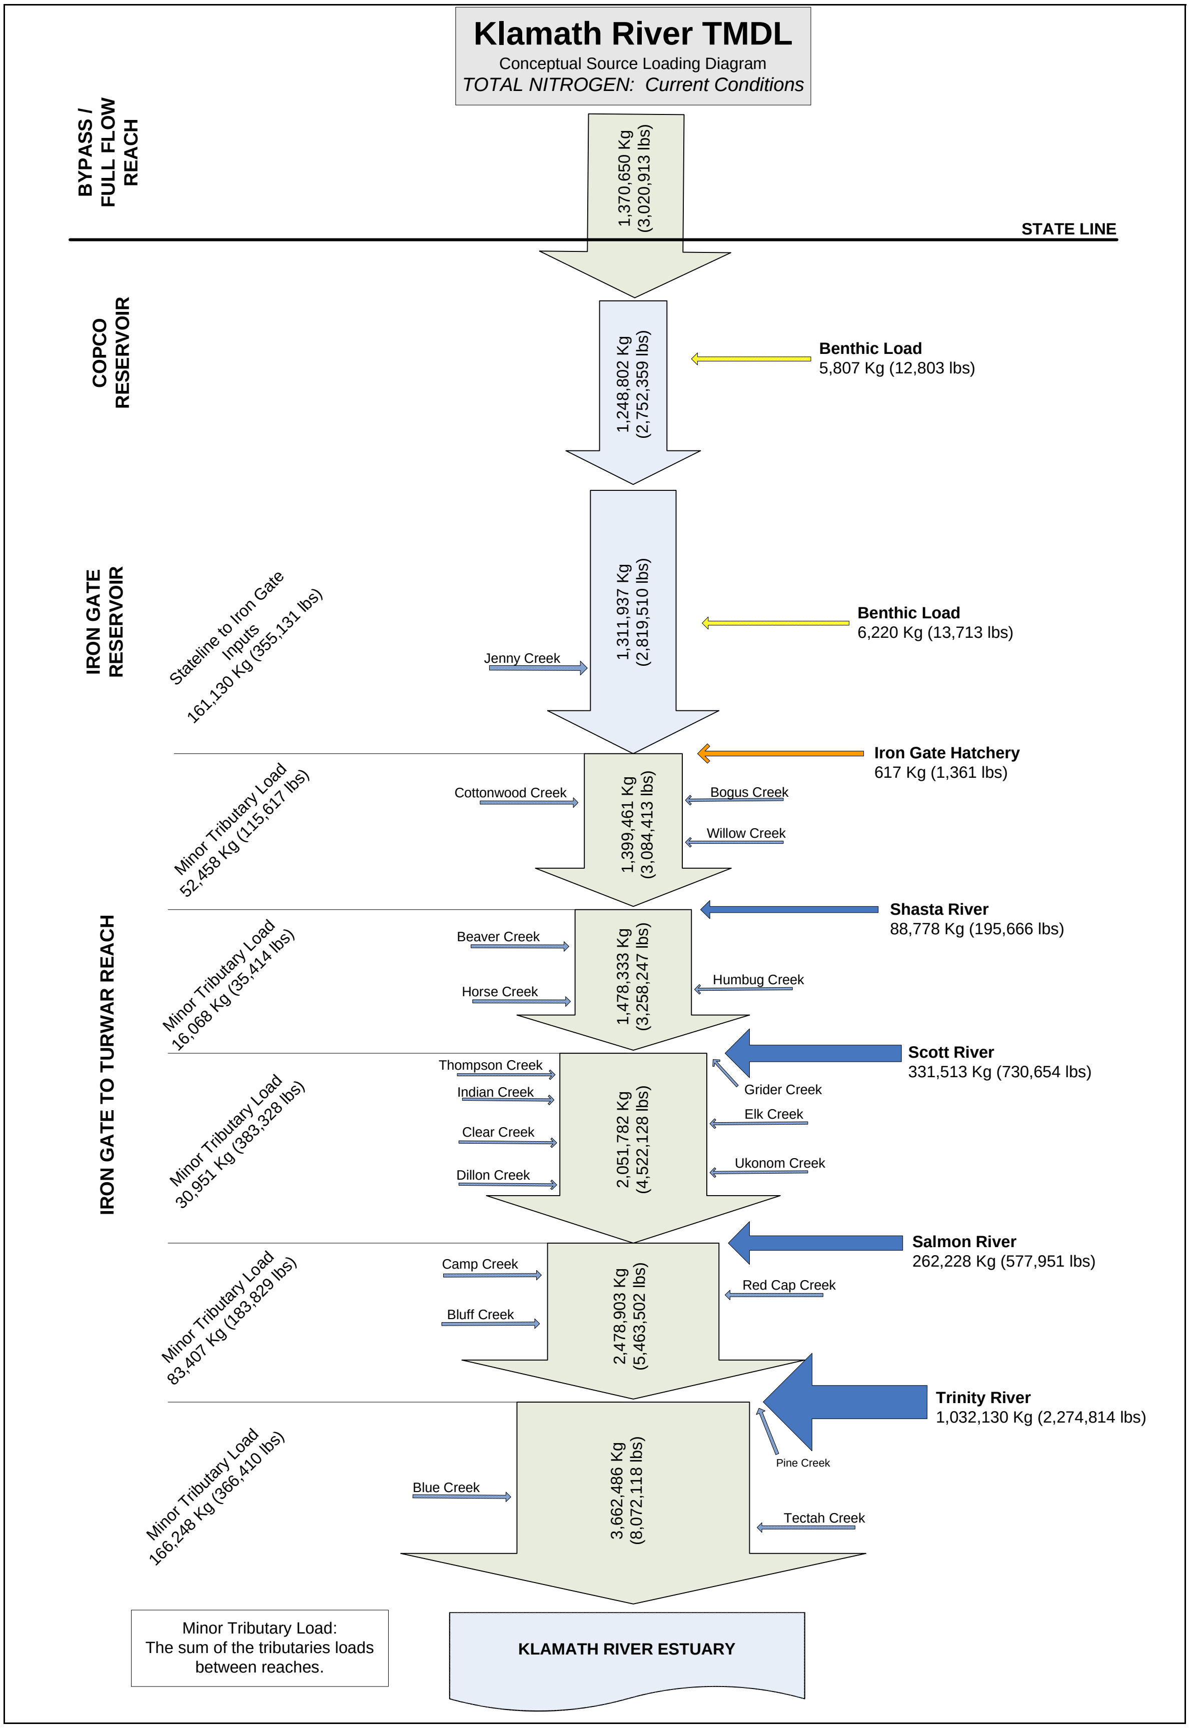

Figure 4.2: Current total nitrogen annual loading diagram

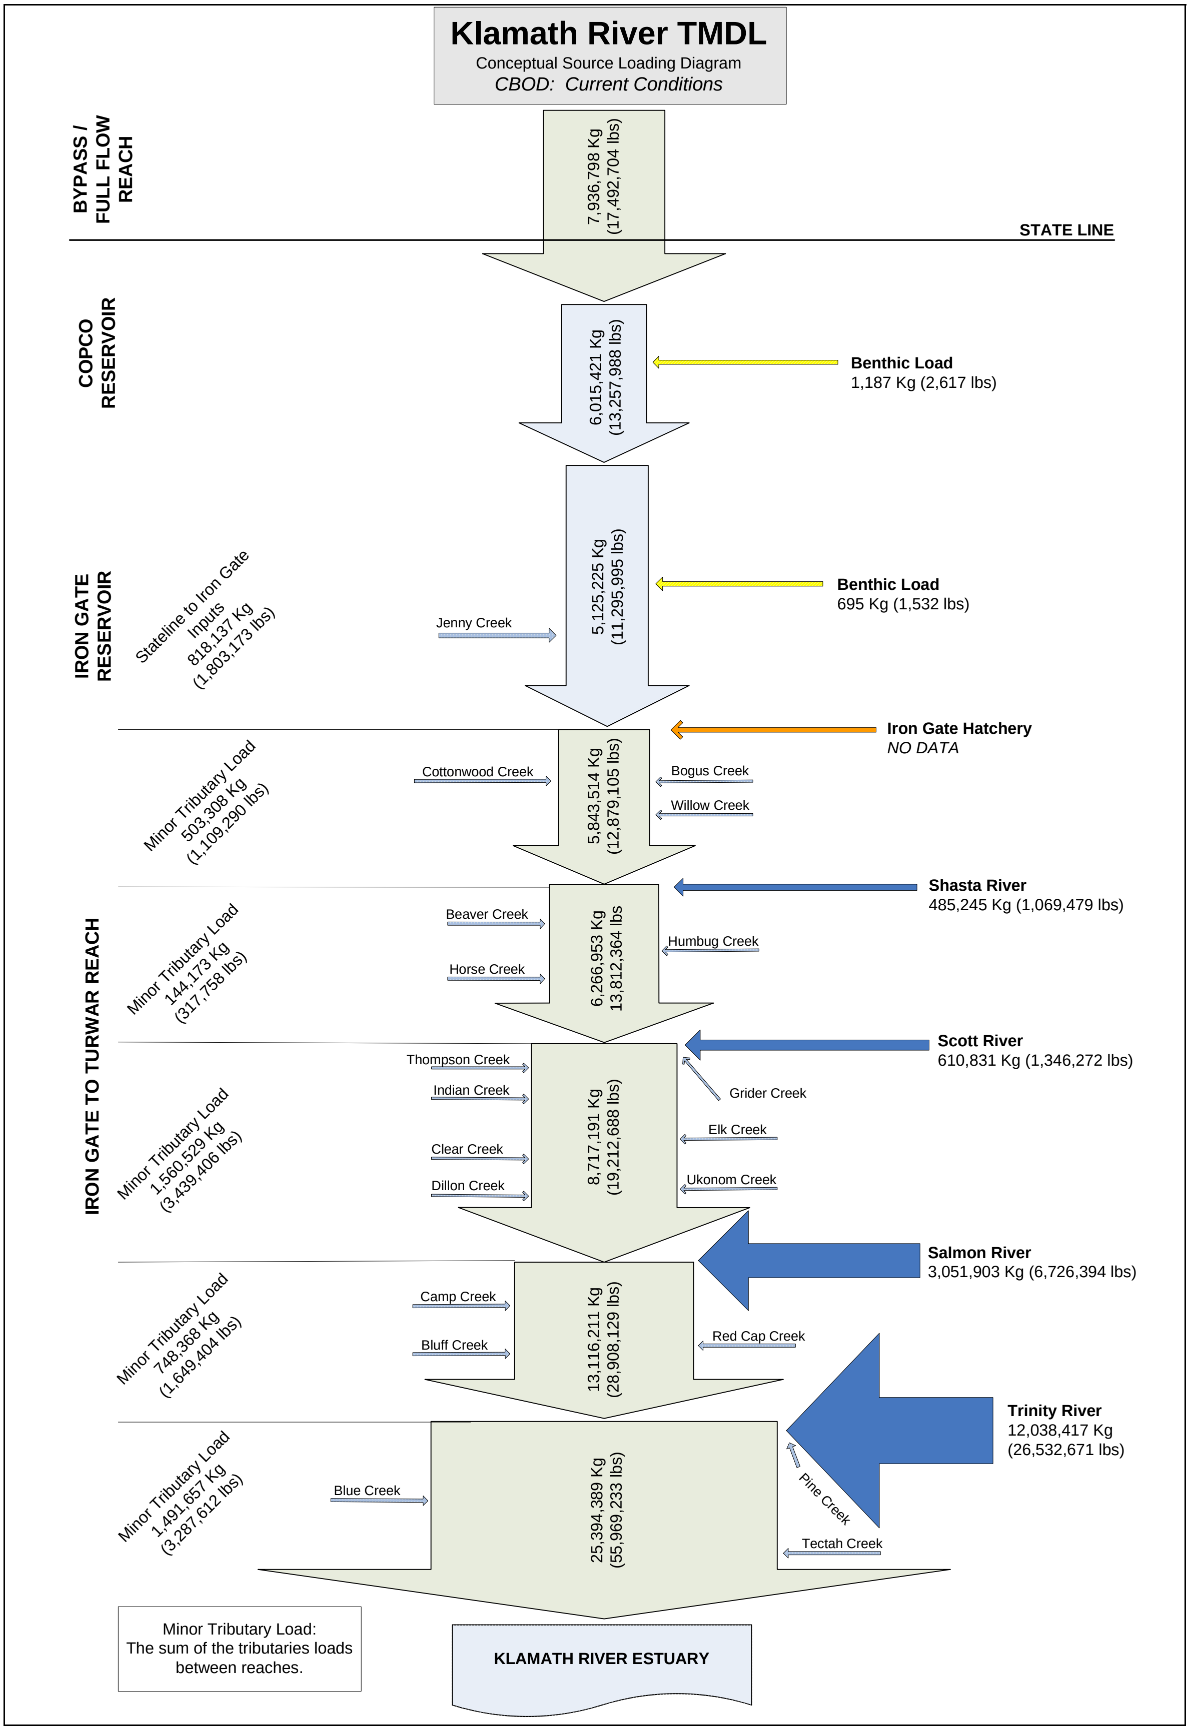

Figure 4.3: Current organic matter (as CBOD) annual loading diagram

The analysis presents load inputs from major and minor tributaries, along with loads along the Klamath River system in California on an annual basis. The loads along the Klamath River system include within-stream and within-reservoir dynamics (e.g., losses, retention, and fluxes). The width of a segment arrow is only approximately proportional to the magnitude of the load for that reach. These figures demonstrate that the Klamath River transports relatively large pollutant loads (~40% of the total load at the mouth of the river) from the upper part of the basin across stateline. The upper basin is relatively low in water yield and high in concentration compared to the relatively high water yield and low concentration contributions of the lower basin tributaries.

The source area loads are also summarized in Table 4.2. Figures 4.1, 4.2, and 4.3 and Table 4.2 provide a comprehensive overview of current loading conditions. For comparison, Table 4.2 also presents estimated annual natural conditions baseline loadings, the current and natural source loading estimates for the critical six month period (May – October) when water quality impairments are generally worst, and the percentage of annual loading associated with each parameter for each source area. The estimates of natural conditions baseline loadings are based on the natural conditions baseline model scenario. The information presented in Table 4.2 is not directly comparable to the information presented in Figures 4.1, 4.2, and 4.3. The vector diagram figures present cumulative loadings along the Klamath River system, incorporating loss and retention within the reservoirs and river reaches, whereas the table only presents the loads to the river from the source areas.

Given the different units typically used to characterize heat load, vector diagrams and a summary table are not presented to summarize the temperature loads to the Klamath River. The temperature effects from different source areas and source categories are presented in Section 4.2.

4.2 Pollutant Source Area Loads

This section discusses the pollutant loads from the key source areas.

4.2.1 Stateline – Upper Klamath Basin

4.2.1.1 Temperature

The combined water temperature effects of sources of increased thermal loads in Oregon were evaluated by comparing the results of the current condition model scenario (i.e. the calibrated model for 2000) with the natural conditions baseline scenario at stateline. The results, summarized in Figure 4.4, indicate that the overall temperature effect of all sources upstream of California leads to significant temperature increases, possibly as much as 6 ^{o}F (3.3 ^{o}C), from approximately April to December. Positive values represent an increase above the natural conditions baseline. The sources represented in the current conditions scenario include alterations due to discharge of irrigation return flows (Klamath Straits Drain, Lost River Diversion Channel) and changes in hydrodynamics resulting from reservoir operations (Keno, JC Boyle).

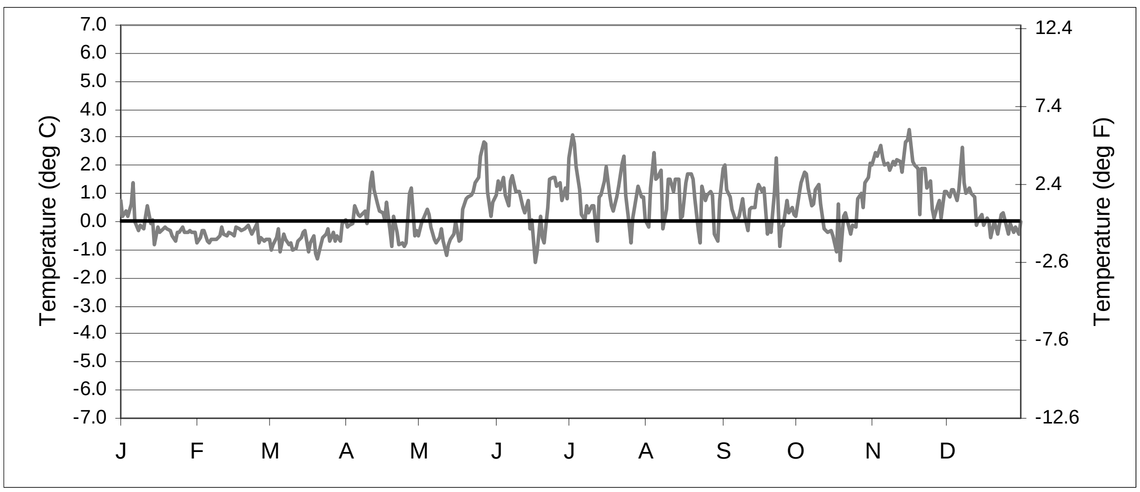

Figure 4.4: Estimated changes of daily maximum temperatures at Stateline due to anthropogenic sources upstream. Positive values represent an increase above the natural conditions baseline.

The diversion of water directly from the Klamath River and its tributaries, including Upper Klamath Lake, greatly alters the flow of the Klamath River, particularly in the spring. Reductions in flow can lead to increased diurnal temperature fluctuations, as well as increased daily average temperatures. These concepts are detailed in Section 2.4.3.3.

As described in Appendix 7, the natural conditions baseline scenario was developed using current flows from Upper Klamath Lake and the Klamath Project area, and therefore does not reflect thermal impacts caused by reduced flows. Thus, Figure 4.4 also does not reflect those thermal effects. To assess the effects of altered flows due to diversions on water temperatures, model scenarios for current flows and natural flows, with all other factors assigned as natural conditions, were compared. The natural flow estimates from the US Bureau of Reclamation's natural flow study (USBR 2005) were used to characterize natural flows. Figure 4.5 presents the difference in daily maximum temperature predicted to occur at stateline solely from differences in flow due to diversion of water (i.e. no dam effects and no irrigation return flow effects are represented in Figure 4.5). Positive values represent an increase in temperatures due to altered flow. The temperature difference between the two scenarios is generally slight, but indicates as much as 2.7 ^{o}F (1.5 ^{o}C) increase in daily maximum temperature in early spring, a 3.6 ^{o}F (2.0 ^{o}C) decrease in May, and a 1.8 ^{o}F (1.0 ^{o}C) increase in November. The results illustrate the effects of the altered annual hydrograph presented in Figure 1.11, in which the unimpaired flows are higher in the Spring and lower in the Fall. This relatively small difference in stream temperatures at stateline during the summer months is likely due to the fact that the source of the Klamath River, Upper Klamath Lake, is a relatively warm waterbody, reaching equilibrium temperatures irrespective of alteration in flow conditions during the summer season.

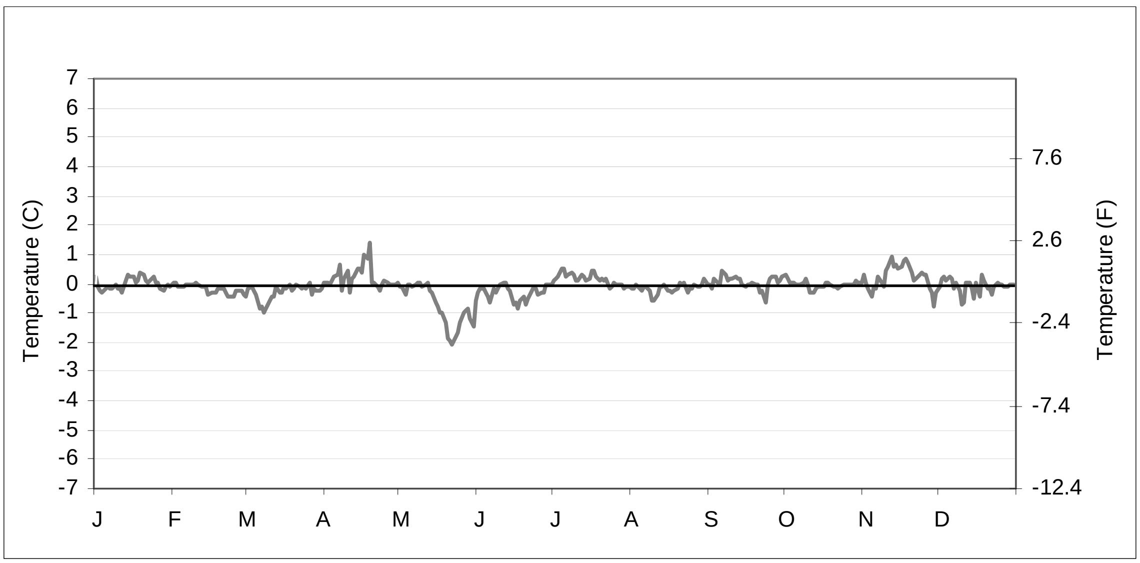

Figure 4.5: Estimated change in daily maximum temperature at Stateline resulting from altered flows, 2000 simulation year. Positive values represent an increase in temperatures due to altered flow.

4.2.1.2 Nutrients and Organic Matter

The largest single source area for nutrient and organic matter loads to the Klamath River originates in the Upper Klamath basin above stateline. Current TP and TN loads at stateline comprise approximately 44% and 37% of the TP and TN loading, respectively, to the Klamath River in California (Table 4.2). The above-Stateline fraction of the total organic matter (CBOD) loading to the California portion of the Klamath River for CBOD is somewhat less at 27%. Figure 4.6 compares the current annual TP, TN, and CBOD loads at stateline to those estimated loads under the natural conditions baseline, reflecting 727%, 248%, and 169% increases in annual loads from natural conditions baseline for TP, TN, and CBOD, respectively.

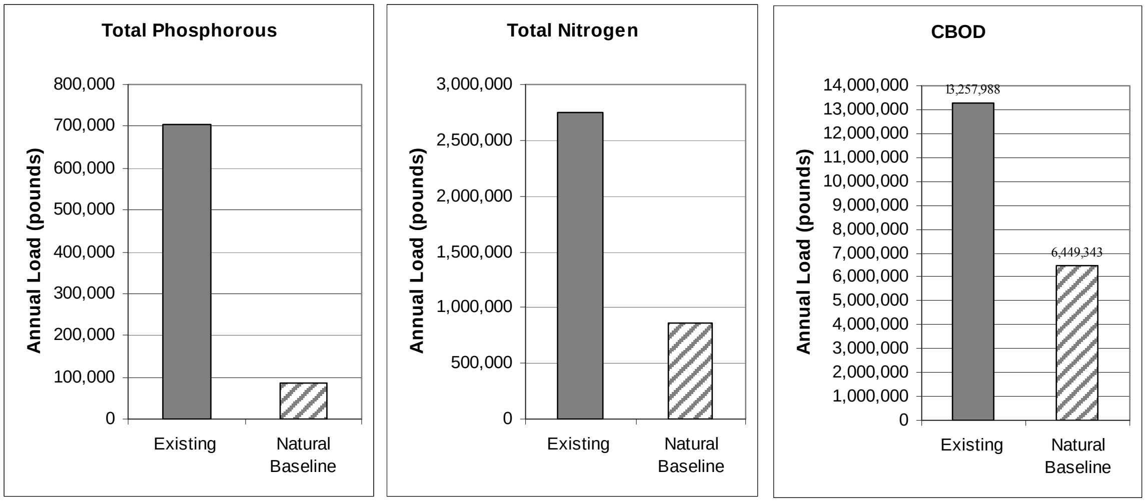

Figure 4.6: Comparison of current annual TP, TN, and CBOD loads at Stateline to natural conditions baseline loads

All of the land use source categories identified in Section 4.1.1 contribute to the increased loads at stateline. The Upper Klamath Lake Drainage TMDL (ODEQ 2002) analyzes the sources contributing loads to Upper Klamath Lake. In addition to irrigated agriculture, upland sources (e.g., gravel road surface erosion, timber harvest operations), nutrient flux from reclaimed wetlands, and internal nutrient loading from Upper Klamath Lake bottom sediments contribute to loading to Upper Klamath Lake. The movement of water from Upper Klamath Lake is regulated and at times much of the flow is diverted to support irrigated agriculture. Some portion of these flows is eventually transferred back to the Klamath River. Working in collaboration with ODEQ, Regional Water Board staff has developed the following source analysis of how the flows diverted to the Lost River basin impact water quality upon their return discharge into the Klamath River.

The Lost River Diversion Channel (LRDC) and Klamath Straits Drain (KSD) are part of United States Bureau of Reclamation’s (USBR’s) Klamath Project and discharge into the Klamath River in the impounded reach upstream of Keno Dam. These facilities, along with water withdrawal canals, hydrologically connect the Klamath River to the Lost River system (for this document the “Lost River system” refers to the hydrologically connected natural and constructed portions of the Lost River, Tule Lake, Lower Klamath Lake, Klamath Straits Drain and other associated canals and drains). ODEQ is also developing a TMDL to address water quality impairments within the Lost River system in Oregon and EPA has promulgated a TMDL for the lower Lost River drainage in California (USEPA 2008). _ODEQ’s Klamath River TMDL investigates the impact of discharge from LRDC and KSD to the Klamath River while the Lost River system TMDL investigates water quality impacts on the Lost River drainage.

USBR’s Klamath Project supplies water to approximately 240,000 acres of cropland (38% of it in California and 62% of it in Oregon) (USBR 2009). Prior to the development of the Klamath Project, there was no surface water connection between the Klamath River and the Lost River system except during extreme flows (NRC 2004).

With the advent of the Klamath Project, water is supplied from Upper Klamath Lake and Klamath River along with reservoirs and tributaries within the Lost River system. Included in the project are reclaimed lands of Tule Lake and Lower Klamath Lakes and facilities related to flood control. In terms of its relationship with the Klamath River, the Klamath Project withdrawals water from Upper Klamath Lake via A-canal and the impounded reach of the Klamath River behind Keno Dam via Ady Canal and North Canal. The LRDC can transfer water to or from the Klamath River. Pump stations at the western end of KSD transfer water to the Klamath River.

A number of studies have concluded that the USBR's Klamath Project is an annual net sink of nutrients in relation to the Klamath River (Rybost and Charlton 2001, Danosky and Kaffka 2002 and Hicks 2009). ODEQ extended the Hicks 2009 analysis to include an entire year, 2002, using DEQ data to supplement the USBR dataset. Daily flow estimates were obtained from USBR's website. When concentration data were not available for a specific canal, a nearby river concentration was used as a surrogate. For this analysis, sources of nutrients to the Klamath River are Klamath Straits Drain and Lost River Diversion Channel and extractions from the Klamath River are A-canal, Lost River Diversion Channel, North Canal and Ady Canal.

Even when examining an entire year of 2002, the Klamath Project appears to be a sink of nutrients in relation to the Klamath River (Figure 4.7). Despite the higher phosphorus concentrations returning to the Klamath River than leaving it, the loading is strongly influenced by the flow and only 30% of the flow that enters the Lost River system from the Klamath is returned to the Klamath River. In 2002, total phosphorus removed from the Klamath River was 2.8×10^5 pounds (130 metric tons) while 1.4×10^5 pounds (64 metric tons) was returned, equivalent to a 50% decrease in estimated total annual load. Total nitrogen removed from the Klamath River was 2.8×10^6 pounds (1300 metric tons) while 9.6×10^5 pounds (440 metric tons), equivalent to a 66% decrease in estimated total annual load.

Even though USBR's Klamath Project appears to be a net sink of nutrients, it also appears to have detrimental impacts to the water quality of Klamath River. Based on mean August 2002 flows, approximately 1255 cfs was diverted out of the Upper Klamath Lake and the Klamath River, leaving approximately 182 cfs in Keno Reservoir just upstream of Klamath Straits Drain (Figure 4.8). Klamath Straits Drain discharge then accounts for approximately half the flow of the Klamath River at Keno Dam. Therefore, its higher concentration of nutrients relative to the Klamath River increases the nutrient concentration which in turn contributes to water quality degradation in the Keno impoundment (Figure 4.9).

The following information is also provided regarding the potential for agricultural operations within the Lost River drainage to affect nutrient dynamics and thus impact water quality within the Klamath basin.

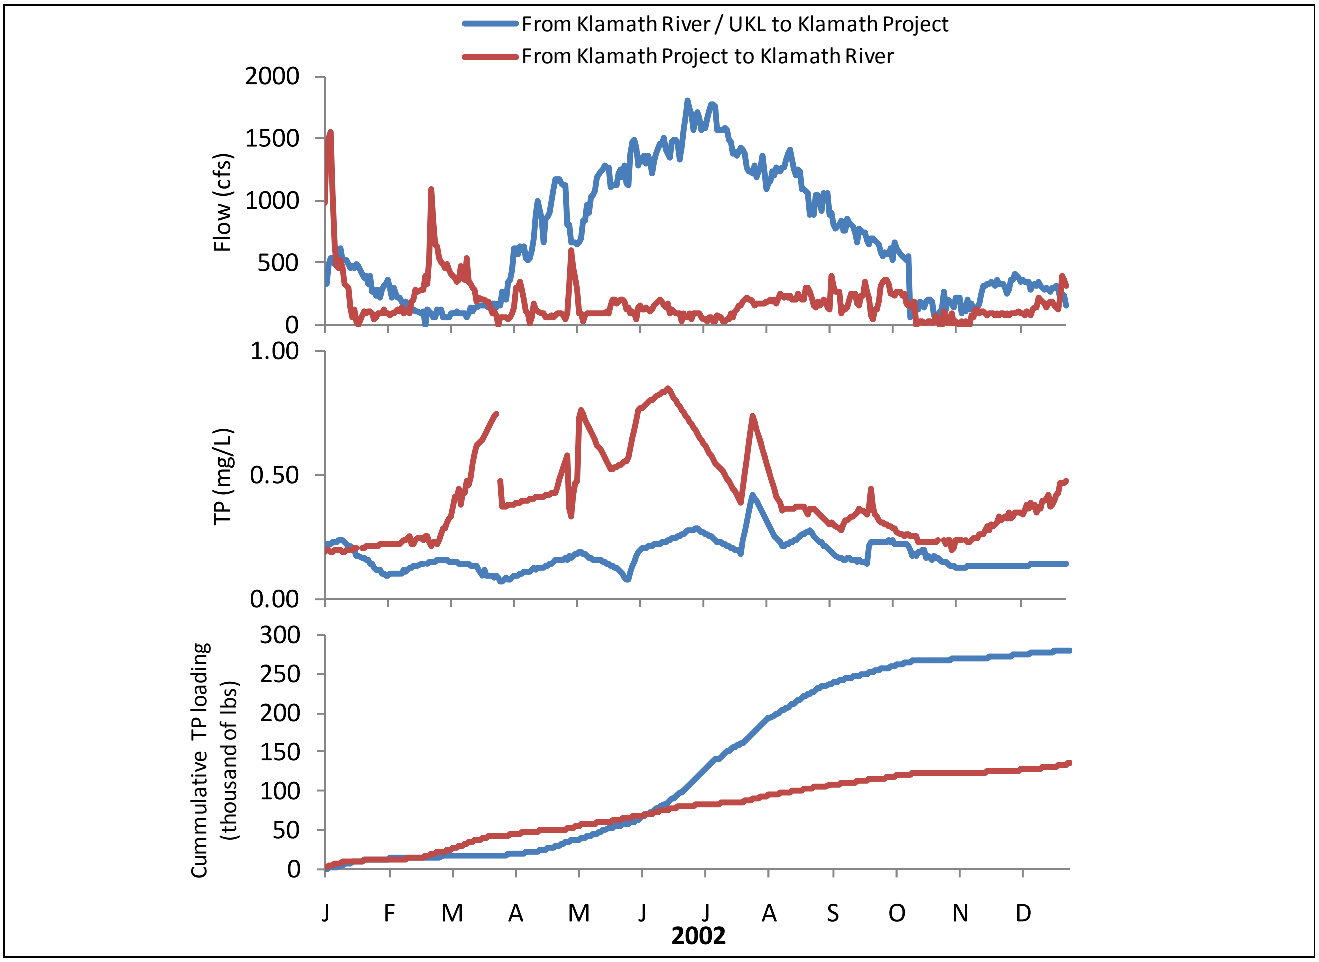

Figure 4.7: Flow, concentration and cumulative loading analysis of USBR's Klamath Project. Total phosphorus (TP) concentrations weighted based on relative flow rates.

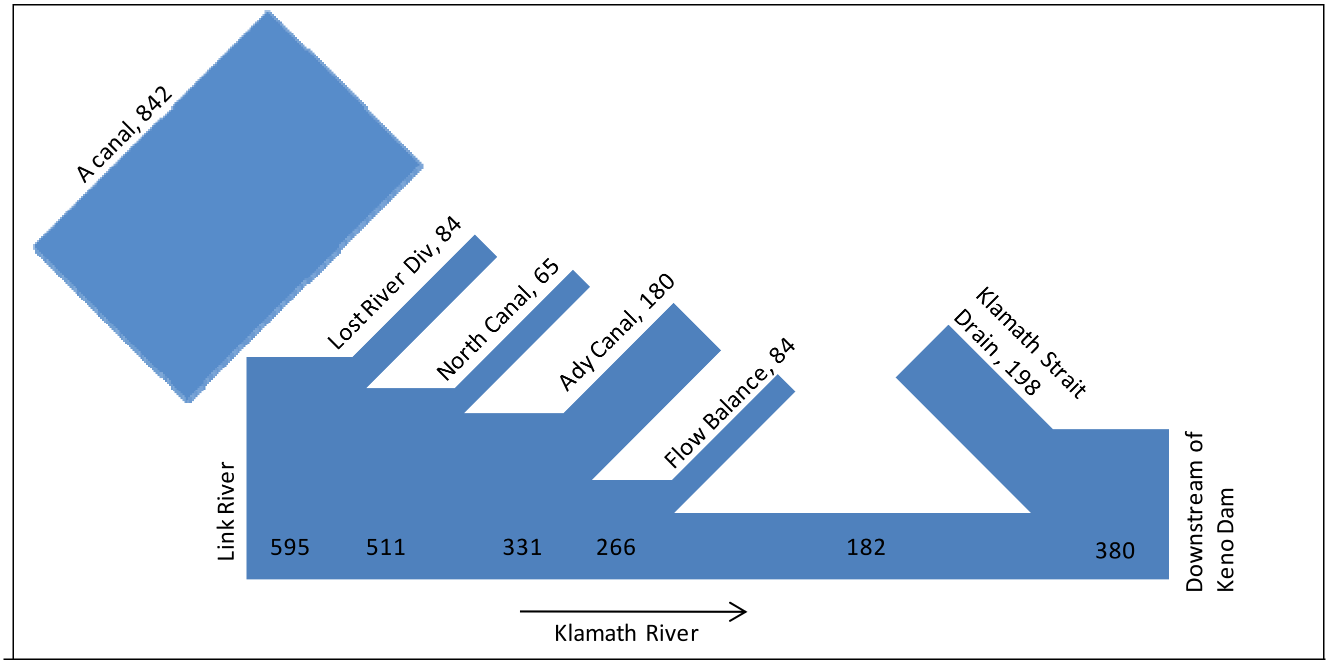

Figure 4.8: Schematic of an example flow balance in cubic feet per second for Keno Reservoir in August 2002. Flows are represented by the thickness of each box. The flow balance portion was derived by subtracting the outflow from the other measured flows.

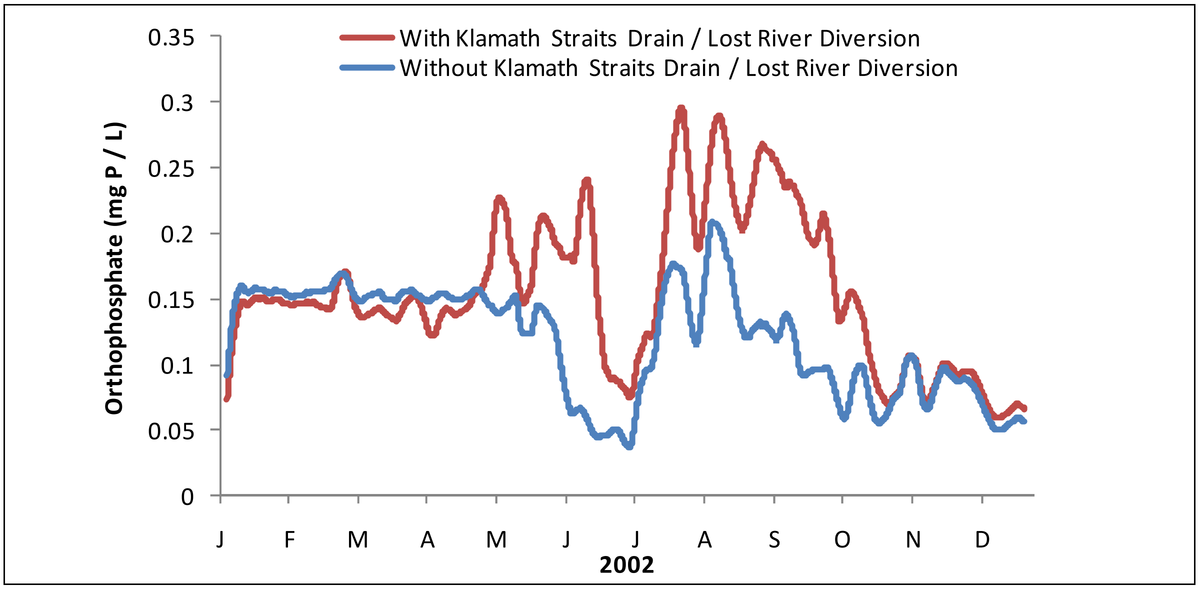

Figure 4.9: Klamath River (Keno Reservoir) model results from just downstream of Klamath Straits Drain discharge. The "With Klamath Straits Drain / Lost River Diversion" results are from the 2002 calibration model. The "Without …" results are from a scenario exactly like the 2002 calibration except the constituent concentrations of parameters for Lost River Diversion and Klamath Straits Drain were set to the same constituent concentrations as Link River.

A water quality study in the Tule Lake irrigation district by the University of California Davis concluded: "The differences in water quality between tiles and drainage ditches suggest that the ditches and water management infrastructure itself has a role in regulating nutrient transfers and can contribute nutrients (especially TP) to the system: from internal hydrologic cycles present in the ditches and canals, from agitation of sediments, from the death and decay of aquatic plants, from N fixation by blue green algae, and from N fixation of sediments due to pumping and transfer of water" (Danosky and Kaffka 2002).

These results are consistent with a water quality investigation by USGS in the Yakima basin (McCarthy and Johnson, 2009). The water quality investigation indicated that combining irrigation and artificial-drainage networks may exacerbate the ecological effects of agricultural runoff by increasing direct connectivity between fields and streams and minimizing potentially mitigating effects of longer subsurface pathways such as denitrification and dilution. Similar findings relative to Upper Klamath Lake are reported by Rykbost and Charlton (2001):

> "Nutrient loading in Klamath Lake is unquestionably enhanced by the drainage of irrigation water from agricultural properties adjacent to the lake. Prior to reclamation, all of these properties were either permanent or seasonal wetlands. Following construction of dikes and drainage systems, the properties were managed for pastures and/or crop production. Soils are high in organic matter content and native fertility; therefore pastures and hay crops on these lands are generally not fertilized. Natural processes associated with mineralization of these soils release nutrients subject to transport in drainage water."

There are also municipal and industrial point sources discharge to the Klamath River within Oregon. There are two municipal wastewater point sources that discharge to the Klamath River in Oregon: South Suburban Sanitation District and Spring Street Sanitation plant run by the City of Klamath Falls. There are two industrial wastewater point sources that discharge to the Klamath River in Oregon: Columbia Forest Products, and Collins Forest Products. There is one municipal wastewater point source that discharges to the Lost River system, the City of Tulelake wastewater treatment plant.

All of these pollutant sources and loads have been considered in the Stateline pollutant source analysis (Figure 4.6).

4.2.2 Copco 1 and 2 and Iron Gate Reservoirs

4.2.2.1 Temperature

An analysis of model results was prepared that isolates the effects of each reservoir (Copco 1 and 2 and Iron Gate), in order to evaluate the impacts of the reservoirs on Klamath River temperature. The effects of the reservoirs were isolated by calculating the change in river temperature between the upstream and downstream limits of each reservoir for both current and natural conditions baseline. The temperature impact of each reservoir was calculated by subtracting the change in temperature that would result from free-flowing conditions (i.e. in the absence of the reservoirs) in the reservoir reaches from the change in temperature that currently occurs in the reservoir reaches. The resulting calculation estimates the change in temperature due to the presence of the reservoirs, by subtracting the amount of heating expected to occur in a natural (free-flowing) state.

The results of the modeling analysis demonstrate that the presence of Copco 1 and 2 significantly influences the temperature of the Klamath River in that reach. Figure 4.10 presents the change in daily maximum temperature associated with the presence of the reservoir for the 2000 calendar year. Positive values represent an increase in temperatures due to the presence of Copco 1 and 2. These results indicate that the presence of Copco Reservoir can increase Klamath River water temperatures by as much as 6.8 ^{o}F (3.8 ^{o}C) during the late summer and fall months, and can decrease daily maximum temperatures by up to 13.3 ^{o}F (7.4 ^{o}C).

The results of the Iron Gate modeling analysis are very similar to the Copco analysis results. The results also demonstrate that the presence of Iron Gate Reservoir significantly influences the temperature of the Klamath River in that reach. Figure 4.11 presents the change in daily maximum temperature associated with the presence of the reservoir for the 2000 calendar year. Positive values represent an increase in temperatures due to the presence of Iron Gate Reservoir. These results indicate that the presence of Iron Gate Reservoir increases Klamath River daily maximum water temperatures by up to 5.8 ^{o}F (3.2 ^{o}C) during the fall months. The timing of this increase coincides with the time when Chinook salmon currently spawn in the Klamath River mainstem directly downstream of the reservoir. The results also indicate that Klamath River daily maximum water temperatures decrease by a similar magnitude (up to 6.8 ^{o}F [3.8 ^{o}C]) for short periods throughout the year, and that the presence of Iron Gate reservoir generally results in reduced daily maximum temperatures by approximately 1.8 ^oF (1.0 ^oC) from February to August.

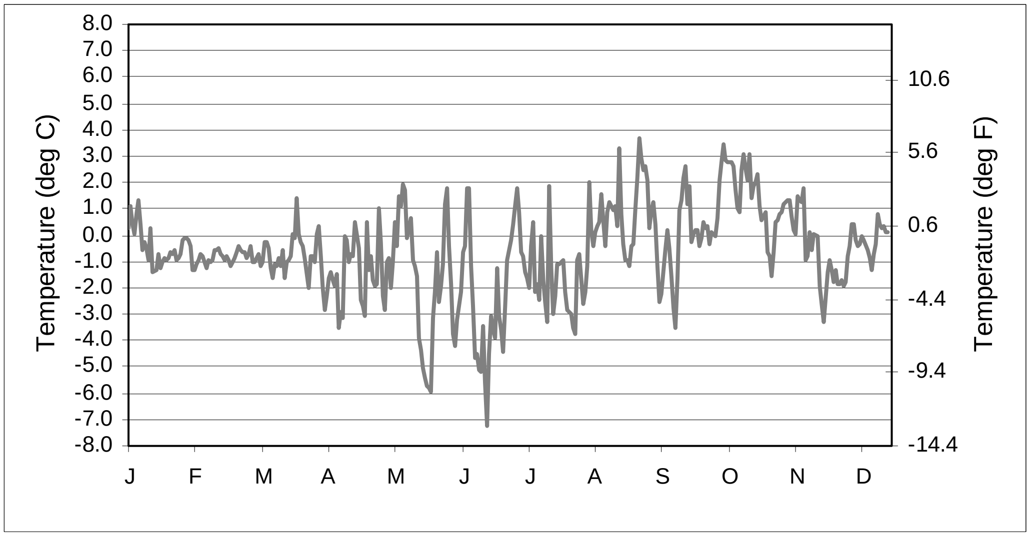

Figure 4.10: Calculated change in daily maximum Klamath River temperatures resulting from the presence of Copco Reservoir for the 2000 calendar year. Positive values represent an increase in temperatures due to the presence of Copco 1 and 2.

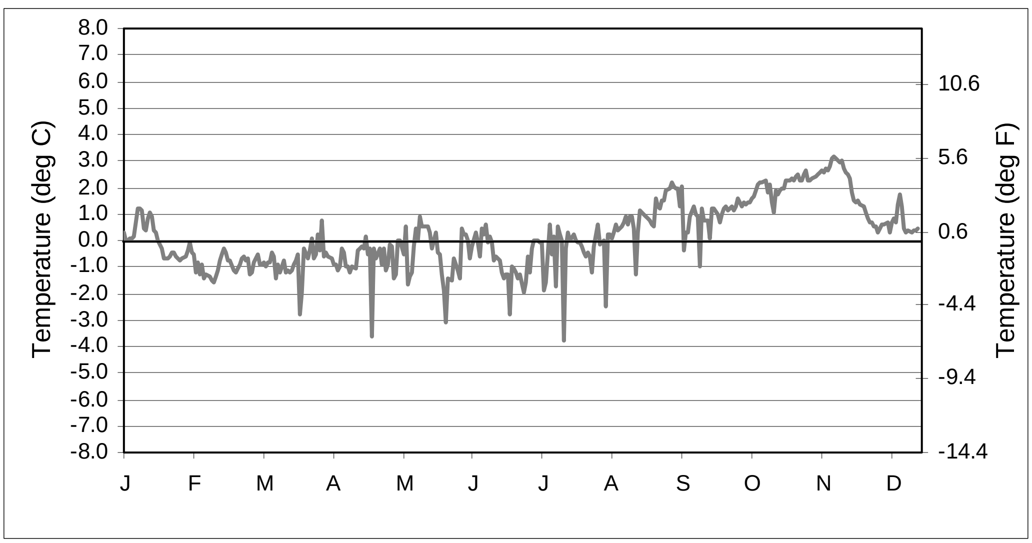

Figure 4.11: Calculated change in daily maximum Klamath River temperatures resulting from the presence of Iron Gate Reservoir for the 2000 calendar year. Positive values represent an increase in temperatures due to the presence of Iron Gate Reservoir.

The analyses of the effects of Iron Gate and Copco 1 and 2 Reservoirs indicate that each of these reservoirs can increase Klamath River water temperatures in these reaches by more than as 5.0 ^oF (2.8 ^oC). Such an increase is explicitly prohibited by the intrastate water quality objective for temperature, which limits temperature increases at any time or place to 5.0 ^oF (2.8 ^oC).

4.2.2.2 Dissolved Oxygen, Nutrients, Organic Matter, Chlorophyll-a, *Microcystis aeruginosa* and Microcystin

The purpose of this section is to describe the complex manner in which increased residence time and heat gain (found in the reservoirs) affect the dynamics of the Klamath River and ultimately impact dissolved oxygen, nutrients, organic matter, chlorophyll-a, *Microcystis aeruginosa* and microcystin. The reservoir related impacts require that reservoirs be considered as a contributing source area and assigned allocations and numeric targets as part of this TMDL.

Dissolved Oxygen

As discussed in Chapter 2 and illustrated in Figure 2.15, within Copco 1 and 2 and Iron Gate Reservoirs DO conditions exist that do not meet water quality standards. The proposed DO objective for the river reaches from Stateline to Iron Gate Dam would require 90% saturation under natural temperatures for October 1 through March 31; and 85% from April 1 through September 30. This objective corresponds to a daily minimum DO concentration ranging from 6.3 mg/L in June to 10.6 mg/L in December from Stateline to Iron Gate Dam. The DO proposed objective is based on the natural conditions baseline TMDL model scenario, which is without dams (i.e., free flowing river). A comparison can be made to Figure 2.15 (Dissolved oxygen and temperature depth profiles in Iron Gate Reservoir – average for July and August 2000 – 2005) where for the period, dissolved oxygen concentrations are well below the proposed objective in the water column, temperatures are below 18.7 ^{0} C. Iron Gate and Copco Reservoirs become stratified during the summer months with warm, DO-rich water near the surface and colder, DO-poor water near the bottom. For much of the summer season, there is no overlapping layer that has DO and temperature conditions where both are simultaneously supportive of the COLD beneficial use. For this assessment, DO concentrations less than 6 mg/L are used as a screening-level target for assessing suitability of DO for COLD. In Iron Gate Reservoir, the levels of DO are only suitable for resident rainbow trout to a depth of 4 meters, on average (rainbow trout are assumed to be the most sensitive cold water-dependent species currently present in the California reservoirs). However, surface water temperatures in Iron Gate reservoir exceed the natural summer mean (18.7 ^{o} C under free-flowing conditions) and frequently reaches levels that are stressful which results in non-supporting conditions for resident rainbow trout above a depth of approximately 10 meters. Copco Reservoir similarly stratifies, with suitable DO above approximately 7.5 meters depth and suitable temperatures below 17 meters deep. Monitoring data demonstrating these conditions, which persist throughout the stratified portions of the reservoirs for much of the summer period, have been reported on several occasions, including the PacifiCorp Water Quality Conditions reports for 2007 and 2008 (PacifiCorp 2008 – Figures 3-14 and 3-16; and PacifiCorp 2009 – Figures 23 and 24). By contrast, under free-flowing river and natural temperature conditions, there would be co-occurring temperature and DO conditions that meet these targets. (Please also see Tables 2.11 and 2.12, as well as Figures 2.25 and 2.26). For additional information regarding DO conditions with the Copco Reservoirs, including depth profile data, see PacifiCorp (2008) and PacifiCorp (2009).

The occurrence of DO conditions that do not provide supporting conditions within Copco 1 and 2 and Iron Gate Reservoirs during summer months is due to the physical characteristics of these reservoirs and the nutrient and organic matter loads entering the reservoirs, and is exacerbated by internal nutrient and organic matter loading within the reservoirs.

Changed Environment, Internal Nutrient Cycling, and Biostimulatory Conditions
Reservoirs alter the nutrient dynamics of a river system. By design, reservoirs represent areas of a river system in which velocity is decreased and residence time increased. The discussion of residence time for Copco and Iron Gate Reservoirs below comes from estimates developed by Tetra Tech (Appendix 3) as part of an evaluation of nutrient retention by Copco and Iron Gate Reservoirs:

> For the two downstream reservoirs in the Klamath system, Copco and Iron Gate, the relevant parameters are given in Table 4.3. Determination of a residence time is problematic for run-of-river reservoirs that are dominated by winter flow-through. Not only does residence time vary throughout the year, but in addition the reservoirs are not well-mixed in summer, and retention time in the hypolimnion may be much longer than in the epilimnion. For the period of May 2005 through May 2006 reported by Kann and Asarian (2007), the overall residence time in both reservoirs was on the order of 6 days, but the summer residence time of surface waters was around 20-25 days for Copco and 25-35 days for Iron Gate (but can reach as high as 50 days in Iron Gate).

Table 4.3 Hydraulic parameters for Klamath reservoirs (May 2005– May 2006)

Impoundments	**Residence Time (*T*, yrs)**	**Mead Depth (*z*, m)**
Copco	0.0384	11.7
Iron Gate	0.0484	16.6

The relatively quiescent waters in Copco and Iron Gate Reservoirs promote the settling of particulate material, including nutrient-bearing organic material and algae, and nutrients (i.e. PO_4 and NH_4) sorbed to inorganic sediment. In addition, the physical characteristics of these reservoirs cause them to stratify during summer months, resulting in the bottom layer of the reservoir (i.e. hypolimnion) becoming devoid of oxygen (i.e. anoxic). Under these conditions, organic debris (including dead algal detritus) that has settled to the bottom of the reservoir is subject to one or more of the following processes that can lead to the transfer of nutrients from the reservoir bottom sediments back into the water column; processes collectively referred to as internal nutrient loading:

- If the sediments are disturbed by wind-driven currents or by other means (organisms or degassing) interstitial nutrients can be transferred to the water column simply by agitation.
- Decrease in the redox potential (increase in the availability of electrons) in the surficial bottom sediments caused by intensive microbial respiration, as would be the case for highly organic sediment, can cause biogeochemical changes that result in accelerated release of mineralized or soluble organic phosphorus and ammonia from the sediments to the overlying water, even if the sediments are immobile.

- High pH at the sediment surface may cause release of adsorbed phosphorus from sediments, with or without agitation of sediments.
- In stratified lakes suspended algae cells may, under calm conditions, sink to deeper waters at or below the thermocline, where phosphorus is more concentrated than in the surface waters where most photosynthesis occurs, and then be re-suspended either by wind or buoyancy control mechanisms after assimilating phosphorus, thus bringing phosphorus from the sediments to the water column. This phenomenon has been documented by Moisander (2008) and illustrated in Figure 4.12.
- Reservoirs having large populations of nitrogen fixing algae and blue-green algae can significantly contribute to nitrogen concentrations in the water column for export downstream.

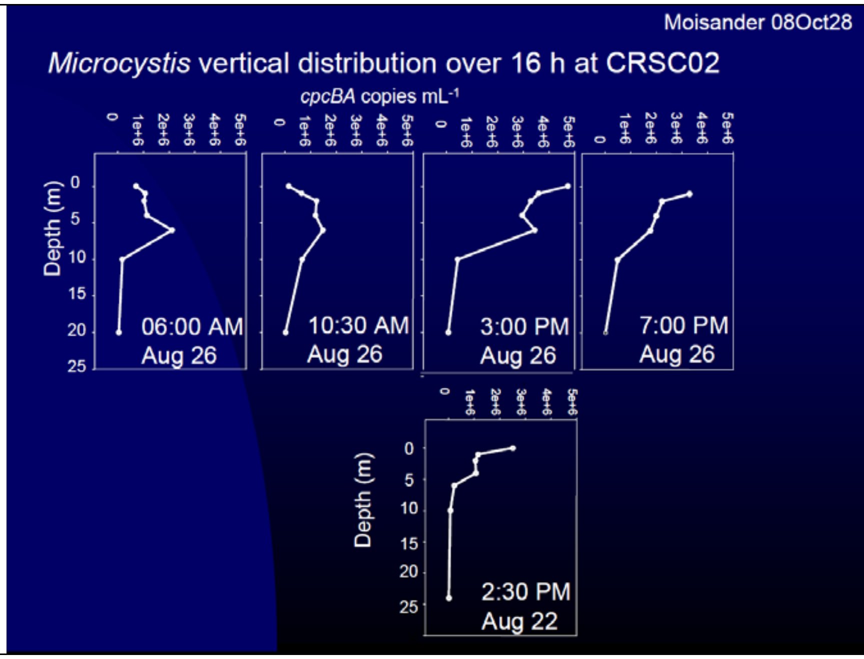

Figure 4.12: Vertical migration of *Microcystis* over a 16 hour period in Copco Reservoir on August 26, 2006.
Source: Moisander 2008

These internal nutrient loading processes can occur simultaneously within a reservoir, and serve as an input (or source) of nutrients into the water column of the reservoir. In addition, phosphate (PO_4) and ammonia (NH_4), the dissolved inorganic nutrients that were once sequestered within the sediments, become available for uptake by planktonic algae within the reservoir.

Role of Copco and Iron Gate Reservoirs in Klamath River Nutrient Dynamics

The purpose of this section is to briefly review the impact of Copco and Iron Gate Reservoirs on Klamath River nutrient dynamics through an evaluation of various estimates of their nutrient retention / export characteristics. Nutrient loads delivered downstream of the reservoirs are influenced by retention and export from the reservoirs. Retention and export can vary annually and seasonally causing the reservoirs to alternate between being either sources or sinks. A recently completed 30-month study of reservoir nutrient budget dynamics (Asarian et al. 2009) provides a strong empirical foundation for this assessment.

For the purposes of this report the term retention is meant as *net* retention, which is the difference between influent (mainstem plus tributaries) and effluent loads. The net retention includes permanent losses (denitrification to atmosphere and deep burial), temporary storage and exchanges (within reservoir water column and active sediment), and gains from the atmosphere due to nitrogen fixation. This definition of net retention is slightly different from that used by Asarian et al. (2009) because that report excluded (subtracted) changes in reservoir storage in calculating retention. However, only the net effect of these processes can be resolved and validated from observed water column concentration data. Ultimately, it is the net retention – the difference in loads and the resulting differences in concentration – that controls eutrophication response in the reservoirs and export of nutrients downstream. Table 4.4 presents the current annual and critical summer growth period (May – October) TP and TN loadings at stateline, Copco 2 outlet, and Iron Gate outlet based on the calibrated TMDL model results for 2000 (note: increasing loads through the reservoirs for TP are due to tributary inputs, not in-reservoir sources).

Table 4.4 TMDL model estimates of current total phosphorus and total nitrogen loads at Stateline, Copco outlet, and Iron Gate outlet

Current Conditions	**Annual Source Loads (lbs.)**		**Critical Period Source Loads (lbs.) May - October**	
Source Area	**TP**	**TN**	**TP**	**TN**
Klamath River - Stateline	717,523	3,020,913	316,898	1,348,967
Copco Reservoirs – tailrace	703,047	2,752,359	315,260	1,109,887
Iron Gate Reservoir – tailrace	772,016	2,891,510	341,109	1,003,978

Table 4.5 presents a summary of analyses regarding nutrient retention and export for Copco and Iron Gate reservoirs. The analyses include model estimates as well as empirical data analysis. As an example, the TMDL model estimates in the first row of each section (TP or TN) of Table 4.5 shows the percentage of reservoir inflow load (mainstem Klamath River plus tributaries) retained in Copco 1, Iron Gate, and the two reservoirs combined. A positive percentage change represents net retention and a negative percentage change represents net export. Within the critical summer growth period (May – October), the TMDL model estimates a combined reservoir retention of TP of 7.6% annually and 6.0% during the period May to October. For nitrogen the annual retention is 14.9% and 30% during the summer growing period (May to October). The TMDL model estimates are consistent with the estimates developed by Asarian et al. (2009) through statistical analysis of empirical monitoring data for the period of May to September. Asarian et al.(2009) have estimated the combined effect of the reservoirs to be 15% retention of TN and 10% retention for TP on an annual basis and seasonally TP 8% and TN 31%. The other estimates included in Table 4.5 were taken from an analysis of nutrient dynamics in the Klamath River performed by Tetra Tech (Appendix 3) and included as Appendix 3 to this report. Some of these estimates have somewhat greater variance, but overall, the analyses demonstrate that the reservoirs retain total nutrients on

an annual basis, with the exception that some of the analyses indicate that the reservoirs have the potential to export a small amount of TP.

Table 4.5: Estimated nutrient retention and export for Copco and Iron Gate Reservoirs

	Time Period Assessed	Method	Copco	Iron Gate	Combined
Total Phosphorous	2000 - annual	TMDL Models	5.1%	3.3%	7.6%
	2000 - May to October	TMDL Models	4.7%	2.0%	6.0%
	2005 - 2006	Asarian et al.2009 empirical model applied by TetraTech (Appendix 3)	16.4%	17.3%	
	2005 - 2006	Nürnberg (1984) empirical model applied by TetraTech (Appendix 3)	4.6%	3.8%	
	2005 - 2006	Range of 5 literature-based empirical models applied by Kann and Asarian (2007)	1.4% - 29%	-1.9% - 29%	
	2005 - 2007 - entire study period	Asarian et al. 2009			10.0%
	2005 - 2007 - May to September	Asarian et al. 2009			8.0%

Table 4.5 (cont.): Estimated nutrient retention and export for Copco and Iron Gate Reservoirs

	Time Period Assessed	Method	Copco	Iron Gate	Combined
Total Nitrogen	2000 - annual	TMDL Models	10.0%	6.7%	14.9%
	2000 - May to October*	TMDL Models	18.6%	16.0%	30.1%
	2002 – March to November	PacifiCorp (2006) , based on Kann and Asarian (2005)			21%
	2005 - 2006	Bachman (1980), empirical model applied by TetraTech (2008)	13.8%	14.5%	
	2005 - 2006	Range of 2 literature-based empirical models applied by Kann and Asarian (2007)	8.7% - 10.3%	9.4% - 10.0%	
	2005 - 2007 - entire study period	Asarian et al. 2009			15.0%
	2005 - 2007 - May to September	Asarian et al. 2009			31.0%

Notes: ▪ TMDL model estimates include river reach from stateline through reservoir tailraces. ▪ Asarian et al. (2009) values based on flow-weighted concentrations in Tables 8 & 9 of that document▪ Positive number is net retention; negative number is net export

Net retention is an important factor in assessing the affect of the reservoirs on nutrient dynamics, but there are several other factors that must also be considered to determine the comprehensive effect on water quality. Several of these factors were discussed previously (Section 2.4.2.1) when considering the impoundments as a risk cofactor for nutrient and organic matter related impacts on beneficial uses. A summary of these factors includes:

- The effect of retaining the nutrients within the reservoirs with respect to contributions to the nuisance algal conditions in the reservoirs.
- The net retention of nutrients within the reservoirs can be substantial -rich conditions downstream of Iron Gate Dam.
- It is clear that the reservoirs spread out event-driven spikes of nutrient loads. However, this is not necessarily a good thing in regard to algal response in the lower river. Without the impoundments, some of the nutrient load would move in event-driven pulses, and a good portion of such loads would flush through the system without elevating concentrations for long enough or at an appropriate time of year to promote elevated periphyton growth.
- For phosphorus, it is inappropriate to assess retention only at an annual time step, as the majority of the retention occurs in Winter-Spring, when more of the phosphorus is in particulate form and water quality conditions (i.e., flow, light, temperature) are not subject to biostimulatory conditions.

The reservoir source analysis provides several key findings for the development of the Klamath River TMDLs:

- Conditions within the reservoirs cause depletion of dissolved oxygen below levels needed for support of the fishery and will require dissolved oxygen allocations to address this deficit and to ensure support of beneficial uses.
- The slow-moving waters of the reservoirs lead to enhanced algal growth. Biostimulatory conditions within the reservoirs are a result of excessive nutrient loads from upstream and the environment created by the presence of the dams. Chlorophyll-a and blue-green algal related targets are achieved above the reservoirs but not within the reservoirs, thus the slower and warmer waters in the reservoir reaches are the cause of these impairments. These conditions are demonstrated previously in Section 2.4 of this document.
- The nutrient retention and export lines of evidence in Table 4.5 suggest that the reservoirs provide some retention of nutrients. The retention during the May to September period is larger for total nitrogen (30.1%) than for total phosphorous (8%). The percent retention for the reservoirs does not account for the retention that would occur under free-flowing conditions. While the reservoir retention rates are higher if the loss of the retention under free-flowing conditions is accounted for, the net retention would be somewhat less than the rate reported above. However, total phosphorous concentrations at Iron Gate can be higher than total phosphorous concentrations above the reservoirs in September (i.e., 2005 and 2007, see Figure 14 in Asarian et al. 2009) when benthic algae standing crop is still very high and can still be increasing (data are limited regarding exact time of fall sloughing).
- Given the recent developments regarding dam removal (see Klamath Hydroelectric Settlement Agreement) it is unclear whether it will be necessary for the Regional Water Board to balance any potential benefits of the nutrient retention provided by the reservoirs versus the negative water quality impacts created by the reservoirs. It is necessary in the development of allocations for these facilities to provide a mechanism to track the progress of upstream nutrient reductions to achieve TMDL targets with the status of dam removal, and track

downstream impacts of nutrient reductions (to address in-reservoir impacts) should the dams remain in-place.

The primary impact of the reservoirs as a source area (aside from temperature impacts already described) is their role in creating biostimulatory conditions leading to high levels of chlorophyll-a and blue-green algae (including microcystin), and the oxygen deficits found in the hypolimnion during the summer months.

4.2.3 Iron Gate Hatchery

The California Department of Fish and Game (CDFG) operates Iron Gate Hatchery, a salmonid fish hatchery and rearing facility immediately downstream from Iron Gate Dam. This facility is operated in accordance with an NPDES permit. Iron Gate Dam was constructed without volitional fish passage capabilities. Thus, the hatchery was constructed concurrently with Iron Gate Dam in 1962 to mitigate for migrating salmonid stocks that would no longer have access to spawning and rearing habitat upstream from Iron Gate Dam. Since the hatchery is part of the mitigation required of PacifiCorp due to the blockage by the dam of salmonid habitat upstream of the dam, PacifiCorp is a co-permittee with CDFG for the facility.

Water for hatchery operations is supplied from Iron Gate Reservoir. There are two intakes from the reservoir which deliver water to the fish hatchery: one at a depth of approximately 18 feet and the other at a depth of approximately 74 feet below normal pool elevation (actual depths vary depending on the water level in the reservoir). During the cooler months, water is withdrawn from 18 feet; as water temperatures in the reservoir warm, the intake point is moved to the lower depth (74 feet). In the existing NPDES permit, average flows through the hatchery system are estimated to be 16.1 million gallons per day (mgd) (24.9 cubic feet per second [cfs]), while maximum flows are 31.9 mgd (49.4 cfs). Upon renewal, the Hatchery NPDES permit will be updated to reflect an average discharge of 12 mgd, equal to 18.6 cfs. The hatchery consists of an aeration tower, adult holding ponds, a fish ladder, an adult trap, spawning facilities, a production pond system (where juvenile fish are reared), and two settling ponds. During daily operations, flows ranging from 7.75 to 15.5 mgd (12.0 to 24.0 cfs) pass through the production and settling ponds and discharge directly into the Klamath River. These flows carry waste generated during the feeding and care of the fish including suspended solids, settleable solids, and chemicals used in disease control. When the fish production ponds are cleaned, flows ranging from 1.9 mgd to 5.5 mgd (2.9 cfs to 8.5 cfs), comprised of metabolic wastes, unconsumed food, algae, silt, and detritus, are released to settling ponds, and then into the Klamath River.

Due to the relatively small discharge flows from Iron Gate Hatchery, and the minimal water quality data characterizing the quality of the discharge, the Klamath River TMDL model does not represent hatchery inputs. Therefore, the analysis of loads from the hatchery is based solely on empirical data.

4.2.3.1 <u>Temperature</u>

Iron Gate Hatchery effluent temperatures were not measured prior to 2008. Effluent temperatures are currently measured as quarterly grab samples. Thus, adequate temperature data are not available to evaluate the effects of the hatchery effluent on the Klamath River. Regardless, because the discharge of elevated temperature waste is not allowed per the interstate water quality objective for temperature, any effluent discharged to the river at a higher temperature than the river exceeds the interstate objective.

4.2.3.2 Nutrients and Organic Matter

Regional Water Board staff conducted a study from September to November 2004 to evaluate the hatchery discharge. Water to support hatchery operations is taken from the Iron Gate Reservoir from the deeper water layer. This water is aerated during transport to the hatchery. As reflected in the existing NPDES permit, flow through the hatchery remains relatively constant at 16.1 million gallons per day. This figure will be updated to reflect an average discharge of 12 mgd in the revised NPDES permit. The hatchery discharges water at two locations: (1) the rearing pens and (2) the settling ponds. Nutrient concentrations measured from these two discharges were statistically compared.

The *Mann-Whitney U Test* was used to assess whether there is a significant difference between the distributions of concentrations for the two hatchery discharges. The test found there was no significant difference between the distributions of discharge concentration for both total phosphorus concentrations ($p = 0.689$) and total nitrogen concentration ($p = 0.479$). Based on these results, the two discharges were combined and treated as a single discharge for the hatchery nutrient loading estimates.

There are two potential sources of loading associated with the hatchery operations. Nutrient loads may be added to the downstream Klamath River due to within-hatchery processes such as stock feeding. Nutrient loads may also be added to the downstream Klamath River due to the withdrawal of water from the deeper, nutrient-enriched water layer in Iron Gate Reservoir for hatchery operations.

To estimate the total nutrient loading for the hatchery, concentrations measured upstream of Iron Gate Reservoir were used as background to compare to the combined discharge concentrations for the rearing and settling pond discharges. Daily loads were determined for each date of the 2004 study. These daily loads were extrapolated to the next date that samples were collected. The total load for the study period (69 days) was determined and normalized to a daily load. Annual loads for total phosphorus and total nitrogen were calculated from these daily load estimates.

The median annual load to the Klamath River due to hatchery operations through the raceways and settling ponds was estimated to be 2109 lbs of total nitrogen and 567 lbs of total phosphorous. These results suggest that the hatchery is a relatively minor source of nutrients to the Klamath River. Organic matter loading of hatchery operations was not estimated since measurements of CBOD were not collected during the 2004 study.

4.2.4 Tributaries

4.2.4.1 Temperature

Regional Water Board staff evaluated whether the major Klamath River tributaries (Shasta, Scott, Salmon, and Trinity Rivers) are contributing to the temperature impairment of the Klamath River by analyzing the influence those tributaries have on the temperature of the Klamath River itself, as well as the potential for those tributaries to provide thermal refugia for salmonids and other cold water species. The approach to analyzing these issues required the estimation of natural tributary flows and temperatures.

Two Klamath River model scenarios were developed to evaluate the effects of the major Klamath River tributaries on the temperatures of the Klamath River, the natural conditions baseline scenario and the California allocation scenario, as described in Appendix 7. Additional analyses were conducted to further understand how water management in the Shasta and Scott basins affects Klamath River temperature conditions, also described in Appendix 7. No additional analysis was conducted to evaluate effects of the Salmon River on the Klamath River, because the Salmon River TMDL found that current temperatures at the mouth of the Salmon River are consistent with the natural conditions baseline.

The natural conditions baseline scenario represents estimated natural flows and temperatures in the Shasta, Scott, and Trinity Rivers, as well as estimated natural temperatures in the Klamath River upstream of the major tributaries. A range of natural Scott River flow estimates was evaluated. The development of these scenarios is described in Appendix 7.

The California allocation scenario represents temperature conditions expected from full compliance with: 1) the Scott and Shasta TMDLs, 2) the Trinity Record of Decision (ROD), and 3) attainment of water quality standards in the Klamath River upstream (i.e. at stateline, Iron Gate, and Copco). The Shasta, Scott, and Trinity River temperature estimates used in this analysis are meant to depict the temperatures resulting from compliance with the Scott and Shasta TMDLs, and Trinity River Record of Decision.

<u>Shasta River</u>

Under the California allocation scenario the Shasta River would have a negligible temperature effect on the Klamath River. Figure 4.13 presents the difference in maximum daily Klamath River temperatures downstream and upstream of the Shasta River for both the current condition and California allocation scenarios. Figure 4.13 shows that the Shasta River could have a slight warming effect on the Klamath River in the fall months under California compliant conditions, but there is only a small temperature difference (generally less than 0.5 ^{o}C (0.9 ^{o}F)) between the two simulation results otherwise.

Figure 4.14 presents the difference in maximum daily Klamath River temperatures downstream and upstream of the Shasta River for both current and natural conditions. The results of the natural conditions baseline scenario modeling analysis indicate that given natural temperature and flow conditions in the Klamath and Shasta Rivers, the Shasta River could cool the daily maximum temperature of the Klamath River by as much as 1.5 ^{o}C (2.7 ^{o}F) during the summer season, with typical reductions of 0.5 – 1.0 ^{o}C (0.9 – 1.8 ^{o}F) occurring from June through September. The Shasta River would be expected to reduce Klamath River temperatures 0.5 ^{o}C (0.9 ^{o}F) or less from October through mid-November, as it currently does. The magnitude of change in Klamath River temperatures downstream of the Shasta River is reflective of the great difference in Shasta River flows and temperatures between current and natural conditions. For instance, irrigation diversions reduce Shasta River flows by approximately 80% at the mouth during late summer (Deas et al. 2004; Deas and Null 2007).

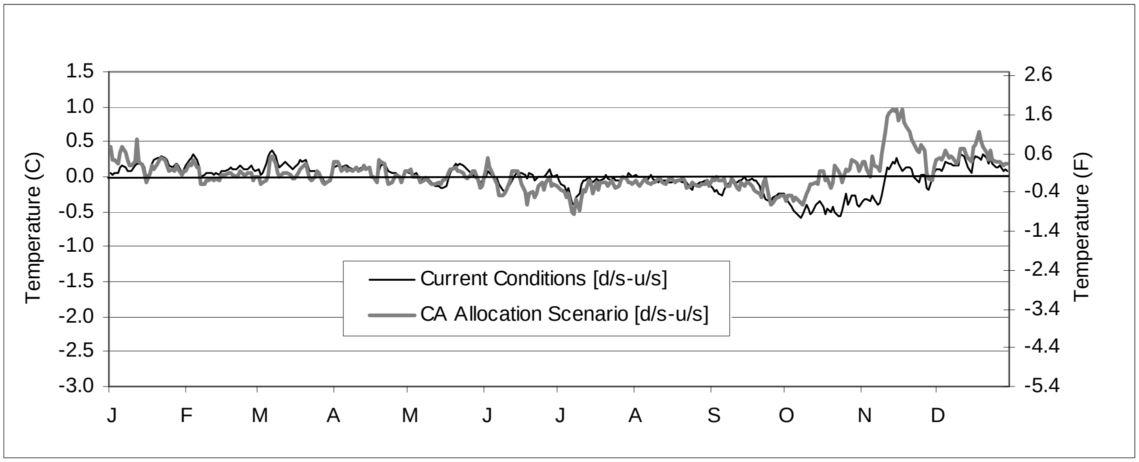

Figure 4.13: Change in Klamath River daily maximum temperatures resulting from current and Shasta TMDL compliant Shasta River conditions. Negative values indicate that the Shasta River is cooling the Klamath River.

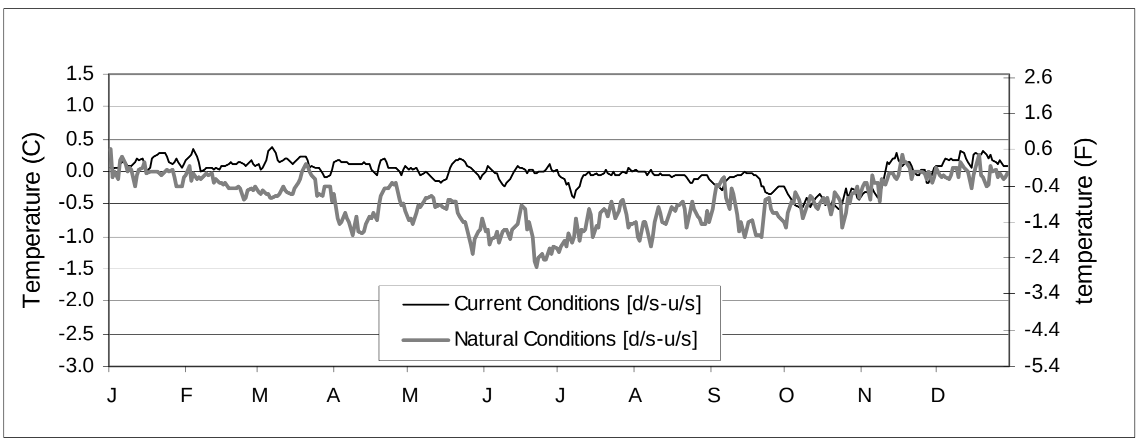

Figure 4.14: Change in Klamath River daily maximum temperatures resulting from current and estimated natural Shasta River conditions. Negative values indicate that the Shasta River is cooling the Klamath River.

Temperatures are too high to support adult salmonids when the 7-day average of the daily maximum temperatures exceeds 20 ^{o}C (68 ^{o}F), and too high to support juvenile salmonids when the 7-day average of the daily maximum temperatures exceeds 18 ^{o}C (64.4 ^{o}F) (see section 2.5.2). Currently, Klamath River temperatures regularly exceed 20 ^{o}C (68 ^{o}F) from July to September (see Figure 2.12, Dunsmoor and Huntington 2006). Shasta River temperatures are also currently too warm in the summer months to provide a thermal refuge for Klamath River salmonids. The California allocation scenario assumes a 1.6 ^{o}C (2.9 ^{o}F) daily average temperature reduction relative to current conditions at the mouth of the Shasta River, based on the Shasta TMDL temperature analysis (Regional Water

Board 2006). The 1.6 °C (2.9 °F) Shasta River temperature reduction depicted in the California allocation scenario improves conditions, but daily average temperatures are 20 °C (68 °F) or greater from mid-June to early September, as seen in Figure 4.15. These temperatures are unsuitable for juvenile salmonids. The Shasta River temperature conditions depicted in the natural conditions baseline scenario, however, only exceed 20 °C (68 °F) for a few days during the year. Daily average temperatures greater than 20 °C (68 °F) are significant because temperatures above 20 °C (68 °F) do not adequately support adult Chinook migration and holding (see section 2.5.2 and Appendix 4, Section 1.3.2). Thus, the results of this analysis indicate that the Shasta River would provide a thermal refuge for Klamath River salmonids under natural conditions, but would only provide adult salmonids a thermal refuge for a short time in the spring and fall under Shasta TMDL compliant conditions.

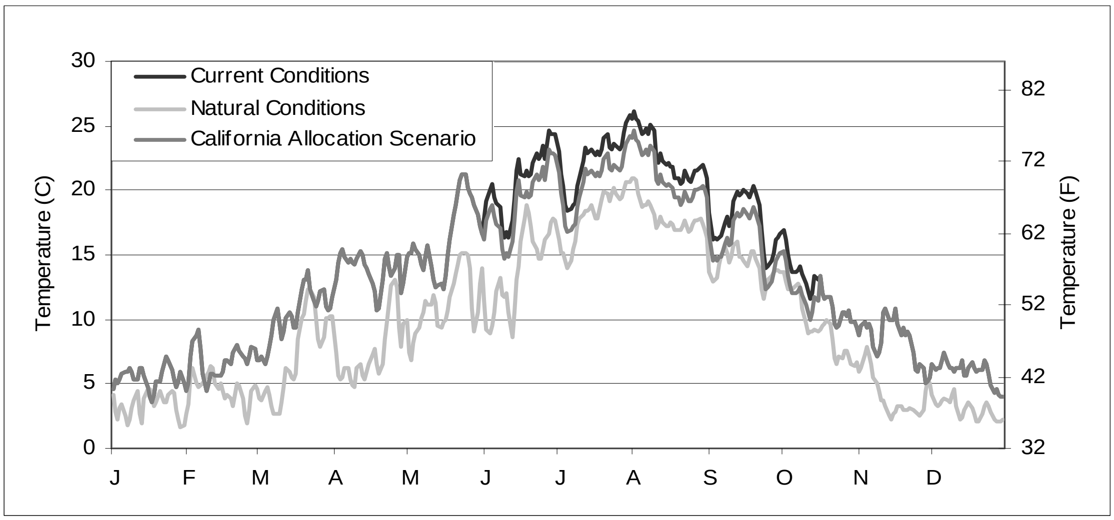

Figure 4.15: Estimated daily average Shasta River temperatures at the mouth of the Shasta River for the three management scenarios evaluated.

<u>Scott River</u>

The Scott River Temperature TMDL does not include a flow recommendation. The Scott River TMDL Action Plan requested Siskiyou County to conduct a groundwater study to further evaluate groundwater-surface water interactions in the Scott Valley. This work is in progress. The Klamath River TMDL California allocation scenario represents flows and temperatures consistent with the Scott River TMDL, and includes current flows. The results of the California allocation scenario compared to current conditions are similar with respect to Klamath River temperatures downstream of the Scott River (Figure 4.16). An exception occurs during the height of the spring snow melt, in late May, when the Scott River cools the Klamath River an additional 1.0 °C (1.8 °F) in the California allocation scenario. Another exception occurs in the fall when the Scott River currently reduces the Klamath River temperature slightly, whereas it increases the Klamath River temperature slightly in the California allocation scenario. The difference is a result of the fact that in the California allocation scenario the Klamath River is much cooler during those months, compared to the current conditions scenario. The Scott River has nearly the same effect on the Klamath River in the two scenarios during the remainder of the year.

The results of the natural conditions baseline scenario indicate the Scott River could potentially have a more significant temperature influence on the Klamath River under natural conditions, reducing temperatures by 2.0 ^{o}C (3.6 ^{o}F) in June, which amounts to as much as an additional 1.0 ^{o}C (1.8 ^{o}F) reduction below the current conditions scenario. The additional Klamath River temperature reduction gradually decreases to 0 by September (Figure 4.17).

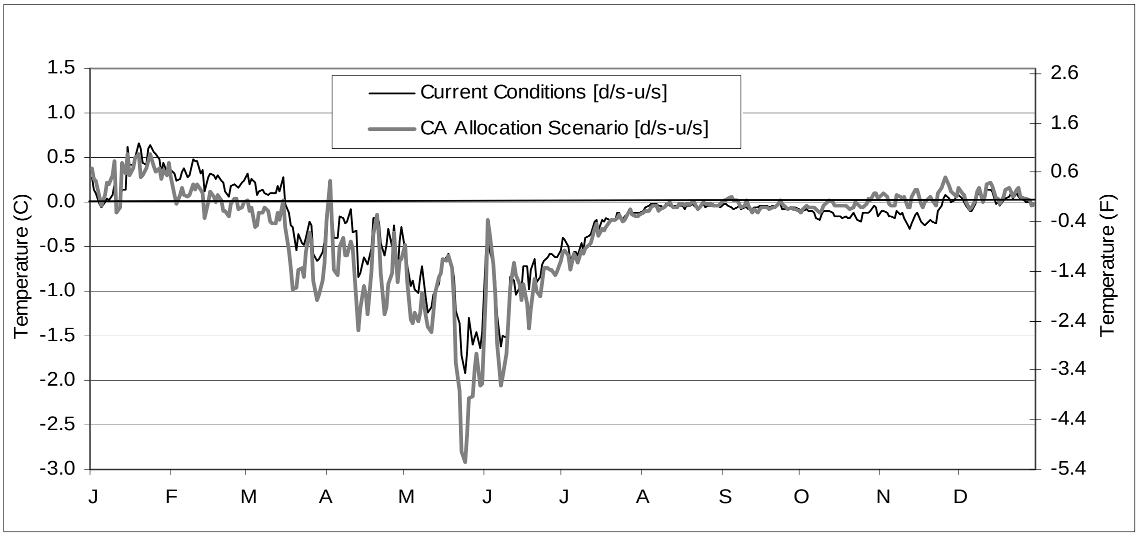

Figure 4.16: Change in Klamath River daily maximum temperatures resulting from current and Scott TMDL compliant Scott River conditions. Negative values indicate that the Scott River is cooling the Klamath River.

This space intentionally left blank

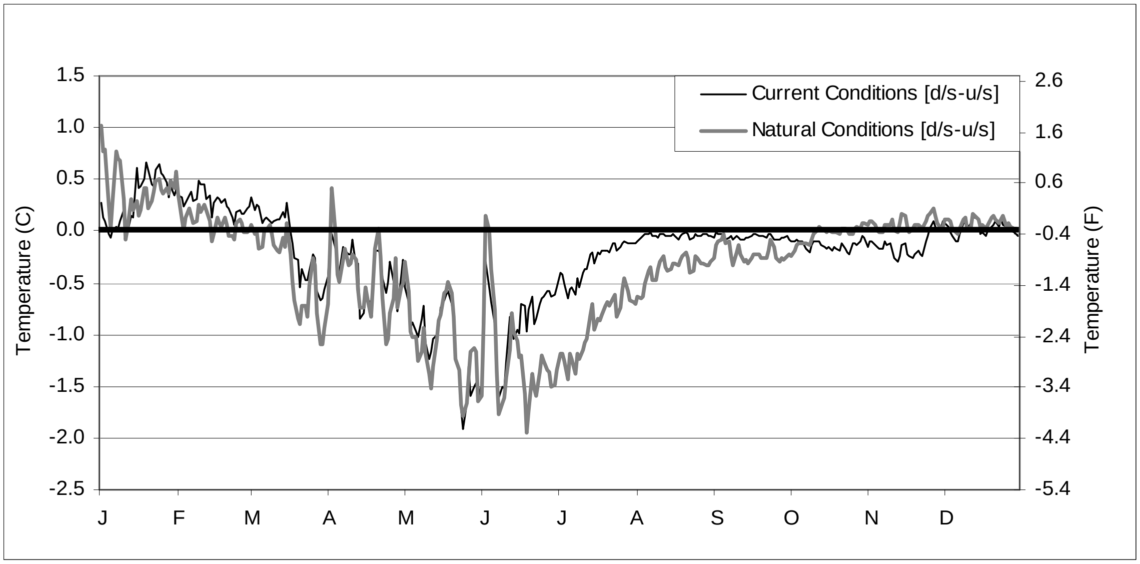

Figure 4.17: Change in Klamath River daily maximum temperatures resulting from current and estimated natural Scott River conditions. Negative values indicate that the Scott River is cooling the Klamath River.

Current Scott River temperatures from June to October are too hot to offer salmonids a thermal refuge from the high temperatures of the Klamath River. The results of the natural conditions baselines scenario indicate the Scott River would provide a thermal refuge during early and late summer under those conditions (Figure 4.18). Such conditions would provide migrating adult salmonids a thermal refuge during their upstream migration prior to spawning, but would not support juvenile rearing throughout the summer.

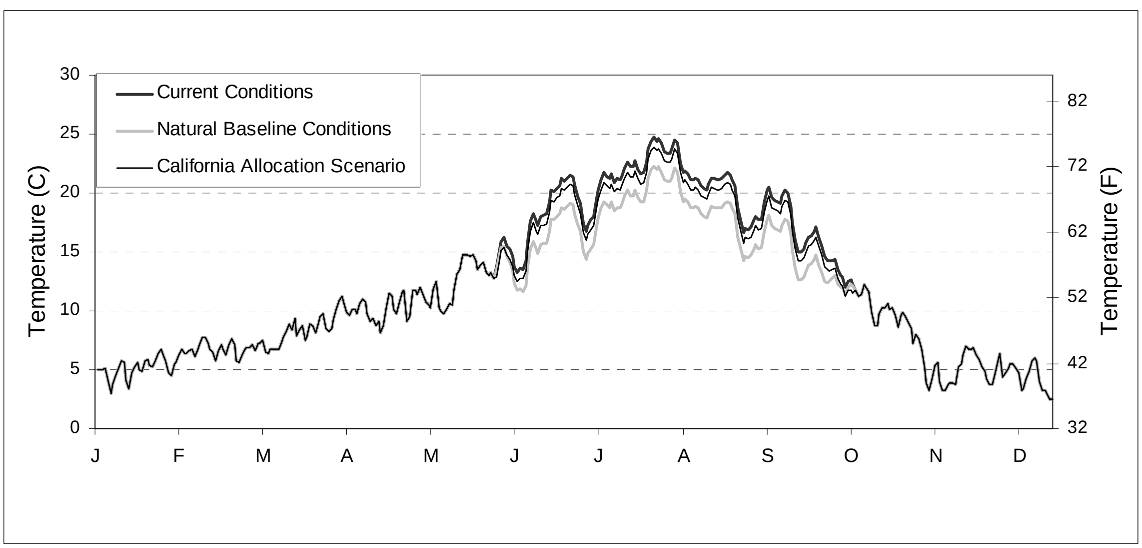

Figure 4.18: Estimated daily average Scott River temperatures at the mouth of the Scott River for three scenarios.

Trinity River
The California allocation scenario modeling analysis indicates that natural Trinity River flows, as well as those prescribed by the ROD, have a moderate cooling effect on the Klamath River downstream of the Trinity River. Figure 4.19 presents the difference in daily maximum Klamath River temperatures downstream and upstream of the Trinity River for both current and Trinity ROD flow (i.e., California allocation scenario) conditions. Similarly, Figure 4.20 presents the difference in daily maximum Klamath River temperatures downstream and upstream of the Trinity River for both the year 2000 (current condition scenario) and natural conditions. .

It is important to note that the upstream temperatures in the natural conditions baseline and California allocation scenarios reflect the absence of upstream reservoirs, as well as the effects of the estimated natural Shasta and Scott River inputs. These results are most apparent when comparing the difference between the estimated natural and Trinity ROD flow (i.e. California allocation) conditions. As discussed in Section 3.3.3.2, the estimated natural Trinity River flows and the Trinity ROD flows are equal during the summer months. However, under the California allocation scenario, the Trinity ROD flow has a bigger effect downstream from June to October because the Klamath River temperatures upstream are warmer in comparison to the natural conditions scenario.

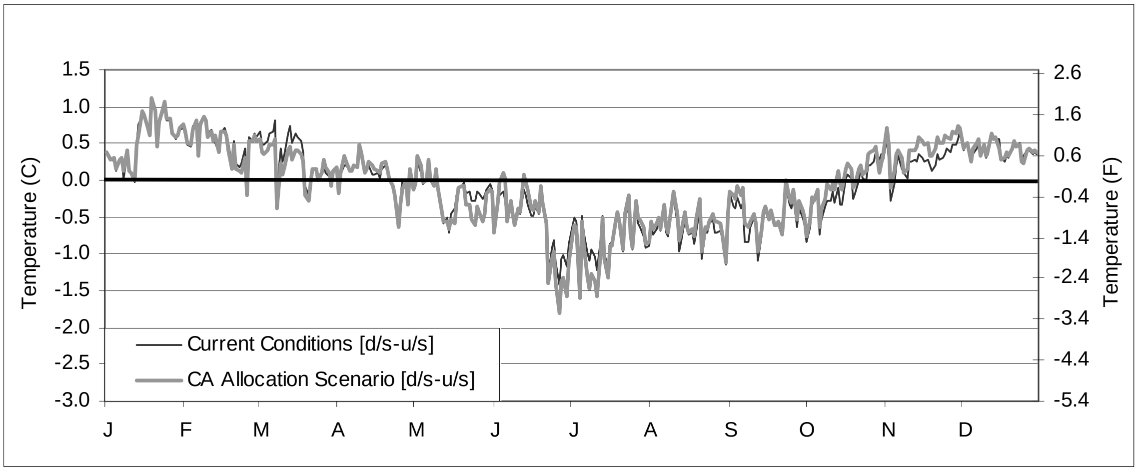

Figure 4.19: Change in Klamath River daily maximum temperatures resulting from current and Trinity ROD compliant Trinity River conditions. Negative values indicate that the Trinity is cooling the Klamath River.

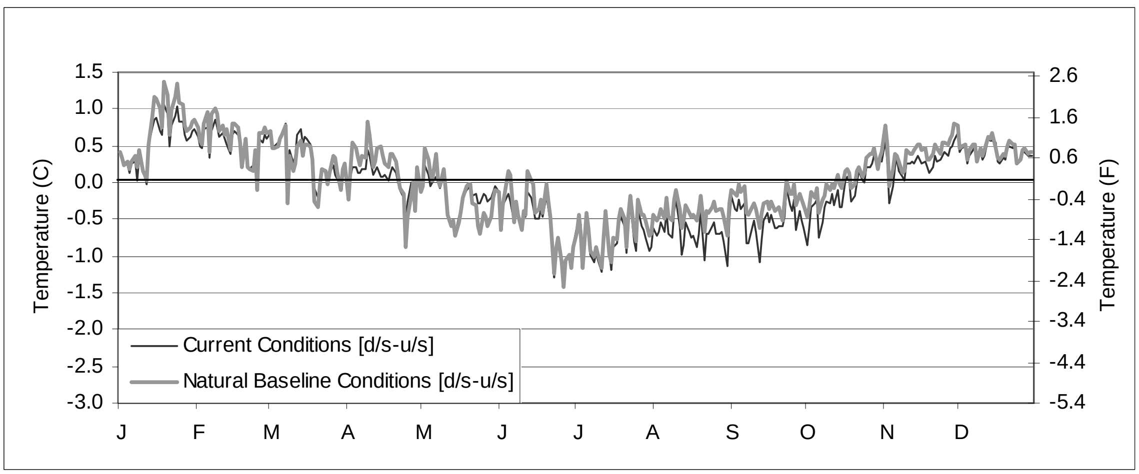

Figure 4.20: Change in Klamath River daily maximum temperatures resulting from current and estimated natural Trinity River conditions. Negative values indicate that the Trinity River is cooling the Klamath River.

<u>Effects of Shade on Klamath River Tributaries</u>

Temperature TMDLs have been established for twelve watersheds in the north coast region of California. These watersheds include three of the major Klamath River tributaries: the Salmon, Scott, and Shasta River watersheds. All twelve temperature TMDLs have evaluated the effects of shade on stream temperatures and each of these analyses have consistently reached the same conclusion regarding stream shade: the temperature of a stream is significantly influenced by the amount of solar radiation the stream receives. A second conclusion of these analyses is that changes in streamside vegetation affect shade (and thus, temperature) to a greater degree in smaller streams than in large streams. This is largely due to the fact that the height of trees is greater in relation to stream width in smaller streams, whereas trees are less effective at casting shade on larger streams. These conclusions are consistent with published literature and temperature analyses conducted in the Pacific Northwest (Independent Multidisciplinary Science Team, 2000; Johnson, 2004; Miner and Godwin, 2003; ODEQ, 2002).

Regional Water Board staff evaluated the sensitivity of Klamath River tributaries to the effects of solar radiation using the USGS stream reach temperature model SSTEMP. That analysis of six moderate-sized tributaries (Indian, Elk, Clear, Dillon, Red Cap, and Bluff Creeks) confirms the importance that solar radiation loads have in determining stream temperatures (Wilder, 2007).

Given the similarity of Klamath River tributaries to other north coast watersheds, and the universal nature of the laws of thermodynamics, Regional Water Board staff have determined that the conclusions of shade-related analyses from previous temperature TMDLs stated above apply region-wide, and especially to Klamath tributaries not already assigned TMDL shade allocations. Riparian shade controls are needed in many Klamath River tributaries not subject to an existing TMDL Action Plan.

Effects of Minor Tributaries on Klamath River Temperatures

The effects of minor Klamath River tributary (i.e., all tributaries except the Shasta, Scott, Salmon, and Trinity Rivers) temperatures on Klamath River temperatures were evaluated early in the modeling process. The segment of the model downstream of Iron Gate reservoir was simulated with and without the tributary temperatures reduced by 2 °C from their current temperature estimates. The comparison showed that the change in minor tributary temperatures had an indistinguishable effect on Klamath River water temperatures. Thus, Regional Water Board staff concluded that at the scale that the model predicts water temperature the Klamath River is not sensitive to the temperature of the minor tributaries. Despite the insensitivity of the Klamath River to minor tributary temperatures, these tributaries are vital where they provide thermal refugia.

Effects of Sediment Loads on Klamath River Tributaries

Historic increases in sediment loads have resulted in the widening of stream channels, reduction of riparian shade, and consequent elevation of stream temperatures. The primary causes of increased sediment loads are both natural and human-caused mass wasting. The US Forest Service has estimated that 446 of the 2260 (20%) total stream miles evaluated within Klamath National Forest lands were significantly altered during the flood of 1997 (De la Fuente and Elder, 1998). Much of the damage done to stream channels happened when debris slides that had initiated in the headwater areas resulted in debris torrents that traveled long distances (up to many miles), and in the process severely disrupted stream channels and removed riparian vegetation. Temperature data from one of the affected streams, Elk Creek, showed that in the summer after the flood, the peak temperature was the highest of seven years of record, and was 2.1 ^{o}C (3.8 ^{o}F) higher than the average from 1990-1995. Likewise, the diurnal variation increased to 6.9 ^{o}C (12.5^{o}F), 2.7 ^{o}C (4.9 ^{o}F) higher than the 1990-1995 average.

Regional Water Board staff (Wilder, 2007) evaluated the sensitivity of Klamath River tributaries to the effects of channel widening, using the USGS stream reach temperature model SSTEMP. The results of that analysis show that daily average stream temperatures can increase in the range of 1 ^{o}C to 2 ^{o}C when the wetted channel width doubles. However, these results are conservative given that the analysis only evaluated the effects of a change in wetted width and did not consider the loss of riparian vegetation (and consequent decrease in shade) that occurs when the active channel increases in width following a debris torrent or aggradation event. Furthermore, because the downstream endpoints of the modeled reaches are near the mouths of the streams where streams are already near equilibrium, it is likely that even larger temperature increases would occur in some reaches upstream where the difference between the current temperature and the equilibrium temperature is greater. Regional Water Board staff have also identified an apparent correlation of decreases in temperature with decreases in channel width in thermal infrared survey data collected in 2004 by Watershed Sciences, LLC (Watershed Sciences LLC, 2004).

Increased sediment loads in tributary streams also create temperature impacts associated with loss of thermal refugia in the Klamath mainstem. Because the daily maximum temperatures of the Klamath mainstem are at lethal levels through most of the summer, the opportunity for salmonids to rear in the mainstem during those times depends on access to thermal refugia. The majority of thermal refugia in the Klamath mainstem are located at the mouths of cold tributaries where they mix with the Klamath River (Belchik 1997). The volume of thermal refugia at tributary mouths can be greatly affected by the sediment loads of the tributaries. Higher sediment loads can cause tributaries to infiltrate into gravels before reaching the river, create barriers that restrict fish from entering tributaries, and fill in pools where cold water exists. Four of the five largest (>1000 ft^2) thermal refuge areas between Iron Gate Dam and Seiad Valley are created by tributaries that were significantly impacted by sediment loads during the 1997 flood event (Belchik 1997; Kier Associates 1999).

4.2.4.2 Literature Review on Effects of Suction Dredging on Geomorphology and Aquatic Resources

This section provides a brief overview of the findings in the literature Regional Water Board staff relied upon to develop the Thermal Refugia Protection Policy. The proper functioning of thermal refugia areas in the Klamath River Basin is necessary to meet the Basin Plan water temperature objective since these areas of cold water in the mainstem Klamath River are representative of natural water temperatures. The literature review specifically addresses the relevant documented impacts of suction dredging and provides the support for the recommendation in the policy to exclude suction dredging from designated buffer areas surrounding known thermal refugia in the Klamath basin. While there has been no direct study of the effects of suction dredging on thermal refugia, per se, studies are available in the literature on the impacts of suction dredging on geomorphology and aquatic resources. The conclusions of the studies are consistent in documenting certain impacts, with the extent and nature of some impacts more dependent on conditions at the study site. In general, studies cite short-term localized effects, while longer term and more widespread impacts are usually less than significant. The literature review that follows focuses on the relevant short-term effects, because of their potential to impact the function of refugia during the summertime period. It is during this time period when mainstem Klamath River temperatures are elevated close to lethal levels and anadromous salmonid rely on thermal refugia for survival.

The fact that sensitive anadromous fish are dependent on cold water and essentially captive in a thermal refuge supports a cautious and a conservative approach to regulating suction dredging in order to maintain and protect these fragile areas. Two prominent fisheries biologists, Moyle and Harvey, have voiced support for such an approach. "Given current levels of uncertainty about the effects of dredging, where threatened or endangered aquatic species inhabit dredged areas, fisheries managers would be prudent to suspect that dredging is harmful to aquatic resources" (Harvey and Lisle1998). In the North American Journal of Fisheries Management, Virginia Thomas similarly advised that "managers should concentrate their control efforts on very sensitive areas and areas of intensive dredge activity" (Thomas 1985). In expert testimony given as part of a 2005 Karuk lawsuit against the California Department of Fish and Game, Dr. Peter Moyle stated that "suction dredging through a combination of disturbance of resident fish, alteration of substrates, and indirect effects of heavy human use of small areas, especially thermal refugia, will further contribute to the decline of the fishes" (Moyle 2006). Brief discussions of the effects of suction dredging relevant to the function of thermal refugia are presented below.

Stream Channel Alteration

The potential impact on the channel and consequent effects on a refugial area provides the greatest support for protecting the area around thermal refugia. Impacts tend to be localized and are dependent on the channel structure and form, the stream flow dynamics, and the intensity and duration of a suction dredging operation. "The majority of suction dredge operators in Canyon Creek did not work long periods or disturb large areas of the streambed. Dredging impacts upon the channel geomorphology were confined to the area dredged and the area immediately down stream." (Hassler et al 1986)

Dredging has a higher potential to result in long-term impacts in smaller streams with lower winter flows that cannot readjust the channel every year. Excavation by dredging causes direct and significant local changes in channel topography and substrate conditions, particularly in small streams (Harvey 1998). Thirty-four percent of the suction dredgers observed were undercutting stream banks. While direct effects observed from suction dredging are generally localized, changes in the local form and structure of the channel may affect larger areas:

- "While deposition of bedload is most notable close to dredging sites, disruption of the continuity of bedload transport can have unpredictable consequences downstream, including both erosion and deposition" (Womack and Schumm 1977, Harvey 1998).
- "Miners commonly pile rocks too large to pass through their dredges. These piles can persist during high flows and, as imposed topographic high points, may destabilize channels during high flows" (Harvey 1998).
- Stream channel morphology and substrate composition can be altered as rocks, gravel, and silt are scoured away and then deposited in a different location within a stream; often in previously undisturbed areas (US District Court, 2004).

- Harvey (1986) reported that a 50-foot reach of a tributary to Butte Creek was completely channelized and riffles were transformed into exposed gravel bars by a 10-day operation by one dredge.

The potential to impact the rather local phenomenon of thermal refugia documented in the Klamath River system is of considerable concern to the sustainability of the anadromous fishery. The fact that thermal refugia enhancement efforts in the summertime are done with hand tools also points to their relative sensitivity to even minor channel alterations. Even though most studies show less than significant long-term effects on channel structure, and some effects may not be well documented, the potential for significant short-term effects in a localized area warrants the enhanced protections proposed in the Thermal Refugia Protection Policy.

Impacts to Streambanks
Dredging the stream banks is particularly problematic. While this is prohibited by DFG regulations, enforcement is not always possible. Stream bank disturbance and destruction of riparian habitat has been documented in the Siskiyou National Forest in Oregon (Nawa 2002). The California Department of Fish and Game also cites observations by McCleneghan and Johnson (1983) and Hassler (1986) of dredgers using prohibited practices and causing streambank erosion (CDFG 2009). Stern (1988) reported that undercutting of stream banks was the most common adverse impact on Canyon Creek.

Pool Filling
Fine sediment mobilized by dredging can fill pools in a low flow condition, (Thomas 1985, Harvey 1986) thereby reducing the amount of space for fish in a refugial area. Harvey (1986) reports that the number of rainbow trout in a small pool in Butte Creek, California declined by 50% after dredging upstream of the pool filled 25% of the pool volume. The potential for suction dredging discharges to fill pools downstream is the basis for the recommendation to exclude suction dredging upstream of thermal refugia.

While it has been postulated that the pools created by suction dredging may in themselves provide a thermal refuge for fish, the potential negative effects on channel structure and stability outweigh this potential benefit. Furthermore, in the Klamath basin, the thermal refugia areas already exist along the river, they simply need to be protected and enhanced.

Impacts to Food Supply
The potential to impact the food supply for fish within a refugial area is also of considerable concern. Macroinvertebrates are entrained in the dredge suction, causing direct mortality (Griffith and Andrews, 1981) and physically removing macroinvertebrates from the refugial area and discharging them below the refugia, which effectively removes a portion of the food supply from the refugial area.

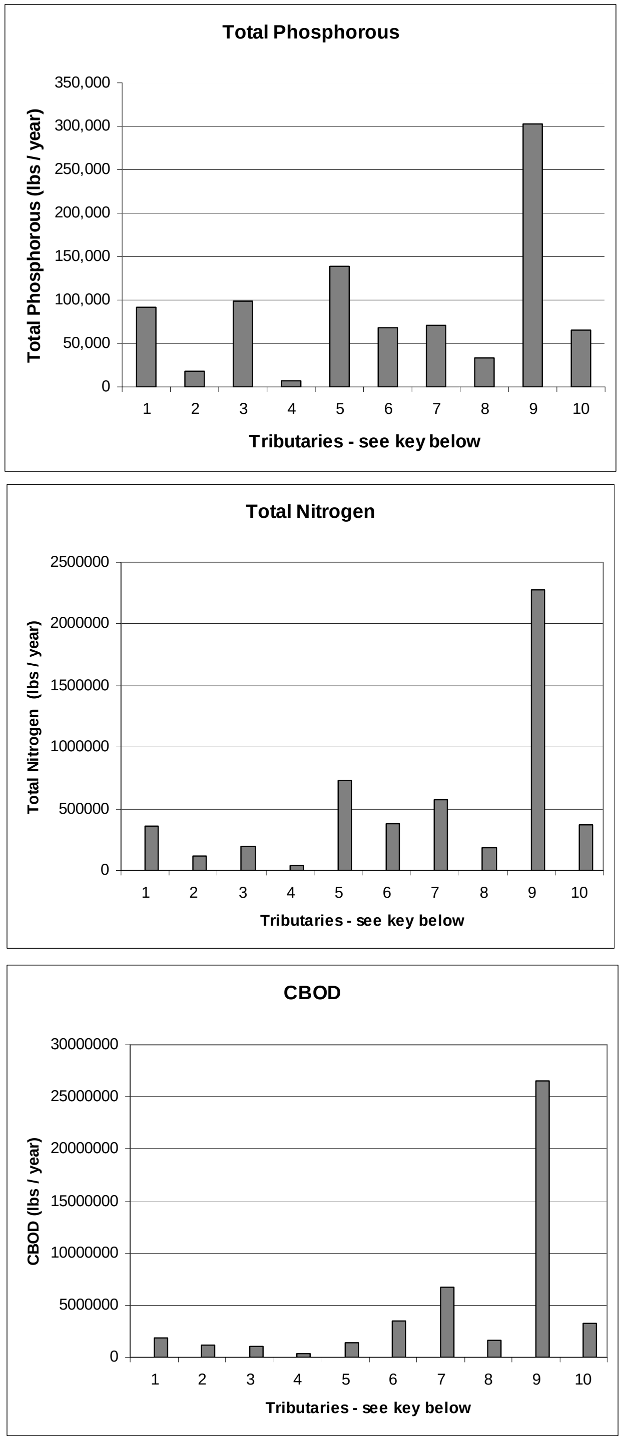
Depending on the type of substrate that the suction dredge is "working," finer material may be displaced from the active dredge area downstream, depositing on the stream bed and causing impacts to aquatic life. The effects of fine sediment deposition on macroinvertebrates are well studied and documented (Bjornn et al 1974 and 1977, Chutter 1969, Sandine 1974). Deposition of fine sediment that buries macroinvertebrates has a negative impact on those food organisms, resulting in changes in overall abundance and the aquatic community structure. Dredging also changes the substrate composition and affects macroinvertebrate populations (Harvey 1986, Somer and Hassler 1992, Thomas 1985), and can have negative consequences for growth and survival of salmonids (Suttle et al 2004). Prussian, et al. (1999) report reduction in benthic macroinvertebrate abundance of 97% and number of taxa by 88% relative to an upstream site. The abundance and diversity of macroinvertebrates returned to values comparable to the reference site by 80 to 160 m downstream of the dredge. Studies of the recovery of impacted macroinvertebrate populations report a return to pre-dredging abundance within 30-45 days (Harvey 1986, Thomas 1985).

These studies point out that the level of impact on macroinvertebrates, an important component of the food supply for fish, is directly related to the extent and duration of the disturbance: the level of impact increases with increases in the duration of and/or spatial extent of disturbance. The extent to which these impacts translate to impacts to fish in a refugial area is a function of how much deposition occurs in the refugial area.

Behavioral Responses
Divers, equipment, and activity in a thermal refugial area may result in "hazing" or scaring juvenile fish from refugia out into the warmer waters of a stream. Roelofs (1983) expressed concern that dredging could frighten adult summer-run steelhead, based on their response to divers, and Campbell and Moyle (1992) indicated that recreational activity increased salmon movement in pools and may increase adult stress" (CDFG 2009). On the other hand, Thomas (1985) documented juvenile fish feeding on entrained organisms at dredge outfalls. Were the plume from the dredge discharge outside of the refugial area, fish, while temporarily having an immediate feeding opportunity, could be "lured" into warmer water by this behavior.

Displacement of Cool Water
Another potential effect for which we have not seen documentation is a suction dredge operating in a thermal refugia displacing cold water from the refugial area to warmer water. This could potentially increase the effective size of the cold water refugia by extending the cold water plume. Alternatively, it also may result in cold water being taken from the refugial area, shrinking the effective size of the refugia, and discharging that cold water into a larger body of warm water, where it could be quickly warmed up.

4.2.4.3 Nutrients and Organic Matter
Current annual nutrient and CBOD loads from the California tributaries to the Klamath River are presented in Figure 4.21. Loads are presented for the Shasta, Scott, Salmon, and Trinity Rivers, and for groups of tributaries located between each of the major tributaries. These loads were calculated based on the best available quality assured concentration data from 2000 through 2007 and flows from the 2000 calendar year. A description of the sources of the data and the methodologies used to calculate the tributary loads is provided in Appendix 6. Cumulatively the California tributary loading comprises the following percentage of the total annual loads estimated for the Klamath River: 55% TP; 62% TN; and 72% CBOD. California tributaries below Iron Gate also



Stations List:

1-	Stateline to Iron Gate Tributaries	2-	Iron Gate to Shasta Tributaries
3-	Shasta River	4-	Shasta to Scott Tributaries
5-	Scott River	6-	Scott to Salmon Tributaries
7-	Salmon River	8-	Salmon to Trinity Tributaries
9-	Trinity River	10-	Trinity River to Turwar Tributaries

Figure 4.21: Current total annual loading (pounds/year) of total phosphorus, total nitrogen, and CBOD to the Klamath River from California tributaries

contribute the largest amount of flow volume to the river, generally at lower nutrient concentrations compared with the lower flows, but higher concentrations from the upper basin. Most tributaries have nutrient and CBOD concentrations that are regarded to be at or below concentrations considered to be reference conditions for the region (US EPA 2000). There are exceptions, such as Shasta River and Bogus Creek.

The Shasta River Temperature and Dissolved Oxygen TMDLs include load allocations and implementation actions, which when achieved will result in reduced nutrient and organic matter loads delivered to the Klamath River. For the Klamath River TMDL's California allocation scenario, the nutrient and CBOD loads from the Shasta River were calculated based on Shasta River TMDL compliant conditions, as described in Appendix 7. These TMDL compliant Shasta River loads reflect the expected annual loads to the Klamath River when the Shasta River TMDL is fully implemented and nutrient/ biostimulatory substances and DO water quality objectives within the Shasta River are achieved. Figure 4.22 compares current and California allocation scenario TP, TN, and CBOD loads from the Shasta River. The California allocation scenario conditions represent 72%, 59%, and 18% reductions, respectively, from current TP, TN, and CBOD loads delivered from the Shasta River to the Klamath River.

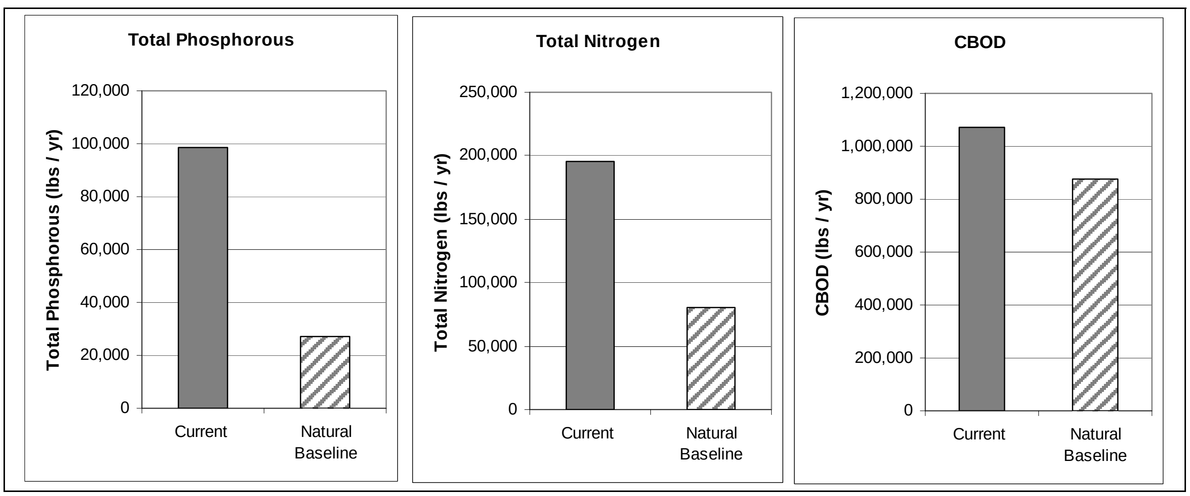


Figure 4.22: Shasta River comparison of current loads (pounds/year) of TP, TN, and CBOD with natural conditions baseline loads.

For the California allocation scenario, the nutrient and CBOD loads at the mouths of the other California tributaries (except Bogus Creek) were represented as the average of the available quality assured concentration data from 2000 through 2007 and flows from the 2000 calendar year. This representation of average tributary nutrient and CBOD loads is sufficient to meet dissolved oxygen and biostimulatory substances objectives in the Klamath River.

CHAPTER 5. KLAMATH RIVER TMDLs – ALLOCATIONS and NUMERIC TARGETS

5.1 Introduction

This chapter presents the numeric targets, loading capacity, and load and waste load allocations for the Klamath River in California. This chapter consists of three sections. Section 5.1 describes the numeric targets, loading capacity, load and waste load allocations, and margin of safety associated with the temperature, dissolved oxygen, and nutrient-related water quality impairments of the Klamath River in California. Section 5.2 presents the specific temperature-related numeric targets, and load and waste load allocations for the Klamath River by river reach and associated source areas. Section 5.3 presents the specific dissolved oxygen and nutrient-related numeric targets, and load and waste load allocations for the Klamath River by river reach and associated source areas. Table 5.1 summarizes the temperature, dissolved oxygen, and nutrient-related numeric targets and allocations.

Table 5.1: Summary of Klamath River TMDLs numeric targets and allocations

Location	Parameter	Target	Allocation
Watershed-wide[1]	Temperature	Riparian Shade: site-potential effective shade. Effective shade is a measure of the percentage of total daily direct beam solar radiation that is blocked by vegetation or topography before reaching the ground or stream surface, and takes into account the differences in solar intensity that occur throughout a day (Approximated in Figures 5.4, 5.5, and 5.6) Instream Target: 0 miles of substantial human-caused sediment-related channel alteration <1% of all road-stream crossings divert or fail as a result of a 100-year or smaller flood Decreasing trend of road-related landslides	Riparian Shade: the shade provided by topography and full potential vegetation conditions at a site, with an allowance for natural disturbances such as floods, wind throw, disease, landslides, and fire Human-caused discharges of sediment: zero temperature increase caused by substantial human-caused sediment-related channel alteration
Stateline	Temperature	Estimated natural temperature, expressed as monthly average temperature (See Table 5.3)	Zero increase above natural temperature
	Dissolved Oxygen	Dissolved oxygen concentrations at 85% saturation under natural temperature conditions expressed as monthly average and monthly minimum concentrations April 1 through September 30 and 90% saturation under natural temperature conditions from October 1 through March 31. (See Table 5.7)	N/A
	Nutrients/ Organic Matter	N/A	Allocations to TN, TP, and CBOD[2] expressed as monthly average concentrations (See Table 5.8)

1 Watershed-wide allocations and targets are assigned to the Klamath River Middle and Lower Hydrologic Areas. Major tributaries are not assigned temperature allocations because the Scott, Shasta and Salmon River watershed already have assigned allocations, and the Lost and Trinity are not listed as impaired for temperature.

2 Section 7.5.2 describes the recommended compliance assessment approach for CBOD targets and allocations that fall below the Method Detection Limit (MDL).

Table 5.1 (cont.): Summary of Klamath River TMDLs numeric targets and allocations

Location	Parameter	Target	Allocation
PacifiCorp Facilities	Temperature /Dissolved Oxygen	N/A	Temperature and dissolved oxygen "Compliance Lens" Or Alternative in-reservoir temperature and dissolved oxygen conditions that provide equal or better protection of COLD and MIGR beneficial uses.
	Nutrients/ Organic Matter	TP, TN, and CBOD concentrations expressed as monthly means reservoir tailraces (Table 5.10) Chlorophyll-a – growing season average of 10 µg/L *Microcystis aeruginosa* cell density ≤ 20,000 cells/L Microcystin toxin < 4 µg/L	Annual nutrient loading reduction necessary to attain chlorophyll-a, *Microcystis aeruginosa*, and microcystin numeric targets: TP = 22,367 lbs.; and TN = 120,577 lbs Or, alternative pollutant load reductions and/or management measures or offsets that achieve the in-reservoir targets.
	Temperature	Estimated natural temperature at reservoir tailrace –expressed as monthly average temperature (See Table 5.4)	Temperature increase expected to naturally occur in the river reach occupied by the reservoirs (See Table 5.5)
	Dissolved Oxygen	DO concentrations ≥ 85% saturation based on natural temperatures at reservoir tailraces expressed as monthly mean and minimum from April 1 through September 31 and 90% saturation based on natural temperatures from October 1 through March 31. (See Table 5.9)	N/A
Iron Gate Hatchery	Temperature	Expressed as monthly average temperatures at Iron Gate Hatchery discharge (See Table 5.6)	Zero increase above natural temperature
	Dissolved Oxygen	Expressed as monthly mean and minimum dissolved oxygen concentrations at Iron Gate Hatchery discharge (See Table 5.11)	N/A
	Nutrients/ Organic Matter	TP, TN, and CBOD concentrations expressed as monthly mean concentrations at Iron Gate Hatchery discharge (See Table 5.12)	Zero net increase of nutrient and organic matter loads above California allocation scenario conditions.
Tributaries	Dissolved Oxygen	Expressed as monthly mean and minimum concentrations greater than or equal to 85% saturation below Salmon River (See Table 5.13)	N/A
	Nutrients/ Organic Matter	Expressed as monthly mean concentrations of TP, TN, and CBOD below the Salmon River (Table 5.14) Reach-averaged maximum density of 150 mg of chlorophyll-a /m^2 below the Salmon River	TN, TP, and CBOD concentrations expressed as monthly mean concentrations (See Table 5.15 and 5.16)

The Klamath River TMDL nutrient, dissolved oxygen, and organic matter (CBOD) allocations and related targets are designed to reduce the impacts of advanced eutrophication driven by land disturbance activities, the presence of reservoirs, flow alterations, and direct inputs of pollutants. The targets and allocations, as discussed in Chapter 2, are consistent with trophic classifications that are ecologically appropriate and supportive of Klamath basin beneficial uses. The allocation strategy addresses all of the stressors that are driving biostimulatory and toxicity related impairments including total phosphorous (TP), total nitrogen (TN), and organic matter (measured as CBOD). While nutrient ratios in the Klamath River can indicate nitrogen limitation in the short-term, a long-term strategy for controlling eutrophication of the Klamath River needs to reduce phosphorus loading. Comprehensive nutrient management strategies that address phosphorous have consistently demonstrated to be essential for successful long-term ecosystem restoration (Welch 2009). Because the vast majority of the nutrient (TP and TN) and organic matter (CBOD) pollutant loads are related to nonpoint sources, pollutant reduction measures are designed to address reductions with all three pollutants. The allocation strategy addresses all identified sources, but the largest reductions are related to loads from the upper basin source area (above Stateline) which exports the largest pollutant loads in comparison historical or undisturbed conditions. Allocations are also assigned to the Klamath Hydroelectric Project (KHP) facilities to address water quality issues within the reservoirs that are controllable water quality conditions within the facilities, and to ensure that water quality standards are met.

5.1.1 Numeric Targets

Numeric targets are the numeric water quality conditions that represent attainment of the water quality standards. Numeric targets serve as the goal post from which TMDLs and associated load and waste load allocations are developed. Numeric targets refer to the desired water quality conditions, and serve as good indicators of progress towards TMDL compliance and beneficial use support. In some cases numeric targets can equal a numeric water quality objective. In other cases, numeric targets are a numeric interpretation of the conditions that meet a narrative water quality objective. Numeric targets are typically instream water quality measures, but in some cases are measures of landscape conditions that affect instream water quality conditions. Targets are set at levels associated with well-functioning stream systems. In all cases, numeric targets are used in the calculation of a TMDL.

5.1.1.1 Temperature Numeric Targets

The primary temperature numeric targets for the Klamath River temperature TMDL are monthly average temperatures calculated from the estimated natural temperature regime of the Klamath River, and are presented in Section 5.2. In addition, secondary targets are established for riparian shade and sediment related channel alteration, diversion potential at stream crossings, and road-related landslides. These secondary targets are also presented in Section 5.2. The riparian shade targets are expressed as effective shade, which is a measure of the percentage of total daily direct beam solar radiation that is blocked by vegetation or topography before reaching the ground or stream surface, and takes into account the differences in solar intensity that occur throughout a day. Instream and watershed targets are established to address sediment-related temperature factors and human-caused mechanisms of sediment delivery associated with sediment-related temperature factors.

5.1.1.2 Dissolved Oxygen and Nutrient-Related Numeric Targets

The numeric DO targets are monthly average and monthly minimum DO concentrations calculated at 85% DO saturation under natural temperatures for most of the mainstem Klamath River except 90% DO saturation upstream of Hoopa from October 1 through April 31 and 80% during the month of August in the upper and middle estuary. These targets are, consistent with the proposed site-specific DO objective for the Klamath River in California (see Appendix 1), and are presented in Section 5.3. Numeric targets are also established for nutrients (TN and TP) and organic matter (CBOD) for the reservoirs, Iron Gate Hatchery, and tributaries, and are expressed as monthly average concentrations in Section 5.3. Additional numeric targets are established to reflect compliance with the narrative biostimulatory substances and toxicity objectives. These additional numeric targets, detailed in Section 2.3.2.2, are:

- Suspended algae chlorophyll-a: summer mean = 10 µg/L;
- *Microcystis aeruginosa* cell density: 20,000 cells/mL;
- Microcystin: 4 µg/L; and
- Benthic algae biomass: 150 mg chlorophyll-a / m^2.

5.1.2 Loading Capacity, Allocations, and Margin of Safety

The *loading capacity* refers to total amount of pollutant loads that a waterbody can receive and meet water quality standards. In order to achieve the loading capacity (i.e. the Total Maximum Daily Load [TMDL]), allocations are attributed to the natural background, non-point sources, and point sources of the applicable pollutants. *Waste load allocations* are contributions of a pollutant from permitted point sources, while *load allocations* are contributions from non-point sources. Contributions from natural background are incorporated into nonpoint source load allocations.

The starting point for the load allocation analysis is the equation that describes the Total Maximum Daily Load or loading capacity:

$$\text{TMDL} = \text{Loading Capacity} = \Sigma\text{WLAs} + \Sigma\text{LAs} + \text{Natural Background} + \text{MOS}$$

where Σ = the sum, WLAs = waste load allocations, LAs = load allocations, and MOS = margin of safety.

A margin of safety in a TMDL is required in the Clean Water Act to account for uncertainty and to assure that the TMDL will achieve water quality standards. The Clean Water Act directs states to develop a margin of safety "which takes into account any lack of knowledge concerning the relationship between effluent limitations and water quality." TMDLs can be developed with explicit and/or implicit margins of safety. An explicit margin of safety is established by withholding an explicit fraction of the loading capacity available for allocation. An implicit margin of safety is established by incorporating conservative assumptions in the calculation of the loading capacity.

5.1.2.1 Temperature Loading Capacity, Allocations, and Margin of Safety

For the temperature TMDL, two separate water quality objectives apply, as described in Section 2.2.1.2. The temperature objective for *interstate* waters prohibits the discharge of elevated temperature waste, whereas the *intrastate* temperature objective states that temperatures must be maintained as natural, unless a proposed increase is less than 5 ^{o}F and doesn't adversely impact beneficial uses. Because water temperatures in Klamath basin streams already adversely affect the beneficial uses during critical time periods, the natural receiving water condition becomes the temperature objective.

The loading capacity provides a reference for calculating the amount of pollutant load reduction required to bring a water body into compliance with standards. Because the applicable objectives do not allow for the discharge of elevated temperature waste, or increases in water temperature, the temperature loading capacity equals the natural receiving water condition, and in turn no increase is permissible and all sources are allocated a temperature load of zero.

The Klamath River watershed temperature TMDL addresses the heat loads that arise from seven sources:

1. Conditions of Klamath River water crossing the Oregon-California border (stateline);
2. Thermal discharges from Copco 2 and Iron Gate dams;
3. The impoundment of water in the reservoirs;
4. Temperature effects of Iron Gate Hatchery;
5. Temperature effects of major tributaries on Klamath River temperatures;
6. Effects of excess solar radiation; and
7. Effects of excess sediment loads.

The TMDL equation for temperature is:

Temperature TMDL = Loading Capacity = ΣWLAs + ΣLAs + Natural Background + MOS

The Klamath River temperature TMDL for California relies on an implicit *margin of safety*. As stated in Section 2.2.1.2, the intrastate Water Quality Objective for Temperature allows for temperature increases of up to 2.8 ^{o}C (5 ^{o}F) if beneficial uses of water are not adversely affected. For most of the year the Klamath River is too hot to accommodate more heat without beneficial uses of water being adversely affected. There are periods in the winter and spring months, however, when temperatures increases of 2.8 ^{o}C (5 ^{o}F) or less may occur without beneficial uses of water being adversely affected. The timing of those periods changes from year to year and is difficult to predict. Therefore, this TMDL takes a conservative approach, allocating no temperature increases year-round. This conservative approach constitutes an implicit *margin of safety*. Substitution of the allocations results in the following temperature TMDL for the Klamath River watershed in California:

Temperature TMDL = Loading Capacity
= 0 increase above natural background
= 0 anthropogenic heat load at stateline
+ 0 heat load discharged from Copco 2 and Iron Gate Reservoirs
+ 0 heat load discharge from Iron Gate Hatchery
+ 0 heat load discharge from tributaries
+ 0 heat load from excess solar radiation
+ 0 heat load from anthropogenic sediment loads
+ natural background.
= natural background

Section 5.2 details the load and waste load allocations for these sources.

5.1.2.2 Dissolved Oxygen, Nutrient and Organic Matter Loading Capacity, Allocations, and Margin of Safety

The TMDLs addressing dissolved oxygen and nutrient-related water quality impairments, including microcystin, are closely interrelated because of the strong relationship between biostimulatory conditions, decomposition of organic matter, and resulting dissolved oxygen conditions. A site-specific DO objective for the Klamath River in California is proposed in conjunction with the Klamath River TMDLs (Appendix 1). The Klamath River TMDLs for California are calculated to attain and maintain this proposed site-specific DO objective in the river reaches of the Klamath River in California. The proposed site-specific DO objective and associated DO targets are the primary driver in establishing the nutrient and organic matter loading capacity for the river reaches of the Klamath River in California. Stateline and tributary allocations for nutrients (TN and TP) and organic matter (CBOD)[3] were set to ensure that the proposed site-specific DO objectives are met in the river reaches in California.

Achievement of the stateline and tributary nutrient and organic matter allocations, however, will not result in compliance with the DO, temperature, chlorophyll-a, *Microcystis aeruginosa* cell density, and microcystin targets within Copco 1 and 2 and Iron Gate Reservoirs during summer months. Therefore, additional temperature and dissolved oxygen load allocations are assigned to the reservoirs for the period of May through October in order to meet temperature and dissolved oxygen standards in the reservoirs, as described in Section 5.3. In addition, TP, TN, and CBOD allocations are assigned to PacifiCorp at the upstream end of Copco 1 Reservoir in order to meet the chlorophyll-a, *Microcystis aeruginosa* cell density, and microcystin targets within the reservoirs, as described in Section 5.3. Alternative pollutant load reductions and/or alternative management measures or offsets may also result in achievement of the in-reservoir chlorophyll-a, *Microcystis aeruginosa*, and microcystin targets.

The loading capacity and associated load and waste load allocations for total phosphorus (TP), total nitrogen (TN), and organic matter (CBOD) for the Klamath River in California, including Copco 1 and 2 and Iron Gate Reservoirs, are presented in Figures 5.1, 5.2, and 5.3, respectively. These figures provide an illustration or graphical representation of the cumulative loading under TMDL compliance conditions to the Klamath River for total phosphorous, total nitrogen, and organic matter (CBOD). Cumulative loads used in this analysis include the total annual mass generated from upstream sources that pass through the assessment location (assessment locations along the Klamath River system were chosen to be just upstream of major tributary input locations). The analysis presents load inputs from major and minor tributaries, along with loads along the Klamath River system, and includes within-river and within-reservoir dynamics (e.g., losses, retention, and fluxes). The width of a segment arrow is only approximately proportional to the magnitude of the load within that reach. These figures present the loading capacities divided into various reaches of the Klamath River in California, and also present the load and waste load allocations assigned the different sources necessary to achieve the loading capacity. For most Klamath River compliance locations, allocations have been set as monthly mean concentrations for nutrients (TP and TN) and organic matter (CBOD). In order to summarize the Total Maximum Daily Load for these parameters, the allocations are also expressed as daily loads (concentration x flow = mass). The contribution of natural background nutrient and organic matter loads is incorporated into the compliance load for each source area.

[3] The allocations for organic matter are expressed as CBOD, and refer to CBOD- ultimate. The water quality models represent CBOD as organic matter; it is converted to CBOD-ultimate for TMDL allocation calculations.

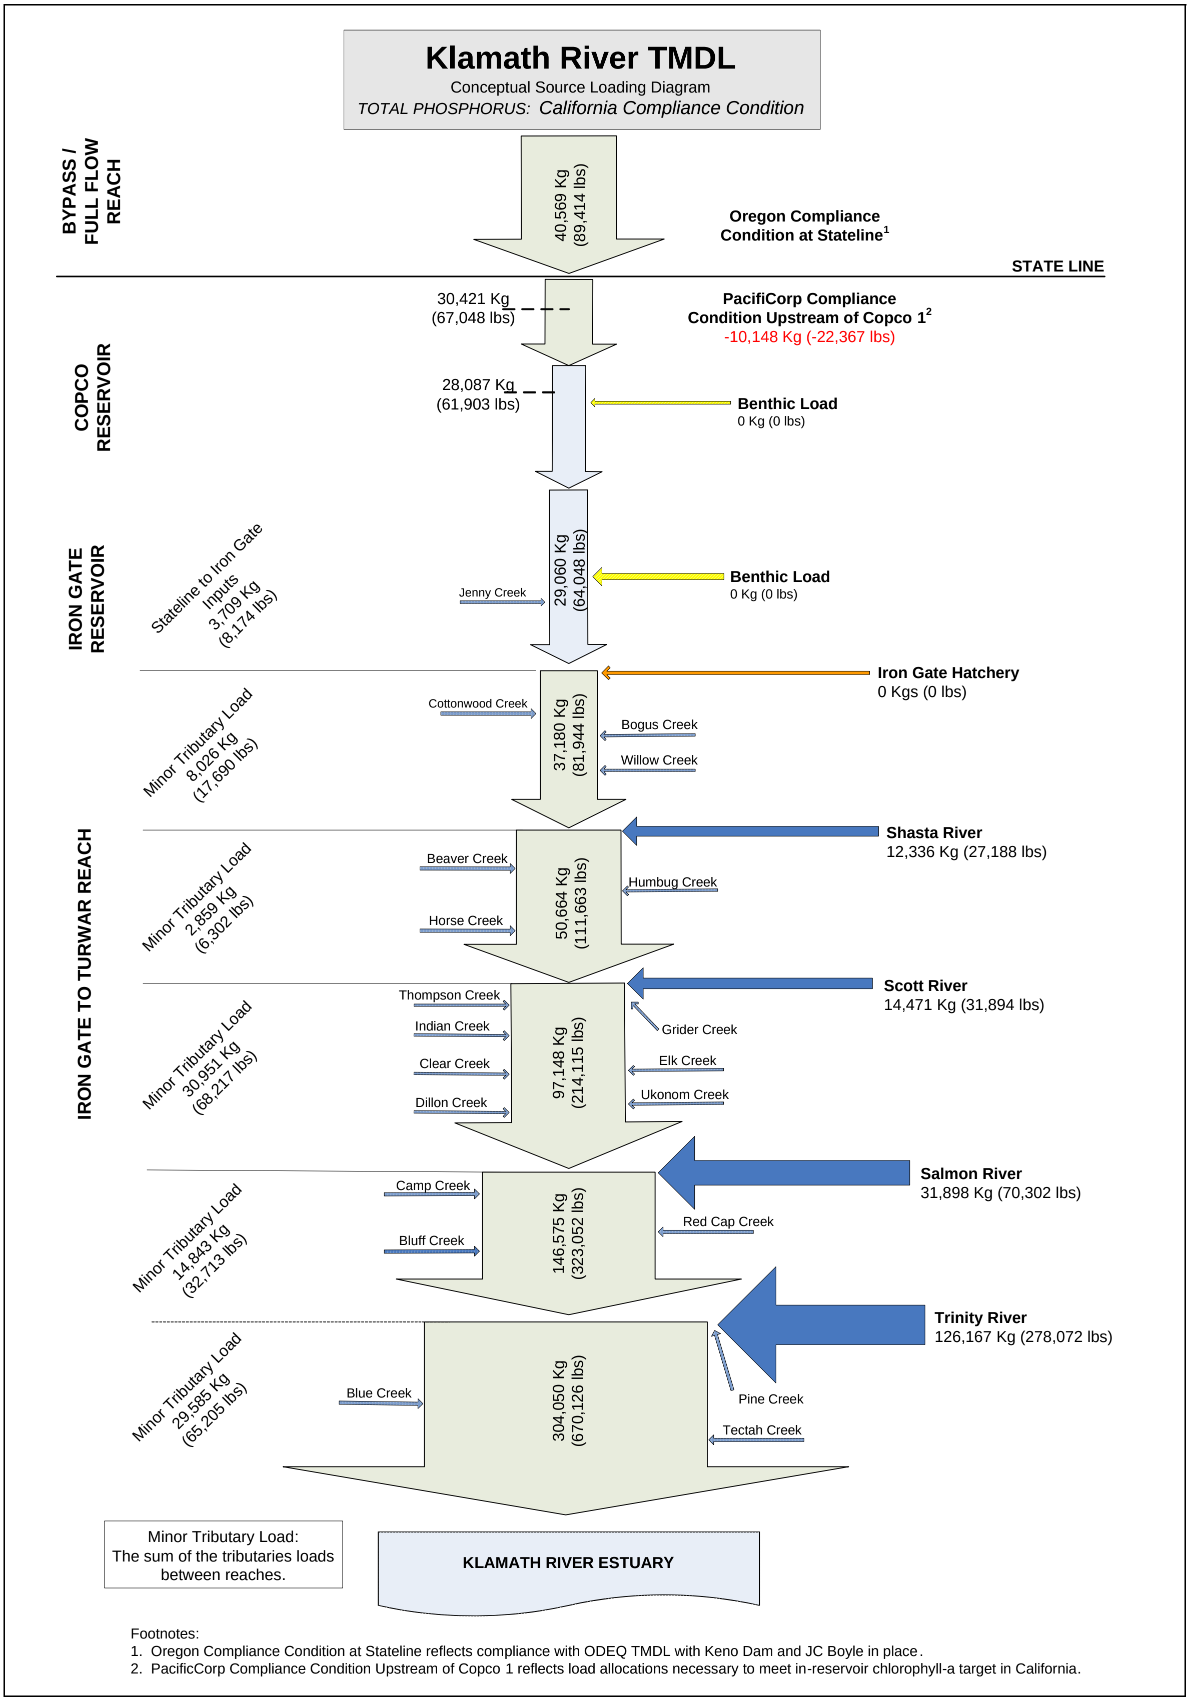

Figure 5.1: Annual total phosphorous loading capacity and allocations for the Klamath River in California

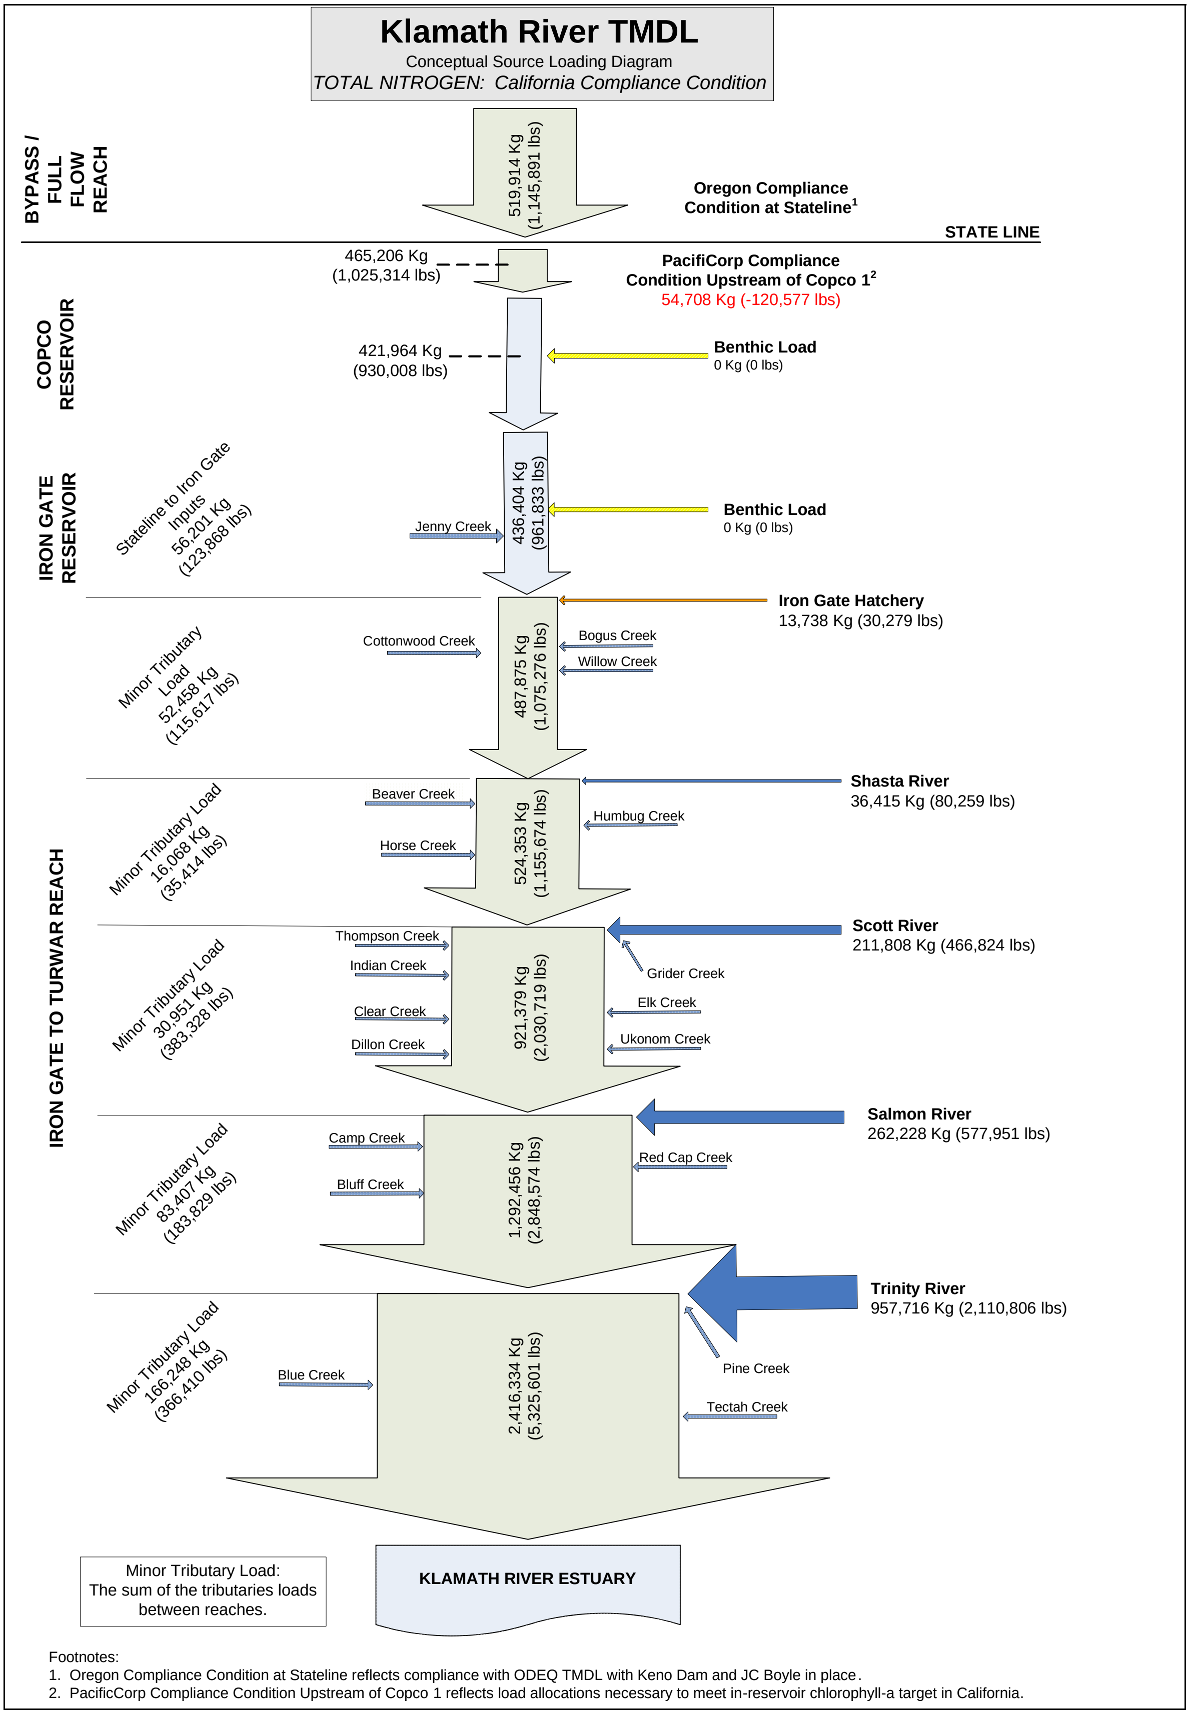

Figure 5.2: Annual total nitrogen loading capacity and allocations for the Klamath River in California.

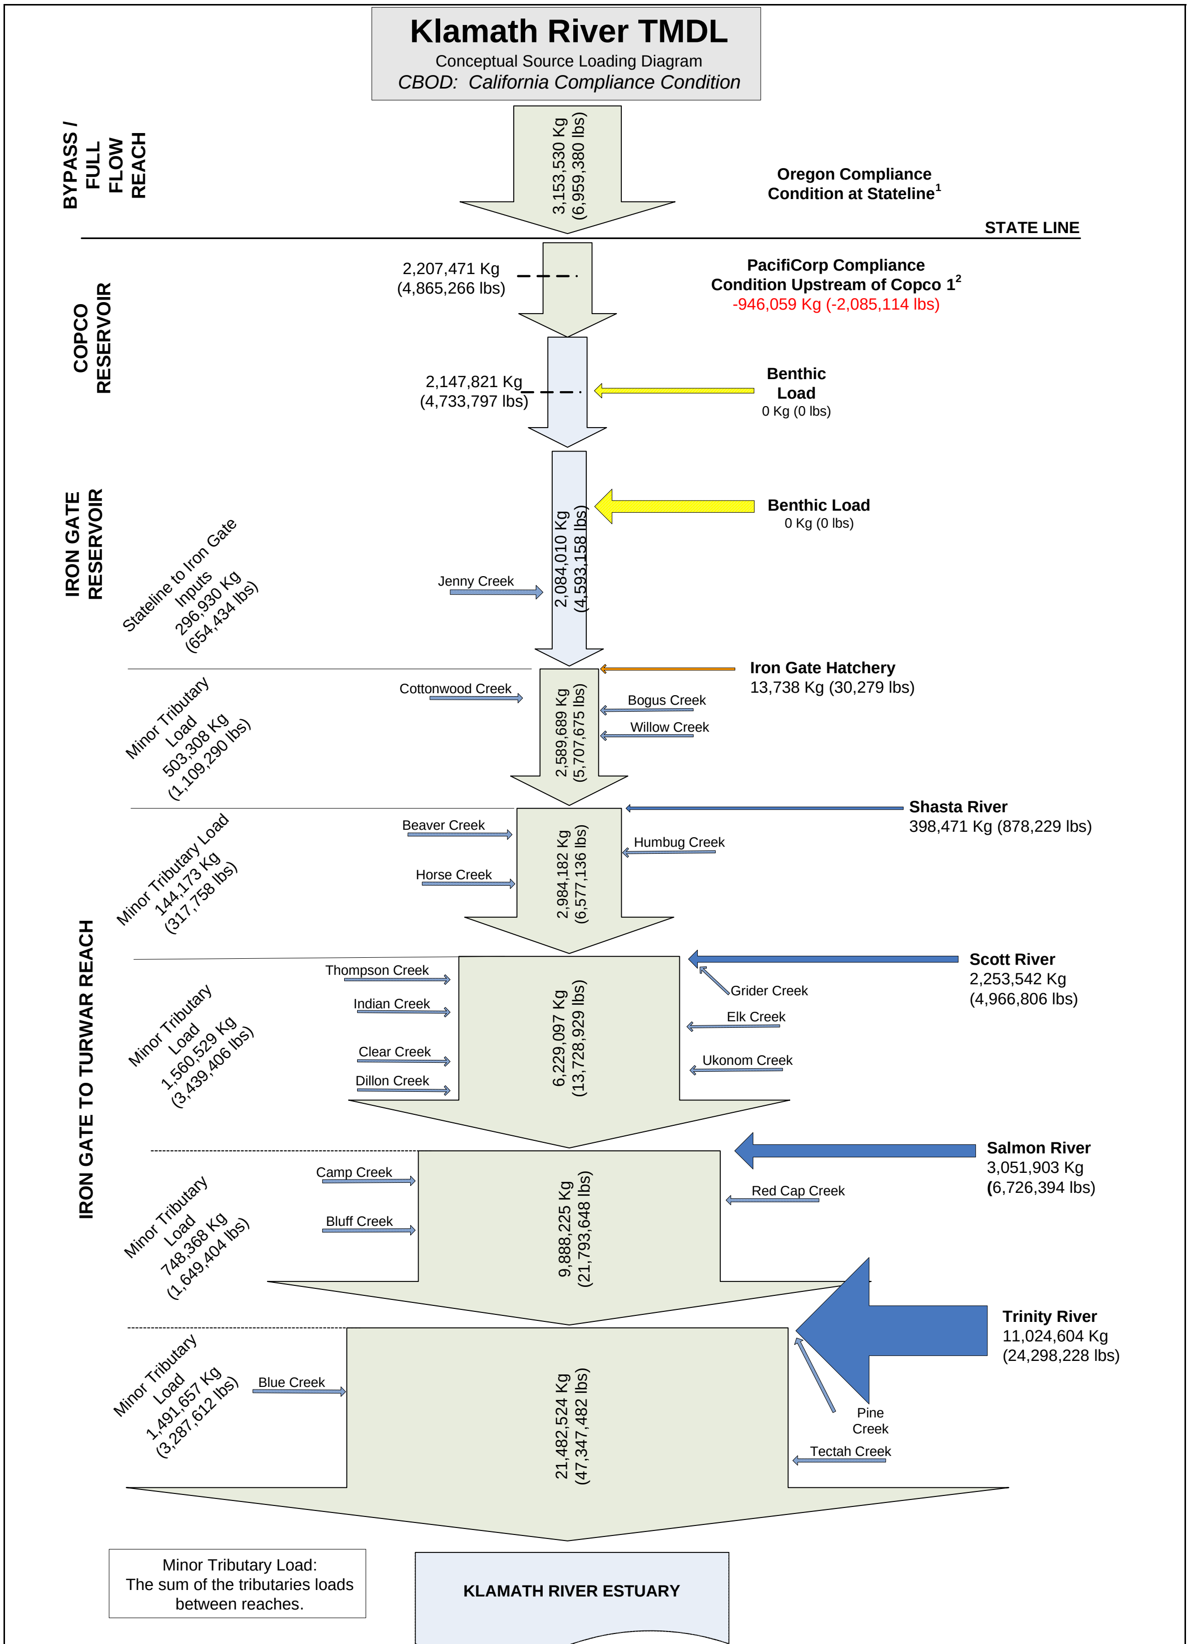

Footnotes:
1. Oregon Compliance Condition at Stateline reflects compliance with ODEQ TMDL with Keno Dam and JC Boyle in place.
2. PacifiCorp Compliance Condition Upstream of Copco 1 reflects load allocations necessary to meet in-reservoir chlorophyll-a target in California.

Figure 5.3: Annual organic matter (CBOD) loading capacity and allocations for the Klamath River in California.

The Klamath River TMDLs addressing, DO, nutrient, and microcystin impairments in California rely on an implicit *margin of safety*. An implicit margin of safety was deemed appropriate because uncertainty was reduced in the analysis by applying a comprehensive, dynamic numerical model to incorporate conservative assumptions into loading estimates and allocations. Incorporation of the conservative assumptions allows for those assumptions to be expressed in the predicted dissolved oxygen and chlorophyll-a levels. The model takes advantage of available data collected over multiple years, and deterministically represents the cause-effect relationship between discrete sources and water quality conditions throughout the Klamath's riverine, reservoir, and estuarine portions. By representing conditions in great spatial and temporal detail, the model effectively considers a spectrum of conditions that may be overlooked by a simpler analysis. It was determined that the largest source of uncertainty in this system is the highly variable and dominant loading from Upper Klamath Lake rather than the numeric water quality model. Conservative assumptions that make up the implicit margin of safety include:

- The numeric model used to predict the impact of allocations assumes that sediment oxygen demand (SOD) does not improve in the riverine sections following upstream load reductions. The magnitude of SOD will likely decrease with the decrease of organic loading allocated by the TMDL, and result in increased DO concentrations over time.
- Predicted conditions in the Klamath River are strongly influenced by the predicted variable conditions of the Upper Klamath Lake TMDL. Conservative allocations were set by using a combination of the predicted conditions. The timing of the allocations within Oregon is based on the scenario which represents the greatest loading from Upper Klamath Lake (i.e. results in the longest period of water quality not meeting numeric criterion). The magnitudes of the allocations are based on median loading conditions from Upper Klamath Lake. This is conservative because allocations are based on the difference from a baseline condition. The closer the concentration or temperature is to the numeric criteria, the less loading is necessary to cause a measurable degradation.
- An empirical analysis suggests that the TMDL model may underestimate nutrient loss and retention within the Klamath River. The underestimate does not appear to be large. However, this potential underestimate results in more conservative allocations upstream.
- The year chosen for developing the water quality models and establishing the TMDL was selected because it included periods of critical low flow and poor water quality conditions, which results in more stringent load allocations.
- Allocations to nonpoint source are for all nutrients (TN, TP, and CBOD), not just the predicted limiting nutrient.
- Year 2000 flows are less than more recent flow requirements (i.e. USBR Klamath Project Operations and PacifiCorp Klamath Hydro Project Biological Opinion flows).

The TMDLs for TP, TN, and CBOD for the Klamath River in California, to address DO, nutrient, and microcystin impairments, are the sum of waste load allocations, load allocations, and natural background for each parameter. The only waste load allocations assigned for these TMDLs is to the Iron Gate Hatchery. The contribution of natural background TP, TN, and CBOD loads is incorporated into the load allocations for each source area.

Daily load and waste load allocations for total phosphorus, total nitrogen, and organic matter (CBOD) for the Klamath River in California are presented in Table 5.2. These daily loads are those that result in compliance with all TMDL targets.

Table 5.2: TMDLs for TP, TN, and CBOD (lbs.)

Source Area	Daily TP Load Allocations (lbs.)	Daily TN Load Allocations (lbs.)	Daily CBOD Load Allocations (lbs.)
Stateline	245+	3,139.4+	19,042+
Upstream of Copco 1 Reservoir	(61.3)+	(330.3)+	(5,713)+
Stateline to Iron Gate Dam inputs	22.4+	339.4+	1,793+
Δ Iron Gate Hatchery	0+	0+	0+
Tributaries between Iron Gate Dam and the Shasta River	48.5+	317+	3,039+
Shasta River	74.8+	220+	2,406+
Tributaries between Shasta River and Scott River	17.3+	97+	871+
Scott River	87.4+	1,279+	13,608+
Tributaries between Scott River and Salmon River	186.9+	1,050+	9,423+
Salmon River	192.6+	1,583.4+	18,428+
Tributaries between Salmon River and Trinity River	89.6+	504+	4,519+
Trinity River	761.8+	5,783+	66,571+
Tributaries between Trinity River and Turwar Creek	178.6+	1,004+	9,007+
Total	**1844**	**14,986**	**143,019**

5.2 Temperature-Related Numeric Targets and Allocations

This section presents the temperature-related numeric targets, and load and waste load allocations for the Klamath River by river reach and associated source areas.

5.2.1. Watershed-Wide Temperature-Related Targets and Load Allocations in California

There are two temperature-related load allocations that apply to the Klamath River mainstem and all minor tributary watersheds in California. These allocations are for excess solar radiation and human-caused discharges of sediment. For clarity of presentation the numeric targets are presented after presentation of these allocations.

5.2.1.1 Riparian Shade

Regional Water Board staff have concluded that the load allocation for excess solar radiation assigned in previous TMDLs (e.g. Navarro, Mattole, Scott, Shasta, and Eel River Temperature TMDLs), is also an appropriate allocation for excess solar radiation in the Klamath River watershed in California. The load allocation for solar radiation is expressed as its inverse: shade. Accordingly, the **temperature load allocations for shade** are equal to:

> the shade provided by topography and full potential vegetation conditions at a site, with an allowance for natural disturbances such as floods, wind throw, disease, landslides, and fire.

The targets for riparian shade are expressed as effective shade. Effective shade is a measure of the percentage of total daily direct beam solar radiation that is blocked by vegetation or topography before reaching the ground or stream surface, and takes into account the differences in solar intensity that occur throughout a day.

The effective shade curves in Figures 5.4-5.9 graphically present the levels of effective shade that are expected to naturally occur for a given type of vegetation, aspect, and stream width. The effective shade conditions expressed in these curves are those expected to meet the load allocation for excess solar radiation. These curves constitute the numeric targets for riparian shade within the Klamath River basin in California. Other natural factors, such as geologic or soil conditions, may reduce the site-potential effective shade at a location. Where natural factors affect site-potential effective shade, the site-potential effective shade meets the load allocation for excess solar radiation.

The curves in Figures 5.4-5.9 were developed using the Shade-a-lator riparian shade model (Boyd and Kasper 2003), which calculates the effective shade resulting from vegetation and/or topography, given the date, site geometry, and vegetation conditions. The analysis was developed for July 21, the beginning of the period of peak water and air temperatures (NCDC 2009; data collected by Regional Water Board staff). The analysis assumed no topographic shade and no vegetation overhang. The wetted channel width was assumed to be one-third the bankfull width. Wetted depth was assumed to be 0.25 meters (0.82 feet). All other assumptions are expressed in the figure titles. The height and density of the various vegetation types depicted are based on measurements by Regional Water Board staff, literature values, and professional judgment. The level of effective shade is most sensitive to the height of vegetation.

This space intentionally left blank

5.2.1.2 Excess Sediment

Regional Water Board staff have concluded that stream temperature increases in the Klamath River watershed cannot be accommodated without adverse effects to beneficial uses. Therefore, stream temperature increases that result from human-caused discharges of sediment constitute an exceedence of the water quality objective for temperature. Accordingly, the **temperature-related load allocation for human-caused discharges of sediment** equals:

> zero temperature increase caused by substantial human-caused sediment-related channel alteration.

For this purpose, the following definition is used to define *substantial human-caused sediment-related channel alteration*:

> Substantial human-caused sediment-related channel alteration: "A human-caused alteration of stream channel dimensions that increases channel width, decreases depth, or removes riparian vegetation to a degree that alters stream temperature dynamics and is caused by increased sediment loading".

Two types of targets are designated for this category, an instream target and watershed targets.

The instream target associated with *Substantial Human-Caused Sediment-Related Channel Alteration* is:

> 0 miles of substantial human-caused sediment-related channel alteration.

The watershed target for *Stream Crossings with Diversion Potential or Significant Failure Potential* is:

> <1% of all stream crossings divert or fail as a result of a 100-year or smaller flood.

Most roads, including skid trails, cross ephemeral or perennial streams. Crossings are built to capture the stream flow and safely convey it through, under, or around the roadbed. However, stream crossings can fail, adding sediment from the crossing structure (i.e., fill), or from the roadbed, directly into the stream. Stream crossing failures are generally related to culverts that are undersized, poorly placed, plugged, or partially plugged. When a crossing fails, the total sediment volume delivered to the stream usually includes both the volume of road fill associated with the crossing and sediment from collateral failures such as debris torrents that scour the channel and stream banks.

Diversion potential is the potential for a road to divert water from its intended drainage system across or through the road fill, thereby delivering road-related sediment to a watercourse. Generally, less than one percent of stream crossings have conditions where modification is inappropriate because it would endanger travelers or where modification is impractical because of physical constraints (D. Hagans, pers. comm., 1998, in USEPA 1998).

The watershed target associated with *Road-Related Landslides* is:

Decreasing number of potential road-related landslide source areas.

Since road failures usually occur many years after roads are constructed and are often unpredictable, it is expected that the rate of road-related landslides is not likely to decrease until roads in problem areas are treated or decommissioned. Appropriate location, design, construction, and maintenance of roads is expected to result in a reduction of the rate of road failures.

5.2.2 Temperature Numeric Targets and Load Allocations at Stateline

The ODEQ has identified the Klamath River in Oregon on its CWA section 303(d) list as failing to meet Oregon temperature criteria. Accordingly, in 2010, ODEQ intends to issue and implement TMDLs for temperature for the Klamath River in the state of Oregon. These Oregon-issued TMDLs will be based on Oregon's water quality standards. The Oregon temperature standard contains a human use allowance of 0.3 ^{o}C (0.54 ^{o}F) temperature increase when natural temperature conditions are above the numeric temperature criteria, which is 20 ^{o}C (68 ^{o}F) in this situation. The human use allowance is distributed among the point and non-point sources of Klamath River temperature increases in Oregon. Because of the small magnitude and locations of thermal sources in Oregon, the Klamath River temperatures at Stateline that result from implementation of Oregon's temperature standard are consistent with California's water quality objective for temperature (i.e. the small magnitude of the allocated temperature increases and their distance from California results in temperatures that cannot be distinguished from natural temperatures by the time the water reaches Stateline).

Because these TMDLs (and their anticipated load allocations and wasteload allocations) are being developed by Oregon as part of a comprehensive multistate analysis of pollutant loadings to the Klamath River, they are also being designed to meet California water quality standards at the Oregon/California border. It is appropriate for the Regional Water Board to account for these anticipated upstream load reductions in Oregon when developing the TMDLs for the segments of the Klamath River that are downstream in California. For ease of reference, these anticipated reductions in Oregon-source loads are identified in this TMDL in California as load allocations that reflect anticipated water quality at the Oregon/California border once the Oregon TMDLs are fully implemented. Thus, the temperature allocations and targets (Table 5.3) at Stateline reflect an understanding and acknowledgement that meeting water quality standards in Oregon is critical for meeting water quality objectives in California.

The temperature targets at Stateline presented in Table 5.3 are expressed as monthly average temperatures and reflect temperatures at Stateline that are consistent with ODEQ's temperature TMDL.

Table 5.3: Temperature Numeric Targets (°C) at Stateline, expressed as monthly averages, based on the California allocation scenario results. The California allocation scenario is consistent with the Oregon allocation scenario at Stateline.

May	June	July	August	September	October
14.4 °C 58 °F	18.2 °C 64.8 °F	19.1 °C 66.5 °F	18.9 °C 66 °F	15.1 °C 59.2 °F	10.4 °C 50.7 °F
November	**December**	**January**	**February**	**March**	**April**
3.6 °C 38.4 °F	2.3 °C 36.1 °F	3 °C 37.4 °F	6 °C 42.8 °F	9.4 °C 48.9 °F	12 °C 53.5 °F

The allocation for temperature at Stateline is zero increase above natural, in accordance with water quality objectives.

5.2.3 Temperature Numeric Targets and Load Allocations to Copco 2 and Iron Gate

The numeric temperature targets assigned to Iron Gate and Copco 2 tailraces are calculated from the California allocation scenario, and are expressed as monthly average temperatures in Table 5.4. The California allocation scenario is based on achievement of water quality standards, which are set to protect all beneficial uses of water. Regional Water Board staff have determined that achievement of water quality standards is necessary to support a balanced indigenous population of fish and shellfish (see section 2.3.1).

Table 5.4: Temperature numeric targets for Iron Gate and Copco Reservoir tailrace waters

	May	June	July	August	September	October
Copco 1&2	14.8 °C 58.7 °F	18.5 °C 65.3 °F	19.7 °C 67.5 °F	19.3 °C 66.8 °F	15.4 °C 59.7 °F	10.5 °C 50.9 °F
Iron Gate	15.1 °C 59.1 °F	18.7 °C 65.6 °F	19.9 °C 67.9 °F	19.5 °C 67.1 °F	15.5 °C 60 °F	10.6 °C 51 °F
	November	**December**	**January**	**February**	**March**	**April**
Copco 1&2	3.5 °C 38.3 °F	2.2 °C 35.9 °F	2.9 °C 37.3 °F	5.9 °C 42.7 °F	9.4 °C 48.9 °F	11.7 °C 53 °F
Iron Gate	3.4 °C 38.2 °F	2.1 °C 35.8 °F	2.9 °C 37.2 °F	5.9 °C 42.6 °F	9.4 °C 48.9 °F	11.5 °C 52.7 °F

Iron Gate and Copco Reservoirs discharge elevated temperature waste, as defined by the *Water Quality Control Plan for Control of Temperature in the Coastal and Interstate Waters and Enclosed Bays and Estuaries of California* (Thermal Plan). The discharge of elevated temperature waste to the Klamath River is prohibited by the Thermal Plan. Furthermore, temperature alterations caused by the reservoirs adversely affect beneficial uses. Thus, there is no allowable temperature increase that can be allocated to waters from Iron Gate and Copco 1 and 2 Reservoirs. Accordingly, the temperature load allocation for these reservoirs equals zero temperature increase above natural temperatures.

The determination of compliance with water quality objectives for temperature is complicated by the fact that under current conditions the temperature of water entering Copco 1 Reservoir (the most upstream California reservoir) carries an anthropogenic heat load from upstream sources. The upstream heat sources are also allocated temperature loads through the State of Oregon's Klamath River TMDL, although these allocations are expected to be achieved gradually over time. Because the upstream heat loads are outside of the control of the dam operators (PacifiCorp), the allocations apply to the condition of the water as it enters the reservoirs.

Another complicating factor is that even without the presence of the reservoirs the Klamath River would be expected to naturally change temperature through the reaches currently occupied by the reservoirs. Thus, to account for natural processes, the temperature load allocation for the reservoirs includes an allowance for natural temperature increases. The allowable temperature increase was developed from model analysis for the year 2000 that predicts the natural temperature increases that would occur through the free flowing river reaches that would exist in absence of the reservoirs.

The temperature increase that would be expected to occur in the reach of the Klamath River occupied by the Copco 1 and 2 Reservoirs is presented in Figure 5.10. These results indicate that the daily average temperature would naturally increase by approximately 0.5 ^{o}C (0.9 ^{o}F) through the Copco reach. Similarly, the results indicate that the daily maximum temperatures occasionally increase by approximately 0.5 ^{o}C (0.9 ^{o}F); however, from approximately June through December the daily maximum temperature would actually decrease through the Copco reach. The increase in daily average temperatures, coupled with a decrease in daily maximum temperatures indicates a reduced daily range of temperatures. The reduced daily range may be due to more topographic shading in this reach in comparison to upstream reaches.

This space intentionally left blank

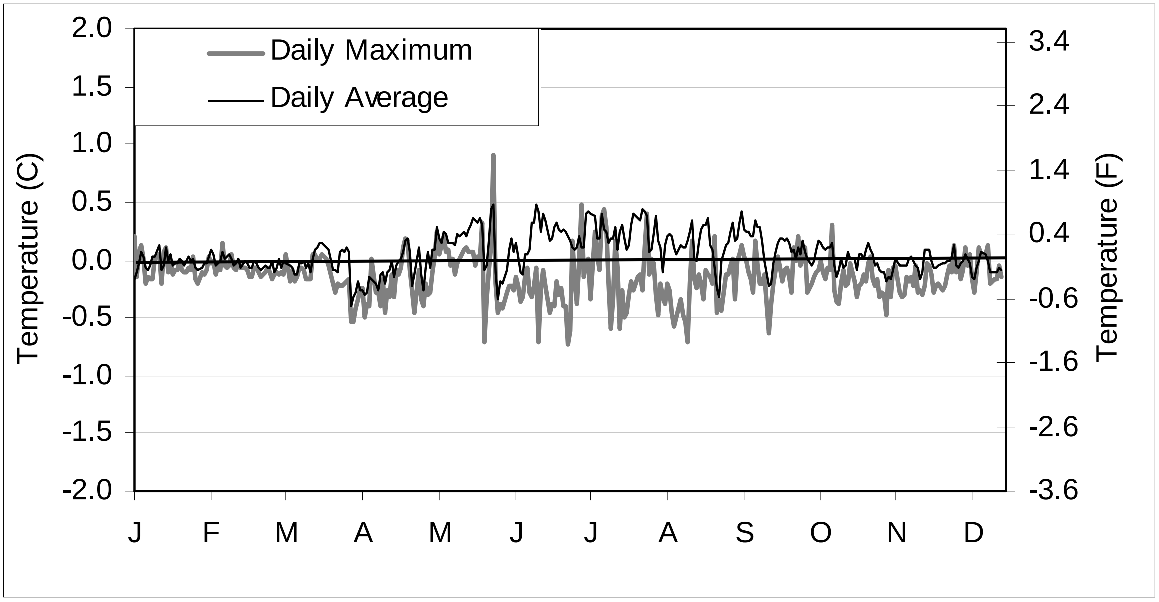

Figure 5.10: Natural temperature change through the Copco Reservoir reaches. Calculated as difference of downstream and upstream[4] daily maximum and daily average temperatures; a positive value indicates warming through the reach.

The temperature increase that would be expected to occur in the reach of the Klamath River occupied by Iron Gate Reservoir is presented in Figure 5.11. These results indicate that the daily average temperature would naturally increase by approximately 0.1 ^{o}C (0.2 ^{o}F) through the Iron Gate reach. Similarly, the results indicate that the daily maximum temperatures would naturally increase by approximately 0.1 ^{o}C (0.2 ^{o}F) in the same reach.

Given that the water quality objectives for temperature do not allow for temperature increases above natural, the water released from Iron Gate and Copco 2 Reservoirs to the Klamath River is allocated temperature increases that correspond to natural temperature increases, as presented in Table 5.5. The temperature allocation is intended to be added to the in-flowing temperature of the river immediately upstream of each reservoir.

This space intentionally left blank

[4] Downstream is at the Copco 2 tailrace location, and upstream is at the inlet to Copco 1.

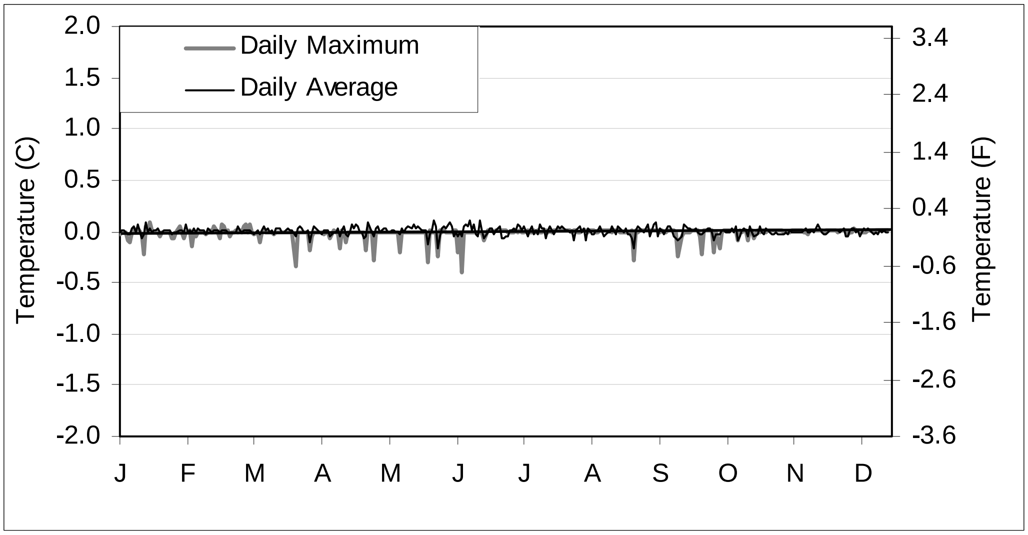

Figure 5.11: Natural temperature change through the Iron Gate Reservoir reach. Calculated as difference of downstream and upstream daily maximum and daily average temperatures; a positive value indicates warming through the reach.

Table 5.5: Temperature load allocations for reservoir tailrace waters, expressed as increase in temperature relative to inflow temperature

Facility	Daily Average	Daily Maximum
Iron Gate	0.1 °C (0.18 °F)	0.1 °C (0.18 °F)
Copco 1 & 2	0.5 °C (0.9 °F)	0.5 °C (0.9 °F)

5.2.4 Temperature Numeric Targets and Waste Load Allocations to Iron Gate Hatchery

The numeric temperature targets assigned to the Iron Gate Hatchery (Table 5.6) are expressed as monthly average temperatures, equal to the temperatures associated with the Klamath River downstream of Iron Gate Dam, and are calculated from the California allocation scenario.

Table 5.6: Temperature numeric targets for Iron Gate hatchery, expressed as monthly averages, based on California allocation scenario results

May	June	July	August	September	October
15.1 °C 59.1 °F	18.7 °C 65.6 °F	20.0 °C 68.0 °F	19.5 °C 67.1 °F	15.6 °C 60.0 °F	10.6 °C 51.0 °F
November	**December**	**January**	**February**	**March**	**April**
3.5 °C 38.2 °F	2.2 °C 35.9 °F	2.9 °C 37.3 °F	5.9 °C 42.7 °F	9.4 °C 48.9 °F	11.5 °C 52.7 °F

The discharge of elevated temperature waste to the Klamath River is prohibited by the state Thermal Plan. Thus, there is no allowable temperature increase that can be allocated to Iron Gate Hatchery. Accordingly, the temperature load allocation for the Hatchery equals zero temperature increase above natural temperatures (see Table 5.6).

5.3 Dissolved Oxygen and Nutrient-Related Numeric Targets and Allocations

This section presents the dissolved oxygen and nutrient-related numeric targets, and load and waste load allocations for the Klamath River by river reach and associated source areas.

5.3.1 Dissolved Oxygen and Nutrient-Related Numeric Targets and Load Allocations at Stateline

The ODEQ has identified the Klamath River in Oregon on its CWA section 303(d) list as failing to meet certain Oregon water quality standards. Accordingly in 2010, ODEQ intends to issue and implement TMDLs addressing chlorophyll-a, dissolved oxygen, and pH impairments for the Klamath River in the state of Oregon. These Oregon-issued TMDLs will be based on the Oregon allocation scenario (see Appendix 7), which is designed to meet Oregon's water quality standards. Because these TMDLs (and their anticipated load allocations and waste load allocations) are being developed by Oregon as part of a comprehensive multistate analysis of pollutant loadings to the Klamath River, they are also being designed to meet California water quality standards at the Oregon/California border. It is appropriate for the Regional Water Board to account for these anticipated upstream load reductions in Oregon when developing the TMDLs for the segments of the Klamath River that are downstream in California. For ease of reference, these anticipated reductions in Oregon-source loads are identified in this TMDL as load allocations at Stateline that reflect anticipated water quality at the Oregon /California border once the Oregon TMDLs are fully implemented. Thus, the load allocations and numeric targets at Stateline reflect an understanding and acknowledgement that improvements in water quality upstream are critical in meeting water quality objectives in California.

Allocation values are based on model output and significant digits have been set based on consideration of analytical method detection limits and criteria / objective reporting requirements. The following convention has been used for each of the following parameters: dissolved oxygen (DO) – tenths of mg/L; nutrients (total nitrogen and total phosphorous) – thousandths of mg/L; and whole units for carbonaceous oxygen demand (CBOD).

The dissolved oxygen targets at stateline are expressed as monthly average and monthly minimum DO concentrations (Table 5.7). These dissolved oxygen targets are consistent with the DO concentrations at Stateline under the Oregon and California allocation scenarios and achieve 85% saturation or better under natural temperature conditions from April 1 through September 30 and 90% saturation or better from October 1 through March 31.

This space intentionally left blank

Table 5.7: Dissolved oxygen numeric targets (mg/L) at Stateline.

	May	June	July	August	September	October
Mean	8.8	8.2	8.2	8.2	8.8	9.6
Minimum	8.1	7.2	7.0	7.1	7.91	8.3
	November	**December**	**January**	**February**	**March**	**April**
Mean	11.5	11.8	11.5	10.5	9.7	9.1
Minimum	10.3	11.3	10.9	10.1	9.2	8.7

Nutrient and organic matter allocations at Stateline are based on the Oregon allocation scenario and are set to control biostimulatory and oxygen consuming effects on DO and to achieve the DO objective/targets at Stateline. These allocations are expressed as monthly mean concentrations (mg/L) for total phosphorous (TP), total nitrogen (TN), and organic matter (CBOD) as shown in Table 5.8.

Table 5.8: Nutrient and organic matter monthly mean concentration (mg/l) allocations at Stateline.

	May	June	July	August	September	October

CBOD[5]	1	1	2	3	3	3

5.3.2 Dissolved Oxygen and Nutrient-Related Numeric Targets and Load Allocations to Klamath Hydroelectric Project Facilities in California

Dissolved oxygen and nutrient-related numeric targets and load allocations are set for the Copco 2 and Iron Gate tailraces as well as for the reservoirs themselves.

This space intentionally left blank

[5] The Method Detection Limit (MDL) and Reporting Limit (RL) for CBOD are equal at 3 mg/L. These levels are operationally defined and do not vary between laboratories. Option 1) Analytical results of CBOD will be assessed using a 3-month running average for compliance evaluation against concentration targets. Analytical results reported as below the MDL will be assessed at one-half the MDL (i.e., 1.5 mg/L). Option 2) Analytical results reported below the MDL for CBOD will be assumed to represent one-half the MDL (i.e., 1.5 mg/L). This assumption is commonly used in water quality assessment (Helsel and Hirsch, 1992). Alternatively, assessment of compliance with CBOD targets can be conducted using the concentration of Total Organic Carbon (TOC). The target concentrations were derived using a conversion factor applied to particulate and dissolved organic matter. Analytical results of TOC can be converted to an equivalent concentration of CBOD using these conversions.

5.3.2.1 Copco 2 and Iron Gate Reservoir Targets

Copco 2 and Iron Gate tailrace targets for dissolved oxygen are calculated from the California allocation scenario, and are expressed as monthly mean and monthly minimum DO concentrations (Table 5.9).

Table 5.9: Dissolved oxygen numeric targets (mg/l) for Copco 2 and Iron Gate tailraces

Copco 2 Tailrace						
	May	**June**	**July**	**August**	**September**	**October**

Mean	11.7	12.1	11.7	10.7	9.8	9.3
Minimum	10.5	11.6	11.2	10.3	9.2	8.6

Numeric targets for nutrients (TP and TN) and organic matter (CBOD) are established for the tailraces of Copco 2 and Iron Gate (Table 5.10). These nutrient and organic matter targets are based on the with-dam TMDL scenario and are established at the monthly mean concentrations that coincide with meeting the in-reservoir chlorophyll-a summer mean target of 10 µg/L, *Microcystis aeruginosa* cell density target of 20,000 cells/mL, and microcystin target of 4 µg/L. See Section 2.3.2.2 for detailed background information regarding the selection of these numeric targets.

In addition, Table 7.9 in Section 7.8 (Chapter 7 – Reassessment and Monitoring Program) includes monthly mean nutrient (TP and TN) and organic matter (CBOD) “trigger” concentrations at the tailrace of Iron Gate. These nutrient and organic matter “trigger” concentrations are based on the California allocation scenario, which represents conditions that comply with water quality standards without dams. As discussed in Section 7.8, nutrient and organic matter conditions, as well as other measures of riverine productivity, should be assessed over time at Iron Gate tailrace and locations downstream, and compared relative to the trigger concentrations at Iron Gate tailrace.

5.3.2.2 Klamath Hydroelectric Project Nutrient Load Allocations

Allocations for nutrients (TP and TN) are assigned to the Klamath Hydroelectric Project facilities in California in order to achieve the in-reservoir chlorophyll-a, *Microcystis aeruginosa* and microcystin numeric targets. These allocations are based on the with-dams TMDL scenario, and are to be achieved at a location upstream of Copco 1. These annual allocations (see Figure 5.1) equal:

- 67,048 pounds TP/year;
- 1,025,314 pounds TN/year;

and equate to the following annual reductions below the nutrient allocations at Stateline:

- 22,367 pounds TP/year;
- 120,577 pounds TN/year.

These allocations or alternative pollutant load reductions and/or alternative management measures or offsets are necessary to: 1) meet the Basin Plan narrative toxicity objective (and the associated chlorophyll-a, *Microcystis aeruginosa*, and microcystin numeric targets), 2) meet the narrative biostimulatory substances objective (and the associated TP and TN targets), and 3) support the REC-1; REC-2, and CUL beneficial uses of the river system with Copco 1, Copco 2, and Iron Gate Reservoirs in place.

Figures 5.12, 5.13, and 5.14 present annual TP, TN, and organic matter (CBOD) loads downstream of Iron Gate Reservoir based on the following model scenarios: current conditions; California allocations scenario conditions; with-dam TMDL scenario condition; and natural conditions baseline. These figures demonstrate that larger nutrient reductions are needed in order to achieve water quality standards with the Klamath

Hydroelectric Project facilities in California in place. Alternative pollutant load reductions and/or alternative management measures or offsets that result in achieving the in-reservoir chlorophyll-a, *Microcystis aeruginosa*, and microcystin numeric targets may be proposed to the Regional Water Board for approval.

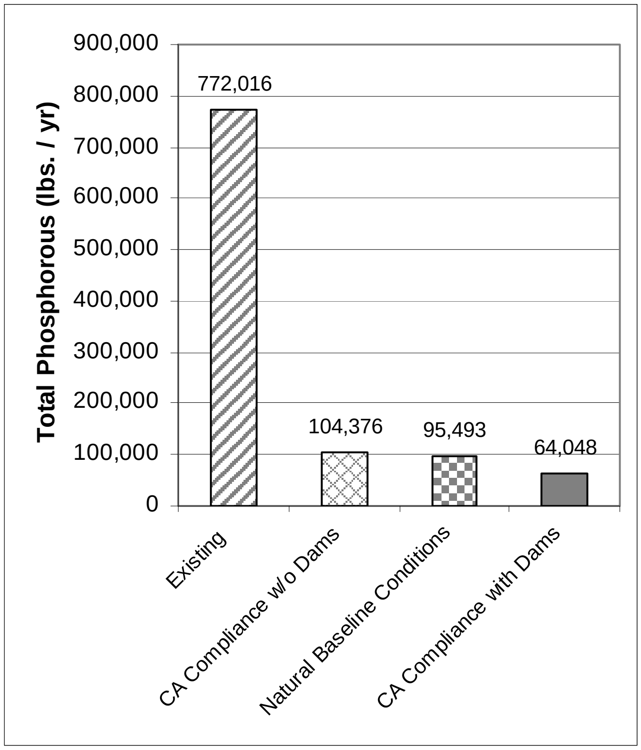

Figure 5.12 Loading condition comparison below Iron Gate Dam for total phosphorus

This space intentionally left blank

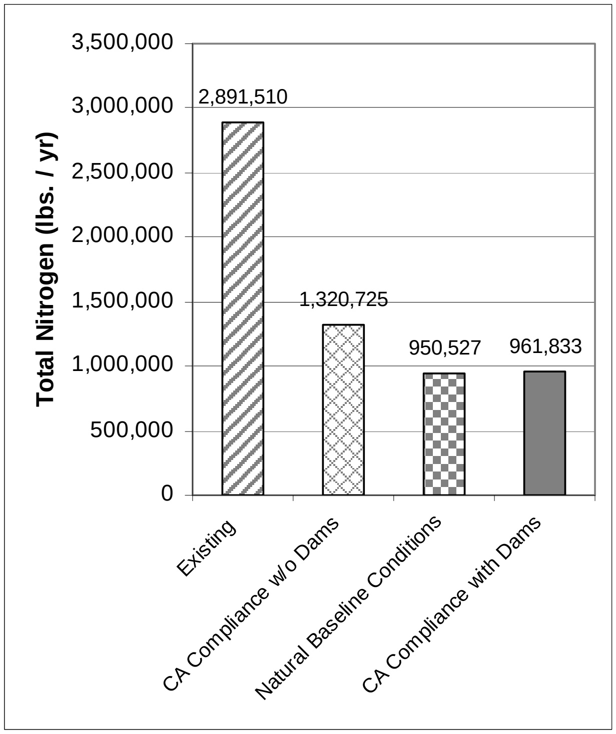

Figure 5.13 Loading condition comparison below Iron Gate Dam for total nitrogen

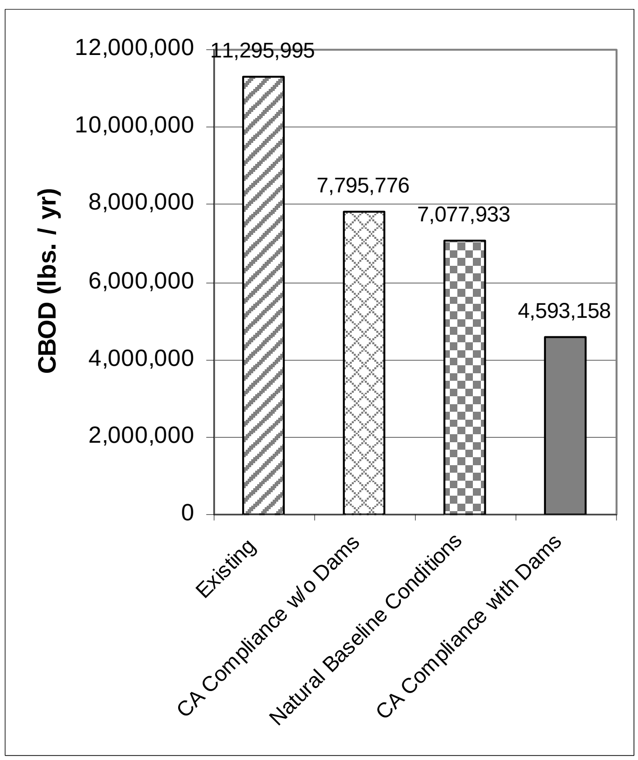

Figure 5.14 Loading condition comparison below Iron Gate Dam for CBOD

Achievement of the nutrient and organic matter allocations at Stateline and the Klamath Hydroelectric Project nutrient allocations will not result in compliance with the DO and temperature targets within Copco 1 and 2 and Iron Gate Reservoirs during periods of thermal stratification. Therefore, additional temperature and dissolved oxygen load allocations are assigned to the reservoirs for the period of May through October to ensure compliance with the DO and temperature targets within the reservoirs, and ensure support of COLD. The temperature and DO allocations for waters within Copco 1 and 2 and Iron Gate Reservoirs are dual allocations, wherein achievement of the water quality objective for temperature must co-occur with dissolved oxygen conditions. Allocations for dissolved oxygen and temperature are intended to create a "compliance lens" where both DO and temperature conditions meet Basin Plan objectives for water temperature and DO and are therefore protective of COLD and MIGR. The concept of the compliance lens where both DO and temperature objectives are met is illustrated in Figure 5.15.

The allocation is for the critical period of May through October and requires that DO concentrations consistent with 85% saturation or better through September and 90% or better in October (based on natural receiving water temperatures) co-occur with temperatures consistent with natural water temperatures (natural baseline summer mean is ~18.7^{o} C) from the point of entry to the reservoirs within a lens and throughout the reservoir.

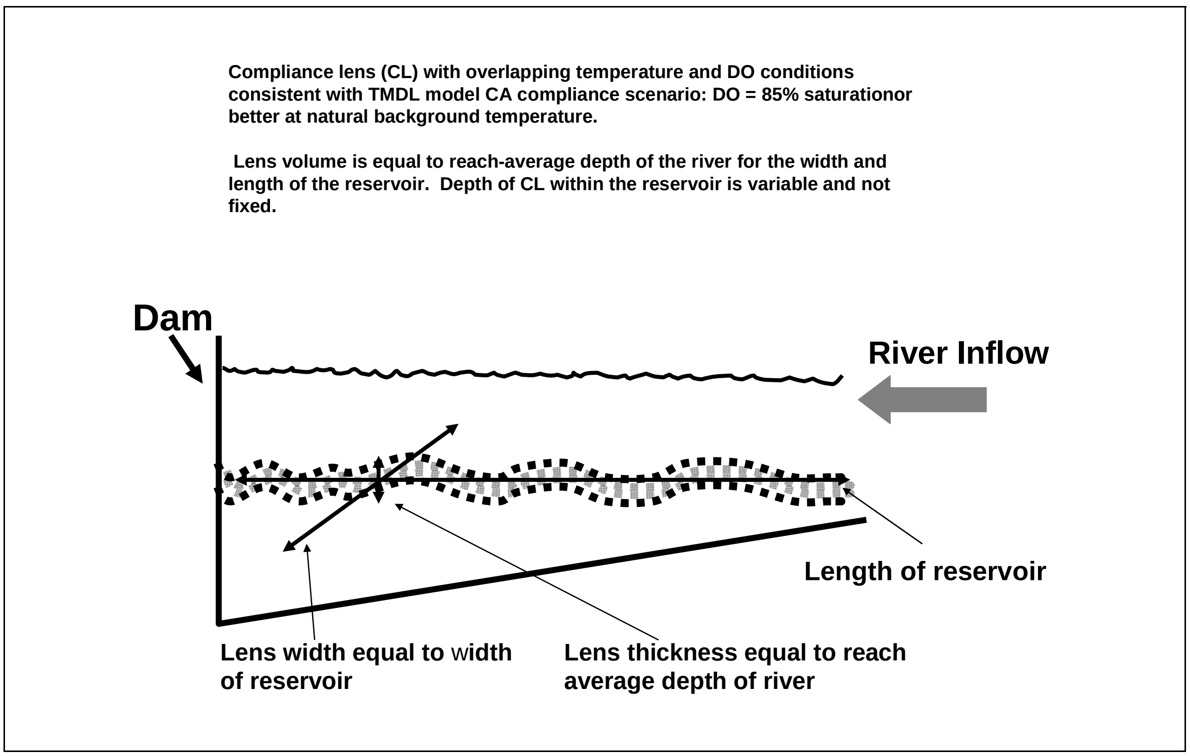

Figure 5.15: Illustrated conceptual model of reservoir compliance lens for temperature and dissolved oxygen

The volume of each reservoir compliance lens is equal to the average hydraulic depth of the river in a free-flowing state for the width and length of the reservoir. The depth at which the compliance lens occurs within the reservoirs will vary, as will an instantaneous mass of DO required to meet the allocation.

Alternative in-reservoir temperature and DO conditions that provide equal or better protection of COLD and MIGR within Copco 1, Copco 2, and Iron Gate Reservoirs may be proposed for Regional Water Board approval.

5.3.3 Dissolved Oxygen and Nutrient-Related Numeric Targets and Waste Load Allocations to Iron Gate Hatchery

The DO targets for Iron Gate Hatchery discharge are monthly mean and monthly minimum DO concentrations (Table 5.11). The targets apply to the Iron Gate Hatchery discharge location just above the mouth of Bogus Creek. The target concentrations were calculated from the California allocation scenario, and reflect compliance DO conditions immediately downstream of Iron Gate Dam.

Table 5.11: Dissolved oxygen numeric targets (mg/L) for Iron Gate hatchery discharge

	May	**June**	**July**	**August**	**September**	**October**
Mean	8.8	8.2	8.2	8.2	8.8	9.7
Minimum	7.9	7.2	6.9	6.8	7.8	8.4
	November	**December**	**January**	**February**	**March**	**April**
Mean	11.6	12.0	11.7	10.7	9.8	9.3
Minimum	10.5	11.6	11.2	10.3	9.2	8.6

The waste load allocation to the Iron Gate Hatchery is zero net increase of nutrient and organic matter loads in the river above California dissolved oxygen compliance conditions (i.e. with no dams). Table 5.12 presents the Iron Gate Hatchery nutrient and organic matter targets, expressed as monthly mean concentrations. These concentration targets reflect California allocation scenario conditions above the confluence with Bogus Creek.

Table 5.12 Nutrient and organic matter monthly mean concentration targets (mg/L) for Iron Gate hatchery based on California allocation scenario conditions

CBOD[5]	1	1	2	2	2.	2

This space intentionally left blank

5.3.4 Dissolved Oxygen and Nutrient-Related Numeric Targets and Load Allocations to California Tributaries

The primary targets associated with California tributary nutrient and organic matter loadings are dissolved oxygen concentrations within the Klamath River mainstem. The monthly mean and monthly minimum DO targets are calculated from the California allocation scenario. The primary DO target compliance location is located downstream of the Salmon River immediately upstream of the boundary of the Hoopa Valley Indian Reservation; these targets are presented in Table 5.13.

Table 5.13: Dissolved oxygen numeric targets (mg/l) for the Klamath River mainstem below the Salmon River

	May	June	July	August	September	October
Mean	9.7	8.9	8.3	8.2	8.8	9.7
Minimum	8.9	8.0	7.5	7.4	8.0	9.0
	November	**December**	**January**	**February**	**March**	**April**
Mean	11.7	12.2	12.2	11.6	11.2	11.7
Minimum	10.7	11.7	11.8	11.2	10.5	10.7

Nutrient and organic matter numeric targets are also set for the Klamath River mainstem downstream of the Salmon River. The TP, TN, and CBOD numeric targets are expressed as monthly mean concentrations (mg/L); consistent with the California allocation scenario (Table 5.14).

A reach-averaged maximum density periphyton biomass numeric target of 150 mg of chlorophyll-a / m^2 is established for the Klamath River mainstem downstream of the Salmon River. This value was developed through the California NNE analysis for the Klamath River[6] (Appendix 2).

Nutrient (TP and TN) and organic matter (CBOD) allocations for the minor California tributaries to the Klamath River are set as monthly mean concentrations that apply year-round. The Shasta, Scott, Salmon, and Trinity River nutrient and organic matter allocations are monthly mean concentrations, but are different for wet (November

---

[6] Compliance with this target shall be assessed by calculating the average periphyton chlorophyll-a from not less than ten samples collected within the Klamath River downstream of the Salmon River and upstream of the Trinity River.

through April) and dry (May through October) seasons. These allocations are calculated from the California allocation scenario, and are summarized in Tables 5.15 and 5.16. The Shasta River TN, TP, and CBOD allocations are consistent with the existing approved Shasta River TMDL. No additional load reductions are required from the Shasta River.

Table 5.15: Nutrient and organic matter seasonal monthly mean concentration allocations (mg/l) for tributaries to the Klamath River

CHAPTER 6. IMPLEMENTATION PLAN

6.1 Introduction

The Klamath TMDL establishes the allowable loadings or other quantifiable parameters for a waterbody that is the total permissible pollutant load that will achieve water quality standards. This “loading capacity” provides a reference for calculating the amount of pollutant reduction needed to bring a waterbody into compliance with water quality standards or designated uses. The TMDL identifies and assigns allocations to all sources of pollution, including waste load allocations to point sources and load allocations to nonpoint sources (40 CFR § 130 .2(i)). The rationale for the allocations and targets is provided in detail in Chapters 2 through 5 of the TMDL Staff Report.

The TMDL Program is the primary program responsible for achieving clean water where traditional controls on point sources have proven inadequate to do so. The program is charged with developing implementation plans that consider all sources and causes of impairment, and allocating responsibility for corrective measures that will attain water quality standards. This chapter of the staff report describes the Klamath TMDL implementation plan that implements the TMDL load allocations in the Klamath River basin in California pursuant to Water Code section 13242. This implementation plan includes measures in the Lost River basin and constitutes the implementation plan for the Lost River TMDL promulgated by the USEPA in 2008. It also implements site-specific water quality objectives for dissolved oxygen that were developed in conjunction with the Klamath TMDL (Appendix 1).

In developing the implementation plan, the Regional Water Board staff considered the nature of the discharges in the Klamath River basin as well as existing efforts to protect and restore water quality in the basin. The implementation plan proposes discrete and identifiable implementation measures that will bring the waterbody into compliance and it identifies the parties responsible for implementing those measures. It also describes the Regional Water Board’s current regulatory strategy for controlling pollutant sources, recommends improvements to existing regulatory controls, and describes the recommended approach to controlling pollutant sources where traditional implementation controls may not apply or where the Regional Water Board lacks implementing jurisdiction. The plan sets time schedules by which the responsible parties will implement their compliance measures and also includes a monitoring plan to track progress towards compliance. The progress of the implementation plan will be tracked through basinwide monitoring of water quality trends as well as through discharger reporting of compliance measures. The Regional Water Board will make any necessary revisions to the implementation plan as needed to achieve water quality standards within a reasonable timeframe. Reassessment and monitoring of the TMDL is discussed in Chapter 7.

Restoration of water quality of the Klamath River requires coordinated basinwide implementation of TMDLs. The implementation plan includes the following measures to achieve this goal:

- A Memorandum of Agreement to coordinate implementation with the Oregon Department of Environmental Quality
- Development of an Memorandum of Agency Agreement with the US Bureau of Reclamation, US Fish and Wildlife Service, and Tulelake Irrigation District
- Measures to address the water quality impacts from the Klamath Hydroelectric Project
- Incorporation of Klamath TMDL requirements into point and nonpoint source permits as appropriate, including timber harvest permits and region-wide permits for Caltrans and the USFS
- Certification of the Five County Salmonid Protection Program to address sediment discharges from county roads
- Development of a conditional waiver by 2012 for discharges associated with agricultural activities, including grazing and irrigated agriculture.
- Adoption of a 'Thermal Refugia Protection Policy'
- Prohibition against unauthorized discharge of waste that violate water quality standards

6.1.1. Geographic Scope

Load allocations and targets are assigned to source categories on the mainstem Klamath, minor tributaries, and the mouths of major tributaries. The technical analysis does not include the Butte Valley Hydrologic Area. Major tributaries are not assigned temperature allocations because the Scott, Shasta and Salmon River watershed already have assigned allocations, and the Lost and Trinity are not listed as impaired for temperature. In contrast, the geographic scope of the implementation plan includes the entire Klamath Basin, and the plan also includes the implementation plan for the Lost River. The Regional Water Board may apply any existing authorities available in a basin plan amendment, and is not necessarily constrained by the scope of the technical TMDL process. Applying the scope of implementation to the entire Klamath basin allows for better coordination with existing programs and permits that may be working to improve water quality basinwide. Load allocations must be enforced through permitting mechanisms and incorporating TMDL implementation into a more broad based nonpoint source approach increases efficiency and consistency in regulation. Often the same types of management measures are needed to address water quality under the core regulatory nonpoint source program with or without the presence of the TMDL allocations. Where possible, it is sensible to combine water quality requirements under one permitting structure.

Staff received comments regarding implementation measures for agriculture, including the development of a basinwide conditional waiver as proposed in the previous drafts. While the recommendation to develop an agricultural waiver remains in this draft, the interim requirements on agriculture were removed, including the interim requirement to develop water quality and ranch management plans. Stakeholders requested the opportunity to develop regulatory measures for agriculture through a local stakeholder process. In response, Regional Water Board staff agree to focus staff resources on development of a locally supported program to address agriculture basinwide. The development of the waiver will proceed through a public stakeholder process and be considered for adoption by 2012. In the meantime, the implementation plan includes interim recommendations for landowners to take in anticipation of the future agricultural water quality program. The Regional Water Board will consider whether to extend existing TMDL waivers in the Scott and Shasta with or without revisions or whether to or incorporate them into the proposed agricultural waiver as part of the Scott and Shasta waiver renewal process.

6.1.2 Coordination with Oregon

Achieving compliance with the Klamath River TMDLs in California and Oregon will require a coordinated approach that involves state and federal agencies as well as responsible parties in both states. To this end, the Regional Water Board, Oregon Department of Environmental Quality (ODEQ), and USEPA Regions 9 and 10 have signed a Memorandum of Agreement (MOA) for implementing the Klamath River basin TMDLs.

Coordinating implementation will focus restoration and regulatory programs on both short-term and long-term goals for the basin. The regulatory process will accommodate short-term measures working in concert with longer-term programs to achieve full compliance over a longer time frame. Short-term measures are needed to immediately lessen the threat to cold water fishery and tribal cultural beneficial uses, among others. Regional Water Board staff encourage implementation of large scale, centralized projects designed to reduce nutrient loads to the Klamath River in Oregon and California. Fundamental for the control of nutrient loads to the Klamath River is coordinating with the U.S. Bureau of Reclamation (USBR) to address discharges from the Klamath Project. To this end, Regional Water Board staff propose development of a Memorandum of Agency Agreement with USBR to control discharges to the Klamath River. In addition, Regional Water Board staff are working with ODEQ and USEPA Regions 9 and 10 in cooperation with PacifiCorp to develop a Klamath basin water quality improvement tracking and accounting program. As planned, this program will provide a mechanism that would allow for collaboration among basin stakeholders on common projects while earning credit towards their regulatory requirements related to TMDLs (See Section 6.7).

6.1.3 Klamath Hydroelectric Project, Klamath Basin Restoration Agreement, and Dam Removal Agreement

The Klamath River TMDLs assign load allocations and targets at levels necessary to achieve water quality standards, including the recalculated SSO for DO as presented in Appendix 1, within the Klamath Hydroelectric Project (KHP) area. Regulation and enforcement of the TMDL allocations is traditionally through the State Water Board water quality certification process that accompanies renewal of a license issued by the Federal Energy Regulatory Commission (FERC). As described in more detail below, certain parties have been engaged in settlement negotiations that contemplate the voluntary removal of the KHP. Because the regulatory process and outcome of the settlement negotiations is largely outside of the Regional Water Board's control, the Klamath River TMDL implementation plan accommodates various alternatives by allowing the use of offsets focused on offsite nutrient reduction for an interim period while options for infrastructure improvements and dam removal are studied.

The Klamath Basin Restoration Agreement (KBRA) is a negotiated settlement agreement among as many as 26 different parties and is designed to settle long-standing disputes in the Klamath River basin. It focuses on water allocations in the upper basin, provides for fisheries restoration, and is structured around the central assumption that an agreement to remove the lower four Klamath River dams will be reached. On November 13, 2008, an Agreement in Principle (AIP) to remove four Klamath River dams was announced after negotiations among representatives of the federal government, the state of California[1], the state of Oregon, and PacifiCorp. The Regional Water Board was not a party to the KBRA nor AIP negotiations. A draft of the final Klamath Hydroelectric Settlement Agreement (KHSA) was released on September 30, 2009. Settlement Parties contemplate federal legislation that would indefinitely delay the relicensing process before the FERC and accompanying Clean Water Act section 401 permitting process before the SWRCB. (See section 6.5 of the draft Agreement [Abeyance of Relicensing Proceeding].) The Regional Water Board staff provided input to the KHSA parties on appropriate interim water quality measures and regulatory pathways for TMDL compliance.

6.1.4 Nonpoint Source Land Use Activities and Controls

Implementation actions taken to achieve load allocations must be consistent with the *Policy for Implementation and Enforcement of the Nonpoint Source Pollution Control Program* (State NPS Policy). This policy requires that "all current and proposed nonpoint source discharges must be regulated under waste discharge requirements (WDRs), waivers of WDRs, a Basin Plan prohibition, or some combination of these tools (Regional Water Board 2007, p.4-33.00)." For some pollutant sources, the method of compliance with this policy is already in place, and if it is determined to be sufficient, no further action by the Regional Water Board is necessary. However, if the source is currently unregulated, or the current permits, waivers and/or prohibitions are not sufficient to attain the TMDL, a means to comply with the State NPS Policy must be proposed as part of the implementation plan. The Regional Water Board may also certify existing pollution control programs as sufficient to implement the Klamath TMDL if it can make the following findings:

This space intentionally left blank

[1] State of California is defined as the State of California Resources Agency and its constituent departments and excludes all other state agencies, departments, boards and commissions. The Regional Water Board is not a constituent department under the Resources Agency.

1. the implementing program is consistent with the assumptions and requirements of the TMDL;
2. sufficient mechanisms exist to provide reasonable assurances that the program will address the impairment in a reasonable period of time; and
3. sufficient mechanisms exist to ensure that the program will be enforced, or that the Regional Water Board has sufficient confidence that the program will be implemented such that further regulatory action would be unnecessary and redundant.

The threats to water quality from nonpoint source activities in the Klamath River basin are mainly associated with timber harvest, roads, grazing, and irrigated agriculture on private and federal lands. The implementation plan focuses on reducing nutrient loading in the upper basin, controlling sediment discharges, and protecting riparian vegetation in the tributaries downstream of Iron Gate Dam in accordance with the technical TMDL allocations. In response to numerous comments received, staff have removed interim requirements on individual landowners and operators discharging waste associated with agriculture, grazing and roads not already covered by a permit or waiver in lieu of incorporating TMDL implementation into basin and/or region wide nonpoint source programs for efficiency and consistency.

To protect against serious and significant individual threats to water quality, staff propose the adoption of a prohibition against discharges of waste that violate water quality standards. This prohibition is a restatement of existing law and is not intended to provide a nonpoint source program that implements measures to control the cumulative impact of individual nonpoint source discharges of waste. Individuals who believe they may need permit coverage for their discharges should contact the Regional Water Board and inquire about obtaining an individual permit. Also in response to numerous comments from individual landowners, staff has removed the conditional sediment prohibition that included requirements to control sediment discharges. The implementation plan now provides Guidance on the Control of Excess Sediment that will help address sediment sources in the Klamath River basin. The implementation plan also proposes a Thermal Refugia Protection Policy that provides enhanced protection of thermal refugia in specific locations on the Klamath mainstem.

With the exception of existing waste discharge requirements (WDRs) and waivers for timber harvest and TMDL waivers adopted as part of the Scott and Shasta River TMDLs, the Regional Water Board has not adopted a regulatory program for discharges of nonpoint source pollution as required by the State Nonpoint Source Policy. To address this and other gaps in regulation, the implementation plan recommends development of nonpoint source programs for controlling discharges from land use activities that discharge waste and contribute to the water quality impairments. It is the Regional Board staff recommendation to enforce TMDL requirements through basinwide and regionwide programs where possible, rather than piecemeal various requirements in each TMDL action plan. Table 6.1 provides an overview of Regional Water Board staff recommendations of regulatory mechanisms to implement the TMDL allocations in the Klamath River basin in California.

Table 6.1: Existing and proposed permitting

Nonpoint Source Regulatory Mechanism	Existing/New (Timeframe)	Responsible Party
Timber Harvest WDRs and waiver on Nonfederal lands	Existing	All parties conducting timber harvest activities on nonfederal lands in the Klamath River basin
Waiver for nonpoint source discharges associated with certain activities on lands managed by the USFS	New (2010)	USFS
Waiver for discharges associated with agriculture including irrigated agriculture and grazing	New (2012)	Parties discharging in association with agricultural activities in the Klamath River basin in California
Waiver Certifying 5C Program for County Roads	New (2010)	Del Norte, Humboldt, Siskiyou, and Trinity Counties
Statewide NPDES Stormwater Permit for Caltrans Activities	Existing	Caltrans

6.1.5 Implementation Plan Development and Consideration of Relevant Factors

On February 19, 2009, the Regional Water Board circulated a draft scoping document for TMDL implementation called the *Water Quality Restoration Plan for the Klamath River Basin in California: Draft Scoping for TMDL Implementation* (Regional Water Board 2009). Regional Water Board staff held five public workshops where an overview of the impairments and potential implementation measures was provided. The document includes an overview of draft load allocations, identifies potential responsible parties, and potential permitting and other applicable implementation mechanisms. The document discusses implementation challenges of controlling sources where traditional controls may not apply or where the Regional Water Board lacks implementing jurisdiction. Readers were encouraged to provide Regional Board staff with any relevant information on implementation, including, but not limited to:

- source inputs not previously identified,
- current efforts to address the TMDL pollutants and any documented success of such efforts,
- other programs that could be incorporated into an implementation plan strategy,
- how to maximize the efficiency of implementation strategies for water quality improvement,
- benefits and burdens of different implementation approaches,
- suggestions for tracking implementation and progress towards meeting water quality standards (i.e. compliance and trend monitoring), and
- potential restoration ideas and other creative solutions for improving water quality in the Klamath Basin.

Regional Water Board staff received numerous submittals that helped inform the development of the proposed implementation plan and received additional input from stakeholders on the June draft Staff Report documents.

This implementation plan reflects the consideration and balancing of various relevant factors including, cost, equity, magnitude of impact, degree of management controls in place, feasibility, and probability of success. For example, the plan acknowledges that the allocation at stateline will require an unprecedented level of cooperation between the states and federal government to achieve pollutant loading reductions necessary to meet water quality objectives and support beneficial uses in both states. Focus on implementation in Oregon is equitable considering its large contribution to the Klamath impairments. This led to the formation of a Management Agency Agreement with Oregon and EPA to help coordinate implementation, including implementation in the Lost River basin. This approach is guided by feasibility, degree of management controls in place, probability of success, political and other considerations.

In addition, the plan proposes structuring a pollutant Tracking and Accounting Program to encourage the implementation of engineered treatment options. The program is intended to provide some flexibility to implementation through the allowance of offsets and time schedules and will consider engineering constraints, costs, feasibility, and other factors. Rather than implement very costly retrofits that may not yield large improvements to overall water quality, contributions toward coordinated restoration efforts are encouraged to maximize water quality improvements through resource consolidation.

The Regional Water Board recognizes that the Klamath Hydroelectric Project will undergo one of two possible processes; either the FERC relicensing and 401 Water Quality Certification process, or the KHSA route. Each are driven by concerns in addition to water quality and will necessarily be decided by a different agency after thorough analyses. The implementation plan allows PacifiCorp to submit a proposed plan that accommodates the possible regulatory processes which reflects staff's consideration of legal feasibility and management controls in effect.

Finally, in this most recent draft, the implementation plan provides a more coordinated and consistent approach to nonpoint source pollution control in response to comments from individual landowners and in order to more effectively address water quality problems. This plan removes additional interim nonpoint source requirements on individual landowners and instead proposes the development of a sensible agricultural waiver, in collaboration with stakeholders. Where possible, staff identifies requirements by other agencies that meet TMDL needs in order to consolidate monitoring and avoid inconsistent terminology. Parties are encouraged to submit any additional and specific information for the Regional Water Board's consideration in this third opportunity for public review of the Klamath TMDL.

This space intentionally left blank

6.1.6 Implementation Plan Organization

This implementation chapter is organized according to the source areas identified in the technical TMDL. Each section provides a summary of the load allocations and targets for that source area, identifies the parties responsible for meeting those allocations, and discusses the Regional Water Board staff's approach to implementation and recommended implementation actions for the responsible parties.

The source areas receiving allocations and targets are:

1. Stateline (section 6.2)
2. Klamath Hydroelectric Project (KHP) and Iron Gate Hatchery (section 6.3)
3. Klamath River tributaries (section 6.4)
4. Watershed-Wide Nonpoint Source Land Use Activities (sections 6.5 and 6.6)

The presentation of the watershed-wide implementation actions in section 6.5 begins with a description of actions to address watershed-wide temperature allocations, proposed Prohibition on discharges of waste that violate water quality standards, and the Thermal Refugia Protection Policy, followed by discussion of the following land use activities:

- Road construction and maintenance;
- Agriculture including grazing and irrigation agriculture; and
- Timber harvest.

Implementation actions associated with all land use activities on federally managed lands are presented in section 6.6. The Klamath River water quality improvement Tracking and Accounting Program is described in section 6.7.

6.2 Stateline

The Oregon-California stateline (Stateline) is the point at which the Klamath River crosses the Oregon-California border, and is designated as a compliance point in the Klamath TMDL. The pollutant loads in the Klamath River entering California are the result of loadings in Oregon, including the Lost River basin, which is partially in California. Nutrient loads in the Klamath River at stateline originate mainly from Upper Klamath Lake, as well as from the Lost River basin through the Klamath Straits Drain and Lost River Diversion Channel, and to a lesser extent from point sources in Oregon. Nutrients coming from these sources contribute to DO and pH swings downstream, as well as to aquatic plant growth within the river and blue-green algae blooms within the Copco and Iron Gate reservoirs in California.

6.2.1 Allocations and Targets

The ODEQ has identified the Klamath River in Oregon on its CWA section 303(d) list as failing to meet Oregon water quality criteria. Accordingly, in 2010, ODEQ intends to issue and implement TMDLs addressing temperature, dissolved oxygen, pH, ammonia, and chlorophyll-a impairments for the Klamath River in the state of Oregon. These Oregon-issued TMDLs will be based on Oregon's water quality standards. Because these TMDLs (and their anticipated load and wasteload allocations) are being developed by Oregon as part of a comprehensive multistate analysis of pollutant loadings to the Klamath River, they are also being designed to meet California water quality standards at stateline. It is appropriate for the Regional Water Board to account for these anticipated upstream load reductions in Oregon when developing the TMDLs for the segments of the Klamath River that are downstream in California. The Regional Water Board's Klamath River TMDLs for California assign nutrient, organic matter, and temperature allocations, as well as temperature and dissolved oxygen targets at stateline. These allocations and targets at stateline are presented in sections 5.2.2 and 5.3.1 and reflect anticipated water quality at stateline once the Oregon TMDLs are fully implemented. Improvements in water quality in Oregon represent a critical part of the solution in meeting water quality objectives in California.

6.2.2 Responsible Parties

Point and Nonpoint Sources in Oregon and Lost River basin in California
Regional Water Board
Oregon Department of Environmental Quality
Oregon Department of Agriculture
USEPA Regions 9 and 10

6.2.3 Implementation

6.2.3.1 Oregon

Consistent with Oregon Administrative Rules (OARs), ODEQ is responsible for developing an implementation plan, called a Water Quality Management Plan (WQMP), to meet the Klamath and Lost River TMDLs in Oregon. The OARs establish the required elements of WQMPs, which include the following:

- Identification of management measures to meet load allocations;
- A timeline for implementation with measureable milestones;
- A timeline for attainment of water quality standards;
- A monitoring plan; and
- General discussion of costs and funding for implementation.

The OARs also require the WQMP to identify persons and agencies responsible for implementation; as well as provide reasonable assurance that implementation will occur through either regulatory or voluntary means. A main difference between TMDL implementation planning in Oregon and California is that ODEQ does not specify the nature of the actions responsible parties are expected to take and is not charged with enforcing the TMDL load allocations and targets directly. Instead, ODEQ implementation plan designates management agencies (DMAs) that must develop 'sector or source specific' implementation plans (also called WQMPs) that meet the TMDL load allocations. DMAs designated in ODEQ's TMDL will likely include USBR, Oregon

Department of Agriculture, and the Irrigation Districts. The WQMPs are subject to approval by ODEQ, but the DMAs maintain the primary authority to enforce the measures in those plans.

Oregon Department of Agricultural (ODA) fulfills its requirement to develop a WQMP pursuant to an existing program established by Oregon Senate Bill 1010. SB 1010 requires ODA to develop administrative rules specific to hydrologic 'subareas' in Oregon. The administrative rules describe water quality requirements for landowners and consist of a description of the subarea, a list of unacceptable water quality conditions, and a process for complaints and investigations. The unacceptable conditions include excessive sheet and rill erosion and downward trending riparian conditions as defined by US Bureau of Land Management (BLM) technical guidelines. Landowners are also prohibited from degrading stream shading consistent with site capability – similar to the California riparian shade allocation.

Landowners are directed by Oregon Senate Bill 1010 to develop Agricultural Water Quality Management Plans that implement the administrative rules and control water pollution resulting from agricultural activities. A Local Advisory Committee typically represents the landowners in development of both the area administrative rules and the management area plans with oversight by ODA. The area management plans include provisions for ODEQ to work with ODA to monitor progress towards plan implementation including the effectiveness of the plan in meeting applicable TMDL load allocations. The rules are enforceable, while the plans are not. The plan in the Lost River basin in Oregon is called the Lost River Subarea Agricultural WQMP and is implemented by the Klamath Soil and Water Conservation District.

ODA maintains primary authority to regulate agriculture to protect water quality. Since ODEQ authority is secondary, it is important for ODA to effectively use its authority in order to achieve the Klamath and Lost River TMDL load allocations and targets in Oregon with oversight by ODEQ. The strength of Oregon's agricultural water quality management program is its focus on landowner driven efforts. By working with the KSWCD in the Lost River basin, landowners have already implemented management measures and water quality improvement projects that address the TMDL pollutants. It is important for ODA to continue to use its authority as appropriate to achieve the Klamath and Lost River TMDL load allocations and targets in Oregon. Regional Water Board staff support the following measures to coordinate the Oregon SB 1010 water quality program with TMDL implementation:

- Update the Oregon Administrative Rules for the Lost River subbasin Area to address nutrients and organic matter in irrigation tailwater;
- Incorporate TMDL implementation measures and timelines into the Lost River Agricultural Water Quality Management Plan;
- Conduct water quality monitoring to track the progress of TMDL implementation towards meeting allocations and targets; and

- Periodic review by ODA and ODEQ to ensure the TMDL requirements are being met.

6.2.3.2 Regional Water Board's Role

The Regional Water Board intends to work closely with ODEQ and ODA in implementing the Klamath and Lost River TMDLs. One of the purposes of coordination with Oregon is to align each state's approach to controlling nonpoint sources of pollution. Currently, the major difference between the states is the regulatory framework and the enforcement authorities of the water quality control agencies in each state. In California, the Regional Water Board is required by the State NPS Policy to regulate all sources of waste, including agricultural activities, directly through permits, waivers and/or prohibitions, as discussed in section 6.1.4. The Regional Water Board has broad enforcement capabilities to ensure compliance with the terms and conditions of permits and prohibitions. While the Regional Water Board's regulatory authority is broader than ODEQ's, the implementation measures required to achieve the TMDL are similar in both states. For the USBR and USFWS, the implementation plan measures include an evaluation and implementation of methods to reduce the water quality impacts of the operation of the U.S. Bureau of Reclamation's Klamath Project and the Klamath River basin Wildlife Refuges and implementation of an effective pollutant reduction strategy. Implementation measures for USBR and USFWS are discussed in section 6.4.3.

6.2.3.3 Memorandum of Agreement to Coordinate State and Federal Agency TMDL Implementation Actions in the Klamath River Basin

Klamath TMDL implementation will be coordinated with the ODEQ and the USEPA. The Regional Water Board, ODEQ, and EPA Regions 9 and 10 have developed a Memorandum of Agreement (MOA) that establishes a framework for joint implementation of the Klamath River and Lost River TMDLs. The MOA includes commitments such as:

- Work to develop and implement a joint adaptive management program, including joint time frames for reviewing progress and considering adjustments to TMDLs;
- Work with the Klamath Basin Monitoring Program (KBMP) and other appropriate entities to develop and implement basinwide monitoring programs designed to track progress, fill in data gaps, and provide a feedback loop for management actions on both sides of the common state border;
- Work jointly with common implementation parties (e.g., USBR, U.S. Forest Service, USFWS, BLM, PacifiCorp, and the Klamath Water Users Association (KWUA) to develop effective implementation plans and achieve water quality standards;
- Explore engineered treatment options such as treatment wetlands, algae harvesting, and package wastewater treatment systems to reduce nutrient loads to the Klamath River and encourage implementation of these options where feasible; and
- Work to develop and implement a basinwide water quality tracking and accounting program that would establish a framework to track water quality

improvements, facilitate planning and coordinated TMDL implementation, and enable appropriate water quality offsets or trades.

<u>Stateline Implementation Measures</u>

Regional Water Board, Oregon (ODEQ) and USEPA 9 and 10:

<u>Measure</u>

- Work together to implement and monitor measures that will achieve compliance with the Klamath and Lost River TMDLs in Oregon and California as specified in the Klamath River/Lost River TMDL Implementation Memorandum of Agreement.

<u>Timeline</u>

- Ongoing

6.3 Klamath Hydroelectric Project and Iron Gate Hatchery

6.3.1 Klamath Hydroelectric Project

The KHP is a federally licensed project owned and operated by PacifiCorp and consists of eight facilities in California and Oregon. The implementation plan will address the impacts of the project facilities in California, which includes the following three dam/reservoir pairs: Copco 1, Copco 2, and Iron Gate. Figure 6.1 shows all the dams on the Klamath River. All except Link River Dam are part of the KHP. The Fall Creek Dam is located on Fall Creek, not the Klamath River.

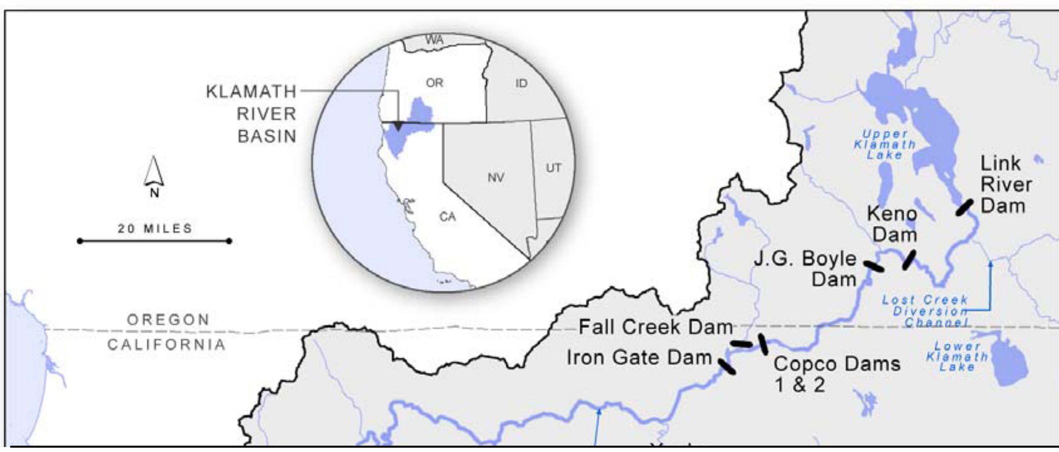

Figure 6.1: Map of Klamath Hydroelectric Project facilities. Link River Dam is not part of the KHP.

The technical TMDL analysis found that the KHP contributes to the impairment of the Klamath River by:

- Altering the nutrient dynamics of the river, and contributing to biostimulatory conditions in the summer/fall growing season;

- Creating physical conditions that promote nuisance blooms of suspended algae, including toxin-forming blue-green algae species;
- Creating low dissolved oxygen and high temperature conditions within the reservoirs and at the tailraces; and
- Altering the temperature regime in the Klamath River downstream.

6.3.1.1 Allocations and Targets

The TMDL includes allocations and targets for the KHP facilities in California. The allocations and targets assigned to meet water quality standards in the reservoirs include a temperature/DO compliance lens, nutrient allocations, as well as nutrient and organic matter targets, and algae-based targets. In addition, temperature allocations and temperature, DO, nutrient and organic matter targets are assigned to the reservoir tailraces. See sections 5.2.3 and 5.3.2 for a complete discussion of these allocations and targets.

6.3.1.2 Responsible Parties

Regional Water Board
State Water Resources Control Board (State Water Board)
PacifiCorp

6.3.1.3 Implementation

To comply with the TMDL, PacifiCorp must implement management measures that result in attainment of the load allocations and targets to the KHP facilities in California. Regulation and enforcement of these TMDL allocations is traditionally through the State Water Board Clean Water Act section 401 water quality certification process, since the Regional Water Board is preempted from issuing a permit to the KHP. The KHP is licensed by FERC with a license that expired on March 1, 2006. The KHP continues to operate under an annual license until renewal. Renewal of the license requires compliance with the California Environmental Quality Act (CEQA) and the issuance of a Clean Water Act section 401 water quality certification by the State Water Board. In issuing water quality certification, the state may impose conditions on the KHP in order to certify that the project protects beneficial uses and meets water quality objectives as specified in the Basin Plan. The Klamath TMDLs, upon adoption, will become part of the Basin Plan and will thus become part of the comprehensive plan that FERC must consider as part of its licensing decision. As authorized by section 401, the State Water Board will apply appropriate state water quality requirements through the FERC licensing proceeding as part of its decision to issue or deny water quality certification.

In 2004, FERC prepared a Final Environmental Impact Statement (FEIS) (PacifiCorp, 2004a) that describes the positive and negative environmental effects of the proposed action to relicense the continued operation of the KHP, and alternative actions, including decommissioning all or part of the project. As part of the 401 certification proceeding, the State Water Board is preparing an Environmental Impact Report (EIR) since the FEIS does not fully comply with CEQA (State Water Board 2008). The FEIS will form the basis of the EIR, and the State Water Board has initiated the process of soliciting information from stakeholders regarding the adequacy of the FEIS and the scope of the EIR. The EIR will evaluate four alternatives for operating the KHP, two of which include removal of two and four of the KHP dams, respectively. Regional Water Board staff will continue to participate in the FERC relicensing and 401 process at the State Water Board to provide information and consultation to ensure that the KHP meets water quality standards and other Basin Plan requirements.

On November 13, 2008, an Agreement in Principle (AIP) to remove four of the Klamath River dams (JC Boyle, Copco 1 and 2, and Iron Gate) was announced after negotiations between the representatives of the federal government, the state of California, the state of Oregon, and PacifiCorp. The Regional Water Board was not a party to the negotiations. A draft of the final Klamath Hydroelectric Settlement Agreement (KHSA) was released on September 30, 2009 and signed on February 18, 2010. Settlement Parties contemplate federal legislation that would indefinitely delay the relicensing process before the FERC and accompanying Clean Water Act section 401 permitting process before the SWRCB. (See section 6.5 of the draft KHSA [Abeyance of Relicensing Proceeding].) In contemplation of the absence of the FERC/401 process, Regional Water Board staff participated in discussions about how the Parties view the regulatory pathways envisioned in the draft KHSA and their relationship to Oregon and California's TMDLs. This is reflected in section 6.3 of the draft KHSA released on September 30, 2009. Section 6.3.2 of the KHSA provides:

> 6.3.2 TMDL Implementation Plans
>
> A. No later than 60 days after ODEQ's and the North Coast Regional Water Quality Control Board (NCRWQCB)'s approval, respectively, of a TMDL for the Klamath River, PacifiCorp shall submit to ODEQ and NCRWQCB, as applicable, proposed TMDL implementation plans for agency approval. The TMDL implementation plans shall be developed in consultation with ODEQ and NCRWQCB.
>
> B. To the extent consistent with this Settlement, PacifiCorp shall prepare the TMDL implementation plans in accordance with Oregon Administrative Rules (OAR) 340-042-0080(3) and California Water Code section 13242, respectively. The plans shall include a timeline for implementing management strategies and shall incorporate water quality-related measures in the Non-ICP Interim Measures set forth in Appendix D. Facilities Removal by the Designated Removal Entity (DRE) shall be the final measure in the timeline. At PacifiCorp's discretion, the proposed plans may further include other planned activities and management strategies developed individually or cooperatively with other sources or designated management agencies. ODEQ and NCRWQCB may authorize PacifiCorp's use of offsite pollutant reduction measures, subject to an iterative evaluation and approval process; provided, any ODEQ authorization of such offsite measures conducted in Oregon solely to

facilitate attainment of load allocations in California waters shall not create an ODEQ obligation to administer or enforce the measures.

Under section 3.3 of the draft KHSA, the Secretary of the Department of the Interior will conduct very detailed studies and assessments to determine, *inter alia*, whether dam removal (i) will advance restoration of the salmonid fisheries of the Klamath Basin, and (ii) is in the public interest. The Secretary is to make a determination by March, 2012, subject to various contingencies, on whether to move forward with the project. As part of this process, a detailed plan for facility removal will be developed that describes the " physical methods to be undertaken to effect Facilities Removal, including but not limited to a timetable for Decommissioning and Facilities Removal, which is removal of all or part of each Facility as necessary to effect a free-flow condition and volitional fish passage." (KHSA, section 3.3.2.)

In its comments on the draft TMDL Action Plan, PacifiCorp objected to the 60 day time frame to submit its proposed implementation plan. Regional Board staff do not object to revisiting the time frame for submittal, and in fact hope to align it with Oregon's TMDL requirements to the extent possible for efficiency. (Note: OR is responsible for water quality certification of J.C. Boyle, one of four hydroelectric facilities in the KHP.) However, the suggestion to allow eighteen months does not seem appropriate here, particularly because the bulk of PacifiCorp's implementation has already been defined in various interim measures agreed to by Settlement Parties.

Since PacifiCorp is a Party to the KHSA and understands its intricacies, it may propose timelines in its implementation plan that best align with the timelines contained in the Settlement. The implementation plan should identify appropriate intervals whereby PacifiCorp will provide the Regional Water Board updates on the status and progress of the plan. At a minimum, the Regional Water Board will want to review the plan in 2012 in light of the Secretary's Determination. Based on the evidence and analyses conducted pursuant to the Secretarial Determination, and the substantive conclusions by the Department of Interior, the Regional Water Board will revisit the content of the KHP implementation plan. In addition, the proposed implementation plan must include a mechanism for Regional Water Board approval of offset projects described in more detail below. Regional Water Board staff are flexible about how this may occur, but the plan must be formulated with the goal of having approved projects ready for implementation in the event of an Affirmative Determination.

Section 6.3.2 of the KHSA describes generally the content of the implementation plan to include a timeline for implementing management strategies, water quality-related measures in Appendix D, and Facilities Removal as the final measure. The proposed plan may further include other planned activities and management strategies developed individually or cooperatively with other sources or designated management agencies. Appendix D contains water-quality measures that could potentially serve to meet TMDL needs if implemented effectively. As described in more detail below, Interim Measures 10 and 11 have significant potential to contribute towards meeting the Klamath River

TMDL load allocations and targets in California. PacifiCorp may propose the use of offsite pollutant reduction measures (i.e. offsets or "trades") to meet the allocations and targets, including those for Iron Gate Hatchery (section 6.3.1.3). Candidate offsite pollutant reduction measures should be informed by Interim Measures 10 and 11 (discussed below) and credits determined through the water quality improvement Tracking and Accounting Program (TAP) (section 6.7).

Interim Measure 10 provides funding for a water quality conference that focuses on the design and implementation of nutrient and organic matter reduction projects. The conference should assess the appropriateness and feasibility of various centralized pollutant removal technologies, including wetland treatment systems, wastewater treatment systems with energy recovery capabilities, aquatic plant harvesting, as well as agricultural best management practices. The conference serves as an opportunity to bring together water quality restoration experts, with the objective of developing recommendations and preliminary conceptual design for projects to achieve large-scale nutrient and organic matter reductions in the basin.

Interim Measure 11 provides funding for interim water quality improvements and is critical for achieving large-scale nutrient reductions in the basin. Under this Interim Measure, PacifiCorp spends $250K/yr until the date of Secretarial Determination to be used for studies or pilot projects. By the date of the Secretarial Determination, a priority list of projects will be developed, informed by the water quality conference and Secretarial Determination studies. In the event of an Affirmative Determination by the Secretary, PacifiCorp provides funding of up to $5.4 million for implementation of projects and $560K/year for operation and maintenance of such projects. As stated in the KHSA, the "purpose of this measure is to improve water quality in the Klamath River during the Interim Period leading up to dam removal. The emphasis of this measure shall be nutrient reduction projects in the watershed to provide water quality improvements in the Mainstem Klamath River, while also addressing water quality, algal and public health issues in Project reservoirs…."

Regional Water Board staff agree that Interim Measure 11 should focus on the development and implementation of nutrient reduction projects, building upon ideas generated from the Interim Measure 10 water quality conference. PacifiCorp should focus on offsets in its proposed implementation plan, and commit to the goal of having viable projects ready for implementation by the date of the Secretarial Determination. Further, a list of priority projects should be completed by PacifiCorp and the Implementation Committee, and select project(s) should be ready for construction by the date of the Secretarial Determination. That means that projects must be presented to the Regional Water Board prior to the Secretarial Determination date with adequate time for review.

The Klamath Hydroelectric Settlement Agreement includes the formation of an Interim Measures Implementation Committee (IMIC - Interim Measure 1) for the purpose of collaborating with PacifiCorp on "ecological and other issues related to the implementation of the Interim Measures set forth in Appendix D" (KHSA, Appendix B). The IMIC will meet, discuss, and seek to reach consensus on implementation of various Interim Measures, including Interim Measure 11. Though not a Party, Section 3.2 of Appendix B states that the North Coast Regional Water Board may be a member of the IMIC, and the Regional Water Board intends to have a staff representative participate on the IMIC with the purpose of providing guidance on a project's potential to meet TMDL requirements. As previously stated, the TMDL implementation plan must provide for separate updates and presentations to the Regional Water Board for approval. The IMIC is not involved in Interim Measure 10: Water Quality Conference. This measure states that PacifiCorp, the North Coast Regional Water Quality Control Board, and the Oregon Department of Environmental Quality, will convene a steering committee to develop the agenda and panels for the water quality conference. The Regional Water Board intends to work closely with ODEQ and PacifiCorp on Interim Measure 10.

Interim Measure 11 also identifies the development of a water quality tracking and accounting framework. Regional Water Board staff support PacifiCorp's involvement in developing a water quality improvement tracking and accounting program for the Klamath River basin. The purpose of the program is to provide a structure that facilitates the efficient application of offset programs by consolidating contributions and distributions. Consistent with the stated purpose of Interim Measure 11 and the goal of TMDL compliance, the majority of PacifiCorp's funding should be focused on the development and implementation of on-the-ground projects that, once implemented, will provide water quality improvements in the mainstem Klamath River.

The Interims contain valuable monitoring provisions and also a Coho Enhancement Fund and turbine venting project that could positively influence water quality. Water quality monitoring performed under Interim Measure 15 will be valuable in tracking baseline water quality conditions and compliance with the TMDLs.

The TMDL accommodates a variety of implementation options to address reservoir-related water quality impairments depending on whether the settlement moves forward or the State Water Board and FERC processes continue. Regardless of the process, PacifiCorp must implement measures designed to move toward compliance with TMDL allocations and protection of beneficial uses. This is true for any process that proposes continued operation of the KHP, as well as for any alternative that considers dam removal. In addition, PacifiCorp must implement adequate water quality control measures to offset on-going reservoir impacts while the reservoirs are modified to meet the load allocations or, alternatively, up to the time they are decommissioned. PacifiCorp may propose the use of offsite pollutant reduction measures in the interim period consistent with the Klamath River water quality improvement tracking and accounting program, subject to an iterative evaluation and approval process. The implementation plan submitted by PacifiCorp should provide certain time periods after which a reassessment process may occur to avoid having to develop an alternative plan in the event that the settlement is discontinued. For now, we think that the acknowledgement that the FERC/401 process resumes if the settlement terminates will suffice. If that occurs, the Regional Water Board will revisit PacifiCorp's implementation plan to discuss possible revisions. The implementation plan must also provide for Regional Water Board review of more site specific environmental assessments of dam removal before approval of that approach as a final TMDL compliance measure.

<u>Implementation Measures for the Klamath Hydroelectric Project</u>

PacifiCorp:

<u>Measure</u>

- Submit a proposed implementation plan that incorporates timelines and contingencies pursuant to the KHSA. In the event that the KHSA does not move forward, the implementation plan should specify that the FERC/water quality certification process shall resume. Section 6.3.2 of the KHSA describes TMDL implementation to include a timeline for implementing management strategies, water quality-related measures in Appendix D, and Facilities Removal as the final measure. PacifiCorp may propose the use of offsite pollutant reduction measures (i.e. offsets or "trades") to meet the allocations and targets in the context of Interim measures 10 and 11. The implementation plan should identify appropriate intervals whereby PacifiCorp will provide the Regional Water Board updates on the status and progress of the plan, and provide adequate time for review so that select project(s) are ready for construction by the date of the Secretarial Determination. The implementation plan must provide for Regional Water Board review of more site specific environmental assessments of dam removal before its approval of that approach as a final TMDL compliance measure.

<u>Timeline</u>

- Within 60 days of when the Basin Plan amendment takes effect.

.

<u>Measure</u>

- Implement measures to meet and/or offset TMDL allocations and targets as prescribed in the approved implementation plan.

<u>Timeline</u>

- As required by the approved implementation plan.

State Water Board:

<u>Measure</u>

- If applicable, process the 401 water quality certification FERC relicensing of the Klamath Hydroelectric Project to meet Basin Plan requirements, including Klamath River

TMDL allocations and targets. This Action Plan is not intended to constrain the discretion of the State Water Board to determine, as appropriate, time periods required for various studies, options for interim requirements, and methods for final compliance.

Timeline

- Pursuant to the FERC licensing process timeline.

6.3.2 Iron Gate Hatchery

Iron Gate Fish Hatchery is owned by PacifiCorp and operated by the California Department of Fish and Game (CDFG). The hatchery is located at the base of Iron Gate Dam and discharges effluent under NPDES Permit No. CA0006688 and WDR No. R1-2000-17.

6.3.2.1 Allocations and Targets

The TMDL assigns temperature, nutrient, and organic matter waste load allocations, as well as temperature, DO, nutrient and organic matter targets to discharges from Iron Gate Hatchery. These allocations and targets are presented in sections 5.2.4 and 5.3.3.

6.3.2.2 Responsible Parties

Regional Water Board
PacifiCorp
California Department of Fish and Game

6.3.2.3 Implementation

The waste load allocations to the Iron Gate Hatchery discharges will be implemented through the federal NPDES permit, which is held jointly by CDFG and PacifiCorp. The current permit passed its expiration date in August 2004, and the hatchery continues to operate under the terms of the existing permit until a new permit is issued. The TMDL wasteload allocations and targets to the hatchery discharge will be translated into effluent limits in the new NPDES permit. The TMDL compliance schedule to accompany the new permit may allow additional time needed for CDFG to make any infrastructure improvements to the hatchery and to implement management measures that meet TMDL allocations. The time schedule will include specific intermediate milestones with the final goal of meeting the Klamath TMDL allocations and targets. Intermediate milestones for pollutant reductions in the hatchery discharges may include:

1. Improving effluent water quality to the level of the intake water to the hatchery; and
2. Meeting current receiving water quality in the Klamath River at the point of discharge.

The hatchery may have the option of achieving some or all of its load reductions through offset mitigation if the potential changes to hatchery operations are limited in their ability to effectively reduce pollutant loads. Any offset mitigation would be coordinated through the Klamath River water quality improvement tracking and accounting program (section 6.7).

Implementation Measures for Iron Gate Hatchery

Regional Water Board:

Measure

- Revise NPDES Permit No. CA0006688 and WDR No. R1-2000-17 to incorporate revised effluent limits to implement the TMDL wasteload allocations, and the recalculated site-specific objectives for dissolved oxygen, and to require that the responsible parties implement measures to improve the water quality of discharges from the Iron Gate Hatchery to meet TMDL allocations and targets on a compliance schedule.

Timeline

Bring revised permit to the Regional Water Board for consideration by December 2011.

PacifiCorp and CDFG:

Measure

- Implement measures to improve the water quality of discharges from the Iron Gate Hatchery to meet and/or offset the Klamath River TMDL wasteload allocations and targets.

Timeline

- As specified in the revised NPDES permit.

This space intentionally left blank

6.4 Implementation in the Klamath Basin Tributaries and Coordination with Existing TMDLs

The tributaries to the Klamath River include five major tributaries and numerous minor tributaries. The major tributaries are the Trinity, Salmon, Scott, Shasta and Lost Rivers. All the major tributaries, except the Lost River, join the Klamath River in California and are also wholly contained within California. The Lost River traverses the Oregon/ California border three times and ultimately joins the Klamath River in Oregon via the Klamath Straits Drain. The major tributaries each have had technical TMDLs completed that are specific to the tributary basin. The Regional Water Board has adopted TMDL implementation plans for the Shasta, Scott, and Salmon River basins. The Trinity, South Fork Trinity, and Lost River basins have had TMDLs promulgated by the USEPA without associated implementation plans. Table 6.2 provides a summary of completed TMDLs and adopted implementation plans in the major tributaries.

Table 6.2: Completed TMDLs for the major tributaries of the Klamath River basin.

Subwatershed	TMDL(s)	Year	Agency
Lower Lost River	Nutrients and Biochemical Oxygen Demand (BOD)	Final Technical TMDL, 2008	USEPA
Shasta River	Temperature, dissolved oxygen	Final Technical TMDL and Implementation Plan, 2007	Regional Water Board
Scott River	Temperature, sediment	Final Technical TMDL and Implementation Plan, 2006	Regional Water Board
Salmon River	Temperature	Final Technical TMDL and Implementation Plan, 2005	Regional Water Board
Trinity River	Sediment	Final Technical TMDL, 2001	USEPA
South Fork Trinity River	Sediment	Final Technical TMDL, 1998	USEPA

This section discusses the approach to implementation specific to each of the major tributaries given existing TMDLs and implementation plans. The intent of the Klamath implementation plan is to make TMDL requirements as consistent as possible throughout the Klamath River basin while considering existing TMDL implementation plans and ongoing water quality improvements efforts.

6.4.1 Allocations and Targets

The Klamath River TMDLs assign nutrient and organic matter load allocations to the mouths of all the major Klamath tributaries in California and 18 specified minor tributaries. The nutrient and organic matter allocations for Klamath River tributaries in California are expressed as monthly mean concentrations, and are presented in section 5.3.4. These allocations are intended primarily to establish boundary conditions and to prevent any increase of nutrients to the Klamath mainstem. The Shasta River is the only tributary in California that has an existing TMDL with nutrient and organic matter-related allocations. The Klamath River TMDL allocations to the mouth of the Shasta River are consistent with the allocations assigned in the Shasta River TMDLs. Since the Lost River discharges to the Klamath River in Oregon, those allocations will be included as part of ODEQ's Klamath River TMDLs. Other major tributaries that do not have nutrient TMDLs were set to current conditions.

There are also two temperature-related load allocations and associated targets that apply watershed-wide, i.e. to the Klamath River mainstem and all minor tributaries in California. These allocations and related targets are for excess solar radiation and human-caused discharges of sediment, and are presented in section 5.2.1. Watershed-wide allocations are not assigned to major tributary basins because of their existing allocations that are consistent with the Klamath TMDL.

6.4.2 Implementation

This implementation plan proposes a basinwide prohibition on unauthorized discharges of waste that violate water quality standards and the Thermal Refugia Protection Policy as described in section 6.5. However, there are no additional management measures proposed for responsible parties in the tributary basins that already have existing TMDLs except for the USFS, Caltrans, and the Klamath basin county roads. For these parties, staff recommend a regionwide approach and permitting that will provide consistency in regulation throughout the Klamath basin. The permits should meet the requirements of any existing TMDL implementation plans and should also consider future TMDLs and 303(d) list impairments in the North Coast Region. The following sections outline the existing tributary TMDL requirements and the necessary coordination in implementing the Klamath River TMDLs basinwide. The Lost River implementation plan is presented in section 6.4.3 below. Lost River implementation in California is important because significant load reductions are needed to meet Klamath River water quality standards, and TMDL implementation in this watershed requires coordination with Oregon and federal agencies to meet the allocations at stateline.

6.4.3 Lost River Implementation Plan

The USEPA completed a technical TMDL for the Lost River basin in California in December 2008 (USEPA 2008) that included load allocations to meet water quality standards in the Lost River Basin. Implementation measures in the Lost River basin in California are needed to meet the Klamath River TMDL nutrient and organic matter allocations assigned to the Lost River basin at its discharge points to the Klamath River. This staff report includes measures to implement the Lost River TMDL allocations in coordination with the Klamath implementation plan and constitutes the implementation plan for the Lost River basin. The responsible parties and the specific implementation measures are identified at the end of this section.

Significant load reductions are needed to meet Klamath River water quality standards as well as standards in the Lost River basin. Lost River TMDL implementation will be coordinated with the Oregon Department of Environmental Quality (ODEQ) and federal agencies, including the US Bureau of Reclamation (USBR), US Fish and Wildlife Service (USFWS), and the USEPA. In addition to the measures cited here, individual landowners conducting activities associated with nonpoint source discharges, specifically irrigated agriculture and grazing, will be included in the coverage of the agricultural waiver to be developed by 2012, and are therefore included in section 6.5.6 that includes recommendations and encourages early participation in that process.

6.4.3.1 Background

Historically, the Lost River was only hydrologically connected to the Klamath River in years with extremely high flow. The Lost River was physically linked to the Klamath River when the Lost River basin was engineered to its current configuration in the early 1900s to accommodate the development of the USBR Klamath Project (Reclamation's Klamath Project). Reclamation's Klamath Project diverts water from the Klamath River at three separate locations just downstream of Upper Klamath Lake, and from one location in Upper Klamath Lake. Reclamation's Klamath Project delivers water to approximately 200,000 acres of farmland as well as four National Wildlife Refuges (Figure 6.2). Of the total acreage of Reclamation's Klamath Project, approximately 70,000 acres are in California. The Lost River originates in California, enters Oregon, flows through Reclamation's Klamath Project in Oregon and then into the Tule Lake National Wildlife Refuge (TLNWR) in California, the historical terminus of the Lost River. Water from the TLNWR is pumped through a tunnel into the Lower Klamath National Wildlife Refuge (LKNWR) to maintain farmland in the TLNWR, stabilize water levels in the Tule Lake sump, remove salt from the Tule Lake basin, and provide water to LKNWR.[2] Drainage from LKNWR flows back across Oregon through the Klamath Straits Drain (KSD), which discharges into the Klamath River in Oregon. Return flows from Reclamation's Klamath Project are also discharged seasonally into the Klamath River through the Lost River Diversion Channel (LRDC) in Oregon. Based on the Klamath TMDL analysis, the current loading from the KSD comprises approximately 13 percent of the total phosphorus loading, 23 percent of the total nitrogen loading, and 40 percent of the organic matter loading in the Klamath River at stateline. While on a seasonal basis, Reclamation's Klamath Project diverts more nutrient and organic matter loads from the Klamath River than it returns to it, Reclamation's Klamath Project discharges contribute to exceeding the Klamath River water quality standards.

The principal sources of water inflows to the Lost River system in California are agricultural drains that collect irrigation return flows from privately owned agricultural lands within Reclamation's Klamath Project. The drains and canals are owned by USBR, but are operated by various irrigation districts that hold water delivery contracts with USBR. The KSD and LRDC are owned and operated by USBR, but receive pollutant inputs from upstream agricultural operators. All of Tule Lake and the open water areas of LKNWR are currently part of the National Wildlife Refuge system and are managed by U.S. Fish and Wildlife Service (USFWS). Some refuge lands are jointly managed by USBR for agricultural use.

---

[2] Information concerning the purpose of this pumping was provided in a comment letter submitted by the Klamath Water Users Association. USBR has subsequently commented that "Water is not pumped from TLNWR to LKNWR 'to maintain farmland in the TLNWR' or 'remove salt from the Tule Lake basin'. Water is pumped for water elevation control in the wildlife refuge year round, for flood control in winter and early spring months, and for refuge water supply in the summer and fall months."

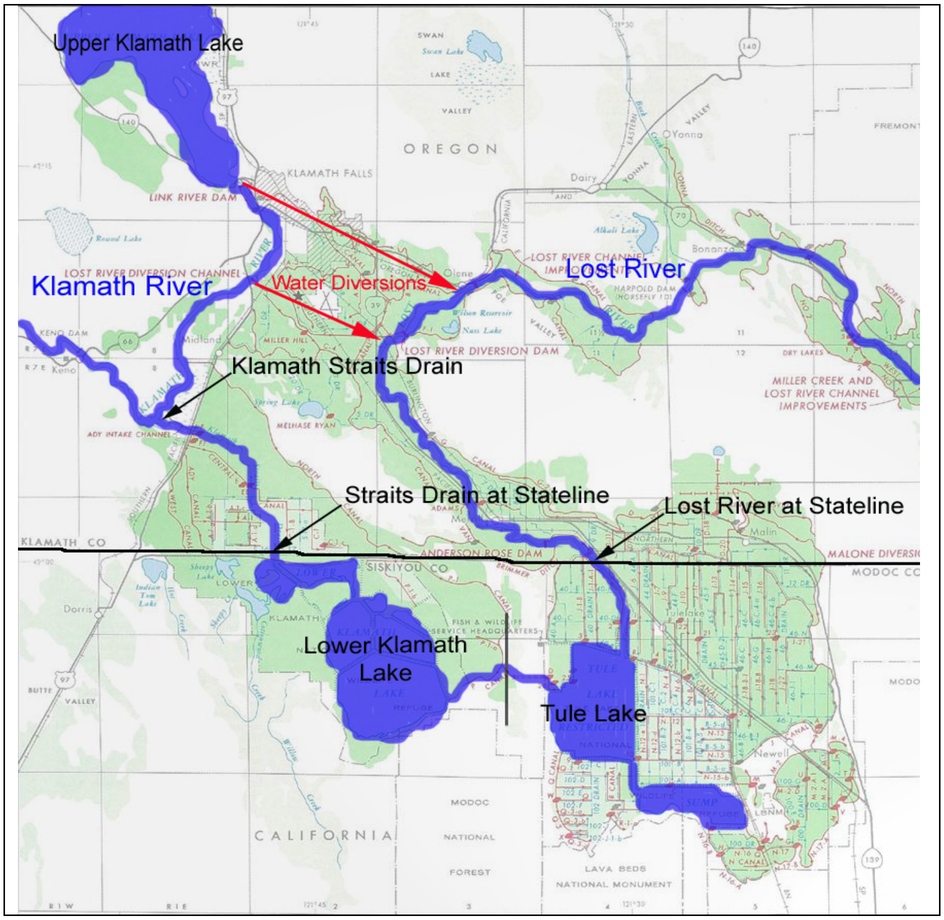

Figure 6.2: The Lost River basin

The load allocations from the USEPA Lost River TMDL in California are shown in Table 6.3.

This space intentionally left blank.

Table 6.3: Lost River, California TMDLs and allocations by segment.

Segment	Source	Dissolved inorganic nitrogen (DIN) (metric tons/yr)	Dissolved inorganic nitrogen (DIN) (average kg/day)	Carbonaceous biochemical oxygen demand (CBOD) (metric tons/yr)	Carbonaceous biochemical oxygen demand (CBOD) (average kg/day)
1	Lost River at Stateline Road (OR Border) Load Allocation	27.8	76.0	54.3	148.6
	Load Allocation for irrigation drainage loads to Lost River between Stateline Rd and Tule Lake Refuge	1.2	3.2	17.5	47.8
	Wasteload Allocation-CalTrans	0.1	0.3	0.2	0.5
Total	Lost River (from border to Tule Lake Refuge) TMDLs	29.0	79.5	71.9	197.0
2	Upstream load - from Lost River	29.0	79.5	71.9	197.0
	Load Allocation for irrigation drainage loads to Tule Lake Refuge	36.2	99.0	253.3	694.0
	Wasteload Allocation-CalTrans	0.1	0.3	0.2	0.5
	Wasteload Allocation City of Tulelake WWTP	1.0	2.7	3.5	9.6
Total	Tule Lake Refuge TMDLs	66.3	181.5	328.9	901.1
3	Upstream load - from Tule Lake Refuge[a]	19.4	53.2	245.9	673.7
	Load Allocation for irrigation drainage loads to Lower Klamath Refuge	3.9	10.7	39.4	107.8
	Load Allocation to Ady Canal	4.4	12.1	39.4	107.8
	Wasteload Allocation -CalTrans	0.1	0.3	0.2	0.5
Total	Lower Klamath Refuge TMDLs	27.8	76.2	324.8	889.9
4	Upstream load from Lower Klamath Refuge[b]	20.2	55.2	193.3	529.5
	Load Allocation for irrigation drainage loads to Klamath Straits Drain[c]	1.5	4.1	10.5	28.8
Total	Klamath Straits Drain (Stateline Highway to border) TMDLs	21.7	59.3	203.8	558.2

Source: USEPA 2008

[a]Upstream load from Tule Lake Refuge—only a portion of the waters from Tule Lake Refuge are pumped to Lower Klamath Refuge. Additionally, the model assumes that Tule Lake Refuge is a single mixed segment; to avoid transferring uncertainties associated with the coarse spatial resolution to the next downstream segment, monitoring data collected at the D Pumping Plant intake was used as the basis for upstream inputs for this segment.

[b]Because the model assumes that Lower Klamath Refuge is a single mixed segment, water quality inputs to the next segment were based on monitoring data collected at Klamath Straits Drain at Stateline Highway.

[c]In comments on the draft Lost River TMDLs, USBR stated that the portion of the Klamath Straits Drain that exits the Lower Klamath Lake National Wildlife Refuge, and is within California, does not have any agricultural contributions. The table above is taken directly from the Lost River Basin TMDL, in California (USEPA 2008) and has not been altered.

6.4.3.2 Responsible Parties in the Lost River Basin
The parties responsible for implementing water quality control measures that meet the Lost River and Klamath River TMDL allocations in California include:

- US Bureau of Reclamation
- US Fish and Wildlife Service
- Tulelake Irrigation District
- City of Tulelake
- Any party whose activities have the potential to contribute towards the TMDL impairments through the discharge of nutrients or organic material.

6.4.3.3 Implementation
Significant load reductions are needed in the Lost River basin to meet water quality standards in the Lost River basin and to meet the Lost River TMDL load allocations in California. Agricultural operators in the Lost River basin in California and Oregon have been implementing water quality control measures for a number of years. For example:

- The NRCS has funded approximately $50 million in projects through the Environmental Quality Incentive Program; a program funded by the US Department of Agriculture (USDA). The funds were split evenly between projects in California and projects in Oregon.
- The Conservation Reserve Program (CRP), also funded by the USDA, pays for conservation easements to establish riparian buffers on agricultural land. In Oregon, this program is expanded and called the Conservation Reserve Enhancement Program to include active restoration of riparian areas.
- Water quality improvement projects have been implemented through the Oregon Water Enhancement Board.
- The Lava Beds/Butte Valley Resource Conservation District (RCD) in Tulelake and the Klamath Soil and Water Conservation District in Oregon have obtained funding through the Agricultural Water Enhancement Program.

Regional Water Board staff support and encourage the continuation of these ongoing programs and coordinating current efforts with TMDL implementation. The implementation measures described in this section apply to dischargers in the Lost River basin in California and, combined with the measures listed below, are sufficient to implement the Lost River TMDL in California. The Regional Water Board's proposed basinwide nonpoint source program for agriculture, to be developed separate from this implementation plan (section 6.5.6) will include agricultural dischargers in the Lost River basin. Tulelake Irrigation District is responsible for discharges in California associated with the conveyance and delivery of water within the district's boundaries. They are named as a party to the MAA because their operations are linked with the overall operation of the project. There will be more opportunity for water quality improvements if TID's management practices are coordinated with USBR and USFWS. The load allocations assigned in the Oregon Klamath River TMDL will be implemented by ODEQ through their regulatory authority in Oregon. The Regional Water Board will coordinate with ODEQ on implementation as defined by the implementation Memorandum of Agreement signed in June 2009 (see section 6.2.3.3).

6.4.3.4 Proposed Management Agency Agreement

Regional Water Board staff proposes the development of a Management Agency Agreement (MAA) between USBR, USFWS, the Tulelake Irrigation District, and the Regional Water Board to implement the Lost River and Klamath River TMDLs. The MAA would be a voluntary and cooperative means of implementing the TMDL The MAA should be completed within six months of when the Klamath River TMDL Action Plan takes effect and should include the following actions items:

- Complete a water quality study based on best available science to characterize the seasonal and annual nutrient and organic matter loading through Reclamation's Klamath Project and refuges. The study should be completed and inform the development of a water quality management plan described in the following bullet.
- Based on the results of the water quality study, develop a water quality management plan to meet the Lower Lost River and Klamath River TMDL allocations and targets. The plan should be submitted to the Regional Water Board for approval within 18 months of the time the Klamath River TMDL Action Plan takes effect.
- Include a schedule with interim milestones for meeting the TMDL allocations and targets;
- Coordinate implementation actions with other responsible parties discharging pollutants within Reclamation's Klamath Project and refuges;
- Develop a monitoring and reporting program with the Regional Water Board to evaluate the effectiveness of management measures and track progress towards meeting the Lower Lost River and Klamath River TMDL allocations and targets;
- Coordinate with the Klamath River water quality improvement tracking and accounting program in implementing offset projects; and
- Periodically report to the Regional Water Board on actions taken to implement the TMDL and progress towards meeting the TMDL allocations and targets.

6.4.3.5 Coordination with ODEQ and US EPA

As stipulated in the Klamath River and Lost River TMDL Implementation Memorandum of Agreement (MOA) developed by the Regional Water Board, ODEQ and US EPA Regions 9 and 10, the agencies agree to work jointly with common implementation parties, including USBR, USFWS, and the Klamath Water Users Association (KWUA) to develop effective implementation plans and achieve water quality standards. Regional Water Board staff suggest that USBR and USFWS develop the water quality management plan in conjunction with the development of an implementation plan to meet the Klamath River TMDLs in Oregon.

6.4.3.6 Tulelake Wastewater Treatment Plant

The Tulelake Wastewater Treatment Plant (WWTP) is owned and operated by the City of Tulelake and discharges effluent under NPDES Permit No. CA0023272 and WDR No. R1-2004-0075. The waste load allocations to the Tulelake WWTP discharges will be implemented through the federal NPDES permit, which is held by the City of Tulelake. The current permit was as adopted in October 2004, and the treatment plant will continue to operate under the terms of the existing permit until a new permit is issued. The TMDL waste load allocations and targets to the treatment plant discharge will be translated into effluent limits in the new NPDES permit. The TMDL compliance schedule to accompany the new permit may allow additional time needed for the City of Tulelake to make any infrastructure improvements to the treatment plant and to implement management measures that meet TMDL allocations. The City of Tulelake is assessing the possibility of moving to a land discharge system, in which case, the current NPDES permit would be rescinded, and the discharge would be regulated through WDRs. A land discharge system would meet the TMDL waste load allocations, since there would no longer be a discharge to surface waters from the WWTP.

Implementation Measures in the Lost River Basin

Regional Water Board, USBR, USFWS, and TID:

Measure
- Develop and implement a Management Agency Agreement (MAA) between USBR, USFWS, TID and the Regional Board that addresses the water quality impacts of Reclamation's Klamath Project. The MAA should include the action items identified above in section 6.4.3.4.

Timeline
- Complete MAA within six months of when the Klamath River TMDL Action Plan takes effect.

Regional Water Board:

Measure
- Revise NPDES Permit No. CA0023272 and WDRs No. R1-2004-0075 to include a compliance schedule and ensure that the discharge requirements are consistent with the Basin Plan requirements and the Lower Lost River TMDL wasteload allocations. Timeline
- Bring revised permit to the Regional Water Board for consideration by June 2012

City of Tulelake:

Measure
- Implement measures to improve the water quality of discharges from the Tulelake WWTP to meet the Lower Lost River TMDL wasteload allocations.

Timeline
- As specified in the revised NPDES permit.

6.4.4 Coordination with the Shasta River TMDL

The Klamath River TMDL analysis found that the load reductions called for in the Shasta River TMDL are sufficient to meet water quality standards in the Klamath River. The

Shasta River TMDL Action Plan includes a goal to increase dedicated instream cold water flows by 45 cubic feet per second (cfs), or alternative flow regime that achieves the same temperature reductions from May 15 to October 15. Achieving the Shasta River 45 cfs flow goal, or alternative flow regime that achieves the same temperature reductions from May 15 to October 15, is necessary for attainment of the Klamath River temperature TMDL and associated temperature standards. Water made available through the implementation of conservation measures should be dedicated to beneficial use in order to be effective under this Plan. 'Dedicated' means that the diverter, either individually or as a group, can demonstrate that the measure contains assurances that it will result in water quality benefits. The Regional Water Board staff, with help from the Division of Water Rights, is providing information to assist landowners who want to voluntarily dedicate instream flow. Under Water Code section 1707, any person entitled to use water, whether based on an appropriative, riparian or other water right, may petition the State Water Board to change the purpose of use to the preservation and enhancement of wetlands habitat, fish and wildlife resources, or recreation. The State Water Board may approve the petition if the change does not increase the amount of the original entitlement, does not unreasonably affect any legal user of water, and meets other requirements of the Water Code. These efforts are not a requirement of the Klamath TMDL and are provided here for informational purposes only.

The Shasta River TMDL Action Plan includes a conditional waiver of WDRs for parties discharging to the Shasta River basin as long as they comply with the Action Plan measures. The agricultural conditional waiver of WDRs proposed for development as part of a future stakeholder process (see section 6.5.6) may eventually supersede the Shasta River basin conditional waiver when they are adopted. The Regional Water Board will assess the effectiveness of the Shasta River TMDL waiver when it expires. At that time, the Regional Water Board will decide whether to extend the Shasta TMDL waiver, revise and reissue the Shasta TMDL waiver, or incorporate it into the proposed regionwide conditional waiver developed for nonpoint source discharges from agricultural activities. In the meantime, compliance with the Shasta River waiver is sufficient to meet the requirements of the Klamath River TMDL.

6.4.5 Coordination with the Scott River TMDL

The Scott River TMDL Action Plan includes sediment and temperature control measures, and it is anticipated that these measures are sufficient to meet the Klamath River TMDL watershed-wide temperature allocations and targets. The Scott River TMDL recommended that the County of Siskiyou, in cooperation with other appropriate stakeholders, develop a plan for a study of the connection between groundwater and surface water in the Scott Valley. This study plan has been completed. The Regional Water Board has provided funds to implement the initial phases of the plan. This plan should move forward in order to help assist Scott water users to develop appropriate management practices that can be implemented following the study in order to ensure adequate flow in the Scott River. This is not a requirement of the Klamath TMDL and is provided here for informational purposes only.

The Klamath River TMDL assigns nutrient and organic matter allocations to the Scott River, and the Scott River Action Plan does not include measures to control discharges of these pollutants. The Regional Water Board will assess the effectiveness of the Scott River TMDL waiver when it expires. At that time, the Regional Water Board will decide whether to extend Scott TMDL waiver, revise and reissue the Scott TMDL waiver, or incorporate it into the proposed regionwide conditional waiver for nonpoint source discharges from agricultural activities. The need for nutrient control measures will be addressed as part of that determination.

6.4.6 Coordination with the Salmon River TMDL

The USFS manages 97% of the land in the Salmon River basin, and the Regional Water Board passed a resolution in 2005 to develop an MOU with the USFS that would implement the Salmon River TMDL. The MOU was signed in September 2009. As discussed in section 6.6 (Implementation on Federally Managed Lands) Regional Water Board staff are in the process of developing a conditional waiver of WDRs to address USFS nonpoint source discharges in the Region, including the Salmon River basin. This waiver would incorporate the implementation measures agreed upon in the MOU and would also require compliance with the Klamath TMDL allocations and targets.

This space intentionally left blank

6.4.7 Trinity River Implementation

6.4.7.1 Responsible Parties
The Bureau of Reclamation is identified here as the party responsible for implementing the Trinity River Restoration Project as described below.

6.4.7.2 Implementation
The USEPA completed sediment TMDLs for the South Fork Trinity River in 1998 and for the mainstem Trinity River in 2001. These USEPA promulgated TMDLs do not currently include implementation plans. The Trinity River is also assigned nutrient and organic matter allocations in the Klamath River TMDL that are consistent with current conditions. Watershed-wide allocations do not apply to the Trinity River because allocations were already assigned in previous TMDLs. Riparian shade protection measures will be implemented in the Trinity River basin through existing or future Regional Water Board regulatory programs that address sediment discharges.

The primary adverse impacts associated with excessive sediment in the Trinity River pertain to anadromous salmonid fish habitat, which the Trinity River Restoration Program (TRRP) was designed to correct. The TRRP is a management program, headed by the Department of the Interior, to restore the fish and wildlife populations in the Trinity River basin to levels that existed prior to construction of the Trinity and Lewiston dams. The EPA cites implementation of the TRRP 2000 Record of Decision (ROD), including flow regime, mainstem/watershed restoration, and adaptive management, in its TMDL implementation recommendations. The Regional Water Board is in the process of developing a general permit for the restoration component of the ROD and considers its proposed permitting action on TRRP measures to be early TMDL implementation of the Trinity TMDL.

The Klamath River TMDL analysis used flows for the Trinity River that were specified in the ROD and signed by the US Secretary of the Interior and the Hoopa Valley Tribal Chairman. The TMDL analysis found that these flows are necessary to meet water quality objectives for water temperature in the mainstem Klamath River. Implementation of the TRRP, including the ROD, has been added to the Basin Plan Amendment language.

Implementation Measures in the Trinity River Basin

Regional Water Board:

Measure
- Develop general Waste Discharge Requirements/401 water quality certification for TRRP mechanical restoration.

Timeline
- 2010

USBR: Measure

- Implement Trinity River Restoration Plan Record of Decision

Timeline

- Ongoing

6.5 Nonpoint Source Control and the Watershed-Wide Allocations

This section presents the proposed TMDL implementation measures assigned to responsible parties that are discharging nonpoint sources of waste in the Klamath Basin. The following land uses were identified as the primary nonpoint sources of pollution in the Klamath River basin that contribute to the water quality impairments:

- Road construction and maintenance;
- Agriculture including grazing and irrigated agriculture;
- Timber harvest; and
- Land use activities on land managed by the USFS.

This section summarizes the watershed-wide allocations and targets for temperature, introduces a proposed prohibition on unauthorized discharges that violate water quality standards, provides guidance on control of excess sediment discharges, and introduces the Thermal Refugia Protection Policy. It then presents the implementation measures associated with the above named land use categories. For each of the land use activities, Regional Water Board staff evaluate the effectiveness of current regulatory programs and strategies as well as other regulatory and non-regulatory water quality protection efforts. Staff then make recommendations for implementation measures as needed to ensure the Klamath TMDLs and measures are coordinated within the context of the Regional Water Board’s regionwide nonpoint source planning approach. Ultimately it is the Regional Water Board’s goal to combine as many discharge requirements for various land use activities as comprehensively as possible into one permitting structure.

Changes from the June 2009 draft

The Regional Water Board staff have made the following changes to this section of the draft implementation plan in response to comments received during the public comment period for the previously released June 2009 draft:

1. Prohibition on Unauthorized Discharges of Waste that Cause a Violation of Water Quality Standards. (section 6.5.2)
2. Removal of the proposed sediment prohibition and replace with Guidance for the Control of Excess Sediment. (section 6.5.3)
3. Removal of the proposed prohibition on the discharge of waste in and around thermal refugia in the Klamath Basin and replace with Thermal Refugia Protection Policy for the Klamath Basin to be included in the Action Plan. (Section 6.5.4)

4. Changes to the implementation measures for the USFS to incorporate the current development of a conditional waiver for certain nonpoint source activities on lands managed by the USFS. The waiver is scheduled for Regional Water Board adoption in April 2010. (section 6.6)

These changes are discussed in the sections indicated above. Other smaller changes have also been made, including a discussion on how TMDL requirements for maintenance of riparian shade relate to the Anadromous Salmonid Protection Rules for timber harvest, recently adopted by the California Board of Forestry section 6.5.7.6.

6.5.1 Watershed-wide Allocations and Targets for Water Temperature

The following watershed-wide allocations and targets apply only to the Klamath River mainstem and minor tributaries.

6.5.1.1 Riparian Shade Allocations and Targets

The Klamath River TMDL assigns allocations and targets for riparian shade to limit water temperature increases due to solar radiation (section 5.2.1). Land use activities in the Klamath River basin have the potential to degrade riparian conditions, and all parties are responsible for meeting the same riparian shade allocation. The following discussion is intended to clarify implementation of the riparian shade allocation and provide the basis for the implementation recommendations specific to each land use.

The riparian shade allocation requires the maintenance of the following *shade conditions*:

> the shade provided by topography and full potential vegetation conditions at a site, with an allowance for natural disturbances such as floods, wind throw, disease, landslides, and fire.

The allocation allows for site-specific determination of shade potential, recognizing that potential varies by location. Shade conditions can be equated to the *effective shade* to the waterbody. Effective shade is defined as:

> a measure of the percentage of total daily direct beam solar radiation that is blocked by vegetation or topography before reaching the ground or stream surface, taking into account the differences in solar intensity that occur throughout a day.

The process for assessing compliance with the Klamath River TMDL riparian shade allocation begins by comparing the current effective shade and the site potential effective shade. The site potential effective shade is designated as the riparian shade target in the TMDL. The TMDL provides general targets for effective shade based on the shade percentages that are expected to naturally occur for a given type of vegetation, aspect, and stream width. The effective shade curves in Figures 5.4 – 5.9, found in Chapter 5 of this staff report, represent the numeric targets for riparian shade within the Klamath River basin in California. The targets are intended as a guide for riparian management, and may be modified based on site-specific conditions, as discussed in Section 5.2.1.1.

In simple terms, compliance with the shade allocation is achieved by not removing trees that provide shade to the waterbody. To accomplish this, it is recommended that responsible parties delineate a separate management area for riparian vegetation that has the potential to shade a waterbody, and manage these riparian areas differently than the surrounding land. These areas are referred to variously as a riparian management zone, streamside buffer area, or a watershed and lake protection zone. The riparian management area should be large enough to include any trees that have the potential to provide shade to surface waters once they reach their site potential height. In most cases, the landowner will not be required to actively restore riparian conditions by planting trees in order to comply with the TMDL. However, active restoration of riparian conditions may be appropriate in instances where riparian vegetation has been removed and causes violation of the Basin Plan temperature standards and the Klamath River shade allocations and targets, or where natural vegetation is not readily becoming reestablished on its own. Regional Water Board staff acknowledge that it may be necessary in some cases to remove some riparian vegetation to hasten recovery towards site potential effective shade conditions.

6.5.1.2 Sediment Related Water Temperature Allocation and Targets

The TMDL found that sediment discharges in the Klamath River basin have a potential cumulative impact on water temperatures through the alteration of channel structure, particularly in the tributary basins. To control the impacts of excess sediment on water temperature, the Klamath River TMDL assigns the following temperature-related load allocation for human-caused discharges of sediment (section 5.2.1.2):

> Zero temperature increase caused by substantial human-caused sediment-related channel alteration.

Substantial human-caused sediment-related channel alteration is defined as:

> A human-caused alteration of stream channel dimensions that increases channel width, decreases depth, or removes riparian vegetation to a degree that alters stream temperature dynamics and is caused by increased sediment loading.

The TMDL also identifies three targets related to the impacts of excess sediment:

1. 0 miles of substantial human-caused sediment-related channel alteration.
2. Less than 1% of all stream crossings divert or fail as a result of a 100-year or smaller flood.
3. Decreasing number of potential road-related landslide source areas.

This space intentionally left blank

6.5.2 Prohibition of Discharges in Violation of Water Quality Objectives in the Klamath River Basin

In response to numerous comments received, staff have removed any interim requirements on individual landowners and operators to control discharges associated with irrigated agriculture and grazing activities and sediment discharges in lieu of incorporating TMDL implementation into basin and/or region wide nonpoint source programs for efficiency and consistency. The following prohibition against unauthorized discharges of waste that violate water quality standards is proposed to protect against serious and significant individual threats to water quality. This prohibition is a restatement of existing law and is not intended to provide a nonpoint source program that implements measures to control the cumulative impact of individual nonpoint source discharges of waste from agricultural activities. Individuals who are concerned about any discharges that violate water quality standards should contact the Regional Water Board and inquire about obtaining an individual permit.

<u>Prohibition of Discharges in Violation of Water Quality Objectives in the Klamath River Basin</u>

> Discharges of waste that violate any narrative or numerical water quality objectives that are not authorized by waste discharge requirements or other order or action by the Regional or State Water Board, are prohibited

6.5.3 Guidance to Control Excess Sediment Discharges

To help achieve the watershed-wide TMDL allocations and targets, the implementation plan provides guidance for the control of excess sediment. This guidance is suggestive only and in no way limits the enforcement authority of the Regional Water Board under applicable law.

Parties conducting land use activities that have the potential to discharge excess sediment should implement the following sequential measures:

1. <u>Prevent</u> – Plan, design, and implement the project or activity in such a way that no excess sediment discharge occurs or could occur to waters of the state.
2. <u>Minimize</u> – If the discharge or threatened discharge of excess sediment cannot be fully prevented, then plan, design, and implement the project in such a way that discharges to waters of the state are minimized to the maximum extent possible.

Parties responsible for existing sediment sources (including human-caused legacy sources) should implement the following measures:

1. <u>Inventory</u>: Identify sources of excess sediment discharge or threatened discharge and quantify the discharge or threatened discharge from the sources.

2. Prioritize: Prioritize efforts to control the inventoried sediment sources based on, but not limited to, severity of threat to water quality and beneficial uses, the feasibility of source control, and source site accessibility.
3. Schedule: Develop a schedule to implement the cleanup of excess sediment discharge sites.
4. Implement: Develop and implement feasible sediment control practices to prevent, minimize, and control the discharge.
5. Monitor and Adapt: Use monitoring results to direct adaptive management in order to refine excess sediment control practices and implementation schedules.

6.5.4 Thermal Refugia Protection Policy

The Thermal Refugia Protection Policy proposed by the Klamath implementation plan intends to provide enhanced protection of cold water refugia along the mainstem Klamath River and in the lower Scott River. Thermal refugia are typically identified as areas of cool water created by inflowing tributaries, springs, seeps upwelling hyporheic flow, and/or groundwater in an otherwise warm stream channel offering refuge habitat to cold-water fish and other cold water aquatic species (Watercourse, 2005). The refugia created by some tributaries in the Klamath River basin are typically in the plumes and pools of cold water that form in the mainstem at the tributary confluence. Refugia also exist in some tributary streams themselves. Thermal refugia in the Klamath River basin are essential to the support of the cold water fishery because they moderate the impact of naturally elevated temperatures in the mainstem Klamath River and also can provide a refuge from depressed mainstem dissolved oxygen levels. Their protection has become even more important since the Klamath River has become impaired for temperature. The implementation plan focuses on protecting the critical function of thermal refugia in moderating mainstem Klamath River temperatures in the mid-to later-summer months.

The elements of the Thermal Refugia Protection Policy are:

1. The identification of known thermal refugia locations in the Klamath basin where the policy would apply.
2. The designation of an instream buffer area surrounding thermal refugia where discharges of waste associated with suction dredging are restricted unless otherwise permitted by the Regional Water Board.
3. Recommendations to the State Water Resources Control Board and the California Department of Fish and Game to incorporate the provisions of the Policy into any future permit(s) addressing suction dredging activities.
4. Heightened scrutiny in Regional Board permitting and water quality certification of activities that have the potential to impact the function of thermal refugia.
5. A recommendation to the State Water Board to consider the impact of increased diversions in tributaries that provide thermal refugia when issuing water rights permits to divert surface water or other water rights actions in the Klamath River basin in California.

6. Recommendation to large landowners in the Klamath basin to prioritize restoration and water quality control efforts in tributary watersheds that provide thermal refugia.

6.5.4.1 Identification of Thermal Refugia in the Klamath River Basin in California

The shape and extent of refugia are highly variable and are dependent on stream geomorphology, riparian canopy, sediment dynamics, and flow. Regional Water Board staff recognize that there are a number of factors that can cause seasonal and inter-annual changes in the existence, location, and size of the thermal refugia in the basin. Taken as a whole, these thermal refugia comprise a network of support for populations of cold water fishes in the Klamath River basin.

In order to identify the locations of known thermal refugia in the basin, Regional Water Board staff solicited information from fisheries biologists working in the Klamath River basin through a formal request in April 2009. Based on the information staff received, as well as review of the available reports on the topic, staff compiled a list of the known thermal refugia in the Klamath River basin in California (Table 6.4). References consulted to compile the list of tributaries include the following and will be included in the administrative record of the Klamath TMDL:

1. Grunbaum, Jon B. Memo of Recommended Suction Dredging Guidelines for the Happy Camp Ranger District of Klamath National Forest. 2005.
2. Superior Court of California, County of Alemeda, Hayward Division. Case No.: RG 05 211597. Declaration of Peter B. Moyle, Ph. D., in Support of Entry of Stipulated Judgment. January 26, 2006.
3. Belchik, Michael. Use of Thermal Refugial Areas on the Klamath River by Juvenile Salmonids; Summer 1998. Yurok Tribal Fisheries Program. November, 2003.
4. Belchik, Michael. Summer Locations and Salmonid Use of Cool Water Areas in the Klamath River. Yurok Tribal Fisheries Program. August 1997.

Letters and emails were received from the following persons in response to the April 2009 request:

- Mark Stopher of the California Department of Fish and Game, April 15, 2009.
- Mike Belchick of the Yurok Tribal Fisheries Program, April 24, 2009.
- Earl Crosby of the Karuk Tribe, April 30, 2009.
- Will Harling, Executive Director of the Mid-Klamath Watershed Council, April 28, 2009.
- Jon Grunbaum, Fisheries Biologist for the Klamath National Forest, May 1, 2009.

6.5.4.2 <u>Designation of the Instream Buffer Areas</u>

Instream buffer areas are located in and around the mouths of the tributaries that create refugia in the mainstem Klamath River. Two buffer areas are recommended within the wetted channel of the Klamath River; one upstream and one downstream of the tributary confluence providing thermal refugia. A third buffer area is recommended in the wetted channel of the tributary stream providing thermal refugia, located upstream of the tributary confluence with the Klamath River. These three buffer areas are assigned different lengths based on the potential impacts of instream activities such as suction dredging within that area. Figure 6.3 shows a generic tributary/river confluence with the different instream buffer areas delineated.

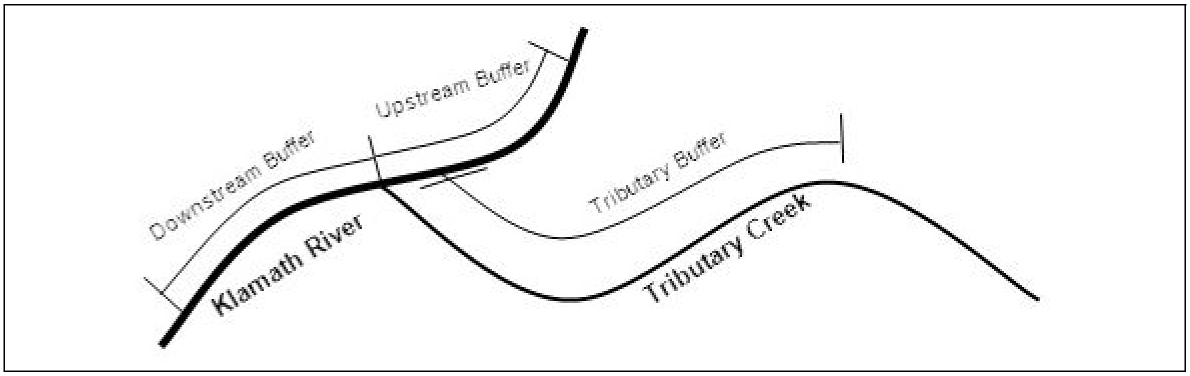

Figure 6.3: Conceptual diagram of proposed buffers in and around the confluence of a tributary providing thermal refugia

Regional Water Board staff recommend a default buffer where no site-specific information is available regarding the spatial extent of the refugia. Where site-specific information is available, an extended buffer may be recommended. Regional Water Board staff referenced a thermal infrared study of the Klamath River basin conducted in August 2003 to identify creeks where a more extensive buffer is appropriate (Watershed Sciences 2004). The study showed the spatial dimensions and water temperatures of cold-water refugia in the mainstem Klamath River. Staff also considered information submitted in response to the April 2009 solicitation.

The buffer length that extends downstream of the tributary confluence is sized to protect cold water plumes that form in the Klamath River where tributaries enter the mainstem river. Most thermal refugia formed by cold water plumes are located within 300 feet of the tributary confluence. Adding a margin of safety to this distance, staff recommend an instream buffer of 500 feet from the tributary confluence in the downstream direction. The responses Regional Water Board staff received from the April 2009 solicitation identified a number of refugia locations where a buffer of 500 feet would not be sufficient to protect the refugia from impacts of instream activities such as suction dredging. For these refugia, staff are recommending a 1500 foot buffer. The tributaries where a 1500 foot buffer is recommended include: Aubrey, Beaver, Clear, Dillon, Elk Creek, Grider, Horse, Indian, Rock, Swillup, Thompson, and Ukonom (See Appendix 9 for a map showing locations).

To protect the refugia from activities upstream of the tributary confluence, the buffer needs to be large enough so that instream activities such as suction dredging have a negligible impact on the function of the refugia downstream. Suction dredging can create plumes of sediment that usually settle out downstream within 300 ft. Adding a margin of safety to this distance, Regional Water Board staff recommend a buffer area of 500 feet in the Klamath River upstream of tributary confluences where known refugia exist.

The portion of the tributary that is just upstream of the tributary mouth can function either as a water supply for the cold water plume in the mainstem, or it can function as a thermal refuge itself. The functions provided by the tributary depend partially on whether fish have physical access to that tributary. If the tributary itself is the refugia, the buffer should extend at least as far as the thermal refuge area within the tributary. To protect the tributaries that provide cold water refugia, staff recommend the buffer be established within the lower 500 feet of the tributary. As with the buffer extent in the downstream direction in the Klamath River, the fisheries biologists that responded to the April 2009 solicitation identified a number of tributaries known to provide refugia for fish. To protect these tributaries from the impacts of instream activities, it is recommended that the buffer be extended to 3000 feet within the tributary upstream of its confluence with the mainstem river. The following is a list of tributary creeks that Regional Water Board staff recommend be provided this added protection: Aubrey, Beaver, Clear, Dillon, Elk Creek, Empire, Fort Goff, Grider, Horse, Indian, King, Little Horse, Little Humbug, Mill, Nantucket, O'Neil, Portuguese, Reynolds, Rock, Sandy Bar, Seiad, Stanshaw, Swillup, Thompson, Ti and Titus (See Appendix 9 for a map showing locations).

6.5.4.3 Changes to List of Thermal Refugia Locations and Designated Buffer Lengths

Staff recommend that the list of identified thermal refugia in the Klamath basin and/or the designated buffer lengths be updated as new information becomes available. This should be done through a public process. Persons proposing modification to the list should submit supporting evidence to the Executive Officer. The Executive Officer may add or remove thermal refugia and/or buffer length designations after public notice and opportunity for public comment. The current list and maps showing the locations of thermal refugia and designated buffer lengths will be maintained on the Regional Water Board website at www.waterboards.ca.gov/northcoast/water_issues/programs/tmdls/klamath_river/.

6.5.4.4 Discharge Restriction In Designated Instream Buffer Areas

The implementation plan recommends restricting discharges associated with suction dredging activities within the designated instream buffer areas described above. These discharges are not currently covered by a permit from the Regional Water Board. The restriction would apply April 15 – September 15. The time period has been changed from the December 2009 public review draft of the Klamath TMDL based on public comments and further review by Regional Water Board staff of the impacts of suction dredging discharges on water quality and fish habitat. The December 2009 draft recommended that the discharges be restricted from June 15 – September 15 based on data that shows this as the critical time period when thermal refugia are needed to support the cold water fishery in the Klamath basin. Staff added two months on the front end to ensure that the impacts of suction dredging during these two months do not compromise the function of the refugia during the critical period. Studies cited in section 4.2.4 of the staff report show that suction dredging can have short term impacts on channel structure and benthic macroinvertebrates populations that are a food source for salmonid using the refugia. The two month period provides time for the channel to readjust and invertebrate populations to recover in time for the June 15-September 15 critical period when the refugia are needed to support the fishery. The discharge restriction during the April 15 – September 15 time period would not apply to other activities where discharges are already regulated by a separate regulatory mechanism such as WDRs, waiver(s) of WDRs, and/or a 401 water quality certification.

6.5.4.5 Status of Suction Dredging as a Point or Nonpoint Source
The status of a discharge from a suction dredge as a point or nonpoint source is currently undefined in California, but other states have designated it a point source and developed NPDES permits to address these discharges. Should suction dredging discharges be found to be point sources in California, they would be prohibited from discharging in the Klamath Basin by an existing general prohibition against all point source discharges in the Basin Plan (Basin Plan at 4-1.00). The State of California would also be obliged to develop an NPDES permit for suction dredging to regulate it as a point source. To accommodate this scenario, the Regional Water Board staff propose that the Basin Plan prohibition on point source discharges only apply to discharges associated with suction dredging activities within the buffer areas designated in the Thermal Refugia Protection Policy. Suction dredging outside of these areas would be permitted by an NPDES permit.

6.5.4.6 SB 670 and the CA Department of Fish and Game Suction Dredging Permit
The California Department of Fish and Game (CDFG) had been administering a permit for suction dredging activities in the Klamath River basin up until May 2009 when the State Senate passed a bill (SB 670) requiring the CDFG to temporarily halt issuance of all suction dredge mining permits. Senate Bill 670 prohibits the use of suction dredge mining equipment in rivers and streams that provide critical habitat to spawning salmon and steelhead until the CDFG updates its suction dredge rules so they comply with CEQA. Pursuant to SB 670, the California Department of Fish and Game is in the process of developing a Fish and Game permit for suction dredging activities in California with input from the State Water Resources Control Board. The Klamath River TMDL implementation plan supports this process as the means to address the impacts of suction dredging activities, and Regional Water Board staff recommend that CDFG be directed in the Basin Plan to incorporate the Thermal Refugia Protection Policy into the revised permit. In the event that the State Water Board issues a state-wide permit for suction dredging, Regional Water Board staff recommend that the Thermal Refugia Protection Policy be incorporated into the revised permit. This directive in no way limits either permitting agency from implementing more stringent requirements.

6.5.4.7 Tributary Flows
Maintaining near natural flows in the Klamath River tributaries in California is an important component of meeting the Basin Plan water temperature objective. In particular, cold water flows are necessary to maintain the function of thermal refugia in the Klamath River basin. Regional Water Board staff will work with other state and federal agencies and tribes to identify and address illegal diversions in the Klamath River basin in California. In addition, Regional Water Board staff recommend that the State Water Board, in administering water rights permits to divert surface water and other actions in the Klamath River basin in California consider the impact of increased diversions on tributaries that provide thermal refugia.

6.5.5 Road Construction and Maintenance on Nonfederal Lands
The road networks in the Klamath River basin contribute to elevated temperatures in tributary watersheds through the discharge of excess sediment. The implementation plan

includes measures for parties responsible for construction and maintenance of roads in the Klamath River basin to meet the road-related TMDL allocations and targets. The road-related TMDL targets (section 6.5.1.2) are measurable and will be used to track the progress of implementation in the basin.

6.5.5.1 Responsible Parties

- All parties responsible for the construction and maintenance of roads
- Modoc, Del Norte, Humboldt, Siskiyou, and Trinity Counties
- California Department of Transportation (Caltrans)

6.5.5.2 Existing Regulatory Structure

The Regional Water Board currently has the following regulatory mechanisms in place:

- Discharges from roads associated with a timber harvest plan (THP) or NTMP are regulated through the Regional Water Board's existing WDRs and waivers of WDRs as described in Section 6.5.7. Existing plans used to meet the TMDL requirements may need to be updated so they meet the applicable watershed-wide allocations and targets.
- Discharges from roads related to logging or construction are subject to discharge prohibitions in the Basin Plan.
- Discharges from state highways managed by Caltrans are regulated through a statewide NPDES permit.
- Any road construction over one acre must enroll in the state-wide construction stormwater permit, which functions similarly to a nonpoint source permit by requiring BMPs and other management measures designed to reduce runoff and erosion. The State Water Board has recently adopted an updated construction permit.
- A water quality certification pursuant to section 401 of the Clean Water Act must be obtained from the Regional Water Board by anyone proposing to conduct a project that requires a federal permit. The most common trigger for a 401 water quality certification is the federal Section 404 US Army Corp of Engineers permit that is required of anyone who proposes an activity that would discharge dredged or fill material into waters of the United States. The 404 permit applies to roads in the Klamath River basin not associated with silviculture or agriculture, which are specifically exempted. All other road construction and/or maintenance projects in and around stream channels in the Klamath River basin are required to apply for this 404 permit. Regional Water Board staff routinely require water quality protection measures in certifying these types of projects.

The construction of roads that involves less than one acre of land disturbance, as well as routine maintenance of existing roads, including county roads, roads associated with grazing and irrigated agriculture, and rural residential roads in the Klamath River basin, are currently not regulated by the Regional Water Board through waivers or WDRs.

This space intentionally left blank

6.5.5.3 Implementation to Address Road-Related Discharges on Private Lands

Most roads located on private lands in the Klamath River basin are associated with timberland ownerships, however roads associated with other land uses, such as agriculture, also exist as do a significant number of rural residential roads. Measures to address road-related discharges will also be incorporated into any land use specific WDRs and waivers proposed as part of this implementation plan such as those proposed for grazing activities and irrigated agriculture. Regional Water Board staff encourage the larger landowners in the Klamath River basin that are responsible for maintaining a significant road network on their land to work with staff to develop ownership-wide WDRs that meet the TMDL requirements on a programmatic level. One of the benefits of ownership-wide WDRs is that they may be developed with input from regulated entities to consider site-specific conditions within the ownership and existing road management plans.

Following are three excellent references on constructing and maintaining forest and ranch roads that can be used to select management practices to comply with the TMDL.

1. National Management Measures to Control Nonpoint Source Pollution from Forestry, US EPA, 2005. (see road sections within) http://www.epa.gov/owow/nps/forestrymgmt

2. Handbook for Forest and Ranch Roads, Weaver and Hagans, 1994. http://www.krisweb.com/biblio/gen_mcrcd_weaveretal_1994_handbook.pdf

3. Environmentally Sensitive Maintenance for Dirt and Gravel Roads, compiled for US EPA, 2005. http://www.epa.gov/owow/nps/sensitive/sensitive.html

If you do not have access to the internet, call the Regional Board at 707-576-6750 to obtain a hardcopy of any of these documents.

6.5.5.4 Existing Management Plans and Programs

Parties managing roads in the Klamath Basin may have already developed property-wide plans that include management measures to control nonpoint source pollution. Roads are often a major component of these plans, since they have significant potential to impact water quality. Implementation of existing plans and programs may be used to fulfill the requirements of the TMDL. For example, industrial timber companies may be implementing a Habitat Conservation Plan (HCP) as part of their Endangered Species Act compliance. Another existing management plan that may be used in part to comply with the TMDL is the Non-Industrial Timber Management Plan (NTMP). NTMPs are developed by individual landowners under 2,500 acres to comply with the Forest Practice Rules and must include water quality protection measures for roads. It is the responsibility of the landowner to ensure existing plans and programs achieve TMDL allocations and that additional measures are implemented as needed for compliance. Regional Board staff are available to work with landowners to implement the Klamath TMDLs and revise existing programs accordingly.

Green Diamond WDRs

The Regional Water Board staff are currently in the process of developing WDRs for Green Diamond Resource Company (Green Diamond) to address potential discharges associated with road-related maintenance and management activities as part of their Aquatic HCP. The WDRs are scheduled for adoption by the Regional Water Board by April 2010. These WDRs will incorporate implementation measures to meet the Klamath River TMDLs. By complying with the WDRs in the Klamath basin, Green Diamond will be in compliance with the Klamath TMDL requirements for road-related discharges.

Green Diamond's HCP establishes a solid framework for TMDL compliance because it contains stringent water quality protections implemented across their landownership. For example, the HCP requires watershed assessments of road-related sediment sources, prioritization of those sources, and implementation of appropriate management practices to upgrade or decommission roads according to the assessment. The monitoring included in the HCP can also comply with the Klamath TMDLs because the HCP and the TMDL both track implementation of management practices that control pollution as well as progress towards meeting instream water quality objectives.

Following are some of the examples of management measures summarized from the Green Diamond HCP (2006) relevant to TMDL implementation for controlling impacts from roads:

Slope Stability

- Establishes a system for identifying slope stability management zones (SMZ) where steep slopes lead to Class I and II waters.
- Road construction is prohibited in the SMZ without approved review and harvest is limited

Road Management

- Conduct assessments in 58 sub-watershed road work units (RWUs) to identify sediment source sites
- Provides $2.5 million a year for 15 years for treating high and moderate priority sites
- Road use is seasonally restricted and prohibited if sediment delivery is identified
- All new culverts must meet 100-year return interval flow design standard and existing culverts must be within 15% of the design flow to not be replaced
- Conduct emergency inspections of all accessible rocked roads if a storm produces 3 or more inches of rain in a 24-hour period, and prioritize repairs

Monitoring

- Monitor road-related delivery of fine sediment and evaluation of the effectiveness of road management measures

Regional Board staff will work with Green Diamond to integrate the HCP with the WDRs and TMDL implementation.

6.5.5.5 Implementation Measures to Address County Roads

Del Norte, Humboldt, Modoc, Siskiyou, and Trinity Counties are responsible for maintaining county roads and meeting water quality standards. The potential for roads to discharge sediment in amounts that can cause alteration to stream channels is documented in the technical TMDL source analysis (Chapter 4). The Regional Water Board does not currently regulate discharges associated with county roads and plans to develop a regulatory approach in compliance with the State NPS Policy. The approach recommended by the Klamath implementation plan is to certify the Five County Roads Program (5C Program) that includes all counties in the Klamath Basin except Modoc County. Discharges from Modoc County will be addressed through the Regional Board's Basin Plan prohibitions.

Pursuant to the Impaired Waters Policy, Regional Water Boards may rely upon the 5C program to implement the TMDL if it can determine the following:

- the implementing program is consistent with the assumptions and requirements of the TMDL;
- sufficient mechanisms exist to provide reasonable assurances that the program will address the impairment in a reasonable period of time; and
- sufficient mechanisms exist to ensure that the program will be enforced, or that the Regional Water Board has sufficient confidence that the program will be implemented such that further regulatory action would be unnecessary and redundant.

Five Counties Salmonid Conservation Program

Five counties in the North Coast Region, four of which are in the Klamath River basin, have already initiated a unified program that addresses sediment discharges on county roads. In 1997, the Counties of Del Norte, Humboldt, Mendocino, Siskiyou, and Trinity agreed to form the Five Counties Salmonid Conservation Program (5C Program) in response to federal Endangered Species Act listings of salmon species as 'Threatened'. The program objectives include: "identify(ing) potential problem sites through systematic inventories of fish passage barriers and potential erosion sources on County maintained roads (Five Counties Salmonid Conservation Program 2009)." The 5C Program includes inventorying road-related sediment sources and implementing management practices to address those sources. The program has made considerable progress, and as of 2007, more than 2113 miles of county roads have been inventoried within the five counties. In consultation with state and federal agencies, the 5C Program has also developed *A Water Quality and Stream Habitat Protection Manual for County Road Maintenance in Northwestern California Watersheds* (5C Manual, Five Counties Salmonid Conservation Program 2002). The 5C Manual prescribes management practices for both routine and emergency repair and maintenance of county roads, bridges and related facilities. The 5C Manual contains a protocol for developing County Road Sediment Source Inventories of portions of county roads in order to set priority locations for erosion and sediment control efforts. The resulting Direct Inventory of Roads and Treatments (DIRT) provides a useful database for the counties' road departments to track progress in treating priority sites and associated sediment savings. The 5C Manual includes implementation and effectiveness monitoring and requires an annual report that summarizes the counties' self-evaluation of the effectiveness of road maintenance BMPs in protecting water quality and stream habitat.

<u>Recommendation</u>

The Regional Water Board staff recommend certifying the 5C Program because it contains measures adequate to meet the TMDL allocations and water quality standards. The certification will require a monitoring plan, and conditions that require trackable progress. The program's success will be assessed by the Regional Water Board every five years and the certification may be revoked if the program is found to be not adequately implemented, not achieving its goals, or is no longer adequate to restore water quality. To receive coverage under the waiver and certified 5C Program, each county must certify its intent to comply with the 5C program or otherwise indicate its intention to participate. This can be accomplished by acceptance and implementation of the 5C Manual by the County Board of Supervisors as a CEQA-exempt project, or other evidence of intent such as an agreement with the Director of Public Works or County Road Department to abide by the practices in the 5C Manual. The certification and waiver will not cover activities that otherwise require coverage under a different permit including the state-wide construction stormwater permit for new construction, or projects that require water quality certification under section 401 of the Clean Water Act. In the alternative, a county may submit a report of waste discharge and the Regional Water Board will process a WDR for county roads. This may be an option for Modoc County, which is not one of the five counties participating in the 5C Program.

<u>Implementation Measures for County Roads</u>

Regional Water Board:

<u>Measure</u>

- The Regional Water Board shall consider adopting a resolution and accompanying waiver for maintenance of county roads certifying the Five Counties Salmonid Conservation Program (5C Program) if it complies with the TMDL and attains standards in accordance with California Impaired Waters Guidance.

<u>Timeline</u>

- December 2010

Measure

- In the event that a county does not show intent to implement the 5C Program, develop Waste Discharge Requirements or a waiver of WDRs for that county.

Timeline

- June 2011

Siskiyou, Humboldt, Del Norte and Trinity Counties:

Measure

- Implement measures through the Five Counties Salmonid Conservation Program.

Timeline

- Pursuant to the 5C Program timelines.

6.5.5.6 California Department of Transportation

In the Klamath River basin within California, Caltrans has jurisdiction over segments of three state highways: State Route 96, State Route 169, and State Route 299. There are also two segments of the federal transportation system that Caltrans manages and maintains within the Klamath River basin in California: U.S. Interstate Highway 5 and U.S Interstate Highway 101. Discharges of waste from Caltrans' facilities are regulated by the State Water Board under the NPDES Permit for Caltrans (Order No. 99-06-DWQ and NPDES No. CAS000003), adopted on July 15, 1999. The State Water Board is in the process of revising the Caltrans NPDES permit with input from the Regional Water Boards.

The Klamath TMDL analysis identified Caltrans facilities as contributing to water temperature impairments mainly through the discharge of excess sediment (e.g. eroding shoulders, failed culverts, and unstabilized cut and fill slopes). The Klamath implementation plan recommends measures for Caltrans to implement basinwide through their Statewide NPDES permit. The Scott and Shasta TMDL implementation plans also address discharges from Caltrans facilities and both require the Regional Water Board to evaluate the adequacy of the Caltrans NPDES permit. Since the permit is being revised, there is an opportunity to incorporate TMDL measures for all three TMDLs into the permit based on the Regional Water Board's evaluation. The Klamath implementation plan makes the following recommendations concerning Caltrans facilities:

1. Include measures in the revised NPDES permit consistent with the Guidance to Control Excess Sediment for Caltrans facilities in the Klamath basin.
2. Incorporate measures to protect riparian shade in the revised NDPES permit and in 401 water quality certifications, and
3. Remove barriers to migratory fish passage associated with Caltrans road and highway facilities in tributary creeks identified in the Thermal Refugia Protection Policy.

Senate Bill 857 (Kuehl 2005), enacted into law effective January 1, 2006, requires Caltrans to prepare a yearly report describing its efforts to assess and remediate the negative impacts of state highway or road structures that serve as barriers to migratory fish passage. This mandate is consistent with the goals of the implementation plan to protect and provide access to thermal refugia in and around the mouths of tributaries to the mainstem Klamath River. There are several barriers to migration along Highway 96 caused by undersized culverts and the presence of the highway. If fish barrier removal in thermal refugia cannot be incorporated into the NPDES permit, the implementation plan contains a recommendation to Caltrans to implement this measure.

<u>Implementation Measures for Caltrans Facilities</u>

State Water Board and Regional Water Board:

<u>Measure</u>

- Incorporate the following measures into the Caltrans NPDES permit:
    1. <u>Inventory</u>: Identify sources of excess sediment discharge or threatened discharge and quantify the discharge or threatened discharge from the source(s).
    2. <u>Prioritize</u>: Prioritize efforts to control the inventoried sediment sources based on, but not limited to, severity of threat to water quality and beneficial uses, the feasibility of source control, and source site accessibility.
    3. <u>Schedule</u>: Develop a schedule to implement the cleanup of excess sediment discharge sites.
    4. <u>Implement</u>: Develop and implement feasible sediment control practices to prevent, minimize, and control the discharge.
    5. <u>Monitor and Adapt</u>: Use monitoring results to direct adaptive management in order to refine excess sediment control practices and implementation schedules.
- Incorporate measures to meet the riparian shade allocation in the statewide Caltrans NPDES permit and 401 water quality certifications.

<u>Timeline</u>

- The revised statewide Caltrans NDPES permit is scheduled for adoption by the State Water Board by August 2010, with USEPA adoption anticipated by December 2010.

Caltrans:

<u>Measure</u>

- Implement the measures outlined above to control the discharge of excess sediment from their facilities and comply with the Klamath TMDL allocations and targets, even if measures are not incorporated into the statewide Caltrans permit.

Measure

- Implement measures to meet the riparian shade allocation, even if measures are not incorporated into the statewide Caltrans permit.

Measure

- Fully assess all barriers and potential barriers to migration caused by Caltrans road and highway facilities along the mainstem Klamath River and in the tributary watersheds identified in the Thermal Refugia Protection Policy. Develop a priority ranking and time schedule for modifying the identified fish passage barriers to accommodate free passage of fish upstream and downstream.

Timeline

- Caltrans shall submit an annual report to the Regional Water Board documenting measures taken to address fish passage barriers caused by its facilities.

6.5.6 Agriculture (Grazing and Irrigated Agriculture)

Agricultural activities in the Klamath River basin have the potential to contribute to TMDL impairments mainly through erosion, alteration of riparian functions, discharge of nutrients and organic matter, and water diversions. Grazing on nonfederal lands in California occurs mostly in the tributary basins in the upper middle reach of the Klamath River from Scott River to Iron Gate dam, including the Scott and Shasta River basins, and in the Lost River basin that drains into the Klamath River in Oregon. Irrigated agriculture occurs in the Klamath River basin in California mostly in the tributary basins in the upper middle reach of the Klamath River from Scott River to Iron Gate dam, including the Scott and Shasta River basins, and in the Lost River basin that drains into the Klamath River in Oregon. The Regional Water Board currently does not regulate agricultural activities in the Klamath River basin, except through waivers of WDRs adopted as part of the Scott River and Shasta River TMDL Action Plans or through an NPDES permit if an operation is classified as a concentrated animal feeding operation (CAFO).

6.5.6.1 Responsible Parties

Parties conducting activities associated with irrigated agriculture and grazing that discharge waste or have the potential to discharge waste in the Klamath River basin in California

6.5.6.2 Implementation

Several changes have been made in the regulatory approach to grazing and irrigated agriculture based on comments received during the public comment period since the last draft. Many of the commenters stated that the draft implementation measures were confusing and did not provide for a streamlined regulatory approach. Staff also received numerous comments on the proposed agricultural waiver and the interim waiver requirements for agriculture proposed in the June 2009 draft. The interim waiver would have required agricultural dischargers to comply with various implementation measures, which included the development of a water quality management plan. Commenters stated that they were not aware that the Klamath TMDL would impose additional requirements on responsible parties in the Scott and Shasta basins, where landowners are already subject to the requirements of previously adopted TMDLs. Staff also received comments stating that stakeholders were not involved enough in the development of the recommended implementation measures for agriculture and called for a public process to develop the waiver.

Staff considered comments and the potential for overlapping regulatory requirements in the Klamath Basin and decided to remove the recommendation of an interim waiver and specific requirements in order to allow time for the agricultural conditional waiver program to be fully developed. It is staff's intention that the stakeholder process will lead to a sensible agricultural program developed in collaboration with the regulated community and all interested stakeholders. The Regional Water Board will initiate the stakeholder process after adoption of the TMDL. In the interim time period before the waiver is adopted, the Klamath implementation plan recommends several steps for landowners to take that will help to develop the waiver program:

1. Document past projects and current practices that address sources of pollution from their operations.
2. Organize into watershed groups to report to the Regional Board as a group as part of the future waiver program.
3. Participate in the development of the conditional waiver through a Technical Advisory Group that will convene to develop the draft waiver by December 2011.
4. Attend water quality training on implementing management practices and/or water quality management plan development.
5. Sign up on the Regional Water Board Klamath River TMDL mailing list to receive information about the development of the waiver and water quality training.

6.5.6.3 Content of the Future Agricultural Waiver

Staff also received comment concerning specific requirements for agriculture and the content of the proposed waiver program. Regional Board staff have not yet decided on the appropriate recommendations, which will depend the outcome of the stakeholder process. The issues that were raised by the commenters will be included on the agenda for the stakeholder meetings. In general, the agricultural waiver would support a locally driven landowner effort to control these sources of pollution and report on progress to the Regional Board. There will also be a provision to define and allow de minimus discharges under the waiver program.

Under the conditions of the waiver, agricultural owner/operators would work towards meeting water quality standards for the State of California. The waiver requirements will be based on meeting applicable water quality standards, and effective implementation will depend on local landowner knowledge in identifying management practices. While the waiver will establish the performance standards that must be met, landowners will have the flexibility to choose the management practices that are appropriate for their operation and protect water quality.

Compliance would be achieved by actively identifying sources of pollution, implementing management practices to control those sources, documenting efforts, monitoring, and reporting to the Regional Water Board. It is generally the owner/operator's responsibility to select the management practices that are most effective at controlling pollution from their lands. The Regional Water Board staff are considering developing a checklist to assist in the selection of the appropriate management practices and also to serve as the reporting mechanism to track compliance.

The Regional Board is flexible in its approach to a waiver and would like to incorporate existing programs and input from the affected communities as part of the process. The information provided below is intended to provide an idea of what a conditional waiver for agricultural activities might look like and to solicit input on its development. These provisions are not requirements of the Klamath TMDL and are provided for informational purposes only.

To address sources of pollution, the waiver may include conditions such as:

1. Minimizing water contact with animal manure and preventing livestock from damaging streams and riparian vegetation
2. Managing riparian areas
3. Controlling nutrients and elevated temperatures in tailwater.

The State Nonpoint Source Program Plan provides performance standards called 'management measures' to guide implementation of water quality control practices. The management measures are grouped into the following categories in the plan:

- Erosion and Sediment Control
- Nutrient Management
- Irrigation Water Management
- Grazing Management
- Pesticide Management

These management measures are available at the following website: http://www.waterboards.ca.gov/water_issues/programs/nps/docs/guidance/agricmms.pdf.

Examples of management practices that may be implemented to meet the NPS Program Plan management measures are provided by the following reference:

- USEPA *National Management Measures for the Control of Nonpoint Pollution from Agriculture* is available from the USEPA or may be printed from the following website: http://www.epa.gov/nps/agmm/index.html.

6.5.6.4 Monitoring and Reporting

The waiver must contain monitoring and reporting conditions to track compliance with water quality standards. Enrollees in the waiver would have the option of reporting to the Regional Water Board either individually or as part of a group organized by a third party such as the local resource conservation district or watershed council. The Regional Water Board would review the effectiveness of the waiver program at least every five years and make changes as needed considering discharger compliance rates and water quality conditions. The monitoring and reporting requirements would be developed to achieve the following objectives:

1. Document the implementation of management practices selected to address water quality problems associated with agricultural operations
2. Evaluate the effectiveness of the selected practices
3. Measure long-term trends in water quality to evaluate the overall effectiveness of the waiver program. Long term trend monitoring may be done through either an existing group monitoring program or a through a group program that is developed to track compliance with the waiver.

6.5.6.5 Other Regional Board Agricultural Programs Around the State

There are agricultural waivers in place for Regions Water Boards 2 (San Francisco), 3 (Central Coast), 4 (Los Angeles), 5 (Central Valley), and 9 (San Diego). A description of the current North Coast Regional Water Board (Region 1) existing interim TMDL waivers and the agricultural waiver programs in Region 2 and 3 is provided below as examples of existing agricultural regulatory programs in California. More information about these programs can be found on each region's respective websites that can all be accessed from www.waterboards.ca.gov.

Region 1

The North Coast Regional Water Board adopted two separate waivers as a part the Scott and Shasta basin TMDL implementation plans. These waivers have been in effect since adoption of those TMDLs in 2005 and 2006 respectively and will expire in five years from the date of adoption. The waiver requires responsible parties in those basins to participate in ongoing programs that address discharges that contribute to TMDL impairments. Staff have periodically updated the Regional Water Board on the progress of implementation in the Scott and Shasta basins. The Regional Water Board will consider whether or not to extend the TMDL waivers when they expire in 2010 for the Scott basin and 2011 for the Shasta basin. The Regional Water Board may decide not to extend the existing TMDL waiver and instead incorporate the measures in the Scott and Shasta implementation plans into the development of the agricultural waiver proposed in the Klamath TMDL to make requirements of agricultural discharges more consistent throughout the basin.

Region 2

The San Francisco Regional Water Board (Region 2) adopted a waiver to regulate discharges associated with grazing activities in the Tomales Bay basin in July 2008 as part of TMDL implementation in that basin. The waiver requires the submittal of a Notice of Intent (NOI) to enroll in the waiver program, due in January 2009. It also requires ranchers to develop a Farm Plan by November 2009 and keep it onsite. The NOI asked for the address of the owner/operator, identification of the receiving water(s), whether a farm plan has been completed or will be by November, and if the facility is in compliance with the waiver conditions. The waiver requires annual certification which consists of the submittal a single page of the farm plan template that was provided to ranchers. The submittal page asks for:

- the name/address/APN
- when a ranch plan is to be completed or when it was completed
- the dates of compliance monitoring inspections performed during the wet season and dry season
- when a survey of streams on the ranch was completed
- whether further BMPs are needed and if yes when such projects will be completed.
- The Farm Plan is a fill in the blank exercise and includes the following required information:
- Property information
- A field assessment with a checklist addressing rangeland conditions, roads, livestock distribution, manure management, and mercury.
- A stream assessment with a similar checklist addressing the stream channel, stream temperature factors, and algae growth in the stream.
- A list of past water quality projects completed is optional but information regarding future water quality projects is required.

Region 3

The Central Coast Regional Water Board (Region 3) adopted a waiver to address all discharges associated with irrigated lands in July, 2004. The waiver required the submittal of an NOI by January 1, 2005; 6 months after adoption of the waiver. Their NOI form requested basic information such as address, whether monitoring would be done as a group or individually, whether a farm plan has been completed, and the hours of water quality education that had been completed. It also required the following to be submitted alongside the NOI:

- A ranch information form that asked for the APN, the types of crops grown, how many acres of sprinkler irrigation, flood irrigation, etc.
- A map of the property
- A certificate of completed education if applicable

- A management practices form that consisted of a checklist of about 40 questions in four categories: pesticide management, irrigation water management, nutrient management, and erosion control. The rancher could circle 'yes, I am doing this', 'no, but I plan to within 3 years', or 'no and not planned'.

Implementation Measures for Agriculture

Regional Water Board:

Measure

- Develop a conditional waiver of WDRs for discharges associated with agricultural activities, including grazing and irrigated agriculture, in the Klamath River basin. The conditional waiver shall require compliance with the Klamath River TMDL load allocations where they apply and will serve as the means of compliance with the Lower Lost River TMDL load allocations associated with agricultural sources. Timeline
- Regional Water Board staff shall propose the conditional waiver for Regional Water Board consideration by December 2012.

Any party conducting activities associated with irrigated agriculture that discharge waste or have the potential to discharge waste in the Klamath River basin in California:

Measures (recommended)

- Document past projects and current practices that address sources of pollution from their operations.
- Organize into watershed groups to report to the Regional Board as a group as part of the future waiver program.
- Participate in the development of the conditional waiver through a Technical Advisory Group that will convene to develop the draft waiver by December 2011.
- Attend water quality training on implementing management practices and/or water quality management plan development.
- Sign up on the Regional Water Board Klamath River TMDL mailing list to receive information about the development of the waiver and water quality training.

Timeline

- From Regional Water Board adoption of the Klamath TMDL Action Plan until adoption of the conditional waiver addressing agricultural discharges

6.5.7 Timber Harvest on Nonfederal Lands

Timber harvest activities can impact water temperature and can contribute to dissolved oxygen and nutrient water quality impairments. The Klamath River TMDL implementation plan focuses on controlling sediment and protecting riparian functions from timber harvest activities to meet the watershed-wide TMDL allocations and targets. Timber harvest on nonfederal lands is currently regulated through a combination of general WDRs (Order No R1-2004-0030) and a conditional waiver of WDRs (Order No R1-2009-0038). The existing general WDRs and waiver contain a requirement that all provisions of the Basin Plan must be met to qualify for enrollment in the WDRs or waiver. By amending the Basin Plan through adoption of the Klamath River TMDL Action Plan, the requirement to meet the TMDL load allocations will be incorporated by reference into the existing general WDRs. The waiver contains TMDL requirements for temperature based on 85%/65% canopy, which is slightly different terminology from the Anadromous Salmonid Protection (ASP) Rules recently adopted by the California Board of Forestry. The implementation recommendations for shade conditions described below are consistent and equally protective as the shade conditions in the existing conditional waiver of WDRs for timber harvest activities on nonfederal lands, and may be used for enrolling THPs under the waiver until the waiver is updated.

6.5.7.1 Responsible Parties

- Regional Water Board
- Any party conducting timber harvest activities that discharge waste or have the potential to discharge waste in the Klamath River basin

6.5.7.2 The General WDRs

In 2004, the Regional Board adopted Order R1-2004-030: *General Waste Discharge Requirements for Discharges Related to Timber Harvest Activities on Non-Federal Lands in the North Coast Region*. These General Waste Discharge Requirements (WDRs) rely on the *Forest Practice Rules* (FPRs) managed by CALFIRE as lead agency, as the baseline requirements to achieve water quality goals. Per CEQA, under separate and concurrent authority established by the Porter-Cologne Water Quality Control Act, the Regional Water Board may impose additional restrictions to achieve compliance with water quality standards. The WDRs require:

1) Notification of a discharge that violates water quality standards, and a schedule for addressing the problem.
2) Implementation of an ECP (similar to the ECP required by NTMP categorical waiver) for the project area.

3) Regular self inspections to track the effectiveness of implementation. Inspections are to take place before, during, and after the winter period.

6.5.7.3 Watershed-wide and Ownership WDRs

Timber companies and larger landholders may also be permitted through watershed-wide or ownership WDRs. Watershed-wide WDRs are issued for timber harvest activities within a specific watershed. The watershed may be fully contained within the permit holder's ownership, or the watershed may cross ownership boundaries. The ownership WDRs, on the other hand, may apply to the permit holder's entire property, crossing watershed boundaries. These WDRs represent a programmatic approach to addressing water quality concerns and are more comprehensive than the general permit or waivers. They can be made more specific to the ownership or watershed as a whole. Future ownership or watershed-wide WDRs adopted will incorporate measures necessary to meet the TMDL load allocations and water quality standards in the Klamath Basin.

6.5.7.4 Individual WDRs

The Regional Board may choose to regulate a given timber harvest project through individual WDRs if the General WDRs are not appropriate. Individual WDRs contain requirements that are more specific to the threats to water quality proposed by the THP. To implement the TMDL, the Regional Board will include Klamath implementation plan measures as part of individual WDRs for timber harvest activities in the Klamath Basin.

6.5.7.5 Board of Forestry Forest Practice Rules

Timber harvest on nonfederal lands is also subject to the requirements of the California FPRs. These rules were recently amended to include the *Anadromous Salmonid Protection Rules* (a subset of the FPRs that applies to CALWATER planning watersheds where populations of anadromous salmonids are currently present or can be restored). The FPRs may be sufficient to implement the Klamath TMDL in many situations; however, the FPRs may not always be protective enough to meet the water quality standards.

6.5.7.6 Riparian Shade Allocation and Temperature Water Quality Standards

The riparian shade allocation in the Klamath TMDL is based on the existing intrastate water quality objective for temperature. The allocation requires the shade provided by topography and full potential vegetation conditions at a site, with an allowance for natural disturbances such as floods, wind throw, disease, landslides, and fire. Regional Water Board staff prefer to rely on the FPRs to address water temperature concerns related to timber harvesting, and wish to avoid establishing different rules governing the same activity. Regional Water Board staff have reviewed the ASP Rules and determined that the new rules substantially increase riparian retention standards, and are much more protective of stream temperatures than the previous rules. In most cases, timber operations occurring in areas where the ASP rule canopy prescriptions apply will achieve compliance with the temperature TMDL. However, while the ASP Rules are expected to address temperature issues in the majority of timber harvest situations, they do not ensure compliance with the temperature water quality objective nor the Klamath TMDL riparian shade allocation in all cases where they apply. There are instances where adherence to the ASP rules would result in a reduction in riparian shade and an increase in water temperature that is not consistent with the allocation or water temperature objective. An example of a circumstance where the ASP Rules are insufficient is in a 'Class II small' stream where they only require 50% canopy retention where cold-water dependent species are present. In addition, nothing in the ASP Rules prevents a five degree increase in water temperature, which the temperature objective specifically prohibits. A noticeable gap in the ASP Rules is that they only apply in watersheds that are within the range of anadromous salmonids, while the water quality objective for temperature applies to all waters of the state, regardless of what species are present. Therefore to comply with the TMDL, responsible parties may be required to implement additional riparian shade protections where Regional Water Board staff determines that the Forest Practice Rules are insufficient to meet the Klamath TMDL allocation. Regional Water Board staff recommend and may require foresters manage riparian areas consistent with the Anadromous Salmonid Protection Rules' riparian prescriptions where salmonids are present regardless of whether a reach is open to anadromy. Foresters proposing to reduce effective shade on watercourses or prevent recovery of site-potential shade must justify such proposals in light of the water quality objective for temperature. To meet the water temperature objective, which applies regionwide, and to address gaps in ASP riparian protections, it is recommended that this approach also be incorporated into all WDRs, and conditional waivers of WDRs regionwide.

6.5.7.7 Existing Plans and Programs

Parties conducting timber harvest activities in the Klamath Basin may have already developed property-wide plans that include water quality protections. Existing plans and programs may be used to fulfill the requirements of the TMDL. For example, industrial timber companies may be implementing a Habitat Conservation Plan (HCP) as part of their Endangered Species Act (ESA) compliance. To obtain a federal incidental take permit, authorizing 'incidental take' of an ESA listed species, an applicant must submit a Habitat Conservation Plan (HCP) outlining what will be done to "minimize and mitigate" the impact of the permitted take. The impact of the 'take' in many cases relates to impacts on water quality, and thus the HCP in many cases contains water quality protections relevant to TMDL implementation. Green Diamond completed their HCP in 2007, which considers impacts to listed species on company lands and includes water quality protections. Another existing management plan that may be used in part to comply with the TMDL is the Non-Industrial Timber Management Plan (NTMP). NTMPs are developed by individual landowners with holdings under 2500 acres to comply with the FPRs and must include water quality protection measures. In either case, plans or programs may need to be updated, and/or additional measures may need to be developed and implemented in order to comply with the TMDLs and water quality standards. Regional Board staff will work with landowners to implement the Klamath TMDLs through these existing programs.

This space intentionally left blank

Implementation Measures for Timber Harvest on Nonfederal Lands

Regional Water Board:

Measure
- The Regional Board shall adopt individual watershed-wide and ownership WDRs, in lieu of the general WDR or conditional waiver of WDRs, to achieve the TMDL load allocations and water quality standards as needed and/or at the request of the discharger.

Measure
- Regional Water Board staff shall make recommendations for additional measures to ensure the water quality objective for temperature is achieved during the timber harvest review process, if necessary

Timeline
- Ongoing

Parties conducting timber harvest activities on nonfederal lands that discharge waste or have the potential to discharge waste in the Klamath River basin:

Measure
- Implement riparian management measures that meet the riparian shade allocations and water quality standards. Where the Forest Practice Rules, including the ASP rules, are not sufficient to meet the TMDL allocations or water quality standards, implement additional measures as directed by Regional Water Board staff during the timber harvest review process.

Timeline
- Ongoing

6.6 TMDL Implementation on Federally Managed Lands

There are two federal land managers in the watershed, BLM and the USFS. The USFS manages over half of the total acreage in the Klamath River basin in California on four National Forests: Six-Rivers, Klamath, Shasta-Trinity, and Modoc. Land use activities on USFS lands that were identified in the Klamath River TMDL as potentially contributing to the TMDL impairments include but are not limited to timber harvest, grazing, and road construction and maintenance. BLM manages small, isolated areas of land in the Klamath

River basin in California, and therefore the implementation plan focuses on the lands managed by the USFS. The approach to regulating USFS activities will inform our approach to BLM in the future.

The Regional Water Board regulates USFS timber harvest activities through an existing regionwide waiver of WDRs, and Regional Water Board staff are in the process of developing a new waiver of WDRs that would be expand oversight to most nonpoint source activities on lands managed by the USFS. The new waiver is scheduled to be considered by the Regional Water Board for adoption in April 2010 and would take the place of the existing timber harvest waiver. The waiver will implement applicable provisions of the State NPS Policy to establish a regulatory mechanism for all nonpoint source discharges. It will contain measures that implement existing TMDLs in the North Coast Region including the proposed Klamath TMDL. Meeting the conditions of the proposed regionwide waiver will be sufficient for TMDL compliance in the Klamath basin in California. The waiver is coordinated with existing USFS plans and programs that address water quality in the Klamath River basin and is being developed with input from the USFS. This section first gives the recommended implementation measures and then describes the water quality elements of existing USFS plans and programs and how they can be coordinated with TMDL requirements.

6.6.1 Responsible Parties

- Regional Water Board
- US Forest Service
- Parties conducting timber harvest activities on federal lands under the terms of a timber harvest sale contract.
- Parties conducting grazing activities on federal lands in designated grazing allotments.

Implementation Actions

Regional Water Board:

Measure
- Develop a conditional waiver of WDRs for nonpoint source activities on USFS lands that includes conditions that implement the Klamath TMDL.

Timeline
- To be proposed for consideration by the Regional Water Board in April 2010.

USFS:

Measure
- Conduct land management activities in compliance with the waiver of WDRs when adopted.

Timeline
- As required in the waiver of WDRs.

6.6.2 USFS Plans and Policies

As a manager of the National Forests, the USFS follows several policy documents and administrative rules that address water quality concerns The guiding policy for USFS water quality management at the statewide level in California is the *Water Quality Management for Forest System Lands in California, Best Management Practices* (USFS 2000) guidance document developed jointly by the State Water Board and the USFS. The USFS adopted the federal *Northwest Forest Plan* (USFS 1994b) standards and guidelines, and the *Aquatic Conservation Strategy*. The National Forests have incorporated this policy direction into their forest level *Land and Resource Management Plans* (USFS 1994a, USFS 1994c, and USFS 1995). While Regional Water Board staff support these plans and policies as viable implementation vehicles, there is also an expectation that the plans be revised as necessary to comply with the TMDL. Regional Water Board staff will continue to work with the USFS to ensure these programs effectively meet TMDL allocations and targets in the Klamath Basin.

6.6.2.1 <u>State Water Board and USFS guidance document</u>

In 1981, the State Water Board and the USFS entered into a Management Agency Agreement (MAA) in which the USFS agreed to implement the 1979 *Water Quality Management for Forest System Lands in California, Best Management Practices* that protect water quality on USFS lands in California (USFS and SWRCB 1981). In 2000, the USFS revised some of the performance standards for meeting water quality standards and released an updated version of the *Water Quality Management for Forest System Lands in California, Best Management Practices* (USFS 2000) guidance document. The performance standards described in this document for different categories of land use are called ‘Best Management Practices’. This terminology is slightly confusing because the document refers to performance standards as ‘Best Management Practices’ (BMPs) that are met through the implementation of appropriate management practices, whereas the term ‘BMP’ usually refers to the practices themselves. For example, in the guidance document, “BMP 2-7 ‘Control of Road Drainage’ dictates that roads will be correctly drained to disperse water runoff to minimize the erosive effects of concentrated water flow” (USFS 2000). This is a performance standard that must be met through the implementation of on-the-ground practices that are not specified in the document, such as the installation of rolling dips or road outsloping. The USFS forms interdisciplinary teams to select the appropriate practices that meet the performance standards based on an assessment of project site conditions. It is essential that the practices selected to meet the water quality ‘BMPs’ be included in any project controlling documents to ensure practices are implemented as part of the project. Regional Water Board staff continues to actively work with the USFS staff to identify where and when the selected management practices are identified in their planning documents.

6.6.2.2 <u>Northwest Forest Plan</u>

The Northwest Forest Plan (NWFP) was adopted by the USFS in 1994 and is implemented by the National Forests in the Klamath River basin. The mission of the NWFP is to adopt coordinated management direction for the lands administered by the Federal government, including the USFS. The Northwest Forest Plan Record of Decision (USFS 1994b) presents a combination of land allocations and "Standards and Guidelines" for the management of those allocations. While the Standards and Guidelines consider more than just water quality protection, the NWFP also includes the Aquatic Conservation Strategy (ACS) that specifically focuses on water quality. Regional Water Board staff support the objectives of the ACS as consistent with the objectives of Klamath TMDL implementation. The ACS can be found at: <http://www.reo.gov/library/reports/newsandga.pdf> (page B-9).

6.6.2.3 Land and Resource Management Plans

The USFS forest-level planning documents are called Land and Resource Management Plans (LRMPs). Each National Forest in the Klamath River basin has their own LRMPs that guide their land management activities. Shortly after the NWFP went into effect, the National Forests updated their LRMPs to incorporate the new Standards and Guidelines and the ACS. The LRMPs also incorporate the State Water Board and USFS guidance document described above. The Regional Water Board staff support the implementation of the LRMPs as a means to achieve the watershed-wide allocations and targets. The Regional Water Board will work with the USFS to update their LRMPs as necessary.

6.6.3 Timber Harvest

Currently, the Regional Water Board regulates timber harvest on federal lands through a conditional waiver of waste discharge requirements (Order No R1-2004-0015). The waiver and its regulatory requirements will be incorporated into the future waiver that addresses other nonpoint source activities conducted by the USFS. The current timber waiver contains requirements that will be carried over into the new waiver and will be coordinated with TMDL implementation. Per the current waiver conditions, the USFS must include water quality control practices from the *Water Quality Management for Forest System Lands in California, Best Management Practices* (USFS 2000) guidance document and conduct an analysis of the cumulative effects of the permitted project. The cumulative effects analysis uses one or more models to determine whether the proposed project will raise the local watershed above a predetermined 'threshold of concern'. If the watershed is found to be above the threshold, or the project will put the watershed over the threshold, the USFS is required to implement a monitoring plan for the project. The monitoring plan should be developed in part to track compliance with TMDL requirements.

6.6.3.1 USFS Water Quality Guidance Document

The 'BMPs' or performance standards for timber harvest activities are organized into the following categories: timber management, road and building site construction (related to timber harvest), vegetation manipulation, fire suppression and fuels management, and watershed management. For every USFS timber harvest project, an interdisciplinary team conducts an onsite evaluation of the project area to identify the applicable performance standards and appropriate management practices. The guidance document establishes the means for implementing the selected practices on the ground. "The appropriate BMPs, and the methods and techniques of implementing the BMPs, are included in the environmental documentation, permit, contract, or other controlling document used to conduct and administer the project" (USFS 2000).

Implementing this process for each USFS timber harvest project is essential to meeting TMDL requirements, and the USFS includes the selected practices in their project document prepared pursuant to the National Environmental Policy Act (NEPA). The selected management practices must also be included in the timber sale contract or other controlling document used to administer the project as stated in the guidance document. Regional Water Board staff will review the NEPA document and any other controlling documents to ensure that the management practices proposed by the USFS meet the TMDL allocations and targets. Regional Water Board staff will continue to coordinate TMDL implementation with the USFS through the future waiver proposed for Regional Water Board consideration in April 2010. There is no need for additional TMDL implementation measures at this time. Regional Water Board staff will also work with the USFS to track progress towards meeting the watershed-wide targets and allocations.

6.6.4 Grazing

Grazing on federal lands principally takes place in the Klamath and Shasta-Trinity National Forests on designated grazing allotments. The allotments have been in use since the early 1900's and are mostly located in high mountain meadows closer to the headwaters of Klamath River tributaries. Grazing is managed by the USFS through the development and implementation of individual Allotment Management Plans (AMPs). Every year, the USFS develops Annual Operating Instructions (AOIs) for each allotment to implement the AMPs based on the current conditions of the allotment. Ranchers grazing animals on federal lands are required to follow the AOIs as well as meet the overall AMP objectives in order to continue grazing the allotment.

6.6.4.1 USFS Water Quality Guidance Document

The agreement on performance standards between the USFS and the State Water Board serves as the basis for controlling water quality impacts from grazing. An interdisciplinary team determines the management practices included in the AMP following an onsite evaluation of the project area. Regional Water Board staff are supportive of this process as a means to meet the TMDL allocations as long as the AOIs are effective and enforceable. The 'BMPs' or performance standards for grazing activities on federal lands identified in the guidance document include the following:

- *Range Analysis and Planning*: The district ranger is responsible for the analysis of range allotments and the preparation of AMPs. The permittee is expected to carry out the AOIs under the immediate direction and supervision of the district ranger.
- *Grazing Permit System*: Field checks and measurements will be made annually by the USFS. The grazing permit will be modified, cancelled or suspended in whole or part as needed to ensure proper use of the range resource and protection of other resources, such as water quality.
- *Rangeland Improvements*: The grazing allotment analysis may indicate the need for certain rangeland improvements such as further protection of sensitive areas, stream channel stabilization measures or water

developments. The district ranger will assure that the permittee is involved as a cooperator in rangeland improvements (USFS 2000).

The LRMP for the Klamath National Forest gives the following goals for grazing management that are consistent with TMDL implementation (USFS 1994a):

- Manage vegetation to provide for healthy ecosystems and to make forage available on a sustainable basis for use by livestock, wildlife and wild horses. Manage vegetation to provide for a desired condition of herbaceous shrub and forested vegetation according to site potential and resource needs.
- Manage grazing activities to not retard or prevent attainment of the Aquatic Conservation Strategy objectives.

Regional Water Board staff recommend that the USFS meet the above performance standards in their project document prepared pursuant to the National Environmental Policy Act (NEPA) as part of Klamath TMDL implementation. The management practices selected to meet the performance standards must be included in the grazing AMP, AOIs, and other controlling document(s) used to manage the allotment. Grazing activities on federal lands will be addressed as part of the proposed waiver of WDRs.

6.6.5 Road Management

The USFS is responsible for managing well over 10,000 miles of roads on federal lands within the Klamath River basin on four National Forests. This extensive road network has been identified in the Klamath technical analysis as contributing to the TMDL impairments. The water quality impacts of roads are described in section 5.2.1.2. The Klamath Implementation Plan focuses on road management in the Klamath, Six Rivers, and Shasta-Trinity National Forests.

Regional Water Board staff recommend that the proposed waiver of WDRs should require the USFS to continuously inventory and address sources of sediment from roads across its ownership as needed; similar to the process outlined in the Guidance to Control Excess Sediment. This approach is consistent with existing USFS programs to inventory and assess roads on federal lands. Existing programs are being coordinated with TMDL implementation and compliance with the proposed waiver.

6.6.5.1 USFS Water Quality Guidance Document

The guidance document describes 28 'BMPs' or performance standards that must be met to control nonpoint source pollution from roads on federal lands. The BMPs address aspects of road management such as planning, erosion control, slope stability, stream crossing installation, riparian management, maintenance, decommissioning, and others. Klamath River TMDL implementation requires the selection and timely implementation of the appropriate management practices that meet the BMP performance standards in the guidance document. Staff recommend that the proposed waivers of WDRs for most nonpoint source activities on federal lands include, as a condition of the waiver, a requirement to meet the performance standards described in the guidance document.

6.6.5.2 USFS Road Maintenance Needs

The National Forests are directed by the USFS Road Management Policy (USFS 2001) to assess the status of the road network on National Forest lands and to minimize the network to the extent feasible. Part of the reason for this is that the National Forests, including those in the Klamath River basin, do not have adequate funding for maintenance of the current road network. Changes in timber harvest practices have also resulted in a reduction of the miles of road needed to manage timberlands. In the Shasta-Trinity National Forest, for example, only 20% of the roads are maintained to design standards, and as of 2002, there was a $76 million backlog of deferred maintenance (USFS 2002b). Without proper maintenance, roads have a higher probability of failing and contributing sediment that can alter stream temperatures. Regional Water Board staff support the USFS Road Management Policy and encourage the USFS to reduce road densities on federal lands through road decommissioning. Reducing road density has the added benefit of increasing infiltration, which can add base flow to Klamath River tributaries. Regional Water Board staff recognize that decommissioning roads is not always the most prudent use of available road maintenance funds.

6.6.5.3 USFS Road Management Policy

The National Forests are directed to reduce the impacts of roads on natural resources in the USFS Road Management Policy and the Northwest Forest Plan. The National Forests in the Klamath River basin are responding to this directive by assessing sediment sources and threats to water quality on National Forest land and implementing road restoration and decommissioning projects as funding permits. This existing assessment and prioritization process can be used to comply with the Klamath River TMDLs. The Regional Water Board will work with the USFS to ensure their efforts are consistent with TMDL implementation and water quality standards. The following are descriptions of the existing road management programs in each of the National Forests.

6.6.5.4 Existing Road Management in the Klamath National Forest

The Klamath National Forest (KNF) developed the *Klamath National Forest Forestwide Roads Analysis* (USFS 2002a) that addresses road impacts to natural resources and guides the restoration actions related to roads. To date, KNF staff have conducted Road and Sediment Source (RSS) inventories in the following watersheds: Elk, Indian, Irving, Ti, Clear, Dillon, upper Beaver, Grider, and Horse Creeks, and the Salmon and Scott Rivers. The RSS inventories identify "specific locations where road drainage structures and fill have the potential to adversely impact watershed processes, then assess the relative environmental risk of each site" (USFS 2002a). The completed inventories and sediment source ratings are used to prioritize road restoration projects in the KNF. KNF has implemented fixes on the top 10% of sediment sources identified in the RSS assessments. Road management measures are recommended as part of watershed levels analyses. Once Environmental Assessments for the analyses are completed, KNF will begin implementing road maintenance measures based on funding and priority.

6.6.5.5 Existing Road Management in Six Rivers National Forest

The Six Rivers National Forest staff analyze the road network by ranger district. *The Orleans Roads Analysis and Off-Highway Vehicle Strategy* (USFS 2006) (Orleans RAP) recommends road management measures in the Orleans Ranger District; the only Six Rivers district in the Klamath River basin. The Orleans RAP tiers to the *Six Rivers National Forest Roads Analysis*, which is a forest-level plan for roads. Where the forest-level plan only evaluates passenger car roads of Maintenance Levels 3-5, the Orleans RAP evaluates high clearance roads (Levels 1-2) and non-system roads in the forest. The findings of the Orleans RAP can be used to develop a prioritization strategy for road restoration work in the Orleans Ranger District. The analysis identified the following items that relate to controlling the impacts of sediment from roads in the Orleans Ranger District:

- needed and unneeded roads,
- site-specific priorities for improvements and decommissioning, and
- roads associated with environmental risk (USFS 2006).

Projects to implement the RAP will be funded based on availability of grants and data from the roads analysis. The Regional Water Board staff will work with the Six Rivers Forest staff on prioritization of road restoration work that will address the impacts of sediment on Klamath River tributaries and thermal refugia in the mainstem Klamath River.

6.6.5.6 Existing Road Management in Shasta-Trinity National Forest

The Shasta-Trinity National Forest staff completed their forest-level roads analysis in July 2002 entitled the *Shasta-Trinity National Forest Roads Analysis Report* (USFS 2002b). This forest-level analysis evaluates passenger car roads of Maintenance Levels 3-5 and makes recommendations regarding road maintenance needs and prioritization. High clearance roads (Levels 1-2) and non-system roads are evaluated in watershed-level analyses that tier to the forest-level analysis.

6.6.6 Fire Management

Wildfires are common during the summer in the Klamath River basin and can lead to severe impacts on water quality through the destruction of riparian vegetation and increased runoff and erosion rates. The fire regime in the Klamath River basin has been altered through years of suppression that has resulted in increased fuel loads and fire severity. The USFS carries out timber harvest projects related to fire management both to control fuel loads and to salvage timber after a fire. The Regional Water Board’s current waiver for timber harvest activities on federal lands covers these projects. The USFS also takes measures to control erosion after a wildfire that focus on maintenance of drainage features and revegetation if needed. The practices for controlling post fire erosion sources are, in most cases, the same as those used to control erosion sources on forestlands with the added consideration of increased runoff volume. Regional Water Board staff recommend that the proposed waiver that will address most nonpoint source activities on federal lands include measures that address post fire sediment sources. The following management measures are recommended to address potential water quality impacts of fire management activities:

- Hydrologically disconnect firelines;
- Remove all temporary crossings;
- Improve the existing road drainage system to handle post-burn flows;
- Clear blockages to restore drainage function;
- Remove minor slumps and slides where needed;
- Ensure the function of drainage systems after storm events; and
- Implement post fire revegetation on severe burns areas (an area where duff and overstory canopy consumption has occurred) considering steep slopes that statistically receive high rainfall as a priority. Burned areas that receive snow are less likely to cause erosion problems.

6.7 Klamath River Water Quality Tracking and Accounting Program

Regional Water Board staff, in coordination with ODEQ, US EPA, and PacifiCorp, have begun developing a Klamath River basin water quality improvement tracking and accounting program. The Klamath River basin has several attributes that could benefit from a water quality improvement tracking and accounting program. This program will provide a record of individual actions and, perhaps, the basis for a market that facilitates a higher level of activity and collaboration than could be achieved by a regulatory approach alone. These attributes include:

- A large, geographically complex watershed that straddles two states, six tribes and two EPA regions thus requiring a framework for project collaboration that extends beyond the jurisdiction of any individual participant;
- Numerous and diverse sources of water quality impairments that vary widely in costs and feasibility of control strategies;
- Significant influence of nonpoint sources of pollutants, particularly from upstream sources in the basin, on water quality throughout the basin;
- The presence of dams that are under consideration for removal in the relatively near future thus reducing the desirability of long-term investments in reducing their near-term water quality impacts; and
- A large number of regulatory programs with overlapping goals and drivers that would benefit from coordinated action.

The Tracking and Accounting Program provides a mechanism that would allow for collaboration among basin stakeholders on common projects while earning credit towards their regulatory requirements related to TMDLs and other mandated programs (e.g., KHSA interim measures, state and federal Endangered Species Acts).

6.7.1 Program Goals

The overall program goals are to provide a program to achieve water quality improvements required in all Klamath Basin TMDLs, in a manner that is consistent with state and federal policy and regulations, is technically sound, and is tailored to meet the specific needs and conditions in the Klamath Basin. More specifically, the goals are to develop a basinwide accountability program to track water quality improvements, facilitate planning, and coordinate TMDL implementation based upon a market-like system. The Tracking and Accounting Program should also:

- Provide a decision tool to guide expenditure of implementation resources towards projects with greatest/earliest impact.
- Encourage the pooling of resources to support engineered solutions and enable the spending of resources across state boundaries by tracking and accounting for the contribution of each project participant.

6.7.2 Program Objectives

Establish and operate a program for tracking water quality improvements that:

- Encourages early reductions and progress towards water quality improvements;
- Reduces the cost of TMDL implementation through greater efficiency and flexible approaches;
- Creates economic incentives for innovation, emerging technology, voluntary pollutant reductions from all sources, and for potential trading and/or offsets amongst these sources;
- Achieves ancillary environmental benefits beyond the required reductions in specific pollutant loads, such as the creation and restoration of wetlands, floodplains and fish and/or waterfowl habitat;
- Establishes an accountability Program whereby a common metric (or sets of metrics) is/are used for estimating and tracking water quality improvements;
- Establishes a credible baseline, linked to the two states' TMDLs, and incorporates effectiveness monitoring and an adaptive management approach;
- Uses standardized protocols to quantify pollutant loads, load reductions, and credits/offsets, or other water quality improvements (e.g., stream channel restoration) that contribute to supporting conditions for beneficial uses;
- Recognizes cross-pollutant benefits (e.g. acknowledges that upstream nutrient reductions can improve downstream low dissolved oxygen levels and algal bloom conditions); and
- Allows participants to contribute to program-sponsored projects without having to develop partner-specific agreements or contracts thus minimizing administrative and transaction costs.
- Provides a mechanism to allow new discharges if sufficient offsets are implemented that would not otherwise be required by law.

6.7.3 Next Steps

Regional Water Board staff are committed to the continued development and implementation of a water quality improvement tracking and accounting program, as stipulated in the Klamath River and Lost River TMDL Implementation MOA signed by the Regional Water Board, ODEQ, and US EPA Regions 9 and 10. The Regional Water Board has received federal funding to hire a contractor to work closely with PacifiCorp's contractors and support the Regional Water Board, ODEQ, and EPA in developing such a program. Regional Water Board staff plan to coordinate with stakeholders and tribal governments interested in the program in 2010.

CHAPTER 7. REASSESSMENT and MONITORING PROGRAM

7.1 Introduction

The Klamath River TMDLs and implementation plan will be adaptively managed in consideration of the changing status of water quality and beneficial uses in the Klamath River basin, the effectiveness of the implementation programs in achieving the TMDL allocations and targets, and any necessary refinements to the technical TMDL analysis. The Klamath River TMDL reassessment and monitoring plan is designed to provide critical feedback to inform the adaptive management process. Because of the linkage between the Klamath River TMDLs and monitoring workgroups such, as the Klamath Basin Monitoring Program (KBMP) and the Statewide and Klamath Blue-Green Algae Work Groups, the Regional Water Board is in a good position to be aware of and act upon any new information or mitigation practices that could help to restore and protect water quality conditions in the Klamath River.

7.2 Klamath River TMDL Reassessment

Within five years of USEPA approval of the Klamath River TMDL, and every five years thereafter, the Regional Water Board staff will conduct a comprehensive assessment of the effectiveness of implementation of the Klamath River TMDL Action Plan and Lost River Implementation Plan. During these reassessments, the Regional Water Board will consider how effective the implementation actions have been at achieving water quality objectives and protecting the beneficial uses of the Klamath River basin.

The primary measure of success for TMDL implementation is attainment of water quality standards. The Klamath River TMDL establishes clear and reasonable numeric targets and allocations that can be used to track progress towards restoration of supporting water quality conditions. However, recognizing that many factors may affect the attainment of water quality standards and the TMDL, other measures of success will also be considered in evaluating the implementation program such as annual reports, nonpoint source pollution control implementation programs, BMP implementation status, evaluations submitted by responsible parties, and other available information.

The Regional Water Board may conclude that ongoing implementation efforts are insufficient to ultimately achieve the allocations and numeric targets. If the Regional Water Board makes this determination, responsible parties may be required to improve and increase their reporting, monitoring, and/or implementation efforts, as necessary, to ensure any applicable allocations and numeric targets are achieved within a reasonable amount of time. Individual landowners conducting nonpoint source discharge activities are only responsible for their own discharges. The Regional Water Board may otherwise conclude, at the time of review, that implementation efforts are expected to result in achieving water quality standards and the allocations and numeric targets. In that case, responsible parties must continue to implement existing and anticipated reporting, monitoring, and implementation efforts. Responsible parties will continue monitoring according to this plan for at least five more years, at which time the Regional Water

Board will determine the need for continuing or otherwise modifying the monitoring requirements. Monitoring and assessment results (see for instance Section 7.8 regarding special study considerations) may also demonstrate that water quality standards can be achieved without full attainment of the TMDL allocations and targets. Alternatively, monitoring and assessment results may demonstrate that although water quality objectives are not being achieved in receiving waters, controllable sources of pollutants are not contributing to the exceedance. In these cases, the Regional Water Board may re-evaluate the numeric targets and allocations in the TMDL.

Regional Water Board staff will also report back to the Regional Board as necessary on the status and progress of the implementation programs, and the timeframes within which current efforts are reasonably expected to achieve water quality standards. The reports will assess:

- Water quality improvement,
- BMP implementation,
- BMP effectiveness/performance,
- Level of compliance with measures and timeframes established in the implementation plan, and
- Level of compliance with measures and timelines agreed to in responsible party water quality management plans developed pursuant to the TMDL implementation plan.

Table 7.1 shows the water quality metrics and initial timelines that will be used to assess TMDL implementation. Collection of water quality data will be coordinated with ongoing Klamath monitoring programs organized through the KBMP as described later in this chapter. The timelines for attainment of the various TMDL allocations and targets are meant as guides for the Regional Water Board to evaluate the success of the Klamath TMDL. They were selected based on staff estimates of the time needed for basinwide implementation of management measures necessary for TMDL attainment. In some cases, the timelines for compliance may be refined based on further evaluation of potential compliance mechanisms and/or refinement of the TMDL analysis. For some larger dischargers, the implementation plan requires the development of implementation plans that include timelines for implementing management measures to achieve the TMDLs. These dischargers will periodically report to the Regional Water Board on progress. The Regional Water Board may at that time require modification of the discharger's plan and/or timelines as necessary.

This space intentionally left blank

Table 7.1: Basinwide water quality trends

Parameter	Water Quality Metric	Location(s)	Timeline
Temperature – Numeric	Numeric targets – Daily average temperatures (use MWAT and MWMT statistics for spring, mid-, and late summer)	Stateline and critical location(s) in mainstem.	40 years
	Numeric targets – Daily average temperatures (use MWAT and MWMT statistics for spring, mid-, and late summer)	Reservoir tailraces	40 years
	Compliance lens biological optimum for different life stages measured as MWAT and MWMT statistics for spring, mid-, and late summer.	In reservoirs	Coinciding with schedule for volitional fish passage if Sec Det. is negative 2020 if Sec Det. is affirmative
	No change in natural temperatures due to reservoirs (use daily mean, max, and minimum statistics).	Upstream and downstream of reservoirs	2014 if Sec Det. is negative 2020 if Sec Det. is affirmative
	Iron Gate Hatchery monthly mean temperature	Hatchery discharge	Per NPDES permit
	Thermal Refugia temperatures	In key thermal refugia in Klamath during critical period	Trend tracking, no TMDL allocation or target
Dissolved oxygen	Monthly means of the daily minimum DO levels.	Stateline, below Salmon River and other critical locations in mainstem Klamath River (summer).	20 years
	Compliance lens	Copco 1 and Iron Gate	Coinciding with schedule for volitional fish passage if Sec Det. is negative 2020 if Sec Det. is affirmative
Dissolved oxygen	Dissolved oxygen as mean and minimum	Reservoir tailraces	2014
	Iron Gate Hatchery dissolved oxygen as monthly mean and minimum	Hatchery discharge	Per NPDES permit
Nutrients and Organic Matter	Numeric targets as monthly mean concentrations	Stateline and below Salmon River. Copco 1 and 2 and Iron Gate Reservoirs and tailraces	20 years
	Nutrient load reductions assigned to KHP facilities in California	Upstream of Copco 1 and at Iron Gate tailrace	Based on PacifiCorp implementation plan, subject to Regional Water Board approval
	Iron Gate Hatchery numeric targets as monthly mean concentrations	Hatchery discharge	Per NPDES permit
Chlorophyll *a*	10 ug/L growing season average	Copco 1 and 2 and Iron Gate Reservoirs	20 years
Microcystis aeruginosa	Cell density relative to blue-green algae biomass and cells/L. Microcystin Toxin	Copco 1 and 2 and Iron Gate Reservoirs and in mainstem at critical locations	Based on PacifiCorp implementation plan subject to Regional Water Board approval
Periphyton Chlorophyll *a*	Numeric targets for chlorophyll *a* density	Below Salmon River and below Iron Gate Dam	20 years
Fish disease spore counts	Per the KBMP – may include other water quality parameters found to be related to spread of fish disease	At disease hot spots	

7.3 Klamath Basin Water Quality Monitoring Program

The purpose of the remainder of this chapter are: 1) to provide a description of a larger basinwide monitoring program; and 2) present an initial design for a monitoring plan that is specific to the California Klamath River TMDL. The two purposes have significant overlap because the Regional Water Board will integrate the California Klamath River TMDL monitoring plan into the larger basinwide program monitoring plan. Both monitoring plans are essential for an adaptive management program to restore and protect beneficial uses within the Klamath River, and are described briefly below:

- The basin wide monitoring plan initiative (described in Section 7.2) is a broader program for monitoring and assessment for the entire Klamath River basin. The basinwide component calls for data collection and compilation into a common database from all of the subbasins within the Klamath River basin, including the Lost River. This component of the monitoring program is based on the *Review Draft: Klamath Basin Water Quality Monitoring Plan*, Prepared for the Klamath Basin Monitoring Program (KBMP) (Royer and Stubblefield 2009).
- The California Klamath River TMDL monitoring plan (described in Sections 7.3-7.5) provides the initial structure and details for a TMDL specific monitoring plan to assess status and trends for compliance with the Klamath River TMDL targets and allocations within California. This component of the monitoring program is based on the recently completed AIP Interim Measure 12[1]: *Water Quality Monitoring Activities – Monitoring Year 2009* (Royer and Stubblefield 2009).

This two-tiered strategy recognizes the need for a coordinated basinwide understanding of the resource use and resource protection issues outlined in the National Research Council recommendations (NRC 2004). The strategy is to integrate the TMDL specific monitoring plan into the emerging more comprehensive basinwide monitoring coordination network.

7.3.1 Components of the TMDL Monitoring Program

The primary purposes of the TMDL monitoring program are to evaluate water quality conditions and trends with respect to the TMDL targets and allocations, and to determine the status of beneficial use support in the California reaches of the Klamath River.

---

[1] On November 13, 2008, the United States, the States of California and Oregon, and PacifiCorp executed an Agreement in Principle (AIP) describing the framework for an approach to study the water quality conditions of the Klamath River pursuant to the possible removal of several PacifiCorp's dams on the Klamath River. Interim Measure 12 of the AIP stipulates to a water quality monitoring program, including on-going public health monitoring of blue-green algae (cyanobacteria) and associated toxins. Interim Measure 12 of the AIP further stipulates that PacifiCorp will provide funding of $500,000 per year for this measure, and that monitoring will be performed by an entity or entities agreed upon by the parties to the AIP and in consultation with the appropriate water quality agencies.

Support for these assessments will require various types of monitoring including:

- **Compliance and Trend Monitoring** is intended to determine, on a watershed scale, if water quality objectives are being met, and if beneficial uses are being protected from the adverse effects of one or more pollutants. This will require stations to be established at specific compliance points identified in the TMDL (compliance) and at locations of special beneficial use and water quality condition sensitivity (trend). The sampling frequency and density should be of a high enough resolution so that over a reasonable period time it can be determined whether management actions are having the desired effect on water quality conditions.
- **Public Health Monitoring** is a special subset of compliance and trend monitoring. Due to the seasonal presence of toxins associated with blue-green algae blooms in Iron Gate and Copco Reservoirs and in the river below Iron Gate Dam, the Klamath River TMDL monitoring plan includes public health monitoring activities to alert agencies to potentially hazardous conditions, and will provide them with information for posting health advisories as part of a public outreach and education program.
- **Implementation Monitoring** assesses whether activities and control practices were carried out as planned. For the Klamath River TMDL, examples of control practices may include construction of treatment wetlands, wetland restoration, and follow up to practices covered under existing or new permits. Implementation Monitoring activities are site-specific and can be as simple as a photographic record of activities.
- **Special Studies** address key questions, unknowns, or uncertainties that require more than an ambient water quality monitoring program to provide the information necessary for a more complete understanding of a water quality issue. Special studies can be critical to the adaptive management process to resolve issues related to changes in management practices. Examples of key questions to be addressed through special studies include: the relationship between fish disease and water quality conditions; nutrient mass balance to better understand the sources and sinks of nutrients and organic matter within the Klamath River basin; role of upstream blue-green algal sources for inoculation of downstream waters; improved characterization of periphyton conditions on Klamath River reaches below Iron Gate Dam; among others.
- **Project Effectiveness Monitoring** is similar to Implementation Monitoring and is keyed to an assessment of whether individual projects achieve the environmental benefits expected of them. Constructed wetlands and improvements to irrigation return flow operations are examples of two types of projects that would include project effectiveness monitoring as part of any grant funding.

The primary focus of this section is on public health monitoring (section 7.4), compliance and trend monitoring (Section 7.5), and key questions for future special studies (Section 7.6).

7.3.2 Monitoring Program Organization

Section 7.4 provides an overview of the emerging Klamath Basin Monitoring Program (KBMP) framework. Section 7.5 provides a summary of the monitoring stations, compliance points, and station objectives for the TMDL monitoring plan for California. Section 7.6 describes the public health components of the TMDL monitoring plan for California. Section 7.7 then describes the ambient trend and compliance component of the TMDL monitoring plan for California. Section 7.8 presents key questions to be addressed through recommended special studies. Section 7.9 describes how the Klamath River TMDL will be reassessed and potentially updated in coming years.

7.4. Overview of the Klamath Basin Monitoring Program Framework

The State Water Board and Regional Water Board, with funding and technical support from the USEPA, initiated a contract to facilitate the development of a coordinated monitoring and assessment program within the Klamath River basin. Much of the material in this section is adapted from the *"Review Draft: Klamath Basin Water Quality Monitoring Plan,* Prepared for the Klamath Basin Monitoring Program (KBMP)" (Royer and Stubblefield 2009).

The development of the multi-party Klamath River basin water quality monitoring program has been facilitated by the Klamath Watershed Institute, an affiliate of Humboldt State University. The KBMP consists of representatives from multiple agencies, Tribes, and organizations. A comprehensive list of participating entities is presented in Table 7.2. The KBMP has worked together over the past two years to develop a Draft *Klamath Basin Water Quality Monitoring Plan*. The Draft *Klamath River Basin Water Quality Monitoring Plan is* a working document intended to be updated as the needs of the KBMP change over time. It is the hope that a coordinated monitoring effort will support decisions made in the Klamath River basin regarding resource management, including such things as: implementation measures to achieve TMDL allocations and targets; appropriate conditions for the operation of PacifiCorp's Klamath Hydroelectric Project and the U.S. Bureau of Reclamation's (USBR) Klamath Project; nonpoint source (NPS) pollution controls; and how to expedite the recovery of impaired beneficial uses for the benefit of all California and Oregon residents and Tribal communities.

Many of the goals outlined by the Regional Water Board and ODEQ are echoed in the KBMP goals and objectives. The KBMP Water Quality Subcommittee drafted goals and objectives that seek to develop and maintain a network of sites that capture the status and trends of selected indicators throughout the basin over time and space. The backbone of the network is built on legacy sites identified by organizations conducting monitoring in the basin as well as sites identified in the TMDL implementation plan.

The evaluation of the current monitoring effort was based upon a review of TMDL listings at a subbasin level, and other monitoring conducted by participating organizations within the basin. Since TMDL listings are based on water quality impairment to beneficial uses, sampling at the subbasin scale may be evaluated for meeting the goals and objectives of the Regional Water Board, ODEQ and KBMP.

7.4.1 Overview of the Klamath Basin Monitoring Program (KBMP)

The parties comprising the KBMP recognize the value of coordinating monitoring programs throughout the Klamath River basin and that collaboration among agencies, organizations and tribal governments is essential to protecting the health of the basin. Given the complexity and severity of the problems facing the basin, and the decreasing level of available resources at all levels, there is a clear need for this effort. To this end, the KBMP is working to develop a collaborative monitoring program for the basin that will:

- improve short- and long-term collaboration on annual water quality monitoring activities in the Klamath River basin to support beneficial uses and improve understanding of the ecology of the basin;
- develop and maintain a network of long-term monitoring sites that capture status and trends of selected indicators throughout the basin over time and space;
- develop a sustainable monitoring program for the Klamath River basin that does not replace individual water quality monitoring efforts but expands coordinated monitoring in a way that benefits long-term collaboration;

- include all agencies and organizations that engage in water quality monitoring in the Klamath River basin;
- develop consistency in quality assurance and control regarding all monitoring activities;
- develop and maintain a system to encourage the transfer and sharing of fundamental water quantity and quality information amongst monitoring organizations needed to inform water resources studies;
- establish an online clearinghouse for housing and disseminating water quality monitoring data as well as other information about the Klamath River basin and planning and restoration efforts, allowing users to contribute, access and download data;
- create protocols for providing data and information in a timely manner to better inform adaptive management; and
- identify and communicate monitoring program results and research needs to its members, research institutions, the public, and policy makers.

Another common goal of the Regional Water Board and ODEQ is to identify and document the effects of climate change on water quality within the basin. In the state of California, climate change is expected to dramatically alter water resource availability in both time and location. The California Climate Change Center predicts increased temperature, reduced snowpack, truncated rainy season and increased fire frequency and severity (CCCC 2006). There is currently a data gap concerning the implications of climate change on the Klamath River basin.

7.4.2 KBMP Monitoring Plan Statement of Purpose

The purpose of the Klamath River Basin Water Quality Monitoring Plan is to serve as a collaborative and comparable plan for sampling and analyzing water quality in the Klamath River basin.

This comprehensive approach seeks to include all agencies and organizations engaging in water quality monitoring in the Klamath River basin. The Klamath River Basin Water Quality Monitoring Plan is not intended to replace individual water quality monitoring efforts or autonomy, but to expand coordinated monitoring in a way that benefits long-term coordination and collaboration in the basin.

The development of the Klamath River Basin Water Quality Monitoring Plan consists of a review of existing efforts and identification of data gaps, recommended enhancements, implementation of comparable Quality Assurance and Quality Control (QA/ QC) using multistate (Oregon and California) guidelines, and development of a sustainable monitoring and funding framework that addresses both long and short-term needs.

7.4.3 KBMP Monitoring Plan Goals

KBMP members developed the following goals to guide the development of the comprehensive water quality monitoring plan for the Klamath River basin:

- Coordinate monitoring activities to inform TMDL development and progress towards goals;
- Develop and maintain long-term monitoring network of sites that capture status and trends of selected indicators throughout the basin over time and space;
- Frame monitoring objectives by subbasin in terms of supporting beneficial uses and improving the understanding of the ecology of the Klamath basin;
- Strive for consistent quality assurance and control regarding all monitoring activities;
- Provide accessible data in a timely manner to better inform regulatory agencies, organizations, tribal community and the public; and
- Identify and document the effects of climate change and supply data to support climate change models to enhance the understanding of future impacts on water quality within the basin.

7.4.4 Description of Current KBMP Members Monitoring Efforts and Maps

The current collection of water quality data in the Klamath River basin is a multi-organizational effort. While there has been some informal coordination and collaboration amongst members of various organizations, many entities have worked independently on discrete projects addressing water quality issues. The Klamath Watershed Institute (KWI) compiled an inventory of organizations conducting water quality monitoring and the location of these monitoring activities in the Klamath River basin. These organizations are listed in Table 7.3. From this comprehensive list, members of the KBMP selected a subset of sites for inclusion in the Klamath River Basin Water Quality Monitoring Plan that is illustrated in Figure 7.1.

Table 7.3: Organizations collecting water quality data in the Klamath River basin as of February 15, 2009

California Department of Water Resources	The Nature Conservancy
Hoopa Tribe	Timber Products Company
Karuk Tribe	University of California Santa Cruz
Klamath Tribes	U. S. Bureau of Reclamation
Oregon Department of Environmental Quality	U. S. Bureau of Land Management
PacifiCorp	U. S. Environmental Protection Agency
North Coast Regional Water Quality Control Board	U. S. Fish and Wildlife Service
Quartz Valley Indian Reservation	U. S. Forest Service
Salmon River Restoration Council	U. S. Geological Survey
Scott River Conservation District	Yurok Tribe
Shasta Valley Resource Conservation District	

7.4.5 Schedule for Completion of the Klamath River Basin Coordinated Water Quality Monitoring Plan

The final Klamath River Basin Water Quality Monitoring was completed in December 2009. In addition to having the final Klamath River Basin Water Quality Monitoring Plan, the framework will also include a web portal for uploading and accessing data. This portal will be managed by a third party. Regional Water Board staff recommend that the California Klamath River TMDL monitoring recommendations be included in the final Klamath River Basin Water Quality Monitoring Plan.

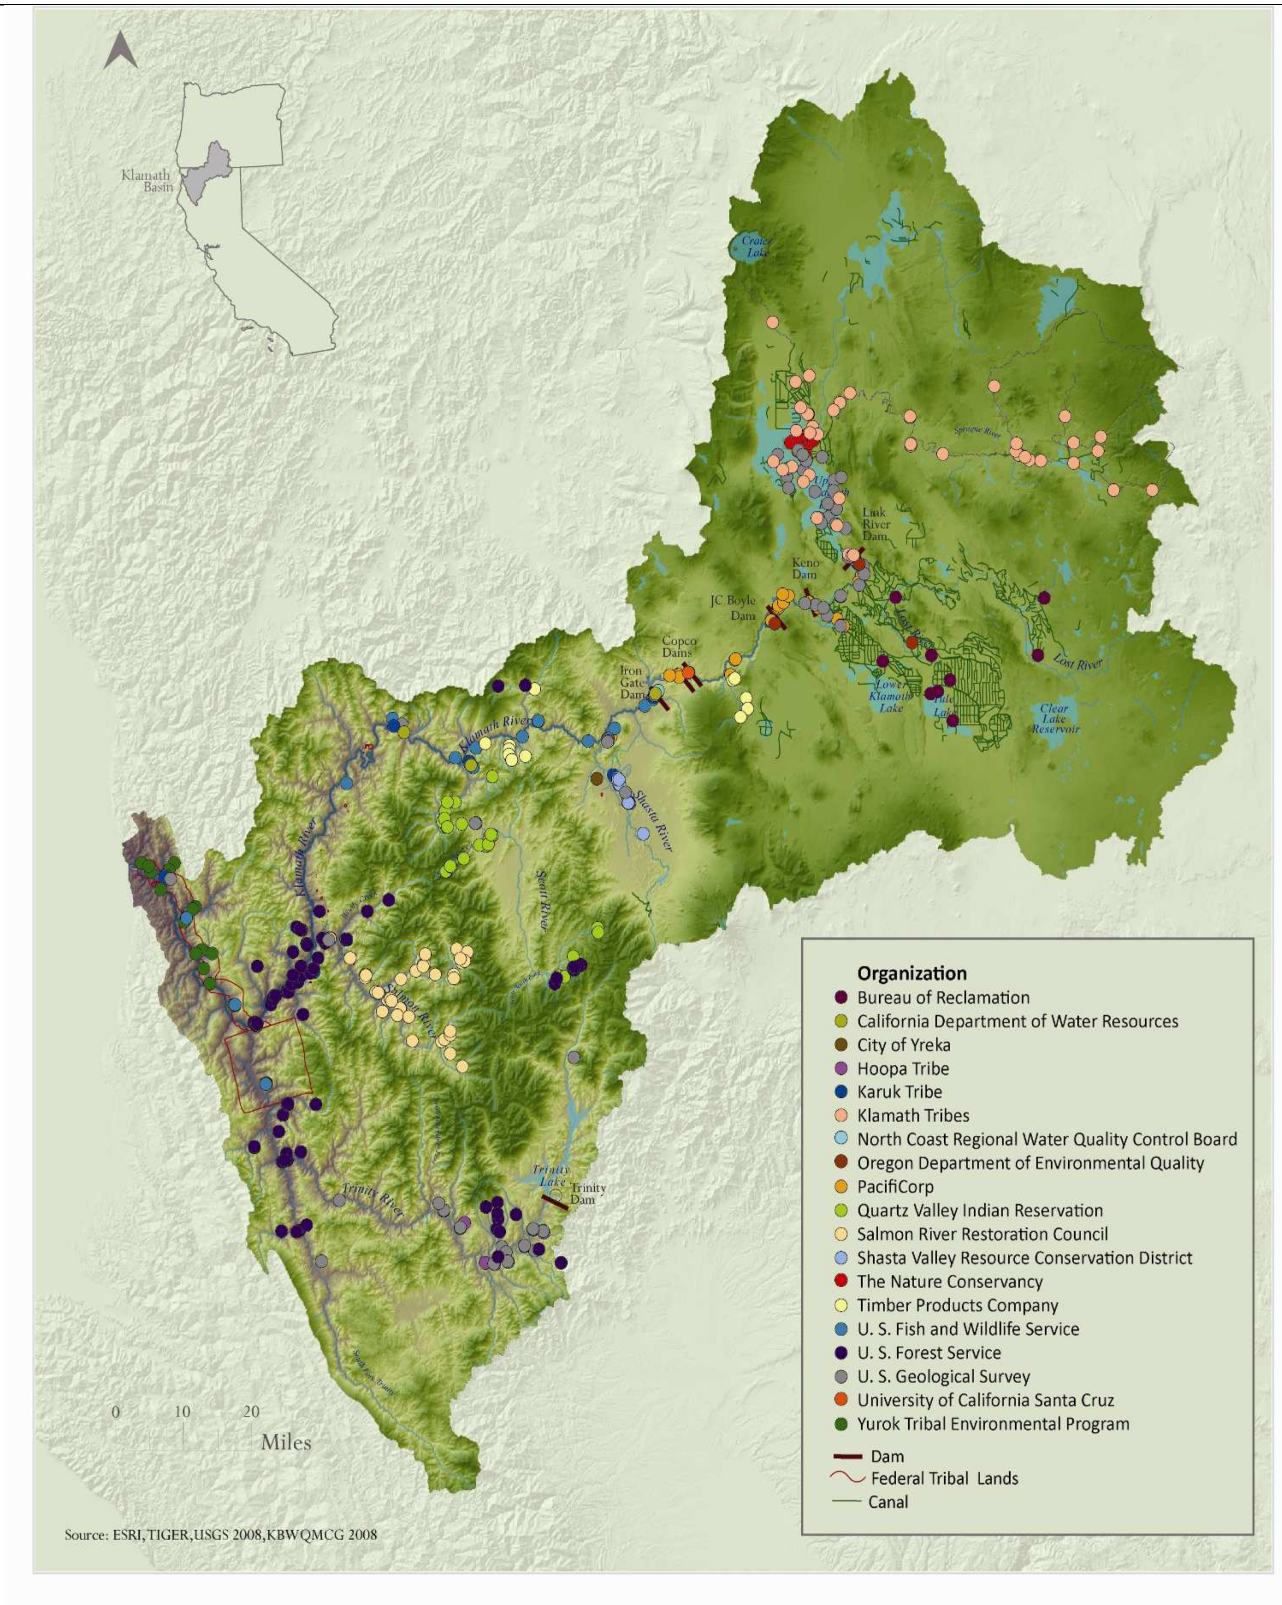

Figure7.1: KBMP monitoring sites in 2008 by organization Source: Royer and Stubbelfield 2009
Note: The sites from the Link Dam to Keno Dam are incorrectly identified as U.S. Geologic Survey sights, and are actually sites monitored by the U.S. Bureau of Reclamation.

7.5 California Klamath River TMDL Monitoring Stations, Compliance Points, and Station Objectives

Chapter 5 presents the allocations and targets for the California Klamath River TMDL. Those allocations (**A**) or targets (**T**) are assigned at specific locations within the Klamath River basin that are considered to be compliance points for the TMDL. That is, sources will be evaluated regarding the success of their controls based on conditions at the compliance locations. This monitoring plan also calls for additional monitoring stations within the Klamath River mainstem. Table 7.4 includes a summary of all of the proposed monitoring locations and monitoring components, and presents a rationale and purpose for each location.

For the purposes of addressing TMDL compliance, the compliance locations are the highest priority for conducting monitoring activities. Stations are also noted for public health (**PH)** and special studies (**SS**). Special study stations have been included to better understand water quality processes, beneficial use support status, and to address key questions (see Section 7.6) important to adaptive management decisions. Not all monitoring objectives described for specific monitoring locations in Table 7.4 are represented by an A, T, PH, or SS indicator. The locations of the compliance monitoring public health and special study stations for the California Klamath River TMDL are illustrated in Figure 7.2. More detailed descriptions of public health and trend monitoring are provided in Sections 7.4 and 7.5.

7.6 Public Health Monitoring

This section addresses monitoring to evaluate risks to public health associated with TMDL impairments. Due to the seasonally high concentrations of cyanobacteria and associated toxins in the reservoirs and downstream of Iron Gate Dam, the Regional Water Board is including a public health monitoring component in the California Klamath River TMDL monitoring plan. This section presents protocols to be used in conducting sampling for public health monitoring, including sampling locations, frequency and procedures. The information included in this section has been adapted from the *AIP Interim Measure 12: Water Quality Monitoring Activities Monitoring Year 2009* (AIP June 2009). This plan was developed through collaboration among the Regional Water Board; ODEQ; PacifiCorp; USEPA Region 9; USBR; Karuk Tribe Natural Resources Department; and Yurok Tribe Environmental Program, with support from the Klamath Watershed Institute. Members of the KBMP reviewed earlier drafts of the AIP 2009 Monitoring Plan. The AIP Monitoring Plan will be updated each year involving the same collaborators listed above with review by other interested parties from the KBMP. As described earlier the plan was developed in part to address TMDL objectives and information needs.

Table 7.4: California Klamath TMDL monitoring locations, parameters, and objectives

Location (River Mile; Station ID)[1]	Monitoring Parameter: Allocations (A); Targets (T); Public Health (PH) & Special Studies (SS)	Rationale / Purpose
Klamath River above Shovel Creek - Stateline (206.4; KR2064)	Temperature[2] **(A & T)** TN, TP, CBOD[3] **(A)** Chlorophyll –a [4] **(T)** Dissolved Oxygen[5] **(T)**	▪ This station is a compliance point for both targets (temperature and dissolved oxygen), and allocations (nutrients and organic matter). ▪ Represents both Klamath River at Stateline and Klamath River above Copco Reservoir. ("Stateline" has been represented by agencies and other entities as the Klamath River above Shovel Creek for several years.) ▪ Location provides opportunity to assess nutrient, organic matter, and chl-a loads generated in the upper basin including Upper Klamath Lake and Lost River and provides information on critical period concentrations entering the reservoirs. ▪ Assessment point for chlorophyll-a concentrations downstream of JC Boyle and prior to entering quiescent waters of Copco and Iron Gate Reservoirs. ▪ Evaluates temperature of that water entering CA which should not be elevated above natural temperature (expressed as monthly average). ▪ Assess if dissolved oxygen concentrations are at or above 85% saturation under natural temperature conditions[6].
Copco Reservoir - several stations including outlet (199.0; KR1990)	Temperature **(A & T)** TN, TP, CBOD **(T)** Chlorophyll –a **(T, PH & SS)** Dissolved Oxygen **(A &T)** *Microcystis aeruginosa* cell density[6] (**T, PH & SS)** Microcystin toxin[6] **(T, PH & SS)**	▪ These stations are compliance points for targets (TN, TP, CBOD, chlorophyll-a, *Microcystis aeruginosa*, and microcystin) and allocations (TN and TP). ▪ Multiple stations to assess public health risk due to cyanobacteria (blue-green algae) critical period blooms in both water column and fish tissue. This objective will require the addition of special studies. ▪ Assess for presence of dissolved oxygen and temperature compliance lens. ▪ Monitor for potential temperature impacts of reservoir impoundments and transfer of these impacts downstream. ▪ Assess nutrient dynamics for potential release of nutrients from reservoir sediments during critical growth period.
Downstream of Copco Reservoir (195.0; KR1950)	TN, TP, CBOD **(A)** Dissolved Oxygen **(A)** *Microcystis aeruginosa* cell density (**T, PH)** Microcystin toxin **(T, PH)** Periphyton **(SS)**	▪ Contribute to an improved nutrient and organic mass balance for the reservoirs.

Table 7.4(cont.): California Klamath TMDL monitoring locations, parameters, and objectives

Location (River Mile; Station ID)[1]	Monitoring Parameter:Allocations (A); Targets (T); Public Health (PH) & Special Studies (SS)	Rationale / Purpose
Iron Gate Reservoir - several stations including outlet (192.0; KR1920)	Temperature **(A & T)** TN, TP, CBOD **(T)** Chlorophyll –a **(T)** Dissolved Oxygen[5] **(A&T)** *Microcystis aeruginosa* cell density (**T, PH)** Microcystin toxin **(T, PH)**	▪ These stations are compliance points for targets (TN, TP, CBOD, chlorophyll-a, *Microcystis aeruginosa*, and microcystin) ▪ Multiple stations to assess public health risk due to cyanobacteria (blue-green algae) critical period blooms in both water column and fish tissue. ▪ Assess for presence of dissolved oxygen and temperature compliance lens. ▪ Monitor for potential temperature impacts of reservoir impoundments and transfer of these impacts downstream. ▪ Assess nutrient dynamics for potential release of nutrients from reservoir sediments during critical growth period.
Iron Gate Hatchery - Discharge locations	Temperature **(A & T)** TN, TP, CBOD **(A & T)** Dissolved Oxygen **(T)**	▪ Track Iron Gate Hatchery discharge to evaluate compliance with NPDES / TMDL discharge requirements for nutrients, organic matter, and temperature. ▪ Monitoring requirements will be specified in revised NPDES permit
Klamath River below Iron Gate Dam -Hatchery Bridge (189.7; KR1897)	TN, TP, CBOD (**SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH)** Microcystin toxin **(PH)**	▪ Trend monitoring for dissolved oxygen, temperature, nutrients, and organic matter. ▪ Public health water column monitoring related to cyanotoxins generated within reservoirs. ▪ Fish tissue sampling to assess exposure of salmonids to microcystin. ▪ Evaluate temperature regime effect of reservoirs.
Klamath River at Shasta River at Walker Bridge (176.7; KR1767)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH)** Microcystin toxin **(PH)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature. ▪ Public health monitoring related to cyanotoxins including water and tissue samples.
Klamath river at Brown Bear River Access (157.5; KR1575)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH)** Microcystin toxin **(PH)** Periphyton **(SS)**	▪ Public health monitoring related to cyanotoxins including water and tissue samples. ▪ Trend monitoring for nutrients, organic matter, dissolved oxygen, temperature. ▪ Measure periphyton densities to assess impact on: 1) water quality (e.g., DO, pH); 2) stream nutrient dynamics; and 3) increases in parasite densities. ▪ Special studies to better understand relationship between water quality conditions and prevalence of fish diseases below Iron Gate Dam.

Table 7.4 (cont.): California Klamath TMDL monitoring locations, parameters, and objectives

Location (River Mile; Station ID)[1]	Monitoring Parameter: Allocations (A); Targets (T); Public Health (PH) & Special Studies (SS)	Rationale / Purpose
Klamath River at Seiad Valley (128.5; KR1285)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH**) Microcystin toxin **(PH)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature. ▪ Public health monitoring related to cyanotoxins including water and tissue samples.
Klamath River at Happy Camp (108.4; KR0935)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH**) Microcystin toxin **(PH)** Periphyton **(SS)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature. ▪ Public health monitoring related to cyanotoxins including water and tissue samples. ▪ Measure periphyton densities to assess impact on: 1) water quality (e.g., DO, pH); 2) stream nutrient dynamics; and 3) increases in parasite densities. ▪ Special studies to better understand relationship between water quality conditions and prevalence of fish diseases below Iron Gate Dam.
Klamath River at Orleans (59.1; KR0591)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH**) Microcystin toxin **(PH)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature. ▪ Public health monitoring related to cyanotoxins including water and tissue samples.
Klamath River at Saints Rest Bar (44.5; KR0445)	TN, TP, CBOD **(T)** Dissolved Oxygen **(T)** *Microcystis aeruginosa* cell density **(PH)** Microcystin toxin **(PH)** Periphyton **(T)**	▪ Evaluate compliance with Hoopa Valley Tribe Water Quality Criteria
Klamath River at Weitchpec (43.5; KR00425)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH**) Microcystin toxin **(PH)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature. ▪ Public health monitoring related to cyanotoxins in water column.
Klamath River below Trinity River – above Tully Creek (38.5; KR0385)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature. ▪ Public health monitoring related to cyanotoxins including water and tissue samples.
Klamath River at Turwar (6.0; KR0060)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH**) Microcystin toxin **(PH)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, *Microcystis aeruginosa* , microcystin, and temperature.

Table 7.4 (cont.): California Klamath TMDL monitoring locations, parameters, and objectives

Location (River Mile; Station ID)[1]	Monitoring Parameter: Allocations (A); Targets (T); Public Health (PH) & Special Studies (SS)	Rationale / Purpose
Klamath River Estuary (0.5; KR0005)	TN, TP, CBOD **(SS)** Dissolved Oxygen **(SS)** *Microcystis aeruginosa* cell density (**PH)** Microcystin toxin **(PH)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, *Microcystis aeruginosa*, microcystin, and temperature.
Shasta River near mouth (SHR00)	TN, TP, CBOD **(A)** Dissolved Oxygen **(T)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature.
Scott River near mouth (SCR00)	TN, TP, CBOD **(A)** Dissolved Oxygen **(T)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature.
Salmon River near mouth (SAR00)	TN, TP, CBOD **(A)** Dissolved Oxygen **(T)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature.
Trinity River near mouth (TR00)	TN, TP, CBOD **(A)** Dissolved Oxygen **(T)** *Microcystis aeruginosa* cell density (**PH)**	▪ Trend compliance monitoring for nutrients, organic matter, dissolved oxygen, and temperature. ▪ Public health monitoring related to cyanotoxins including water and tissue samples (control).
Watershed-wide (N/A)	Riparian Shade and Sediment **(A & T)**	▪ Monitoring to evaluate status of riparian shade conditions relative to site-potential to track trends in effective shade levels for all Klamath tributaries. ▪ Assessment of human-caused mass wasting hazards (e.g., stream crossings) that have potential to contribute sediment delivery to streams above background levels that could contribute to channel alterations that affect stream temperature or fish refugia. ▪ Assess road conditions to ensure that best management practices are being implemented to reduce the incidence of road related landslides.

[1] River miles are approximate, and station ID's are per the KBMP.
[2] Temperature shall be monitored at hourly or sub-hourly interval.
[3] Nutrient and organic matter grab samples shall be analyzed for inorganic nitrogen (ammonia, nitrite, nitrite), organic nitrogen, inorganic phosphorus (orthophosphate) organic phosphorus, and CBOD-ultimate. Allocations and targets expressed as monthly mean concentrations.
[4] Surface grab samples shall be analyzed for chlorophyll-a ; the mean of bi-monthly growing season (June through September) sample results shall be calculated to assess compliance with the chlorophyll-a target.
[5] Dissolved oxygen concentrations shall be monitored at hourly or sub-hourly intervals; targets and allocations based on 85% saturation at natural temperature.
[6] Sampling procedures for Microcystis aeruginosa and microcystin are presented in Section 7.4.1.3.

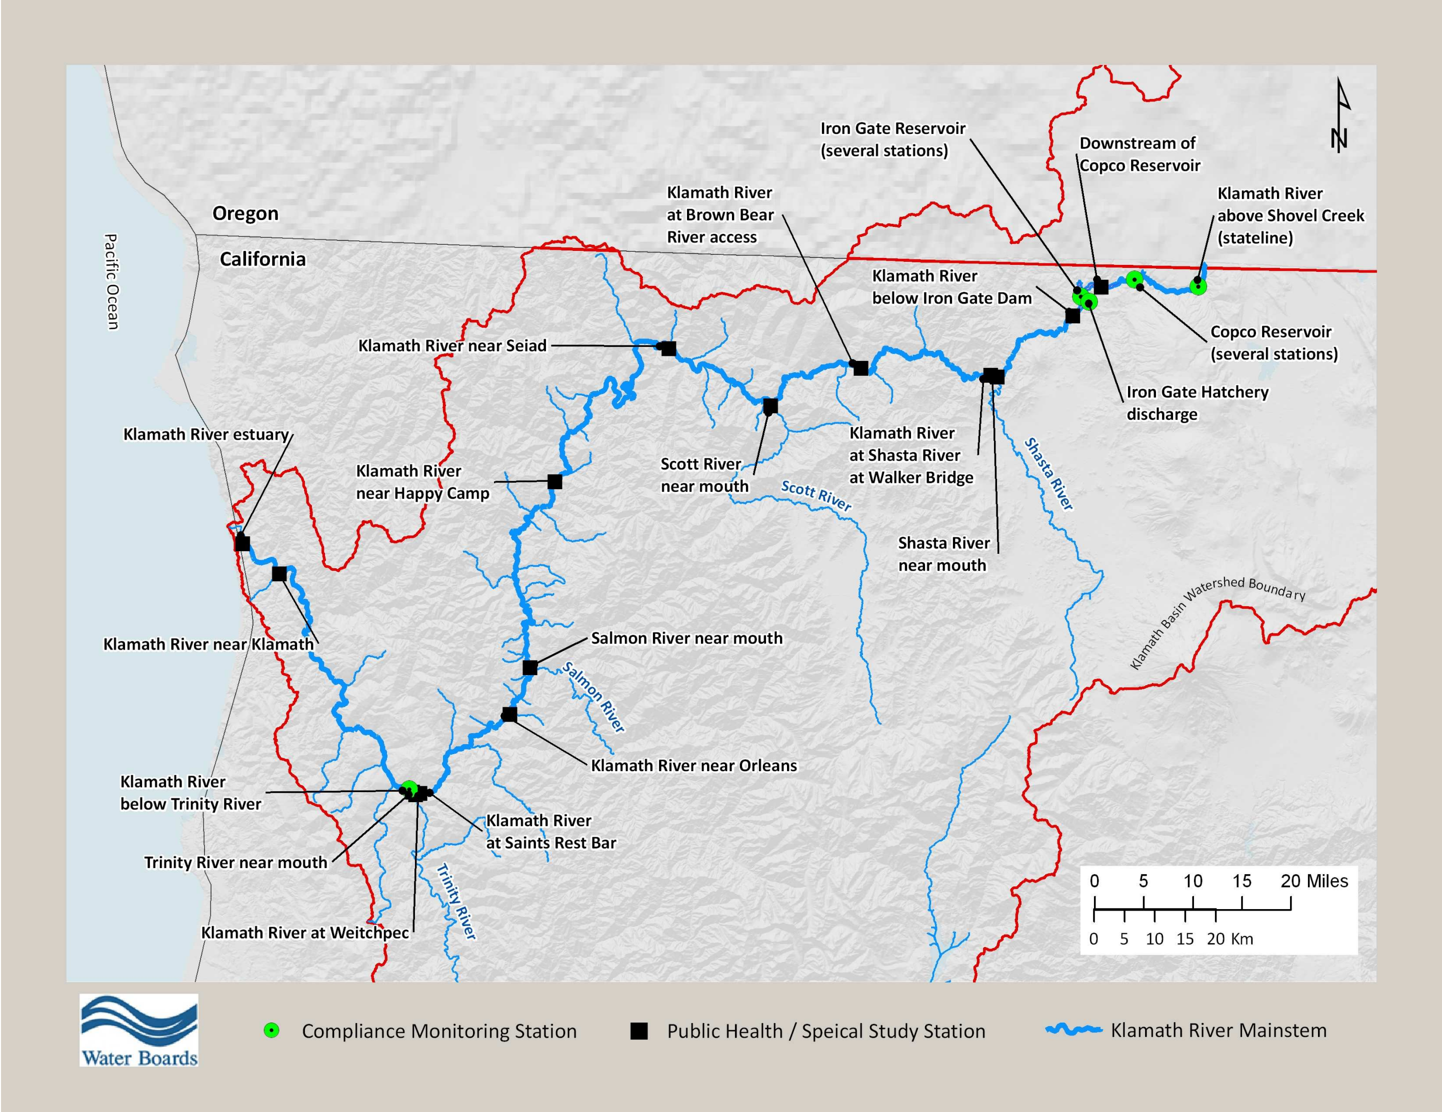

Figure 7.2: Location of California Klamath River TMDL monitoring stations – compliance, public health, and special study

Risks to public and ecological health related to cyanobacteria and cyanotoxin exposure will be evaluated through water sampling, tissue sampling, and identification of the presence of scums, using the monitoring procedures described in the standard operating procedures (SOPs) presented in Appendix A of the AIP 2009 Monitoring Plan (AIP 2009).. Water quality monitoring of cyanobacteria and related cyanotoxins for purposes other than public and ecological health evaluation is addressed in Section 7.5.

The primary concern of this monitoring is public health. In addition to direct exposure to impacted waters (ingestion, inhalation and dermal exposures), exposures to microcystins are possible from ingestion of fish (e.g., caught during recreational fishing in the reservoirs), or consumption of freshwater mussels collected from the Klamath River. Mussels from the Klamath River are part of the traditional diet of tribal people. Additionally, mussels as filter feeders may be sensitive indicators of cyanobacteria levels and toxin levels in ambient water and food sources.

Cyanotoxins can also have an impact on the health of fish and other exposed species, which result in direct impacts to those species, as well as consumers of those impacted species including humans. Additionally, the information from the public health monitoring component can provide valuable information relative to other beneficial uses including the status of both COLD and WARM water beneficial uses. For example, microcystin concentrations in fish tissue can disrupt liver function in fish at levels considered to be moderate or low for human consumption. Therefore these measures should not be interpreted for human health assessments alone. Rather the results also should be applied to determine whether microcystin exposures are a contributing factor to ecological impacts such as fish disease and fish health both within the reservoirs and below Iron Gate Dam.

7.6.1 Water Sampling

7.6.1.1 <u>Sampling Locations</u>

Public health monitoring for cyanobacteria and microcystin toxin in water samples will occur at a total of 12 designated locations used for public access and recreation. These are listed in Table 7.5, and include:

- Four shoreline sites in coves on Copco (Mallard Cove and Copco Cove) and Iron Gate reservoirs (Camp Creek and Williams Boat Ramp). These cove sites provide public access, are known areas of likely accumulation during blooms, and have been monitored since 2005.
- Eight (8) river sites stretching from Iron Gate dam (RM 189.7) to Turwar (RM 6.0). Most of these sites have been monitored since 2005, and all represent areas of public access.

In recent years, monitoring programs have also been conducted to evaluate cyanobacteria and cyanotoxin levels in reaches of the Klamath River upstream of the Copco reservoirs, in Oregon between Upper Klamath Lake (Link River Dam) and Copco 1 Reservoir. Those locations are not addressed in this document.

Table 7.5: 2009 Klamath River sampling sites for public health monitoring of cyanobacteria and cyanotoxins in surface water samples and the entities responsible for 2009 sample collection

Location	Approx RM	Sampling Entity
Copco Reservoir and Mallard Cove	200.8	PacifiCorp
Copco Reservoir at Copco Cove	198.5	PacifiCorp
Iron Gate Reservoir at Camp Creek	192.8	PacifiCorp
Iron Gate Reservoir at Williams Boat Ramp	192.4	PacifiCorp
Klamath River below Iron Gate Dam (Hatchery Bridge)	189.7	PacifiCorp
Klamath River at I-5 Rest Area	176	Karuk
Klamath River at Brown Bear River Access	157.5	Karuk
Klamath River at Seiad Valley	128.5	Karuk
Klamath River at Happy Camp	108.4	Karuk
Klamath River at Orleans	59.1	Karuk
Klamath River at Weitchpec	43.5	Yurok
Klamath River at Turwar	6.0	Yurok

7.6.1.2 <u>Sampling Frequency</u>

Sampling frequencies for public health monitoring for both water and tissue samples under the 2009 plan are summarized in Table 7.6 and briefly discussed below:

1. Prior to and following cyanobacteria blooms, once per month (May and November).
2. During the presence of visible cyanobacterial populations or blooms, and cyanotoxins at levels approaching concentrations that warrant the posting of public health advisories by regulatory agencies (e.g., the Regional Water Board), biweekly (aka, every two weeks) (June through October). Sampling will continue at a biweekly frequency until State Board guidelines for posting have been met for *Microcystis aeruginosa.*
3. Following the posting of public health advisories for *Microcystis aeruginosa*, sampling at selected shoreline locations will be reduced to monthly until bloom densities and toxin levels in those areas have reduced and risks to public health are no longer a concern. Sampling at those locations will then resume as in Items 1 or 2, above, depending on the time of year.

7.6.1.3 <u>Sampling Procedures</u>

Water samples will be collected, by all reach monitoring entities, for species identification/enumeration, and for toxin analysis, in accordance with the *Standard Operating Procedures, Environmental Sampling of Cyanobacteria for cell enumeration, identification and toxin analysis* (AIP 2009 - Appendix A). To address public health concerns, water samples will be collected at sampling depths representative of reasonable maximum exposure by incidental ingestion exposures to sensitive populations (i.e., children).

Under the AIP 2009 Monitoring program, Microcystin toxins in water samples are being analyzed by the U.S. EPA Region 9 laboratory, in accordance with the U.S. EPA Region 9 Laboratory Standard Operating Procedure (SOP 1305 for Microcystin analysis by ELISA). In accordance with the *Environmental Sampling SOP* (Appendix A) samples

Table 7.6: Klamath River AIP monitoring program 2009 – summary table of public health monitoring locations, constituents, method, and frequency

J/J2 June-July bimonthly rushed

M3/BM3 bimonthly June through October and monthly in May and November

BM/W bimonthly June through October, weekly Aug/Sept

S2 Two seasonal sampling events

S4 Four seasonal sampling events

S1 One seasonal sampling event

BM5 bimonthly June through October

should be chilled immediately upon collection and maintained at or below 6 degrees C prior to and throughout shipping to the laboratory.

Water samples are also being collected for cyanobacterial cell identification/enumeration to determine the presence and abundance of cyanobacterial species (e.g., *Anabaena sp.*, *Aphanizomenon sp., Microcystis sp.*, etc). These analyses will be conducted to the species level at minimum. Depending on the severity (e.g., density and size) of the algal bloom, river monitoring entities will specify whether the phytoplankton analysis samples will be rushed and/or enumerated using a 400 cell count protocol.

Analysis and data QA/QC review and reporting are being conducted in accordance with the Quality Assurance (QA) plans requirements for each reach monitoring entity identified in Table 7.6 (QA plans are included in Appendix B to the AIP 2009 Monitoring Plan). Appendix B.

7.6.2 Tissue Sampling

During 2009, public health monitoring includes sampling of yellow perch from Copco and Iron Gate Reservoirs, and mussel sampling from locations on the Klamath River below Iron Gate Dam. Sampling conducted in the summer of 2007, with analysis by CDFG using LC/MS/MS, found levels of microcystin in mussels collected in the Klamath River below Iron Gate Dam, and in fish tissue (yellow perch) collected from Copco and Iron Gate reservoirs, exceeding the advisory level of 26 ng/g wet weight total microcystin/gram tissue, developed by the California Office of Environmental Health Hazard Assessment (letter dated August 6, 2008, to Randy Landolt, PacifiCorp from OEHHA (OEHHA 2008).

In 2008, PacifiCorp collected yellow perch and crappie samples from Iron Gate and Copco reservoirs, and rainbow trout from the Klamath River above Copco Reservoir and below Iron Gate dam prior to, during, and after the algal bloom season. Tissue samples were analyzed by Dr. Greg Boyer, University of Syracuse, New York, using HPLC with UV detection. Fish tissue samples collected in May, July, and September 2008 were below detection for total free microcystins (CH2M HILL 2009). PacifiCorp also collected mussel samples below Iron Gate dam during November 2008. A final report for these samples is expected by the end of 2009.

7.6.2.1 Yellow Perch Tissue Sampling

Yellow perch sampling is being conducted at both Copco and Iron Gate reservoirs. Sampling for yellow perch will occur twice during the anticipated bloom season. One sampling event will occur early in the bloom season (July) and the other towards the end of the bloom season (September). During each sampling event, a minimum of 5 (if possible) and up to 15 yellow perch, will be collected from each reservoir. Samples from each reservoir will be weighed and measured to fork length, wrapped in foil, and shipped in accordance with the SOP in Appendix A of the AIP 2009 Monitoring Plan.

In the future, fish sampling in the reservoirs should also be conducted prior to and soon after the collapse of the bloom, as recommended by OEHHA, to evaluate pre-bloom levels and cumulative impacts to evaluated fish species. Additionally, fish sampling in reaches of the river is anticipated.

7.6.2.2 Mussel Tissue Sampling

Mussel sampling is being conducted from a total of 7 locations and one control location, listed below in Table 7.7. The control sampling location (Trinity River) will only be sampled once during the anticipated bloom season (July through September). For all other locations, there will be 4 sampling events; one pre-bloom (May/June), two during the bloom (August and September) and one post-bloom (late October/November).

The proposed locations on the Klamath River below Iron Gate Dam are known to be fishing/harvesting locations, and will be used to evaluate potential ingestion exposure related to recreational, commercial and subsistence fishing activities. Mussel tissue sampling will also be used to support analysis of elevated concentrations in mussel tissues co-occurring with cyanobacterial abundance and elevated cyanotoxin levels in water samples.

Table 7.7: Sample sites in the Klamath River for 2009-2010 monitoring of cyanotoxins in mussel tissue

Location	Approximate RM	Sampling Entity
Klamath River at I-5 Rest Area	176	Karuk
Klamath River at Brown Bear River Access	157.5	Karuk
Klamath River at Seiad Valley	128.5	Karuk
Klamath River at Happy Camp	108.4	Karuk
Klamath River at Orleans	59.1	Karuk
Klamath River at Turwar	6.0	Yurok
Control sample from Trinity River near mouth	na	Yurok

For each Klamath River sampling event and location, five mussels will be collected from each location, and prepared for submittal to the laboratory in accordance with the *Environmental Sampling SOP* (AIP 2009 - Appendix A). Additionally, two water samples will be collected and analyzed for microcystin toxins by LC/MS/MS, and phytoplankton species and enumeration. The California Department of Fish and Game laboratory, in Rancho Cordova, CA, is providing analytical services for all tissue samples and water samples evaluated by LC/MS/MS.

7.6.2.3 Data Quality

Water quality monitoring data (cell count, and ELISA data presenting total microcystin concentrations) for the protection of public health, will be evaluated against the following water quality criteria and guidance. Data should be of sufficient quality to fully and unquestionably meet the following criteria and guidance.

To evaluate water quality data, criteria to be used for purposes of protecting public health include those presented in the California State Water Board 2008 Guidance about

Harmful Algal Blooms, for Monitoring and Public Notification[2], and criteria issued by California's Office of Environmental Health and Hazard Assessment (OEHHA). Exceedance of any of these criteria for the protection of human health and aquatic life may result in the posting of a waterbody by local health agencies:

- Surface scums are present containing toxigenic species[3];
- *Microcystis aeruginosa* or *Planktothrix* cell densities ≥ 40,000 cells/mL;
- Total microsystin concentrations ≥ 8 µg/L; and
- Others as specified in the California State Water Board 2008 Guidance.

To evaluate tissue samples, the current Advisory Tissue Level for one serving (8 oz uncooked, 6 oz cooked) will be applied to analytical results for cyanotoxin concentrations in mussel tissues (26 ng/g wet weight in June 2009, per OEHHA, August 6, 2008). For the protection of human health from tissue contaminated with microcystins, total microcystin concentrations for three or more individual mussels (samples composited, or discrete mussel data averaged) will be evaluated against the current criteria (OEHHA 2008).

7.7 TMDL Ambient Compliance and Trend Monitoring

7.7.1 Continuous/ Multi-Probe Monitoring

For each of the following parameters, capturing sub-daily variability is important to understanding the dynamics present in the system. Continuous monitoring devices will be deployed to address the period May to November, important for characterizing current conditions. Winter deployments can be minimal (December 1-March 31), with certain exceptions where winter water quality conditions are poorly understood.

- **Temperature -** controls rate reactions in aquatic system and can be a stressor to aquatic life.
- **Dissolved Oxygen -** is important to aquatic ecosystem function. Low concentrations can be a stressor to certain aquatic life.
- **pH -** conditions are important for aquatic life, with typical acceptable pH concentrations in a range of 6 to 9. At elevated pH, unionized ammonia can be toxic to aquatic life, a condition exacerbated by elevated temperatures.
- **Conductance -** represents ions that are in solution. This parameter is often used as a conservative constituent and to identify inputs or effects of land use practices.

---

2 Per the posting guidelines established by the Blue Green Algae Work Group of the California State Water Resources Control Board, Department of Public Health, and Office of Environmental Health and Hazard Assessment; *Cyanobacteria in California Recreational Water Bodies; Providing Voluntary Guidance about Harmful Algal Blooms, Their Monitoring, and Public Notification*. Draft, September 2008.

3 When using the presence of scums to establish the need to post, staff trained in recognizing *Microcystis aeruginosa* scums must compile a photographic record as part of the monitoring program.

7.7.2 Water Quality Grab Sample Parameters

For the following parameter, limited sampling (frequency and locations) is proposed:

- **CBOD -** To address TMDL issues, sampling of CBOD will occur every two weeks from June to October, and approximately monthly the remainder of the year. Sampling for CBOD will occur at the following locations below Stateline: Link River Dam, below Keno Dam, above Copco Reservoir at Shovel Creek, and below Iron Gate Dam. Sampling procedures will be based on the USGS National Field Manual (2009) and as part of the studies recently completed by Sullivan (2008). Because many of the CBOD targets and allocations are below the method detection limit (MDL) the Regional Water Board proposes the following procedure for tracking compliance.

  Analytical labs commonly assess results against two precision thresholds. The Method Detection Limit (MDL) is defined as the minimum concentration of a substance that can be measured and reported with 99% confidence that the analyte concentration is greater than zero. The reporting limit (RL) is defined as the lowest concentration at which an analyte can be detected in a sample and its concentration can be reported with a reasonable degree of accuracy and precision. Analytical results between the MDL and RL are often reported as estimated values.

  The MDL and RL for TP are based on procedural results and can vary between laboratories. There are several commercial laboratories that can achieve an RL below the TP concentration targets. For example, the Dept. of Fish and Game laboratory in Rancho Cordova used by the California State SWAMP Program achieves a RL of 0.01o mg/L and a MDL of 0.005 mg/L, well below target concentration.

  The MDL and RL for CBOD are equal at 3 mg/L. These levels are operationally defined and do not vary between laboratories.

  > Option 1) Analytical results of CBOD will be assessed using a 3-month running average for compliance evaluation against concentration targets. Analytical results reported as below the MDL will be assessed at one-half the MDL (i.e., 1.5 mg/L).
  >
  > Option 2) Analytical results reported below the MDL for CBOD will be assumed to represent one-half the MDL (i.e., 1.5 mg/L). This assumption is a commonly used in water quality assessment (Helsel and Hirsch, 1992).

  Alternatively, assessment of compliance with CBOD targets can be conducted using the concentration of Total Organic Carbon (TOC). The target concentrations were derived using a conversion factor applied to particulate and dissolved organic matter. Analytical results of TOC can be converted to an equivalent concentration of CBOD using these conversions.

Sampling for the following parameters will occur from May through December at frequencies noted in Table 7.8. Capturing short term variability (biweekly or daily) may be important for several or all of these parameters, and could be added in future monitoring plans.

- **Inorganic/Organic N (ammonia, nitrate, nitrite, organic N) -** Inorganic nutrients (ammonia, nitrite, nitrate) are readily available for primary production. Total nitrogen (organic plus inorganic forms) is an indicator of overall status of an aquatic system. It is important to collect and assess/consider both organic and inorganic forms. Ammonia can be toxic (unionized ammonia) when elevated pH and temperature conditions are present. The conversion of ammonia to nitrite and nitrate consumes oxygen.
- **Inorganic/Organic P (orthophosphate, organic P) -** Inorganic nutrients (orthophosphate) are readily available for primary production. Total phosphorus (organic plus orthophosphate) is an indicator of overall status of an aquatic system. It is important to collect and assess/consider both organic and inorganic forms.
- **Particulate and Dissolved C (particulate and dissolved organic carbon) -** This is a measure of the organic matter within the system, and is necessary for the partitioning of organic matter fractions into particulate, dissolved, labile, and refractory. Organic matter consumes oxygen during decay and releases nutrients. Analysis of organic carbon is used to determine organic matter loads. Special studies will be used to identify stoichiometry of organic matter (C, N, and P fraction) and to partition particulate and dissolved matter into refractory and labile forms.
- **TSS/VSS (total and volatile suspended solids) -** TSS and VSS together define the organic (VSS) and inorganic (TSS-VSS) fraction of suspended material. This provides insight on bulk organic matter loads, and coupled with inorganic suspended solids can be used to estimate light extinction.
- **Alkalinity -** Understanding alkalinity, helps to identify the buffering capacity of waters and the ability of an aquatic system to resist changes in pH (e.g., in response to primary production).
- **Water Column Chlorophyll-a/Pheophyton -** This measure of chlorophyll-a and pheophyton in reservoirs can be used to estimate the standing crop of phytoplankton. Current modeling estimates of the export of carbon from the reservoirs do not include live algal biomass. An improved understanding of algal biomass export during the summer months would lead to improved estimates of downstream organic matter contributions from the reservoirs. Chlorophyll-a concentrations are also a key indicator of the probability of nuisance blooms dominated by blue-green algae. For the purpose of assessing the TMDL, summer mean target for chlorophyll-a should be calculated using the results of bimonthly surface grab samples from reservoir stations for the growing season (June through

September). Mid-winter measurements are not critical and could be reduced to monthly or once every two months.

- **Phytoplankton species -** The TMDL target for the reservoir for suspended algae chlorophyll-a = 10 µg/L (as a growing season mean - May to October) are linked to the public health monitoring for blue-green algae and the sampling regimen and protocol applies to both. Monitoring requirements to assess these targets for each reservoir with recreational uses are: a minimum of one sample per month at each of 3 near shore reservoir entry areas and 1 open water reservoir sample, collected in accordance with *Standard Operating Procedures, Environmental Sampling of Cyanobacteria for Cell Enumeration, Identification and Toxin Analysis* (June 2099) or other protocol as approved by the Regional Board. Interpretation of monitoring data for these targets will conform to World Health Organization guidance for low probability of adverse health effects, from the *Guidelines for Safe Recreational Water Environments* (Table 8.3), or superseding guidance. (WHO guidelines are also summarized in *Cyanobacteria in California Recreational Water Bodies, Blue-Green Algae Work Group of the State Water Resources Control Board, Department of Public Health, and Office of Environmental Health and Hazard Assessment* (Sept 2008).) Sampling is needed to identify species presence and absence. Determination of population variations can provide insight into trophic status, nutrient availability, blue-green algae species, potential toxins and health advisories. Consideration should be given to further reducing the sampling frequency in mid-winter.
- **Microcystin -** The California 2006 Section 303(d) list identified microcystin as an impairment in the segment from and including the Copco Reservoirs down to Iron Gate Dam, including the segment of Klamath River between those reservoirs. California's 2008 *Public Review Draft Staff Report for the 2008 Integrated Report for the Clean Water Act Section 305(b) Surface Water Quality Assessment and the 303(d) List of Impaired Waters* (Regional Water Board 2008) recommends that the mainstem Klamath River from downstream of Iron Gate Dam to the confluence of the Trinity River be listed as impaired for microcystin (Klamath River from Iron Gate Dam to Scott River - Middle Klamath River HA, and from Scott River to the Trinity River - Middle & Lower Klamath River HA). The target values for these parameters are *Microcystis aeruginosa* cell density = 20,000 cells/mL; and Microcystin = 4 µg/L. The sampling protocol and regimen are consistent with phytoplankton (above). These are minimum requirements, the AIP monitoring plan may exceed the proposed sampling regimen.
- **Preriphyton** (algal biomass) - The reach average is for the summer growing season and will be measured at a minimum of three points during the growing season (e.g., June, August, September) using the protocols described in: *Standard Operating Procedures for Collecting Stream Algae Samples and Associated Physical Habitat and Chemical Data for Ambient Bioassessments in California* (Fetscher et al. 2009). Sampling locations will be in close proximity to TMDL compliance points.

7.7.3 Trend Monitoring Locations, Parameters, Frequency

Table 7.8 provides a summary of the trend monitoring and special study monitoring locations. Several of the trend monitoring stations also double as public health monitoring stations. Some of the trend monitoring stations include public health parameters but are sampled at a reduced frequency compared to the primary public health stations identified in Table 7.6. The Klamath River TMDL monitoring network will require the participation of several organizations to conduct all of the proposed sampling. It may be necessary to reduce the number of stations over time as information regarding the consistency between stations becomes better known.

7.8 Additional Monitoring Needs and Key Questions for Special Study Consideration

Development and implementation of the Klamath River TMDL is an adaptive management process, responding at regular intervals to new information and new findings to ensure that management decisions and actions are directed to the most effective solutions. Following years of study and analysis many questions remain regarding the Klamath River basin water quality conditions. Enough is known that many fundamental decisions regarding load reductions can be safely made, however special studies are recommended. The purpose of this section is to provide a list of topics / issues that can be used to guide the development of future study plan proposals. These studies are described in a conceptual manner. Any final study designs would be developed in coordination with the Klamath Basin Water Quality Monitoring Coordination Group. The key questions are organized by topic or parameter. However, it is possible and desired that any proposed study address as many of the questions as possible.

Key:

Sampling Method
T – thermistor
P – probe or data sonde (minimum seasonal deployment – April to November)
G – grab sample

Sampling Frequency
VP – vertical profile at stated sampling frequency
H – hourly measurements (in some instances sub-hourly data may be desired)
M – monthly sampling

Sampling Frequency
M/S – monthly sampling, seasonally from May through October
M/BM – Bi-monthly sampling May - October and monthly sampling the remainder of the year
W/S – weekly sampling, seasonally from June through September

7.8.1 Assessment of Primary Productivity Limitation

To address concerns that nutrient and organic matter reductions in the Klamath River basin could lead to limitations on primary productivity in the river system over time, careful monitoring and assessment of primary productivity and associated food web dynamics within the Klamath River is appropriate and warranted. Nutrient and organic matter conditions at Iron Gate tailrace and downstream locations should be compared to the monthly mean TP, TN, and CBOD "trigger" concentrations in Table 7.9. These "trigger" concentrations are based on the California allocation scenario, which represents conditions that comply with water quality standards without dams. If observed nutrient and organic matter conditions at Iron Gate tailrace or downstream locations are comparable to the "trigger" concentrations, and if there is evidence of potential limitations to primary productivity at levels deleterious to water quality standards, then the Regional Water Board should reevaluate the TMDL allocations and targets and nutrient controls in the basin or take other appropriate action.

Table 7.9: Nutrient (TP and TN) and organic matter (CBOD) monthly mean "trigger" concentrations (mg/L) at Iron Gate tailrace

	Jan	**Feb**	**Mar**	**Apr**	**May**	**Jun**
Average of TP	0.023	0.028	0.029	0.030	0.029	0.025

	Jul	**Aug**	**Sep**	**Oct**	**Nov**	**Dec**
Average of TP	0.025	0.024	0.024	0.023	0.026	0.029
Average of TN	0.238	0.238	0.252	0.284	0.320	0.360
Average of CBOD	1.526	1.442	1.117	1.120	1.076	1.416

7.8.2 Comprehensive Water Quality Monitoring

To bolster modeling analyses and significantly improve our understanding of water quality conditions in the Klamath River basin, an extended monitoring effort that repeatedly and simultaneously evaluates conditions along the entire length of the river, its impoundments, and the estuary, as well as for nearly all boundary conditions, would be ideal. Due to the size and complexity of this system, however, such a long-term and spatially-intense monitoring program is cost-prohibitive. Therefore, it is recommended that intensive monitoring be conducted for a two to three month period during the summer, when water quality conditions are of the most concern. Limiting the time span for data collection would ideally enable more concurrent data to be collected within the system and for critical inputs to the system.

Additionally, less intensive sampling during the fall, winter, and spring seasons is necessary to develop a reliable mass-balance for nutrient related constituents for the Klamath system. Currently the only method to estimate mass-balance conditions for free-flowing reaches and the reservoirs is to interpolate between a very sparse set of data points and limited information on system flows. A more complete mass-balance is of high value to the ongoing TMDL adaptive management program and will be important in evaluating dam operation or removal scenarios. System wide mass balance monitoring will also provide information regarding nutrient and organic matter loading to the estuary.

Key data to collect, listed by location, are as follows:

- **Link River boundary condition:** Collect a full suite of data, including temperature, DO, total PO_4 (PO_4-T), NH_4/NH_3, NO_2/NO_3, $CBOD_5$, $CBOD_{20}$, Inorganic Suspended Solid (ISS), chlorophyll-a, algal biomass : chlorophyll-a ratio, algal C:N:P ratio, dissolved organic matter (C,N, and P), particulate organic matter (C, N, and P), alkalinity, and pH

  Time span and frequency: Data should be collected on a **weekly** basis from approximately **June 1st to July 31st (see footnote[4])**, as this period covers the most critical water quality conditions at this location. For DO and temperature, continuous data (i.e., on an hourly-basis) is recommended. Monitoring pre-dawn and afternoon concentrations of several key nutrients, such as PO_4-T, NH_4/NH_3, NO_2/NO_3, and chlorophyll-a would be ideal, in order to characterize the magnitude of diurnal fluctuation.

- **Lost River Diversion Channel (LRDC):** Data are needed to characterize the contribution of loading to the Klamath River only during the period when water flows from the Lost River to the Klamath River. The same suite of temperature and water quality data recommended for Link River is necessary.

  Again, flow data are necessary and assumed to be available.

- **Klamath Strait Drain (KSD):** The same suite of constituents noted above for Link River are also needed for KSD, in order to better characterize this boundary. Diurnal DO and temperature, and pre-dawn and afternoon nutrient monitoring are not as important.

  The monitoring frequency should be weekly, and the starting time can be 4 days later than that for Link River (i.e., it can start from June 5th and extend to August 4th). This shift in dates takes into account the time of travel from Link River to the KSD entrance location.

- **Lake Ewauna/Keno Reservoir:** Monitoring is recommended at Miller Island and Hwy 66 for temperature (continuous), DO (continuous), NH_4, NO_2/NO_3, PO_4-t, chlorophyll-a, algae biomass, Org-N, Org-P, $CBOD_5$, $CBOD_{20}$, alkalinity, and pH.

---

[4] The dates presented in this section are approximate and meant to reflect the recommended shift is sample days for the various monitoring locations.

These data would need to be monitored on a weekly basis. For Miller Island, the monitoring time span should be June 5th to August 4th (the same as for KSD). For the Hwy 66 station, a monitoring time span from June 7th to August 6th would be appropriate.

It would also be valuable to measure hydrogen sulfide levels at least one or two times over the course of the monitoring event, during the anoxic period.

- **Keno Reach:** A monitoring station should be set up at the end of the Keno Reach, before entry to J.C. Boyle Reservoir. Similar constituents and frequency as for KSD would be useful. The starting time, however, can be shifted to June 7th to August 6th (which is the same as for the Hwy 66 location.

  These data would be useful in characterizing water quality processes occurring within the Keno Reach. They would also ensure more accurate representation of boundary conditions for the downstream J.C. Boyle model.

- **J.C. Boyle Reservoir:** Continuation of monitoring at the current location upstream of the dam is recommended. The same suite of parameters as for the Lake Ewauna/Keno Reservoir should be collected. The monitoring should be performed weekly from June 7th to August 6th.

- **Full Flow:** Four monitoring stations are recommended: 100 meters downstream of J.C. Boyle Dam, 100 meters after the Powerhouse return flow enters, within 100 meters of where the last spring enters, and at Stateline. The same suite of constituents as for the Lake Ewauna/Keno Reservoir are recommended. Monitoring should be performed weekly from June 7th to August 6th. Three parcel tracking events at twelve stations along the Klamath River should be initiated from (1) below the JC Boyle and below the last spring. Using the KBMP coordination framework and the model hydraulic simulation parcel sampling could be part of an optimized set of regular sampling events. The following locations should also be included in the parcel tracking sampling events: (2) above Copco; (3) above Iron Gate; (4) below Iron Gate; (5)above Shasta River; above (6) Scott River; (7) at Seiad Valley; (8) above Salmon River; (9) USGS station near Orleans; (10) at Weitchpec (above Trinity); (11) below Trinity River ; and (12) at Turwar. An estuary water quality sampling program needs to be established distinct from the run of river program. However for the parcel tracking events effort should be made to coordinate with ongoing estuary sampling events.

  The purpose of this sampling recommendation is to better understand the nutrient dynamics of the Klamath mainstem (retention and loss) on a seasonal basis.

- **Springs:** Measure, if possible, the major springs along the full flow reach, for PO_4, NH_4, NO_2/NO_3, Alk, pH, temperature, and DO. Two to three weekly monitoring events should be conducted to evaluate the temporal variability of concentration. If concentrations are highly variable, monitoring should be continued for a longer period.

- **Copco Reservoir:** Two monitoring stations are recommended: one at the upstream end and one near the dam. The same suite of constituents collected for Lake Ewauna/Keno Reservoir should be collected here, at a weekly frequency. For the upstream station, samples should be collected from June 7th to August 6th. For the downstream station, data should be collected from June 17th to August 16th.

- **Jenny Creek:** A monitoring station at the mouth of Jenny Creek is recommended. Similar constituents and frequency as for KSD would be useful. The monitoring period should be from June 17th to August 16th.

- **Iron Gate Reservoir:** Two monitoring stations are recommended: one that characterizes the outflow from Copco Reservoir before it enters Iron Gate Reservoir, and one immediately upstream of Iron Gate Dam. Constituents should be the same as for Lake Ewauna/Keno Reservoir and should be collected at a weekly frequency. The upstream station should be monitored from June 17th to August 16th and the downstream station from July 1st to August 31st.

- **Immediately Downstream of Iron Gate Dam**: One monitoring station should be located downstream of Iron Gate Dam - at the end of the turbulent region. Monitoring should include the same parameters collected for Link River. This will help to characterize inputs to the longest uninterrupted reach of the Klamath River. Samples should be collected on a weekly basis, with pre-dawn and post-dawn monitoring, if possible. Diurnal DO and temperature should be included. The time period should extend from July 1st to August 31st.

- **Low Gradient Reach Between Shasta and Scott Rivers**: This station has recently been demonstrated to have the highest rate of parasite infection of fish within the Klamath system. This station would also be crucial to understanding the nutrient dynamics of the reservoirs. To assess nutrient dynamics, diurnal hourly sampling events on three to four days from early spring to mid-fall would be useful. This would help to characterize daily variability in nutrient dynamics. The Iron Gate station should also be located at the same location as the station used by the Humboldt State University / Oregon State University Fish Health research teams. In addition to water chemistry the NNE parameter for benthic algal biomass should be sampled four times (late spring, early summer, late summer, and late fall). Monitoring should be conducted in close collaboration with the Fish Health Research Group (Bartholomew and Foot) to evaluate: planktonic food source enrichment from reservoir discharges; timing and concentration of parasite spore release; and parasite infection rates among fish and polychaetes.

- **Major Tributaries** : Based on modeling to date, it has been found that water quality from the minor tributaries do not have a significant impact on conditions in the

Klamath River. Therefore, monitoring these tributaries is not a high priority for understanding mainstem conditions and water quality drivers.

Monitoring the major tributaries, including Shasta, Scott, Salmon and Trinity, however, is important. Stations for these tributaries should be located as close to the tributary mouths as possible, while avoiding potential backwater effects from the Klamath River. Constituents monitored should be the same as for Lake Ewauna/Keno Reservoir. Monitoring should be conducted weekly from July 1st to August 31st. Additional samples should be collected for the Salmon and Trinity Rivers to evaluate day-to-day variability. These samples should be collected one or two days after the weekly monitoring data are collected at these locations.

- **Iron Gate to Turwar:** Monitoring stations downstream of the Shasta River, downstream of the Scott River, at Seiad Valley, upstream of the Salmon River, downstream of the Salmon River, upstream of the Trinity River, downstream of the Trinity River, and at Turwar are recommended. The same suite of constituents monitored for Lake Ewauna/Keno Reservoir should be monitored at these locations. Sampling should be conducted weekly from July 1st to August 31st.

  These stations should also conduct three to four diurnal hourly sampling events to address daily variability in nutrient dynamics. The Iron Gate station should be located at the same location as the station used by the Humboldt State University / Oregon State University Fish Health research teams. In addition to water chemistry the NNE parameter for benthic algal biomass should be sampled four times (late spring, early summer, late summer, and late fall).

- **Estuary:** Two to three monitoring locations in the estuary should be selected (longitudinally). Constituents monitored should be the same as for Lake Ewauna/Keno Reservoir, with the addition of salinity.

  A periphyton survey, as noted above for Iron Gate to Turwar, should also be conducted. Currently the model cannot accurately reproduce the significant diurnal fluctuation of DO in the estuary. This may be a result of periphyton growth.

- **Open Ocean Boundary Condition:** A monitoring station should be located in the Pacific Ocean, at a distance far enough from the estuary to avoid impacts from flushing. Tidal elevation, temperature, salinity, and the suite of constituents collected for Lake Ewauna/Keno Reservoir should be monitored. Both surface and bottom data are needed. Continuous tidal, temperature, and DO are recommended. The other parameters can be collected weekly. The sampling period should be from July 1st to August 31st.

- **Flow Gages and Flow Analysis:** Additional flow gages along the length of the river would be useful to further understand flow characteristics and the flow balance. This would improve hydrodynamic representation in the model, by refining representation of accretion/depletion. Currently, flow accretion is lumped with the minor tributaries in the model. This introduces some amount of uncertainty. Ideally, a higher resolution survey would reduce the need to lump these accretions, and would serve to better represent their spatial variability.

- **Water Quality Monitoring for Accretions:** In the event that any significant accretions (e.g., springs) are identified, water quality monitoring is recommended. Monitoring should be conducted using a scheme similar to that for the springs downstream of J.C. Boyle Reservoir.

- **Updated Bathymetric Survey**: In 2004, a bathymetric survey was conducted in the estuary. A new survey is recommended to cover a larger area. The area should include that surveyed in 2004, but also extend to the sand bar (and characterize the dimensions of the sand bar opening) and include a survey of the bathymetry in the Pacific Ocean, just outside the estuary (since the model grid extends into the ocean). Conduct additional historical analysis of the pattern and frequency of the status (open or closed) of the estuary mouth. Include measurement of the estuary mouth in the bathometry study. Measure flow at estuary mouth to better characterize tidal exchange with ocean.

7.8.3 Temperature / Fish Refugia

Temperature improvements in the Klamath River basin are contingent upon improvements from several contributing factors throughout the watershed. Achieving temperature standards in the Klamath River basin is critical for protecting beneficial uses of the basin, particularly in light of the real threats associated with global warming. The following are recommended special studies to better understand the opportunities for improving temperature conditions in the Klamath River basin:

- The influence of sediment delivery and tributary flows on thermal refugia volume in the Klamath River. Monitoring thermal refugia dimensions in relation to flows in tributaries, flows in the Klamath River, and sediment loads in the tributaries will lead to a better understanding of the most important factors limiting the availability of thermal refugia in the Klamath River.
- Monitoring of groundwater-surface water interaction in the Scott Valley. This monitoring is being conducted as part of the Scott River Temperature TMDL, and includes instream flow and temperature measurements, as well as monitoring of static water table height. The results of this study will contribute to a better understanding of potential temperature improvements in the Scott River.
- To better understand the status of fish access to the tributaries cross-sections surveys should be conducted at the mouth of each tributary to assess connection status to main stem Klamath. Conduct channel surveys of all major tributaries to assess the impact of excess sediment deposition and flow regime alteration on connection to the main stem Klamath.

7.8.4 Relationship of Water Quality Conditions and Fish Disease

The Klamath Fish Health Research team (Humboldt State University, Oregon State University, USFWS, and CA Fish and Game) is taking the lead on formulating key questions, developing research proposals, and conducting the research to better understand and manage fish disease processes in the Klamath River basin. The annual Klamath Fish Health Conference held in Fortuna, California has provided an excellent forum for presentation and discussion of research results. The questions of interest to the Regional Water Board relate more specifically to how water quality conditions, especially those impacted by TMDL control strategies, affect the severity and magnitude of fish disease processes in the Klamath River. The Klamath Fish Health team is currently developing a fish disease model that eventually will incorporate water quality factors to develop estimates of fish infection and mortality rates within the Klamath mainstem.

- What monitoring information is needed to continue to develop the Klamath fish disease model algorithms?

7.8.5 Blue-Green Algae / Cyanotoxins

The California and Klamath Blue-Green Algae Work Groups meet on a regular basis and discuss results of ongoing monitoring and future research needs. Much is unknown about the algae species dynamics, ecological impacts, and the potential effectiveness of within reservoir mitigation strategies. The following are questions that will be raised at the existing forums for further refinement and possible recommendation for development into special study proposals.

- What environmental factors, or capabilities unique to the blue green algae contribute to the competitive advantage that the blue-green algal species exhibit in the California reservoirs during the peak summer growth period?
- How do environmental factors affect cyanotoxin production?
- How long does microcystin remain in tissue once an organism has been exposed?
- How long are the effects manifested within the affected tissues of various organisms?
- Proposed blue-green algae monitoring should consider tracking the depth that blue-algal cells descend to during their diurnal rising and sinking. Do blue-green algae cells reach the hypoliminion and have access to higher nutrient concentrations than those in the epiliminion? This could be a principal factor leading to their competitive advantage relative to other algal species during the late summer period.

7.8.6 Periphyton Characterization in the Mainstem Klamath River

Attached algae (periphyton) has a major impact on DO and pH diurnal patterns in the mainstem Klamath River. Periphyton is also believed to have a connection to the distribution and abundance of fish parasites (*C. Shasta)*. Periphyton also plays an important role in nutrient dynamics (retention and loss) within the Klamath River. Therefore periphyton density / algal biomass is a key monitoring and TMDL implementation indicator.

- An improved characterization of periphyton / algal biomass conditions is needed on the Klamath River. Algal biomass should be sampled on four dates at seven locations beginning (1) below Iron Gate Dam (below the channelized reach). Other periphyton stations should include: (2) above the Shasta River; (3) above the Scott River; (4) at

Seiad Valley; (5) above Trinity; (6) below Trinity; and (7) at Turwar. The protocol should be consistent with the methods recommended by the Surface Water Ambient Monitoring Program Periphyton Technical Advisory Committee and should include a visual or photographic estimation method for those locations where due to flow conditions sampling in the mainstem is deemed to be unsafe. The sampling dates should include early spring, mid-summer, late summer, and late fall. Sampling events should note any obvious scour (early spring) or desiccation (late summer / late fall).

CHAPTER 8. ANTIDEGRADATION ANALYSIS

8.1 Introduction

This chapter briefly describes the state and federal antidegradation policies and how they apply to the Klamath River TMDL Action Plan.

8.2 State and Federal Antidegradation Policies

The state and federal antidegradation policies are independently enforceable requirements, despite being referred to as policies. The state antidegradation policy is titled the *Statement of Policy with Respect to Maintaining High Quality Waters in California*, codified in 23 CCR §2900, and is commonly known as "Resolution 68-16." The California's antidegradation policy is also included in the Basin Plan as a General Objective (Basin Plan pages 3-2.00 to 3-3.00). The federal antidegradation policy is found at 40 CFR §131.12 and it has been incorporated into the Basin Plan.

Although there are some differences, where the state and federal policies overlap they are consistent with each other. Both the state and federal antidegradation policies require that where surface waters are of higher quality than necessary to protect the designated beneficial uses, the high quality of those waters be maintained unless otherwise provided by the policies. Both policies require that certain findings be made before any adverse change to water quality can be permitted. The State Water Board has concluded that Resolution No. 68-16 incorporates the federal Antidegradation Policy (see State Water Board Order No. WQ 2001-16, p. 19, fn 83).

The state antidegradation policy applies to groundwater and surface water whose quality meets or exceeds (is better than) water quality objectives. The state policy establishes several conditions that must be met before the quality of high quality waters may be lowered by waste discharges.

The state must determine that lowering the quality of high quality waters:

1. Will be consistent with the maximum benefit to the people of the state,
2. Will not unreasonably affect present and anticipated beneficial uses of such water, and
3. Will not result in water quality less than that prescribed (e.g., by water quality objectives).

In addition, before any degradation of water quality is permitted, it must be shown that the discharge will be required to meet waste discharge requirements that result in best practicable treatment or control of the discharge necessary to assure that:

1. Pollution or nuisance will not occur;
2. The highest water quality consistent with maximum benefit to the people of the State is maintained.

The federal antidegradation policy applies to surface water regardless of the quality of the water. In allowing an activity to degrade or lower water quality, the federal antidegradation policy requires states to ensure that:

1. The activity is necessary to accommodate important economic or social development in the area,
2. Water quality is adequate to protect and maintain existing beneficial uses fully, and
3. The highest statutory and regulatory requirements and best management practices for pollution control are achieved.

The federal antidegradation policy also applies to surface waters that do not meet the applicable water quality objectives (i.e., impaired waters). Under the federal policy, an activity or discharge would be prohibited if the activity will lower the quality of surface water that does not have assimilative capacity (i.e., the water quality is not sufficient to support designated beneficial uses) with limited exceptions set forth in federal regulations.

Both the state and federal antidegradation policies acknowledge that minor or repeated activities, even if individually small, can result in violation of antidegradation policies through cumulative effects, especially, for example, when the waste is a cumulative, persistent, or bioaccumulative pollutant.

8.3 Applicability to the Klamath River TMDL Action Plan

The proposed Klamath River TMDL Action Plan is based in part on the principles contained in the state and federal antidegradation policies. The recommended alternative – adoption of the proposed Klamath River TMDL Action Plan – will not delete or limit beneficial use designations and will not relax any water quality standard. This proposal will result in water quality improvements; therefore, state and federal antidegradation analyses are not required.

CHAPTER 9. CALIFORNIA ENVIRONMENTAL QUALITY ACT (CEQA) ENVIRONMENTAL ANALYSIS

Staff from the North Coast Regional Water Quality Control Board (Regional Water Board) developed two proposed amendments to the *Water Quality Control Plan for the North Coast Region* (Basin Plan) that would incorporate the *Klamath River Watershed Temperature, Dissolved Oxygen , Nutrient and Microcystin Total Maximum Daily Loads* (hereinafter draft Klamath TMDLs) and the implementation program into the Basin Plan. The Klamath River implementation plan includes the Implementation Plan for the EPA-promulgated Lost River TMDL in California. In addition, the second proposed amendment would modify Table 3-1 of the Basin Plan by eliminating the existing site-specific dissolved oxygen (DO) water quality objectives (objectives) applicable to the Klamath River mainstem and replacing them with an alternate method of calculating objectives based on percent saturation and natural background temperatures. The proposed amendment would also modify Section 4 of the Basin Plan by adding a new *Klamath River Total Maximum Daily Load Action Plan and Lost River Implementation Plan* (hereinafter proposed Action Plan). These proposed amendments are necessary to comply with existing federal and State laws, regulations, plans and policies. In addition, the development of the Klamath TMDLs is mandated under a court-ordered Consent Decree.

9.1 California Environmental Quality Act Requirements for Exempt-Regulatory Programs

The Regional Water Board is the lead agency for evaluating the environmental impacts of Basin Plan amendments pursuant to the California Environmental Quality Act (CEQA). Although subject to CEQA, the Regional Water Board basin planning process is certified by the Secretary for Resources as "functionally equivalent" to CEQA, and therefore exempt from the requirement for preparation of an environmental impact report or negative declaration and initial study[1]. The State Water Resources Control Board (State Water Board) has promulgated guidelines for exempt regulatory programs that describe the documents required for the adoption or approval of standards, rules, regulations or plans[2]. These documents must at least do the following:

1. <u>Provide a brief description of the proposed activity</u>.
   In this case, the proposed activity is the adoption of two Basin Plan Amendments: a) Revised DO objective for the Klamath River mainstem and b) "*Action Plan for the Klamath River Watershed Temperature, Dissolved Oxygen, Nutrient and Microcystin Total Maximum Daily Loads*" (proposed Action Plan). The rationale to support the proposed DO objective and Action Plan is fully described in the Staff Report. A brief description is provided in Section 9.2.

[1] Cal. Code Regs., tit. 14, § 15251(g).
[2] Cal. Code Regs., tit. 23, § 3777.

2. Provide a reasonable discussion of alternatives to the proposed activity. Discussion is provided in Section 9.4.

3. Provide an analysis of mitigation measures needed to minimize any significant adverse environmental impacts of the proposed activity. Discussion is provided in Section 9.5.

Additionally, for actions by the Regional Water Board that adopt a rule or regulation requiring the installation of pollution control equipment, establish a performance standard or establish a treatment requirement, CEQA[3] and CEQA Guidelines[4] require an environmental analysis of the reasonably foreseeable methods by which compliance with that rule or regulation will be achieved. A Substitute Environmental Document (SED) satisfies this requirement if it contains the following components, some of which are repetitive with the list above:

1. An analysis of the environmental impacts from the reasonably foreseeable methods of compliance. The reasonably foreseeable methods of compliance (hereinafter compliance measures) are the potential actions that responsible parties may employ to comply with the TMDL load allocations, numeric targets and the implementation measures in the proposed Action Plan. This analysis is presented in Section 9.5.
2. An analysis of the reasonably foreseeable feasible mitigation measures relating to the identified environmental impacts. This analysis is presented in Section 9.5.
3. An analysis of reasonably foreseeable alternative means of compliance with the rule or regulation, which would avoid or eliminate any identified impacts. This analysis is presented in Section 9.7.

The environmental analysis must take into account a reasonable range of:[5]

- Environmental factors (see Environmental Setting and Land Use, Section 9.3);
- Technical factors (see Analysis of Compliance Measures, Associated Environmental Impacts, and Potential Mitigation Measures, Section 9.5);
- Population (see Environmental Setting and Land Use, Section 9.3);
- Geographic areas (see Environmental Setting and Land Use, Section 9.3);
- Specific sites (see Analysis of Compliance Measures, Associated Impacts, and Potential Mitigation Measures, Section 9.5); and
- Economic factors (see Economic Considerations, Chapter 10).

While the regulations require consideration of a "reasonable range" of the factors listed above, an examination of every site is not required, only consideration of a reasonably representative sample of them. The statute specifically states that the agency shall not

---

3 Cal. Pub. Resources Code, § 21159 (a).
4 Cal. Code Regs., tit.14 § 15187 (c).
5 Cal. Code Regs., tit. 14 § 15187(d); Cal. Pub. Resources Code, § 21159 (c).

conduct a "project level analysis[6]." Rather, in most circumstances, the project level analysis will be performed by the responsible party to be eligible for enrollment/coverage under the applicable permit (e.g., 401 Water Quality Certification, waste discharge requirements [WDRs], or waiver of WDRs).

Notably, the Regional Water Board is prohibited from specifying the manner of compliance with its regulations[7], and accordingly, the actual environmental impacts will necessarily depend upon the compliance strategy selected by the responsible party. There could be adverse environmental impacts from specific methods if inappropriate methods are selected or if the management measures selected are not properly implemented. Regional Water Board staff intends that the compliance measures selected by a responsible party be the most cost effective available with the least potential to adversely impact the environment. Responsible parties will develop the suite of compliance measures they will implement to achieve the TMDL load allocations and be compliant with the proposed implementation plan and the revised DO objective. A number of regulatory approaches are (or will be made) available for responsible parties' use in achieving compliance with the TMDLs. This includes compliance with applicable prohibitions, WDRs or conditional waivers of WDRs.

This Substitute Environmental Document (hereinafter SED) identifies broad mitigation approaches that could be considered for the general categories of land use activity identified in the TMDL pollutant source analysis and implementation plan (Chapters 4 and 6, respectively of this Staff Report). Consistent with CEQA, this document does not engage in speculation or conjecture, but rather considers the reasonably foreseeable environmental impacts of the reasonably foreseeable methods of compliance, and the reasonably foreseeable mitigation measures which would be required to avoid, eliminate, or reduce the identified impacts.

An analysis of the reasonably foreseeable alternative means of compliance is also provided as part of this environmental analysis (see Section 9.7).

9.2 Description of the Proposed Activity

In this case, the proposed activity (or project) is the revision of DO objectives for the Klamath River mainstem; the establishment of the total maximum daily loads (TMDLs) for the temperature, dissolved oxygen, nutrient and microcystin impairments in the Klamath River watershed; and, the adoption of an implementation plan (proposed Action Plan) for the Klamath River watershed necessary to achieve these TMDLs and fully attain water quality standards, including the revised DO objectives. The goal of the proposed implementation plan is to achieve the TMDLs and thereby achieve temperature, dissolved oxygen, nutrient and microcystin-related water quality standards, so as to protect and restore the beneficial uses of water in the Klamath River watershed. The

---

[6] Public Resources Code section 21159(d)
[7] Water Code section 13360

proposed Action Plan sets outs the pollutant loads and conditions to be considered and incorporated into regulatory and non-regulatory actions in the Klamath River watershed. The Klamath River Action Plan is not directly and independently enforceable, except as incorporated into permitting or enforcement actions or through the application of waste discharge prohibitions or other permits or orders.

- Regional Water Board staff has developed a proposed site-specific DO objective for the Klamath River in California (Appendix 1 of the TMDL Staff Report) for the Regional Water Board's consideration to address the inaccuracies in the existing Klamath River DO objectives. The Basin Plan Amendment for DO is an amendment to Table 3-1 in which the existing site-specific DO objectives for the Klamath River mainstem are removed and a method for calculating revised site-specific DO objectives is described, based on percent saturation and natural receiving water temperatures.
- Regional Water Board staff has also developed the proposed Klamath River TMDL Action Plan for the Regional Water Board's consideration to address the water quality impairment in the Klamath River watershed downstream of the Oregon border. The proposed Basin Plan Amendment, as developed by staff, is an amendment to Section 4 of the Basin Plan to provide an *"Action Plan for the Klamath River Watershed Temperature, Dissolved Oxygen, Nutrient and Microcystin Total Maximum Daily Loads"* (proposed Action Plan).

The proposed Basin Plan Amendment language, including Table 9.1, for the site-specific Klamath River mainstem DO is as follows:

Site-specific dissolved oxygen water quality objectives for the Klamath River are derived by calculating the daily minimum dissolved oxygen necessary to maintain, at a minimum, the percent DO saturation criteria given in Table 9.1 under site salinity, site atmospheric pressure, and natural receiving water temperatures.

Table 9.1: Percent dissolved oxygen saturation based on natural receiving water temperatures

Location	**Percent DO Saturation based on natural receiving water temperatures***	**Time period**
Stateline to upstream of California- Hoopa boundary	90%	October 1 through March 31
	85%	April 1 through September 30
Downstream of Hoopa-California boundary to Turwar	85%	All year
Upper and Middle Estuary	80%	August 1 through August 31
	85%	September 1 through July 31
Lower Estuary	For the protection of estuarine habitat (EST), the dissolved oxygen content of the lower estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors.	

*These objectives apply throughout the length of the mainstem Klamath River except for where there is Tribal jurisdiction.

The proposed Action Plan consists of a description of the TMDL temperature, dissolved oxygen, nutrient and microcystin-related load allocations and numeric targets and implementation actions necessary to comply with the TMDLs.

The proposed Action Plan includes the following items as part of the implementation program:

- Adoption of a *Prohibition of Discharges in Violation of Water Quality Objectives in the Klamath River Basin*

  "Discharges of waste that violate any narrative or numerical water quality objectives that are not authorized by waste discharge requirements or other order or action by the regional or state water board, are prohibited."

- Adoption of a Thermal Refugia Protection Policy that provides enhanced protection of thermal refugia in and around the mainstem Klamath River and in the Lower Scott River.

  The policy would be applicable to all tributary streams in the Klamath River basin that provide known thermal (cold-water) refugia

- Adoption of Guidance to Control Sediment Discharges

  The guidance encourages responsible parties to implement specific measures to address sediment source discharges in the Klamath basin.

The SED to support the Regional Water Board's consideration of the draft Klamath River TMDLs includes:

- The draft Staff Report which provides the technical and environmental analysis necessary to support adoption of the revised site specific DO objective for the Klamath River mainstem and the Klamath River TMDLs;
- The proposed Basin Plan Amendment for the revision of the Klamath River DO objectives; and
- The proposed Action Plan that includes, in part, load allocations and implementation actions necessary to achieve the TMDL and attain water quality standards, including the protection and restoration of beneficial uses of water in the Klamath River watershed.

9.3 Environmental Setting and Land Uses

The Klamath River watershed originates in southeastern Oregon and flows through northern California to the Pacific Ocean in Del Norte County, California. The Klamath River watershed is approximately 12,600 square miles in size, with forty-four percent (44%) of the watershed within the boundaries of Oregon, and the remaining fifty-six percent (56%) located in California.

The human population in the Klamath River basin was estimated in the 2000 US Census to be about 114,000 (United States Census Bureau [USCB] 2000). The largest population concentrations lie in the upper Klamath agricultural area, the Shasta River Valley, and Scott Valley. The largest population center is Klamath Falls in Oregon (19,462 people in 2000) followed by Yreka, California (7,290 people). The Klamath River basin can generally be characterized as a rural watershed with limited population-related water quality issues.

The watershed is composed of large tracts of remote forest and wilderness area, as well as agricultural areas and isolated small-scale urban areas. The watersheds support threatened and endangered species of plants and animals, including runs of anadromous salmon and steelhead trout. The principal reaches of the Klamath River are designated as “wild and scenic” under federal and State law and therefore are protected from development of additional large-scale water use projects.

The current air quality in the region is above average to good. However, Humboldt, Del Norte, and Trinity Counties do not fully meet the state health standards[8] for clean air. The two pollutants of greatest concern are ozone and particulate matter. The sunny climate, pollution-trapping mountains and valleys, along with the growing population, all contribute to this problem. Particulate matter is fine mineral, metal, soot, smoke and dust particles suspended in the air. The exceedence of state health standards are most often due to catastrophic wildland fires.

The underlying geology in much of the Upper Klamath basin is of volcanic origin. Soils derived from this rock type are naturally high in phosphorus. Through natural erosion and leaching processes, these soils contribute a high background phosphorus load to Upper Klamath basin waters

The geographic source areas in the Klamath River in California can generally be grouped as follows:

- Stateline – Waters entering California from Oregon at Stateline, which includes the Williamson and Sprague River watersheds; Upper Klamath Lake; the Lost River watershed that drains the U.S. Bureau of Reclamation’s Klamath Project (Reclamation’s Klamath Project) area; municipal and industrial point sources to the Klamath River in Oregon; and Klamath River waters passing through Lake Ewauna, the Keno Reach, and JC Boyle Reservoir. Oregon’s Klamath River TMDL source analysis evaluates the contributions from these various sources on the water quality of the Klamath River in Oregon;
- Reservoirs – The reservoirs on the Klamath River within California: Copco 1 and 2 and Iron Gate Reservoirs. Copco Reservoirs 1 and 2 are treated as a single source for the purposes of this TMDL;

---

8 http://www.arb.ca.gov/research/aaqs/caaqs/caaqs.htm

- Iron Gate Hatchery; and
- Tributaries – These include the Lost, Shasta, Scott, Salmon, and Trinity Rivers, and a number of smaller tributary creeks.

The Klamath River has historically been referred to as the “river of renewal”. The Klamath is unusual in that it has its origins in a naturally shallow, eutrophic lake, Upper Klamath Lake, which delivers warm water with high levels of nutrients and organic matter to the Klamath River. Due to an increasing stream gradient and inputs from tributaries with water that is both cooler and generally lower in nutrient content, the Klamath River undergoes a renewal process that leaves it less eutrophic as the river approaches the Pacific Ocean, creating conditions that historically made it one of the most productive cold-water fisheries on the Pacific coast. Despite this unique attribute, current source loads have overwhelmed the historic renewal capabilities of the Klamath, leading to its impaired status. Table 9.2 presents the anthropogenic pollutant source land use categories.

Table 9.2: Anthropogenic pollutant source land use categories[9]

Land Use Source Categories	Temp.	DO	Nutrient	Organic Matter
Wetland conversion		X	X	X
Grazing	X	X	X	X
Irrigated agriculture	X	X	X	X
Timber harvest	X	X	X	X
Roads	X		X	

High ambient air temperatures, coupled with the high levels of biological productivity and respiration that are enhanced by the high levels of biostimulatory nutrients, yield a large mass of organic matter, seasonally high water temperatures, daily low dissolved oxygen, and high pH levels. All of these water quality conditions can be extremely stressful to many forms of aquatic life. These natural background heat, nutrient, and organic matter loads to the Klamath River underscore the very limited capacity of the river to assimilate anthropogenic pollutant sources, and the necessity for establishing load allocations that will result in attainment of water quality standards.

The existing DO objectives for the Klamath River mainstem are based on grab sample data collected in the 1950s and 1960s during daylight hours. They are identified as instantaneous minima. But, because they do not reflect DO conditions during the night time when DO concentrations decrease with the loss of photosynthetic contributions, the existing DO objectives are best applied only during daylight hours. The TMDL analyzes conditions in the Klamath River throughout the day and night and over the course of a year. As such, the model shows that even under natural conditions—in the absence of anthropogenic influences—the Klamath River can not meet the existing DO conditions during the pre-dawn hours of the summer when temperatures are warm and photosynthesis is temporarily arrested. Staff proposes the revision of the DO objectives for the Klamath River to better reflect minima expected across a full 24 hours. The

---

9 From Chapter 4 of this Staff Report

TMDLs are calculated based on the proposed revisions to the Klamath River DO objectives.

The States of Oregon and California are responsible for calculating the TMDL load allocation for each of the pollutants of concern that can be discharged to the watershed and still protect and restore the beneficial uses of the water within their respective jurisdictions.

In the California portion of the Klamath River, increased water temperatures, elevated nutrient levels, low dissolved oxygen concentrations, elevated pH, potential ammonia toxicity, increased incidence of fish disease, an abundance of aquatic plant growth, high chlorophyll-a levels (both planktonic and periphytic algae), and high concentrations of potentially toxigenic blue-green algae (microcystin), particularly in the impounded reaches (reservoirs), decrease the quality and quantity of suitable habitat for fish and aquatic life, and have disrupted traditional cultural uses of the river by resident Tribes. These conditions contribute to the non-attainment of beneficial uses, including the most sensitive beneficial uses: those associated with the cold water fishery (specifically the salmonid fishery), and those related to cultural uses and practices.

California listed the portions of the Klamath River within its jurisdiction for water quality impairments due to elevated water temperatures, elevated nutrients, and organic enrichment/low dissolved oxygen. The portion of the Klamath River downstream of the Trinity River, within the Yurok Reservation, was also listed for sedimentation/siltation impairment. In March 2008, the USEPA added the reach of the Klamath River that incorporates the Copco 1 and 2 and Iron Gate Reservoirs (located near the California - Oregon Stateline) to the Clean Water Act 303(d) List of Impaired Waterbodies for the blue-green algae toxin microcystin.

The Klamath River numeric and narrative water quality objectives and beneficial uses that are the comparative benchmarks for the TMDL assessment are described in Table 2-1 of the Basin Plan and in the Hoopa Tribal water quality standards,[10] with the exception of the DO objectives for the Klamath River mainstem which are proposed for revision. The Basin Plan, proposed Basin Plan Amendment for DO, and Tribal water quality standards provided the baseline regulatory context for the TMDL assessment and development.

9.4. Analysis of Reasonable Alternatives to the Proposed Activity

Regional Water Board staff has identified four approaches (or alternatives) to address protection and restoration of the beneficial uses of water in the Klamath River watershed. The purpose of this analysis is to determine if there is an alternative that would feasibly attain the basic objective of the rule or regulation, but would lessen, avoid, or eliminate any identified impacts. The first alternative, as required by law, analyzes a “No Action”

[10] Hoopa Tribe Water Quality Control Plan: http://hoopa-nsn.gov/doccument/WQCP.pdf

alternative with no change to the Basin Plan or program implementation. The second alternative also contemplates no change to the Basin Plan but describes an approach that focuses on implementation of existing Regional and State Water Board programs with a phasing in of new regulatory programs for activities not yet covered under a prohibition, conditional waiver or WDRs. The other two alternatives would include amending the Basin Plan, Table 3-1 and Section 4 – Implementation Plans, in some fashion. Alternative three would be based on the USEPA approving the technical aspects of the TMDL prior to the Regional Water Board concluding their deliberative process. This approach would be based on the Regional Water Board adopting an implementation plan based on the federally approved TMDLs. This approach would not include a revised DO objective. The final alternative, and staff's recommended approach, would be to:

- Revise the Basin Plan (Table 3-1) to include the proposed revision to the site-specific DO objectives for the Klamath River mainstem,
- Amend the Basin Plan Section 4 to include the proposed Action Plan.

The staff report for the "*Proposed Site-Specific Dissolved Oxygen Objective for the Klamath River in California*" is included as Appendix 1 of this Staff Report.

The alternatives are compared on the basis of their ability to protect water quality and beneficial uses (i.e., their likelihood of success), and whether the approach is feasible, flexible and equitable.

9.4.1 No Action - No Change in Basin Plan Language or in Program Implementation

Under the "No Action" alternative, no amendment to the Basin Plan would occur and staff would continue to implement existing Regional and State Water Board programs as in the past. Under this alternative, USEPA, as required under the court-ordered Consent Decree, would approve a TMDL by December 2010. Since USEPA has the authority to approve the technical, science-based portions of the TMDL (e. g., the source analysis and load allocations) but not the implementation program, this alternative would not increase the likelihood of water quality protection nor lead to the restoration of the impaired beneficial uses of water. Nor would it correct the inaccuracies in the existing DO objectives for the Klamath River mainstem. It would also be limited to implementation actions from responsible parties engaged in land use activities that are currently covered by a State or Regional Water Board permit.

Under this alternative, discharges of waste and impacts to water quality will likely continue as no comprehensive program would be put in place that describes the implementation actions necessary to achieve compliance with water quality standards. This is true for a number of reasons. First, there are a number of land use activities identified in the source assessment and implementation plan that have the potential to discharge non-point sources of waste that are not covered by a regulatory program. The No Action approach would allow some dischargers to continue to engage in activities that discharge waste without any control, while other landowners must comply with permits already in place (i.e. timber is already regulated under WDRs and waivers while grazing and irrigated agriculture are not currently). This is not equitable. Moreover, state law requires that unregulated discharge eventually be covered by some permitting mechanism. Allowing some discharges of waste to continue indefinitely is not legally feasible, and will not likely result in the attainment of water quality standards. Second, federal and state implementation grants and other funding sources are typically only available for projects located in watersheds that have an approved TMDL Action Plan or some other effective watershed-scale management plan in place.

Pros:

- Allows re-direction of Basin Planning staff to begin/continue work on the next issue on Triennial Review Priority List.
- Allows TMDL Development staff to begin/continue work on the development of the next TMDL on Impaired Waters List.

Cons:

- No comprehensive watershed program would be put in place.
- Inaccurate DO objectives for the Klamath River mainstem would remain in place.
- Restoration of the suite of beneficial uses of water impaired by controllable water quality factors would be unlikely.
- This alternative would likely result in legal challenge and substantial diversion of Regional Water Board resources.

9.4.2 No Basin Plan Amendment and Increased Staff Focus on Implementation (and Development) of State and Regional Regulatory Programs

As with the "No Action" alternative, this approach would not result in any revision to the Basin Plan and would necessitate USEPA's approval of the TMDLs. This approach is based on using existing State and Regional regulatory programs and permits as the implementation program for the protection and restoration of beneficial uses of water in the Klamath River watershed. This approach would necessitate the re-direction of staff from other programs or geographic areas, to allow for the increased focus necessary to fully engage in the permitting, inspections and enforcement actions (as appropriate) that would be required to fully staff this approach. This approach could include increased staff focus on the statewide Caltrans stormwater NPDES permit, general statewide construction stormwater permit, U.S Forest Service timber waiver, General WDRs – conditional waiver for timber activities on private lands, and 401 water quality certification program. New regulatory programs (i.e. prohibitions, waivers or WDRs) for activities not currently regulated would be developed as staff resources allowed.

Pros:

- As with Alternative 1, would save basin planning resources and allow planning staff to start addressing the next issue on Triennial Review Priority List.
- As with Alternative 1, would save TMDL resources and allow TMDL Development staff to begin/continue development of the next watershed on Impaired Waters List.
- Would allow staff to engage more actively in existing regulatory programs at the watershed scale.

- Would help watershed enforcement priorities due to staff familiarity with the watershed.
- Could result in significant revenue for the State's Cleanup and Abatement Account, through assessment of fines in conjunction with enforcement actions.

Cons:

- Would not address nonpoint sources of discharge from a number of sources identified in the TMDL pollutant source analysis and implementation plan (e.g. grazing, road building, alteration of riparian habitat or impacts to thermal refugia) in the near term.
- Would not correct inaccurate DO objectives for the Klamath River mainstem.
- Would require re-direction of staff from other priority work (e.g. landfills, cleanups, stormwater, etc.).

9.4.3 Adopt Basin Plan Amendments Based on the Federally Approved Klamath River TMDL and Proposed Regionwide DO Objective Revision

This alternative would be predicated on the USEPA approving the Klamath River TMDLs before the Regional Water Board had concluded its deliberative process and adopted its TMDL and DO objective revision. The time frame for final approval of the TMDLs is driven by a court-order Consent Decree. As such USEPA will be required to approve the TMDLs by the end of December 2010, regardless of whether the Regional Water Board has taken formal action or not. Since Regional Water Board and USEPA staff have been working jointly over the preceding six (6) years to develop this draft Klamath River TMDL report, it is likely that USEPA would approve some version of the TMDLs developed by the Regional Water Board. In the event USEPA approves the TMDL, the Regional Water Board could still elect to amend the Basin Plan by: 1) incorporating the federally approved TMDLs and an implementing program as described in Chapter 6 of the Staff Report, or 2) incorporating only the Klamath River implementation plan (as an Action Plan) into the Basin Plan.

Also, Regional Water Board staff intends to propose a regionwide revision to the DO objectives contained in Table 3-1 of the Basin Plan, based on the same rationale for their revision in the Klamath River mainstem. The Regional Water Board could elect to postpone adoption of a Basin Plan Amendment to revise the DO objectives for the Klamath River and wait to adopt a revision to all the DO objectives contained of Table 3-1 of the Basin Plan in concert with USEPA's approval of the technical TMDL.

Pros:

- Would save TMDL Unit staff time and resources, allowing them to focus on next highest priority TMDL.
- Would save Basin Planning staff time and resources by reducing the number of Basin Plan Amendments necessary for processing.
- Deflects threat of litigation and legal challenge on the technical aspects of the TMDLs to USEPA.

Cons:

- Defers establishment of the technical-basis of the TMDL (e.g., load allocations and numeric targets) to the USEPA.
- Postpones correction of the DO objectives for the Klamath River.
- NPDES permits, WDRs, and waivers issued by the Regional Water Board will need to be compliant with federal load allocations.
- Does not honor commitments made to USEPA and the Consent Decree plaintiffs to develop the Klamath River TMDL in a timely fashion.
- Will still require significant Basin Planning Unit staff resources to develop an Action Plan based on the federal TMDL.

9.4.4 Adopt Basin Plan Amendment Based on the Klamath River TMDL developed by Regional Water Board staff (Recommended Alternative)

Staff recommends amending Table 3-1 of the Basin Plan to revise the DO objectives for the Klamath River mainstem and amending Section 4- Implementation Plans of the Basin Plan to include an "*Action Plan for the Klamath River Watershed Temperature, Dissolved Oxygen, Nutrient and Microcystin Total Maximum Daily Loads*". Table 3-1 of the Basin Plan would be amended to eliminate the existing DO objectives for the Klamath River mainstem and replace them with a method for calculating alternate site-specific DO objectives based on percent saturation and natural receiving water temperatures. The Action Plan would include the source assessments for each of the listed impairments, load allocations for each of the identified sources and an implementation program describing the actions likely necessary to achieve the TMDL load allocations and numeric targets. The proposed Action Plan (see Basin Plan language link) can be found at: http://www.waterboards.ca.gov/northcoast/water_issues/programs/tmdls/klamath_river/. The technical support for the proposed Action Plan can be found, in part, in Chapters 1-6 of this Staff Report. The Staff Report is also available at the above referenced Regional Water Board webpage.

Pros:

- Maintains Regional Water Board authority in establishing load allocations, numeric targets, and water quality standards for the Klamath River watershed, in lieu of the establishment of federal load allocations.
- Ensures swift correction of inaccurate DO objectives for the Klamath River to aid in the compliance of the TMDLs with water quality objectives.
- Allows Regional Water Board staff to develop a proposed Action Plan for the Board's consideration based on the information developed by their staff.
- Takes full advantage of the opportunity provided to interested stakeholders, other agencies, and the regulated community, and the input received from these outreach efforts, in the development of the staff-sponsored TMDLs and proposed Action Plan.

Cons:

- Will require extensive Regional Water Board staff resources to develop, bring to the Regional Water Board for their consideration, and prepare the administrative record for the State Water Board's consideration.
- Focuses threat of litigation onto Regional Water Board.

9.5 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures

Analysis of the potential environmental impacts resulting from basin planning projects is required by State law and policy (see Section 9.1). This analysis of potential environmental impacts was conducted by considering the numerous alternative methods available to comply with the revised DO objectives and TMDLs. The Regional Water Board is prohibited by law from specifying the means by which responsible parties will comply with water quality requirements, including water quality objectives and TMDL implementation. As such, potential environmental impacts associated with compliance with the revised DO objectives and TMDLs depend, in large part, upon the specific compliance methods selected by the responsible parties, some of whom will be public agencies subject to their own CEQA obligations. (See Pub. Res. Code, § 21159.2). Environmental impacts associated with individual projects that occur on federal land (approximately 66% of the watershed) will be further evaluated under the federal National Environmental Policy Act (NEPA) process.

Because the TMDLs are calculated based on the proposed revisions to the DO objectives for the Klamath River mainstem, the methods chosen to comply with the load allocations identified in the TMDLs will be the same as those appropriate to comply with the revised DO objectives. To assess the potential environmental impacts associated with the various methods of complying with the TMDLs and DO objectives, this environmental analysis first identifies the reasonably foreseeable means (compliance measures) by which a responsible party could achieve compliance. Compliance measures are those actions that will likely be needed, beyond those required under other regulatory programs, to ensure compliance with the TMDLs and revised DO objectives. Second, the environmental effects associated with implementation of the compliance measures are identified. If a potential adverse environmental impact was identified, an analysis was then conducted to determine if feasible mitigation measures could be applied that would lessen the significance of the identified impact. Consistent with Public Resources Code section 21159, this SED does not engage in speculation or conjecture, but rather considers the reasonably foreseeable environmental impacts of the foreseeable methods of compliance. This analysis also considers reasonably foreseeable alternative means of compliance that could avoid or reduce the identified impacts (see Section 9.7).

Specific compliance measures (including best management practices or BMPs and other pollution controls) that likely will be used to comply with requirements of the TMDLs and revised DO objectives will depend on a number of conditions such as the impairment category being addressed (e.g., temperature, dissolved oxygen, nutrients or microcystin), source category (e.g., land use activity such as road and crossing construction, reservoir management, or irrigated agriculture) and environmental setting (such as forestland, grazing lands, or impounded river reaches). A combination of structural (e.g., engineered) and non-structural (e.g., operation and maintenance) compliance measures will likely be used by responsible parties. In response to numerous public comments objecting to additional interim land use requirements for nonpoint source discharges that overlapped with already existing or proposed future basin or region-wide programs, staff has eliminated the proposed interim waiver requirements and Sediment Prohibition to allow time to develop basin or region-wide programs that will address these discharges in a sensible and systematic way. Management measures likely to be included as part of those future programs are analyzed broadly in this document. Landowners may chose to implement measures voluntarily and are encouraged to follow the Sediment Guidance previously articulated in the Sediment Prohibition. Future programs implemented by waste discharge requirements, waivers or certifications will be accompanied by additional CEQA analyses as appropriate.

The measures that could be used to comply with the proposed implementation plan and DO objectives, and the potential environmental impacts associated with their implementation are discussed below. The categories of resources that the Regional Water Board has identified as potentially being impacted by the implementation of the BMPs includes:[11]

- Aesthetics;
- Air quality;
- Biological resources;
- Cultural resources;
- Geology and soils; and
- Hydrology and water quality.

In most cases, any potential impacts would be temporary and the result of installing, maintaining and/or removing structural BMPs. Most of the structural BMPs identified as reasonably foreseeable methods of compliance with the proposed implementation plan would cause very minimal, if any, adverse impacts. Only those BMPs that involve installation of structural features that result in land disturbance or alteration would potentially have the ability to cause adverse environmental impacts. These impacts include such things as air quality impacts from the use of heavy equipment for road construction projects and, impacts to biological resources from disturbance to habitat by heavy equipment, or the installation of fencing for riparian protection or grazing management, and impacts to cultural resources from heavy equipment use. However, it is staffs' judgment that all of these potential impacts can be mitigated to levels expected to be less than significant. Staff has added a programmatic analysis of dam decommissioning in response to public comments on the first circulated draft. Several impacts related to dam decommissioning activities are identified in addition to those

---

[11] See CEQA Checklist (Section 9.7.2)

already previously identified, including aesthetics impacts, air quality impacts from blasting and heavy equipment use, and biological and water quality impacts from release of turbid water from dam decommissioning activities. As the decision on whether to decommission the dams has not been made and, therefore, the exact nature of the decommissioning activities has not yet been developed, Regional Water Board staff has based the analysis of potential environmental effects of dam decommissioning on the readily available decommissioning studies conducted in the Klamath River watershed. Staff has determined that potentially significant impacts may occur to biological resources and water quality, and it is unclear without further study whether the potentially significant adverse environmental effects can be fully mitigated to levels of insignificance.

The following examples are not meant to be exhaustive of the suitable suite of compliance measures but rather provide a representative sample with the widest range bracket to accommodate as many compliance scenarios as possible.

This analysis is organized to correspond with the format presented in Chapter 6 – Implementation Plan of the draft Staff Report which lays out implementation actions based on source areas receiving allocations and targets. As described above, the load allocations are calculated based on the proposed revision to the DO objectives for the Klamath River. As such, reasonably foreseeable compliance measures to achieve compliance with the load allocations will necessarily achieve compliance with the proposed revised DO objectives, as well. This format presents the environmental analysis for likely implementation actions from sources associated with the following:

- Stateline (Staff Report Section 6.2)
- Klamath Hydroelectric Project and Iron Gate Hatchery (Staff Report Section 6.3)
- Klamath River tributaries (Staff Report Section 6.4)
  - Lost River
  - Shasta River
  - Scott River
  - Trinity River
- Watershed-wide (Staff Report Section 6.5)
  - Road construction and maintenance
  - Grazing
  - Irrigation agricultural
  - Timber harvest
  - Measure to protect thermal refugia

An analysis is included on the environmental effects from fire management activities on federals lands as the proposed implementation plan recommends actions relative to post-fire treatment in control discharge of nutrients and excess sediment.

9.5.1 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures Associated with Actions to Achieve Load Allocations and DO Objectives at Stateline

The Oregon-California stateline (Stateline) is the point at which the Klamath River crosses the Oregon-California border. Stateline is designated as a compliance point in the draft Klamath TMDLs. The pollutant loads in the Klamath River entering California are the result of loadings in Oregon, including the Lost River basin, which is partially in California. Oregon has listed the Klamath River in Oregon on its CWA section 303(d) list as failing to meet Oregon water quality criteria. The Oregon-issued TMDLs will be based on Oregon's water quality standards. Because these TMDLs (and their anticipated load and wasteload allocations) are being developed by Oregon as part of a comprehensive multistate analysis of pollutant loadings to the Klamath River, they are also being designed to meet California water quality standards, including the proposed revised DO objectives, at Stateline. Improvements in water quality in Oregon represent a critical part of the solution in meeting water quality objectives in California.

Oregon is responsible for developing an implementation plan to meet the Klamath and Lost River TMDLs in Oregon. The implementation plan will include the following elements:

- Identification of management measures to meet load allocations;
- A timeline for implementation with measureable milestones;
- A timeline for attainment of water quality standards, including the proposed revised DO objectives;
- A monitoring plan; and
- General discussion of costs and funding for implementation.

The Regional Water Board intends to work closely with Oregon in implementing the Klamath and Lost River TMDLs. One of the purposes of coordination with Oregon is to align each States' approach to controlling nonpoint sources of pollution.

9.5.1.1 <u>Analysis of Compliance Measures Associated with Actions to Achieve Load Allocations and Proposed Revised DO Objectives at Stateline</u>

- Implementation of the Klamath TMDLs will be coordinated with the Regional Water Board, Oregon Department of Environmental Quality and the USEPA. A Memorandum of Agreement (MOA) has been established that provides a framework for joint implementation of the Klamath River and Lost River TMDLs. The MOA includes commitments such as:
  - Work to develop and implement a joint adaptive management program.
  - Work with appropriate entities to develop and implement basin wide monitoring programs.
  - Work jointly with responsible parties to develop effective implementation plans to achieve water quality standards, including the proposed revised DO objectives.

- o Explore centralized treatment options such as treatment wetlands, algae harvesting, and package wastewater treatment systems to reduce nutrient loads to the Klamath River.
- o Work to develop and implement a basin wide water quality tracking and accounting program that would establish a framework to track water quality improvements, facilitate planning and coordinated TMDL implementation, and enable appropriate water quality offsets or trades.

9.5.1.2 Potential Environmental Impacts Associated with Actions to Achieve Load Allocations and Proposed Revised DO Objectives at Stateline

- None identified. It is staffs' judgment that the development of a coordinated program to develop comprehensive basin wide implementations actions will not result in potential environmental impacts. The MOA contemplates the exploration, development and implementation of centralized treatment options which may yield projects that could result in environmental impacts; however, this program is still in the early stage of development and any environmental analyses would be highly speculative and not useful at this time. If a given project is identified in the future that may have associated environmental impacts, the Regional Water Board will conduct a CEQA analysis in accordance with California Code of Regulations, title 14, section 15277 [projects located outside California]. To the extent that some future projects are similar or overlap with those discussed in the context of the Klamath Hydroelectric Project, those impacts are addressed below.

9.5.1.3 Possible Mitigation Measures to Avoid Impacts Associated with Actions to Achieve Load Allocations and Proposed Revised DO Objectives at Stateline

- Not applicable.

9.5.2 Analysis of Compliance Measures, Associated Potential Environmental Impacts, and Possible Mitigation Measures for Klamath Hydroelectric Project

The Klamath Hydroelectric Project (KHP) is a federally licensed project owned and operated by PacifiCorp and consists of eight facilities in California and Oregon. The implementation plan addresses the impacts of the project facilities in California, which include the Copco 1, Copco 2, and Iron Gate dams/reservoirs. As described in the Klamath TMDL Staff Report, the presence of dams impacts water quality by increasing stream temperatures and increasing the bioavailability of sediment-sorbed nutrients. They also serve to alter the natural pattern and range of river flows.

The Klamath River TMDLs assign load allocations and targets at levels necessary to achieve water quality standards within the KHP area, including the proposed revised DO objectives. Regulation and enforcement of the TMDL allocations is traditionally through the State Water Board water quality certification process that accompanies renewal of a license issued by the Federal Energy Regulatory Commission (FERC). As described in more detail below, certain parties have been engaged in settlement negotiations that contemplate the voluntary removal of the KHP. Because the regulatory process and outcome of the settlement negotiations is largely outside of the Regional Water Board's control, the Klamath River TMDL implementation plan is developed to accommodate various alternatives.

To comply with the TMDL, PacifiCorp must implement management measures that result in attainment of the load allocations and targets from the KHP facilities in California, including the proposed revised DO objectives, regardless of whether the dams remain or are ultimately decommissioned. Regulation and enforcement of these TMDL allocations is traditionally through the SWRCB Clean Water Act section 401 water quality certification process, since the Regional Water Board is preempted from issuing a permit to the KHP. The KHP operates under a FERC license that expired on March 1, 2006. The KHP will continue to operate under an annual license until the license is renewed or a decision to decommission the dams is made. Renewal of the license requires compliance with the CEQA and the issuance of a Clean Water Act section 401 water quality certification by the SWRCB. In issuing water quality certification, the state may impose conditions on the KHP in order to certify that the project protects beneficial uses and meets water quality objectives as specified in the Basin Plan. The Klamath TMDLs and proposed revised DO objectives, upon adoption, will become part of the Basin Plan and will thus become part of the comprehensive plan that FERC must consider as part of its licensing decision. In 2004, FERC prepared a Final Environmental Impact Statement (FEIS) that describes the positive and negative environmental effects of the proposed action to relicense the continued operation of the KHP, and alternative actions, including decommissioning all or part of the project. As authorized by section 401, the SWRCB will apply appropriate state water quality requirements through the FERC licensing proceeding as part of its decision to issue or deny water quality certification. SWRCB staff is preparing an Environmental Impact Report (EIR) that relies in part on the FEIS. The EIR will evaluate four alternatives for operating the KHP, two of which include removal of two and four of the KHP dams, respectively.

At the same time, certain parties have been engaged in settlement negotiations that contemplate the voluntary removal of the KHP. These negotiations and subsequent agreements stemmed from a larger negotiation of the Klamath Basin Restoration Agreement (KBRA) that addresses water rights issues in Oregon. Completion of the KBRA was contingent on completion of the Klamath Hydroelectric Settlement Agreement (KHSA). On November 13, 2008, an Agreement in Principle (AIP) to remove four of the Klamath River dams (JC Boyle, Copco 1 and 2, and Iron Gate) was announced after negotiations between the representatives of the federal government, the state of California, [12] the state of Oregon, and PacifiCorp. On September 30, 2009 a draft Klamath Hydroelectric Settlement Agreement (KHSA) was released. (Documents are available at http://www.edsheets.com/Klamathdocs.html.)

---

[12] State of California is defined as the State of California Resources Agency and its constituent departments and excludes all other state agencies, departments, boards and commissions. The Regional Water Board is not a constituent department under the Resources Agency.

Under section 3.3 of the draft KHSA, the Secretary of the Department of the Interior will conduct very detailed studies and assessments to determine, *inter alia*, whether dam removal (i) will advance restoration of the salmonid fisheries of the Klamath Basin, and (ii) is in the public interest. The Secretary is to make a determination by March, 2012, subject to various contingencies, on whether to move forward with the project. As part of this process, a detailed plan for facility removal will be developed that describes the " physical methods to be undertaken to effect Facilities Removal, including but not limited to a timetable for Decommissioning and Facilities Removal, which is removal of all or part of each Facility as necessary to effect a free-flow condition and volitional fish passage." (KHSA, § 3.3.2.)

In the absence of the FERC/401 process, the TMDL load allocations (and existing water quality objectives) as they apply to the KHP cannot be directly implemented and enforced. Settlement Parties address TMDL implementation in Oregon and California in section 6.3 of the draft KHSA. Section 6.3.2 of the KHSA describes generally the content of PacifiCorp's implementation plan to include a timeline for implementing management strategies, water quality-related measures in Appendix D and Facilities Removal as the final measure. The proposed plan may further include other planned activities and management strategies developed individually or cooperatively with other sources or designated management agencies. Appendix D contains water-quality measures that could potentially serve to meet TMDL needs in the interim while additional studies are conducted. The interim measures identified in Appendix D of the draft KHSA are taken by Regional Board staff as the compliance measures on which PacifiCorp will base the implementation program designed to meet their TMDL waste load allocations until a decision is made on which regulatory path PacifiCorp will proceed, and if dams are decommissioned, until the dams are finally removed. If the decision is ultimately made not to remove the dams, the interim measures are not presumed to provide final compliance with the TMDL load allocations, and the FERC/401 process resumes.

The Regional Water Board can only determine whether the selected outcome will meet its TMDL needs. The implementation plan provides for Regional Water Board review of more site specific environmental assessments of dam removal. Both dam alteration/modifications and dam removal are recognized as possible strategies by which final compliance with the TMDL load allocations may be accomplished. Whether the dams are ultimately removed is a decision before several federal and state agencies in consideration of other factors in addition to water quality, including water allocations, species protection and power needs. These decisions will necessarily be informed by detailed environmental review.

In the previous draft Klamath TMDL, staff had not attempted to analyze dam removal impacts or permanent infrastructure modifications because the action was indeterminate and would certainly require CEQA compliance before proceeding. In its comments on the draft Klamath TMDL, PacifiCorp submitted that dam removal was a foreseeable means of compliance with the TMDL and requested that it be included in the environmental documentation. PacifiCorp listed a series of studies that have been conducted to date on dam removal that could be appropriately relied upon for a programmatic assessment. Accordingly, the following programmatic environmental analysis will evaluate the potential environmental impacts of dams removal and proposed modifications if dams are not removed in addition to the previous analyses of interim measures (note that reference to Exhibit 1C of the AIP is replaced by Appendix D of the draft KHSA, which are the same in substance). The environmental effects of dam removal are not intended to be site-specific. A detailed environmental analysis of impacts and subsequent Regional Water Board approval is required before this activity may occur.

What follows is an environmental analysis of the potential adverse environmental impacts arising from implementation of two distinct implementation strategies related to attaining TMDL load allocations and meeting water quality standards at the KHP.

The first part of the analysis is an evaluation of the environmental effects associated with interim compliance measures that PacifiCorp has identified as actions that might reasonably be taken to move the existing KHP dams toward compliance with the TMDL load allocations and applicable water quality standards. Section 9.5.2.1 through 9.5.2.10 of this Staff Report presents the analysis of the potential environmental impacts associated with implementation of ten (10) measures identified in Exhibit 1C of the AIP that Regional Water Board staff identified as being viable now or in the near future or measures that will require additional study before implementation is possible. These measures, identified by PacifiCorp as being reasonable compliance measures, are discussed below. Staff has determined that these measures represent reasonable interim measures that could be used to improve water quality and beneficial uses until a final decision is made on the KHP. Exhibit 1C of the AIP is included in this Staff Report by reference.

The second part of this assessment analyzes the environmental effects of the decommissioning or removal or one or more of the three KHP dams located in California. Section 9.5.2.11 contains an environmental analysis of the effects of a dam(s) removal scenario. Several dam decommissioning studies have been conducted over the past few years, many of them focused on removal of dams on the Klamath River system. These studies evaluated various scenarios for dam removal, physical methods of dam decommissioning, identification of reasonable compliance measures to mitigate for effects associated with dam removal and an estimate of costs associated with different aspects of dam removal and decommissioning. The list of studies Regional Water Board staff relied on in preparation of the programmatic environmental analysis for a dam removal scenario is presented below in section 9.5.2.11, and incorporated herein by reference. These studies are available for review online (see page 9-34 of this Staff Report) and at the Regional Water Board office.

This analysis does not include consideration of any of the measures to be taken in Oregon.

9.5.2.1 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Constructed Wetlands Treatment

The feasibility of constructed treatment wetlands has been considered as a potential action for use PacifiCorp in the Klamath Hydroelectric Project. Three different types of constructed treatment wetlands were considered. They include:

- Upstream “preventative” wetlands;
- In-reservoir treatment through vegetative swales; and
- In-reservoir floating wetlands.

Analysis of Compliance Measures Associated with Constructed Wetlands Treatment

- The upstream “preventative” treatment wetlands would be constructed on sites upstream of the Copco Reservoir and downstream of Upper Klamath Lake. Surface flow would be routed through the treatment wetlands in multiple cells and with multiple parallel flow paths using existing and new river diversions for irrigation and existing irrigation canals. Pumping from the river would be a last resort. If necessary, alum or aluminum polymers could be added to enhance phosphorus and particulate removal. Mulch gabions could also be distributed throughout the wetlands to deliver a steady flow of carbon to enhance microbial denitrification.
- The in-reservoir approach consists of the potential removal of cyanobacteria biomatter from reservoir coves into adjacent subsurface flow or infiltration-based vegetated swales. Algae would be removed by surface skimming and then pumped into adjacent gravel-filled gabions planted with native grasses (bioswale).
- The floating treatment wetlands would be built directly in the reservoirs. The complex aquatic root systems serve to filter out particulate matter, take up nutrients, and provide habitat and shelter for zooplankton and fish that consume algae. Floating treatment wetlands also can provide shade that helps to reduce algae development.

Potential Environmental Impacts Associated with Constructed Wetlands Treatment

- Temporary construction-related discharges of sediment.
- Temporary air quality impacts from heavy equipment use.
- Impacts to archaeological and cultural resources.
- Temporary impacts to plant and animal species, including disturbance to habitat.
- Temporary impacts to water quality from construction-related increases in turbidity.
- Impacts to water quality from the release of soil-sequestered nutrients once land is flooded to create wetlands.

Possible Mitigation Measures to Avoid Impacts Associated with Constructed Wetlands Treatment

- Restrict work to days in which soil detachment by wind or water is not expected.

- Time the completion of work to coincide with planting to reduce the length of time in which bare soil is exposed.
- Cover exposed soil that will not receive immediate planting with straw or other suitable erosion control material.
- Protect drainage channels from sediment contributions with vegetated buffers, wattles, or similar erosion control devices.
- Time heavy equipment use to occur during period of good air quality.
- Conduct a project-level CEQA analysis to identify archaeological and cultural resources requiring protection.
- Conduct a project-level CEQA analysis to identify biological resources, including threatened and endangered species and their habitat, requiring protection.
- A turbidity curtain can be used to contain turbidity effects within an acceptable minimum location during construction activities.
- Amend constructed wetland soil with alum, calcium carbonate (calcite), or calcium-magnesium carbonate (dolomite) to bind labile phosphorus and prevent it from entering the water column.

9.5.2.2 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Mechanical Removal of Algae Biomatter

PacifiCorp is evaluating the efficacy of mechanical removal of algae biomatter from Copco and Iron Gate reservoirs as a technique for improving water quality conditions in localized places such as near picnic sites or boat launches. According to PacifiCorp (2009), they have not yet identified specific harvesting techniques. Nor have they evaluated the alternatives for disposal, except the use of bioswales.

The mechanical removal of algae biomatter is described in wastewater treatment literature, as well as literature associated with the production of algae as a food source. Harvesting techniques may include three steps: 1) methods for concentrating algae into a harvestable mat, 2) removal of algae mats from the water column, and 3) disposing of waste.

Analysis of Compliance Measures Associated with Mechanical Removal of Algae Biomatter

- Concentrate algae into harvestable mats using:
  - Air bubbles
  - pH adjustment
  - Coagulants (e.g., alum or ferric chloride)
- Removal of algae mats can be accomplished by using:
  - Suction equipment
  - Mechanical harvesting equipment.
- Disposal of waste is accomplished by:
  - Dewatering
  - Landfill disposal
  - Use as a soil amendment.

Potential Environmental Impacts Associated with Mechanical Removal of Algae Biomatter

- Temporary effects of elevated turbidity resulting from compressed air, coagulants, suctioning, and/or mechanical harvest.
- Effects of pH adjustment, alum or ferric chloride on aquatic species.
- Disturbance of habitat important to threatened or endangered species, or other sensitive species or species of special concern.
- Temporary effects of elevated odors associated with algae disposal in bioswales, dewatering sites, and/or land application as fertilizer.
- Effects on native species associated with the potential increase in pest species drawn to decomposing algae.
- Increase in microcystin toxic concentration in the column from disturbance of algal cells.
- Increase in waste loads to the local solid waste handling facility.

Possible Mitigation Measures to Avoid Impacts Associated with Mechanical Removal of Algae Biomatter

- A turbidity curtain can be used to contain turbidity effects within an acceptable minimum location during construction activities.
- Only use pH adjustment, alum or ferric chloride in locations and during times when harmful effects on aquatic species can be avoided.
- Only harvest algae from locations where threatened and endangered species habitat will not be disturbed. Alternatively, apply to the appropriate wildlife agency for an incidental take permit.
- Choose locations for algae dewatering that are suitably downwind of any population center.
- Actively compost algae to ensure a reduction in odors and development of a product suitable for land application and/or to prevent overwhelming local solid waste facilities.
- Stop work if bioswales, dewatering sites, or compost piles are attracting pest species that harm native species.
- Stop work if harvesting of algae results in an increase in the microcystin toxin concentration.

9.5.2.3 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Conventional Wastewater Treatment

Conventional wastewater treatment involves primary treatment (e.g., screening, grit removal, and primary sedimentation), secondary treatment (e.g., attached growth process or suspended growth process of biological treatment), advanced treatment (e.g., nitrification/denitrification, coagulation-sedimentation, carbon adsorption), and disinfection (e.g., chlorination/declorination, ozone), as appropriate.

Analysis of Compliance Measures Associated with Conventional Wastewater Treatment

- The installation of a wastewater treatment system is a major construction project, involving all the environmental risks common to large-scale construction. If chosen as a preferred alternative and once the design of the project is complete, a project-level CEQA analysis will be required.

Potential Environmental Impacts Associated with Conventional Wastewater Treatment

- Construction and excavation activities have the potential to result in soil erosion, which could adversely impact nearby waterways as a result of siltation and water quality degradation.
- Construction and excavation activities have the potential to result in disturbance to cultural and archaeological resources.
- Construction could result in impacts to threatened, endangered species, or candidate species.
- Construction could result in impacts to nesting birds.
- Construction could result in impacts to wetlands.
- During the construction phase of the project, construction noise would dominate the noise environment in the immediate area.
- Construction of a wastewater treatment plant would not introduce any uses that would generate long-term changes in traffic. Construction of the treatment plant would temporarily increase traffic along haul routes and the main access roads to the WWTP property.
- Construction of a wastewater treatment plant would not change the design of existing roadways and does not include any operational features that would impact traffic or increase hazards. However, large truck traffic associated with the import of material for the construction of the plants could accelerate the deterioration of the roadway surface due to the high number of trips.
- Construction activities will likely generate fugitive dust and diesel exhaust emissions from construction/excavation activities and vehicle/equipment operation.

Possible Mitigation Measures to Avoid Impacts Associated with Conventional Wastewater Treatment

- Off-site impacts due to erosion must be prevented by implementation of a Stormwater Pollution Prevention Plan (SWPPP) as required under the Clean Water Act. Measures to consider in a SWPPP are those related to: grading, existing vegetation, land disturbance during peak runoff periods, utility installations, control of runoff velocity and quality, truck traffic, storage of construction materials, permits, spill prevention, fuel and vehicle maintenance areas, sanitary facilities for construction works.
- In the event of any inadvertent discovery of archaeological resources, all such finds shall be subject to PRC 21083.2 and CEQA *Guidelines* 15064.5, including cessation of work until professional archaeologist or paleontologist can evaluate the significance of the find, professional curation of significant finds, and notification of county coroner and Native American Heritage Commission, if appropriate, if find is a human remain.
- A qualified biologist should be present during initial grubbing and clearing activities to ensure that species identified during the project-level CEQA analysis are not harmed by construction activities. If threatened, endangered, or candidate species are observed, one potential mitigation would be for the

biologist to relocate it to suitable habitat outside of the construction zone.

- If feasible, grubbing and grading activities should be conducted outside of the nesting season. If initial tree-removal, grubbing or clearing activities will occur during the nesting season, a pre-construction survey for nesting bird species should be conducted by a qualified biologist within proposed vegetation removal areas, including a substantial buffer from construction activities.
- Construction activities resulting in the discharge of dredged or fill material into Waters of the US will require permit approval from the US Army Corps of Engineers and water quality certification from the Regional Water Board pursuant to Section 401 of the Clean Water Act. Any compensatory mitigation shall be provided as required by regulatory permits to offset impacts to Waters of the US. Compliance with full mitigation, as required by regulatory permits, would ensure that measures are implemented to avoid, compensate, or offset impacts to Waters of the US.
- Any project in California which will cause alteration to the bed, bank, or channel of a stream will require a Streambed Alteration Agreement pursuant to Section 1600 of the California Fish and Game Code.
- Construction contractors should be required to implement mitigation measures to reduce daytime noise levels resulting from construction, such as:
  - Fixed construction equipment (such as compressors and generators) and construction staging areas located as far as feasible from the nearest dwellings.
  - Equipment and trucks used for project construction should utilize the best available noise control techniques (e.g., improved mufflers, equipment redesign, use of intake silencers, ducts, engine enclosures and acoustically-attenuating shields or shrouds, wherever feasible).
  - Construction equipment noise shall be minimized during project construction by muffling and shielding intakes and exhaust on construction equipment (per the manufacturer's specifications) and by shrouding or shielding impact tools.
  - Notification should be given to public transportation providers, school districts, emergency service provides, and affected private residents at least one month prior to commencement of construction to minimize traffic congestion issues.
  - Construction related truck trips shall be limited to the hours between 9:00 a.m. to 3:00 p.m., Monday through Friday to the extent possible. No construction traffic should be permitted between the hours of 10 pm. To 7 a.m.
  - Construction traffic shall comply with the California Vehicle Code (CVC) sections related to vehicle weight and width.
  - The construction contractor should implement best management practices designed to reduce the effects of dust and diesel exhaust, including:
    - Water all active construction areas at least twice daily.
    - Cover all trucks hauling soil and other loose materials or require all trucks to maintain at least 2 feet of freeboard.

- Apply water as needed on a daily basis, or apply (nontoxic) soil stabilizers on all unpaved access roads, parking areas, and staging areas at construction sites.
- Sweep daily (with water sweepers) all paved access roads, parking areas, and staging areas at construction sites.
- Sweep streets daily (with water sweepers) if visible soil material is carried onto adjacent public streets.
- Maintain equipment according to the manufacturer's specifications.
- Restrict idling of construction equipment and vehicles to 10 minutes.
- Gasoline powered equipment and vehicles shall have catalytic converters installed prior to their use on the project site.

9.5.2.4 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Wetlands Restoration

One of the implementation measures considered for achieving compliance with the proposed revised DO objectives, TMDL load allocations and numeric targets is the restoration of wetlands. A large scale restoration project on the Williamson River delta undertaken by Nature Conservancy of Oregon was used as an example in identifying compliance measures.

A project-level CEQA analysis will likely be necessary to ensure that any wetland restoration project is conducted in such a manner as to provide adequate environmental protection. The list of potentially significant environmental impacts below is not intended in any way to restrict the scope of any future project-level CEQA analysis. It is intended only to provide a framework of issues to consider.

Analysis of Compliance Measures for Wetlands Restoration

- Re-establish native wetland and upland vegetation.
- Recreate historic channels.
- Restore historic oxbow channels to allow continuous flow.
- Breach lakeshore levees to create diverse habitat features.
- Lower lake levees to create riparian fringe habitat.

Potential Environmental Impacts Associated with Wetlands Restoration

- Use of heavy equipment to divert flows and dig new channels.
- Use of explosives and/or mechanical equipment to open passages in the levees sufficiently large for water to flow and reconfigure the landscape.
- Large scale planting and temporary irrigation facilities for re-establishing native wetland and upland vegetation.
- Construction and excavation activities have the potential to result in soil erosion, which could adversely impact nearby waterways as a result of siltation and water quality degradation.
- Construction and excavation activities have the potential to result in disturbance to cultural and archaeological resources.
- Construction could result in impacts to threatened, endangered species, or candidate species.

- Construction could result in impacts to nesting birds.
- Construction could result in impacts to existing wetland habitat.
- During the construction phase of the project, construction noise would dominate the noise environment in the immediate area, particularly with the use of explosives.
- Construction of a wetland restoration project would not introduce any uses that would generate long-term changes in traffic. Construction of a wetland restoration project would temporarily increase traffic along haul routes and the main access roads to the restoration site.
- Construction activities will likely generate fugitive dust and diesel exhaust emissions from construction/excavation activities and vehicle/equipment operation.
- Hazards associated with the transport and use of explosives.

<u>Possible Mitigation Measures for Wetlands Restoration</u>

- Off-site impacts due to erosion must be prevented by implementation of a Stormwater Pollution Prevention Plan (SWPPP) as required under the Clean Water Act. Measures to consider in a SWPPP are those related to: grading, existing vegetation, land disturbance during peak runoff periods, utility installations, control of runoff velocity and quality, truck traffic, storage of construction materials, permits, spill prevention, fuel and vehicle maintenance areas, sanitary facilities for construction works.
- In the event of any inadvertent discovery of archaeological resources, all such finds shall be subject to PRC 21083.2 and CEQA *Guidelines* 15064.5, including cessation of work until professional archaeologist or paleontologist can evaluate the significance of the find, professional curation of significant finds, and notification of county coroner and Native American Heritage Commission, if appropriate, if find is a human remain.
- A qualified biologist should be present during initial grubbing and clearing activities to ensure that species identified during the project-level CEQA analysis are not harmed by construction activities. If threatened, endangered, or candidate species are observed, one potential mitigation would be for the biologist to relocate it to suitable habitat outside of the construction zone.
- If feasible, grubbing and grading activities should be conducted outside of the nesting season. If initial tree-removal, grubbing or clearing activities will occur during the nesting season, a pre-construction survey for nesting bird species should be conducted by a qualified biologist within proposed vegetation removal areas, including a substantial buffer from construction activities.
- Construction activities resulting in the discharge of dredged or fill material into Waters of the US will require permit approval from the US Army Corps of Engineers and water quality certification from the Regional Water Board pursuant to Section 401 of the Clean Water Act. Any compensatory mitigation shall be provided as required by regulatory permits to offset impacts to Waters of the US. Compliance with full mitigation, as required by regulatory permits, would ensure that measures are implemented to avoid, compensate, or offset impacts to Waters of the US.

- Any project in California which will cause alteration to the bed, bank, or channel of a stream will require a Streambed Alteration Agreement pursuant to Section 1600 of the California Fish and Game Code.
- Construction contractors should be required to implement mitigation measures to reduce daytime noise levels resulting from construction, such as:
  - Fixed construction equipment (such as compressors and generators) and construction staging areas located as far as feasible from the nearest dwellings.
  - Equipment and trucks used for project construction should utilize the best available noise control techniques (e.g., improved mufflers, equipment redesign, use of intake silencers, ducts, engine enclosures and acoustically-attenuating shields or shrouds, wherever feasible).
  - Construction equipment noise shall be minimized during project construction by muffling and shielding intakes and exhaust on construction equipment (per the manufacturer's specifications) and by shrouding or shielding impact tools.
  - Notification should be given to public transportation providers, school districts, emergency service provides, and affected private residents at least one month prior to commencement of construction to minimize traffic congestion issues.
  - Construction related truck trips shall be limited to the hours between 9:00 a.m. to 3:00 p.m., Monday through Friday to the extent possible. No construction traffic should be permitted between the hours of 10 pm. To 7 a.m.
  - Construction traffic shall comply with the California Vehicle Code (CVC) sections related to vehicle weight and width.
- The construction contractor should implement best management practices designed to reduce the effects of dust and diesel exhaust
- Restrict work to days in which soil detachment by wind or water is not expected.
- Time the completion of work to coincide with planting to reduce the length of time in which bare soil is exposed.
- Cover exposed soil that will not receive immediate planting with straw or other suitable erosion control material.
- Protect drainage channels from sediment contributions with vegetated buffers, wattles or similar erosion control devices.
- Time heavy equipment use to occur during period of good air quality.
- A turbidity curtain can be used to contain turbidity effects within an acceptable minimum location during construction activities.
- Adherence to the industry safety standards for the transport and use of explosives.

9.5.2.5 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Hypolimnetic Oxygenation

Hypolimnetic oxygenation is a technique that adds oxygen to the deeper part of the reservoirs (hypolimnion) without disrupting stratification of the reservoir. This technique increases the amount of oxygenated water available to organisms that use the deeper and cooler waters of the reservoir, and retards the buildup of un-decomposed organic matter and compounds (e.g., ammonium) in the hypolimnion.

Analysis of Compliance Measures for Hypolimnetic Oxygenation

- Application of fine bubbles
  - Using unconfined fine bubble diffuser
  - Using unconfined and diffuse bubble curtain
- Use of a bubble-free system in which a pressurized container placed at the bottom of the reservoir is used to mix water with gas and the mixture is dispersed over the sediments. The system is operated as soon as monitoring indicates that dissolved oxygen levels in the hypolimnion are starting to drop (early spring) and through the summer/fall.
- Oxygen supply facilities would include a liquid oxygen storage tank, vaporizers, and trucked-in oxygen to be used at locations midway along the reservoirs.
- Small onsite oxygen generators might also be used to supply oxygen near the dams

Potential Environmental Impacts Associated with Hypolimnetic Oxygenation

- Construction of underwater facilities
- Temporary increases in turbidity.
- Disturbance to endangered, threatened or sensitive species.
- Temporary increases in traffic
- Temporary increases in noise
- Increased need for sanitary services
- Liquid oxygen storage tanks present the risk of fire and explosion.

Possible Mitigation Measures for Hypolimnetic Oxygenation

- Iron Gate Reservoir, install 3 long diffuser lines:
  - One upstream end of the reservoir to provide initial oxygenation of incoming organics
  - One upstream of the dam
  - One in the metalimnion along the side of the reservoir
- For Copco Reservoir, install five (5) long diffuser lines:
  - Two (2) at the upstream end of the reservoir to provide initial oxygenation of incoming organics
  - Two (2) upstream and downstream of the bathymetric outcropping
  - One in the metalimnion along the side of the reservoir.
- Install turbidity curtains around construction area to contain any turbidity resulting from construction activities.
- Conduct a project-level CEQA analysis to identify biological resources, including threatened and endangered species and their habitat, requiring protection.
- Avoid construction during periods in which threatened or endangered species are present and/or apply to the appropriate resource agencies for an incidental take permit, if threatened or endangered species may be present.

- Implement best management practices for the reduction and control of vehicle noise, traffic, dust and need for sanitary services, as described above.
- Observe standard safety procedures for the locating, installation, and use of liquid oxygen, including:
  - Keep combustibles away and eliminate ignition sources.
  - Keep the area and exterior surfaces clean to prevent ignition.
  - Maintain adequate ventilation.
  - Ensure personnel use proper safety gear when there is any risk of splashing or spilling liquid oxygen.
  - Ensure replacement parts are suitable for oxygen service.

9.5.2.6 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Epilimnion Circulation

The epilimnion is the upper layer of a thermally stratified lake or reservoir where photosynthetic activity takes place. Epilimnion circulation is intended to induce vertical circulation thereby reducing cyanobacteria by reducing their light exposure and disrupting the generally quiescent conditions that may contribute to bloom formation.

Analysis of Compliance Measures Associated with Epilimnion Circulation

- Use solar-powered water circulators.

Potential Environmental Impacts Associated with Epilimnion Circulation

- Disruption of cyanobacteria by agitation may result in the lysing of cell membranes and release of microcystin toxin to the water column.

Possible Mitigation Measures with Epilimnion Circulation

- Conduct a demonstration installation of a higher-energy circulator in a selected cove and compare water quality outcomes to an untreated cove.
- Monitor microcystin levels, upon full-scale installation.
- Stop mechanical circulation if microcystin levels increase as a result of the activity.

9.5.2.7 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Riparian Restoration

Responsible parties in the Klamath River basin, including PacifiCorp, may use riparian restoration to improve in-stream temperature conditions by restoring the site-potential for riparian shade. Restoration activities will generally include the reduction of activities in a riparian buffer zone. Tree planting may include the importation of saplings, equipment and personnel; the hand digging of holes; and the installation of irrigation facilities. Measures to stabilize a stream bank and/or remove/repair riparian roads may include the use of heavy equipment, importation of rip rap or other materials, and/or temporary rerouting of stream flow.

Analysis of Compliance Measures Associated with Riparian Restoration

- Reduction of tree harvesting, grazing, and irrigated agricultural activities.
- Stream bank stabilization to support shade species.

- Include tree planting, and where necessary.
- Removal or repair of roads in riparian areas.

Potential Environmental Impacts Associated with Riparian Restoration

- Temporary construction-related discharges of sediment
- Temporary air quality impacts from heavy equipment use
- Impacts to archaeological and cultural resources
- Temporary impacts to plant and animal species, including disturbance to habitat.
- Temporary impacts to water quality from construction-related increases in turbidity.

Possible Mitigation Measures with Riparian Restoration

- Restrict work to days in which soil detachment by wind or water is not expected.
- Time the completion of work to coincide with planting to reduce the length of time in which bare soil is exposed.
- Cover exposed soil that will not receive immediate planting with straw or other suitable erosion control material.
- Protect drainage channels from sediment contributions with vegetated buffers, wattles or similar erosion control devices.
- Time heavy equipment use to occur during period of good air quality.
- Conduct a project-level CEQA analysis to identify archaeological and cultural resources requiring protection.
- Conduct a project-level CEQA analysis to identify biological resources, including threatened and endangered species and their habitat, requiring protection.
- A turbidity curtain can be used to contain turbidity effects within an acceptable minimum location during construction activities.

9.5.2.8 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Selective Withdrawal from a Variable Outlet Structure

PacifiCorp will evaluate the installation of a variable outlet structure from which to selectively withdraw water for release. A variable outlet structure is constructed on the inside of the dam face. To retrofit an existing dam with a variable outlet structure requires that the reservoir water be held back from the inside of the dam by such means as a coffer dam while the infrastructure is installed. Once infrastructure construction is completed, the coffer dam is removed, and the release of water downstream is resumed.

A variable outlet structure allows the operator to draw water from various depths in the reservoir. This flexibility allows the operator to respond to water quality conditions of the reservoir and the water quality needs of the river downstream so as to release water that most closely meets the overall environmental objectives.

A rigorous monitoring program is required to provide the operator with sufficient information regarding the temperature, DO concentration, *Microcystis* concentrations, microcystin concentrations, and other water quality characteristics.

Analysis of Compliance Measures Associated for Selective Withdrawal from a Variable Outlet Structure

- Install coffer dam.
- Install necessary infrastructure for outlet.

Potential Environmental Impacts for Selective Withdrawal from a Variable Outlet Structure

- Impacts as typically associated with construction activities.

Possible Mitigation Measures Protection for Selective Withdrawal from a Variable Outlet Structure

- Mitigations for construction activities such as described above.

9.5.2.9 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Curtain Installation at Iron Gate Dam

In 2008, PacifiCorp installed a floating barrier curtain along the log boom in the Iron Gate reservoir near the dam intake. The primary objective of the barrier curtain was to enhance water quality in the vicinity of the dam intake by excluding or reducing the potential entrainment of biomass from blooms of cyanobacteria such as *Microcystis* and potential associated algal toxins (i.e., microcystin).

Use of a turbidity curtain is often for the purpose of controlling the release of sediment to the water column as a result of instream work. The turbidity curtain acts to slow and contain turbidity until it can settle out of the water column. It is unclear whether use of the turbidity curtain for controlling algae is intended to work in the same way. The Reservoir Management Plans for 2008 and 2009 do not describe the details of use. This analysis is based on the assumption that algal cells, when contained by a turbidity curtain, will decompose and settle out of the water column, and remain in the reservoir as settled organic matter, rather than be released downstream. A project level CEQA analysis must clarify the details of this implementation measure.

PacifiCorp proposes to monitor its effectiveness during 2009, including:

1. Water quality monitoring within and without the curtained area;
2. Current monitoring in the vicinity of the curtain to characterize vertical velocity profiles; and,
3. Modeling to assess curtain effects on water quality under varying conditions.

Analysis of Compliance Measures Associated for Curtain Installation at Iron Gate Dam

- Install turbidity curtain made of synthetic fabric material, suspended down 10 feet and across the width of the reservoir, a distance of 1100 feet, approximately 1800 feet upstream of the dam

Potential Environmental Impacts for Curtain Installation at Iron Gate Dam

- Release of microcystin toxin to the water column as algal cells lyse.
- Interference of fish movement through a compliance lens, if lens occupies a space within 10 feet of the surface.

Possible Mitigation Measures Protection for Curtain Installation at Iron Gate Dam

- Implement monitoring program sufficiently rigorous to detect increases in microcystin toxin to the water column. Post public warnings if microcystin concentrations exceed target levels as described in the Klamath TMDL.
- Remove turbidity curtain and evaluate alternative microcystin controls if turbidity curtain does not meet the objective of excluding or reducing the potential entrainment of algal toxins.
- Implement a monitoring program sufficiently rigorous to detect the dimensions of the compliance lens (i.e., water quality conditions meeting both DO and temperature objectives) and if within 10 feet of the surface, whether fish movement is impaired.
- Remove turbidity curtain and evaluate alternative Microcystis and microcystin controls if turbidity curtain impairs fish movement through the compliance lens.

9.5.2.10 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Turbine Venting

According to PacifiCorp, the Klamath River downstream of Iron Gate dam periodically experiences during summer months, low dissolved oxygen emanating from the deep reservoir intake on Iron Gate Reservoir. PacifiCorp conducted turbine venting tests in the summer of 2008 to determine if full air admission through the existing turbine vent valve could positively improve the dissolved oxygen (DO) of discharged water. The tests indicated that DO could be increased up to 2 mg/L and 20% saturation. PacifiCorp plans to install a forced-air blower on an existing (but previously closed) air introduction manifold to increase air entrainment into the turbine draft tube. This should then increase DO concentration below the Iron Gate powerhouse. Should these tests prove further success with the technique, turbine venting will be used as an interim implementation measure to improve DO conditions downstream of Iron Gate Dam.

Analysis of Compliance Measures Associated for Turbine Venting

- Install a forced-air blower on an existing, but previously closed, air introduction manifold.

Potential Environmental Impacts for Turbine Venting

- None identified.

Possible Mitigation Measures Protection for Turbine Venting

- Not applicable.

9.5.2.11 Analysis of Compliance Measures, Potential Environmental Impacts and Possible Mitigation Measures for Dam Decommissioning Activities

As described previously (see section 9.5.2) the decommissioning (or removal) of one or more of the existing dams that comprise the KHP have been the subject of much discussion and investigation as part of PacifiCorp's FERC relicensing efforts. A number of reports have been produced by various groups evaluating the potential environmental effects of a number of dam removal scenarios. The reports used in the preparation of this CEQA analysis are incorporate herein by reference and include:

- *The Final Environmental Impact Statement for Relicensing of the Klamath Hydroelectric Project No. 2082-027* (FEIS) released by the Federal Energy Regulatory Commission on November 16, 2007 (FERC 2007). This FEIS contains, in part, evaluations of two dam removal scenarios. One alternative involves the retirement of the Iron Gate and Copco No. 1 developments (dams and associated hard structures). The other involved the retirement of Iron Gate, Copco No. 2, Copco No. 1, and J.C. Boyle developments. This report[13] is available at the following web site: http://www.ferc.gov/industries/hydropower/enviro/eis/2007/11-16-07.asp.

- *Klamath River Dam and Sediment Investigation* (November 2006) prepared by Gathard Engineering Consulting, at the request of the California State Coastal Conservancy and the Ocean Protection Council (Gathard Engineering Consulting 2006). This report characterized the sediment behind Iron Gate, Copco No. 1 and 2, and J.C. Boyle and examined the possibility of removing these dams removal. This report[14] is available at the following web site: http//www.fws.gov/yreka/KRI/GECFinalReport.pdf.

- *Dam Removal and Klamath River Water Quality: A Synthesis of the Current Conceptual Understanding and an Assessment of Data Gaps*. This report was prepared by Stillwater Sciences (2009a) at the request of the State Coastal Conservancy and describes, in part, potential water quality impacts of dam removal. This report[15] is available from the following web site: http://www.stillwatersci.com/resources/2009klamathWQsynthesis.pdf.

- *Effects of Sediment Release following Dam Removal on the Aquatic Biota of the Klamath River* (January 2009) prepared by Stillwater Sciences (2009b) at the request of the State Coastal Conservancy and describes, in part, potential water quality impacts to aquatic biota from dam removal. This report[16] is available at the following web site: http://www.stillwatersci.com/resources/2009klamathdamremovalBA.pdf.

---

[13] Report downloaded, November 23, 2009.
[14] Report downloaded, November 23, 2009.
[15] Report downloaded, November 23, 2009.
[16] Report downloaded, November 23, 2009.

All of these reports make clear that additional studies and more detailed project designs are needed before a complete environmental analysis of any dam decommissioning scenario can be completed. However the reports also contain as thorough an evaluation of the environmental impacts and costs associated with dam removal as is possible at this time due to the speculative nature of the actual project(s). Any dam decommissioning activity would require a full environmental analysis of the decommissioning plan as part of the federal and/or state permitting process. (For a more detailed discussion on dam removal scenarios, compliance measure, environmental effects and potential costs, please see these reports above, which are incorporated here by reference.)

Most of the dam removal scenarios evaluated in these reports consists of decommissioning either two or four of the dams and reservoirs by removal of the dam structures and most of the appurtenant structures. Physical removal of the dam structure will require drawing down (lowering) of each reservoir sufficiently to allow safe access to the dam structure. Approximately 1.3 to 2.9 million metric tons of fine-grained sediment (sand, silt and clay) is estimated to be stored behind the four dams associated with the KHP. Dam removal studies done on the Klamath indicate that the greatest potential for adverse environmental effects is from the release of fine grained sediment during the lowering of the reservoir surface water elevation. Removal of the dam structures would involve either demolishing most concrete structures at the dam sites or excavating earth embankment at earthen structure dams. Drilling and blasting techniques, followed by heavy equipment operations would likely be used in the removal of concrete structures. Earthen material in embankment dams and on dam approaches would be removed using heavy equipment or in other cases may be removed through stream erosion. Drawdown of the reservoirs would be implemented through a progressive series of actions, including breaching the dams in a planned sequence and in such a way as to establish a rate of reservoir lowering that will result in the most controlled discharge of the fine grained sediment.

All the studies recommend allowing natural erosion of in-reservoir sediment by the stream system rather than relying on mechanical excavation of the sediment, unless contaminated sediments are present. Previous cost analysis have shown that the cost of mechanically excavating in-reservoir sediment is cost prohibitive and can result in more discharge of uncontrolled fine sediment. It is expected that not all sediment trapped behind the reservoirs would be delivered to the river. Sediment outside of the active river channel(s) will likely remain in place. The limited studies conducted to date do not indicate that significant source of contaminated sediments are present behind the reservoirs. However, additional characterization of the sediments would be required prior to any dam decommissioning operations.

<u>Analysis of Compliance Measures Associated with Dam Decommissioning</u>

- Develop a dam decommissioning plan which would contain at a minimum:
  - Clearly stated goals and objectives for decommissioning;
  - Specific and detailed decommissioning methods (blueprints) containing relevant information such as:

        - Drawdown plan to lower reservoir surface water level to allow safe access to dam structures.
        - Remove concrete dam and appurtenant structures by drilling, blasting, and mechanical removal.
        - Remove earthen dam and appurtenant structures by mechanical removal and/or erosion by river.
        - Identification of mitigation measures such as timing requirements, sequential decommissioning of dams to control release of turbid and consideration of ocean conditions to lessen adverse environmental impacts; and a
    - Monitoring and reporting component to document compliance with the goals and objectives.

Potential Environmental Impacts from Dam Decommissioning

- Short term aesthetics impacts from freshly exposed reservoir bottom and sides.
- Long term aesthetics impacts from the presence of dam and appurtenant structures on the landscape.
- Short term air quality impacts from greenhouse gas emissions from heavy equipment and blasting operations.
- Short term air quality impacts from release of air-born particle matter from blasting activities.
- Short term air quality impacts from offensive odors affecting the surrounding community from exposure of anaerobic sediments.
- Short term biological impacts due to increased duration and concentration of in-stream fine sediment (total suspended sediment). Studies indicate between 1.3 and 2.9 million metric tons of fine sediment are stored behind four of the dams associated with the KHP (J.C. Boyle in Oregon and the three California dams Copco 1 and 2 and Iron Gate).
- Short term biological impacts due to increased turbidly and total suspended sediment loads from erosion of earthen dams and approaches.
- Short term and long term biological impacts from release of contaminated sediments (e.g., metals, VOCs, pesticides and herbicides, dioxin).
- Short term biological impacts due to loss of riparian habitat surrounding the reservoirs.
- Short term biological impacts from heavy equipment used to install structural compliance measures such riparian fencing, erosion control on road systems and reconstruction of failed/failing stream crossings.
- Long term biological impacts from transmission of fish disease upstream and from increased water temperatures during the spring time downstream of the dams.
- Long term biological impacts from introduction of invasive species on exposed reservoir surfaces.
- Long term biological impacts from loss of reservoir acres available for resting of migratory waterfowl and foraging on open water by piscivorous birds and bats.
- Long term cultural impacts from exposure of previously submerged cultural

resources, subject them to looting.

- Short term hydrology/water quality impacts from release of in-reservoir stored organic carbon (including nitrogen and phosphorus), which could also include dissolved oxygen conditions below the proposed DO objective of 85% saturation and lower than the current 8.0 mg/L due to increased oxygen demand from the decomposition of organic material in suspended sediment.
- Long term hydrology/water quality impacts from increased wintertime total suspended sediment and turbidity, with peak levels associated with storm events.
- Long term hydrology/water quality impacts from episodic increased levels of total suspended sediment and turbidity during late spring and summer due to transport of algae blooms from the upper Klamath River.
- Long term hydrology/water quality impacts on the annual nutrient budget.
- Long term hydrology/water quality impacts from increased average annual flow and magnitude and frequency of floods.
- Short term impact from noise generating activities such as heavy equipment use and blasting activities.
- Long term recreation impacts from decreases acres of reservoir available for flat-water recreation and warm water fishing and the subsequent re-direction of reservoir users to other neighborhood or regional recreation areas.

Possible Mitigation Measures for Dam Removal Activities

- Include a native vegetation management as part of any dam decommissioning actions to mitigate any short term aesthetics and long term biological impacts from introduction of invasive species on exposed reservoir surfaces.
- Remove all hardscape (e.g. dams, powerhouses, power lines, etc) associated with the dam and hydroelectric project to mitigate for long term aesthetics impacts from the presence of dam and appurtenant structures on the landscape.
- Conduct activities on days when inversion layer is not present and basin air quality is good, use fuel efficient equipment, and limit number of vehicle trips to the sites to offset short term air quality impacts from greenhouse gas emissions from blasting and heavy equipment operations.
- Control access to site, conduct activities when wind direction will not take particle matter into populated areas to mitigate short term air quality impacts from release of air-born particle matter from blasting activities.
- Inform surrounding communities of dam decommissioning plans to allow voluntary re-location during periods when offensive odors from exposure of anaerobic sediments from dam removal are present.
- Design reservoir drawdown plans to limit the duration of the increased turbidity and total suspended sediment loads to mitigate for the short term biological and water quality impacts from release of in-reservoir fine grained sediment.
- Divert surface water away from construction sites to decrease turbidity and total suspended sediment loads to mitigate for the short term biological and water quality impacts from removal of the dam and appurtenant structures.
- Conduct dam decommissioning operations to coincide with a strong year class of fall Chinook to allow for rapid re-colonization to mitigate for a long term

biological impacts from transmission of fish disease upstream and from increased water temperatures during the spring time downstream of the dams.

- Coordinate with local tribes to develop a cultural resources management plan that contains mitigation measures such as relocation, reburial or other protection strategies to mitigate for long term cultural impacts from exposure of previously submerged cultural resources.
- Time dam decommissioning to "wet" hydrologic year to facilitate flushing to mitigate for the short term hydrology/water quality impacts from release of in-reservoir stored organic carbon (including nitrogen and phosphorus). The multi-year analysis of Asarian et al. (2009) shows the combined annual retention for Copco and Iron Gate reservoirs is nine percent (9%) for total phosphorous and thirteen percent (13%) fro total nitrogen. These increased nutrient loads will likely have minimal, if any, water quality impacts downstream. The minimal water quality impact can be attributed to the following:
  - Retention within the reservoirs occurs largely in the winter and early spring when nutrients exist in a particulate form which is less bioavailable;
  - The higher flows (as a result of a dams out scenario) will carry most of the nutrient load through the system and out to the ocean.
  - The winter and early spring loading period is not a critical growth period for periphyton or phytoplankton; and
  - Increase scouring of the downstream periphyton as a result of increase flow.
- The impacts on organic matter cycling from dam removal activities is offset in part due to the export of organic carbon (phytoplankton) in the summer months that will occur if dams are not in place. The increased nutrient and organic matter load without reservoirs can be mitigated through the development of treatment wetlands and restored natural wetlands.
- Prevent the development of hard structures in the floodplain that are not designed to handle the anticipated increased floods to mitigate for the long term hydrology impacts from increase average annual flow and magnitude and frequency of floods. Iron Gate, Copco 1 and Copco 2 reservoirs are small and have not been managed to attenuate peak flows. In addition a very small percentage of the flood flows ($\leq$ 10%) originate upstream of the reservoirs. The vast majority of flood flows ($\geq$ 90%) originate downstream of Iron Gate dam.
- Re-vegetate exposed soils along the river banks and floodplains to prevent the long term hydrology/water quality impacts from increased wintertime total suspended sediment and turbidity, which have peak levels during storm events.
- Time dam decommissioning to "wet" hydrologic year to facilitate flushing to mitigate for the long term hydrology/water quality impacts from episodic increased levels of total suspended sediment and turbidity during late spring and summer due to transport of algae blooms from the upper Klamath River.
- Staff has determined that no compliance measures are necessary to mitigate for the long term hydrology/water quality impacts from increase average annual flow and magnitude and frequency of floods in large part as the reservoirs were not designed for flood protection. These reservoirs were designed to have a low residence time and especially under peak flows they did little to reduce peak

hydrograph flows downstream.

- Notify landowners adjacent to blasting sites of the planned use of explosives, restrict public access to the sites and plan explosives operations to take into account noise considerations to mitigate for the short term impacts from noise generating activities such as heavy equipment use and blasting activities.
- Redirect existing reservoir (flatwater) users to the twelve (12) other existing reservoirs/lakes in the region, conduct a survey of the existing recreation facilities at the other reservoir/lakes as part of any dam decommissioning plan, include recreational facility installation/upgrade at the existing flatwater areas to mitigate for any long term recreation impacts from decreased acres of reservoir available for flat-water recreation and warm water fishing and the subsequent re-direction of reservoir users to other neighborhood or regional recreation areas.

Although potentially significant adverse impacts from dam removal were identified, it is impossible without further study to know whether those impacts may be able to be mitigated to less than significant levels. If the Settlement Parties decide to go forward with decommissioning of one or more of the dams, additional environmental review will be required at that time. If, at that time, adverse environmental impacts are identified that cannot be mitigated to less than significant levels, the Regional Water Board, when required to take a discretionary action for approval of dam decommissioning as a final TMDL compliance measure, will balance the economic, legal, social, technological, or other benefits of removing the dams against any identified unavoidable environmental risks when determining whether to approve the project, and make a statement of overriding considerations, if it finds that the adverse environmental impacts are acceptable given the identified benefits. At this time, however, the Regional Water Board is not taking any action to approve decommissioning of one or more of PacifiCorps' dams and there is insufficient information for the Regional Water Board to know what potential impacts exist, if they can be mitigated to less than significant levels, and if not, whether the benefits outweigh those potential impacts.

9.5.3 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Iron Gate Hatchery

Iron Gate Fish Hatchery is owned by PacifiCorp and operated by the California Department of Fish and Game (CDFG). The hatchery is located at the base of Iron Gate Dam and discharges effluent into the mainstem Klamath River. The TMDL assigns temperature, nutrient, and organic matter waste load allocations, as well as temperature, DO, nutrient and organic matter targets to discharges from Iron Gate Hatchery. The waste load allocations, based in part on the proposed revised DO objectives, to the Iron Gate Hatchery discharges will be implemented through the federal NPDES permit, which is held jointly by CDFG and PacifiCorp.

The issues associated with the Iron Gate Hatchery are complex due to the location and issues surrounding the hatchery operation. Site-constraints and technical factors make it necessary for an engineering study to be completed before a full environmental analysis can be completed for the hatchery aspect of the TMDL.

The TMDL compliance schedule to accompany the new permit may allow additional time needed for CDFG to make any infrastructure improvements to the hatchery and to implement management measures that meet TMDL allocations. The time schedule will include specific intermediate milestones with the final goal of meeting the Klamath TMDL allocations and targets. Intermediate milestones for pollutant reductions in the hatchery discharges may include:

1. Improving effluent water quality to the level of the intake water to the hatchery; and
2. Meeting current receiving water quality in the Klamath River at the point of discharge.

The hatchery may have the option of achieving some or all of its waste load reductions through offset mitigation if the potential changes to hatchery operations are limited in their ability to effectively reduce pollutant loads.

9.5.3.1 Analysis of Compliance Measures Associated for Iron Gate Hatchery

- Improvements to settling ponds.
- Improvement in treatment technologies (such as installation of a package treatment plant).
- Modifications to plant operations.
- Engage in potential off-sets program, including up-stream treatment activities.

9.5.3.2 Potential Environmental Impacts for Iron Gate Hatchery

- Impacts as typically associated with construction activities.

9.5.3.3 Possible Mitigation Measures Protection for Iron Gate Hatchery

- See mitigations below (Section 9.5.5) for use of heavy equipment and other infrastructure impacts.

9.5.4 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Tributaries

The tributaries to the Klamath River include five major tributaries and numerous minor tributaries. The major tributaries are the Trinity, Salmon, Scott, Shasta and Lost Rivers. All the major tributaries, except the Lost River, join the Klamath River in California and are also wholly contained within California. The Lost River traverses the Oregon/ California border three times and ultimately joins the Klamath River in Oregon via the Klamath Straits Drain. The major tributaries each have had technical TMDLs completed that are specific to the tributary basin. The Regional Water Board has adopted TMDL implementation plans for the Shasta, Scott, and Salmon River basins. The Trinity, South Fork Trinity, and Lost River basins have had TMDLs promulgated by the USEPA without associated implementation plans. Lost River actions are included in those contained in the Stateline discussion.

The Klamath River TMDLs assign nutrient and organic matter load allocations to all the major Klamath tributaries in California and eighteen (18) specified minor tributaries to ensure that water quality standards in the mainstem, including the proposed revised DO objective, of the Klamath River are met. The Shasta River is the only tributary in California that has an existing TMDL with nutrient and organic matter-related allocations.

The Klamath River TMDL allocations to the Shasta River are consistent with the allocations assigned in the Shasta River TMDLs.

The Lost River discharges to the Klamath River in Oregon and as such the allocations for the Lost River are included as part of the Oregon Klamath River TMDLs.

It is anticipated that the Scott River TMDL includes the necessary sediment and temperature control measures to meet the Klamath River TMDL watershed-wide temperature allocations and targets and will be consistent with the proposed prohibition on the discharge of excess sediment.

Regional Water Board staff is currently working with the U. S. Forest Service on the development of a Memorandum of Understanding (MOU) that would provide the framework for the implementation (compliance) measures that would be undertaken in the Salmon River basin. These compliance measures would be formalized in WDRs/waiver that would require compliance with the proposed revised DO objectives, Klamath TMDL allocations and targets.

The Trinity River is assigned nutrient and organic matter allocations in the Klamath River TMDL. The implementation measures described in Section 6.5 apply to the Trinity River watershed. Implementation of sediment and riparian control measures to meet the watershed-wide temperature allocations and targets applicable to the Trinity River are expected to be sufficient to meet the nutrient and organic matter allocations for the Trinity River. The Klamath River TMDLs was modeled on the Trinity River Restoration Program (TRRP) Record of Decision, including flows. These actions, including flow levels were previously analyzed under NEPA, therefore no CEQA analysis is required for these actions. The restoration portion of TRRP (EIS circulating now

The compliance measures that might reasonably be implemented in the eighteen (18) minor tributaries are discussed below in the section on compliance measures for the proposed watershed wide allocations and targets.

9.5.4.1 Analysis of Compliance Measures Associated for Tributaries

- No additional compliance measures identified beyond those required under existing TMDLs, watershed programs or with the application of the watershed wide allocations discussed below.

9.5.4.2 Potential Environmental Impacts for Tributaries

- Not applicable.

9.5.4.3 Possible Mitigation Measures Protection for Tributaries

- Not applicable.

9.5.5 Analysis of Compliance Measures, Potential Environmental Impacts, and **Possible** *Mitigation Measures for Actions to Comply with the Watershed Wide Allocations and Targets and Proposed Revised DO Objective*

The environmental analysis of the compliance measures, potential impacts and possible mitigation measures to avoid those impacts is presented below. It is generally organized to correspond with the organization of the proposed implementation actions present in Chapter 6 of this Staff Report. This analysis includes a discussion on:

- Road construction and maintenance (on both public and private lands, unlike the Staff Report).
- Grazing.
- Irrigated Agriculture.
- Timber Harvest (on both public and private lands).
- Fire Management on U.S. Forest Service Lands (a component of the discussion on land management activities on Federal lands in Chapter 6 of the Staff Report).

9.5.5.1 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Road and Crossing Construction and Maintenance Activities

Discharge of sediment from roads and watercourse crossings was identified during development of the TMDLs as contributing to the temperature impairment of the Klamath River. The draft Klamath River TMDLs (Chapter 5, Allocations and Numeric Targets, page 5-14) concludes that "stream temperature increases from human-caused discharge of sediment constitute an exceedence of the water quality objective for temperature" and establishes a temperature-related load allocation. The proposed temperature-related load allocation equals:

- Zero (0) temperature increase caused by substantial human-caused sediment-related channel alteration[17].

The draft Klamath River TMDLs also proposes the inclusion of three road and crossing related targets to control temperature impacts from human–caused sediment sources. The crossing related targets (or goals) include:

---

[17] As used in this analysis, substantial human-caused sediment-related channel alteration is defined as "A human-caused alteration of stream channel dimensions that increase channel width, decrease depth, or remove riparian vegetation to a degree that alters stream temperature dynamics and is caused by increased sediment loading".

- Zero (0) miles of substantial human-caused sediment related channel alteration.
- Less than one percent (1%) of all stream crossings divert or fail as a result of a 100-year or smaller flood.

The proposed road-related target is as follows:

Decreasing number of potential road-related landslide source areas.
See Chapter 5 of this Staff Report for more on load allocations and numeric targets.

To attain the load allocations and reach the proposed targets, the draft implementation program (see Chapter 6 of the Staff Report for more information) proposes the use of all three of the regulatory approaches mandated by the California Water Code and reaffirmed in the State's 2004 Non-Point Source Policy (i.e., application of prohibitions, WDRs, and conditional waivers of WDRs) to control discharge of excess sediment from road and crossing construction and maintenance activities. See Chapter 6 for more on the Non-Point Source Policy.

The Klamath TMDLs identify the following parties as responsible for road and crossing construction and maintenance activities:

- US Forest Service (USFS)
- US Bureau of Land Management (BLM)
- State of California (Caltrans)
- Del Norte, Humboldt, Siskiyou and Trinity Counties (Counties)
- Private landowners, including timber, agricultural and residential

New road construction, except for on statutorily exempt land uses (e.g. agricultural and timber) are required to obtain coverage under the Statewide construction stormwater permit if the road results in point source discharge to waters of the State.

The USFS currently has waiver coverage for the roads associated with their silvicultural activities (Order Nos. R1-2004-0015 and R1-2009-0028). The conditional waiver is based on the understanding that the existing USFS road-related BMP program is implemented. The existing waiver will expire on December 10, 2009. Regional Water Board staff is currently working with the USFS on a revised permit which would include, in part, additional categories of land use (e.g., pre- and post-fire treatment), road design and construction standards, and a monitoring program. The suite of compliance measures that will be used on USFS roads likely will be similar regardless of the land use associated with the road use (e.g. timber, recreation, or grazing) or the regulatory approach that is used (e.g. prohibitions, WDRs, or conditional waivers of WDRs). The proposed implementation plan recommends the use of the proposed "*Prohibition of Discharges in Violation of Water Quality Objectives in the Klamath River Basin*" for those roads (including on USFS lands) that are not covered by an applicable State or Regional Water Board permit. As staff resources are made available, new or revised permits will be developed to cover a wider range of activities providing additional coverage options. Because road-related compliance measures are not currently required for roads not covered by the USFS silvicultural waiver, the full suite of road-related compliance measures, potential impacts and possible mitigation measures will be evaluated in this environmental analysis.

Currently, discharge of excess sediment from roads on lands managed by the US Bureau of Land Management (BLM) is unregulated. As stated above, the implementation plan proposes the application of the "*Prohibition of Discharges in Violation of Water Quality Objectives in the Klamath River Basin"* until such time as applicable permits are developed. Because the implementation of road-related compliance measures to control excess sediment is currently not required for roads under BLM's jurisdiction, the full suite of road-related compliance measures will be evaluated for potential adverse impacts and possible mitigation measures as part of this environmental analysis.

Discharges of waste from roads under the control of the State of California are the responsibility of Caltrans. These discharges are regulated under the State Water Board *NPDES Permit for Storm Water Discharges from the State of California, Department of Transportation (Caltrans) Properties, Facilities and Activities* (Order No. 99–06-DWQ). The draft Klamath River TMDL and implementation plan proposes the inclusion of three measures to address water quality impacts of Caltrans facilities and activities in the Klamath River watershed. One addresses the control of excess sediment, the second addresses barriers to migratory fish, and the third is addresses riparian shade to meet the temperature load allocation. Thus, this environmental analysis will evaluate likely compliance measures designed to control excess sediment discharge and to alleviate barriers to migratory fish passage and to protect or restore riparian shade.

No formally adopted regulatory framework currently exists for discharges of excess sediment from existing county-controlled road systems in the Klamath River watershed. However, the Counties (Humboldt, Del Norte, Trinity and Siskiyou) are all participants in the Five Counties Salmonid Conservation Program (5C Program). The 5C Program is guided by a management practices manual titled "*A Water Quality and Stream Habitat Protection Manual for County Road Maintenance in Northwestern California Watersheds*" which was endorsed by the National Marine Fisheries Service (NMFS) in 1999. As part of their approval, NMFS made the following determination: "all adverse impacts of the proposed action have been addressed to reach the conclusion of no significant impacts". The compliance measures (BMPs) recommended in the Road Management Plan are widely recognized as being effective in the control of sediment discharge from roads and watercourse crossings and are used by a number of responsible parties throughout California to control sediment discharges from rural road networks, and associated sediment-related impacts to water quality and aquatic resources. Since the implementation proposes certification of the 5C Program, the likely suite of compliance measures will be evaluated as part of this environmental analysis.

The final category of roads considered as part of this environment analysis includes roads owned by private landowners such as timberland owners, ranchers, farmers and rural residents. Roads on privately owned timberlands are covered under the existing timber WDRs or conditional waiver. The discharge of excess sediment from the remainder of these existing road systems is currently unregulated. As with the other categories of roads described above, the proposed implementation plan recommends the application of the "*Prohibition of Discharges in Violation of Water Quality Objectives in the Klamath River Basin"*, until such time as additional permits are developed.

Regional Water Board staff have identified a broad range of compliance measures to be analyzed as part of this environmental analysis. The compliance measures identified by Regional Water Board staff as likely being needed to meet the TMDL load allocation and numeric targets are presented below. An evaluation of the environmental impacts associated with implementation of specific measures or groups of measures and potential mitigation measures to decrease environmental impacts is also provided below.

As part of the Klamath River TMDL implementation plan, all landowners in the Klamath River watershed are encouraged to implement measures to control the discharge of excess sediment from their road systems. This includes the treatment of the road surfaces, cut and fill slopes, and drainage facilities, as appropriate, to prevent discharge of excess sediment. A number of compliance measures are available to control the discharge of excess sediment from the road system. Selection of compliance measures depends on a number of site specific factors including, but not limited to:

- Road surface material;
- Road drainage design;
- Timing and intensity of road use;
- Proximity of roads to watercourses;
- Proximity of roads to unstable or landslide prone areas; and
- Public health and safety concerns.

All of these factors should be considered during the selection, design and implementation of appropriate compliance measures. Due to the comparable nature of many of the identified compliance measures, potential environmental impacts will be analyzed in groups, regardless of who owns or controls the road system.

<u>Analysis of Compliance Measures, Potential Environmental Impacts and Possible Mitigation Measures to Control Impacts from Road Construction and Maintenance Activities</u>

Depending in part on the factors described above, a number of compliance measures to control excess sediment from the road surfaces (or the travelled portion of the road way) are available and routinely implemented by those parties responsible for roads in California.

<u>Analysis of Compliance Measures to Control Impacts from Road Construction and Maintenance Activities</u>

Compliance measures include treating the surface with the appropriate material to prevent expected road use from destabilizing the road surface. Surface stabilization measures include:

- Paving the road (asphalt)
- Chip sealing (gravel and petroleum-based binder)
- Rocking
- Dust abatement of native surface roads

Discharge of excess sediment from road fill slopes and cutbanks will require the implementation of compliance measures to prevent soil erosion or mass wasting. Fill slope and cut slope compliance measures include:

- Removal/stabilization of unstable fill
- Soil stabilization (mulching/vegetation) of fill and cut slopes.

An important factor in controlling discharge of excess sediment from road systems is properly designed road drainage and an active maintenance program. Compliance measures to control discharge of excess sediment as a result of drainage treatments are presented below based on road drainage design.

Insloped roads are those roads designed and constructed to drain the road surface towards the cutbank. Road and cutbank runoff is collected in an inboard ditch and drained with a series of cross drains, either directly to watercourses or onto the hillslope. Compliance measures to control discharge of excess sediment from insloped roads include:

- Disconnect road drainage from watercourses (drain to hillslopes).
- Install drainage structures at intervals that prevent erosion of the inboard ditch or gully formation at the hillslope outfall.
- Outslope the road.

Outsloped roads are those roads designed and constructed to drain the road surface towards the hillslope and away from the cutslope. This type of road design prevents the concentration of road surface runoff that could result in hillslope gully formation or discharge of road surface material directly into watercourses. Compliance measures to control discharge of excess sediment from outsloped roads include:

- Maintain outslope to prevent the concentration of road runoff.

Crowned roads are those roads designed and constructed to drain the road surface in two directions. Part of the road prism is drained towards the hillslope with the remainder of the road prism drained towards the cutslope. Hence, compliance measures to control discharge of excess sediment from crowned roads are the same as those identified above for insloped and outsloped roads.

Potential Environmental Impacts Associated with Road Related Compliance Measures

- Excess sediment discharge in violation of prohibition and exceedence of objectives from soil disturbance, earth movement and mass wasting or landslide events.
- Air quality impacts from heavy equipment use.

- Impacts to cultural sites from equipment use.
- Wildlife species impacts from disturbance to habitat.
- Increase in landslide hazard from placement of road cut and fill.
- Decrease in instream flows from water withdrawal for dust abatement.
- Alteration of natural hydrology by concentrating or redirecting road runoff.

Possible Mitigation Measures to Avoid Environmental Impacts Associated with Road Related Compliance Measures

- Install and maintain erosion control measures (e.g. waterbars, rolling dips, mulch, rock rip-rap) to prevent discharge of excess sediment from soil disturbing activities.
- Relocate roads away from unstable and landslide prone terrain.
- Drain roads away from unstable areas during construction, reconstruction of maintenance activities.
- Locate new roads on stable ground to the maximum extent practicable. Consult with professional geologist or engineer if road must be construction across landslide prone terrain.
- Time heavy equipment use to occur during periods of good air quality.
- Consult with Tribes, historical societies, federal, state and local agencies regarding location of cultural resources prior to use of heavy equipment in areas with known or suspected cultural resources.
- Consult with federal, state and local agencies regarding location of sensitive (e.g., threatened or endangered) wildlife resources.
- Minimize cutbank height and avoid placement of fill on steep slopes.
- Use off-channel water collection features for dust abatement purposes.
- Install adequate number/type of road drainage features to prevent concentration of road runoff.

Analysis of Compliance Measures, Associated Environmental Impacts and Potential Mitigation Measures to Avoid Impacts from Stream Crossing Activities

Discharge of excess sediment and loss of fisheries habitat from undersized, failing or poorly maintained watercourse crossings and crossing approaches is a high priority in the implementation of the Klamath TMDLs due to the high delivery potential associated with failing crossings and the loss of habitat created by human-caused fish migration barriers. As such, additional measures , identified below, likely will be required of all responsible parties in the Klamath River watershed who own or control these features.

Analysis of Compliance Measures to Avoid Impacts Associated with Crossing Activities

- Stabilize/treat crossing approach (road surface draining directly to crossing).
    - Rock road surface,
    - Use water for dust abatement,
    - Install additional road drainage features (e.g., waterbars, rolling dips, cross drains)
- Stabilize/treat crossings and associated fills.
    - Remove undersized/failing culverts
    - Remove unstable fill

    - Rock armor, rip rap fill slopes
    - Provide "fail safe" road drainage on crossings with diversion potential
    - Drain road away from unprotected fills
    - Install bioengineered structures (e.g. willow wattles)
    - Mulch, vegetate or rock exposed soil with access to watercourses
- Construct storm-proof (or fail-safe) crossings and associated fills.

Potential Environmental Impacts Associated with Crossing Related Compliance Measures

- Excess sediment discharge in violation of prohibition and exceedence of objectives from soil disturbance and earth movement.
- Air quality impacts from heavy equipment use.
- Impacts to cultural sites from equipment use.
- Wildlife species impacts from disturbance to habitat.
- Impacts to sensitive (e.g., threatened or endangered) wildlife resources.
- Creation of migration barriers to aquatic species, including cold water fisheries.
- Decrease in riparian vegetation needed to prevent temperature impacts.

Possible Mitigation Measures Associated with Crossing Related Environmental Impacts

- Avoid construction within wetted channel. Divert stream flow around crossing site, if necessary.
- Install and maintain compliance measures to prevent discharge of excess sediment from soil disturbing activities.
- Consult with Tribes, historical societies, federal, state and local agencies regarding location of cultural resources prior to use of heavy equipment in areas with known or suspected cultural resources.
- Consult with federal, state and local agencies regarding location of sensitive (e.g., threatened or endangered) wildlife resources.
- Time heavy equipment use to occur during period of good air quality (e.g.,. no air quality impacts from wildland fires).
- Size and construct stream crossing to allow unrestricted passage of aquatic species.
- Re-vegetate disturbed stream banks with native species.

Analysis of Compliance Measures, Potential Environmental Impacts and Possible Mitigation Measures to Avoid Impacts from Road Planning Activities

Good road planning can result in decreased road construction costs, lower maintenance requirements, and greater protection for the environment, including water quality. The compliance measures associated with good road planning are presented below.

Analysis of Compliance Measures to Avoid Road Planning Related Impacts

- Design road to support intended use (e.g., winter use, high traffic, etc.).
    - Surface material (e.g., pavement, chip seal, rock, native material).
    - Road width (e.g., single lane, double lane).
- Design road drainage to prevent road runoff concentration.
    - Drain road away from watercourses.

    - Drain road away from unstable areas.
    - Install sufficient drainage to prevent erosion at outfall.
- Locate roads on stable ground.
- Minimize crossing number and size of fill, to the extent feasible.
- Design crossing to handle anticipated stream flow and to prevent diversion of stream down the road.
- Avoid sensitive areas (wildlife, cultural).

Potential Environmental Impacts Associated with Road Planning Related Compliance Measures

- Staff has not identified any environmental impact from road planning activities.

Possible Mitigation Measures to Avoid Impacts with Road Planning Related Compliance Measures

- Not applicable.

Analysis of Compliance Measures, Potential Environmental Impacts and Possible Mitigation Measures to Avoid Impacts from Road Decommissioning

Road decommissioning may be a necessary action as part of a responsible party's management program to achieve the applicable TMDL load allocation. Road decommissioning may be appropriate if maintaining the road is cost prohibitive, if the road is not needed for access or public health and safety, or if it is a source of uncontrollable excess sediment discharge.

Analysis of Compliance Measures Associated with Road Decommissioning Activities

- Re-contour road to provide for a stable, hydrologically "invisible" site (e.g., remove perched fill, outslope old road prism, remove crossings).
- Minimize road system (density) to correspond with maintenance resources.
- Decommission roads adjacent to watercourse and relocate to midslope or ridgetop if possible.

Potential Environmental Impacts Associated with Road Decommissioning Compliance Measures

- Excess sediment discharge in violation of prohibition and exceedence of objectives from hillslope, in-channel and stream bank activities.
- Air quality impacts from heavy equipment use.
- Impacts to cultural sites from equipment use.
- Wildlife species impacts from disturbance to habitat.
- Cultural impacts from soil disturbance.
- Decrease in riparian vegetation needed to prevent temperature impacts.

Possible Mitigation Measures to Avoid Impacts from Road Decommissioning Compliance Measures

- See the mitigation measures identified above for road and crossing related activities.

9.5.5.2 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Grazing Activities

The draft Klamath River TMDL recommends adoption of two temperature-related load allocations that are applicable to grazing activities on both federal and non-federal (private) land in the Klamath River watershed. One is a load allocation for excess solar radiation (expressed as its inverse, shade) and the other is related to sediment discharge related to human activity. See the discussion above in Sections 9.5.5.1 for more on these allocations and targets.

The draft Klamath River TMDL recommends adoption of one load allocation relative to nutrients/organic matter and two nutrient-related numeric targets. See Table 5.18 and 5.19 in Chapter 5 of this Staff Report for more information on load allocations and numeric targets. The load allocation and targets are designed to achieve the proposed revised DO objective. As such, the compliance measures discussed here are appropriate for both compliance with the TMDL and with the DO objective.

The load allocation is expressed as "*TN, TP, and CBOD concentrations expressed as monthly mean concentrations*".

The nutrient-related numeric targets include:

- Expressed as monthly mean concentrations of TP, TN, and CBOD below the Salmon River (Table 5.17 in the Staff Report).
- Reach-averaged maximum density of 150 mg of chlorophyll-a /m2 below the Salmon River.

For the purpose of this analysis a discussion of environmental impacts associated with irrigated agricultural is presented separately below in Section 9.5.5.3.

Grazing on federal land is regulated primarily by the USFS under Rangeland Project Decision documents and Annual Operating Instructions designed to meet the "*Northwest Forest Plan*" objectives for individual public forests. In addition, through the execution of a formal Management Agency Agreement with the USFS in 1981, the State Water Board designated the USFS as the Water Quality Management Agency for National Forest System lands in California. A document entitled "*Water Quality Management for Forest System Lands in California: Best Management Practices*" (USDA 2000) describes the means by which the USFS endeavors to meet their responsibility with respect to water quality protection.

Grazing on non-federal lands in the Klamath River Basin goes largely unregulated, except in the Scott and Shasta River watersheds (as a result of ongoing implementation of the approved Scott and Shasta River TMDLs and on concentrated animal feeding operations (CAFOs)). TMDL implementation plans adopted by the Regional Water Board in the Scott and Shasta River watersheds provide a waiver of WDRs for activities, including grazing, that implement measures contained in the applicable plan. NDPES permits are issued to CAFOs.

In the Klamath River TMDL, staff proposes the development of a conditional waiver of WDRs for discharges associated with agricultural activities that will include grazing as a means of implementing the TMDL and water quality standards. The Regional Water Board does not typically specify those measures necessary to achieve compliance with WDRs. Instead, the Regional Water Board typically allows land owners/managers to apply their own expertise and ingenuity to determine the best means of compliance. With respect to the TMDL, the waiver will be designed to implement the watershed-wide allocations, and the numeric nutrient and organic matter allocations.

For the purpose of CEQA, Regional Board staff must identify the reasonably foreseeable compliance measures that could be employed to achieve compliance with the TMDL and analyze their potential to cause environmental impact. With respect to the field of grazing on non-federal land, staff has used USEPA's (2003) *National Management Measures to Control Nonpoint Pollution from Agriculture* for guidance on the compliance measures that could be implemented to comply with a grazing waiver or WDR.

Four separate areas of management necessary to reduce the environmental harm resulting from grazing activities are described below. They include:

A. Grazing Management Practices
B. Alternative Water Supply Practices
C. Riparian Grazing Practices
D. Monitoring Grazing Land Condition

Grazing management practices are well suited to address the sediment–related temperature allocations proposed under the Klamath TMDL. Alternative water supply practices are well suited to address both the sediment–related temperature allocations and the nutrient and organic matter allocations. The riparian grazing practices are well suited to address the riparian shade allocation. The land and stream bank stabilization practices are also well suited to address the sediment-related temperature allocation. Monitoring is an activity necessary to ensure that the predicted effects are in fact occurring.

<u>Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Grazing Management Practices</u>
USEPA (2003) states that appropriate grazing management systems ensure proper grazing use by adjusting grazing intensity and duration to reflect the availability of forage and feed designated for livestock uses, and by controlling animal movement through the operating unit of grazing land. The use of grazing management systems can help maintain riparian and other resource objectives and can help meet the specific management objectives of the desired quality, quantity, and age distribution of vegetation.

<u>*Analysis of Compliance Measures Associated with Grazing Management Practices*</u>

- Develop a grazing management plan for upland and riparian management.

- Calculate the number of livestock that can be maintained while maintaining adequate vegetative cover, stream corridor integrity, and water resources.

- Establish native or introduced forage species (grasses, forbs, legumes, shrubs, and trees) through pasture, hay field and rangeland planting.
- Implement the controlled harvest of vegetation with grazing or browsing animals to achieve a specific objective.
- Exclude animals, people, or vehicles from an area to protect, maintain, or improve the quantity and quality of plant, animal, soil, air, water, and aesthetic resources and human health safety.
- Manage the amount, source, placement, form and timing of the application of nutrients and soil amendment through nutrient management.

Potential Environmental Impacts Associated with Grazing Management Compliance Measures

- Introduction of invasive (introduced) species thorough pasture, hay and rangeland planting and management.
- Decrease standing cover crop from removal of forage.
- Increase risk of soil compaction from heavy equipment use.
- Risk of increase soil erosion from fence installation.
- Risk of disturbing cultural/archaeological resources from fence installation
- Risk of disturbing threatened or endangered species or their habitat from installation of fencing.

Possible Mitigation Measures to Avoid Impacts from Grazing Management Practices

- Use certified weed-free grass and seed mix to prevent the introduction of invasive species.
- Manage livestock numbers and grazing patterns to retain adequate standing or cover crop,
- Limit the use of heavy equipment for grazing management activities to dry conditions.
- Consult with Tribes, historical societies, federal, state and local agencies regarding location of cultural resources prior to use of heavy equipment in areas with known or suspected cultural resources.
- Consult with federal, state and local agencies regarding location of sensitive (e.g. threatened or endangered) wildlife resources.
- Plant a cover crop on exposed soil to reduce the length of time in which soil is exposed to wind and water.
- Cover exposed soil that will not receive immediate planting with straw or other suitable erosion control material; and
- Protect drainage channels from sediment contributions with vegetated buffers, wattles or similar erosion control devices.

Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Alternative Water Supply Practices

USEPA (2003) states that providing water and mineral supplement facilities away from streams will help keep livestock away from stream banks and riparian zones, thereby protecting water quality. In some locations, artificial shade may also be constructed to encourage use of upland sites for shading and loafing, rather than the stream corridor. Installing alternate water supplies for livestock is an essential component of this measure.

Analysis of Compliance Measures Associated with Alternative Water Supply Practices

- Install a pipeline to convey livestock water to an off-stream pond, trough or tank.
- Construct/improve system (well, pump, etc) to provide groundwater for irrigation, livestock, wildlife, or recreation in lieu of instream withdraws.
- Improve springs and seeps by excavating, cleaning, capping, or providing collection and storage facilities. To facilitate off-stream watering.
- Place water, shade, and mineral supplements in locations separate from one another to encourage livestock dispersal.
- Ensure water, shade and mineral supplements are not placed on unstable areas, including gullies and landslides.

Potential Environmental Impacts Associated with Alternative Water Supply Practices

- Increased risk of short-term erosion impacts from construction activities.
- Increased risk of disturbing archaeological or cultural artifacts.
- Increased risk of disturbing threatened or endangered species and their habitat.
- Increased risk of soil disturbance that comes from the concentration of animals in a limited area.

Possible Mitigation Measures for Alternative Water Supply Practices

- Exercise surface erosion control measures, such as laying out straw or downslope wattles, where necessary.
- Restricting work to days in which soil detachment by wind or water is not expected.
- Timing the completion of work to coincide with planting to reduce the length of time in which bare soil is exposed.
- Covering exposed soil that will not receive immediate planting with straw or other suitable erosion control material.

Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Riparian Grazing Practices

The TMDL implementation plan includes an allocation intended to protect riparian vegetation from disturbance and preserve shade potential along the stream corridor. As such, any grazing in the riparian zone where this allocation applies must be conducted within certain parameters designed to protect the shade potential. Protection of specific trees, groves, or a streamside buffer zone may be necessary to accomplish this goal. The identification of the shade producing elements within the riparian zone will be necessary.

Analysis of Compliance Measures Associated with Riparian Grazing Practices

- Minimize livestock access to riparian zones, ponds or lake shores, wetlands, and stream banks to protect these areas from physical disturbance.
- Construct animal trails to provide movement of livestock through difficult or ecologically sensitive terrain.

- Stabilize stream crossings to provide controlled access across a stream for livestock and farm machinery.

Potential Environmental Impacts Associated with Riparian Grazing Practices

- See impacts identified above for grazing management in general.
- An analysis of the environmental impacts of stream crossings is provided in the section on roads and crossings.

Possible Mitigation Measures to Avoid Impacts from Riparian Grazing Practices

- See mitigation measures identified above for grazing management in general.
- See mitigation measures identified above for crossing management in general.

Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Monitoring Grazing Land Condition

The grazing management strategy as described by USEPA (2003) seeks to protect water quality by encouraging the development of an understanding of the carry capacity of a piece of land and the site specific land management measures necessary for grazing operations to be conducted within the limitations of the carrying capacity. A critical piece of this kind of management is the collection and analysis of environmental data from which to measure the conditions of the land. USEPA (2003) recommends an integrated approach to monitoring to evaluate nutrient cycling, soil and water quality, and plant community dynamics. Monitoring should be conducted on both a site specific level and at the subwatershed level to determine rangeland conditions status and trends. Monitoring can include photo points, vegetation sampling, soil assessments, water quality and quantity analyses and assessments of watershed, riparian and stream conditions.

Analysis of Compliance Measures Associated with Monitoring Condition of Grazing Lands

- None identified.

Potential Environmental Impacts Associated with Monitoring Conditions of Grazing Lands

- Not applicable.

Possible Mitigation Measures to Avoid Impacts from Monitoring Condition of Grazing Lands

- Not applicable.

9.5.5.3 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Irrigated Agriculture

Irrigated agriculture is identified in the Klamath River TMDL as a category of anthropogenic pollutant loads (source category) impacting water quality parameters of concern. The draft TMDL Implementation Plan identifies the development of a general conditional waiver of WDRs for the purpose of controlling discharges associated with agricultural activities that includes irrigated agriculture.

Staff has turned to USEPA's (2003) *National Management Measures to Control Nonpoint Pollution from Agriculture* for guidance on the compliance measures that reasonably could be implemented to comply with the Klamath River TMDL. USEPA (2003) identifies four categories of management measures responsible parties should consider when attempting to reduce nonpoint source pollution from their farms. These measures include:

- Nutrient management
- Pesticide management
- Erosion and sediment control
- Irrigation water management

Staff judges each of these areas of management to be relevant to implementing the Klamath River TMDLs for temperature, dissolved oxygen, organic matter, nutrients and microcystin-related load allocations and numeric targets, as well as the proposed revised DO objectives. In addition, staff encourages riparian management to achieve the temperature-excess sediment TMDL allocation.

<u>Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures from Nutrient Management Practices</u>

The goal of proper nutrient management is "to minimize nutrient losses from agricultural lands occurring by edge-of-field runoff and by leaching from the root zone" (USEPA 2003). USEPA (2003) describes four important elements to successful nutrient management: 1) determine realistic yield goals, preferably on a field-by-field basis, 2) account for available nutrients from all sources before making supplemental applications, 3) synchronize nutrient applications with crop needs (nitrogen is needed most during active crop growth and may be lost at other times), and 4) reduce excessive soil-phosphorus levels by balancing phosphorus inputs and outputs. Where nutrients are in the dissolved phase, source reduction and reduction of water runoff or leaching are important goals. For nutrients adsorbed to soil particles, the prevention and control of soil erosion is important.

<u>Analysis of Compliance Measures Associated with Nutrient Management</u>

- Monitor soil, irrigation water, and residual plant matter for nutrient content.
- Time fertilizer application to be consistent with plant needs to avoid runoff of excess nutrients to surface waters or leaching of excess nutrients to groundwater.
- Use appropriately sized vegetated buffers to prevent discharge of nutrients to surface waters.

<u>Potential Environmental Impacts Associated with Nutrient Management</u>

- None identified. It is staff's judgment that monitoring, timing, use of cover crops and a vegetated buffer have no reasonable potential to cause environmental harm.

<u>Possible Mitigation Measures to Avoid Impacts from Nutrient Management Practices</u>

- Not applicable.

Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures from Pesticide Management

The goal of proper pesticide management is to reduce contamination of ground and surface water from pesticides by using less pesticide (quantity), less toxic (toxicity) pesticides, and applying pesticides in a manner that reduces the risk of runoff, leaching or air-borne transport.. With respect to the Klamath River TMDL, the application of herbicides is of most relevance. For example, herbicides applied to drainage channels or applied in such a manner as to risk overspray to a water body or riparian zone, could result in an increased risk of organic matter loading as treated plants die and their organic matter is available for delivery to a stream. Similarly, the spraying of herbicides in a riparian zone or overspray from adjacent fields could result in the temporary loss or harm to riparian shade.

Analysis of Compliance Measures Associated with Pesticide Management

- Inventory pest problems.
- Evaluate the soil and physical characteristics of the site, including locations for safe mixing, loading, and storage of pesticides.
- Use integrated pest management strategies that apply pesticides only to the area of need, only when there is an economic benefit to the grower, and at times when runoff losses are least likely, including losses of organic matter from dead plant material.
- Consider the persistence, toxicity, runoff potential, and leaching potential of pesticide products.
- Periodically calibrate pesticide application equipment.
- Use anti-backflow devices on water supply hoses, and other mixing/loading practices designed to reduced the risk of runoff and spills.

Potential Environmental Impacts Associated with Implementation of Compliance Measures for Pesticide Management

- None identified. It is staff's judgment that none of the identified compliance measures have a reasonable potential to cause environmental harm.

Possible Mitigation Measures to Avoid Impacts Associated with Implementation of Compliance Measures for Pesticide Management

- Not applicable.

Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures from Erosion and Sediment Control Measures

USEPA (2003) describes two general strategies for controlling erosion and the deposition of sediment to waters of the State from irrigated agricultural operations. These strategies can be used singly or in combination. The first, and most desirable, is "to implement practices on the field to minimize soil detachment, erosion, and transport of sediment from the field" (USEPA 2003).

Analysis of Compliance Measures Associated with Erosion and Sediment Control Practices

- Maintain crop residue or vegetative cover on the soil.
- Improve soil properties by tilling or otherwise loosening the soil.
- Reduce field slope length, steepness, or unsheltered distance.
- Reduce effective water velocities.
- Reduce effective wind velocities by installing windbreaks (e.g. trees).
- Direct field runoff to areas that filter, trap, or settle soil particles.

Potential Environmental Impacts Associated with Implementation of Compliance Measures for Erosion and Sediment Control

- Short term increases in sediment discharge from wind and water erosion from soil disturbance activities.
- Short term increases in sediment discharge from heavy equipment use.
- Increased short-term risk of soil erosion from re-contouring of fields.
- Air quality impacts from use of heavy equipment
- The construction of measures designed to filter, trap or settle sediment could result in short-term increased risk of erosion.
- Impacts to cultural resources from heavy equipment use.
- Impacts to threatened or endangered species or their habitat from heavy equipment use.

Possible Mitigation Measures to Avoid Impacts Associated with Implementation of Compliance Measures for Erosion and Sediment Control

- Avoid soil disturbing activities on windy and wet days.
- Design measures to filer, trap or settle sediment particles (sediment and/or water basins, field borders, and filter strips and the protection and management of natural wetland and riparian areas).
- Restrict work to days in which soil detachment by wind or water is not expected.
- Time the completion of work to coincide with planting to reduce the length of time in which bare soil is exposed.
- Cover exposed soil that will not receive immediate planting with straw or other suitable erosion control material.
- Protect drainage channels from sediment contributions with vegetated buffers, wattles or similar erosion control devices.

9.5.5.4 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Irrigation Management

According to USEPA (2003), “a primary concern for irrigation water management is the discharge of salts, pesticides, and nutrients to ground water and discharge of these pollutants plus sediment to surface water.” The goal of managing irrigation water is to reduce the movement of pollutants from land into ground or surface water as a result of irrigation. This is accomplished by:

1. Irrigation scheduling;
2. Efficient application of irrigation water;

3. Efficient transport of irrigation water;
4. Use of runoff or tailwater; and
5. Management of drainage water.

It is staff's judgment that irrigation scheduling involves monitoring and planning and has no environmental impacts. Staff has also concluded that efficient application of irrigation water similarly has no environmental impacts. As such, no further analysis of these two activities will be provided.

<u>Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures Associated with Efficient Transportation of Irrigation Water</u>
The efficient transport of irrigation water could include the construction or modification of a number of engineered features.

<u>*Analysis of Compliance Measures Associated with Efficient Transportation of Irrigation Water*</u>

- Lining of an irrigation channel.
- Installation of a pipeline in lieu of an uncovered channel.

<u>*Potential Environmental Impacts Associated with Compliance Measures for the Efficient Transportation of Irrigation Water*</u>

- Use of heavy equipment and soil movement resulting in soil erosion.

<u>*Possible Mitigation Measures to Avoid Impacts from Implementation of Compliance Measures for the Efficient Transportation of Irrigation Water*</u>

- See discussion on wetland restoration, roads, grazing above for potential mitigation measures to address environmental impacts associated with heavy equipment use.

<u>Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures Associated with Use of Runoff or Tailwater</u>
For irrigation systems that use runoff or tailwater, a tailwater management program could be developed and implemented. This could include the construction of a tailwater recovery system designed to collect, store and transport irrigation tailwater (or runoff) for reuse/use in the irrigation distribution system.

Use of runoff or tailwater may be restricted in some areas, depending on legal issues associated with downstream water rights. But, where it is possible the reuse of tail water as irrigation water can serve to reduce the load of agricultural chemicals and sediment that are ultimately delivered to a stream.

<u>*Analysis of Compliance Measures Associated with Use of Runoff or Tailwater*</u>

- Operate the irrigation system so that the timing and amount of irrigation water applied matches crop needs.
- Use backflow flow preventers for wells protection.
- Minimize discharge from edge of fields.

- Construct tailwater management system.
  - Construction of a reservoir and pumping facilities.
- Land leveling to prevent discharge from field edges to surface waters.

Potential Environmental Impacts Associated with Compliance Measures for Use of Runoff or Tailwater

- Increased risk of soil or groundwater contamination with concentrated minerals, salts, or persistent pesticides.
- Loss of wetlands habitat from repair of leaky conveyance system.

Possible Mitigation Measures to Avoid Impacts from Installation of Compliance Measures for Use of Runoff or Tailwater

- Use precision (site specific) farming techniques; monitor chemical condition of soil, water, and plant residuals carefully prior to applying fertilizers, pesticides, or water, including tailwater.
- Leach soils within the root zone as necessary to prevent salt build up in that portion of the soil profile. Monitor ground water to ensure no salt (or other constituents) accumulate in ground water.
- Divert "saved" water (or portion thereof) to a wetland or wildlife refuge.
- Avoid introduction of storm water into tailwater system to prevent impacts to storm water.
- Maintain filter strips between fields and surface water to prevent discharge of tailwater directly into surface waters.
- Install surface drainage field ditch to collect excess water.

Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures Associated with the Management of Drainage Water

Drainage from irrigation systems should be managed to reduce deep percolation, move water to reuse system, reduce erosion and help control adverse impacts to surface and ground water.

Analysis of Compliance Measures Associated with the Management of Drainage Water

- Construct vegetated filter strips.
- Construct surface drainage field ditch.

Potential Environmental Impacts Associated with Compliance Measures for the Management of Drainage Water

- Cause a temporary increased risk of soil erosion from soil disturbance.
- Leaching of pesticides, fertilizers, and trace minerals through an under drain system.

Possible Mitigation Measures to Avoid Impacts from Compliance Measures for the Management of Drainage Water

- Don't concentrate drainage such that toxic levels of constituents are discharge to waters.

9.5.5.5 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Timber Harvest Activities on Public and Private Land

Timber harvest and related activities are identified in the Klamath River TMDL as an anthropogenic (human-caused) pollutant source category impacting water quality parameters of concern. The draft Klamath River TMDLs identifies a number of allocation and numeric targets that are applicable to timber harvest activities. See the discussion in Section 9.5.5.1 for a discussion of the sediment-related allocations and targets. The draft TMDL also recommends a temperature-related load allocation for excess solar radiation. This proposed allocation for excess solar radiation is expressed as its inverse "effective shade" and is as follows:

- The shade provide by topography and full potential vegetation conditions at a site, with an allowance for natural disturbance such as floods, wind throw, disease, landslides, and fire.

The draft implementation plan recommends actions for the purpose of controlling water quality impacts emanating from activities associated with timber harvest activities. It is staff's judgment that these actions are likely necessary to achieve compliance with the Klamath TMDL load allocations and numeric targets.

With respect to timber harvest activities on land managed by the USFS, staff has not identified any additional compliance measures beyond the USFS and the Regional Water Board's existing regulatory framework. This framework includes, in part, the Regional Water Board conditional waivers (Resolutions R1-2004-0015 and R1-2009-0028), the USFS "*Water Quality Management Plan for the Forest System Lands in California, Best Management Practices*" (USDA, 2000) and the "*Northwest Forest Plan*" and "*Aquatic Conservation Strategy*". See Chapter 6 of this Staff Report for details on the existing USFS/Regional Water Board regulatory program for timber harvest activities on USFS lands. As such, there is no additional analysis of management measures required under CEQA. Staff is currently working with the USFS to develop a WDR/waiver for the Regional Water Board's consideration that will potentially cover all their land use activities involving the discharge of nonpoint source of pollution. As envisioned by staff, the proposed permit would include, in part, silvicultural activities, roads construction and maintenance, post fire treatment and a monitoring and reporting program.

The California Forest Practice Rules (2009) describe the intent of the watercourse protection regulations and provides specific measures (narrative or numeric) to ensure adequate protection to the beneficial uses of water from sediment and temperature impacts. As part of the development of the Klamath River TMDL, staff has identified the need to ensure that watercourses that deliver surface (or hyporheic) flows to fish bearing streams have additional requirements in place beyond those required by the 2009 FPR to meet the TMDL temperature load allocation.

Regional Water Board staff identified an implementation action (beyond measures required by other regulatory programs) that likely will be necessary to comply with the TMDL allocations and numeric targets for timber activities on privately owned lands.

See Chapter 6 of this Staff Report for details on the existing CalFire/Regional Water Board regulatory program for timber harvest activities on private land. The compliance measure pertains to the possibility that staff may require additional riparian protections beyond those required by the Anadromous Salmonid Protection Rules (ASP Rules), which take effect on January 1, 2010, in order to meet the Klamath TMDL temperature allocation. Additional riparian protections will be required by Regional Water Board staff on a timber harvest plan-specific basis as part compliance with applicable WDRs and waivers of WDRs for timber harvest activities.

Analysis of Compliance Measures Associated with Timber Harvest Activities on Private Land

- Increased riparian canopy retention for surface waters that support beneficial uses (e.g. Class I[18] and II[19] watercourses) on private timberland.
- Retain in-channel trees following timber operations on private timberlands.

Potential Environmental Impacts Associated with Timber Harvest Activities on Private Land

- Staff has not identified any adverse environmental impacts associate with increasing the post-harvest riparian canopy retention.

Possible Mitigation Measures to Avoid Impacts Associated with Timber Harvest Activities on Private Land

- Not applicable. It is staff's judgment that the retention of additional post-harvest riparian canopy does not have a reasonable potential to cause any environmental harm.

9.5.5.6 Analysis of Compliance Measures, Associated Environmental Impacts, and Potential Mitigation Measures Associated with Fire Management on Federal Lands

The fire regime in the Klamath River basin has been altered through years of suppression that has resulted in increased fuel loads and fire severity. The USFS carries out timber harvest projects related to fire management both to control fuel loads and to salvage timber after a fire.

The practices for controlling post fire erosion sources are, in most cases, the same as those used to control erosion sources on forestlands with the added consideration of increased runoff volume. Regional Water Board staff recommends that the WDRs/waiver address all activities on federal lands including measures that address post fire sediment sources.

Analysis of Compliance Measures Associated with Fire Management on Federal Land

---

18 For the purpose of this report, a Class I watercourse is defined as being a "Domestic supplies or having fish always or seasonally present".

19 For the purpose of this report, a Class II watercourse is defined as "Aquatic habitat for nonfish aquatic species".

- Hydrologically disconnect firelines.
- Remove all temporary crossings.
- Improve the existing road drainage system to handle post-burn flows.
- Clear blockages to restore drainage function.
- Remove minor slumps and slides where needed.
- Ensure the function of drainage systems after storm events.
- Implement post fire re-vegetation on severe burns areas.

Potential Environmental Impacts Associated with Fire Management on Federal Land

- See discussion on potential impacts in the sections on road construction and maintenance and soil and erosion control practices for identification of possible impacts.

Possible Mitigation Measures to Avoid Impacts Associated with Fire Management on Federal Land

- See discussion on mitigation measures in the sections on road construction and maintenance and soil and erosion control practices for identification of potential mitigation measures.

A discussion on the significance (or level) of environmental impact on specific environmental factors such as air, biologic resources, and water quality associated with likely implementation actions are provided in Section 9.7.3 below.

9.5.5.7 Analysis of Compliance Measures, Potential Environmental Impacts, and Possible Mitigation Measures for Thermal Refugia Protection

Suction dredging is identified in the Klamath River TMDL as contributing to impacts on the critical functions associated with thermal refugia in moderating mainstem Klamath River temperatures for salmonids and other species of concern.

No regulatory program is currently in place for permitting instream suction dredging activities. CDFG, required under the Fish and Game Code with developing the program, is currently working on developing CEQA compliant regulation to implement the program.

The proposed implementation plan includes the Thermal Refugia Protection Policy that would be applied in certain locations to all tributary streams in the Klamath River watershed that provide known thermal (cold water) refugia (see Appendix 9 for identified locations of thermal refugia).

The application of the Thermal Refugia Protection Policy will not require implementation of any compliance measures as all responsible parties would be restricted from discharging waste within the prescribed buffer area.

In addition to protecting the quality of cold water by restricting the discharge of waste within an instream buffer zone, staff also proposes the protection of the quantity of cold water delivered by tributaries to the Klamath River mainstem. Staff proposes that the

State Water Resources Control Board ensure that any water rights decisions on refugia tributary streams be made only after an analysis of the individual and cumulative effects of water diversion on tributary and mainstem stream temperatures. Staff proposes that a water right not be granted if the loss of cold water flow would conflict with the temperature goals of the TMDL.

Analysis of Compliance Measures Associated with Thermal Refugia Protection

- None required.

Potential Environmental Impacts Associated with Thermal Refugia Protection

- No environmental impacts identified.

Possible Mitigation Measures Protection of Thermal Refugia

- Not applicable.

9.6 Alternative Means of Compliance

The CEQA requires an analysis of reasonably foreseeable alternative means of compliance with the rule or regulation, which would avoid or eliminate the identified impacts[20]. Responsible parties can use the structural and non-structural BMPs (compliance measures) described above in Section 9.5, or other structural and non-structural BMPs, to control and prevent pollution, and meet the requirements of the proposed Action Plan and revised DO objectives. The alternative means of compliance with the proposed Action Plan and revised DO objectives consist of the different combinations of structural and non-structural BMPs that responsible parties might use. Because there are innumerable ways to combine compliance measures, all of the possible arrangements of alternative means of compliance cannot be discussed here. However, because most of the adverse environmental effects are associated with the construction and installation of large scale structural BMPs to avoid or eliminate impacts, compliance alternatives should minimize structural BMPs, maximize non-structural BMPs, and site, size, and design structural BMPs in ways to minimize environmental effects.

9.7. Environmental Checklist and Discussion of Findings

9.7.1 Environmental Checklist Cover Form

1. Project title:

Proposed Amendment to the *Water Quality Control Plan for the North Coast Region* to Revise the DO objectives for the Klamath River mainstem as contained in Table 3-1 and add a *Klamath River Total Maximum Daily Load Action Plan and Lost River Implementation Plan* (Action Plan),

[20] Cal. Code Regs., tit. 14, § 15187(c)(3).

2. Lead agency name and address:
North Coast Regional Water Quality Control Board
5550 Skylane Blvd., Suite A
Santa Rosa, CA 95403

3. Contact person and phone number:
Matt St John (707) 576-3762

4. Project location:
The project would be applicable to the California portion of the Klamath River watershed under jurisdiction of the North Coast Regional Water Quality Control.

5. Description of the project: (Describe the whole action involved, including but not limited to later phases of the project, and any secondary, support, or off-site features necessary for its implementation).
The proposed project is the adoption of a Basin Plan Amendment, which consists of revised DO objectives for the Klamath River as contained in Table 3-1 and a new *Klamath River Total Maximum Daily Load Action Plan and Lost River Implementation Plan*. The proposed revision to the DO objectives involves the elimination of the existing DO objectives for the Klamath River mainstem as contained in Table 3-1 and their replacement with new site-specific DO objectives based on percent saturation, natural receiving water temperatures and salinity. The goal of the revised DO objectives for the Klamath River mainstem is to correct existing inaccuracies and allow for the application of the DO objectives regardless of the time of day.

The Action Plan includes TMDLs for temperature, dissolved oxygen, nutrients and microcystin and the implementation actions necessary to achieve these TMDLs and attain water quality standards in the Klamath River watershed. The goal of the Action Plan is to fully protect and restore the beneficial uses of water in the Klamath River watershed. The Action Plan sets outs the pollutant loads and conditions to be considered and incorporated into regulatory and non-regulatory actions in the Klamath River watershed. The Klamath River Action Plan is not directly and independently enforceable, except as incorporated into appropriate permitting or enforcement action or through the applicable of waste discharge prohibitions.

This space intentionally left blank.

9.7.2 Environmental Checklist

	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact
I. AESTHETICS -- Would the project:				
a) Have a substantial adverse effect on a scenic vista?	☐	☐	☑	☐
b) Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?	☐	☐	☑	☐
c) Substantially degrade the existing visual character or quality of the site and its surroundings?	☐	☑	☐	☐
d) Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?	☐	☐	☑	☐
II. AGRICULTURE RESOURCES: In determining whether impacts to agricultural resources are significant environmental effects, lead agencies may refer to the California Agricultural Land Evaluation and Site Assessment Model (1997) prepared by the California Dept. of Conservation as an optional model to use in assessing impacts on agriculture and farmland. Would the project:				
a) Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use?	☐	☐	☑	☐
b) Conflict with existing zoning for agricultural use, or a Williamson Act contract?	☐	☐	☑	☐
c) Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use?	☐	☐	☑	☐
III. AIR QUALITY -- Where available, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the following determinations. Would the project:				
a) Conflict with or obstruct implementation of the applicable air quality plan?	☐	☐	☑	☐
b) Violate any air quality standard or contribute substantially to an existing or projected air quality violation?	☐	☑	☐	☐
c) Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors)?	☐	☑	☐	☐
d) Expose sensitive receptors to substantial pollutant concentrations?	☐	☐	☑	☐

	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact
III. AIR QUALITY (cont.)-- Where available, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the following determinations. Would the project:				
e) Create objectionable odors affecting a substantial number of people?	☐	☑	☐	☐
IV. BIOLOGICAL RESOURCES -- Would the project:				
a) Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service?	☑	☐	☐	☐
b) Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations or by the California Department of Fish and Game or US Fish and Wildlife Service?	☐	☑	☐	☐
c) Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?	☐	☑	☐	☐
d) Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?	☐	☑	☐	☐
e) Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?	☐	☑	☐	☐
f) Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?	☐	☐	☑	☐
V. CULTURAL RESOURCES -- Would the project:				
a) Cause a substantial adverse change in the significance of a historical resource as defined in § 15064.5?	☐	☑	☐	☐
b) Cause a substantial adverse change in the significance of an archaeological resource pursuant to § 15064.5?	☐	☑	☐	☐
c) Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?	☐	☐	☑	☐
d) Disturb any human remains, including those interred outside of formal cemeteries?	☐	☑	☐	☐

	Potentially Significant Impact	**Less Than Significant with Mitigation Incorporated**	**Less Than Significant Impact**	**No Impact**
VI. GEOLOGY AND SOILS -- Would the project:				
a) Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving:	☐	☐	☐	☐
i) Rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? Refer to Division of Mines and Geology Special Publication 42.	☐	☐	☐	☑
ii) Strong seismic ground shaking?	☐	☐	☐	☑
iii) Seismic-related ground failure, including liquefaction?	☐	☐	☐	☑
iv) Landslides?	☐	☑	☐	☐
b) Result in substantial soil erosion or the loss of topsoil?	☐	☑	☐	☐
c) Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse?	☐	☑	☐	☐
d) Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?	☐	☐	☐	☑
e) Have soils incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water?	☐	☐	☑	☐
VII. HAZARDS AND HAZARDOUS MATERIALS -- Would the project:				
a) Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?	☐	☐	☑	☐
b) Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?	☐	☑	☐	☐
c) Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?	☐	☐	☑	☐
d) Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment?	☐	☐	☑	☐
e) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?	☐	☐	☐	☑

	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact
VII. HAZARDS AND HAZARDOUS MATERIALS (cont.)-- Would the project:				
f) For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area?	☐	☐	☑	☐
g) Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?	☐	☐	☐	☑
h) Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?	☐	☐	☐	☑
VIII. HYDROLOGY AND WATER QUALITY -- Would the project:				
a) Violate any water quality standards or waste discharge requirements?	☑	☐	☐	☐
b) Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?	☐	☐	☑	☐
c) Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site?	☑	☐	☐	☐
d) Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-site?	☑	☐	☐	☐
e) Create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff?	☐	☐	☑	☐
f) Otherwise substantially degrade water quality?	☐	☐	☑	☐
g) Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?	☐	☐	☑	☐
h) Place within a 100-year flood hazard area structures which would impede or redirect flood flows?	☐	☐	☐	☑
i) Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?	☐	☐	☑	☐
j) Inundation by seiche, tsunami, or mudflow?	☐	☐	☐	☑

	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact
IX. LAND USE AND PLANNING -- Would the project:				
a) Physically divide an established community?	☐	☐	☐	☑
b) Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?	☐	☐	☑	☐
c) Conflict with any applicable habitat conservation plan or natural community conservation plan?	☐	☐	☑	☐
X. MINERAL RESOURCES -- Would the project:				
a) Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?	☐	☐	☐	☑
b) Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan?	☐	☐	☐	☑
XI. NOISE -- Would the project result in:				
a) Exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?	☐	☐	☑	☐
b) Exposure of persons to or generation of excessive groundborne vibration or groundborne noise levels?	☐	☐	☑	☐
c) A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☐	☑	☐
d) A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?	☐	☑		☐
e) For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?	☐	☐	☑	☐
f) For a project within the vicinity of a private airstrip, would the project expose people residing or working in the project area to excessive noise levels?	☐	☐	☑	☐

	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact
XII. POPULATION AND HOUSING -- Would the project:				
a) Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure)?	☐	☐	☐	☑
b) Displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere?	☐	☐	☐	☑
c) Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere?	☐	☐	☐	☑
XIII. PUBLIC SERVICES				
a) Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:				
Fire protection?	☐	☐	☐	☑
Police protection?	☐	☐	☐	☑
Schools?	☐	☐	☐	☑
Parks?	☐	☐	☐	☑
Other public facilities?	☐	☐	☐	☑
XIV. RECREATION				
a) Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?	☐	☑	☐	☐
b) Does the project include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment?	☐	☐	☐	☑

	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact
XV. TRANSPORTATION/TRAFFIC -- Would the project:				
a) Cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to capacity ratio on roads, or congestion at intersections)?	☐	☐	☑	☐
b) Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways?	☐	☐	☐	☑
c) Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?	☐	☐	☐	☑
d) Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?	☐	☐	☑	☐
e) Result in inadequate emergency access?	☐	☐	☐	☑
f) Result in inadequate parking capacity?	☐	☐	☐	☑
g) Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks)?	☐	☐	☐	☑
XVI. UTILITIES AND SERVICE SYSTEMS -- Would the project:				
a) Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?	☐	☐	☑	☐
b) Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☐	☑	☐	☐
c) Require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?	☐	☐	☑	☐
d) Have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?	☐	☐	☑	☐
e) Result in a determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments?	☐	☐	☑	☐
f) Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?	☐	☐	☑	☐
g) Comply with federal, state, and local statutes and regulations related to solid waste?	☐	☐	☑	☐

	Potentially Significant Impact	Less Than Significant with Mitigation Incorporated	Less Than Significant Impact	No Impact
XVII. MANDATORY FINDINGS OF SIGNIFICANCE				
a) Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of a rare or endangered plant or animal or eliminate important examples of the major periods of California history or prehistory?	☑	☐	☐	☐
b) Does the project have impacts that are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of a project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)?	☑	☐	☐	☐
c) Does the project have environmental effects which will cause substantial adverse effects on human beings, either directly or indirectly?	☐	☐	☑	☐

9.7.3 Discussion of Environmental Checklist Findings

As stated previously, the environmental analysis must include an analysis of the reasonably foreseeable environmental impacts of the methods of compliance and the reasonably foreseeable feasible mitigation measures relating to those impacts. This section provides answers to the questions presented in the environmental checklist.

In formulating these answers, the impacts of implementing structural and non-structural BMPs described in Section 9.5 were evaluated. At this time, the exact type, size, and location of BMPs that might be implemented for future proposed projects to comply with the proposed Action Plan and revised DO objectives are unknown. This analysis considered a range of structural and non-structural BMPs that might be used by responsible parties, but is by no means an exhaustive list of available BMPs. Responsible parties will be required to develop and implement site-specific BMPs to control the discharge of waste from their activities.

Potential impacts of the reasonably foreseeable compliance measures were evaluated with respect to earth, air, water, plant life, animal life, noise, light, land use, natural resources, risk of upset, population, housing, transportation, public services, energy, utilities and services systems, human health, aesthetics, recreation, and archeological/historical concerns. Additionally, mandatory findings of significance regarding short-term, long-term, cumulative and substantial impacts were evaluated. Based on this review, staff concluded that any potentially significant impacts can be mitigated to less than significant levels with the exception of several impacts resulting from dam decommissioning activities.

The evaluation considered whether the construction or implementation of the BMPs would cause a substantial, adverse change in any of the physical conditions within the area affected by the BMP. In addition, the evaluation considered environmental effects in proportion to their severity and probability of occurrence. For the dam decommissioning activities, the environmental analysis was based upon several reports that have analyzed generally the effects of taking out one or more of the dams. Because there is not a proposed project for decommissioning at this time, the evaluation of potential impacts was general in nature and any specific plan for dam removal would require additional analysis.

A significant effect on the environment is defined in statute as "*a substantial, or potentially substantial, adverse change in the environment*" where "*Environment*" is defined by Public Resources Code section 21060.5 as "*the physical conditions which exist within the area which will be affected by a proposed project, including air, water, minerals, flora, fauna, noise, objects of historic or aesthetic significance*."[21]

Social or economic changes related to a physical change of the environment were also considered in determining whether there would be a significant effect on the environment. However, adverse social and economic impacts alone are not significant effects on the environment.

In this analysis, the level of significance was based on baseline or current conditions. Short-term impacts associated with the construction of structural BMPs (with the exception of dam decommissioning activities) were considered less than significant because the impacts due to construction activities are temporary and similar to typical capital improvement projects and maintenance activities currently performed throughout the region. All of the identified impacts are, however, short-term. Until the actual design for dam decommissioning activities is available for review it is impossible to make a determination that all adverse impacts can be mitigated to a less than significant level. Because of this, where it is uncertain whether the potential impacts could be mitigated to levels of insignificance, the Regional Water Board acted conservatively and concluded in this analysis that decommissioning of one or more of the dams would result in a potentially significant impact.

1. Aesthetics: a.) Have a substantial adverse effect on a scenic vista?

Answer: Less than significant.

Discussion: None of the identified compliance measures (e.g. structural and non-structural BMPs) would cause a substantial adverse effect on a scenic vista. None require the permanent construction of a sizable structure that would either block a scenic vista or substantially degrade the vista.

[21] Pub. Resources Code §21068

1. Aesthetics: b.) Substantially damage scenic resources, including, but not limited to, trees, rock outcroppings, and historic buildings within a state scenic highway?

Answer: Less than significant.

Discussion: There are no officially designated state scenic highways in the Klamath River watershed. However, the measures that may be implemented to comply with the Klamath River TMDL and revised DO objectives would not be expected to have an adverse effect on scenic resources.

If a BMP was selected that required land disturbance, such as the construction of a settling basin or a riparian fence, there may be minor surface soil excavation or grading during construction of these structural BMPs, which could result in increased disturbance of the soil. If, however, scenic resources were identified at the site, they would be avoided, and standard construction techniques should not result in damage to scenic resources.

1. Aesthetics: c.) Substantially degrade the existing visual character or quality of the site and its surroundings?

Answer: Less than significant with mitigation.

Discussion: Neither the structural nor the non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would be expected to degrade the existing visual character or quality of a site and its surroundings with the application of appropriate mitigation measures.

Although implementation of structural BMPs could result in some change in visual character or ground surface relief features, most of the compliance measures identified as part of the environmental analysis are of relatively small scale, such as installation of road drainage features, riparian fencing, or tailwater retention systems, that changes to the visual character or quality of the site and its surroundings will not be noticeable. The larger scale projects, such as dam decommissioning, road decommissioning on USFS land, construction of treatment wetlands, or construction of a conventional wastewater treatment facility, will require a project-level analysis of potential environmental effects, including effects on aesthetic resources. Visual impacts associated with dam decommissioning can be addressed through the decommissioning plan by including mitigation measures such as early establishment of native vegetation (grass, forbes and trees) on exposed surfaces.

1. Aesthetics: d.) Create a new source of substantial light or glare which would adversely affect day or nighttime views in the area?

Answer: Less than significant.

Discussion: Neither the structural nor the non-structural compliance measures that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would be expected to create a new source of substantial lighting or glare.

2. Agriculture Resources: a.) In determining whether impacts to agricultural resources are significant environmental effects, lead agencies may refer to the California Agricultural Land Evaluation and Site Assessment Model (1997) prepared by the California Dept. of Conservation as an optional model to use in assessing impacts on agriculture and farmland. Would the project:

Convert Prime Farmland, Unique Farmland, or Farmland of Statewide Importance (Farmland), as shown on the maps prepared pursuant to the Farmland Mapping and Monitoring Program of the California Resources Agency, to non-agricultural use?

Answer: Less than significant.

Discussion: Staff judges that there may be incidental loss of agricultural use in lands mapped as Prime Farmland, Unique Farmland or Farmland of Statewide Importance. These losses, however, would be less than significant because not only do they affect a very narrow band of land on either side of the watercourse. But, as derived from the readily accessible information from the Farmland Mapping and Monitoring Program, no more than 5% of the Klamath River basin is mapped as Prime Farmland, Unique Farmland, and Farmland of Statewide Importance.

2. Agriculture Resources: b.) In determining whether impacts to agricultural resources are significant environmental effects, lead agencies may refer to the California Agricultural Land Evaluation and Site Assessment Model (1997) prepared by the California Dept. of Conservation as an optional model to use in assessing impacts on agriculture and farmland. Would the project:

Conflict with existing zoning for agricultural use, or a Williamson Act contract?

Answer: Less than significant.

Discussion: Neither the structural nor the non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would be expected to conflict with existing zoning for agricultural use, or a Williamson Act contract.

2. Agriculture Resources: c.) In determining whether impacts to agricultural resources are significant environmental effects, lead agencies may refer to the California Agricultural Land Evaluation and Site Assessment Model (1997) prepared by the California Dept. of Conservation as an optional model to use in assessing impacts on agriculture and farmland. Would the project:

Involve other changes in the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use?

Answer: Less than significant.

Discussion: Neither the structural nor the non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan or revised DO objectives would be expected to result in changes to the existing environment which, due to their location or nature, could result in conversion of Farmland, to non-agricultural use. The three KHP dams located in California were built as part of a hydroelectric system and not as part of irrigation deliver system. As such, even in the event of dam decommissioning, no impacts are expected to arise that would result in the conversion of Farmland to non-agricultural use.

3. Air Quality: a.) Where available, the significance criteria established by the applicable air quality management or air pollution control district may be relied upon to make the following determinations. Would the project:

Conflict with or obstruct implementation of the applicable air quality plan?

Answer: Less than significant.

Discussion: Neither the structural nor the non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would be expected to result in any conflicts with or obstruction to the implementation of the applicable air quality plan.

Implementation of structural BMPs that require the use of heavy equipment, such as the dam decommissioning, construction of settling basins, road drainage installation or re-contouring of existing road prisms, could result in vehicle emissions during construction; however, these impacts would be short-term, and would not result in conflicts with, or obstruction of the implementation of the applicable air quality plan.

3. Air Quality: b.) Violate any air quality standard or contribute substantially to an existing or projected air quality violation?

Answer: Less than significant with mitigation.

Discussion: Neither the structural nor the non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would be expected to result in any violation of air quality standards or contribute substantially to an existing or projected air quality violation if appropriate mitigation measures are applied.

The implementation of structural BMPs in order to comply with the requirements of the Action Plan and revised DO objectives could result in the generation of fugitive dust and particulate matter during construction or maintenance activities, which could temporarily impact ambient air quality. Any such impacts would be temporary, and would be controlled with standard construction operations, such as the use of moisture to reduce the transfer of particulates and dust to air and conducting operations when the air quality in the basin is good (i.e. no catastrophic wildfires). The emission of air pollutants during short-term construction activities associated with reasonably foreseeable methods of compliance would not likely change ambient air conditions, because long-term ambient air quality would not change after short-term construction activities are completed.

3. Air Quality: c.) Result in a cumulatively considerable net increase of any criteria pollutant for which the project region is non-attainment under an applicable federal or state ambient air quality standard (including releasing emissions which exceed quantitative thresholds for ozone precursors)?

Answer: Less than significant with mitigation.

Discussion: Neither the structural nor the non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives will result in a cumulatively considerable net increase of any criteria pollutant for which the region is non-attainment under an applicable federal or state ambient air quality standard.

The implementation of BMPs that could result in fine particulate matter and vehicle emissions, such as the BMPs associated with earth movement and dam decommissioning, could contribute to the problems with these pollutants. However, any contribution would be very small, given both the temporary nature of any such impacts and the fairly small nature of any such construction activity given the size of the basin.

3. Air Quality: d.) Expose sensitive receptors to substantial pollutant concentrations?

Answer: Less than significant.

Discussion: Neither the structural nor the non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would be expected to expose sensitive receptors to substantial pollutant concentrations. The primary BMPs expected to be implemented would be to control discharge of earthen and organic matter and are not related to conventional pollutants.

3. Air Quality: e.) Create objectionable odors affecting a substantial number of people?

Answer: Less than significant with mitigation.

Discussion: The majority of the structural and non-structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would not be expected to result in objectionable odors affecting a substantial number of people.

Construction and installation of structural BMPs may result in objectionable odors in the short-term due to exhaust from construction equipment and vehicles, but no more so than during typical construction and maintenance activities currently performed throughout the region. However, certain structural BMPs, such as settling basins and filtration basins, could become a source of objectionable odors if the BMP designs allow for water stagnation or collection of water with sulfur-containing compounds. This could also be the case if anaerobic sediment is exposed to the air as a result of dam removal operations. The application of mitigation measures designed to offset the number of people impacted will likely decrease this to a less than significant effect. Any odors would be very short-lived. Dischargers will be required to monitor the implementation of BMPs to ensure they are working correctly. If a discharger found that odors were occurring from implementation of a settling or filtration basin, measures, such as proper BMP design to eliminate standing water, covers, aeration, filters, barriers, and/or odor suppressing chemical additives, would be required if the odors were becoming a nuisance to the community. The Regional Water Board will require structural BMPs that could result in stagnant water to be inspected regularly to ensure that treatment devices are not clogged, pooling water, odorous, or mosquito vectors.

4. Biological Resources: a.) Would the project:

Have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game (CDFG) or U.S. Fish and Wildlife Service (USFWS)?

Answer: Potentially significant impact.

Discussion: The measures that may be implemented to comply with the proposed Action Plan and revised DO objectives may have a potential impact upon species identified as a candidate, sensitive, or special status species in local or regional plan, policies or regulations or by the CDFG or USFWS if they occur in an area where such species are located.

Non-structural BMPs will not have a substantial adverse effect, either directly or through habitat modifications, on any species identified as a candidate, sensitive, or special status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS.

BMPs that may not have an impact when implemented in one area could potentially have an impact if they are implemented in a sensitive area. Therefore, when installing structural BMPs that involve substantial earth moving, responsible parties will be required under their applicable permit to consult with federal, state and local agencies, including but not limited to the county the project is located in, CDFG and the USFWS, and implement mitigation identified by the agencies to avoid impacts to rare, threatened or endangered species. If no such mitigation is available, the activity would not be permitted without additional review and findings. For example, the Regional Water Board is considering the development of a Basin Plan amendment to provide "Exception Criteria for Restoration Projects" as part of the 2007-2010 Triennial Review process to establish procedures for approving projects that have potentially significant short-term water quality impacts if certain findings can be made after site –specific environmental analysis. USFS and the TRRP both provided comments in support of the development of this amendment during the Triennial Review hearing. In most cases the installation of structural BMPs would be of relatively small scale and any impacts could be avoided by adjusting the timing and/or location of the BMPs to take into account candidate, sensitive, or special status species or their habitats.

Because of these mitigation requirements, substantial adverse effects either directly or through habitat modifications, on any species identified as a candidate, sensitive or special status species in local or regional plans, policies, or regulations, or by the CDFG or USFWS are not expected to occur.

4. Biological Resources: b.) Would the project:

Have a substantial adverse effect on any riparian habitat or other sensitive natural community identified in local or regional plans, policies, regulations, or by the California Department of Fish and Game or US Fish and Wildlife Service?

Answer: Less than significant with mitigation.

Discussion: Substantial adverse effects on any riparian habitat or other sensitive natural community are not expected because the proposed Action Plan requires protection of riparian areas through the application of a temperature-related load allocation for solar radiation (expressed as its inverse shade).

According to one of the dam decommissioning studies approximately 480 acres of riparian area surrounding the three reservoirs could be lost through dam removal. If wetland construction, watershed-wide riparian protection and replanting, and re-vegetation of the exposed reservoir surfaces are applied as mitigation measures the impact from the loss of riparian habit from these sites will likely be less than significant.

The actual impacts associated with this activity would need to be fully evaluated under a federal and/or state environmental impact analysis before decommissioning could occur.

None of the proposed non-structural BMPs would have the potential to adversely affect any riparian habitat or other sensitive natural community of plants identified in local or regional plans, policies, regulations, or by the CDFG or USFWS.

BMPs that may not have an impact when implemented in one area could potentially have an impact if they are implemented in a sensitive area. Therefore, when installing structural BMPs that may include substantial earth moving or other alteration to riparian habitat, responsible parties will be required under their applicable permit, to avoid riparian habitat or other sensitive natural communities.

Because of these mitigation requirements, substantial adverse effects either directly or through habitat modifications, on any species identified as a candidate, sensitive or special status species in local or regional plans, policies, or regulations, or by the California Department of Fish and Game or U.S. Fish and Wildlife Service are not expected to occur.

4. Biological Resources: c.) Would the project:

Have a substantial adverse effect on federally protected wetlands as defined by Section 404 of the Clean Water Act (including, but not limited to, marsh, vernal pool, coastal, etc.) through direct removal, filling, hydrological interruption, or other means?

Answer: Less than significant with mitigation.

Discussion: The application of compliance measures in federally protected wetland areas would not be allowed if doing so would affect the beneficial uses associated with that wetland. All activities in federally protected wetlands, except those statutory exemption like agricultural, require the responsible party to obtain a Clean Water Act 404 permit. The federal permit must include compliance measures that ensure that all water quality objectives for the wetland are protected. Implementation of most BMPs would not be allowed within a wetland because doing so would interfere with the protection of the beneficial uses of that wetland. For example, any BMP that required construction, such as a filtration or siltation basin, would not be allowed in the wetland because it would interfere with the beneficial uses of the wetland.

4. Biological Resources: d.) Would the project:

Interfere substantially with the movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors, or impede the use of native wildlife nursery sites?

Answer: Less than significant with mitigation.

Discussion: The Klamath River and its tributaries provides habitat, including the migration, for both native resident and migratory fish. Most of the reasonably foreseeable compliance measures identified as part of this environmental analysis will likely not interfere with the movement of these species. However, although dam removal would ultimately result in greater movement for spawning fish, significant adverse effects on fish movement could occur at least temporarily unless appropriate mitigation is implemented to limit the duration of increased turbidly associated with dam removal and the decommissioning activities are timed to protect the most sensitive species/life stages.

A migratory corridor is generally described as a landscape feature (such as a ridgeline, canyon, or riparian strip) within a larger natural habitat area that is used frequently by animals to facilitate movement and provide access to necessary resources such as water, food, or den sites. Wildlife corridors are generally an area of habitat, usually linear in nature, which connect two or more habitat patches that would otherwise be fragmented or isolated from one another. It is unlikely that construction of structural BMPs for compliance with the proposed Action Plan and revised DO objectives would restrict wildlife movement because the sizes of the compliance measures are generally too small to obstruct a corridor.

However, if a responsible party will be conducting substantial earth movement to implement BMPs, they are encouraged to consult with various Federal, State and local agencies, including but not limited to the CDFG and the USFWS to confirm that the BMPs would not substantially interfere with movement of any native resident or migratory fish or wildlife species or with established native resident or migratory wildlife corridors and native wildlife nursery. If there was the potential for an adverse impact to wildlife migration and/or use of a native wildlife nursery, the timing of the discharge or the location of the BMP would have to be changed to avoid the impact. None of the structural BMPs would, therefore, result in direct or reasonably foreseeable indirect impacts to fish and wildlife movement, migration or use of a native wildlife nursery site.

None of the non-structural BMPs that are reasonably foreseeable means of compliance with the Basin Plan Amendments will result in a barrier to the migration or movement of aquatic or wildlife species.

4. Biological Resources: e.) Would the project:

Conflict with any local policies or ordinances protecting biological resources, such as a tree preservation policy or ordinance?

Answer: Less than significant with mitigation.

Discussion: The reasonably foreseeable compliance measures that would be implemented to comply with the proposed Action Plan and revised DO objectives are not expected to conflict with ordinances protecting biological resources, such as a tree preservation policy.

4. Biological Resources: f.) Would the project:

Conflict with the provisions of an adopted Habitat Conservation Plan, Natural Community Conservation Plan, or other approved local, regional, or state habitat conservation plan?

Answer: Less than significant.

Discussion: It is unlikely that the implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the revised DO objectives would conflict with the provisions of an adopted Habitat Conservation Plan (HCP), Natural Community Conservation Plan or other approved local, regional, or state habitat conservation plan. More likely the compliance measures would be similar to measures already committed to under other plans. Such similarities are likely to ensure that compliance measures are in alignment with any adopted Habitat Conservation Plan, Natural Community Conservation Plan or other approved local, regional, or state habitat conservation plan.

5. Cultural Resources: a.) Would the project:

Cause a substantial adverse change in the significance of a historical resource as defined in § 15064.5

Answer: Less than significant with mitigation.

Discussion: The implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would not result in the alteration of a significant historical resource. Non-structural BMPs will not result in the alteration of a significant historical resource because none of the non-structural BMPs would involve any physical effects.

Similarly, it is unlikely that implementation of any structural BMP would result in a substantial adverse change in the significance of a historical resource. However, in cases where the installation of structural BMPs may involve large scale excavation activities or the construction of a large scale infrastructure, a cultural resources investigation should be conducted before any substantial disturbance of land that has not been disturbed previously. The cultural resources investigation will include, at a minimum, a records search for previously identified cultural resources and previously conducted cultural resources investigations of the project parcel and vicinity.

5. Cultural Resources: b.) Would the project:

Cause a substantial adverse change in the significance of an archaeological resource pursuant to § 15064.5?

Answer: Less than significant with mitigation.

Discussion: It is unlikely that the implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would cause a substantial adverse change in the significance of an archaeological resource pursuant to section 15064.5. Non-structural BMPs will not cause a substantial adverse change in the significance of an archaeological resource pursuant to section 15064.5.

Similarly, it is unlikely that implementation of any structural BMP would cause a substantial adverse change in the significance of an archaeological resource pursuant to section 15064.5. However, in cases where the installation of structural BMPs may involve excavation activities (such as dam decommissioning), a cultural resources investigation should be conducted before any substantial disturbance of land that has not been disturbed previously. The cultural resources investigation should include, at a minimum, a records search for previously identified cultural resources and previously conducted cultural resources investigations of the project parcel and vicinity. This record search should also include, at a minimum, contacting the appropriate information center of the California Historical Resources Information System, operated under the auspices of the California Office of Historic Preservation. In coordination with the information center or a qualified archaeologist, a determination regarding whether previously identified cultural resources will be affected by the proposed project must be made and if previously conducted investigations were performed to satisfy the requirements of CEQA. If not, a cultural resources survey would need to be conducted. The purpose of this investigation would be to identify resources before they are affected by a proposed project and avoid the impact. If the impact is unavoidable, mitigation will be determined on a case-by-case basis, as warranted.

5. Cultural Resources: c.) Would the project:

Directly or indirectly destroy a unique paleontological resource or site or unique geologic feature?

Answer: Less than significant.

Discussion: The implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would not directly or indirectly destroy a unique paleontological resource or site or unique geologic feature. Non-structural BMPs will not result in the direct or indirect destruction of a unique paleontological resource or site or unique geologic feature.

Similarly, it is unlikely that implementation of any structural BMP would result in the destruction of a unique paleontological resource or site or unique geologic feature. However, in cases where the installation of structural BMPs may involve excavation activities, an investigation of paleontological resources would need to be conducted by a trained professional before any substantial disturbance of land that has not been disturbed previously.

5. Cultural Resources: d.) Would the project:

Disturb any human remains, including those interred outside of formal cemeteries?

Answer: Less than significant.

Discussion: It is staff's judgment the selection and implementation of appropriately designed measures to comply with the proposed Action Plan and revised DO objectives will not directly or indirectly result in the disturbance of any human remains, including those interred outside of formal cemeteries.

Similarly, it is unlikely that implementation of any structural BMP would cause a substantial adverse change in the significance of an archaeological resource pursuant to section 15064.5. However, in cases where the installation of structural BMPs or dam decommissioning may involve excavation activities, a cultural resources investigation should be conducted before any substantial disturbance of land that has not been disturbed previously. The cultural resources investigation should include, at a minimum, a records search for previously identified cultural resources and previously conducted cultural resources investigations of the project parcel and vicinity. This record search should also include, at a minimum, contacting the appropriate information center of the California Historical Resources Information System, operated under the auspices of the California Office of Historic Preservation. In coordination with the information center or a qualified archaeologist, a determination regarding whether previously identified cultural resources will be affected by the proposed project must be made and if previously conducted investigations were performed to satisfy the requirements of CEQA. If not, a cultural resources survey would need to be conducted. The purpose of this investigation would be to identify resources before they are affected by a proposed project and avoid the impact. If the impact is unavoidable, mitigation will be determined on a case-by-case basis, as warranted.

This space intentionally left blank.

6. Geology and Soils: a.)(i) Would the project:

Expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault? Refer to Division of Mines and Geology Special Publication 42.

Answer: No impact.

Discussion: Implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would not result in exposing people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving rupture of a known earthquake fault, as delineated on the most recent Alquist-Priolo Earthquake Fault Zoning Map issued by the State Geologist for the area or based on other substantial evidence of a known fault as there will be no means of compliance involving moving permanent structures or people onto an earthquake fault.

6. Geology and Soils: a)(ii) Would the project:

Expose people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving strong seismic ground shaking?

Answer: No impact.

Discussion: Implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would not expose people or structures to potential substantial adverse effects, including the risk of loss, injury, or death involving strong seismic ground shaking as there will be no implementation of compliance measures involving moving permanent structures or people onto an earthquake fault.

6. Geology and Soils: a.)(iii) Would the project:

Expose people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving seismic-related ground failure, including liquefaction.

Answer: No impact.

Discussion: Implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would not expose people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving seismic-related ground failure, including liquefaction as none of the reasonably foreseeable compliance measures involves moving permanent structures or people into an area potential susceptible to liquefaction.

6. Geology and Soils: a.)(iv) Would the project:

Expose people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving landslides?

Answer: Less than significant with mitigation.

Discussion: Implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would not expose people or structures to potential substantial adverse effects, including the risk of loss, injury or death involving landslides as none of the reasonably foreseeable compliance measures involves moving permanent structures or people into an area potentially subject to landslides.

6. Geology and Soils: b.) Would the project:

Result in substantial soil erosion or the loss of topsoil?

Answer: Less than significant with mitigation.

Discussion: Implementation of compliance measures as recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives may result in minor, temporary soil excavation or disturbance during implementation of compliance measures that involve construction of structural BMPs such as road drainage installation, field leveling for irrigation management or installation of off channel stock watering ponds. However, construction related erosion impacts will cease with the cessation of construction activity. Appropriate selection, implementation and maintenance of mitigation measures to prevent concentration of water and exposure of disturbed (unprotected) soil to rainfall and winds will result in less than significant loss of top soil or substantial soil erosion.

6. Geology and Soils: c.) Would the project:

Be located on a geologic unit or soil that is unstable, or that would become unstable as a result of the project, and potentially result in on- or off-site landslide, lateral spreading, subsidence, liquefaction or collapse?

Answer: Less than significant with mitigation.

Discussion: Most structural BMPs that were recommended under the proposed implementation plan and as necessary to comply with the TMDL load allocations and revised DO objectives would not have any significant adverse effect if located on unstable soil, nor would they cause soil to become unstable. The road related compliance measures encourage locating roads on stable terrain and preventing the placement of road material on unstable slopes that could cause a landslide or other type of mass wasting event.

> **6. Geology and Soils: d.)** Would the project:
>
> Be located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), creating substantial risks to life or property?
>
> **Answer**: No impact.

Discussion: Even if structural BMPs that were recommended under the proposed implementation plan as necessary to comply with the TMDL load allocations and revised DO objectives were located on expansive soil, as defined in Table 18-1-B of the Uniform Building Code (1994), they would not create substantial risks to life or property. The structural BMPs that have been identified as the foreseeable means of compliance do not involve moving permanent structures or people into a new area, and so there would be no risk to life or property created.

> **6. Geology and Soils: e.)** Would the project:
>
> Have soils incapable of adequately supporting the use of septic tanks or alternative waste water disposal systems where sewers are not available for the disposal of waste water?
>
> **Answer**: Less than significant.

Discussion: There is no data to date that indicates that septic tanks are contributing to the impairment of the Klamath River due to soil conditions. It is staff's judgment that the proposed Action Plan (and the identified compliance measures) will not result in significant impacts from septic tanks or alternative waste water disposal systems.

> **7. Hazards and Hazardous Materials: a.)** Would the project:
>
> Create a significant hazard to the public or the environment through the routine transport, use, or disposal of hazardous materials?
>
> **Answer**: Less than significant.

Discussion: It is staff's judgment that none of the identified compliance measures would create a significant hazard to the public or the environment through the routine transport, use or disposal of hazardous materials. There is the possibility that hazardous materials (e.g., oil, gasoline) may be transported to a site and be present during compliance measure construction and installation activities. Any potential risks of exposure would be small, especially with proper handling and storage procedures. All risks of exposure would be short term and would be eliminated with the completion of compliance measure construction and installation activities.

7. Hazards and Hazardous Materials: b.) Would the project:

Create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment?

Answer: Less than significant with mitigation.

Discussion: The implementation of non-structural BMPs to comply with the requirements of the proposed Action Plan and revised DO objectives would not create a significant hazard to the public or the environment through reasonably foreseeable upset and accident conditions involving the release of hazardous materials into the environment.

The structural compliance measures that may be used to comply with the requirements of the proposed Action Plan, with the exception of dam decommissioning, would not be subject to explosion or the release of hazardous substances in the event of an accident because these types of substances would not be present. Again, there is the possibility that hazardous materials (e.g., oil, gasoline) may be present during construction and installation activities, but potential risks of exposure would be small, especially with proper handling and storage procedures. All risks of exposure would be short term and would be eliminated with the completion of construction and installation activities.

The dam decommissioning studies evaluated to develop this environmental analysis were all premised on the use of blasting (explosives) to remove the concrete dam and related structures. Any blasting activities would need to be conducted by a licensed professional and mitigation measures clearly described in the dam decommissioning plan, including a transportation plan for the explosive materials. At a minimum these measures should include, all non-essential workers being prohibited from entering the site and stationed downwind at a safe distance away from blasting operations.

The presence of hazardous materials stored in the sediments trapped behind the reservoirs would need to be thoroughly analyzed prior to any dam decommissioning that proposed the release of sediment and associated waste into the Klamath River. The dam decommissioning plan would need to include a proposal to allow for the characterization of the in-reservoir sediment to ensure that any material identified as hazardous is not released into the environment.

This space intentionally left blank.

7. Hazards and Hazardous Materials: c.) Would the project:

Emit hazardous emissions or handle hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school?

Answer: Less than significant.

Discussion: The implementation of non-structural and structural BMPs that would potentially be used to comply with the requirements of the proposed Action Plan and revised DO objectives would not reasonably emit hazardous emissions or result in the handling of hazardous or acutely hazardous materials, substances, or waste within one-quarter mile of an existing or proposed school. Again, there is the possibility that hazardous materials (e.g., oil, gasoline) may be present during construction and installation activities, but potential risks of exposure would be small, especially with proper handling and storage procedures. All risks of exposure would be short term and would be eliminated with the completion of construction and installation activities.

7. Hazards and Hazardous Materials: d.) Would the project:

Be located on a site which is included on a list of hazardous materials sites compiled pursuant to Government Code Section 65962.5 and, as a result, would it create a significant hazard to the public or the environment?

Answer: Less than significant.

Discussion: The measures that may be reasonably used to comply with the requirements of the proposed Action Plan and revised DO objectives would not likely be located on a site which is on a list of hazardous materials sites. The location of these sites are well known throughout the Region and are subject to regulation by the Regional Water Board and/or USEPA.

7. Hazards and Hazardous Materials: e.)
For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project result in a safety hazard for people residing or working in the project area?

Answer: No impact.

Discussion: It is unlikely that the compliance measures identified in this SED would result in a safety hazard for people residing or working in the project area due to the relatively small scale of the structural BMPs contemplated for use by responsible parties.

This space intentionally left blank.

7. Hazards and Hazardous Materials: f.)
For a project within the vicinity of a private airstrip, would the project result in a safety hazard for people residing or working in the project area?

Answer: Less than significant.

Discussion: Under the unlikely possibly that installation of compliance measures involving structural BMPs were located in the vicinity of a private airstrip, they would not result in a safety hazard for people residing or working in the project area due to the relatively small scale of the structural BMPs contemplated for use by responsible parties.

7. Hazards and Hazardous Materials: g.) Would the project:
Impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural or non-structural BMPs that would impair implementation of or physically interfere with an adopted emergency response plan or emergency evacuation plan. Consideration of public health and safety is a key component in the development of site specific compliance measures for road construction and maintenance activities.

7. Hazards and Hazardous Materials: h.) Would the project:
Expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands?

Answer: No impact.

Discussion: None of the structural and non-structural BMPs identified in this SED would expose people or structures to a significant risk of loss, injury or death involving wildland fires, including where wildlands are adjacent to urbanized areas or where residences are intermixed with wildlands.

8. Hydrology And Water Quality: a.) Would the project:
Violate any water quality standards or waste discharge requirements?

Answer: Potentially significant impacts.

Discussion: By requiring the implementation of compliance measures to reduce pollutants and the implementation of management plans to control all sources of non-point pollution, it is anticipated that compliance with the proposed TMDL Action Plan and revised DO objectives will have an overall beneficial impact on water quality in the Klamath River watershed. The creation of a comprehensive regulatory process by which the implementation of compliance measures (non-structural and/or structural BMPs) by all responsible parties in the watershed for all non-point sources of pollution will dramatically minimize the level of pollutants discharged to waterbodies and will help ensure that waterbodies will meet water quality objectives and that beneficial uses are protected and restored.

If a decision is reached by the KHSA Settlement Parties that one or more of PacifiCorps dams in California will be decommissioned, then potentially significant adverse impacts to the water quality standards in place for the Klamath River could likely occur.

The dam decommissioning studies used to develop this environmental analysis indicate that the primary environmental impact associated with dam removal is the short term impact to water quality from the release of the stored in-reservoir sediment. The studies indicate that the material is primarily fine grained and will likely stay in suspension until it reaches the ocean. Based on conditions in the watershed (e.g. “wet” versus “dry” water year) the increase turbidity and suspended sediment loads could last from weeks to months. It is almost certain that dam decommissioning will result in potentially significant environmental impacts due to in increased turbidity and suspended sediment loads, which would likely violate Basin Plan water quality standards for turbidity and suspended sediment. Short term water quality violations may be acceptable in cases where long term benefits to be beneficial uses outweigh short term impacts, based on detailed, site-specific information and findings.

8. Hydrology And Water Quality: b.) Would the project:
Substantially deplete groundwater supplies or interfere substantially with groundwater recharge such that there would be a net deficit in aquifer volume or a lowering of the local groundwater table level (e.g., the production rate of pre-existing nearby wells would drop to a level which would not support existing land uses or planned uses for which permits have been granted)?

Answer: Less than significant.

Discussion: The proposed implementation plan has only identified one compliance measure that could potentially affect ground water supplies. This measure contemplates the use of groundwater (via well construction) in lieu of on-stream livestock watering. Due to the likely dispersed nature of this compliance measure and the relatively high cost in well development, it is staff’s judgment that the use of wells in lieu of other off-stream watering systems (e.g. spring development) will result in a less than significant risk of substantially depleting groundwater.

8. Hydrology And Water Quality: c.) Would the project:
Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, in a manner which would result in substantial erosion or siltation on- or off-site?

Answer: Potentially significant impacts.

Discussion: This SED has identified a number of compliance measures that could result in the construction of structural BMPs, such as infiltration basins, field leveling or road construction, which could potentially cause an alteration of the existing drainage pattern of a site. In most cases however, these measures would be small and installed with appropriately designed mitigation measures, which would limit any alteration of the existing drainage pattern, and therefore would not result in substantial erosion of siltation on- or off-site.

The exception would be in the event of dam decommissioning when the Klamath River would establish a new channel through the reservoirs. The studies evaluated by Regional Water Board staff indicated that the greatest impacts from erosion or siltation would be during drawing down of the reservoir water level. However, once a new channel was established, the erosion of the in-reservoir sediment would dissipate.

8. Hydrology And Water Quality: d.) Would the project:
Substantially alter the existing drainage pattern of the site or area, including through the alteration of the course of a stream or river, or substantially increase the rate or amount of surface runoff in a manner which would result in flooding on- or off-site?

Answer: Less than significant.

Discussion: This SED has identified a number of compliance measures that could result in the construction of structural BMPs such as infiltration basins, field leveling or road construction, which could potentially cause an alteration of the existing drainage pattern of a site. In most cases however, these measures would be small and be installed with appropriately designed mitigation measures, which would reduce the chance of alterations of the existing drainage pattern causing an increased rate or amount of surface runoff in a manner which would result in flooding on- or off-site.

8. Hydrology And Water Quality: e.) Would the project:
Create or contribute runoff water which would exceed the capacity of existing or planned storm water drainage systems or provide substantial additional sources of polluted runoff?

Answer: Less than significant.

Discussion: It is unlikely that the compliance measures identified in this SED would be located in either an area that was serviced by an existing or a planned storm water drainage system due to the lack of urbanized areas with storm drain systems in the Klamath River watershed. In addition, the implementation of properly designed compliance measures would not result in the concentration of runoff.

8. Hydrology And Water Quality: f.) Would the project:
Otherwise substantially degrade water quality?

Answer: Less than significant impact.

Discussion: As the goal of this project is to develop and implement a comprehensive watershed recovery plan for the restoration of the beneficial uses of water in the Klamath River, it is staff's judgment that it is extremely unlikely that thoughtfully selected, well-designed and implemented compliance measures would result in the substantial degradation of water quality. The exception to this is dam decommissioning and its impacts are addressed above under 8a and 8c above.

8. Hydrology And Water Quality: g.) Would the project:
Place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map?

Answer: Less than significant impact.

Discussion: None of the compliance measures identified in this SED would place housing within a 100-year flood hazard area as mapped on a federal Flood Hazard Boundary or Flood Insurance Rate Map or other flood hazard delineation map.

Staff has determined that this finding is still appropriate even under a dam decommissioning scenario as the dams were not designed nor operated as flood control structures. As such their ultimately removal would not significant impact housing with a flood area as described above.

8. Hydrology And Water Quality: h.) Would the project:
Place within a 100-year flood hazard area structures which would impede or redirect flood flows?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED would place structures within a 100-year flood hazard area which would impede or redirect flood flows.

8. Hydrology And Water Quality: i.) Would the project:
Expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of non-structural or structural BMPs that would expose people or structures to a significant risk of loss, injury or death involving flooding, including flooding as a result of the failure of a levee or dam.

8. Hydrology And Water Quality: j.) Would the project:
Cause inundation by seiche, tsunami, or mudflow?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of non-structural or structural BMPs that would cause inundation by seiche, tsunami, or mudflow.

9. Land Use And Planning: a.) Would the project:
Physically divide an established community?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of non-structural or structural BMPs that would physically divide an established community.

9. Land Use And Planning: b.) Would the project:
Conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect?

Answer: Less than significant.

Discussion: The primary goal of this project is the protection and restoration of water quality and beneficial uses of water in the Klamath River watershed.

Therefore, it is staff's judgment that it is unlikely that compliance with the proposed Action Plan and revised DO objectives would conflict with any applicable land use plan, policy, or regulation of an agency with jurisdiction over the project (including, but not limited to the general plan, specific plan, local coastal program, or zoning ordinance) adopted for the purpose of avoiding or mitigating an environmental effect

9. Land Use And Planning: c.) Would the project:
Conflict with any applicable habitat conservation plan or natural community conservation plan?

Answer: Less than significant.

Discussion: It is unlikely that measures implemented to comply with this proposed Action Plan and revised DO objectives could conflict with the provisions of an adopted Habitat Conservation Plan or Natural Community Conservation Plan, as explained previously in the question 4(f), above.

Depending on the structural BMPs selected, direct or indirect impacts to existing fish or wildlife habitat may occur; however, any such impact would be temporary. BMPs that may not have an impact when implemented in one area could potentially have an impact if they are implemented in a sensitive area. Therefore, when installing structural BMPs that may include substantial earth movement, responsible parties will be required under their applicable permit (or as necessary to comply with applicable prohibitions), to consult with various Federal, State and local agencies, including but not limited to the county the project is located in, CDFG and the USFWS. If appropriate to avoid conflicts with any Habitat Conservation Plan or Natural Community Conservation Plan, the timing and/or location of the BMPs may be adjusted to reduce any potential conflict with any Habitat Conservation Plan or Natural Community Conservation Plan. If, however, such adjustments could not be made, the BMP would have to be changed to avoid any adverse impacts to rare, threatened or endangered species, or the discharge would not be permitted to occur.

Because of these mitigation requirements, conflict with the provisions of an adopted Habitat Conservation Plan or Natural Community Conservation Plan is not likely to occur.

10. Mineral Resources: **a.)** Would the project:
Result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of non-structural or structural BMPs that would result in the loss of availability of a known mineral resource that would be of value to the region and the residents of the state.

10. Mineral Resources: b.) Would the project:
Result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of non-structural or structural BMPs that would result in the loss of availability of a locally-important mineral resource recovery site delineated on a local general plan, specific plan or other land use plan.

11. Noise: a.) Would the project result in:
Exposure of persons to or generation of noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in an increase in exposure of persons to, or generation of, noise levels in excess of standards established in the local general plan or noise ordinance, or applicable standards of other agencies.

The implementation of some structural BMPs may result in localized increased noise levels. Such increased noise levels would likely be associated with heavy equipment operation associated with construction of structural BMPs. These impacts would be temporary, associated with the use of heavy equipment and would, therefore, not considered to be a significant impact.

11. Noise: b.) Would the project result in:
Exposure of persons to or generation of excessive ground-borne vibration or ground-borne noise levels?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in the exposure of persons to or generation of excessive ground-borne vibration or ground-borne noise levels.

The implementation of some structural BMPs may result in localized increased ground-borne vibration or ground-borne noise levels. Such increased levels would likely be associated with heavy equipment operation associated with construction of structural BMPs. These impacts would, however, be temporary and associated directly with the use of heavy equipment. Therefore, staff judges that the impact would not be considered significant.

11. Noise: c.) Would the project result in:
A substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in a substantial permanent increase in ambient noise levels in the project vicinity above levels existing without the project as noise generation is associated with the short term, temporary use of heavy equipment.

11. Noise: d.) Would the project result in:
A substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project?

Answer: Less than significant with mitigation.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in a substantial temporary or periodic increase in ambient noise levels in the project vicinity above levels existing without the project with the exception of a dam decommissioning scenario.

The construction and installation of some structural BMPs, such as filtration or settling basins, could result in temporary increases in existing noise levels, but this would be short term and only exist until construction is completed. The noise associated with the construction and installation of structural BMPs would be the same as typical construction activities in rural and urbanized areas, such as ordinary road and infrastructure maintenance and building activities. Although noise will be increased in the vicinity of where BMPs requiring heavy equipment use are constructed, these noise impacts will not be substantial.

Dam decommissioning activities will likely involve drilling and blasting of the concrete structures, this will likely cause an impact to the noise level in the surrounding communities. With the application of appropriate mitigation measures, such as notifying the community of noise generating activities such as drilling and blasting to allow for those sensitive to high noise levels to voluntarily be re-located during those periods or protect their hearing in other ways (e.g. staying indoors, using hearing protection), the impact would be less than significant.

11. Noise: e.) Would the project result in:
For a project located within an airport land use plan or, where such a plan has not been adopted, within two miles of a public airport or public use airport, would the project expose people residing or working in the project area to excessive noise levels?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would likely be located within an airport land use plan or within two miles of a public airport or public use airport. However, even if this were to occur, the implementation of the compliance measures would not result in excessive noise levels. The use of heavy equipment for the construction and installation of some structural BMPs could result in temporary increases in existing noise levels, but the noise associated with heavy equipment use is not any louder than noises that would typically occur within two miles of an airport.

11. Noise: f.) Would the project result in:
For a project within the vicinity of a private airstrip, would the project expose people residing or working in the project area to excessive noise levels?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would likely be located in the vicinity of a private airstrip.

However, even if this were to occur, the compliance measures identified in this SED would not result in excessive noise levels. The use of heavy equipment for the construction and installation of some structural BMPs could result in temporary increases in existing noise levels, but the noise associated with heavy equipment use is not any louder than noises that would typically occur within the vicinity of a private airstrip.

12. Population And Housing: a.) Would the project:
Induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure)?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would induce substantial population growth in an area, either directly (for example, by proposing new homes and businesses) or indirectly (for example, through extension of roads or other infrastructure).

12. Population And Housing: b.) Would the project:
Displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would displace substantial numbers of existing housing, necessitating the construction of replacement housing elsewhere.

12. Population And Housing: c.) Would the project:
Displace substantial numbers of people, necessitating the construction of replacement housing elsewhere?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED would displace substantial numbers of people, necessitating the construction of replacement housing elsewhere.

This space intentionally left blank.

13. Public Services: a.)
Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:

Fire protection?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would have an effect upon, or result in a need for new or altered fire protection services.

13. Public Services: b.)
Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:

Police protection?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would have an effect upon, or result in a need for new or altered police protection services.

13. Public Services: c.)
Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:

Schools?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would have an effect upon, or result in a need for new or altered schools or school services.

13. Public Services: d.)

Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:

Parks?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would have an effect upon, or result in a need for new or altered parks.

13. Public Services: e.)

Would the project result in substantial adverse physical impacts associated with the provision of new or physically altered governmental facilities, need for new or physically altered governmental facilities, the construction of which could cause significant environmental impacts, in order to maintain acceptable service ratios, response times or other performance objectives for any of the public services:

Other public facilities?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would have an effect upon public facilities.

14. Recreation: a.)

Would the project increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated?

Answer: Less than significant with mitigation.

Discussion: None of the compliance measures identified in this SED, with the exception of dam decommissioning, contemplate the use of structural BMPs that would increase the use of existing neighborhood and regional parks or other recreational facilities such that substantial physical deterioration of the facility would occur or be accelerated.

In the event that the three reservoirs are decommissioned, flatwater recreation users will have to use the other flatwater facilities in the region. Once a decommissioning plan is developed, mitigation measures identified in the plan must include measures to ensure that the other regional facilities have the infrastructure in place to support the increased user base. Likely mitigation measures could include such things as installation of restrooms, boat ramps, garbage service, etc.

14. Recreation: b.)

Does the project include recreational facilities or require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment?

Answer: No impact

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would require the construction or expansion of recreational facilities which might have an adverse physical effect on the environment.

15. Transportation/Traffic: a.) Would the project:

Cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to capacity ratio on roads, or congestion at intersections)?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED, other than for centralized treatment, contemplate the use of structural BMPs that would cause an increase in traffic which is substantial in relation to the existing traffic load and capacity of the street system (i.e., result in a substantial increase in either the number of vehicle trips, the volume to capacity ratio on roads, or congestion at intersections). If the centralized treatment option is pursued a site specific environmental analysis to comply with CEQA would be required. This site specific analysis would provide the level of detail needed to evaluate the related traffic impacts and potential mitigation measures.

15. Transportation/Traffic: b.) Would the project:

Exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways?

Answer: No impact.

Discussion None of the compliance measures identified in this SED, other than for centralized treatment, contemplate the use of structural BMPs that would exceed, either individually or cumulatively, a level of service standard established by the county congestion management agency for designated roads or highways. See discussion above more on centralized treatment analysis.

15. Transportation/Traffic: c.) Would the project:

Result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in a change in air traffic patterns, including either an increase in traffic levels or a change in location that results in substantial safety risks.

15. Transportation/Traffic: d.) Would the project:

Substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses (e.g., farm equipment)?

Answer: Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would substantially increase hazards due to a design feature (e.g., sharp curves or dangerous intersections) or incompatible uses.

15. Transportation/Traffic: e.) Would the project:

Result in inadequate emergency access?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in inadequate emergency access.

15. Transportation/Traffic: f.) Would the project:

Result in inadequate parking capacity?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in inadequate parking capacity.

15. Transportation/Traffic: g.) Would the project:

Conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks)?

Answer: No impact.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would conflict with adopted policies, plans, or programs supporting alternative transportation (e.g., bus turnouts, bicycle racks).

> **16. Utilities and Service Systems: a.)** Would the project:
>
> Exceed wastewater treatment requirements of the applicable Regional Water Quality Control Board?
>
> **Answer:** Less than significant.

Discussion None of the compliance measures identified in this SED contemplate the use of structural BMPs would cause any exceedence of wastewater treatment requirements.

> **16. Utilities and Service Systems: b.)** Would the project:
>
> Require or result in the construction of new water or wastewater treatment facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?
>
> **Answer:** Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in a wastewater treatment provider needing to expand existing treatment facilities.

> **16. Utilities and Service Systems: c.)** Would the project:
>
> Require or result in the construction of new storm water drainage facilities or expansion of existing facilities, the construction of which could cause significant environmental effects?
>
> **Answer:** Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would result in a need for new storm water systems or the expansion of existing facilities.

> **16. Utilities and Service Systems: d.)** Would the project:
>
> Have sufficient water supplies available to serve the project from existing entitlements and resources, or are new or expanded entitlements needed?
>
> **Answer:** Less than significant.

Discussion: None of the compliance measures identified in this SED contemplate the use of structural BMPs that would require new or expanded entitlements for water supplies.

A number of compliance measures identified in this SED include use of water supplies for such things as dust abatement on native surface roads, construction of off-channel livestock watering facilities or temporary irrigation for riparian restoration (tree planting) activities. The selection of the appropriate compliance measures by responsible parties will need to take into consideration their existing water resources. Basing selection of compliance measures on existing water resources will prevent the need to seek new entitlements.

16. Utilities and Service Systems: e.) Would the project:

Result in a determination by the wastewater treatment provider which serves or may serve the project that it has adequate capacity to serve the project's projected demand in addition to the provider's existing commitments?

Answer: Less than significant.

Discussion: It is unlikely that the implementation of compliance measures identified in this SED as would be located in areas serviced by a wastewater treatment provider. Therefore it is unlikely that implementation of the structural BMPS identified in this SED will have resulted in the need for the treatment provider to make this determination.

16. Utilities and Service Systems: f.) Would the project:

Be served by a landfill with sufficient permitted capacity to accommodate the project's solid waste disposal needs?

Answer: Less than significant.

Discussion: Other than the discussion of compliance measures for algae dewatering and disposal, none of the compliance measures identified in this SED contemplate the use of structural BMPs that would generate a significant source of solid waste contemplate. Not much information was provide on the solid waste disposal aspects of the algae dewatering options, as such analysis of the possible impacts and potential mitigation measures would be based on conjecture and speculation. If this option were selected a site specific environmental analysis (most likely an environmental impact report [EIR]) would be required to comply with CEQA.

Construction and implementation of structural BMPs may generate solid wastes requiring disposal such as earthen material or erosion control materials (e.g. silt fences, temporary fencing, rusted out culverts). The amount of waste needing disposal, however, will be very minimal, and could therefore be served by an existing landfill.

16. Utilities and Service Systems: g.) Would the project:

Comply with federal, state, and local statutes and regulations related to solid waste?

Answer: Less than significant.

Discussion: As noted above, implementation of structural BMPs to comply with requirements of the proposed Action Plan and revised DO objectives will generate very little solid waste. There will, therefore, be no problems with compliance with federal, state, and local statutes and regulations related to solid waste disposal. See discussion above for more on potential impacts related to landfills.

In the event of dam decommissioning, a disposal site for the waste concrete will need to be designated. Given the re-use of concrete debris for building material (riprap, reuse at concrete batch plants) it is unlikely that a significant amount of solid waste would be generated from dam decommissioning.

17. Mandatory Findings of Significance:

Does the project have the potential to degrade the quality of the environment, substantially reduce the habitat of a fish or wildlife species, cause a fish or wildlife population to drop below self-sustaining levels, threaten to eliminate a plant or animal community, reduce the number or restrict the range of a rare or endangered plant or animal or eliminate important examples of the major periods of California history or prehistory?

Answer: Potentially significant impacts.

Discussion: All of these compliance measures identified in this environmental analysis will likely improve water quality from the current baseline, where many discharges of pollutants are currently occurring in the watershed and will likely continue without the application of these additional protections. This also would be the case if the Parties involved in the AIP decide to decommission one of more of PacifiCorps' dams in California.

Non-structural BMPs will not result in the substantial degradation of the environment for plant and animal species because none of the non-structural BMPs would have any physical effects that could degrade the environment or impact plant or animal species.

As discussed above, under Biological Resources- Category 4d, plant and animal species could potentially be adversely affected by the installation and operation of structural BMPs that involve substantial earth movement. If a responsible party proposed installation of a BMP that would require substantial earth movement, the discharger would be required to consult with federal, state and local agencies, including but not limited to the county the project is located in, CDFG and the USFWS, and implement mitigation identified by the agencies to avoid impacts to rare, threatened or endangered species. If no such mitigation is available, the use of that compliance measure in the specific area should not be implemented. In most cases the installation of structural

BMPs would be temporary, and any impacts could be avoided by adjusting the timing and/or location of the BMPs to take into account any candidate, sensitive, or special status species or their habitats.

The exception to this would be short term impacts associated with dam decommissioning which has the potentially to significantly impact water quality from the release of increased loads of fine grained sediment. It is estimated that impacts to water quality would range from weeks to months with the application of appropriate mitigation measures.

The potential impacts of the project will not cause a significant cumulative impact in the environment with the exception of a dam decommissioning scenario. In fact, the adoption of the proposed Action Plan and revised DO objectives should result in improved water quality in the Klamath River watershed and will have significant beneficial affects on the environment over the long term.

17. Mandatory Findings of Significance:

Does the project have impacts that are individually limited, but cumulatively considerable? ("Cumulatively considerable" means that the incremental effects of a project are considerable when viewed in connection with the effects of past projects, the effects of other current projects, and the effects of probable future projects)?

Answer: Potentially significant impacts.

Discussion: Cumulative impacts, defined in section 15355 of the CEQA Guidelines, refer to two or more individual effects, that when considered together, are considerable or that increase other environmental impacts. Cumulative impact assessment must consider not only the impacts of the proposed Action Plan and revised DO objectives, but also the impacts from other Basin Plan Amendments, municipal, and private projects, which have occurred in the past, are presently occurring, and may occur in the future, in the watershed during the period of implementation.

Structural BMPs that may be implemented are not likely to have cumulative impacts on the environment. Implementation of most of the structural BMPs will be short-term, temporary and spatially distributed across the watershed, and will not have significant adverse effects on the environment. BMPs that involve substantial earth movement could have potentially significant cumulative impacts. However, many of these activities will be regulated under existing State and Regional permits, including but not limited to state-wide CalTrans stormwater permit, stormwater permit for construction sites over one (1) acre or timber harvest operations on public and private lands. The likelihood of installation of structural BMPS on federal land is quite high as 66% of the watershed is in federal ownership. Compliance measures implemented for activities such as significant road construction projects will be subject to NEPA requirements. It is also important to note that Regional Water Board staff is currently developing a permit (WDR/waiver) for the Regional Water Board's consideration to regulate all sources of non point source pollution from lands managed by the USFS. Regional Water Board staff's engagement in these regulatory programs will provide an opportunity to limit the potential for cumulative impacts by ensuring that multiple projects proposing implementation of BMPs with the potential to cause short-term impacts are phased appropriately to limit potential cumulative impacts.

Based on a review of the referenced dam removal studies, Regional Water Board staff has determined that short term impacts from elevated turbidity and suspended sediment loads as a result of dam decommissioning will potentially result in a significant cumulative impact to the already stressed fisheries and aquatic resources in the Klamath River. As there is no decommissioning plan available for review, the actual environmental impacts are difficult to determine.

17. Mandatory Findings of Significance:

Does the project have environmental effects which will cause substantial adverse effects on human beings, either directly or indirectly?

Answer: Less than significant

Discussion: As explained previously, the proposed Action Plan, including measures to comply with the revised DO objectives, will improve long term water quality by providing a regulatory program designed to protect and restore water quality and the beneficial uses of water in the Klamath River watershed. An important objective of the Klamath River TMDLs is the restoration of a healthy and viable salmonid fishery. This important beneficial use is critical for the subsidence and health of the Tribes in the watershed.

9.8 Alternative Means of Compliance

The CEQA requires an analysis of reasonably foreseeable alternative means of compliance with the rule or regulation, which would avoid or eliminate the identified impacts[22]. The responsible parties can use the structural and non-structural compliance measures (BMPs) described in section 9.5, or other structural and non-structural BMPs, to control and prevent pollution, and meet the requirements of the proposed Action Plan and revised DO objectives. The alternative means of compliance with the proposed Action Plan and revised DO objectives consist of the different combinations of structural and non-structural BMPs that the responsible parties might use to meet their load allocations and achieve the numeric targets and revised DO objectives. Because there are innumerable ways to combine BMPs, all of the possible alternative means of compliance cannot be discussed here. However, because most of the adverse environmental effects are associated with the construction and installation of structural BMPs related to earth movement or construction of infrastructure (e.g., fencing) to avoid or eliminate impacts,

---

[22] Cal. Code Regs., tit. 14, § 15187(c)(3).

compliance alternatives should maximize the use of non-structural BMPs to the extent feasible, minimize use of structural BMPs to the extent feasible, and design structural BMPs to take into consideration site-specific conditions to minimize environmental effects.

9.9 CEQA Determination

Adoption of the proposed Action Plan and revised DO objectives is both necessary and beneficial. Currently the Basin Plan does not include a comprehensive regulatory program designed to protect and restore the beneficial uses of water in the Klamath River basin. The Klamath TMDL implementation plan would provide the framework for this comprehensive program. The implementation of compliance measures that likely may be implemented to comply with the proposed Action Plan and revised DO objectives will not result in significant adverse impacts that cannot be reduced to levels of insignificance with the implementation of thoughtfully designed and executed mitigation measures with the exception of several potentially significant adverse environmental impacts associated with dam decommissioning. Implementation of many of the identified compliance measures, including dam decommissioning, could result in temporary (short term) adverse impacts to the environment. Most of these impacts, however, can be reduced to levels of less than significant with mitigation. For example, implementation of BMPs that require substantial earth movement, such as construction of filtration or settling basins, and road construction, reconstruction and maintenance could result in significant impacts if they were conducted in sensitive areas or during time periods when the most sensitive life stages of fall Chinook salmon are present. To alleviate any such impacts, dischargers will be required to consult with federal, state and local agencies, including but not limited to the county the project is located in, CDFG and the USFWS, and implement mitigation identified by the agencies to avoid impacts to rare, threatened or endangered species. In most cases the installation of structural BMPs would be small scale in size and application, and any impacts could avoided by adjusting the timing and/or location of the BMPs to take into account any candidate, sensitive, or special status species or their habitats.

If the KHSA Parties decide to move forward with dam decommissioning, a plan would have to be developed, which would then require a thorough environmental review (EIS and/or EIR) prior to the federal and/or state agencies permitting the activity. Only once a plan has been developed will it be possible to assess potentially significant adverse effects and mitigation measures that could reduce impacts to levels of insignificance. If no such mitigation is available, the activity would not be authorized until such time as a regulatory path was made available to allow for large-scale restoration projects such as dam decommissioning, Trinity River restoration actions and restoration work on USFS lands.

The Staff Report, the draft Basin Plan Amendments, and the Environmental Checklist and associated analysis provide the necessary information pursuant to state law to conclude that the proposed Action Plan, revised DO objectives, and the associated reasonably foreseeable methods of compliance (i.e. BMPs) will not have a significant adverse effect on the environment with the exception of potentially significant impacts associated with a dam decommissioning. Regional Water Board staff have made this determination based on best available information in an effort to fully inform the interested public and the decision makers of potential environmental impacts.

In accordance with state law, the North Coast Regional Water Board finds that with the exception of activities connected with dam decommissioning, the proposed Action Plan and DO objectives, with the implementation of the mitigation measures identified in this SED, will not have a significant adverse impact on the environment. This finding is supported by the evidence provided in the impact evaluation section of this document, which indicates that all foreseeable impacts are either short-term or can be readily mitigated.

Although potentially significant adverse impacts from dam removal were identified, it is impossible without further study to know whether those impacts may be able to be mitigated to less than significant levels. If the KHSA Parties decide to move forward with decommissioning of one or more of the dams, additional environmental review will be required at that time. If, at that time, adverse environmental impacts are identified that cannot be mitigated to less than significant levels, the Regional Water Board, when required to take a discretionary action for approval of dam decommissioning, will balance the economic, legal, social, technological, or other benefits of removing the dams against the unavoidable environmental risks when determining whether to approve the project, and make a statement of overriding considerations, if it finds that the adverse environmental impacts are acceptable given the identified benefits. At this time, however, there has been no decision to decommission one or more of PacifiCorps' dams and there is insufficient information for the Regional Water Board to know what potential impacts exists, if they can be mitigated to less than significant levels, and if not, whether the benefits outweigh those potential impacts. A detailed environmental analysis of impacts and subsequent Regional Water Board approval is required before dam removal activity may occur for TMDL compliance.

This space intentionally left blank.

CHAPTER 10. ECONOMIC ANALYSIS

10.1 Introduction

The Regional Water Boards are legally required to consider economics in Total Maximum Daily Load (TMDL) development and water quality control planning (basin planning), as described in a memorandum from Sheila K. Vassey, Senior Staff Counsel in the Office of Chief Counsel of the State Water Resources Control Board (Vassey 1999). Under state law, there are three triggers for Regional Water Board consideration of economics or costs in basin planning. They are:

- The Regional Water Boards must estimate costs and identify potential financing sources in the basin plan before implementing any agricultural water quality control program.
- The Board must consider economics in establishing water quality objectives that ensure the reasonable protection of beneficial uses.
- The Boards must comply with the California Environmental Quality Control Act (CEQA) when they amend their basin plans. CEQA requires that the Boards analyze the reasonably foreseeable methods of compliance with proposed performance standards and treatment requirements. This analysis must include economic factors.

Chapter 9 is the analysis of potential environmental impacts associated with implementation of the TMDL and compliance with the recalculated Site Specific Objectives (SSOs) for dissolved oxygen (D0) as required under CEQA. In Chapter 9, staff identifies the reasonably foreseeable compliance measures necessary of land owners/dischargers to achieve compliance with the TMDLs and the proposed revised DO objectives. These compliance measures, or best management practices, are not requirements of individual landowners/dischargers. They are simply those management practices most likely to be necessary to achieve compliance. Land owners/dischargers have the responsibility of identifying the means of achieving compliance best suited to the site specific characteristics of their particular land and operation.

What follows is an estimate of the costs associated with those management practices which are reasonably foreseeable as necessary to achieve compliance with the TMDL and proposed revised DO objectives. The costs are given as a range, dependent on the specific characteristics of the land or operation to which a given management practices is applied. A list of potential funding sources is also given.

The Regional Water Board is not obligated to consider the balance of costs and benefits associated with implementation of a TMDL or basin plan amendment. It is only obligated to consider economic factors and may adopt a TMDL or basin plan amendment even if the costs are significant.

10.2 Scope of the Economic Analysis

10.2.1 Existing Requirements

Landowners and dischargers are bound by various existing regulatory requirements that involve water quality and natural resource protection. The economic impact of existing obligations should not be attributed to the costs of compliance with the proposed Klamath River TMDL Action Plan and revised DO objectives. But, limiting the scope of the economic analysis is difficult given the similarity of measures necessary to achieve a wide range of water quality and wildlife protection goals. To remain as focused as possible, this economic analysis only contemplates the costs of measures identified as reasonably foreseeable (see Chapter 9) in the implementation of the Klamath River TMDL Action Plan and revised DO objectives. But, if taken as a whole, they are likely an overestimate of the actual costs of compliance. This is because of the multiple and overlapping regulatory programs under which the same measures are reasonably foreseeable.

For example, some temperature, nutrient, or dissolved oxygen control costs are related to actions necessary to avoid a violation of the sediment prohibitions in the Basin Plan and to avoid a taking under the Endangered Species Act or to fully mitigate impacts of authorized takes. Other costs may be incurred as a result of compliance with the Clean Water Act, other related statutes and regulations, or local land use ordinances. Conversely, compliance with the proposed Klamath River TMDL Action Plan will help dischargers comply with the other regulatory requirements.

Applicable existing requirements include:

- Existing Basin Plan requirements (such as the federal and state antidegradation policies, the controllable factors requirement, the general Waste Discharge Requirements and general waiver for timber harvest activities, and the existing water quality objectives for temperature, dissolved oxygen).
- State nonpoint source program requirements.
- Porter-Cologne Act requirements (such as the requirement of Section 13260 for every person who discharges a waste that impacts water quality to file a report of waste discharge with the Regional Water Board, and the cleanup and abatement requirements of Section 13304).
- The California Department of Forestry and Fire Protection requirements for timber harvest activities.
- The federal and state endangered and threatened species requirements.
- Obligations imposed by other local, state and federal natural resource agencies.

As discussed in Chapter 9, the decommissioning of one or more of PacifiCorp's dams is being contemplated in other forums and not in the context of the TMDL Action Plan and revised mainstem Klamath River DO objectives. Whether the dams are ultimately removed is a decision before several federal and state agencies in consideration of other factors in addition to water quality, including water allocations, species protection and

power needs. Both dam alteration/modifications and dam removal are recognized as possible strategies by which final compliance with the TMDL load allocations may be accomplished. The Regional Water Board can only determine whether a selected outcome will meet its TMDL. The implementation plan provides for Regional Water Board review of more site specific environmental assessments of dam removal.
Dam removal is something that may or may not occur, and is separate and independent of the TMDL. Nonetheless, at PacifiCorp's request and consistent with the Chapter 9 CEQA analysis, economic considerations from the Final Environmental Impact Statement for Relicensing of the Klamath Hydroelectric Project No. 2082-027 have been incorporated into this analysis. Because there is not yet a plan for dam decommissioning, the proposed costs are very broad, and actual costs remain uncertain.

10.2.2 Geographic Scope

The implementation actions proposed by the Klamath River TMDL Action Plan for compliance with the TMDLs and revised DO objectives (see Chapter 6) are not uniformly required across the Klamath River watershed or even across properties with similar land uses. Instead, many of the implementation actions will be required of landowners/dischargers on an as-needed, site-specific basis or are simply activities that are encouraged by the Regional Water Board. While this flexibility adds greatly to the effectiveness of the Klamath River TMDL Action Plan, it is one factor preventing this economic analysis from totaling costs on a watershed scale. Another factor preventing the development of watershed scale costs is the lack of a watershed scale inventory of pollution-causing activities/features (e.g., miles of roads requiring decommissioning).

Additionally, more intensive land use activities will face greater costs than less intensive land use activities. Activities on steep, erosive slopes in proximity to waterbodies will require greater care and higher costs than activities on lands that do not deliver to a water body or on lands that are not highly erosive.

10.2.3 Methodology

The costs identified in this chapter primarily come from four sources of information: the Natural Resources Conservation Service (NRCS) ProTracts cost dataset; California Department of Fish and Game (CDFG) Salmonid Stream Habitat Restoration Manual (2006) (Manual) for road-related costs, estimates provided by PacifiCorps for reservoir-related measures and the *Final Environmental Impact Statement for Relicensing of the Klamath Hydroelectric Project No. 2082-027* released by the Federal Energy Regulatory Commission on November 16, 2007. ProTracts is a national dataset maintained by NRCS to assist local NRCS Districts in setting cost shares for implementing conservation practices. Cost estimates are provided at the county level and the data used for this analysis are specific to Siskiyou County, as described in their California Approved Fiscal Year 2008 Payment Schedule.

The costs included in the CDFG Manual are described as upslope erosion inventory and sediment control guidance. The numbers are based on estimates from Pacific Watershed Associates, a consulting firm specializing in erosion control work. Actual costs can vary considerably depending on operator skill and experience, equipment types, local site conditions, and regional location.

The cost estimates for interim measures to work toward compliance with the TMDL and DO objectives while it is determined whether PacifiCorp will decommission one or more of its dams are set forth in the AIP. Despite the fact that the parties to the AIP have not yet decided whether or not to decommission one or more of PacifCorp's dams and no plans for how that process will look have yet been created, the Regional Water Board has nonetheless attempted to consider economics of dam decommissioning, as those costs have been reported in the Final Environmental Impact Statement for Relicensing of the Klamath Hydroelectric Project No. 2082-027, prepared by FERC, which is incorporated herein by reference.

10.3 Estimated Costs of Compliance

10.3.1 PacifiCorp

PacifiCorp has entered into an agreement in principle (AIP) with the State of Oregon, the State of California, and the federal government to resolve "certain litigation and other controversies in the Klamath Basin, including a path forward for possible Facilities removal" (AIP 2008).[1] The AIP constitutes PacifiCorp's interim funding commitments while the negotiations continue on the topic of dam removal. Table 10.1 presents the costs associated with the measures related to interim compliance with the TMDL while decisions are being made to determine which regulatory path to pursue. Costs for the breadth of interim measures discussed in Chapter 6 (Implementation Plan) and Chapter 9 (CEQA Environmental Analysis) are included as a lump sum in item #11. Costs for dam removal are taken from the Final Environmental Impact Statement for Relicensing of the Klamath Hydroelectric Project No. 2082-027 (page 4-6 of the EIS). Costs to remove Copco 1 and 2 and Iron Gate dams range from $51 million to 75.3 million with additional decommissioning costs (e.g. re-vegetation) of between $9.2 million to to 55.3 million depending on individual site constraints.

Table 10.1: Costs to PacifiCorp of interim compliance measures

#	Interim Measure Task Title	Funding Commitment
9	California Klamath Restoration Fund/Coho Enhancement Fund	$500,000 annually until dams removed
10	Iron Gate Turbine Venting	$73,310 annually
11	Nutrient Reduction Measures	$5 million plus $500,000 annually
12	Water Quality Monitoring	$500,000 annually
13	Fish Tissue Consumption Risk Analysis	$250,000 one time cost
21	Iron Gate Gravel Placement	$7,131 annually
23	Water Quality Technical Conference	$100,000 one time cost
	One time costs	$5,350,000
	Annual costs	$1,580,441

[1] State of California is defined as the State of California Resources Agency and its constituent departments and excludes all other state agencies, departments, boards and commissions. The Regional Water Board is not a constituent department under the Resources Agency.

10.3.2 Irrigated Agriculture

Irrigated agriculture occurs primarily in the upper Klamath Basin, including the Lost, Shasta and Scott River valleys. USBR reports that approximately 225,000 acres of rangeland in the upper Klamath Basin (south-central Oregon and north-central California) have been transformed into productive farmland due to the availability of irrigation water provided by USBR. Principal irrigated crops are barley, irrigated pasture, alfalfa hay and other hay, oats, potatoes, and wheat (http://www.usbr.gov/dataweb/html/klamath.html). Table 10.2 presents the estimated costs to irrigated agriculture in California of reasonably foreseeable compliance measures for the Klamath River TMDL, and are taken from the Natural Resources Conservation Service (NRCS) Siskiyou County District Office Fiscal Year 2008 payment schedule. For most of the management practices, a range of costs is given, depending on numerous site-specific factors to be determined by landowners/dischargers.

Table 10.2: Estimated costs to irrigated agriculture of reasonably foreseeable compliance measures

Reasonably Foreseeable Compliance Measure	NRCS Practice Name	NRCS Practice Cost	NRCS Practice Code
Nutrient Management			
Comprehensive Nutrient Management Plan	Nutrient management	$2000-6000/plan	#100
Monitor soil, irrigation water and residual plant matter	To	be determined	
Time fertilizer application with plant needs	Timing No	cost	NA
Water Management (see below)	See below	See below	See below
Cover crops	Irrigated or non-irrigated	$61-112/acre	#340
Buffer areas	Non-native or native seedbed preparation; tree/shrub establishment	$75-371/acre #	386, #612
Pest Management			
Precision Pest Control Application	Precision pest control	$30/acre	#718
Pest Management	IPM, reduced risk, or transition to organic certification	$30-125/acre #	595
Erosion and Sediment Control			
Maintain crop residue or vegetative cover	Cover crop	$60-112/acre	#340
Improve soil properties	Deep tillage Mulch till Cover crop	$55-105/acre $30/acre $60-112/acre	#324 #345 #340
Reduce slope length, steepness, or unsheltered distance	Precision land forming	$175/acre	#462
Practices to reduce detachment	Chiseling and subsoiling Conservation cover Conservation crop rotation Residue management Cover crop Critical area planting Seasonal residue management Diversion Windbreak/shelterbelt establishment	$55-106/acre $97-750/acre $50/acre $60-113/acre $249-1,229/acre $30/acre $10/ft $0.08-1.47/ft	#324 #327 #328 #329 #340 #342 #344 #362 #380

Table 10.2 (cont.): Estimated costs to irrigated agriculture of reasonably foreseeable compliance measures

Reasonably Foreseeable Compliance Measure	NRCS Practice Name	NRCS Practice Cost	NRCS Practice Code
Erosion and Sediment Control (cont.)			
Practices to reduce detachment (cont.)	Windbreak/shelterbelt renovation Mulching Irrigation water management Cross wind ridges/stripcropping/trap strips Surface roughening Tree planting Waste utilization Wildlife upland habitat management	$0.13-0.57/ft $78-299/acre $5-50/acre Not available Not available $75-283/acre $30-50/acre $10-50/acre	#650 #484 #449 #589 #609 #612 #633 #645
Practices to reduce transport within the field	Contour farming Field windbreak Grassed waterway Contour stripcropping Herbaceous wind barriers Field stripcropping Terrace Contour buffer strips	Not available Not available $250-470/acre Not available $400/acre Not available $5/acre Not available	#330 #392 #412 #585 #442A #586 #600 #332
Practices to trap sediment below the field or critical area	Sediment basins Field border Filter strip Water and sediment control basin	$4701/no. $82-370/acre $117-393/acre $245-4,902/no.	#350 #386 #393 #638
Protect and manage existing wetland and/or riparian areas for their natural filtering functions	Riparian herbaceous cover/forest buffer, wetland restoration	$75-1,200/acre #	390, #391, #657
CEQA Mitigation Measures			
Mulch exposed areas	Mulching	$78-299/acre	#484
Protect drainage channels from sediment contributions with vegetated buffers, wattles, or similar erosion control devices	Filter strip	$117-393/acre	#393
Wetland wildlife habitat management	Low, medium or high intensity	$10-50/acre	#644
Installation of grade stabilization structures	Grade stabilization structure	$250-10,000/no.	#410
Streambank and shoreline protection	Low-high complexity	$24-122/ft	#580
Stream channel stabilization	Stream channel stabilization	$25/ft	#584
Use exclusion	Forage exclusion, wetlands	$15/acre	#472
Riparian forest buffer/herbaceous cover	Riparian forest buffer/herbaceous cover	$75-1170/acre #	390, #91
Control of streambank erosion via vegetative or structural practices	Streambank and shoreline protection	$23-122/ft #	580

Table 10.2 (cont.): Estimated costs to irrigated agriculture of reasonably foreseeable compliance measures

Reasonably Foreseeable Compliance Measure	NRCS Practice Name	NRCS Practice Cost	NRCS Practice Code
Irrigation Management			
Irrigation scheduling	Irrigation water management	$5-50/acre	#449
Efficient application of irrigation water	Microirrigation, sprinklers	$250-1250/acre	#441, 442
Efficient transport of irrigation water	Installation of piping to replace open ditches	$2-5/ft #	516
Use of runoff or tailwater	Irrigation system/tailwater recovery	$77-102/acre #	447
Management of drainage water	Runoff management system	$5000/no.	#570
CEQA Mitigation Measures			
Vegetated filter strips	Filter strip	$117-393/acre	#393
Surface field ditch	Field ditch	$3/cy	#607
Water table control, controlled drainage	Subsurface drain	$1-2/ft	#606

Source: California Approved Fiscal Year 2008 Payment Schedule for Siskiyou County District of the Natural Resources Conservation Service.

10.3.3 Grazing

Grazing activities occur throughout the Klamath River basin both on private and public lands. As with the estimated costs to the irrigated agricultural community to comply with the Klamath River TMDL and revised DO objectives, the estimates to the grazing community are derived from NRCS Fiscal Year 2008 Payment Schedule for Siskiyou County. Costs for each of the reasonably foreseeable compliance measures identified in Chapter 9 are provided in Table 10.3

Table 10.3: Costs to grazing of reasonably foreseeable compliance measures

Reasonable Foreseeable Compliance Measure	NRCS Practice Name	NRCS Practice Cost	NRCS Practice Code
Grazing Management Practices			
Grazing Management Plan		To be determined	
Pasture and hay planting	Seedbed preparation, see and seeding, non-native	$125/acre #	512
Rangeland planting	Drill or broadcast, native or non-native	$26-644/acre #	550
Forage harvest management	Forage harvest management	Not available	#511
Vegetation control with grazing	Prescribed grazing	$10/acre	#528A
Use exclusion	Forage exclusion	$15/acre	#472
Nutrient management	AFO Manure Management	$25/acre	#590

Table 10.3 (cont.): Costs to grazing of reasonably foreseeable compliance measures

Riparian Grazing Practices			
Use exclusion	Fence	$0.39-5.25/ft	#382
Animal trails and walkways	Animal trails and walkways	$3/ft	#575
Stream crossing	Ford, culvert, bridge	$1000-50,000	#578
Alternate Water Supply Practices			
Irrigation management	Irrigation water management	$5-50/acre	#449
Installation of pipeline for off-channel water	Pipeline, rough terrain, steel or plastic	$2-5/ft #	516
Constructing off-stream pond	Pond up to 50 AcFt	$4,534-23,625/no.	#378
Installing trough or tank for off-channel water	Watering facility	$245-1,230/no.	#614
Constructing well	Water well	$990-9,905/no.	#642
Improving springs	Spring development	$981-1,981/no.	#574
Land and Streambank Stabilization Practices			
Nutrient management	AFO Manure Management-North Coast	$25/acre #5	90
Channel vegetation	Channel bank herb., tree, shrub vegetation	$321-536/acre #	322
Pasture and hay planting	Seedbed preparation, see and seeding, non-native	$125/acre #	512
Rangeland planting	Drill or broadcast, native or non-native	$26-644/acre #	550
Critical area planting	Tackifier, erosion blanket, strawmulch	$248-1,229/acre	#342
Brush management	Biological, mechanical	$47-462/acre	#314
Grazing land mechanical treatment		To be determined	#548
Grade stabilization structure	Grade stabilization structure	$250-10,000/no.	#410
Prescribed burning	Prescribed burning	$70/acre	#338
Stream corridor improvement Str	eam crossing	$1000-50,000/no.	#578
Land reclamation	Landslide treatment No	t available	#453
Sediment basin	Sediment basin	$4701/no.	#350
Wetland wildlife habitat management	Low-high intensity	10-50/acre	#644
Stream channel stabilization	Stream channel stabilization	$25/ft	#584
Wetland restoration	Northern CA, coast, planting only, shaping/grading	$157-1,200/acre	#657
Streambank and shoreline protection	Low-high complexity	$24-122/ft	#580
Riparian forest buffer/herbaceous cover	Riparian forest buffer/herbaceous cover	$203-971/acre #	391A #390
CEQA mitigations			
Mulch	Moisture and erosion control	$299/acre	#484B
Protecting drainage channels from sediment contributions	Channel bank vegetation	$321/acre	#322B

10.3.4 Suction Dredging

Staff recommends to the Regional Water Board the limitation of suction dredging in the Klamath River Basin to certain times and locations in order to protect thermal refugia that mitigate water temperatures that are stressful to salmonids. Staff concludes that there are no specific costs to the suction dredging community associated with the TMDL or revised DO objectives. This is because the prohibition proposed for adoption does not prohibit suction dredging throughout the watershed; only in those tributaries in which thermal refugia exists.

10.3.5 Iron Gate Hatchery

The issues associated with the Iron Gate Hatchery are complex due to the location and issues surrounding the hatchery operation. Site-constraints and technical factors make it necessary for an engineering study to be completed before an economic analysis can be completed for the hatchery aspect of the TMDL and revised DO objectives. Some of the potential improvements that might be required in order for the hatchery to meet the TMDL requirements and revised DO objectives under a revised NPDES permit, could include improvements to settling ponds, treatment technologies (such as installation of a package treatment plant), modifications of operations, additional monitoring and laboratory analyses, and a potential off-sets program including up-stream treatment.

PacifiCorp has agreed to provide certain funding to the hatchery including "100% of the hatchery operations and maintenance necessary to fulfill annual mitigation objectives developed by the California Department of Fish and Game in consultation with the National Marine Fisheries Service (AIP 2008)." There may be some overlap in the requirements of these agencies and those of the Regional Water Board under the Klamath TMDL Action Plan. Further, some of these costs to the hatchery associated with water quality protection would be required as part of the upcoming NPDES permit update, regardless of the TMDL or revised DO objectives.

At present both the reasonably foreseeable compliance measures and their costs are too speculative to include here. Staff concludes that addressing these complex issues and creating an effective implementation plan is likely to be costly. The Regional Water Board has already begun working with the CDFG to address these difficult issues.

10.3.6 Roads

The road networks in the Klamath Basin contribute to elevated temperatures in tributary watersheds through the discharge of excess sediment. The implementation plan requires parties responsible for managing roads in the Klamath Basin to implement measures that meet the TMDL allocations, TMDL targets, and revised DO objectives. In some cases, an inventory of roads will determine that decommissioning or upgrading of roads is required. Table 10.4 outlines the estimated costs for this type of work. The targets, rationale for the targets, and the specific implementation measures that will be required under the TMDL for private, county, state (Caltrans) and federal (USFS, BLM) maintained roads are discussed in Chapter 6.

Regardless of the method of regulation or the responsible party, the requirements for controlling sources of sediment from roads are similar and implementation will potentially focus on the following process:

1. Inventory: Identify sources of excess sediment discharge or threatened discharge and quantify the discharge or threatened discharge from the source(s).
2. Prioritize: Prioritize efforts to control discharge of excess sediment based on, but not limited to, severity of threat to water quality and beneficial uses, the feasibility of source control, and source site accessibility.
3. Implement: Develop and implement feasible sediment control practices to prevent, minimize, and control the discharge. Road decommissioning may be required as part of a responsible parties' load allocation if maintaining the road is cost prohibitive, road is not needed or is a source of uncontrollable excess sediment discharge.
4. Monitor and Adapt: Use monitoring results to direct adaptive management in order to refine excess sediment control practices and implementation schedules until discharges are reduced to a level that meets the TMDL load allocations and water quality standards.

Table 10.4: Estimated costs for reasonably foreseeable compliance measures for roads

Reasonably Foreseeable Compliance Measure	Best Management Practice	BMP estimated cost	Source of data
Costs for Road and Crossing Construction and Maintenance Activities			
Surface stabilization	Asphalt paving	$238,000/mile	Siskiyou County Public Works
	Chip sealing	$57,000/mile	Siskiyou County Public Works
	Rocking	$4,250-10,000/1000 ft	Weaver, et. al. (2006)
	Dust abatement	$90hr	Harris Blade Rental, Livermore - operated water truck
Fill slope/cutbank compliance measures	Removal/stabilization of unstable fill.	$2-5/cubic yard	Weaver, et. al. (2006)
	Soil stabilization (mulch/vegetate) of fill and cut slopes.	$19-22/1000 ft.	Weaver, et. al. (2006)
Control sediment discharge from insloped or crowned roads	Disconnect road drainage from watercourses (drain to hillslopes).	$170/1000 ft	Weaver, et. al. (2006)
	Install rolling dip	$85-170/ each	Weaver, et. al. (2006)
	Install ditch relief culvert	$645-825/ each	Weaver, et. al. (2006)
	Install stream crossing	$3,270/each	Weaver, et. al. (2006)
CEQA mitigation measures	Conservation cover	$189-509/acre	NRCS#327
Mu	lching	$299/acre	NRCS #484

Table 10.4 (cont.): Estimated costs for reasonably foreseeable compliance measures for roads

Reasonably Foreseeable Compliance Measure	Best Management Practice	BMP estimated cost	Source of data
Costs for Stream Crossing Activities			
Stabilize/treat crossing approach	Rock road surface	$4,250-10,000/1000 ft	Weaver, et. al. (2006)
	Water for dust abatement	To be determined	
	Install additional road drainage: waterbars, rolling dips, cross drains	$85-3,270/each Weave	r, et. al. (2006)
	Mulching $	299/acre	NRCS #484
	Streambank and shoreline protection	$24-122/ft N	RCS #580
Stabilize/treat crossings and associated fills	Remove undersized/failing culverts	$3-10/cubic yard	Weaver, et. al. (2006)
	Remove unstable fill	$2-5/cubic yard	Weaver, et. al. (2006)
	Rock armor, rip rap fill slopes	To be determined	
	Provide "fail safe" road drainage on crossings with diversion potential	To be determined	
	Drain road away from unprotected fills	$10,000-75,000/mile	Weaver, et. al. (2006)
	Bioengineered structures (e.g. willow waddles)	To be determined	
	Mulch, vegetate or rock exposed soil with access to watercourses	To be determined	
Construct storm-proof crossings and associated fills		To be determined	
CEQA mitigation measures	Conservation cover	$189-509/acre	NRCS#327
	Mulching $	299/acre	NRCS #484
	Streambank and shoreline protection	$24-122/ft N	RCS #580
Costs of Road Planning Activities			
Develop a Road System Plan	Erosion Control Plan, non-timber land use	$3528-7,740/100 acres	R. Fitzgerald Memo dated August 6, 2005
	Erosion Control Plan, timber land use	$2,370-7,740/100 acre	
	Road System Plan	To be determined	
Road decommissioning	Recontour road to provide for a stable, hydrologically "invisible" site (e.g. remove perched fill, outslope old road prism, remove crossings)	$2,000-$50,000/mile depending on steepness and location of road	Weaver, et. al. (2004)
	Minimize road system (density) to correspond with maintenance resources	$2,000-$50,000/mile to recontour unnecessary roads	Weaver, et. al. (2004)
	Decommission roads adjacent to watercourse and relocate to midslope or ridgetop if possible	To be determined	
CEQA mitigation measures	Conservation cover	$189-509/acre	NRCS#327

10.3.7 Timber

Timber harvest activities can substantially impact water temperature. The Klamath implementation plan focuses on controlling sediment and protecting riparian functions from timber harvest activities to meet the watershed-wide TMDL allocations for temperature described earlier in this section. Timber harvest on nonfederal lands is currently regulated by the Regional Board through a combination of general WDRs and conditional waivers of WDRs. The costs associated with WDRs are not outlined here as they are a current requirement. Roads that are part of a timber harvest plan or Non-Industrial Timber Management Plan (NTMP) area require an erosion control plan to be implemented by the WDRs and waivers for timber harvest on nonfederal lands. Table10.5 includes the reasonably foreseeable compliance measures identified in Chapter 9. However, staff judges that there are no additional costs to timber operators associated with TMDL compliance.

Table 10.5: Estimated costs to timber operators of reasonably foreseeable compliance measures

Reasonably Foreseeable Compliance Measures	**Best Management Practice**	**Estimated cost of BMP**	**Source of data**
Compliance measures on private land	Increased riparian canopy retention in Class I and II watercourses	None St	aff judgment
	Retain in-channel trees following timber operations	None St	aff judgment
	No timber harvest activities (including tree felling) within the channel zone of a Class III watercourse except for use and maintenance of road and crossings.	None St	aff judgment
	Implement Threatened and Impaired Rules (Forest Practice Rules, 2009, section 916.9, 936.9) watershed-wide in the Klamath River watershed.	No additional cost	Staff judgment

10.3.8 Summary

Sunding and Zwane (2004) produced the Recovery Strategy for California Coho Salmon: Report to the California Fish and Game Commission (Strategy) in which they assessed the costs of implementing the Strategy in each hydrologic unit, including the Klamath River. The main activities associated with implementation of the Strategy are similar to those associated with compliance with the Klamath River TMDL and revised DO objectives, the estimated costs of which are reproduced in Table 10.6. As described above, where costs are incurred as a result of the implementation/enforcement of another program, they can not be attributed to the Klamath River TMDL and revised DO objectives. However, because these costs were estimated for the whole watershed, they are included here for illustration purposes.

Table 10.6: Estimated costs of coho recovery actions for the Klamath River basin

Action	Potential Sites (#)	Actual Sites (#)	Estimated Cost ($)	Unit Cost ($/unit)
Barrier removal (dam)	31	16	7,137,216	460,456
Barrier removal (non-structural sites)	752 37	6	3,635,213	9,668
Barrier removal (stream crossings)	291	146	18,220,276	125,225
Barrier removal (unknown/other barriers)	17 9		94,292	37,367
Barrier removal (water diversions)	78	39	1,344,905	34,485
Riparian revegetation	NA	103 stream miles	18,721,487 1	80,993
Streambank restoration	NA	20 stream miles	25,893,312 1,	316,722
Fencing NA		1,748 stream miles	12,830 7	
Klamath Basin Total			75,059,531	

Monies spent under the Strategy are monies saved under the Klamath River TMDL and revised DO objectives for the following categories of expenditures:

- Non-structural barrier removal to temperature refugia,
- Stream crossing repairs,
- Riparian revegetation,
- Streambank restoration, and
- Fencing.

10.4 Sources of Funding

Potential sources of funding include monies from private and public sources. Public financing includes, but is not limited to: grant funds, as described below; single-purpose appropriations from federal, state, and/or local legislative bodies; and, bond indebtedness and loans from government institutions.

10.4.1 Funding Source Provided through the Agreement In Principle (AIP)

The United States, State of California, State of Oregon, and PacifiCorp signed an Agreement In Principle (AIP) on November 13, 2008 in which certain interim provisions are made with respect to the hydroelectric facilities on the Klamath River prior to final agreement on the decommissioning of the dams.[2] In the AIP, PacifiCorp agreed to provide $500,000 annually to the California Klamath Restoration Fund/Coho Enhancement Fund (Restoration and Enhancement Fund) to be administered jointly by

[2] State of California is defined as the State of California Resources Agency and its constituent departments and excludes all other state agencies, departments, boards and commissions. The Regional Water Board is not a constituent department under the Resources Agency.

the California Department of Fish and Game (in conjunction with the State Water Resources Control Board) and NOAA Fisheries. The Restoration and Enhancement Fund is intended to fund habitat and fish restoration actions within the Klamath Basin that will benefit coho salmon.

10.4.2 Summary of Pertinent State Funding Programs

There are several potential sources of public financing through grant and funding programs administered, at least in part, by the Regional Water Board and the State Water Board. These programs vary over time depending upon federal and state budgets and ballot propositions approved by voters. State funding pertinent to the proposed Action Plan for the Klamath River are summarized and described below. Additional information can be found on the State Water Resources Control Board webpage (http://www.waterboards.ca.gov/water_issues/programs/grants_loans/).

10.4.2.1 Agricultural Drainage Loan Program

The Agricultural Drainage Loan Program was created by the Water Conservation and Water Quality Bond Act of 1986 to address treatment, storage, conveyance, or disposal of agricultural drainage water that threatens waters of the State. There is a funding cap of $20 million for implementation projects and $100,000 for feasibility studies. Loan repayments are for a period of up to 20 years.

10.4.2.2 Agricultural Drainage Management Loan Program

The Agricultural Drainage Management Loan Program, created by Proposition 204 and distributed through the Agricultural Drainage Management Subaccount, provides loan and grant funding for Drainage Water Management Units. Drainage Water Management Units are land and facilities for the treatment, storage, conveyance, reduction or disposal of agricultural drainage water that, if discharged untreated, would pollute or threaten to pollute the waters of the State. This program is available to any city, county, district, joint power authority, or other political subdivision of the State involved with water management.

10.4.2.3 Agricultural Water Quality Grants Program

The Agricultural Water Quality Grant Program provides funding for projects that reduce or eliminate non-point source pollution discharge to surface waters from agricultural lands. Funding from Propositions 40 and 50 were administered through two solicitations, most recently the 2005-2006 Consolidated Grants Process. Additional funds will be made available in the future through Proposition 84.

10.4.2.4 Federal Clean Water Act Section 319 Nonpoint Source Implementation Program

This program is an annual federally funded nonpoint source pollution control program that is focused on controlling activities that impair beneficial uses and on limiting pollutant effects caused by those activities. States must establish priority rankings for waters on lists of impaired waters and develop action plans, known as Total Maximum Daily Loads (TMDLs), to improve water quality. Project proposals that address TMDL implementation and those that address problems in impaired waters are favored in the selection process. There is also a focus on implementing management activities that lead to reduction and/or prevention of pollutants that threaten or impair surface and ground waters.

10.4.2.5 Clean Water State Revolving Fund

The Federal Water Pollution Control Act (Clean Water Act or CWA), as amended in 1987, provides for establishment of a Clean Water State Revolving Fund (CWSRF) program. The program is funded by federal grants, State funds, and Revenue Bonds. The purpose of the CWSRF program is to implement the CWA and various State laws by providing financial assistance for the construction of facilities or implementation of measures necessary to address water quality problems and to prevent pollution of the waters of the State.

The CWSRF Loan Program provides low-interest loan funding for construction of publicly-owned wastewater treatment facilities, local sewers, sewer interceptors, water recycling facilities, as well as, expanded use projects such as implementation of nonpoint source (NPS) projects or programs, development and implementation of estuary Comprehensive Conservation and Management Plans, and storm water treatment.

10.4.3 Summary of Pertinent Federal Funding Programs

Several federal agencies, including but not limited to the U.S. Environmental Protection Agency, NOAA Fisheries, U.S. Fish and Wildlife Service, and USDA Natural Resources Conservation Service, also provide grants and other funding opportunities. The U.S. Environmental Protection Agency provides access through its webpage to a catalog of federal funding opportunities: <http://cfpub.epa.gov/fedfund/>. Table 10.7 lists the federal funding programs pertinent to the water quality protection work required in the Klamath River watershed.

Table 10.7: Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
Aquatic Ecosystem Restoration (CAP Section 206)	Work under this authority may carry out aquatic ecosystem restoration projects that will improve the quality of the environment, are in the public interest, and are cost-effective. There is no requirement that an existing Corps project be involved	$28.7 million
Bring Back the Natives Grant Program	The Bring Back the Natives initiative (BBN) funds on-the-ground efforts to restore native aquatic species to their historic range. Projects should involve partnerships between communities, agencies, private landowners, and organizations that seek to rehabilitate streamside and watershed habitats. Projects should focus on habitat needs of species such as fish, invertebrates, and amphibians that originally inhabited the waterways across the country. Funding for the BBN program is administered through NFWF from federal agencies cooperating to support this program. Cooperating agencies and organizations include the US Fish and Wildlife Service (USFWS), Bureau of Land Management (BLM), USDA Forest Service (USFS), and Trout Unlimited (TU).	TBD

Table 10.7 (cont.): Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
Coastal Program	The U.S. Fish and Wildlife Service (USFWS) Coastal Program works to conserve healthy coastal habitats on public or private land for the benefit of fish, wildlife, and people in 22 specific coastal areas. The program forms cooperative partnerships designed to (1) protect costal habitats by providing technical assistance for conservation easements and acquisitions; (2) restore coastal wetlands, uplands, and riparian areas; and (3) remove barriers to fish passage in coastal watersheds and estuaries. Program biologists provide restoration expertise and financial assistance to federal and state agencies, local and tribal governments, businesses, private landowners, and conservation organizations such as local land trusts and watershed councils.	$14.74 million
Community-based Habitat Restoration Partnership Grants	The NOAA Community-based Restoration Program (NOAA CRP) provides funds for small-scale, locally driven habitat restoration projects that foster natural resource stewardship within communities. The program seeks to bring together diverse partners to implement habitat restoration projects to benefit living marine resources. Projects might include restoring salt marshes, mangroves, and other coastal habitats; improving fish passage and habitat quality for anadromous species; removing dams; restoring and creating oyster reefs, removing exotic vegetation and replanting with native species; and similar projects to restore habitat or improve habitat quality for populations of marine and anadromous fish.	$6.3 million
Conservation Reserve Program	The Conservation Reserve Program (CRP) is a voluntary program for agricultural landowners. Through CRP, you can receive annual rental payments and cost-share assistance to establish long-term, resource conserving covers on eligible farmland.	$1.9 billion
Conservation Security Program	The Conservation Security Program (CSP) is a voluntary conservation program that supports ongoing stewardship of private lands by providing payment for maintaining and enhancing natural resources. CSP identifies and rewards those farmers and ranchers who are meeting the highest standards of conservation and environmental management on their operations.	$283 million
Emergency Watershed Protection	The USDA Natural Resources Conservation Service's Emergency Watershed Protection (EWP) program helps protect lives and property threatened by natural disasters such as floods, hurricanes, tornadoes, droughts, and wildfires. EWP provides funding for such work as clearing debris from clogged waterways, restoring vegetation, and stabilizing river banks. The measures that are taken must be environmentally and economically sound and generally benefit more than one property owner. EWP also provides funds to purchase floodplain easements as an emergency measure. Floodplain easements restore, protect, maintain, and enhance the functions of the floodplain; conserve natural values including fish and wildlife habitat, water quality, flood water retention, ground water recharge, and open space; reduce long-term federal disaster assistance; and safeguard lives and property from floods, drought, and the products of erosion. EWP can provide up to 90 percent cost share in limited resource areas as determined by the US Census.	TBD (Total funding depends on the amount of emergency funds requested during the fiscal year)

Table 10.7 (cont.): Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
Environmental Quality Incentives Program	The USDA Natural Resources Conservation Service's Environmental Quality Incentives Program (EQIP) was established to provide a voluntary conservation program for farmers and ranchers to address significant natural resource needs and objectives. EQIP offers contracts with a minimum term that ends one year after the implementation of the last scheduled practices and a maximum term of ten years. These contracts provide financial assistance to program participants to implement conservation practices. Persons or legal entities, who are owners of land under agricultural production or who are engaged in livestock or agricultural production on eligible land may participate in EQIP. EQIP activities are carried out according to an environmental quality incentives program plan of operations developed in conjunction with the producer that identifies the appropriate conservation practice or practices to address the resource concerns. The practices are subject to NRCS technical standards adapted for local conditions. NRCS approves the plan of operations and obligates contract funds for the conservation practices listed in the plan of operations.	$1.067 billion
Farm and Ranch Lands Protection Program (FRPP)	The USDA Natural Resources Conservation Service's Farmland Protection Program (FPP) is a voluntary program that helps farmers and ranchers keep their land in agriculture and prevents conversion of agricultural land to non-agricultural uses. The program provides matching funds to organizations with existing farmland protection programs that enable them to purchase conservation easements. These entities purchase easements from landowners in exchange for a lump sum payment, not to exceed the appraised fair market value of the land's development rights. The easements are for perpetuity unless prohibited by state law. Eligible land is land on a farm or ranch that has prime, unique, statewide, or locally important soil or contains historical or archaeological resources; supports the policy of a State or local farm and ranch land protection policy; is subject to a pending offer by an eligible entity; and includes cropland, rangeland, grassland, pasture land, forest land and other incidental land that is part of an agricultural operation.	$105 million (for technical and financial assistance)
Five-Star Restoration Program	The EPA supports the Five-Star Restoration Program by providing funds to the National Fish and Wildlife Foundation and its partners, the National Association of Counties, NOAA's Community-based Restoration Program and the Wildlife Habitat Council. These groups then make subgrants to support community-based wetland and riparian restoration projects. Competitive projects will have a strong on-the-ground habitat restoration component that provides long-term ecological, educational, and/or socioeconomic benefits to the people and their community. Preference will be given to projects that are part of a larger watershed or community stewardship effort and include a description of long-term management activities. Projects must involve contributions from multiple and diverse partners, including citizen volunteer organizations, corporations, private landowners, local conservation organizations, youth groups, charitable foundations, and other federal, state, and tribal agencies and local governments. Each project would ideally involve at least five partners who are expected to contribute funding, land, technical assistance, workforce support, or other in-kind services that are equivalent to the federal contribution.	$300,000

Table 10.7 (cont.): Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
Healthy Forests Reserve Program	The Healthy Forests Reserve Program (HFRP) is a voluntary program established for the purpose of restoring and enhancing forest ecosystems to: 1) promote the recovery of threatened and endangered species, 2) improve biodiversity; and, 3) enhance carbon sequestration. Program implementation has been delegated by the Secretary of Agriculture to the Natural Resources Conservation Service.	TBD
Forest Legacy Program	Through its Forest Legacy Program (FLP), the USDA Forest Service supports state efforts to protect environmentally sensitive forest lands from the conversion to non-forest uses through the use of conservation easements and fee-simple purchase. Designed to encourage the protection of privately owned forest lands, FLP is an entirely voluntary program. The program enables landowners to retain ownership of their land and continue to earn income from it while keeping drinking water safe and clean, conserving valuable open space as well as protecting critical wildlife habitats and outdoor recreation opportunities. The program promotes professional forest management and requires forest management plans. The program emphasizes strategic conservation - working in partnership with States, local communities and non-governmental organizations to make a difference on the land and for communities by conserving areas of unbroken forest, watershed or river corridor forests or by complimenting existing land conservation efforts. FLP conservation easements restrict development, protect a range of public values and many require public access for recreation.	$57 million
NOAA Open Rivers Initiative	The NOAA Open Rivers Initiative (ORI) provides funding and technical expertise for community-driven, small dam and river barrier removals, primarily in coastal states. Projects are expected to provide an economic boost for communities, enhance public safety, and improve populations of NOAA trust resources such as striped bass, Atlantic and shortnose sturgeon, Atlantic and Pacific salmon, American eel, American shad, blueback herring, and alewife. Proposals selected will be implemented through a cooperative agreement	$7 million
National Integrated Water Quality Program (NIWQP)	The National Integrated Water Quality Program (NIWQP) provides funding for research, education, and extension projects aimed at improving water quality in agricultural and rural watersheds. The NIWQP has identified eight "themes" that are being promoted in research, education and extension. The eight themes are (1) Animal manure and waste management (2) Drinking water and human health (3) Environmental restoration (4) Nutrient and pesticide management (5) Pollution assessment and prevention (6) Watershed management (7) Water conservation and agricultural water management (8) Water policy and economics. Awards are made in four program areas - National Facilitation Projects, Regional Coordination Projects, Extension Education Projects, and Integrated Research, Education and Extension Projects. Please note that funding is only available to universities.	$12 million

Table 10.7 (cont.): Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
National Wildlife Refuge Friends Group Grant Program	The National Fish and Wildlife Foundation provides grants for projects that help organizations to be effective co-stewards of our Nation's important natural resources within the National Wildlife Refuge System. This program provides competitive seed grants to help increase the number and effectiveness of organizations interested in assisting the refuge system nationwide. The program will fund: (1) Start-up Grants to assist starting refuge support groups with formative and/or initial operational support (membership drives, training, postage, etc.); (2) Capacity Building Grants to strengthen existing refuge support groups' capacity to be more effective (outreach efforts, strategic planning, membership development); and (3) Project Specific Grants to support a specific project (conservation education programs for local schools, outreach programs for private landowners, habitat restoration projects, etc.)	TBD
Native Plant Conservation Initiative	The National Fish and Wildlife Foundation's Native Plant Conservation Initiative (NPCI) supports on-the-ground conservation projects that protect, enhance, and/or restore native plant communities on public and private land. Projects typically fall into one of three categories and may contain elements of each: protection and restoration, information and education, and inventory and assessment. Applicants are encouraged, when appropriate, to include a pollinator component in their project. This program is funded by the Bureau of Land Management, Forest Service, Fish and Wildlife Service, and National Park Service.	TBD
North American Wetlands Conservation Act Grants Program	The U.S. Fish and Wildlife Service's Division of Bird Habitat Conservation administers this matching grants program to carry out wetlands and associated uplands conservation projects in the United States, Canada, and Mexico. Grant requests must be matched by a partnership with nonfederal funds at a minimum 1:1 ratio. Conservation activities supported by the Act in the United States and Canada include habitat protection, restoration, and enhancement. Mexican partnerships may also develop training, educational, and management programs and conduct sustainable-use studies. Project proposals must meet certain biological criteria established under the Act. Visit the program web site for more information. (Click on the hyperlinked program name to see the listing for "Primary Internet".)	$83 million
Partners for Fish and Wildlife Program	The Partners for Fish and Wildlife Program provides technical and financial assistance to private landowners to restore fish and wildlife habitats on their lands. Since 1987, the program has partnered with more than 37,700 landowners to restore 765,400 acres of wetlands; over 1.9 million acres of grasslands and other upland habitats; and 6,560 miles of in-stream and streamside habitat. In addition, the program has reopened stream habitat for fish and other aquatic species by removing barriers to passage.	TBD

Table 10.7 (cont.): Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
Pesticide Environmental Stewardship Grants	EPA's Pesticide Environmental Stewardship Program (PESP) offers grants to support the reduction of risks from pesticides in agricultural and non-agricultural settings, and to implement pollution prevention measures. All organizations with a commitment to pesticide risk reduction are eligible to join PESP as members, either as Partners or as Supporters. For more information about membership requirements and available grants, click on the program name and refer to the link listed under "Primary Internet."	$500,000
Project Modifications for Improvement of the Environment (CAP Section 1135)	Work under this authority provides for modifications in the structures and operations of water resources projects constructed by the Corps of Engineers to improve the quality of the environment. Additionally, the Corps may undertake restoration projects at locations where an existing Corps project has contributed to the degradation. The primary goal of these projects is ecosystem restoration with an emphasis on projects benefiting fish and wildlife. The project must be consistent with the authorized purposes of the project being modified, environmentally acceptable, and complete within itself	$28.7 million
Pulling Together Initiative	The National Fish and Wildlife Foundation's Pulling Together Initiative (PTI) provides a means for federal agencies to partner with state and local agencies, private landowners, and other interested parties to develop long-term weed management projects within the scope of an integrated pest management strategy. The goals of PTI are: (1) to prevent, manage, or eradicate invasive and noxious plants through a coordinated program of public/private partnerships; and (2) to increase public awareness of the adverse impacts of invasive and noxious plants. PTI provides support on a competitive basis for the formation of local weed management area (WMA) partnerships, allowing them to demonstrate successful collaborative efforts and develop permanent funding sources for the maintenance of WMAs from the involved parties. Successful projects will serve to increase public awareness and interest in future partnership projects.	TBD
Watershed Protection and Flood Prevention Program	Also known as the 'Watershed Program' or the 'PL 566 Program,' this program provides technical and financial assistance to address water resource and related economic problems on a watershed basis. Projects related to watershed protection, flood mitigation, water supply, water quality, erosion and sediment control, wetland creation and restoration, fish and wildlife habitat enhancement, agricultural water conservation, and public recreation are eligible for assistance. Technical and financial assistance is also available for planning new watershed surveys.	$40 million

Table 10.7 (cont.): Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
Sustainable Agriculture Research and Education	The Sustainable Agriculture Research and Education (SARE) program of the U.S. Department of Agriculture works to advance farming systems that are more profitable, environmentally sound and good for communities through an innovative grants program. More specifically, SARE funds scientific investigation and education to reduce the use of chemical pesticides, fertilizers, and toxic materials in agricultural production; to improve management of on-farm resources to enhance productivity, profitability, and competitiveness; to promote crop, livestock, and enterprise diversification and to facilitate the research of agricultural production systems in areas that possess various soil, climatic, and physical characteristics; to study farms that have are managed using farm practices that optimize on-farm resources and conservation practices; and to promote partnerships among farmers, nonprofit organizations, agribusiness, and public and private research and extension institutions. Click on program name and check the link in the Primary Internet box for more information about grant opportunities and program results.	$14.4 million
Watershed Rehabilitation Program	This program provides Federal cost-share funding for the rehabilitation of aging dams that were installed primarily through the Watershed Protection and Flood Prevention Program over the past 55 years. The purpose for rehabilitation is to extend the service life of dams and bring them into compliance with applicable safety and performance standards or to decommission the dams so they no longer pose a threat to life and property.	$40 million through the FY2009 Appropriations, $50 million through the American Recovery and Reinvestment Act
Watershed Rehabilitation Program	This program provides Federal cost-share funding for the rehabilitation of aging dams that were installed primarily through the Watershed Protection and Flood Prevention Program over the past 55 years. The purpose for rehabilitation is to extend the service life of dams and bring them into compliance with applicable safety and performance standards or to decommission the dams so they no longer pose a threat to life and property.	$40 million through the FY2009 Appropriations, $50 million through the American Recovery and Reinvestment Act
Wetlands Reserve Program	Through this voluntary program, the USDA Natural Resources Conservation Service (NRCS) provides landowners with financial incentives to restore and protect wetlands in exchange for retiring marginal agricultural land. To participate in the program landowners may sell a conservation easement or enter into a cost-share restoration agreement (landowners voluntarily limit future use of the land, but retain private ownership). Landowners and the NRCS jointly develop a plan for the restoration and maintenance of the wetland.	$500 million

Table 10.7 (cont.): Summary of pertinent federal funding programs

Funding Program	Program Description	FY2009 Funds
Wildlife Habitat Incentives Program	The Wildlife Habitat Incentives Program (WHIP) is a voluntary program for people who want to develop and improve wildlife habitat on private lands. It provides both technical assistance and cost sharing to help establish and improve fish and wildlife habitat. Participants work with USDA's Natural Resources Conservation Service to prepare a wildlife habitat development plan in consultation with a local conservation district. The plan describes the landowner's goals for improving wildlife habitat, includes a list of practices and a schedule for installing them, and details the steps necessary to maintain the habitat for the life of the agreement.	$74 million

CHAPTER 11. PUBLIC PARTICIPATION

This chapter describes some of the opportunities that have been made available to the public for comment on and participation in the development of the Klamath River TMDL Staff Report and Action Plan as well as the recalculated Site Specific Objective (SSO) for dissolved oxygen (DO). (See Appendix 1)

11.1 Public Outreach

Regional Water Board staff have held numerous meetings to update and inform the public throughout the Klamath River TMDL development process and recalculated SSO for DO in the mainstem Klamath. Opportunities for public participation in the recalculation of the SSOs for DO in the mainstem Klamath began in 2009 when staff efforts first began on this separate project. The first public outreach meeting related to the Klamath River TMDLs was held on February 25, 2004 in Yreka, California. Since that time there have been 17 additional outreach meetings held in various locations throughout the Klamath River basin and the North Coast Region, the most recent meeting occurring on July 9, 2009. A complete list of the public meetings that have been held about the Klamath River TMDL is presented in Table 11.1.

Table 11.1: Public meetings for the Klamath River TMDL

	March 12, 2009	Santa Rosa, CA
June 2009 Public Review Draft of the Klamath River TMDL and SSO for DO	July 6, 2009	Klamath Falls, CA
	July 7, 2009	Yreka, CA
	July 8, 2009	Orleans, CA
	July 9, 2009	Klamath, CA

11.1.1 CEQA Scoping Meetings

The purpose of the California Environmental Quality Act (CEQA) Scoping Meetings was to solicit public comments to help staff assess the potential environmental scope of the environmental analysis. Holding a scoping meeting is a requirement of the CEQA. Given the vast expanse of the Klamath River basin and the statewide and national interest in Klamath River issues, Regional Water Board held several Scoping Meetings throughout the basin, as well as meetings outside the basin, to ensure that all parties who wished to give input would have an opportunity to do so. Table 11.1 summarizes the scoping meetings for the Klamath River TMDL. The comments received at the CEQA Scoping Meetings that concerned the scope of the environmental review are summarized in Chapter 9. These comments, and others, helped to shape the scope of the environmental review and specific aspects of the analysis.

11.1.2 Klamath River TMDL Webpage

In addition to holding public meetings, Regional Water Board staff have maintained a webpage on the North Coast Regional Water Quality Control Board's website where the latest, up-to-date information on the Klamath River TMDL development process can be found. Fact Sheets, which contain summary information on the TMDL development process in the Klamath River basin, are also located on the website. The first Fact Sheet was posted in November 2004. There have been six updates to the fact sheets since that time, the latest on January 27, 2006. The website can be accessed at: <http://www.waterboards.ca.gov/northcoast/water_issues/programs/TMDL/klamath_river/>.

11.2 Presentations to the Regional Water Board

Periodically, Regional Water Board staff have presented updates and status reports to the Regional Water Board and interested members of the public on the Klamath River TMDL. The presentations were opportunities for the public and Board members to hear status updates and background information regarding progress and emerging issues related to the TMDL development process. At each of these meetings, the public also had the opportunity to give comment before the Board. All such comments are part of the public record. Table 11.2 presents a complete list of the presentations given to the Regional Water Board about various aspects of Klamath River TMDL development.

Table 11.2: Presentations given at Regional Water Board meetings

Subject	Date	Location
Status Report on TMDL Development	February 10, 2004	Santa Rosa, CA

Update on Klamath River TMDLs Water Quality Modeling Technical Analysis	December 10, 2009	Santa Rosa, CA

11.3 Presentations to Various Organizations and Conferences

In order to reach a broad audience regarding the details of the Klamath River TMDL, Regional Water Board staff have presented updates on the TMDL at public meetings held by other organizations and agencies. Additionally, staff have given presentations at conferences specifically focused on the Klamath River basin, as well as science conferences pertaining to water quality protection. A complete list of these presentations is available in Table 11.3.

11.4 Other Meetings about the Klamath River TMDL

There have been numerous targeted stakeholder meetings to discuss the progress of the Klamath River TMDL and SSOs for DO with individual agencies and organizations including, but not limited to, PacifiCorp, California Department of Fish and Game, U.S. Forest Service, U.S. Bureau of Reclamation, the North Coast California Consent Decree Plaintiffs, and watershed groups such as the Upper Mid Klamath Watershed Council.

The USEPA and the Regional Water Board have initiated an informal consultation process with the U.S. Fish and Wildlife Service (USFWS) and the National Oceanic and Atmospheric Administration, Fisheries (NOAA Fisheries) on Klamath River TMDL and SSOs for DO. Regional Water Board and USEPA staff have used this process to provide information and updates on the TMDL and SSOs for DO.

The USEPA and Regional Water Board have also held regular meetings with representatives of the Klamath River basin tribes in California to provide updates on the TMDL process, as part of USEPA's tribal trust responsibilities. These meetings have been held approximately quarterly since 2004.

Finally, there has been and continues to be informal contact with many individuals and organizations active in the Klamath River basin.

11.5 Peer Review

Prior to development of the Public Review Draft of the Klamath River TMDL Staff Report, a peer- review draft report was reviewed by the following four PhDs as part of a formal state-mandated peer-review process:

- Dr. Gregory Characklis, Professor of Environmental Sciences and Engineering at the University of North Carolina;
- Dr. G. Mathias Kondolf, Professor of Environmental Planning and Geography at the University of California, Berkeley;
- Dr. Christopher A. Myrick, Associate Professor of Fishery Biology at Colorado State University; and
- Dr. Desiree Tullos, Assistant Professor of Biological and Ecological Engineering at Oregon State University.

Responses to the peer-review comments from these reviewers are presented in Appendix 8.
For a discussion of peer review of the revised DO objective, please see Appendix 1.

11.6 June 2009 Public Review Draft

Chapters 1-3 and five appendices of the June 2009 Public Review Draft of the Staff Report were posted on the Regional Water Board website on June 15, 2009. Additional Chapters and Appendices were posted as they were completed, with the final Chapters of the Staff Report and the Action Plan available for public review and comment on July 9, 2009.

The public review period for the Staff Report and Action Plan was initially set to close on August 17, 2009. However, the review period was extended twice to allow for the full legally required review period. The first extension was to August 23, 2009, and finally the public review and comment period was extended to August 27, 2009. This final extension allowed for a 74 day review period from the time the first Chapters and appendices were posted (June 15, 2009), and a 50 day review period once the complete Staff Report and Action Plan were available on the Regional Water Board website (July 9, 2009).

The June 2009 Public Review Draft release and public comment period dates are summarized below.

June 2009 Public Review Draft Release: First Postings:....... June 15, 2009
Final Chapters Posted: ....July 9, 2009

End of June 2009 Public Review Draft Comment Period ....August 27, 2009
Total Comment Period: 50 days

11.7 December 2009 Public Review Draft and Opportunities for Input

The December 2009 Public Review Drafts, including Appendix 1 (recalculated SSO for DO in the mainstem Klamath) was released on December 23, 2009 for public review and comment. Throughout the Basin Plan amendment process, there are opportunities for public participation and comment, including at the CEQA scoping meetings, at the Regional Water Board and associated workshops prior to the Regional Water Board hearing for the proposed TMDL Basin Plan amendment, at the Regional Water Board hearing to consider adoption of the TMDL Basin Plan amendment, before the State Water Board, and during public forum at any Regional Water Board meeting. The following opportunities and their estimated dates remain for public comment on the proposed Klamath River TMDL Basin Plan amendment. Please note that the following dates and meeting locations may change and additional meetings may be scheduled. Interested parties should check the Regional Water Board website for announcements regarding Regional Water Board meetings, revisions to the DO objectives, and the Klamath River TMDL at: http://www.waterboards.ca.gov/northcoast/.

End of December 2009 Public Review Draft Comment Period	February 9, 2010
December 2009 Public Review Draft Regional Water Board Workshop in Yreka, CA	January 27, 2010
Public Adoption Hearing before the Regional Water Board in Eureka, CA	March 24-25, 2010

EXECUTIVE SUMMARY

Ambient water quality objectives for the Klamath River are contained in Table 3-1 of the *Water Quality Control Plan for the North Coast Region* otherwise known as the Basin Plan. The existing site specific objectives (SSOs) for dissolved oxygen (DO) in the Klamath River were developed based on grab sample data collected during the 1950s and 1960s and represent the elevated, sometime supersaturated, DO conditions typically found during the day when photosynthesis is active. Twenty four-hour DO data collected using DataSonde data probes can not reasonably be compared to the existing SSOs for DO. Further, conditions of barometric pressure and temperature prevent the attainment of the existing SSOs for DO in some locations during some times of the year. Finally, the T1BSR natural conditions run of the *Klamath TMDL model* indicates that under natural conditions, the ambient DO concentrations are frequently less than the existing SSOs for DO.

This Staff Report assesses the DO objectives for the mainstem Klamath, analyzes new DO information, evaluates several alternative methods for recalculating the SSOs for DO, and proposes a recalculated SSO for DO in the mainstem Klamath River. The proposed recalculated SSOs for DO are achievable under natural conditions and are protective of the beneficial uses of the watershed. The proposed recalculated SSOs for DO are based on the natural DO conditions in the basin as estimated using percent saturation and natural receiving water temperatures. Based on natural conditions, the recalculated SSOs for DO necessarily protect any beneficial uses which naturally are or were present in the basin prior to anthropogenic disruption. In a memorandum dated November 5, 1997, Tudor Davies, Director of the Office of Science and Technology at USEPA headquarters in Washington, D.C. corroborates this approach by saying: “For aquatic life uses, where the natural background concentration for a specific parameter is documented, by definition that concentration is sufficient to support the level of aquatic life expected to occur naturally at the site absent any interference by humans.” (p. 2)

The proposed alternative is Alternative 3 which is summarized below. It is to apply to the maximum extent allowed by law. To the extent that the State lacks jurisdiction, the proposed SSO is extended as a recommendation to the applicable regulatory authority."

THIS SECTION INTENTIONALLY LEFT BLANK

Location	Percent DO Saturation Based on natural receiving water temperatures	Time period
Stateline to Scott River	90%	October 1 through March 31
	85%	April 1 through September 30
Scott River to Hoopa	90%	Year round
Hoopa to Turwar	90%	September 1 through May 31
	85%	June 1 through August 31
Upper and Middle Estuary	80%	August 1 through August 31
	85%	September 1 through October 31 and June 1 through July 31
	90%	November 1 through May 31
Lower Estuary	For the protection of estuarine habitat (EST), the dissolved oxygen content of the lower Klamath estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors.	

Table 7.4 of the Staff Report presents the DO concentrations corresponding to the percent saturation criteria as based on estimates of natural receiving water temperatures contained in the *Klamath TMDL model.*

National Criteria for the protection of early life stages of coldwater organisms require: 9.5 mg/L DO as a 7-day mean in the water column, 6.5 mg/L as a 7-day mean in the intergravel environment, 8.0 mg/L as a 1-day minimum in the water column and 5.0 mg/L as a daily minimum in the intergravel environment. For the protection of other life stages of coldwater organisms, the National Criteria require 6.5 mg/L DO as a 30-day mean, 5.0 mg/L as a 7-day mean of the daily minima, and 4.0 mg/L as a 1-day minimum. US Environmental Protection Agency (USEPA 1986) provides guidance on the development of alternate aquatic life criteria for DO based on the degree to which local criteria must protect against any production impairment, or can allow for slight or moderate production impairment. USEPA (1986) also allows that "where natural conditions alone create dissolved oxygen concentrations less than 110 percent of the applicable criteria means or minima or both, the minimum acceptable concentration is 90 percent of the natural concentration." (p. 35)

Staff compared simulated DO concentrations under natural conditions as produced by the T1BSR natural conditions run of the *Klamath TMDL model* to the National Criteria. Simulated DO concentrations under natural conditions meet a 4.0 mg/L daily minimum all year long, as well as 6.5 mg/L as a 30-day mean. From October to March, simulated natural DO concentrations also meet an 8.0 mg/L daily minimum protecting incubating salmonids. An 8.0 mg/L daily minimum is even met from September through May with exceptions from a location upstream of Iron Gate Dam to a location upstream of the Shasta River. The spawning and incubation period in the Klamath mainstem is generally estimated to last from October 1 through April 30, with the possibility of inter-annual variation.

The DO modeling output does not provide a convenient way of assessing consistency with the 7-day mean National Criteria. But, if the 9.5 mg/L DO criteria is increased to 10.0 and applied as a 30-day mean, simulated DO concentrations under natural conditions as produced by the T1BSR natural conditions run of the *Klamath TMDL model* meets the criteria from November 1 through March 31 at all locations and from October 1 through April 1 at all locations from Seiad to the Lower Estuary.

While simulated natural DO concentrations generally meet the National Criteria, staff believe that the threatened and endangered status of salmonids in the basin require the establishment of DO objectives based on protection against any further production impairment. The T1BSR run of the *Klamath TMDL model,* however, demonstrates that the mainstem Klamath River under natural conditions does not consistently produce DO consistent with no production impairment, as defined by USEPA (1986). As such, staff proposes DO criteria based on natural conditions. As described by Davies (1997) for aquatic life uses, by definition natural conditions are sufficient to support the level of aquatic life expected to occur naturally at the site absent any interference by humans.

The biochemical processes influencing ambient DO concentrations are complex and difficult to simulate site-specifically with perfect accuracy. As such, staff estimated natural DO conditions using percent saturation and natural receiving water temperatures. Receiving water temperatures can be estimated with greater accuracy than can DO and are comparatively consistent in pattern and range from year to year. The *Klamath TMDL model* simulates percent saturation at various locations throughout the mainstem Klamath as a result of barometric pressure, salinity, and natural temperatures at those locations, as influenced by boundary conditions for percent saturation estimated from historical data. The mainstem Klamath under natural conditions meets a minimum percent DO saturation of 85% throughout its length (with an exception during August in the estuary) and 90% during the winter months.

The proposed recalculated SSOs for DO are protective of the beneficial uses for the following reasons:

- They are based on natural conditions, thereby providing water quality comparable to the water quality in which the beneficial uses naturally exist.
- They result in DO concentrations that vary with the seasons, thereby ensuring greater DO concentrations in the winter months when salmonids embryos and alevin reside in the gravels.
- They result in daily minimum DO concentrations greater than 4.0 mg/L throughout the year (National Criteria).
- They result in daily minimum DO concentrations greater than 8.0 mg/L at all locations and throughout all of the identified incubation season (National Criteria).
- They result in 30-day means greater than 6.5 mg/L DO all year and greater than 10.0 mg/L at most locations during the identified spawning and incubation season (National Criteria).
- The transfer of DO from the water column to the intergravel environment may be more efficient than predicted by USEPA (1986) indicating a difference between the water column and intergravel environment of less than 3.0 mg/L, on average. Monitoring data should be collected to determine the relationship between water column DO and intergravel DO at key locations throughout the mainstem Klamath. In this way, staff could better define the DO conditions

required in the water column to ensure no production impairment in the intergravel environment.

- They include protections, through the implementation of the Klamath River TMDLs of thermal refugia in the tributaries where most of the spawning and incubation in the basin actually occurs. In addition, they are companions to the TMDL load allocations and source control measures, including measures designed to reduce sediment, decrease temperatures, and decrease organic matter and nutrient inputs.
- They are companions to other water quality objectives contained in the Basin Plan such as narrative objectives that protect natural temperature conditions and protect against suspended sediment, turbidity and settleable matter in quantities that harms beneficial uses.

Further, the proposed recalculated SSOs for DO in the mainstem Klamath River are consistent with the Hoopa Valley Tribe's water quality objectives for DO. That is, though the T1BSR run of the *Klamath TMDL model* indicates that natural conditions prevent the attainment of the life cycle-based DO requirements contained in the Hoopa Valley Tribe's Basin Plan, the proposed 90% DO saturation criteria based on natural receiving water temperatures from the Scott River to Hoopa is identical to the natural conditions clause included in Hoopa's Basin Plan. Staff proposes the T1BSR run of the *Klamath TMDL model* as the tool for quantifying natural DO conditions.

This Staff Report incorporates by reference several chapters of the Klamath TMDL Staff Report of which it is a part. For example, Chapters 6 (Implementation Plan), 7 (Monitoring Plan), 9 (CEQA Analysis), 10 (Economic Analysis), and 11 (Public Participation) describe factors related to both the Klamath TMDL and the recalculated SSOs for DO.

CHAPTER 1.
INTRODUCTION

The purpose of this Staff Report is to present the scientific justification for a recalculation of the existing Site Specific Objectives (SSO) for Dissolved Oxygen (DO) in the Klamath River mainstem (Klamath). Staff to the North Coast Regional Water Quality Control Board (Regional Water Board) has:

1. Reviewed the existing SSO for DO in the Klamath;
2. Analyzed new sources of data and information related to DO conditions in the Klamath; and
3. Recalculated an SSO for DO in the Klamath based on a series of water quality models used to establish the Total Maximum Daily Loads (TMDL) for organic matter, nutrients, temperature, dissolved oxygen, and microcystin necessary to achieve water quality objectives, including objectives for DO.

This Staff Report is an appendix to the Klamath River Total Maximum Daily Load (TMDL) Staff Report which includes an implementation plan, monitoring plan, economic analysis, discussion of public participation, and California Environmental Quality Act (CEQA) analysis applicable to both the proposed TMDL and DO SSO basin plan amendments for the Klamath River.

1.1 Description of the Klamath River Watershed

The Klamath River basin[1] is 12,680 square miles in area. The Klamath River originates in southern Oregon and flows through northern California to meet the Pacific Ocean at Requa in Del Norte County, California. Forty-four percent of the watershed lies within the boundaries of Oregon, while the remaining 56% of the basin lies within the boundaries of California. Figure 1.1 is a map of the Klamath River basin.

The Klamath River basin is of vital economic and cultural importance to the states of Oregon and California, as well as to the Klamath Tribes in Oregon; the Hoopa, Karuk, and Yurok Tribes in California; the Quartz Valley Indian Reservation in California; and the Resighini Rancheria in California. It provides fertile lands for a rich agricultural economy in the upper basin. Irrigation facilities, known as the Klamath Project, owned by the U.S. Bureau of Reclamation, support this economy as does hydroelectric power provided via a system of five dams operated by PacifiCorp. The basin is the home spawning grounds of a once vast tribal, sport, and commercial fishery and provides other aquatic resources of cultural significance to the local tribes. The watershed supports an active recreational industry, including activities that are specific to the Wild and Scenic portions of the river designated by both the state and federal governments in Oregon and California. Finally, the watershed continues to support what were once historically significant mining and timber industries.

---

[1] For the purposes of this report, the terms "basin" and "watershed" are synonymous and will be used to refer to the area that drains flows to the Pacific Ocean at Requa.

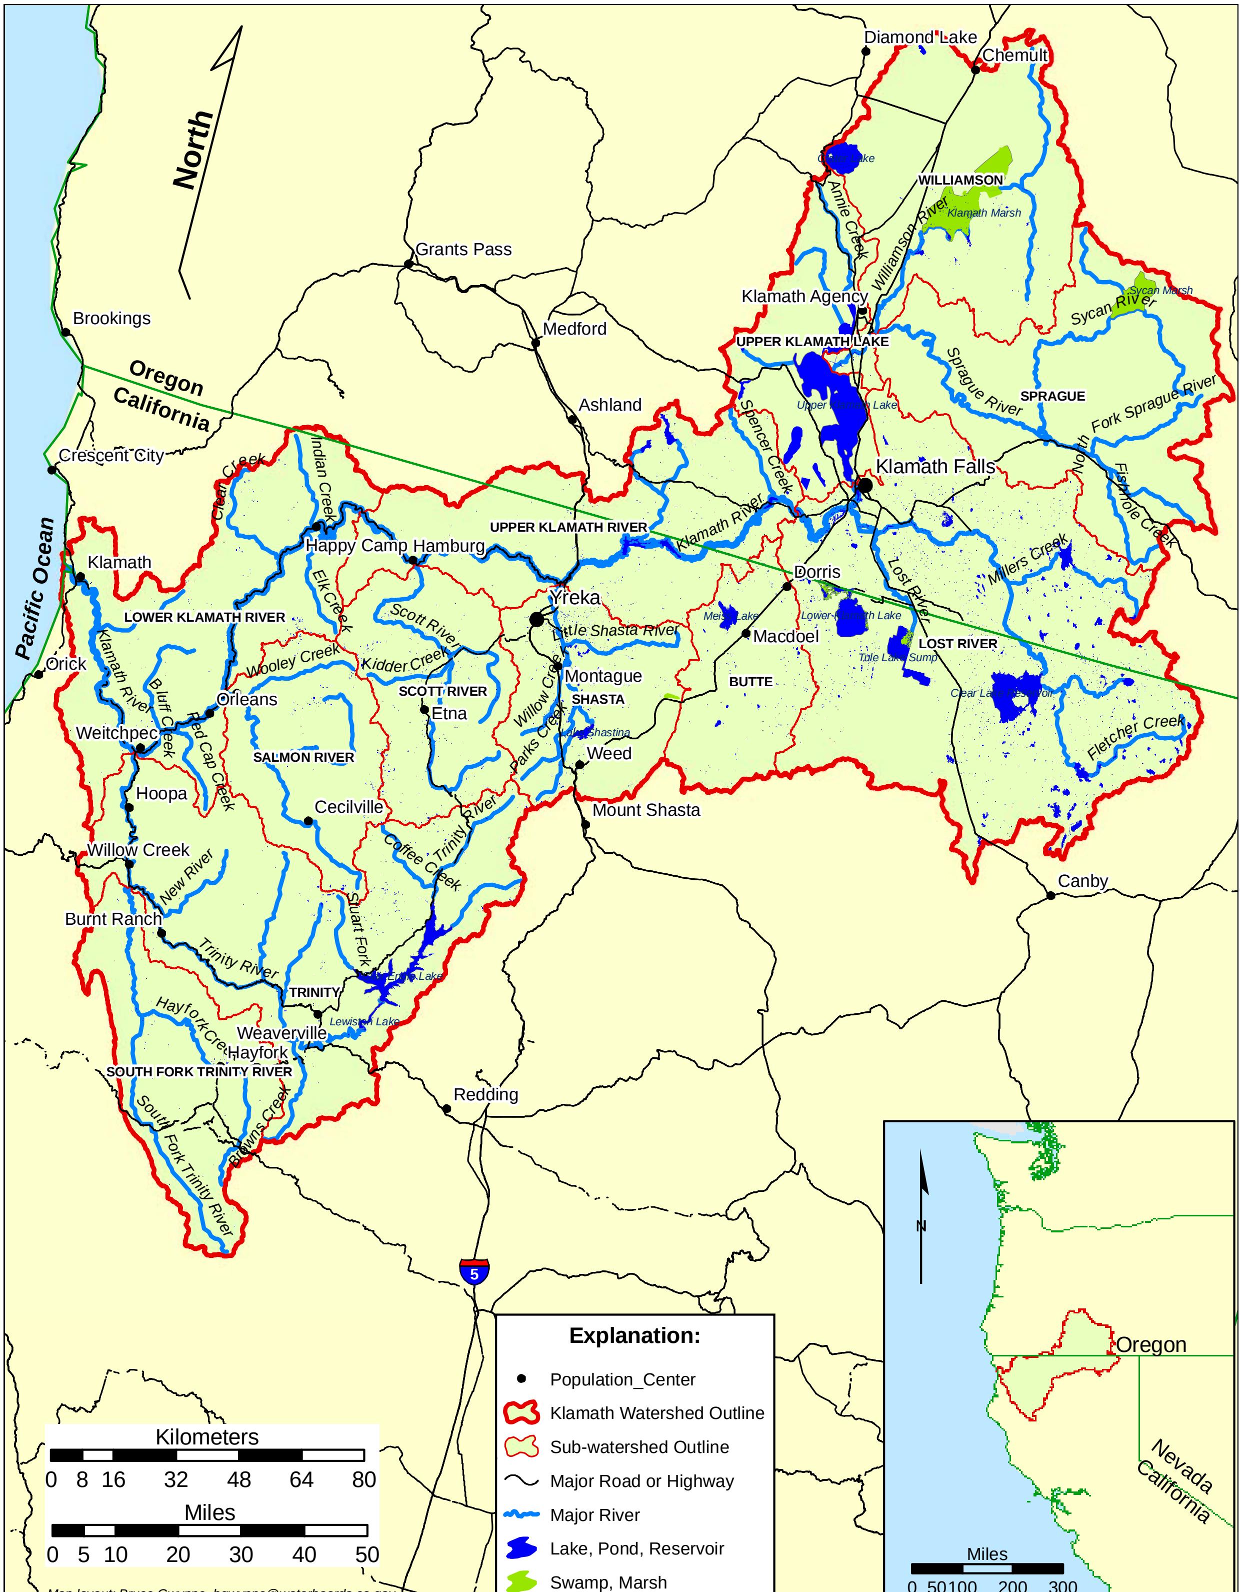

Figure 1-1: Klamath River Basin Showing Rivers, Lakes and Reservoirs, Population Centers, and Major Roads

A decline in the fisheries is one of several indicators of ecological distress in the basin. Congress passed Public Law 99-552 (Klamath Act) in 1986 to establish the Klamath River Basin Conservation Area Restoration Program with the intention of rebuilding the river's dwindling fish resources. Since that time several of the fish species endemic to the basin have been listed by federal and state agencies as threatened or endangered. Impairments to water quality have been identified as one of the factors contributing to the continued decline of native fish populations. This has led to water quality assessments by the States of Oregon and California and the listing of the Klamath River as impaired under section 303(d) of the federal Clean Water Act (CWA).

Table 1-1: Klamath River Water Quality Impairments in California

Hydrologic Area (HA)[2]	**CalWater Watershed**	**Pollutant/Stressor(s)**
Middle HA, Oregon to Iron Gate	10530000	Temperature Nutrients Organic enrichment/low dissolved oxygen
Middle HA, Copco 1 and 2 and Iron Gate Reservoirs	NA	Microcystin
Middle HA, Iron Gate Dam to Scott River	10530000	Temperature Nutrients Organic enrichment/low dissolved oxygen
Middle HA, Scott River to Trinity River	10500000	Temperature Nutrients Organic enrichment/low dissolved oxygen
Lower HA, Klamath Glen HSA, Trinity River to Pacific Ocean	10511000	Temperature Nutrients Organic enrichment/low dissolved oxygen Sedimentation/Siltation

The U.S. Environmental Protection Agency (USEPA) Region 9 has listed the portions of the Klamath River within its jurisdiction (from the CA/OR Stateline to the mouth) for impairments due to elevated water temperatures, elevated nutrients, and organic enrichment/low dissolved oxygen. In addition, the portion of the Klamath River watershed downstream of the Trinity River, partially within the Yurok Reservation, is listed for sedimentation/siltation impairment. Finally, in March 2008, the USEPA added the reach of the Klamath River that incorporates Copco 1 and 2 and Iron Gate Reservoirs to the 303(d) List for the blue-green algae toxin microcystin. Each of these impairments has an effect on ambient DO in the Klamath River mainstem. Table 1.1 summarizes the waterbody-pollutant combinations for the Klamath River in California as identified on the current (2006) section 303(d) List.

A consent decree entered into by the USEPA in March 1997 (*Pacific Coast Federation of Fisherman's Associations et al. v. EPA*) establishes the date by which TMDLs for seventeen northcoast California watersheds must be completed. The Klamath River TMDLs for the listed temperature and nutrient impairments were scheduled for

[2] Hydrologic Area (HA) is the terminology used in the CalWater watershed delineation system to identify a sub-unit of a watershed. Similarly, Hydrologic Sub Area (HSA) identifies a smaller hydrologic unit within a HA.

completion by 2007. Negotiations between USEPA and the plaintiffs resulted in an extension of that deadline to 2010.

1.2 Summary of the Proposed Action The action proposed in this Staff Report addresses the SSOs for DO on the Klamath mainstem, only. It does not affect any of the tributaries to the Klamath River.

Table 3-1 of the *Water Quality Control Plan for the North Coast Region* (Basin Plan) currently requires Klamath mainstem ambient water quality DO conditions as follows:

1) An instantaneous minimum DO upstream of the Iron Gate Dam of 7.0 mg/L. Half of the monthly mean DO values for the year must be 10.0 mg/L or greater.
2) An instantaneous minimum DO downstream of the Iron Gate Dam of 8.0 mg/L. Half of the monthly mean DO values for the year must also be 10.0 mg/L or greater.

The proposed action is an amendment to the Basin Plan to remove from Table 3-1 the instantaneous minimum and 50% lower limit numeric criteria for DO applicable as follows:

- In the Middle Klamath River HA, Klamath River above Iron Gate Dam including Iron Gate & Copco Reservoirs and Klamath River below Iron Gate Dam; and,
- In the Lower Klamath River HA, Klamath River.

In its place, language is to be inserted requiring that the DO objective for the Klamath River mainstem from the Oregon border to the Pacific Ocean is as depicted below. The percent DO saturation criteria are to be calculated as twelve (12) individual daily minima, one for each calendar month of the year using site salinity, site barometric pressure and natural receiving water temperatures.

Proposed Recalculated SSO for DO in the mainstem Klamath River
(To be applied from the Stateline to the Pacific Ocean except where there is Tribal jurisdiction).

From Stateline to Upper Hoopa Boundary

- 90% DO saturation based on natural receiving water temperatures from October 1 through March 31
- 85% DO saturation based on natural receiving water temperatures from April 1 through September 30

From Lower Hoopa Boundary to Turwar

- 85% DO saturation based on natural receiving water temperatures all year

Upper and Middle Estuary

- 80% DO saturation based on natural receiving water temperatures from August 1 through August 31

- 85% DO saturation based on natural receiving water temperatures from September 1 through July 31

Lower Estuary
For the protection of estuary habitat (EST), the Dissolved Oxygen content of the Lower Klamath Estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors.

1.3 History of the Proposed Basin Plan Amendment for DO
Regional Water Board staff has been assessing the need to revise the existing DO objectives for several years. In an August 2000 review of Russian River water quality objectives (focusing on DO, temperature, pH, oil and grease, and turbidity) for the protection of salmonid species prepared for the Sonoma County Water Agency, Regional Water Board staff found that the DO and water temperature objectives for the Russian River Basin, among others, did not afford adequate protection for species listed on the State and Federal Endangered Species Acts (CESA/ESA). In order to address this, Regional Water Board staff recommended developing numeric objectives specific to each salmonid life stage.

In 2005, staff distributed for public review a region wide proposal for the revision of both the temperature and DO objectives contained in the Basin Plan. Zabinsky and Azevedo (2005) proposed numeric temperatures objectives and updated numeric DO objectives for the protection of individual life stages of salmonids. A workshop on this subject was held before the Regional Water Board in April 2005.

Shortly thereafter, staff was diverted to the development of the Klamath Total Maximum Daily Loads (TMDL). As a result, the proposal to amend the Basin Plan's temperature and DO objectives was put on hold. As part of the Klamath TMDL, a series of models were developed to estimate water quality conditions, including temperature and DO, in the Klamath River mainstem under varying pollutant loading scenarios. Once the models were validated and calibrated, they were run to estimate natural conditions as the baseline.

One of the important findings of the TMDL natural conditions model run (T1BSR) is that DO fluctuates widely in the Klamath River mainstem due to such natural conditions as elevated summer temperatures, elevated nutrients emanating from the volcanic geology and organic-rich wetland soils of the upper basin, and elevated phytoplankton activity resulting from these natural conditions. As a result of the elevated phytoplankton activity, DO concentrations fluctuate both daily and seasonally. This fluctuation results in periodic noncompliance with the existing SSO for DO in the Klamath, particularly during the night time hours of the summer months. That is, the model demonstrates that under natural conditions, water quality in the mainstem of the Klamath River can not consistently meet the existing SSOs for DO. This is primarily due to the fact that the existing SSOs for DO are based on day time grab sample data and do not reflect the night time minima. This differs from the TMDL modeling which was calibrated and validated using 24 hour day.

After some evaluation, staff determined that the issues associated with the SSOs for DO in the Klamath River are also reflected in the SSOs for DO in the rest of the fifty-eight (58) waterbodies listed in Table 3-1 of the Basin Plan. For this reason, staff picked up the regionwide Basin Plan Amendment again, this time focusing just on DO. A CEQA scoping document was distributed and two scoping meetings held in the fall of 2008. A draft Staff Report was prepared and submitted for peer review. Peer review comments were received and responses drafted. Revisions to the regionwide proposal were prepared as a result of the peer review comments.

In the mean time, the need to establish accurate SSOs for DO in the mainstem of the Klamath River has become more pressing because of a court-ordered deadline for establishing the Klamath River TMDL by December 2010. By regulation, a TMDL must demonstrate that it will achieve applicable water quality objectives for it to be approvable. Staff has taken the concepts of the draft regionwide Basin Plan Amendment and applied them to the mainstem Klamath River as the means of establishing accurate SSOs for DO in the Klamath. This Staff Report documents the approach, including the model results which support this proposal.

After the adoption of recalculated SSOs for DO in the Klamath River, staff will finalize its proposal for amending DO objectives on a regionwide basis and bring it before the Regional Water Board for their consideration in the future.

This space intentionally left blank

CHAPTER 2.
PHYSICAL SETTING OF THE KLAMATH RIVER BASIN

The purpose of this chapter is to establish the location and physical characteristics of the Klamath River basin. The Site Specific Objectives (SSO) for Dissolved Oxygen (DO), as developed in this Staff Report, are intended to apply to those portions of the Klamath River mainstem under the jurisdiction of the State of California: from the Oregon border to the Pacific Ocean, but excluding that portion near Saints Rest Bar which is under the independent jurisdiction of the Hoopa Valley Tribe and that portion downstream of the Trinity River through the estuary under the jurisdiction of the Yurok Tribe. Factors such as landuse, topography, geology, vegetation, climate, and hydrology affect the way in which DO dynamics are expressed in the Klamath River mainstem.

2.1 Population and Land Ownership

The population in the Klamath River basin was estimated in the 2000 US Census to be about 114,000 (United States Census Bureau [USCB] 2000). The largest population concentrations lie in the upper Klamath agricultural area, the Shasta River Valley, and Scott Valley. The largest population center is Klamath Falls in Oregon (19,462 people in 2000) followed by Yreka, California (7,290 people). The Klamath River basin can generally be characterized as a rural watershed with limited population-related water quality issues.

According to Natural Resources Conservation Service (NRCS) in a report published in 2004, 63% of the Klamath River watershed is in federal, state or tribal ownership; the remaining 37% of the basin in private ownership. While federal, state, and tribal land ownership surpasses private landownership in the California portion of the Klamath watershed, ownership is more evenly divided in Oregon.

Figure 2.1 shows, among other things, federal lands managed as National Forests, National Wildlife Refuges, and National Parks, in addition to lands administered by the Bureau of Land Management (BLM). The Hoopa Valley Tribe owns land, 12 miles by 12 miles, primarily in the Trinity River watershed but intersecting the Klamath River at Saints Rest Bar upstream of the confluence with the Trinity. The Yurok Tribes' land extends from 1 mile on each side of the Klamath River from the mouth upriver for a distance of 44 miles. The Karuk Tribe owns 800 acres of tribal trust land along the Klamath River between Orleans and Happy Camp, and in Yreka, California. The Quartz Valley Indian Reservation is located near Fort Jones and encompasses 174 acres along the Scott River. The Resighini Rancheria spans 228 acres along the south shore of the mouth of the Klamath River.

Forestland accounts for about 22% of the private lands in the basin, equally divided between California and Oregon, though the private timber activity in California occurs primarily in the lower Klamath basin (NRCS 2004). Cropland/pasture activities and rangeland activities account for 14% and 21%, respectively, of the private land use in the Klamath River watershed. Private cropland and pasture are concentrated in the upper Klamath watershed; but, private rangeland is more evenly divided throughout the basin

(NRCS 2004). Urban development, commercial and industrial lands, and residential lands account for less than 1% each of the landuse activities occurring on privately owned land in the Klamath River watershed. Urban and commercial/industrial development, such as it is, is concentrated in California while residential lands are concentrated in Oregon (NRCS 2004). Commercial landuse activities such as grazing, mining, and timber harvesting occur on Federal lands managed by the U.S. Forest Service and Bureau of Land Management, as well.

By area, the vast majority of streams and lakes present in the Klamath basin are in Oregon (93%). Only 7% of the area covered by water is made up of streams and lakes found in the California portion of the basin (NRCS 2004).

2.2 Topography, Geology and Soils

Topography in the Klamath River watershed varies between steep mountains and flat and rolling valley bottoms with little in between (Figure 2.2). Elevations range from 14,179 feet (4,322 meters) at the summit of Mount Shasta to sea level at the river mouth. The Klamath River watershed crosses four recognized geomorphic provinces, each of which is defined and shaped by its unique geologic history. From east (upstream) to west (downstream) these provinces are the Modoc Plateau, Cascade Range, Klamath Mountains, and Coast Ranges (Figure 2.3). These geomorphic provinces, defined by Oakshott (1978), are the result of the different structure and composition of the underlying rocks and different times of uplift and volcanism.

Headwaters of the Klamath gather in the Modoc Plateau, an area of geologically young lava flows (Pliocene and Pleistocene – less than fifteen million years) and flat valleys punctuated by volcanic cones. The rolling valley bottoms are at about 4000 to 5000 feet (1219 to 1524 meters) elevation and the volcanic cones rise a thousand feet higher. While drainage in this young landscape is through-flowing, many depressions contain shallow lakes, most of which have been augmented by dams. Although rainfall is low, the flat and rolling valley bottoms of rich volcanic and organic soils combine with abundance of water entering from higher surrounding country to create historically vast freshwater wetlands. Many of these wetlands have been converted to farmland. The volcanic soils are naturally rich in phosphorus, a nutrient of concern in the Klamath TMDLs and important to the DO dynamics in the basin. Similarly, the conversion of wetlands to farmland and other land uses has exposed the nutrient and organic rich soils to oxidation, resulting in the release to the water column of nitrogen and phosphorus previously stored in the soil and wetland vegetation (Snyder and Morace, 1997).

The transition between the Modoc Plateau and Cascade Range provinces is not sharp, so a line on a map is by necessity a bit arbitrary (Figures 2.3, 2.4). The Cascade Range province is a belt of mainly volcanic rocks that are younger than rocks of most of the Modoc Plateau and form higher relief. The Cascade Range is defined by a chain of active and potentially active volcanoes that stretches from Mount Lassen, east of Redding, northward through Oregon and Washington into Canada. The most prominent mountain in the Klamath region is Mount Shasta, a composite volcano that rises at the head of Shasta Valley, and which last erupted about 1786. Crater Lake, in the northeast, fills the collapsed crater of a volcano that erupted cataclysmically about 7,000 years ago.

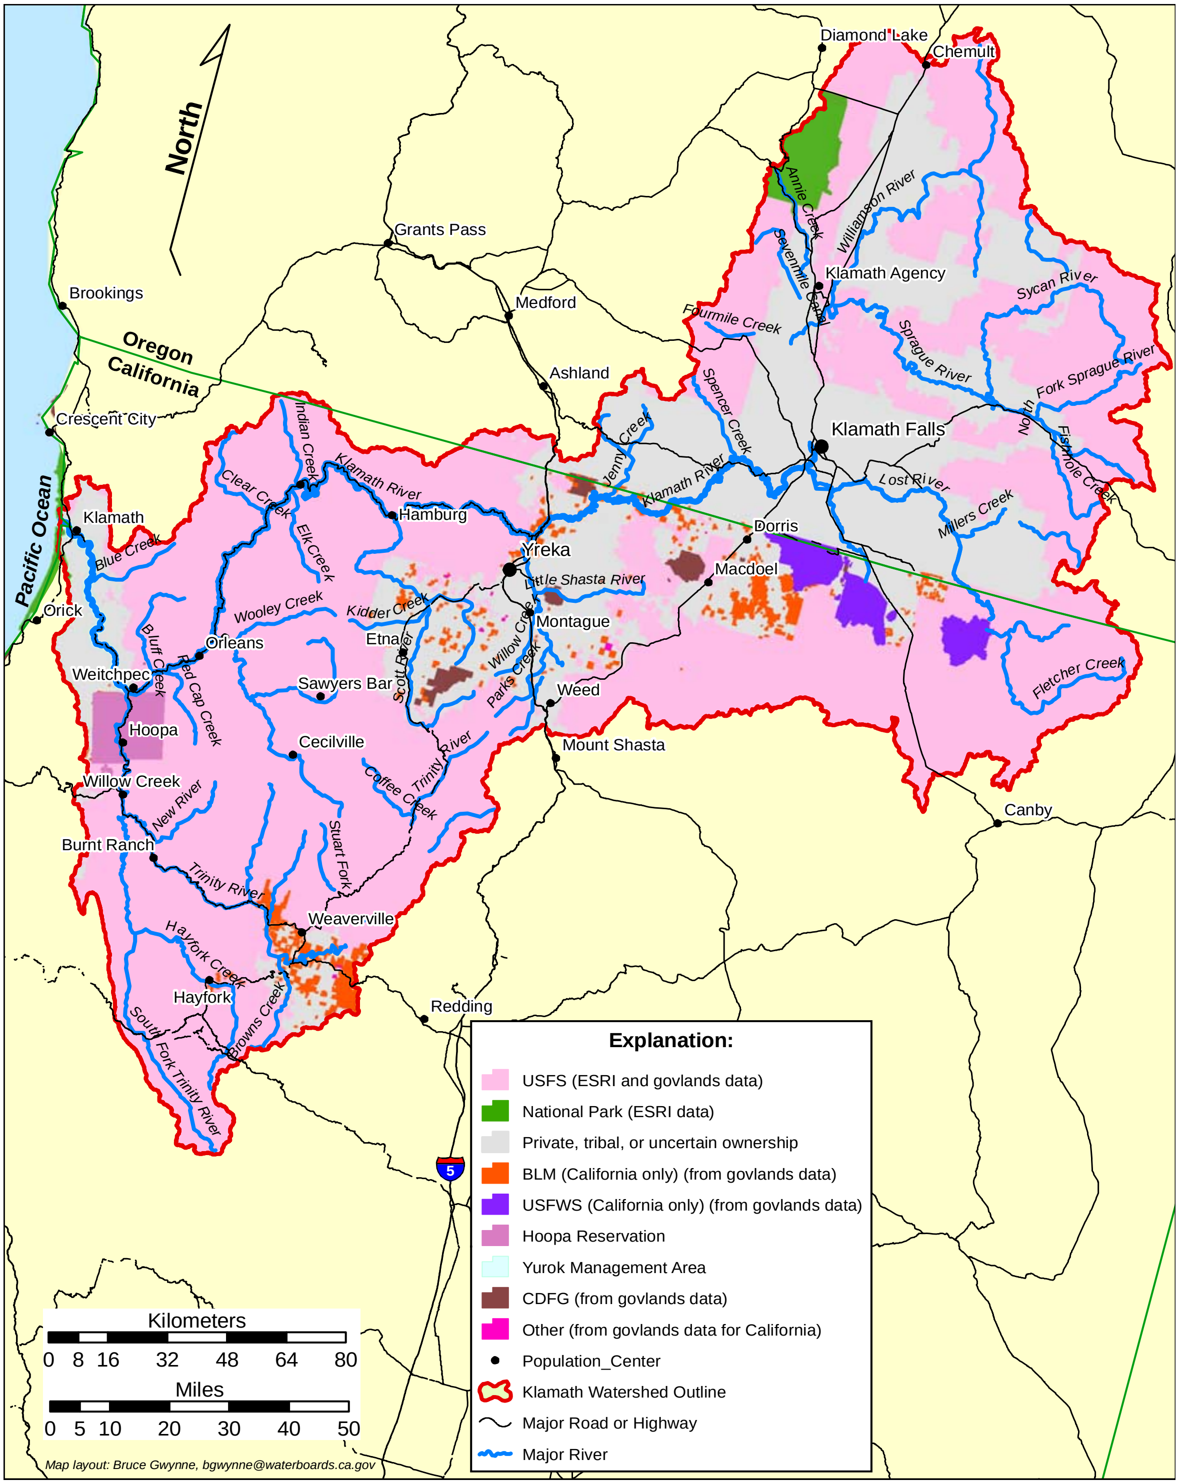

Figure 2.1: Land Ownership in the Klamath River Basin

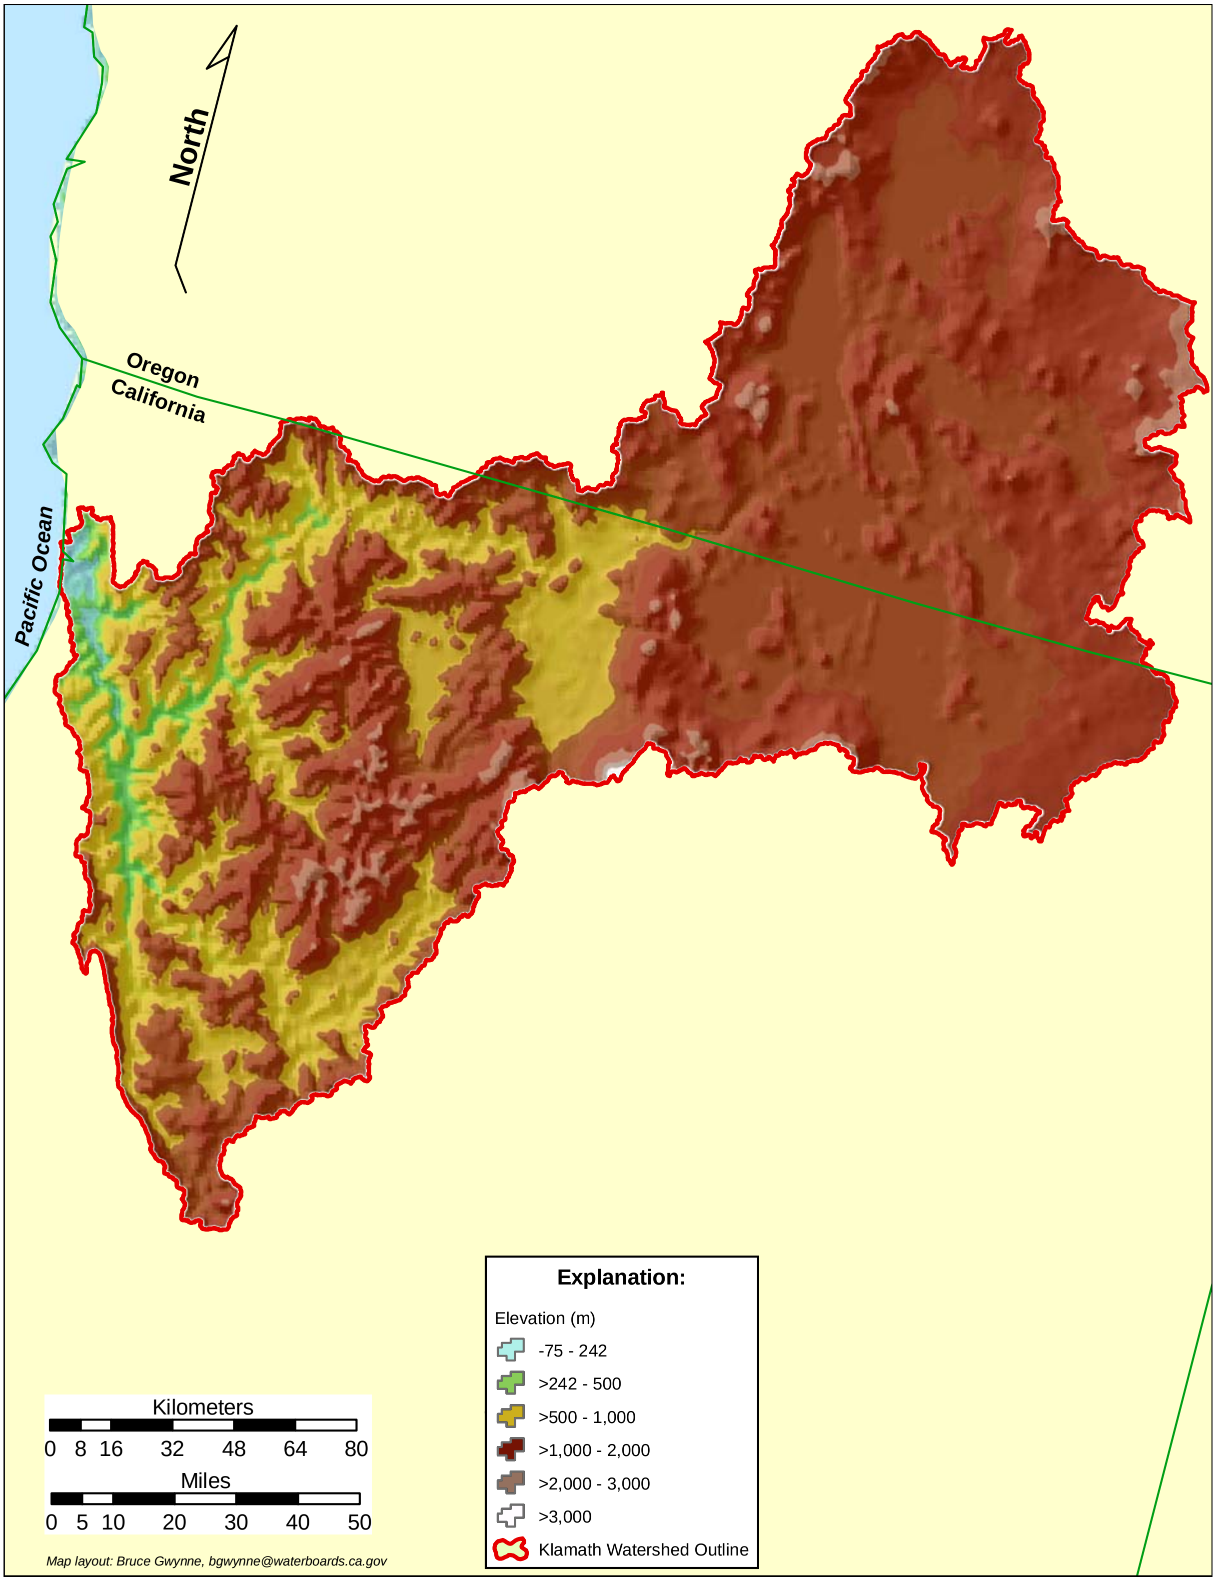

Figure 2.2: Land Elevation in the Klamath River Basin

Figure 2.3: Geomorphic Provinces in the Klamath River Basin - Source: Oakshott 1978

The border between the Cascade province and the Klamath Mountains province is spanned by Shasta Valley and covered by a unique deposit. Most of the floor of this valley is disrupted rolling topography of small hillocks and closed depressions. Crandell (1989) recognized this landscape as the deposits formed by a huge avalanche and debris flow, or series of such events, shed off the north flank of Mount Shasta more than 300,000 years ago.

The Klamath Mountains province is very steep and rugged for the most part, and in the Klamath River watershed consists of several irregularly oriented ranges – the Trinity Alps, Scott Bar Mountains, Siskiyou Mountains, and Marble Mountains. Shasta and Scott Valleys have broad flat valley bottoms that support agriculture, but other valleys are narrower and steeper and therefore less developed. Most of the land in the Klamath Mountains province is in federal ownership (Figure 2.1), and this rugged landscape lends itself more to timber harvest and cattle grazing than to crops.

The bedrock geology of the Klamath Mountains province is extremely varied and complex (Figure 2.4) and largely made up of ocean-floor igneous and sedimentary rocks of a large range in ages. Most of the igneous rocks in this province are dark colored mafic and ultramafic rocks of both intrusive and extrusive origin, most of which have been partly or wholly altered to serpentine and otherwise metamorphosed. Younger, light colored granitic rocks have been intruded in some places. Recent uplift has created a landscape of rapidly downcutting streams and steep slopes that are subject to rapid erosion and landsliding. The granitic rocks in particular weather to form loosely consolidated material that sloughs and ravels easily when disturbed.

The Coast Ranges province, the westernmost province (Figure 2.3), forms about 20 miles of the lower Klamath River valley and part of the west side of the valley of the lower Trinity River and South Fork Trinity River. These rivers have exploited the fault zone that forms the geologic boundary between the Klamath Mountains province and the Coast Ranges province. The Coast Ranges are steep, but are generally more rounded and not as high as the mountains of the Klamath Mountains province. Bedrock is the Franciscan Complex, which is structurally deformed and highly varied. The mix of sedimentary rocks includes sandstone, siltstone, shale, conglomerate, greywacke, and chert. Parts of the complex have been metamorphosed and include blueschist and greenschist as well as low grade mica schist. Some areas are mélange, which is geologic terrain that has been deformed and mixed by prolonged and complex tectonic movement, and lacks continuity of structure, rock type, or age.

The gradient profile of the Klamath River is anomalous for a large river in that it is generally low gradient in the headwaters in the Modoc Plateau and steeper farther downstream (Figure 2.2). This unusual gradient is largely the result of geologic uplift in the upstream portion of the river basin in recent geologic time. It is a defining characteristic of the Klamath watershed and strongly influences the nutrient and DO dynamics of the basin.

Source: Modified from Schruben et al. (1997)

2.3 Vegetation

Vegetation in the Klamath River watershed varies greatly with elevation, precipitation, geology, and degree of disturbance. Figure 2.5 shows the major classifications of vegetation. Conifers dominate in the steep mountains and the higher elevations throughout the watershed and are the major land cover of the basin. Hardwood forest and shrubs are more abundant in the lower country within the Klamath Mountains and Coastal Range Provinces. Grass and brush land, as well as lands converted for agricultural purposes, are abundant in the low gradient landscapes associated with the Scott, Shasta, and Lost River valleys in California, as well as the Lost, Sprague, and Williamson River valleys in Oregon. Wetlands are found throughout Oregon, including around Upper Klamath Lake, as well as in the Lost River valley in California. The wetland habitat present in the Klamath River watershed today represents about 25% of what existed historically (http://www.fws.gov/klamathbasinrefuges/history.html retrieved October 26, 2009). As described above, much of the wetland land cover in the upper watershed has been converted to agricultural use over the last 150 years, significantly altering the natural processes by which organic matter and nutrients are stored and released downstream.

2.4 Climate

The great geographic extent and topographic relief of the Klamath River watershed combine to produce a wide variety of climate conditions (Figure 2.6). On average, the climate is characterized by dry summers with high daytime temperatures and wet winters with moderate to low temperatures. About three quarters of the annual precipitation falls between October and March, producing a snowpack in the higher mountain ranges that feeds streamflow in many lower areas through the summer. As major storms move in from the Pacific Ocean, the moisture-laden air rises over the coastal mountain ranges and condenses as rain and snow (California Department of Water Resources [CDWR] 1986). Further inland, in the valleys of major tributaries and over the lower terrain of the upper Klamath basin, a rain shadow effect is created, and less moisture falls (Figure 2.6).

Figure 2.7 provides a comparison of monthly precipitation values from Orleans, California in the mountainous country of the lower Klamath basin and Klamath Falls, Oregon in the broad valley of the upper Klamath basin as an illustration of rain shadow effect. The mean annual precipitation in the Klamath River watershed is about 32 inches (CDWR 1986); but, local averages range from more than 80 inches in the high elevations to 10 inches in the broad inland valleys (CDWR 1986; United States Forest Service [USFS] 1996).

In the 20th century the Klamath River watershed was characterized by a pattern of floods and droughts. This pattern is discussed by The Klamath River Basin Fisheries Task Force [KRBFTF] (1991, p. 2-3 to 2-7). During a drought in 1976-77, precipitation was only 20 percent of normal in the Scott River watershed and 40 percent of normal in the upper Klamath River basin. The largest floods occurred when relatively warm storm systems melted a pre-existing snow pack such as occurred in 1861, 1955, 1964, 1974 and 1997 (USFS 2000, p.3-3). Many areas of the Klamath River watershed, mostly in the middle third of the basin, are susceptible to these rain-on-snow events.

Klamath Basin air and water temperature data indicate that air and water temperatures have been steadily increasing since at least the 1960s. Bartholow (2005) analyzed air and water temperature records distributed throughout the Klamath basin and evaluated water temperatures simulated using a computer-based water temperature model. The results of Bartholow's analysis strongly suggest a trend of water temperature increases of approximately 0.5 ^{o}C per decade since the 1960s. As described in more detail in Chapter 4.0 of this Staff Report, water temperature is one of three factors controlling DO concentrations at saturation. DO concentrations at saturation are inversely proportional to water temperature. Thus, as water temperatures rise, the DO concentration at saturation decreases.

2.5 Hydrology

Drainage density in the Klamath River watershed is affected by infiltration capacity, tectonics, and underlying bedrock. Figure 2.8 shows dense drainage networks in the

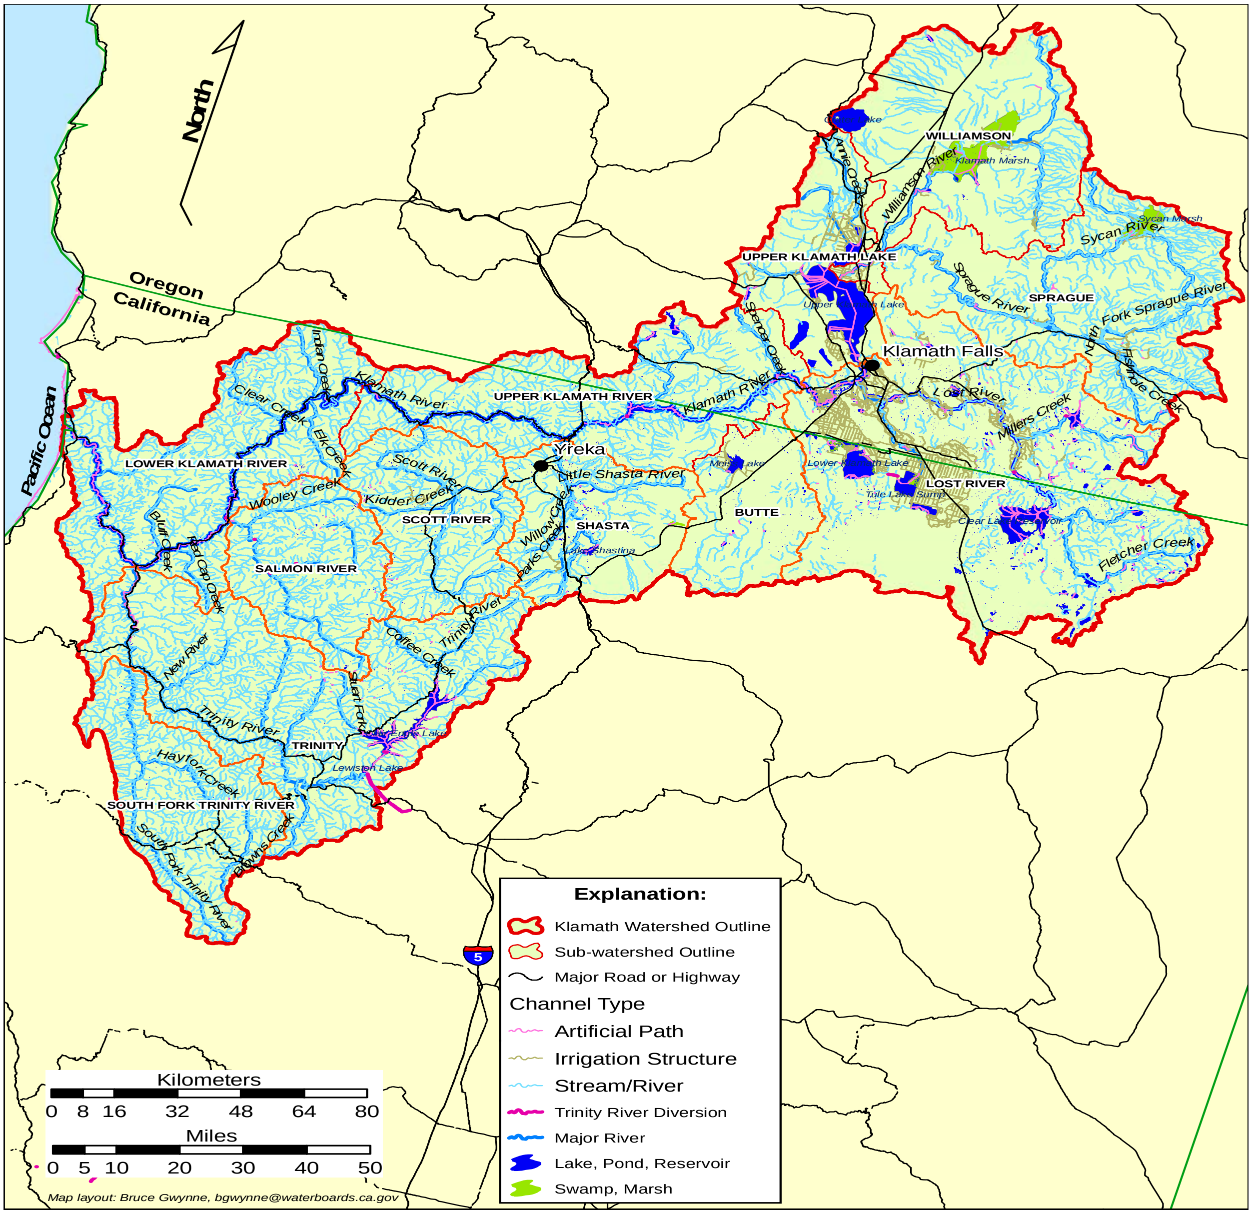

Figure 2.8: Map of Klamath River Basin Emphasizing Subbasins and Surface Drainage

steep, recently uplifted ranges to the west and in the volcanic mountains to the east. The lower, flatter country in the upper Klamath, in the region of Klamath Falls, has a much lower drainage density (though greater percent area covered by water) and is punctuated by lakes and wetlands associated with local tectonic subsidence.

Water yield in the Klamath basin varies by watershed setting. As illustrated in Figure 2.9, approximately half of the February flow measured in the lower watershed at the town site of Klamath, California is drained from that portion of the basin from Orleans, California to Klamath, California, representing about a third of the basin's area. Conversely, only 7% of the flow originates in the upper one third of the basin. This pattern is not as dramatic in the summer months when water yield is more generally proportional to drainage area. It is important to recognize that the data presented in

Figure 2.9 shows the pattern of flow associated with a history of consumptive use (e.g., Klamath Project in the upper basin) and altered flow timing (e.g., PacifiCorp's hydroelectricity generation). However, these factors do not affect the above observations with respect to winter flows.

2.6 Summary

The Klamath River watershed has a number of unique physical characteristics which define the water quality dynamics of the basin. Most watersheds in the North Coast Region share a general topographic profile in which the headwaters flow down steep inner gorges, gather in second and third order streams of more moderate slope, and meander gently across a coastal plain before discharging to the Pacific Ocean. The Klamath River, on the other hand, gathers in the gently sloping wetlands and lakes of southeastern Oregon before leaving Upper Klamath Lake at Keno where the stream slope steepens through California and to the ocean. The soils of the upper basin are defined in large part by the volcanic geology of the southeastern part of Oregon and include naturally high levels of phosphorus which were historically stored in the wetland soils and vegetation of the upper basin. The periodic mobilization of excess organic matter and nutrients from Upper Klamath Lake to the free-flowing portion of the Klamath River created a zone of high productivity downstream which slowly dissipates as the stream channel steepens. This phenomenon has earned the Klamath River its nickname: "the River of Renewal."

The Klamath River watershed includes mountain ranges of higher elevation than most other watersheds in the North Coast Region. Many of the watersheds in the North Coast show a pattern of stream flow that closely mimics rainfall and can be quite flashy during and immediately after large storms. In the Klamath River; however, winter precipitation is stored as snow at the higher elevations. Thus, stream flow increases in the fall as a result of rainfall and is extended through the spring as the winter snows melt. (Though, rain-on-snow events can mobilize stored water quickly and catastrophically).

As is true of most other watersheds in the North Coast Region, the Klamath River is fundamentally a rural watershed, particularly within the boundaries of California. Thus, the water quality impacts associated with human activity in the Klamath River basin have little to do with point source discharges. In fact, point source discharges are prohibited in the California portion of the Klamath River watershed as is described in more detail in Chapter 5.0[1]. The much more significant cause of water quality impact in the Klamath River basin is the modification of *natural* water quality dynamics that has occurred due to human caused alterations of the landscape such as altered: flows and flow pattern; slope and stream channel stability; vegetation type, age, and density; and nutrient and organic matter availability, as examples.[2]

---

1 The Regional Water Board has granted one exception to the prohibition against the point source discharge of waste to the Klamath River. The exception is granted to Iron Gate Hatchery, a fish rearing facility operated jointly by the Department of Fish and Game and PacifiCorp. They are issued a permit restricting the volume and quality of waste which can be discharged.

2 The effects of mining on the Klamath River are an exception to this general description, with large scale discharges of sediment resulting from hydraulic mining and toxics discharged from leach and tailings piles.

CHAPTER 3.
FISHES OF THE KLAMATH REGION

The proposed Site Specific Objectives (SSO) for dissolved oxygen (DO) in the mainstem Klamath River are designed to protect the beneficial uses of the mainstem. As such, the purpose of this chapter is to provide a review of the native fishes of the mainstem Klamath River that are at risk of extinction and identify their dissolved oxygen (DO) requirements. Staff focuses on the native fishes at risk of extinction because of their unique vulnerability. The Cold Freshwater Fishery (COLD) (i.e. salmonids) is identified as the most sensitive beneficial use of the Klamath River, the spawning and incubation of salmonids the most sensitive life stages.

The DO requirements of salmonids are identified in a series of review papers analyzing the relationship between DO and various fish health parameters as described in numerous laboratory and field studies. The review papers span 20 years, beginning with the 1986 DO guidance document published by the USEPA and including reviews conducted by the states of Oregon and Washington, as well as an in-house Regional Water Board review conducted by staff in 2005 (Carter 2005).

Water quality conditions in the mainstem Klamath River have been modeled as part of a Regional Water Board effort to establish Total Maximum Daily Loads (TMDLs) for dissolved oxygen, temperature, nutrients, and microcystin. The models indicate that under natural conditions, the Klamath River mainstem does not consistently produce the ideal DO conditions as defined by the laboratory and field studies of the last several decades. This has led staff to ponder the means by which salmonids have historically coped with less than ideal mainstem conditions. One well-accepted view is that they seek refuge in cool tributary streams and deep mainstem pools (thermal refugia). A listing of existing thermal refugia is also included in this chapter (Figure 3.2).

<u>Upper and Lower Klamath Subprovinces</u>
As described by Moyle (2002), the North Coast Region is divided into two zoogeographic provinces representing two distinct fauna: the Klamath Province and the North Coast Province. The Klamath Province is divided into 4 subprovinces, including the Upper and Lower Klamath through which the Klamath River flows.

Moyle (2002) describes the native fishes of the Upper Klamath Subprovince as primarily freshwater dispersants "most having their closet relatives in the Great Basin." A *freshwater dispersant* is a species that arrived in its present location from a freshwater route or has evolved in place from a distant saltwater ancestor (Moyle 2002). Freshwater dispersants in the Upper Klamath Subprovince arrived from the Great Basin during a time in geologic history when an ancestor of the Snake River, now draining through the Columbia River, previously flowed through the Klamath Region (Aalto et al. 1998 as cited by Moyle 2002). The native fishes of the Upper Klamath Subprovince include three species of sucker; three species of cyprinids (i.e., blue chub, Klamath tui chub, speckled dace); three species of sculpin; several species of salmonid (e.g., bull trout, rainbow trout, redband trout, coastal rainbow trout, and the now extinct Chinook salmon); and three species of lamprey (Moyle 2002). Of these, the Klamath River lamprey, Lost River sucker, shortnose sucker, and slender sculpin are at risk of extinction (Moyle 2002). The slender sculpin, however, only occurs in Klamath and Agency lakes in Oregon and is not discussed here.

The Lower Klamath Subprovince includes 21 native species of fish including: three species of lamprey, two species of sturgeon, one cyprinid (speckled dace), one sucker, two species of smelt, six species of salmonid (the pink salmon now extinct), one stickleback, four species of sculpin, and one flounder. Of these, the river lamprey, green sturgeon, eulachon, longfin smelt, chum salmon, coho salmon, and cutthroat trout are at risk of extinction (Moyle 2002).

What follows is a discussion of the individual life histories and DO requirements, to the degree that they are known, of the native fishes at risk of extinction in the Klamath River. Predictably, the DO requirements of salmonids are the most well understood and represent the largest part of the discussion. Because coldwater DO objectives have generally been developed based on the requirements of salmonids, the information below is intended to confirm that DO objectives developed to protect salmonids will protect the other fishes at risk, as well.

3.1 Salmonids

The present distribution and abundance of salmonids "has been strongly shaped by Pleistocene events. In northern and mountain areas, they followed the advance and retreat of continental glaciers, rapidly colonizing new streams and lakes" (Moyle 2002). Moyle (2002) asserts that salmonids thrive in dynamic environments. But, the water must be fairly cool (<22°C maximum) and well oxygenated (Moyle 2002). Moyle (2002) opines that because they have twice as much genetic material as most fishes, salmonids respond rapidly to evolutionary pressures.

Salmonids are anadromous fish, born in freshwater, migrating to the ocean where they feed and mature, and returning to their natal freshwater stream to reproduce. Salmonids typically die after spawning in fresh water, trout and steelhead being exceptions. Salmonid eggs are laid in a nest (i.e., redd) that the female digs in the gravel. The eggs are fertilized externally and the developing embryos covered with gravel as protection. After the yolk sac fry or alevin hatch, they remain in the interstices of the gravel until ready for emergence to the water column. Juvenile fish grow in freshwater until ready for outmigration to the ocean. They remain in the estuary where they develop osmoregulation facilities capable of life in the ocean. Once in the ocean they feed and grow before reaching sexual maturity. Some salmonids complete their sexual maturation in the freshwater of their natal stream. Others return to their natal stream ready to spawn.

Salmonid species differ in the timing of their life cycle stages, as well as the specific habitat niches they inhabit while in the freshwater environment. For example, spring-run Chinook enter a river system in the spring and hold over in cold water tributaries and deep pools until spawning in the fall. Fall-run Chinook enter a river system in the fall, immediately ready to spawn. However, both species wait until water flows increase and water temperatures decline in the fall before building redds and laying eggs. Other salmonid species arrive throughout the fall and winter for spawning. By June, the fry of all salmonid species have emerged from the gravel and begun their life in the water column. The length of time juvenile fish remain in freshwater before outmigrating to the ocean varies from several months to several years.

Endangered Species Act (ESA) listed salmonids may be present in some locations in the mainstem Klamath river during the entire year. At the Klamath River Fish Health (KRFH) Conference held in 2007, the participants in the "Panel Discussion on the Cultural, Economic, and Management Implications of Fish Disease in the Klamath River" described the Klamath River as historically being dominated by spring-run Chinook; but, population trends have shifted to favor fall-run Chinook. Carter and Kirk (2008) describe in some detail the causes of this shift and the reader is directed to Appendix 5 of the Klamath TMDLs Staff Report for a copy. Rebecca Quinones of the U.S. Fish and Wildlife Service reported at the 2007 KRFH Conference that the population of fall-run Chinook is looking stable; though, hatchery fish spawning is increasing. She also reported that spring-run Chinook are only found in the Salmon River and periodically in Beaver Creek. Coho populations have decreased by 90-95% from historical levels and populations are trending downwards in the Shasta River; though, returns to the Iron Gate Hatchery are increasing (Quinones, KRFH Conference, 2007).

3.1.1 Individual Species Descriptions

Coho Salmon

In California, coho salmon (*Oncorhynchus kisutch*) have a fairly strict 3 year life cycle with about half of its life spent in freshwater and the other half in the ocean (Moyle 2002). Coho adults migrate upstream for spawning after heavy fall or winter rains breach the sandbars of coastal streams allowing the fish to enter. Coho choose smaller coastal streams or the tributaries of larger coastal streams for spawning. They continue upstream when stream flows are rising or falling; though, not necessarily when the streams are in full flood (Moyle 2002). Redd locations generally are at the head of riffles, just below a pool, "where water changes from smooth to turbulent flow and there is abundant medium to small gravel" (Moyle 2002). Embryos hatch after 8-12 weeks of incubation, time being "inversely related to water temperature" (Moyle 2002).

After emergence, fry find quiet stream margins to feed and shelter before establishing territories. Nielsen (1992a and 1992b) as cited by Moyle 2002, documented a complicated division of territories amongst coho juveniles, including distinctions between those she called estuarine, margin, thalweg, and early pulse juveniles. All are as their name implies. "Early pulse juveniles show two pulses of growth, one in spring and one in autumn." (Moyle 2002)

The outmigration of juveniles begins between March and May. The triggers include: "rising or falling water levels, day length, water temperature, food densities, phase of the moon, and dissolved oxygen levels" (Moyle 2002). Migrants transform into silvery smolts often lingering for a period in the estuary while adjustments are made to their osmoregulatory system (Moyle 2002).

The National Marine Fisheries Service (NMFS) issued a biological opinion on the Klamath Project Operations dated May 31, 2002. In it, NMFS (2002) reports "adult and juvenile coho salmon are observed in tributaries and the main stem of the Klamath River." Coho populations are found in the Klamath River mainstem year round and in Klamath tributaries as listed in Table 3-1 below.

Table 3-1: From NMFS (2002) Biological Opinion on the Klamath Project Operations

Klamath River Tributaries in which coho populations are present	
Between Iron Gate Dam and Seiad Valley

Tectah Creek	Johnson Creek
Hunter Creek	Pecwan Creek
East Fork Hunter Creek	Roach Creek
Mynot Creek	Mettah Creek
Hoppaw Creek	Tully Creek
Saugep Creek	Pine Creek

Shaw et al. (1997) studied the life stage periodicities for Chinook, coho, and steelhead in the Klamath River basin from Iron Gate Dam to Seiad Creek. "USFS and USFWS personnel both agree that coho spawning does occur in the mainstem Klamath River (Shaw et al. 1997)." Though not measured, Shaw et al. (1997) believe that coho spawning occurs from November through January in the Klamath system, mostly within tributaries and quiet mainstem habitats. Emergence occurs from late February through April (Shaw et al. 1997). "Coho fry were observed outmigrating from tributaries from early March through late June (Shaw et al. 1997)." Shaw et al. (1997) believe that coho rear in the study area year round.

Coho are listed under the Endangered Species Act as a threatened species in the Southern Oregon/Northern California Coast Ecologically Significant Unit (ESU). The Klamath is listed under the Magnusen Stevens Fishery Conservation and Management Act as Essential Fish Habitat (EFH) for coho.

<u>Chinook Salmon</u>
In California, Chinook salmon (*Oncorhynchus tshawytscha*) are often described by the timing of their freshwater migration: fall-run, late fall-run, winter-run, and spring-run (Moyle 2002). Widely recognized runs in the North Coast Region include: Smith River fall and spring run, Klamath-Trinity fall run, Klamath-Trinity spring run, Klamath late fall run, Redwood Creek fall run, Little River fall run, Mad River fall run, Humboldt Bay tributary fall run, Eel River fall run, Bear River fall run, Mattole River fall run, and Garcia River fall run (Moyle 2002). As described by Moyle (2002), the Klamath-Trinity system has the largest diversity of Chinook salmon runs.

Stream-type Chinook are fish that migrate upstream before reaching sexual maturity, as well as juveniles that spend more than 1 year in freshwater before outmigrating (Moyle 2002). Ocean-type Chinook are fish that spawn immediately upon migrating upstream, as well as juveniles that spend less than 1 year in freshwater before outmigrating (Moyle 2002).

A fall-run Chinook is an ocean-type Chinook, entering the big rivers of the Klamath and North Coast Provinces in the late summer and early fall, and spawning in the lowland reaches within a few days to weeks of arrival (Moyle 2002). Juveniles emerge from the gravel in spring and move downstream within a few months to rear in the mainstem or estuary before going out to sea (Moyle 2002).

A spring-run Chinook is a stream-type Chinook, entering the Smith, Klamath or Eel River in the spring or early summer, going as far upstream as it can, and holding in deep, cold pools until spawning in the early fall (Moyle 2002). The juveniles rear for 3-15 months depending on flow conditions (Moyle 2002). Spring-run Chinook in the Klamath River are considerably less abundant than fall-run Chinook because of the presence of dams, blocking much of their historical mid-elevation habitat (Moyle 2002). Shaw et al. (1997) reports that spring-run Chinook migrate up the Klamath River mainstem beginning in June, tailing off in the Trinity River by mid-September. They hold over until the fall when they spawn primarily in the tributaries. Historically, spring-run Chinook returned to the Iron Gate Hatchery throughout July and August. But, whether or not spring-run Chinook ever spawned in the mainstem is unknown.

Shaw et al. (1997) report that fall-run Chinook enter the Klamath in September with peak migration occurring in October; though, historically they entered as early as August. "Spawning in the mainstem Klamath begins during the second week of October, peaks during the last week of October and declines by the end of November (Shaw et al. 1997)." Fall-run Chinook spawn in the lower reaches of tributaries and in the mainstem Klamath River, although less than 33% spawn in the mainstem (Carter and Kirk 2008).

Juveniles emerge from early February through the end of April, depending on water temperatures. Peak juvenile emigration from the tributaries occurs in mid-March. "Juveniles may emigrate directly to the estuary or remain in the mainstem and emigrate as yearlings (Shaw et al. 1997)."

The Klamath River is listed under the Magnusen Stevens Fishery Conservation Management Act as essential fish habitat for Chinook salmon.

Chum Salmon

In California, small runs of chum salmon were historically present in streams from the Sacramento River north (Moyle 2002). Today, small runs of chum salmon continue in the Smith, Klamath and Trinity Rivers. Hamilton et al. (2005) reports that chum salmon were historically present in the Klamath River basin well below Iron Gate Dam. Chum salmon are generally ocean-type salmon, spending little time in freshwater, and most of that often in the estuary. Chum salmon enter freshwater in the late fall with optimal spawning temperatures of 7.2-12.8 °C and oxygen levels greater than 80% saturation (Moyle 2002). NRC (2004) reports that chum in the Klamath basin are at the southern-most end of their existing range.

Cutthroat Trout

In California, coastal cutthroat trout live in the coastal drainages from the Eel River north (Moyle 2002). Coastal cutthroat trout are more strongly tied to fresh water than most anadromous fishes, leaving freshwater only in the summer months, if at all, and returning to overwinter in freshwater (Moyle 2002). They live primarily in small, low-gradient coastal streams and estuaries where temperatures are cool (<18 °C), well-shaded, and there is abundant cover (Moyle 2002). They especially avoid waters with DO <5 mg/L (Moyle 2002). Embryo survival can be reduced to less than 10% with DO levels lower than 6.9 mg/L (Moyle 2002).

Cutthroat trout migrate upstream in August-October following the first substantial rainfall (Moyle 2002). Cutthroat trout have a prolonged spawning period, lasting as long as September through April (Moyle 2002). Embryos hatch after 6-7 weeks of incubation and alevin remain in the gravel for an additional 1-2 weeks (Moyle 2002), emerging from March to June (Moyle 2002). Juveniles grow in the stream 1-3 years before going to sea (NRC 2004). They spawn 2-4 times. In the Klamath River basin, they occur primarily in the smaller tributaries to the main stem within about 22 miles of the estuary (NRC 2004).

Voight and Gale (1998) "found juvenile and/or adult coastal cutthroat in 13 of the 19 tributaries downstream of and including Johnsons Creek in the lower Klamath River." In several of the tributaries where they were found, cutthroat dominated the electrofishing catch. Voight and Gale (1998) suggest cutthroat trout maybe more abundant in headwater streams than historically because they have become resident above migration barriers. Gale et al. (1998) report large numbers of adult cutthroat in Blue Creek where they seek refuge from inhospitable conditions in the mainstem.

3.1.2 DO requirements of salmonid species

Regional Board staff has relied primarily on four surveys of the scientific literature associated with the DO requirements of salmonids. The first is USEPA's guidance on the development of DO criteria (USEPA 1986). The second is a review conducted by members of the Dissolved Oxygen Technical Advisory Committee (DOTAC) and staff of the Oregon Department of Environmental Quality and published in 1995 (Oregon 1995). The third is a review conducted by staff of the Washington State Department of Ecology and published in 2002 (Washington 2002). And, the fourth is an in-house literature survey conducted by Katharine Carter, peer reviewed, and published in 2005 (Carter 2005). The following discussion is derived primarily from these literature surveys. For a discussion of the original literature from which these conclusions were drawn, the reader is directed to the four above mentioned surveys.

DO criteria for salmonids are generally divided into two categories: those designed to protect early life stages and those designed to protect other life stages. The early life stages of salmonids face specific environmental issues not otherwise confronting other life stages of salmonids, namely relative immobility and life within the intergravel environment. As such, the DO criteria designed to protect the early life stages take into account the inability of embryos to find refuge from inhospitable DO conditions and the difficulty with which fry and alevin avoid inhospitable intergravel DO conditions. They also take into account the reduction in DO concentration that occurs as water from the water column passes through the intergravel environment.

<u>3.1.2.1 Intergravel Dissolved Oxygen (IGDO) Requirements of Early Life Stages of Salmonids</u>

Intergravel dissolved oxygen (IGDO) is the result of a balance between the rate of respiration among gravel dwelling organisms and the rate of oxygen supply. The rate of oxygen supply, in turn, is dependent on the rate of water percolation and convection, as well as oxygen diffusion (USEPA 1986). IGDO has been correlated to embryo survival in some studies, as has apparent velocity and temperature (USEPA 1986, Oregon 1995, Washington 2002). However, the influence of these parameters, one on the others, can not always be separated (Oregon 1995, Washington 2002). A clear relationship between IGDO and alevin growth and development, however, is observable (USEPA 1986, Oregon 1995). Researchers hypothesize that smaller alevin and alevin that hatch later, as a result of depressed IGDO, may be 1) less successful in their competition for food and space as fry and 2) more susceptible to predation (USEPA 1986, Oregon 1995).

USEPA (1986) concludes that the DO requirements of the early life stages of salmonids (i.e., embryo-to-fry emergence from the gravels) are not appreciably different from adult salmonids. In short, a daily minimum of 6.0 mg/L and an average (weekly or monthly) of 8.0 mg/L DO is sufficient to protect the early life stages of salmonids while they reside in the intergravel environment (USEPA 1986). Washington (2002) notes that alevin selectively prefer oxygen concentrations from 8-10 mg/L and will move through the gravel interstices to find favorable DO conditions. Above 7.8 mg/L DO, there may be no size and survival benefit (Washington 2002).

The outstanding question is how to predict from water column DO measurements, the DO available in the intergravel environment. IGDO can be expected to vary widely within redds and between redds (USEPA 1986, Oregon 1995). Yet, USEPA (1986) assumes an average 3 mg/L DO difference between the water column and intergravel environment based on two studies in which the minimum IGDOs were an average of 3 mg/L less than the DO of the overlying water. Early life stage DO requirements as measured in the water column, then, should be 9.0 mg/L as a daily minimum (i.e., 6.0 mg/L + 3.0 mg/L) and 11.0 mg/L as an average (i.e., 8.0 mg/L + 3.0 mg/L). These criteria are intended to apply to unimpaired settings, only. Locations in which sedimentation, elevated temperatures, or reduced flows are complicating factors, the difference between the overlying water and intergravel environment may be substantially more (Oregon 1995).

For comparison, data collected from two streams in Oregon showed IGDO consistently higher than 8.0 mg/L with the IGDO typically less than 1.0 mg/L below surface water measurements (Oregon 1995). In these streams, the observed surface measures fell below 9.0 mg/L and 11.0 mg/L and yet the intergravel data indicated no measureable impairment (Oregon 1995). A 3.0 mg/L difference between water column DO and IGDO, therefore, may sometimes be overly protective and/or unattainable. Washington (2002) identifies from studies a range of 0.5 to 7.2 mg/L difference in DO from the water column to the intergravel environment; but, suggests that 1-3 mg/L difference is the "typical" range and should be used in setting water quality criteria.

Oregon (1995) recommends that in impaired streams, monitoring protocol should be to collect test and control samples, either from paired watersheds; upstream and downstream of a site; or before and after an activity. Reduction in sedimentation through cessation of activity or stream restoration is correlated to improvement in IGDO, either through improvement in apparent velocity and/or reduction in sediment oxygen demand (Oregon 1995).

<u>3.1.2.2 DO Requirements of Other Life Stages of Salmonids</u>

Once fry emerge from the gravels, they enter the water column where they will reside throughout the rest of their freshwater tenure. As young-of-year, salmonids must put on weight, compete for food, and find shelter from predators and adverse environmental conditions. At issue is the effect of DO on swimming performance; growth; avoidance behavior; and synergistic relationship with toxics, temperature, and disease.

<u>Swimming Performance</u>

Laboratory studies demonstrate that any reduction from saturation in DO concentrations can result in reduced swimming performance (USEPA 1986, Oregon 1995, Washington 2002). Salmonids conserve their energy when DO is depressed and remain more active when DO is fully saturated. While the importance of top swimming performance to the health and survivability of salmonids has not been established, it is hypothesized that it is important during spawning and to avoid predators (USEPA 1986, Washington 2002, Carter 2005). With these exceptions, USEPA (1985) concludes that "the moderate levels of swimming activity required by salmonids are apparently little affected by concentrations of dissolved oxygen that are otherwise acceptable for growth and reproduction." Oregon (1995) suggests that reduction in swimming speed may act as a surrogate measure of the effect of chronic stress, a phenomena that influences natural populations, but is not directly measurable.

Growth

Researchers hypothesize that food conversion efficiency is influenced by a number of factors, including DO concentration. Constant exposure studies indicate that when food resources are abundant and temperatures are warm but not lethal, there is a significant correlation between salmonid growth and DO concentration (USEPA 1986, Oregon 1995); though the statistical significance is less universal amongst the studies evaluated for DO concentrations in the range of 5-8 mg/L (USEPA 1986, Washington 2002). Washington (2002) reports a loss of growth when DO concentrations fluctuate from high (>10.0 mg/L) to low concentrations (<5.3 mg/L). Oregon (1995) reports better growth for fish exposed to intermittently low concentrations as compared to those exposed to continuously low concentrations.

In the natural environment, where food resources, temperatures and DO concentrations vary episodically, one expects growth rates less robust than those of fish held under constant, ideal, laboratory conditions. Still, USEPA (1986) concludes that "the attainment of critical size is vital to the smolting of anadromous salmonids and may be important for all salmonids if size-related transition to feeding on larger and more diverse food groups is an advantage." USEPA's (1986) survey of the literature indicates: 1) no reduction in the growth rates of salmonids at temperatures ranging from 12-18 °C and DO ≥8 mg/L, and 2) <10% reduction in growth in the same temperature range and with DO ≥ 6mg/L. Washington (2002) concludes that growth rates may become independent of DO concentrations well below saturation when food availability is low, particularly when temperatures are cool. Washington (2002) notes a general trend for growth rates, even in highly fed salmonids in warm waters, to commonly be indistinguishable from controls at concentrations above 8 mg/L. USEPA (1986) recommends a DO concentration of 8.0 mg/L to ensure no production impairment of other life stages of salmonids and 6.0 mg/L to ensure only slight production impairment. Washington (2002) observes that the highest levels of protection against growth effects are demonstrated under DO conditions ranging from 7.9 to 9 mg/L.

Avoidance Behavior

Juvenile salmonids have the ability to detect areas of substandard DO and avoid them (USEPA 1986, Oregon 1995, Washington 2002, Carter 2005). This is an ability that apparently refines as fry grow and age (Oregon 1995). Even alevin will position themselves in the gravel interstices to avoid DO in the range of 4.5-7 mg/L, showing a selective preference for waters in the range of 8-10 mg/L DO (Washington 2002). Within the water column, studies indicate an avoidance behavior that is triggered by DO conditions below 5-6 mg/L (USEPA 1986, Washington 2002); though, the early avoidance studies for coho typically only tested up to 6 mg/L DO (Oregon 1995). "Later tests conducted at concentrations of 7 mg/L indicated no (coho) avoidance; however, the test temperatures were much cooler which, if reactions are similar to those observed for Chinook juveniles, would be expected to reduce avoidance (Oregon 1995)."

Synergistic Relationships

Salmonids may be exposed to any number of toxicants and/or disease organisms during their time in freshwater, depending on the watershed and the associated anthropogenic activities. Oregon (1995) reports evidence that DO concentrations below saturation act to increase the response of fish to toxicants. Oregon (1995) describes the mechanisms by which adverse actions of a toxicant might be increased by low DO:

1. Increased ventilation of the gill associated with low DO can increase uptake of waterborne toxics;
2. Any toxic which damages the gill epithelium and decreases efficiency of oxygen uptake can thereby increase sensitivity to low DO; and
3. A number of toxics such as pentachlorophenol increase oxygen consumption due to interference with oxidative phosphorylation.

Washington (2002) concludes that maintaining high (>8.5 mg/L) oxygen levels provides added protection from the effects of several very common pollutants.

Washington (2002) also notes the synergistic effects of temperature on the toxicity of pollutants. For several salmonid species, the resistance to lack of oxygen decreases with increasing temperature (Oregon 1995). This is combined with the physical fact that as temperatures rise, the DO concentration at saturation decreases such that less DO is available to aquatic biota in warm water than in cold water. These combined phenomena indicate the importance of cold water refugia, to the success of many salmonids, particularly when summer temperatures otherwise approach levels of concern. Cold water refugia such as deep mainstem pools and tributary streams have the benefit of providing the cool temperatures necessary to many species of salmonids; but also provide DO concentrations at saturation greater than those in the warmer mainstem channel. Without access to cold water refugia, salmonids are confronted with an accelerated metabolism (driven by warmer temperatures) and a reduced ability to swim and feed (driven by lower DO).

In order to identify the locations of known thermal refugia in the Klamath River basin, Regional Water Board staff solicited information from fisheries biologists working in the Klamath through a formal request in April 2009. Based on the information staff received, as well as review of the available reports on the topic, staff compiled a list of the known thermal refugia in the Klamath River basin in California (Table 3-2). The listed tributaries provide thermal refugia at their confluence with the Klamath River mainstem. Maps showing the locations of these creeks in the Klamath River basin are provide in Appendix B. The implementation plan for the Klamath River TMDL and SSO for DO includes a provision to restrict discharges within a buffer zone associated with known thermal refugia (see Chapter 6 of the Klamath TMDL Staff Report).

Table 3-2: Tributaries to the Klamath River Known to Provide Thermal Refugia In and Around Their Confluence.

Tributaries		
Aikens Creek	Halverson Creek	Pine Creek
Aubrey Creek	Hopkins Creek	Portuguese Creek
Barkhouse Creek	Horse Creek	Red Cap Creek
Beaver Creek	Humbug Creek	Reynolds Creek
Blue Creek	Hunter Creek	Roach Creek

Fort Goff Creek	Pecwan Creek	Whitmore Creek
Grider Creek	Pearch Creek	Wilson Creek

[1] Scott River tributary

Poor water quality conditions have been at least partially responsible for a number of documented fish kills in the Klamath River mainstem downstream of Iron Gate Dam through to the estuary from 1994 to 2004. Juvenile fish kills are thought to be fairly common in the mainstem; but, they often go undetected. Low DO was identified as a contributing stressor in the juvenile fish kills documented in 1997, 1998, and 2000. It was also identified as a contributing stressor in the adult fish kill of 1997.

The adult fish kill of 2002 killed a recorded 33,000 adult salmonids. The majority of the dead fish examined were infected with the fish diseases *Ichthyophthiriasis* (Ich) and Columnaris, which was identified as the principal cause of death (CDFG 2004, USFWS 2003). Subsequent study has identified other diseases affecting salmonid populations in the Klamath River.

Ceratomyxa shasta (*C. shasta*) is thought to be indigenous to the Klamath River, and is the primary fish health issue in the Klamath River (Bartholomew et al. 2007). The lifecycle of *C. shasta* is complex because the parasite changes form and the lifecycle involves two hosts, a freshwater polychaete (worm) and a salmonid. Two of the factors associated with the presence of *C. shasta* appear to be the presence and abundance of the polychaete in the Klamath River (Bartholomew and Bjork 2007).

There may be a linkage between the proliferation of *C. shasta* in the mainstem Klamath River, elevated nutrient concentrations, and subsequent increases in the diurnal fluctuation of DO. Elevated nutrient concentrations result in increased periphyton and increased suspended algae and blue-green algal growth in the river, which have been identified as prime habitat for the polychaete. Increased habitat leads to an increased abundance of the polychaete, which in turn leads to a high infectious spore load in the river. This results in a high probability that adult and juvenile salmonids migrating and rearing in the river will be infected by *C. shasta*. *C. shasta* is commonly found in salmonid streams. But, large scale outbreaks of disease are rarely observed unless, as shown in the Figure 3-1, there is an increase in both parasite spores and environmental stressors, including low DO. Oregon (1995) reports that generalized stress causes increased releases of cortisol in salmonids which suppresses immune function and disease resistance, as appears to have been happening in the Klamath River.

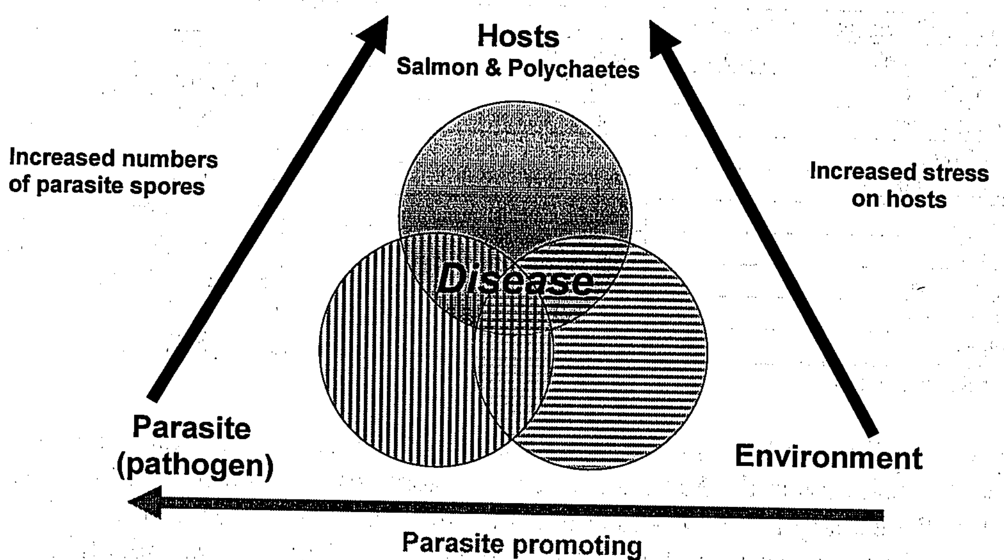

Figure 3-1: Severity of *Ceratomyxosis* in Klamath River suggests a shift in the host/parasite balance towards *C. shasta*

<u>3.1.2.3 Summary of Salmonid DO Requirements</u>
USEPA (1986), Oregon (1995) and Washington (2002) each provide technical recommendations for appropriate DO criteria for the protection of salmonids. Table 3-3 represents USEPA's (1986) recommendations derived from it's synthesis of scientific studies but primarily relying on 1) growth data and 2) information on temperature, disease, and pollutant stresses (USEPA 1986). USEPA (1986) proposes national coldwater criteria for the protection of early life stages of 9.5 mg/L DO in the water column as a 7-day mean and 8.0 mg/L DO in the water column as 1-day minimum. For

other life stages, USEPA (1986) recommends 6.5 mg/L DO as a 30-day mean, 5.0 mg/L DO as a 7-day mean minimum, and 4.0 mg/L DO as a 1-day minimum.

However, "if slight production impairment or a small but undefinable risk of moderate production impairment is unacceptable, then continuous exposure conditions should use the "no production impairment values" as means and the "slight production impairment values" as minima (USEPA 1986)." The Klamath River is a system in which even slight production impairment is unacceptable because of the threatened and endangered status of several of the basin's native fish species. For a river such as the Klamath, then, USEPA (1986) would recommend (see Table 3-3) for early life stages 11 mg/L DO in the water column as a 7- or 30-day mean (8 mg/L IGDO) and 9.0 mg/L DO in the water column as a 1-day minimum (6.0 IGDO). For other life stages, USEPA (1986) would recommend 8.0 mg/L as a 7- or 30-day mean and 6.0 mg/L as a 1-day minimum.

Table 3-3 from USEPA (1986) Ambient Water Quality Criteria for Dissolved Oxygen

	No Production Impairment (mg/L)	**Slight Production Impairment** (mg/L)	**Moderate Production Impairment** (mg/L)	**Severe Production Impairment** (mg/L)	**Limit to Avoid Acute Mortality** (mg/L)
Salmonid Waters-- Embryo and larval stages	11* (8)	9* (6)	8* (5)	7* (4)	6* (3)
Salmonid Waters--Other life stages	8	6	5	4	3
Nonsalmonid Waters— Early life stages	6.5	5.5	5	4.5	4
Nonsalmonid Waters— Other life Stages	6	5	4	3.5	3
Invertebrates	8	5			4

* These are mean water column concentrations recommended to achieve the required intergravel DO concentrations shown in parentheses. The recommended water column concentrations are based on the assumption that there is a 3 mg/L difference between water column and intergravel DO, on average.

USEPA (1986) also considers waterbodies in which natural conditions produce DO in noncompliance with the given criteria. USEPA (1986) recommends that "if natural conditions alone create dissolved oxygen concentrations less than 110 percent of the applicable criteria means or minima or both, the minimum acceptable concentration is 90 percent of the natural concentration (USEPA 1986)." The Klamath River is a productive river which under natural conditions produces DO in noncompliance with the recommended criteria (see Chapter 6.0 of this Staff Report). As such, USEPA's (1986) guidelines suggest that 90% of the natural DO concentrations will provide adequate protection of the beneficial uses.

Oregon (1995) also includes several recommendations with respect to DO criteria suitable to protect salmonids. The Oregon Department of Environmental Quality assembled a Dissolved Oxygen Technical Advisory Committee (DOTAC) for the purpose of reviewing the existing standards, reviewing the current state of the scientific literature associated with the DO requirements of salmonids and other aquatic species, and developing findings and recommendations. The DOTAC was chaired by Dr. Gary Chapman of the USEPA who also authored the USEPA's 1986 guidance on ambient water quality criteria for DO. The DOTAC conducted its review of Oregon standards from 1992-1994. Their findings and recommendations were published in 1995. The DOTAC found that:

1. "The "natural" conditions in some streams will cause dissolved oxygen levels to fall below the numerical criteria, especially the conservative 90-95 percent criteria when interpreted as absolute minimums.
2. Saturation criteria may result in inadequate protection at high temperatures and greater than necessary criteria at low temperatures, often inversely related to the needs of the resource. Because of the high level of protection warranted for salmonid spawning, concentration and saturation criteria would be similar for this use.
3. Current criteria recognize that situations will occur where the achievement of dissolved oxygen standards will not be possible due to naturally occurring conditions or due to human activities which are beyond regulatory control. In these cases, the background conditions become the criteria and no further degradation is permitted. Other states, such as Washington, provide an allowance on the order of 0.20 mg/L for further degradation under similar conditions.
4. 10% of the reference sites and 24% of the Regional Environmental Monitoring and Assessment Program (REMAP) sites in the coast range would violate a 90% saturation criterion, even though they meet a no measureable impact to cold-water fish criteria of 8.0 mg/L.

The DOTAC and staff at the Oregon Department of Environmental Quality jointly reviewed scientific literature related to DO criteria. They reviewed literature associated with salmonid physiology, early life stages and intergravel DO, relationship between intergravel DO and solids, natural range and variation in intergravel DO, swimming performance, fish growth, oxygen cycles, supersaturation; avoidance and behavioral changes; toxics and disease; water temperature; field studies; estuarine criteria; and relationship between pH, CO_2, and DO. From this review, the DOTAC recommended that:

1. Criteria should be related to the biological resources that are to be protected.
2. There should be consistency between the criteria for different river basins.
3. Critical compliance issues related to temperature and dissolved oxygen need to be analyzed. The State needs to manage its aquatic resources much more broadly than by single parameter or by point-source pollution control.
4. Concentration criteria should be used rather than percent of saturation for other life stages of cold-water biological resources, with the exception of supersaturation criteria. The criterion for early life stages of cold-water fish could be equally well presented as a percent saturation.
5. Statistical criteria with associated duration period should be used.

6. Statistical criteria should be applied only when adequate data are available.
7. The early life stages criteria for salmonid protection should apply during the latter stages of incubation of embryos and fry, until after fry emerge from the gravels. The protective criteria need only apply to areas of salmonid spawning.
8. The state should establish intergravel dissolved oxygen criteria for protection of the early life stages of salmonids. For unimpaired watersheds, the expected loss of an average of 3.0 mg/L DO from surface to the gravels provides the method for determining minimum surface-water concentrations. The assumption of a 3.0 mg/L loss between surface and intergravel environments may underestimate the loss that occurs in highly impacted spawning areas.
9. The importance of nutrient and sediment runoff and removal of the riparian canopy as major cause of DO depletion in streams and lakes should be recognized.
10. The impact of stream flows on temperature changes and therefore on DO should be recognized.

In 2002, the State of Washington published the findings and recommendations resulting from its review of the State's DO criteria and the current scientific literature. It notes that any depression of oxygen from saturation will produce some reduction in the performance of fish (Washington 2002). It also notes that statistically significant changes to growth, swimming speed, etc. do not occur until oxygen levels are depressed to levels that are sometimes well below the saturation value (Washington 2002).

Table 3-4 captures the technical recommendations of USEPA (1985), Oregon (1995), and Washington (2002) with respect to DO criteria suitable for the protection of salmonids and other aquatic life.

3.2 Lamprey

Lamprey are a jawless fish from the family *Petromyzontidae* that generally feed on the blood and body fluids that they extract with their sucker-like mouth from live fish (Moyle 2002). This "predatory" phase of the Pacific lamprey is spent in the ocean, except for those species that are landlocked (Moyle 2002).

Pacific lamprey spawning usually begins in early March and lasts through late June (Moyle 2002). There are variations to this schedule. And, in the larger rivers (Klamath, Trinity, and Eel) there may be both spring and fall runs, similar to salmon (Moyle 2002).

THIS SPACE INTENTIONALLY LEFT BLANK

Table 3-4: Recommendations of USEPA (1986), Oregon (1995), and Washington (2002)

	USEPA (1986)—mg/L		Oregon (1995)—mg/L		Washington (2002)—mg/L	
Incubation through emergence[1]	≥11	7- or 30-day mean	≥11[2]	7-day mean	≥9.0-11.5[34]	30- to 90-day average of daily minima
	≥9	1-day minimum	No comment			
	≥8 IGDO	7- or 30-day mean	No comment			
	≥6 IGDO	1-day minimum	≥6 IGDO	1-day minimum		
Growth of Juvenile Fish	≥8	7- or 30-day mean	≥8[5]	30-day mean	≥8.0-8.5	30-day daily minimum
	≥6	1-day minimum	No comment		≥5.0-6.0	1-day minimum
Swimming Performance	No comment		No comment		≥8.0-9.0	1-day minimum
Avoidance	No comment		No comment		≥5.0-6.0	1-day minimum
Acute Lethality	No comment		No comment		≥4.6	7- to 30-day average of daily minima
	No comment		No comment		≥3.0	1-day minimum
Macro-Invertebrates	≥8	7- or 30-day mean	No comment		No comment	
	≥5	1-day minimum	No comment		≥8.5-9.0[6]	1-day minimum or average
					≥7.5-8.0[7]	1-day minimum or average
					≥5.5-6.0[8]	1-day minimum or average
Synergistic Effect Protection	≥8	7- or 30-day mean	No comment		No comment	
	No comment				≥8.5	1-day average
	6	1-day minimum			No comment	
To ensure no risk	No comment		No change from natural		No comment	

1 Applies only during the period of incubation through emergence and only in those locations in which spawning occurs.

2 If conditions of altitude and natural temperature preclude achievement of 11 mg/L, then 95% saturation applies.

3 No measureable change when waters are above 11°C (weekly average) during incubation.

4 Applies throughout the period from spawning through emergence and assumes 1-3 mg/L will be lost between the water column and the incubating eggs.

5 If conditions of altitude and natural temperature preclude achievement of 8 mg/L, then 90% saturation applies.

6 To be applied in mountainous headwater streams

7 To be applied to mid-elevation streams, lakes, and non-salmonid water

8 To be applied to low-elevation streams, lakes and non-salmonid water

Adult lamprey migrate from the ocean to freshwater where a male and female build a nest together in the gravel (Moyle 2002). After the eggs are laid and fertilized, embryos develop and hatch in about 19 days at 15 °C (Moyle 2002). The ammocoetes are washed downstream to a muddy or sand-bottomed backwater where they burrow in the sediment, tail down (Moyle 2002). They remain in the sediment as filter feeders while they undergo a metamorphosis to become adult lamprey (Moyle 2002). Metamorphosis takes from 5-7 years (Moyle 2002).

There is some evidence of temperature requirements of lamprey. But, little information is available regarding dissolved oxygen requirements, though ammocoete development is impaired under very low DO concentrations (Goodman 2008). Of primary concern to lamprey conservation are activities that may directly disturb ammocoetes, result in sedimentation of quiescent stream reaches, or cause localized dewatering (USFWS 2007a). Data on optimal DO conditions for lamprey are not available; however, DO conditions suitable to support salmonids are believed to be adequate for lamprey, as well (Goodman 2008).

3.3 Sucker

The Lost River sucker (*Catostomus luxatus*) and shortnose sucker (*Chasmistes brevirostris*) are two native fish species of the upper Klamath basin. Both sucker species are endangered and belong to a "part of a group of suckers that are large, long-lived, late-maturing, and live in lakes and reservoirs but spawn primarily in streams; collectively, they are commonly referred to as lake suckers" (NRC 2004). Lake suckers differ from most other suckers in having terminal or subterminal mouths that open more forward than down, an apparent adaptation for feeding on zooplankton rather than suctioning food from the substrate (Scoppettone and Vinyard 1991 as cited by NRC 2004). Historically, Lost River suckers and shortnose suckers occurred in the Lost River and upper Klamath River and their tributaries, especially Tule Lake, Upper Klamath Lake, Lower Klamath Lake, Sheepy Lake, and their tributaries (Moyle 2002 as cited by NRC 2004).

The adult suckers reach sexual maturity between years 4 and 6 for the shortnose sucker (USFWS 2007c) and 5 and 14 for the Lost River sucker (USFWS 2007b). They spawn in river riffle and run habitat from February through May in gravel and cobble substrate with moderate flows and depths less than 4 feet (USFWS 2007b and 2007c). Sucker larvae move out of the gravel soon after hatching and generally drift downstream to the lake environment where they disperse in the near shore areas (Cooperman and Markle 2004 as cited by USFWS 2007a; USFWS 2007b). Larval habitat is best described as shallow, nearshore, and vegetated in both rivers and lakes, except Clear Lake and Gerber Reservoir which lack vegetation (NRC 2004). Adult suckers select water depths of 3-15 feet, their strongest preference appears to be for 5-11 feet (NRC 2004). Adult Lost River suckers have been aged to 43 years while shortnose suckers have been aged to 33 years (NRC 2004). The lake suckers spawn numerous times over their life time producing millions of eggs, a life history strategy necessary due to the high natural mortality of the young fish and the low natural mortality of the older adult fish (NRC 2004).

With respect to water quality, Woodhouse et al. (2004) synthesized several studies in the Lost River basin to determine appropriate thresholds for Lost River and shortnose suckers. They were unable to identify appropriate criteria for the protection of suckers; but, did identify acute lethality thresholds, as follows:

- DO < 2.3 mg/L (based on LC_{50} in shortnose sucker larvae);
- pH > 9.5 (based on critical maxima in shortnose sucker adults);
- Water temperature < 30.3 °C (based on LC50 in shortnose sucker juveniles);
- Un-ionized ammonia < 0.48 mg/L (based on LC_{50} in Lost River sucker larvae and shortnose sucker juveniles).

Comparing to the lethality thresholds for salmonids as described by USEPA (1986), Oregon (1995), Washington (2002), staff concludes that DO conditions suitable for the protection of salmonids will adequately protect suckers, as well.

3.4 Green Sturgeon

The green sturgeon (*Acipsenser medirostris Ayres*) is a long-lived anadromous fish that spends most of its time in ocean waters with feeding forays to bays and estuaries (NMFS 2009). Both adults and juveniles are benthic feeders eating shrimp, mollusks, amphipods and small fish (Moyle 2002). The green sturgeon migrates into freshwater systems to spawn. In the North Coast Region, green sturgeon are primarily found in the Klamath and Trinity rivers; though, they will occasionally be seen in the Eel River which once supported a spawning run (Moyle 2002).

Green Sturgeon in the Klamath River system are likely to be part of the Northern Distinct Population Segment (DPS) which is a Federal ESA species of concern, commonly referred to as a candidate species. Adults of the Southern DPS may also enter the river, particularly the estuary to forage; and, they are listed as a threatened species under the Federal ESA. Green sturgeon enter the Klamath River system between February and late July with a spawning period of March to July and a peak from mid-March to mid-June (Moyle 2002). They spawn in deep, fast water where eggs are broadcast and externally fertilized (Moyle 2002). Juveniles remain in freshwater for up to 3 years before migrating to the ocean. Water quality requirements for the green sturgeon are unknown; but, a small amount of silt will prevent the eggs from clumping together and thus reduce viability (Moyle 2002).

Gulf of Mexico sturgeon were found in locations in the Suwannee River estuary ranging from 6.0 to 9.8 mg/L DO with an average of 7.5 mg/L DO (Harris et al. 2005). Eggs were found in areas of the Suwannee River with DO exceeding 5.0 mg/L (Sulak and Clugston 1998). Campbell and Goodman (2004) exposed juvenile shortnose sturgeon, an Atlantic species, to varying laboratory conditions and derived LC50s ranging from 2.2-3.1 mg/L DO depending on the accompanying salinity, temperature, and age of the fish. Younger fish were more sensitive to low DO than older fish.

NMFS 2009 lists as threats to California's green sturgeon:

- ✓ Insufficient freshwater flow rates in spawning areas,
- ✓ Contaminants (e.g., pesticides),

- ✓ Bycatch of green sturgeon in fisheries,
- ✓ Potential poaching (e.g., for caviar),
- ✓ Entrainment by water projects,
- ✓ Influence of exotic species,
- ✓ Small population size,
- ✓ Impassable barriers, and
- ✓ Elevated water temperatures.

DO is not specifically identified as a limiting factor. But, elevated temperatures and decreased flows have the potential to affect DO concentrations. Green sturgeon have an advantage over salmonids with respect to DO and spawning in their choice of deep, fast water as spawning habitat. The DO conditions of this habitat niche are likely superior to that of more shallow, slow moving water. Staff concludes that DO requirements designed to protect salmonids will reasonably protect sturgeon, as well, even though their spawning and incubation period extends past that of salmonids.

3.5 Smelt

The eulachon (*Thaleichthys pacificus*) and longfin smelt (*Spirinchus thaleichthys*) are both in the smelt family *Osmeridae* and are anadromous fish. Within the North Coast Region, the eulachon has been found historically in the Klamath River, as well as in the Mad River, Redwood Creek, and the Smith River while the longfin smelt has been found in Humboldt Bay, the Eel River estuary, the Klamath River estuary, and the Russian River estuary (Moyle 2002). They (eulachon) have been proposed by the National Marine Fisheries Service (NMFS) to be listed as threatened under the Federal ESA and are considered a species of concern.

The eulachon is the largest species of the smelt family (Moyle 2002). It is a very oily fish, also sometimes called the candlefish because of its historic use when dried to be burned as a candle. It is an anadromous fish, spending most of its life at sea and then spawning in the lower reaches of coastal rivers (Moyle 2002). Eulachon return to freshwater between December and May in their third year and their migration appears to be timed with river temperatures between 4-8 °C (Moyle 2002). Migrating fish seldom travel farther than 7.5 miles (12 km) up river, the fish keeping to the river bottom and shallow river edges (Moyle 2002). Spawning occurs where temperatures are between 4-10 °C, velocities are moderate, and substrate consists of pea-sized gravel or gravel mixed with sand, wood or other debris (Moyle 2002). Fertilization is external with females producing an average of 25,000 eggs (Moyle 2002). Eggs have two membranes, the outer one of which ruptures when the egg hits the channel bottom. This allows the sticky edges to adhere to the substrate where the larvae will hatch in 2-3 weeks. The larvae are quickly washed out to sea (Moyle 2002).

Moyle (2002) states "given the extended ocean life phase of eulachon and the apparently sporadic nature of their abundance in recent years, it is likely that oceanic conditions may be important determinants of the size of spawning runs." He continues "eulachon are sensitive to a number of environmental factors and their recent decline in California streams may be the result of changes in water quality or spawning habitat in the lower reaches of rivers" (Moyle 2002).

Longfin smelt have a wide salinity and temperature range, reflecting their ability to occupy various estuarine niches depending on the time of year and life cycle stage (Moyle 2002). They spawn in freshwater over sandy or gravel substrates, rocks and aquatic plants as early as November and up through the month of June (Moyle 2002). Embryos hatch in 40 days at temperatures of 7 °C, the newly hatched larvae drift quickly down to the estuary (Moyle 2002). Larvae metamorphose into juveniles after 30-60 days from hatching, depending on the temperature (Moyle 2002). Most adult longfin smelt die after spawning (Moyle 2002).

Pientka and Parrish (2002) found that in a comparison of habitat use by Atlantic salmon and rainbow smelt, the two occupied similar thermal habitat. But, Atlantic salmon generally chose habitat with higher DO concentrations. Staff concludes that DO objectives designed to protect salmonids will be protective of smelt, as well.

3.6 Summary

In summary, there are a number of native fish species of the Klamath Province that are at risk of extinction, including species of: salmonids, lamprey, sucker, sturgeon, and smelt. These fishes occupy a variety of freshwater and estuarine habitats, some of them overlapping with other native species. The life cycles vary considerably with some species spending a majority of their lives in freshwater and others in the ocean. Yet, the information staff has been able to gather on the DO and/or other water quality requirements of each of the species of interest suggests that DO objectives designed to protect salmonids likely will protect the other native species, as well, even for those species with extended larval stages such as the lamprey. This brief assessment is intended only to confirm that the general bias towards salmonids in the establishing of water quality objectives is, at least for DO, warranted.

A summary of various DO recommendations for salmonids is given in Table 3-4 above. From these recommendations, it is determined that Klamath River fishes, including those at risk of extinction, would ideally enjoy the following DO conditions, including:

Early Life Stages: **9.0-11.5 mg/L** as a 7- or 30-day mean or 30- to 90-day average of daily minima to protect eggs and alevin from growth effects, assuming a 1-3 mg/L decrease in DO from the water column to the intergravel environment.

6.0 mg/L IGDO as a 1-day minimum to protect eggs and alevin from acute lethality and growth effects.

Other Life Stages: **8.0 mg/L** as a 7- or 30-day mean to protect against acute lethality and growth effects.
6.0 mg/L as a 1-day minimum to protect against growth effects, avoidance behavior, acute lethality, and synergistic effects. According to research conducted by Washington (2002), this criterion does not appear to protect optimum swimming performance or macroinvertebrate health (except in low elevation streams). USEPA (1986) concludes that optimum swimming performance is only required in short bursts. Moderate swimming performance is protected by criterion that protects growth and is adequate for the protection of the species. USEPA (1986) also acknowledges that some macroinvertebrates are more DO sensitive than fish; but suggests that 6 mg/L as a 1-day minimum is adequate to protect a reasonably diverse macroinvertebrate assemblage, particularly since DO sensitive species seek high flow environments so as to optimize their DO exposure.

CHAPTER 4.
GENERAL DISCUSSION OF DISSOLVED OXYGEN

The purpose of this chapter is to provide a general discussion of dissolved oxygen (DO), including a discussion of what it is, why it is important, and what factors influence its concentration

Dissolved Oxygen (DO) provides an excellent measure of general aquatic health. It is one of the primary water quality factors that define the habitability of a given aquatic system. Yet, it varies considerably both temporally and spatially in the natural environment. Thus, to interpret DO data, one must know something about the factors influencing its concentration and the expected pattern and range of its variation to be able to discern any deviation from background conditions and/or any critical impact. A general discussion of these issues follows.

4.1 What is Dissolved Oxygen?

Dissolved oxygen, most often measured in mg/L, is the amount of oxygen gas present in a volume of water. Water has a limited capacity to hold oxygen gas in solution. This capacity is defined by a mathematical relationship among the temperature, atmospheric pressure, and salinity at a given site. When water has reached its capacity to hold oxygen gas in solution it is said to be *saturated.* When it exceeds its capacity, it is said to be *supersaturated.* And, when it does not reach its capacity, it is said to be *sub-saturated.*

4.2 Why is Dissolved Oxygen important?

Oxygen is necessary for the respiration of aerobic organisms. Because water has a limited capacity to hold oxygen gas in solution, aquatic organisms have evolved specialized structures or methods of extracting from water the limited amount of oxygen gas that is present in it. These structures or methods generally rely on the partial pressure differential between oxygen in the water column and oxygen in the blood (or the equivalent oxygen receptor). Gills, as an example, are designed to allow the passive diffusion of oxygen from water across the gill membrane to the arterial system.

A healthy riverine system is generally one in which the DO concentration is at or approaches full saturation and is maintained by diffusion (Allan 1995). Under these conditions, aerobic organisms can extract from the water column the oxygen necessary to ensure basic metabolic success (e.g., growth, general health, and reproduction) leading to a greater likelihood of population success. Further, a riverine system approaching DO saturation is better able to support a wide and diverse array of life forms than one which does not.

As the concentration of DO in water is reduced to levels significantly less than saturation, the oxygen partial pressure gradient between the water column and blood (or equivalent oxygen receptor) is reduced and the ability of the gill structure (or equivalent oxygen receptor) to acquire the necessary oxygen for respiration is impaired. This can lead to chronic effects, such as reduced growth, increased susceptibility to disease, reduced reproductive success, or loss of habitat through avoidance. It can also lead to acute effects, such as asphyxiation and death. The term *hypoxia* (meaning "low oxygen") refers to the water quality condition in which the dissolved oxygen present in water is insufficient to provide the oxygen requirements of aerobic organisms. Water devoid of oxygen is known as *anoxic*.

4.3 What are the factors influencing the concentration of Dissolved Oxygen?

The concentration of DO in an aquatic environment is controlled by many interrelated variables, including stream temperature, salinity, atmospheric pressure, turbulence, respiration, photosynthesis, and biological and chemical oxygen demanding reactions. To simplify, these factors can be divided two categories: 1) those that define the capacity of the water to hold DO (DO saturation) and 2) those that affect the percent of that capacity which is actually utilized (% DO saturation).

4.3.1 DO saturation

DO saturation is defined by the mathematical relationship among three variables: atmospheric pressure, temperature, and salinity. Variation in DO saturation is proportional with variation in atmospheric pressure and is inversely proportional with variation in temperature and salinity. Thus, as atmospheric pressure increases so does the concentration of DO at saturation. Because atmospheric pressure decreases as elevation increases, DO at saturation is inversely proportional with elevation. At any one elevation, DO at saturation also will vary based on the presence of low or high pressure storm systems.

As water temperature and/or salinity increase, the concentration of DO at saturation decreases. Water temperature varies depending on numerous factors including: latitude, climate, season, presence of springs, shade, and volume of warm water inputs, as examples. Salinity primarily varies based on the degree of oceanic influence.

One of the primary routes by which oxygen dissolves in water is through the diffusion of oxygen across the air-water interface. Atmospheric oxygen exerts a pressure at the air-water interface allowing for the diffusion of oxygen across the boundary until the partial pressure of atmospheric oxygen equals the partial pressure of oxygen in water. The pressure exerted on the air-water interface by oxygen dissolved in water is defined not only by the concentration of oxygen in water, but by the temperature of the water, as well. For example, O_2 molecules become excited and exert a greater partial pressure on the air-water interface when warm then they do when cool. Thus, the warming of a waterbody serves to slow or even reverse the diffusion of oxygen from the air to the water column.

With respect to salinity, one can visualize water as including H_2O molecules and the spaces between them. The spaces between the H_2O molecules allow for various other molecules to be dissolved in water. If the spaces between the H_2O molecules are filled with molecules such as salts, then the number of spaces available for oxygen is reduced. Salinity is a measure of salts and is generally used to define the gradient between freshwater, brackish water, and saltwater systems. An aquatic system with a high salinity (e.g., the ocean) will naturally have a lower DO concentration at saturation than will a freshwater system with little or no salinity.

Staff has calculated and graphed DO at 100% saturation for individual elevations based on a standard pressure of 760 mm Hg (Figure 4-1). These are theoretical DO concentration values based solely on salinity (i.e., freshwater), atmospheric pressure and temperature and represent the physics associated with holding oxygen in a dissolved state in an aqueous solution. Figure 4-1 does not represent DO concentrations as altered by water quality conditions such as turbulence, aerobic decomposition, photosynthesis, etc. For a given elevation and temperature, Figure 4-1 illustrates the maximum DO concentrations physically possible under conditions of equilibrium.

Figure 4-1: Theoretical DO at 100% Saturation (produced by Rich Fadness of the Regional Water Board)

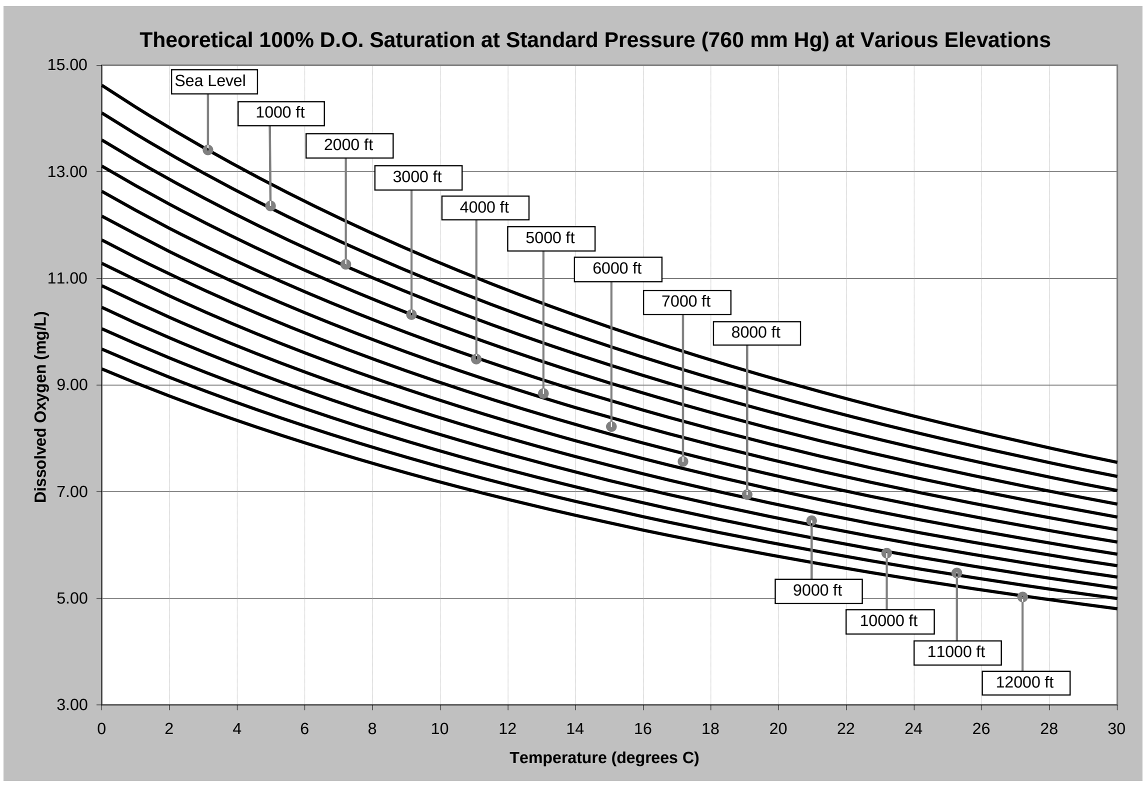

Figure 4-1 illustrates the decline in the ability of water to hold oxygen in solution that occurs as a result of increasing temperatures. For example, at 1,000 feet elevation, DO concentrations range from approximately 14.0 to 7.2 mg/L as temperatures increase from 0 to 30°C. Figure 4-1 also illustrates at a given temperature, an increase in the ability of water to hold oxygen in solution that occurs as water moves from a higher elevation to a lower elevation. For example, at 16°C, DO concentrations range from approximately 6.2 to 10.0 mg/L as water flows from 12,000 feet elevation to sea level. For a given elevation and temperature, Figure 4-1 provides an estimate of the ability of water to hold oxygen in solution (i.e., DO concentration) when in a state of equilibrium. For example, at 3,000 feet elevation, when water temperatures reach 22°C, DO is approximately 7.9 mg/L at 100% saturation.

4.3.2 Percent Saturation

In the natural environment, there are several other factors at play besides the effects of atmospheric pressure, temperature, and salinity. For example, photosynthesis, turbulence, respiration, organic decomposition, and oxygen demanding biological and chemical reactions also effect the concentration of DO in an aquatic system. These factors do not control the capacity of an aquatic system to hold oxygen in solution (DO saturation). Instead, they affect the percentage of the capacity that is actually utilized (percent saturation).

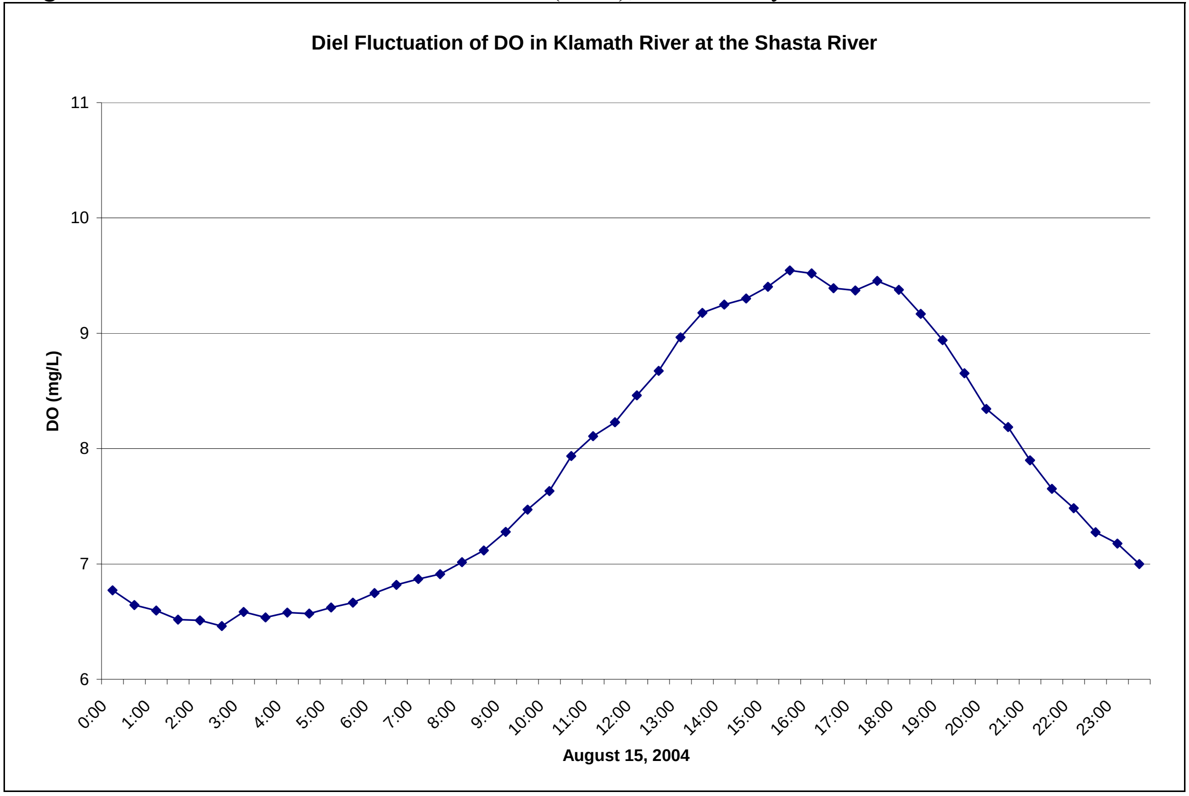
The *photosynthesis* of aquatic plants, algae, and cyanobacteria has a profound effect on the oxygen content of water. Photosynthetic organisms use carbon dioxide to convert the energy contained in sunlight into carbohydrates and oxygen. Aquatic photosynthetic organisms release their oxygen (a waste product) to the water column, temporarily increasing the DO concentration of the water. Areas in which the substrate, light, nutrients and temperature favor the growth of aquatic photosynthetic organisms may see large increases in DO during the late afternoon when the effects of photosynthesis have accumulated through the day. Such areas may be naturally present in an aquatic system (e.g., wetlands; lakes; and slow moving, shallow river reaches) or promoted by anthropogenic activities (e.g., nutrient enrichment, shade removal, reduction in flow, or reduction in water depth through sediment deposition).

The contribution of oxygen to the water column as a result of photosynthesis occurs only during the daylight hours when photosynthesis is active. This source of oxygen is not present during the night when in the absence of sunlight photosynthesis does not occur. The result is a notable cyclical DO pattern where DO is low in the pre-dawn hours, increases slowly during the morning, reaches a peak prior to sunset, and then declines through the night. This is called a *diel* cycle. A typical DO diel cycle results in daily minimum DO concentrations in the pre-dawn hours.

Figure 4-2 depicts the DO diel curve that results from 24-hour DO data collected on August 15, 2004 in the Klamath River at its confluence with the Shasta River. On that day, DO dropped below 7 mg/L sometime prior to 1am and didn't exceed 8 mg/L until 12 noon. The DO concentration peaked at approximately 9.5 mg/L by 3:30pm. These data do not represent natural conditions. But, they do represent the typical shape of a diel DO curve, specifically showing lower DO concentrations at night followed by higher DO concentrations during the day as photosynthesis is active.

The term *turbulence* refers to a physical process in which the air-water interface is disturbed. Turbulence serves to increase the transfer of oxygen across the air-water interface by increasing the surface area of the interface either at the surface of the water or in the form of bubbles of air entrained within the water column (e.g., as occurs at waterfalls or through mechanical mixing). Turbulence can serve to either decrease or increase the transfer of oxygen to the water column depending on whether the water is supersaturated or sub-saturated and whether or not air is entrained in the water column.

Figure 4-2: 24-hour DO data in mid-summer (2004), collected by US Fish and Wildlife Service



The *respiration* of aquatic organisms requires oxygen for the process of converting carbohydrates into energy for growth and reproduction. It also results in the release of carbon dioxide as a waste product. The oxygen fueling the respiration of aquatic organisms comes from the water column and as described above is extracted using specialized structures or methods (e.g., gills

The *decomposition* of organic matter in the aquatic environment is a complex process involving numerous organisms and chemical reactions. Biological oxygen demand is a measure of the pressure exerted on dissolved oxygen supplies by the biological decomposition of organic molecules. Numerous species of micro-organisms are involved in the process of biological decomposition.

Chemical oxygen demand is a measure of the pressure exerted on dissolved oxygen supplies by the chemical oxidation of organic molecules. Some of the reactions are initiated by biological activity. The chemical reactions typically at play in an aquatic environment include: carbonaceous deoxygenation, nitrogenous deoxygenation, nitrification, and methantrophy.

The percentage of the capacity of water to hold oxygen in solution is reported as *percent saturation*. In any given system, it is the unique and fluctuating combination of oxygen sources (e.g., photosynthesis and turbulence) and oxygen sinks (e.g., respiration, biological oxygen demand, and chemical oxygen demand) that define the percent saturation. For example, the infusion of dissolved oxygen into the water column via photosynthesis or turbulence can result in the temporary supersaturation of water (i.e., DO concentrations in excess of that described by 100% saturation). These conditions subside either during the night when photosynthesis is no longer active or downstream as water moves out of the influence of waterfalls or rapids.

In the reverse, respiration and decomposition can remove oxygen from the water column resulting in the temporary sub-saturation of water (i.e., DO concentrations less than those described by 100% saturation). These conditions also subside on the spatial and temporal scale. But, the subsidence might occur seasonally, rather than daily. In highly eutrophic systems, the decomposition of organic matter can result in the temporary removal of oxygen from the water column. The loss of oxygen from an aquatic system can result in the temporary loss of all aerobic organisms, such as observed in fish kills.

Figure 4-3: Theoretical DO at 85% (produced by Rich Fadness of the Regional Water Board)

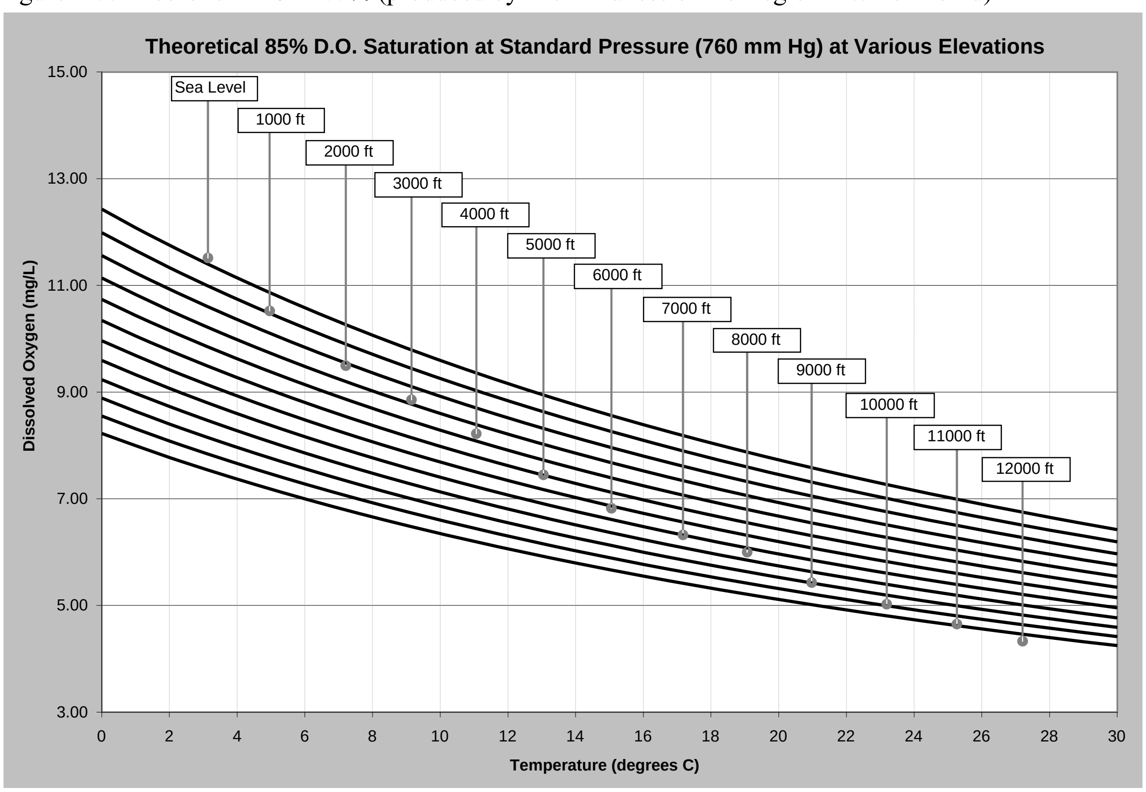


Figure 4-3 represents the theoretical concentration of DO at 85% saturation at various elevations and temperatures. As described in Chapter 7.0 of this Staff Report, staff estimates that 85% saturation is the minimum percent saturation occurring in a healthy, free-flowing stream with moderate nutrient and organic loading.

By comparing Figures 4-1 and 4-3, one can estimate at any given temperature and elevation, the difference in DO concentration at equilibrium versus that influenced by moderate decomposition and respiration, generally estimated to occur at DO saturations no less than 85%. For example, at 3000 feet elevation and 20°C, a DO concentration under equilibrium (100% saturation) decreases from 8.1 mg/L to 6.9 mg/L due to only moderate decomposition and respiration (85%). In a river with a daily minimum DO requirement of 7.0 mg/L, the only way to achieve compliance at 3000 feet or higher is to ensure that temperatures never reach 20°C or natural organic matter and nutrient loading is curtailed.

4.4 Summary

In summary, DO is the amount of oxygen gas present in a volume of water. DO is the source of oxygen used by aquatic aerobic organisms and is thus a critical indicator of aquatic ecosystem health**.** The concentration of DO in a given aquatic system is defined by the capacity of that system to hold oxygen in solution and the percent of that capacity that is utilized. An aquatic system that is saturated with DO is at equilibrium as defined by the effects of barometric pressure, temperature, and salinity. Variation in saturation occurs as a result of the influences of oxygen sources (e.g., photosynthesis and turbulences) and oxygen sinks (e.g. respiration, decomposition, and biological and chemical oxygen demanding processes). A healthy, free-flowing aquatic system maintains DO concentrations close to full saturation (100%), generally no less than 85%.

CHAPTER 5.
EXISTING WATER QUALITY OBJECTIVES
FOR DISSOLVED OXYGEN IN THE KLAMATH RIVER

In this chapter, staff describes the existing Site Specific Objectives (SSO) for Dissolved Oxygen (DO) in the Klamath River mainstem and presents its assessment of their continued appropriateness.

The Regional Water Board adopted the *Water Quality Control Plan for the North Coast Region* (Basin Plan) in which it established the region's water quality standards, including the standards that apply to the portion of the Klamath River basin that falls under the jurisdiction of the State of California. The Basin Plan has been approved by the State Water Board and by USEPA and is in full force and effect.

5.1 Beneficial Uses

Chapter 2 of the Basin Plan identifies 28 beneficial uses of water within the North Coast region. The following beneficial uses have been designated as existing uses of the Klamath River mainstem (Basin Plan, Table 2-1):

- MUN—Municipal and domestic supply
- AGR—Agricultural supply
- IND—Industrial service supply
- PRO—Industrial process supply
- GWR—Groundwater recharge
- FRSH—Freshwater replenishment
- NAV—Navigation
- POW—Hydropower generation
- REC1—Water contact recreation
- REC2—Non-contact water recreation
- COMM—Commercial and sport fishing
- WARM—Warm freshwater habitat
- COLD—Cold freshwater habitat
- WILD—Wildlife habitat
- RARE—Rare, threatened, or endangered species
- MAR—Marine habitat
- MIGR—Migration of aquatic organisms
- SPWN—Spawning, reproduction, and/or early development
- SHELL—Shellfish harvesting
- EST—Estuarine habitat
- AQUA— Aquaculture
- CUL—Native American Culture

The beneficial uses of most importance to the discussion of DO in the Klamath River mainstem are those related to human consumption/contact and aquatic life, including: municipal and domestic supply; water contact recreation; commercial and sport fishing; warm freshwater habitat; cold freshwater habitat; wildlife habitat; rare, threatened and endangered species; marine habitat; migration of aquatic organisms; spawning, reproduction, and/or early development; shellfish harvesting; estuarine habitat; aquaculture; and Native American culture.

The rare, threatened and endangered cold water aquatic species (RARE, SPWN beneficial uses) of the Klamath River mainstem are identified as the most sensitive of the beneficial uses, thereby requiring the greatest dissolved oxygen to ensure their protection. The spawning, incubation and emergence life stage of these species is identified as the most sensitive life stage

5.2 Water Quality Objectives

The water quality objectives for DO are given in the Basin Plan in two parts. The first part is given as *life cycle DO requirements*, designed to protect individual beneficial uses, including: WARM, MAR, SAL[1], COLD and SPWN. The *life cycle DO requirements* were first adopted in 1975 and are given as daily minima. They do not include weekly or monthly average limits by which to prevent chronic effects of DO stress. These objectives apply to all waterbodies in the North Coast Region *except* those listed in Table 3-1 of the Basin Plan.

The second part of the water quality objectives for DO is given in Table 3-1 of the Basin Plan. These are Site Specific Objectives (SSO) designed to protect the background conditions of individual waterbodies based on the statistical analysis of monthly grab sample data collected in the 1950s and 1960s. From these analyses, daily minima and annual means were established for individually named waterbodies, including fifty-eight (58) separate entries. The Klamath River mainstem is included in Table 3-1 of the Basin Plan with two SSOs for DO: a) 7.0 mg/L as an instantaneous minimum for that portion of the mainstem from the Oregon-California state line to Iron Gate Dam and b) 8.0 mg/L as an instantaneous minimum from Iron Gate Dam to the estuary. Fifty percent of the monthly means must be greater than or equal to 10.0 mg/L DO throughout the length of the Klamath mainstem under California's jurisdiction. The *life cycle DO requirements,* as described above, do not apply in the Klamath River basin.

The framework of the Basin Plan is based on the logic that protection of water quality in the North Coast region is best provided by prohibiting the point source discharge of waste. Some exceptions to this framework are included in the Basin Plan for the Lost River at all times and for the Mad, Eel, and Russian Rivers from October 1 through May 14. In all other streams and all other times of the year, the point source discharge of waste is prohibited, except as stipulated in the Thermal Plan, the Ocean Plan, and the action plans and policies contained in the Point Source Measures section of the Basin Plan. In the Klamath River, a single exception has been granted, under the Hatcheries Policy, to the Iron Gate Fish Hatchery, owned by PacifiCorp and operated by the Department of Fish and Game.

THIS SPACE INTENTIONALLY LEFT BLANK

[1] SAL is not a beneficial use identified in the Klamath River.

5.3 Background Conditions

In concept, the DO objectives included in Table 3-1 of the Basin Plan compliment the general framework of the Basin Plan by requiring that background water quality conditions for DO be maintained for all the waterbodies named in Table 3-1, including the Klamath River mainstem. The question that has arisen in recent years is whether or not the SSOs for DO in Table 3-1 truly represent background conditions. Staff has sought to answer this question by assessing two lines of inquiry:

1. Were the landuse activities in the Klamath River basin prior to the 1950s significant with respect to DO?
2. Do the existing SSOs for DO in the Klamath River mainstem represent the true DO minima under background conditions?

5.3.1 Relationship of landuse activities to background DO conditions

Commercial scale mining and logging operations began in areas throughout California, including the North Coast Region in the mid-to-late 1800s spurred by the gold rush of that era. This was followed by dam building and agricultural enterprises, as well as urban development. By the 1950s and 1960s, areas of the North Coast Region were undergoing their second wave of timber cutting, this time with the use of tractors and other heavy ground-based equipment which left a significant foot print on the landscape and downstream watercourses. Though the point source discharge of waste from urban development has been very localized in the North Coast Region, other direct effects on water quality from stream channel modification, road building, dam building, and gravel mining, as examples, have been felt in the North Coast Region for over a century. Further, the indirect effects of nonpoint source pollution emanating from agricultural runoff, wetland reclamation, sedimentation, water diversions, and the like have also been felt in the North Coast for over a century.

The National Research Council, in its assessment of the causes of decline in salmonid populations in the Klamath River watershed, describes the history of land use as the primary factor affecting the decline in the fisheries (NRC 2004). In summary they conclude that

> "The watershed has been drastically altered by human activities. The anadromous fishes have been in decline since the 19th century, when dams, mining, and logging severely altered many important streams and shut off access to the upper basin. The declines continued through the 20th century with the development of intensive agriculture and its accompanying dams, diversion, and warm water." (NRC 2004)

The *Long Range Plan for the Klamath River Basin Conservation Area Fishery Restoration Program* (KRBFTF 1991) provides an excellent description of the history of the land management activities in the Klamath River basin and the reader is referred to it for a good overview. The Natural Research Council's *Endangered and Threatened Fishes in the Klamath River Basin: Causes of Decline and Strategies for Recovery* also includes a description of the basin's history.

5.3.1.1 Fur Trapping

NRC (2004) describes the era of fur trapping in the Klamath Basin during the 1820s as relatively peaceful. Yet, "in an attempt to discourage Americans from laying claim to the region, Hudson Bay Company's written policy was to trap fur-bearing animals from streams south of the Columbia River to extinction (NRC 2004)." Ultimately, the loss of beaver resulted in the degradation of their dams and the draining of the wetlands that had built up behind them. As these wetlands filled in, they became fertile meadows upon which ranching latter thrived (Elmore and Beschta 1987 as cited by NRC 2004). Staff does not hypothesize any direct link between fur trapping and DO conditions. But, staff believes that the failure of beaver dams, conversion of wetlands to meadows, and use of meadows for grazing has had an effect on DO conditions, as described below.

5.3.1.2 Mining

Mining activities historically prominent in the Klamath River basin include hydraulic mining and suction dredging for gold; lode mining for gold, copper, and chromite; and, gravel mining. Water quality concerns related to mining include water diversions, increased sediment loading, channel alteration, habitat alteration and destruction, acid mine drainage, and turbidity. The water quality impacts associated with mining operations can be enormous, depending on the size of the operation and the sensitivity of the associated stream. NRC (2004) reports that "mining in the 19th century was particularly destructive of fish habitat along the lower Klamath basin."

KRBFTF (1991) reports the beginning of exploratory mining by John Scott and his party at Scott Bar in 1850. The towns of Happy Camp, Orleans, Somes Bar, Sawyers Bar, Hamburg, Callahan, Yreka, and Scott Bar owe their origins to the gold mining boom of the 1800s (KRBFTF 1991). "While hydraulic mining was outlawed by the state in the late 1880s for the rivers near Sacramento, the Klamath River was not regulated. Gold production reached a peak in 1894 (KRBFTF 1991)."

Gold mining in the Klamath River basin boomed again in the 1930s, particularly in the Salmon and Scott Rivers, this time using large dredges to rework old tailing dumps and other auriferous gravels (KRBFTF 1991). Stream surveys conducted during this era determined that pools and spawning gravels were filled in with silt and macroinvertebrate production down stream of mining operations was severely impacted (KRBFTF 1991).

> "Many other problems were also noted: increased poaching in the small, clear streams where spawners were forced to congregate; reduced streamflows due to mining diversions into ditches; loss of juvenile salmonids in unscreened mining ditches; and habitat blockage by permanent and temporary diversion dams (KRBFTF 1991)."

Mining in the Klamath, like elsewhere in California, brought with it other subsidiary effects, including population growth, building, timber harvesting, food production, water withdrawl, and fishing, to name a few. Many of these activities also have effects on water quality, including DO conditions as described below.

The information in KRBFTF (1991) regarding the history of gravel mining is fairly vague, particularly with respect to activities prior to 1972. But, KRBFTF (1991) does make the point that "commercial operations are primarily scattered in accessible tributaries near towns." It may be that larger scale gravel activities did not come into operation until the development of Interstate 5 to the east and Highway 101 through Redwood National Park to the west later in the 1970s and 1980s, respectively.

Staff believes it likely that mining activities of the late 19th and early 20th centuries altered DO conditions in select locations as follows:

- Decreased water column DO by decreasing channel depths through increased sediment delivery from increased streambank and hillslope instability and instream modifications.
- Decreased intergravel DO by increasing fines intrusion through increased streambank and hillslope instability and instream modifications.
- Decreased water column and intergravel DO by increasing sediment organic loading and decomposition.

5.3.1.3 Timber Harvest

Timber harvest activities include felling, limbing, and yarding trees, as well as transporting the logs to facilities for milling into lumber. With respect to water quality, the primary issues of concern include:

1. Timber harvest and road building activities in the stream channel which can result in an alteration of stream channel form, loss of hydrologic function, loss of aquatic habitat, increase in sediment loading, increase in organic loading, and the development of migration barriers.
2. Timber harvest and road building activities in the riparian zone which can result in a loss of shade, loss of sources of large woody debris, destabilization of the stream bank, an increase in sediment loading, an increase in organic loading, and an increase in the intensity of stormwater runoff events.
3. Timber harvest and road building activities on the hillslope which can decrease hillslope stability, increase sediment delivery, increase organic loading, decrease rates of transpiration, and increase the intensity of stormwater runoff events.
4. Road building activities which can result in an increase in hillslope instability, increase in stream network density, decrease in soil absorptive capacity, increase in stormwater runoff events, and the development of barriers to surface flow and access to upstream habitat.

NRC (2004) reports that commercial timber operations began in the Klamath basin in 1863 when the U.S. Army constructed a sawmill. In 1881, the Klamath Commercial Company was established to harvest both timber and fish at the mouth of the Klamath River (KRBFTF 1991). "The arrival of the railroad in 1887 near Yreka helped develop the markets for timber in the upper Klamath area (KRBFTF 1991)." Hard wood was shipped to Crescent City for reshipment to San Francisco; and, other mills were built on Hunter Creek near the estuary and Klamathon near what is now Iron Gate Dam (KRBFTF 1991)." Until the development of roads later in the 20th century, logs were "dropped into the Klamath River and floated to the mouth to be made into ocean-going rafts (KRBFTF 1991)."

"Peak lumber production occurred in 1941, when 22 lumber mills processed a total of 808.6 million board feet within the upper basin (NRC 2004)." In the lower Klamath, "timber harvesting began in the 1850s…commensurate with the growth in mining…(and) reached a peak in the 1950s (Sommerstram et al. 1990 as cited by NRC 2004). By 1955, sports fisherman complained that log rafting in the lower Klamath River was destroying the fishery and required regulation (KRBFTF 1991). The California State Assembly's Interim Committee on Fish and Game held a field trip in August of 1955 and observed "small creeks and streams tributary to the Klamath completely obliterated by earth moved into the stream bed from a 'cat' roadway and in other cases by being choked with logging debris (KRBFTF 1991)."

KRBFTF (1991) reports in 1953 that due to its rugged terrain, the southwest half of the Klamath River Basin had not yet been substantially logged. By the mid-1960s, road building allowed greater access to the Scott and Salmon river regions (KRBFTF 1991). "The Hog Fire of 1977 burned 56,000 acres in that subbasin (Salmon River) with an estimated 450 million board feet being salvage logged over the ensuing five years (KRBFTF 1991)." NRC (2004) reports that as logging and fire suppression have generally altered the forest composition of the basin, "the risk of intense fires has increased substantially. Such fires can contribute damaging amounts of sediments and nutrients to streams and rivers."

Staff believes it likely that the timber harvest activities of the early 20th century altered DO conditions in select locations as follows:

- Decreased water column DO by increasing solar radiation through the removal of riparian shade trees;
- Decreased water column DO by decreasing channel depths through increased sediment delivery from increased streambank and hillslope instability.
- Decreased water column DO by increasing organic debris loading and oxygen consumption through decomposition.
- Decreased intergravel DO by increasing fines intrusion through increased streambank and hillslope instability.

5.3.1.4 Agriculture

Agricultural activities in the Klamath River basin include both irrigated agricultural and grazing activities. The Natural Resources Conservation Service (NRCS) has mapped the land use and land cover within the Klamath River basin (NRCS 2004). In California, agricultural activity is shown primarily in the Lost River basin, the Butte River basin, the Shasta River basin, and the Scott River Valley. Considerable additional agricultural activity occurs in Oregon in the Lost River basin, around Upper Klamath Lake, in the Sprague River Valley, and in the Williamson River basin.

Forage crops are the primary agricultural crops served by the Klamath Project, an irrigation project of the US Bureau of Reclamation. But, cereals, field crops, fruits, nuts, and vegetables are also grown in the Upper Klamath Basin (Stene 1994). Irrigated agriculture began in the Upper Klamath Basin in 1882 with the construction of an irrigation ditch connecting the Link River to present day Klamath Falls (Stene 1994). A discussion of water and power projects follows (Section 5.3.1.4). By 1953, approximately 26% of Modoc and Siskiyou counties in California and Klamath County in Oregon was in agricultural production (USBR 1953). Of this, more than half the crop land was irrigated, nearly tripling that which was irrigated 50 years prior (USBR 1953).

KRBFTF (1991) reports that the droughts of the 1860s and heavy grazing pressure reduced the range of native perennial grasses in Siskiyou County, replacing them with annual grasses and forbs. The new grasses and forbs produced less duff than the native grasses, thereby allowing more rapid runoff and surface erosion, as well as greater peak flows in streams (KRBFTF 1991). Grazing caused greater soil compaction which further exacerbated the problem (KRBFTF 1991). NRC (2004) reports that "cattle increased in abundance during the 1870s and 1880s until by the late 1880s overgrazing became a political and ecological issue. "Government inspectors…recommended that the only solution was to provide more grass by draining wetlands and planting them with hay so that there would be less competition for a dwindling resources (NRC 2004). NRC (2004) concludes that the effects of grazing in the watershed "were probably profound but are impossible to quantify."

Agricultural issues of concern to DO include: application and runoff of nutrients, alterations in stream flow and flow timing from water impoundment and/or withdrawl, alteration of riparian vegetation and streambank stability, conversion of wetlands and reduction in nutrient sequestration, increased sedimentation due to channel destabilization and reduction in flows.

5.3.1.5 Water and Power Projects

There exist in the Klamath River basin numerous dams and diversions associated with power generation and irrigation. The histories of many of these are well documented and the effects on water yield quantified. The effects of withdrawals and diversions granted under riparian rights and groundwater withdrawals, however, are not well understood. Beginning around 1850, small dams and diversion ditches were built on smaller tributaries for use in mining and irrigation. Starting out small and temporary in nature, some became more fixed as established use persisted. As early as 1930, these more permanent diversion structures were creating barriers to fish migration (KRBFTF 1991). Among the mining dams, some were left in place after cessation of mining, creating additional barriers (KRBFTF 1991).

Beginning in the 1890s, hydroelectric power facilities were installed, first on the Shasta River, then on the Link River. California Oregon Power Company (COPCO) built Copco Number 1 Dam and Copco Number 2 Dam between 1917 and 1925. These comprise the first major hydroelectric facilities built on the mainstem of the Klamath River (KRBFTF 1991).

Prohibitions on the construction of any obstructions in the Klamath River downstream from the mouth of the Shasta River were enacted as a result of Proposition 11 passed in a statewide election of 1924 (KRBFTF 1991). This effectively ended the prospective efforts to build major hydroelectric and diversion projects in the Klamath River below the mouth of the Shasta River; though no such protections were afforded the flows above the confluence with the Shasta. In 1958, J.C. Boyle (Big Bend) Dam began operations just upstream of the California state line.

In 1962 Iron Gate Dam was built below Copco 1 and 2 at river mile 190. From this point to the ocean the river is protected as free flowing under the National Wild and Scenic Rivers System. Iron Gate Dam was originally built to attenuate flow variations caused by the operations of Copco 1 and 2 Dams. These dams were originally run as peak demand generation facilities but are now used in other ways.

Most of the Klamath River water is used in the Klamath River basin, including the use of water for crop and pasture irrigation within the Williamson River, Sprague River, Lost River, Shasta River, Scott River, and South Fork Trinity River. Facilities built to support consumptive uses in California include the U.S. Bureau of Reclamation Klamath Project (construction began in 1906, first water delivered in 1907) and Lake Shastina (created by the construction of Dwinnell Dam on the Shasta River in 1928). A total of 240,412 acres of irrigable lands, including 235,667 acres of farmland, and 4,745 acres of residential, commercial, and industrial lands, are served by Klamath Project infrastructure.

In addition to in-basin use; however, there are also diversions out of the basin maintained for agriculture and power generation: The Lewiston and Trinity Dams were completed in 1964 on the Trinity River to enable a significant transfer of flow out of the Klamath-Trinity watershed and into the Sacramento River system. An additional, smaller, out-of-basin diversion occurs from the upper tributaries in the Jenny Creek watershed in Oregon and into the Rogue River watershed in Oregon.

The pattern of water use is nearly the opposite of the pattern in drainage density and water yield. That is, the majority of the diversions in the basin are upstream of Seiad Valley where the least amount of the water is produced. As demonstrated by Figure 5.1, some of the effects of this pattern of water use are to:

- Move the timing of the peak spring flows from mid-April to mid-March;
- Make steeper the decline in the spring hydrograph, thus reducing flows by roughly 30-45% in June and July and 20-25% in May and August;
- Lower the minimum summer flows; and
- Move the timing of the minimum summer flow from mid-September to mid-August.

The estimated unimpaired flows represented in Figure 5.1 illustrate the magnitude and pattern of flows that would be expected with natural flows in the Scott and Shasta Rivers and without diversions upstream of Keno, Oregon. This unimpaired data; however, should be viewed with caution because the estimated unimpaired flows are based on the estimated median monthly unimpaired flows at Keno, as reported by the United States Bureau of Reclamation [USBR] (2005), whereas the estimated natural Scott and Shasta

River flows are reported by the USGS (2006) as monthly means. Although the two types of data sets use different metrics, the data are useful for general comparison purposes.

Altering the shape of the hydrograph through anthropogenic manipulation simultaneously alters the seasonal pattern of DO availability. For example, lower flows from April to September likely result in lower DO concentrations by increasing the rate at which the river heats during the summer months, thereby reducing the concentration of DO at saturation. Further, the warm and slow moving conditions behind the dams promote the excess growth of algae which simultaneously promotes wider fluctuations in DO, including much lower night concentrations than occur naturally.

<u>5.3.1.6 Conceptual Model for DO</u>The USEPA's CADDIS (Causal Analysis/Diagnostic Decision Information System) has produced a conceptual model for dissolved oxygen depicting the potential linkages between and among various environmental and anthropogenic factors.

As depicted in Figure 5-2, the causal pathways potentially resulting in DO impairment include: 1) channel alteration; 2) land cover alteration; 3) water impoundment; and, 4) chemical, organic matter, and nutrient loading. Increased stream temperatures, increased ionic strength, and/or increased sediment loading are interacting stressors that can further exacerbate DO impairment. The biotic responses of concern include changes in behavior, increased mortality, impairment of invertebrate assemblages, impairment of fish assemblages, and other biological impairments. Increased susceptibility to disease, decreased growth, and decreased fecundity are also biotic responses of concern, though not specifically indicated in this model.

The following is USEPA's written explanation of the conceptual model:

> "Certain human activities, such as agricultural, residential, and industrial practices, can contribute to DO depletion (or, less frequently, DO supersaturation), and subsequent biological impairment. These practices may directly introduce chemical contaminants, organic loading, and nutrients to streams, via point and non-point sources such as wastewater treatment plant effluents, fertilizers, animal wastes, landfills, and septic systems. Increases in these substances can increase chemical and biochemical oxygen demand, most notably due to increased respiration of plants and especially microbes.
>
> Physical alteration of the stream channel, through impoundments or channel alterations, can contribute to low DO concentrations in several ways. For example, an impoundment downstream of a location will slow water velocities and increase water depths, which will tend to reduce turbulence and lower incorporation of oxygen into the water column via aeration, as well as reduce diffusion of oxygen from the atmosphere. Channel incision also reduces oxygen diffusion due to decreases in surface-to-volume ratio with increasing stream depth. An impoundment upstream of a location (upper far right of figure 4-4) may reduce DO levels if downstream water releases come from deeper, oxygen-depleted waters of the reservoir (i.e., if they are hypolimnetic), but may increase DO levels if discharges are highly turbulent; whether DO levels increase or decrease will depend on impoundment size and type of release.
>
> Land cover alterations also may reduce stream DO levels by altering in-stream physical characteristics. For example, decreases in riparian vegetation often associated with these activities can reduce large woody debris inputs to the channel, reducing turbulence and aeration; homogenization of stream substrates can have similar effects. In addition these alterations may increase delivery of chemical contaminants, organic material, and nutrients to streams with surface runoff.
>
> In addition to these processes discussed above, DO concentrations are closely linked to several other stressors…Nutrient enrichment stimulates oxygen-generating (photosynthesis) and oxygen-depleting (respiration) processes. DO levels also are affected by water temperature, ionic strength, and dissolved solids; oxygen solubility decreases as these parameters increase, reducing the amount of available DO in the water. Increased bedded sediment can decrease interstitial flow, reducing oxygen availability for sediment-dwelling organisms, and decreases in water velocity can lower oxygen delivery rates.
>
> DO concentrations directly impact abiotic and biotic stream environments. Low DO…affects the oxidation and reduction (redox) reactions which determine the

bioavailability of many inorganic compounds, as well as biologically important materials such as nitrogen and sulfur. For example, lower redox potential (↓ Eh) may decrease the release of precipitated metals, which actually may benefit organisms by reducing bioavailability; however, it also may increase the release of precipitated phosphates, encouraging the proliferation of nitrogen-fixing cyanobacteria and potentially altering food resources for fish and invertebrate assemblages.

The most direct effect of low DO is respiratory distress in biota, which may be exacerbated by relatively rapid fluctuations in available DO. During periods of low DO, some species may increase movement to enhance ventilation across gill structures, attempt to gulp air from the surface, or gather around photosynthesizing plants. Respiratory stress can cause low DO-sensitive taxa [e.g., EPT taxa, or Ephemeroptera (mayflies), Plecoptera (stoneflies), and Trichoptera (caddis flies), and salmonid fishes] to decrease; often these taxa are considered indicators of good water quality. Decreases in low DO-sensitive life stages also are potential indicators. Conversely, more tolerant organisms (e.g., cyprinids, amphipods, and chironomids with hemoglobin) and life stages may increase. Increased populations of plant-breathers (e.g., insects that can obtain air from plants, such as certain beetle larvae) and air-breathers (e.g., insects that can carry air bubbles with them underwater) also may be observed. If DO depletion is significant enough, widespread fish kills may occur.

Although biological impairments related to DO usually result from insufficient DO levels, too much DO, or supersaturation, also may pose a problem in certain situations. This supersaturation may result from extremely high levels of oxygen-generating photosynthesis, or from extremely high turbulence and aeration downstream of impoundments. Ultimately, these rapid or large increases in DO may affect organisms by contributing to stressful fluctuations in DO levels, altering redox potentials and bioavailability of potentially toxic substances (e.g., metals), or leading to gas bubble disease (a condition indicated by gas bubbles forming under skin and around eyes) (CADDIS 2007)."

With respect to the kind of activities generally found in the North Coast Region, the conceptual model highlights the importance of evaluating and controlling anthropogenic inputs of chemicals, nutrients, and organic rich wastes. But, it also highlights the importance of evaluating and managing such disturbances as:

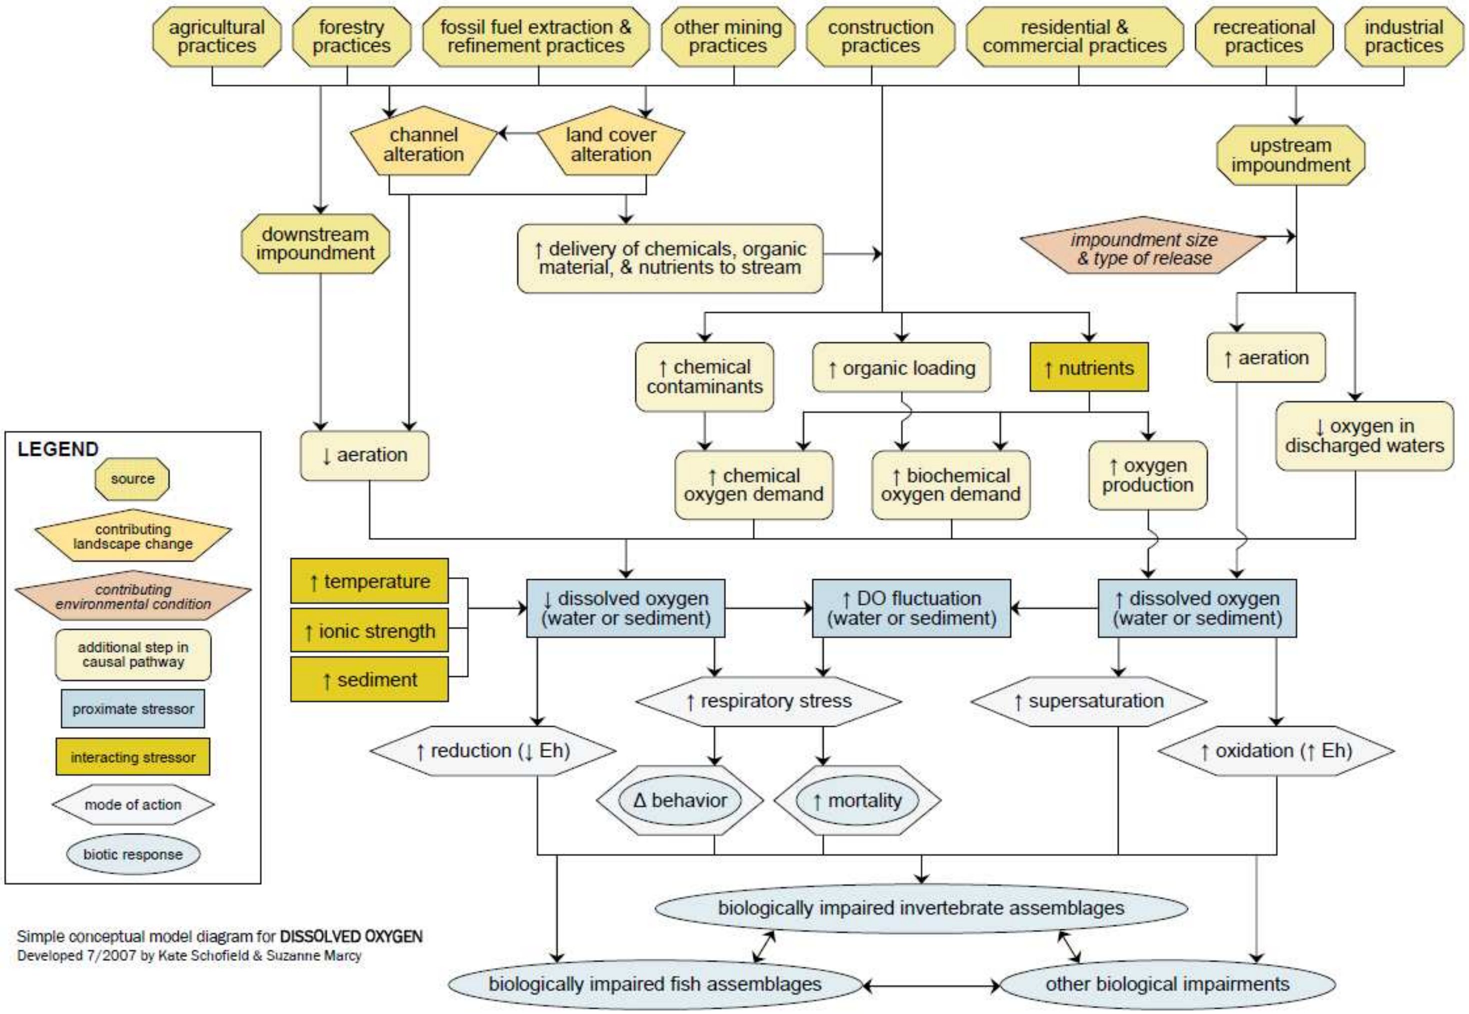
- ✓ Anthropogenic alteration to the natural pattern and range of flows, including stormwater management, groundwater protection, and control of water impoundment and withdrawal;
- ✓ Anthropogenic sources of erosion and sediment delivery;
- ✓ Anthropogenic loss of channel forming materials (e.g., large woody debris);
- ✓ Alteration of the stream channel, such as through gravel mining;
- ✓ Disturbance to wetlands, the flood plain and riparian zone;
- ✓ Anthropogenic sources of nutrients, organic matter, warm water and their delivery to a waterbody, including the discharge of agricultural return flows; and,

- ✓ Threat of loss or alteration (e.g., reduction in flow or increase in temperature) of cold water springs.

Many of these listed disturbances have been impacting the DO conditions of the Klamath River for many decades.

THIS SPACE INTENTIONALLY LEFT BLANK

Figure 5-2 CADDIS Conceptual Model for DO



5.3.1.7 Summary

USEPA's CADDIS generic conceptual model depicts the effects on DO expected from activities such as agriculture, forestry, and mining. Effects include channel alteration, watershed land cover alteration, riparian land cover alteration, and impoundments, flow alteration, and discharges of sediment and nutrients. These can lead to a decrease in water velocity, decrease in turbulence, increase in substrate homogenization, increase in organic loading, and increase in nutrients. Secondary results can include an increase in DO fluctuation, decreases in water column and intergravel DO, and decreases in interstitial flow.

A review of the landuse history of the Klamath River basin indicates that numerous, large scale alterations to the landscape from the 1850s through the 1950s have dramatically changed the aquatic ecology. Such landscape alterations are at least partially responsible for the loss and threatened loss of aquatic species in the basin, as described by NRC (2004). Landuse activities such as mining, timber harvest, agriculture, and the development of water and power have had profound effects on water quality, including:

1. Loss of wetland habitat, including nutrient sequestration and flow moderation;
2. Reduction in summer flows and altering of the pattern of flows;
3. Acceleration of surface erosion and increase in peak flows;
4. Elevation of summer water temperatures;
5. Reduction in channel integrity
6. Increase in algae production

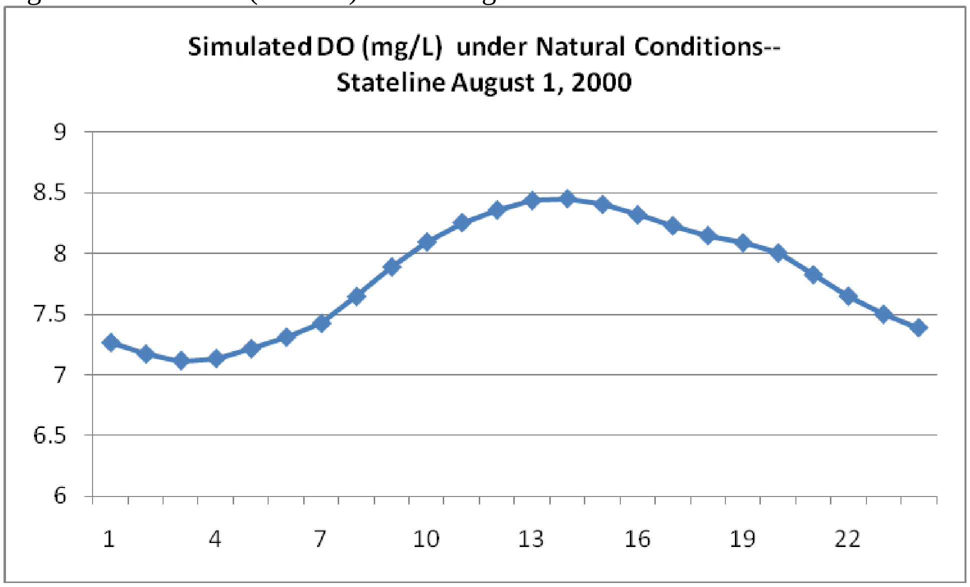
Staff concludes that the landuse history of the Klamath River basin is such that DO conditions in the basin have undoubtedly been altered as a result of them. DO data collected during the 1950s and 1960s most certainly reflect the alteration in water quality resulting from 100 years of landscape manipulation.

5.3.2 Existing SSOs for DO and diel DO fluctuation

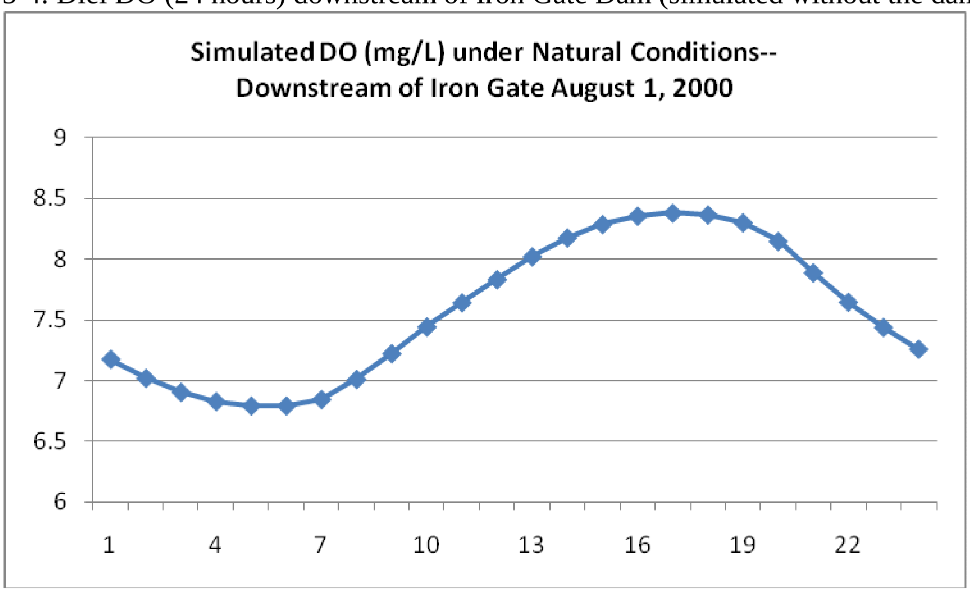
The existing SSOs for DO are contained in Table 3-1 of the Basin Plan and are designed to reflect background conditions as measured in the 1950s and 1960s. The data used to establish these background conditions were collected by a range of partners including federal, state, and local agencies. The Department of Water Resources published the data in annual bulletins beginning with data from 1951. Generally, the data are monthly grab samples that were collected during day light hours and analyzed in the field using the Winkler titration method. The sampling of this period represented an enormous effort, providing results with great statistical power. But, in addition to being collected during a period in which land uses affected water quality, the data were also limited by the fact that they only represented day time conditions.

As discussed in Chapter 4.0 of this Staff Report, the photosynthesis of aquatic plants, algae, and cyanobacteria has a profound effect on the pattern and range of diel DO fluctuation. Photosynthesis has the effect of increasing DO concentrations over the course of the day as plants actively respire oxygen. After reaching a peak in the late afternoon, DO concentrations then decrease through the night until hitting a low in the hours of the early morning. This pattern is apparent in Klamath River as shown in Figures 5-3 and 5-4. These figures depict a simulation of diel DO concentrations

Figure 5-3: Diel DO (24 hour) at the Oregon-California Stateline



5-4: Diel DO (24 hours) downstream of Iron Gate Dam (simulated without the dams)



under natural conditions at the Oregon-California stateline and downstream of Iron Gate Dam (though simulated without the dam) during the summer. The phosphorus-rich volcanic geology and organic matter and nutrients produced and stored in the wetlands of the upper basin naturally feed episodic algae blooms downstream in the Klamath River mainstem leading to diel fluctuations in DO, particularly during the summer months. These natural conditions originate in the reaches downstream of Upper Klamath Lake in Oregon. Under natural conditions, they dissipate slowly as the river heads downslope. Under existing conditions, though, the fluctuation of DO is exacerbated and perpetuated further downstream by impoundments, agricultural return flows, water diversions, reduction in stream bank stability, reduction in stream side shade, and increase in sediment delivery—conditions which were present when the SSOs for DO were first established.

The SSOs for DO contained in Table 3-1 of the Basin Plan are given as absolute minima (7.0 mg/L upstream of Iron Gate Dam and 8.0 mg/L downstream of Iron Gate Dam) and an annual mean of the monthly means (10 mg/L). Because the absolute minima are developed from grab sample data collected during normal working hours in the 1950s and 1960s, they capture only a moment in time and only from a portion of the diel curve. In particular, the actual minimum concentration, typically observed in the early morning hours, is not represented in the dataset from which the existing SSOs for DO were developed. Further, the dataset from which the existing SSOs for DO were developed includes measurements representing supersatured DO conditions which periodically occur during the late afternoon as a result of elevated photosynthetic activity.

With the development of the existing SSOs for DO in 1975, compliance with the SSOs has been measured by collecting grab samples during normal working hours and performing a Winkler titration in the field. As such, compliance monitoring compared reasonably well to the existing daily minimum SSOs. At issue; however, is how to use the existing SSOs when compliance data is collected using a Hydrolab DataSonde data logger (DataSonde).

A DataSonde measures the current resulting from the electrochemical reduction of oxygen diffusing through a selective membrane (HACH 2008a). It is capable of collecting and storing data at intervals (every 15 minutes, for example) over several days. Thus, one is able to record the entire diel DO curve at a given location, identifying, among other things, the actual daily minimum. The existing SSOs for DO do not lend themselves for comparison to 24 hour DO datasets of this kind. Summers and Engle (1993), as cited by Kamer and Stein (2003), found that single, daytime instantaneous measures of DO detected hypoxia[2] only 20% of the time that it was known to occur based on 31 days of continuous sampling in the Gulf of Mexico. While this statistic is unlikely to apply to freshwater streams in the North Coast, it nonetheless illustrates the point that minimum objectives based on data collected during the day can not reasonably represent true daily minimums which are more typically experienced at night.

DataSondes are now widely used in the Klamath Basin for monitoring. The DataSondes sometimes suffer from calibration drift and biofouling of the membrane when the device is deployed for multiple days. Quality assurance procedures are critical to ensuring accurate data collection. The availability of Luminescent Dissolved Oxygen technology may reduce the issues of biofouling; however, the use of this new technology is not yet widespread. But, it is expected to replace the earlier membrane-based probes in the coming year (Fadness 2008). Luminescent Dissolved Oxygen technology has a thicker membrane than its predecessor and is thus less susceptible to biofouling. It is also reported to have the ability to hold a calibration without drift (HACH 2008b). Data can be collected with this device at intervals over a 7-day period (or longer), thus allowing for assessment not only of the daily minimum, but daily and weekly

---

[2] Hypoxia means "low oxygen." In estuaries, lakes, and coastal waters low oxygen usually means a concentration of less than 2 parts per million. In many cases hypoxic waters do not have enough oxygen to support fish and other aquatic animals.

averages, as well. In all other regards, the data collected by Luminescent Dissolved Oxygen technology is comparable to that collected by datasondes (Fadness 2009).

5.4 *Rationale for Revising the SSOs for DO in the Klamath River Mainstem*

Staff has reviewed the existing SSOs for DO in the Klamath River mainstem. The following is a summary of our findings:

1. The SSOs for DO in the Klamath River mainstem are based on a statistical analysis of data collected during the 1950s and 1960s. The background conditions of the Klamath River mainstem codified by Table 3-1 of the Basin Plan are not natural conditions, but conditions modified by decades of mining, timber harvesting, agricultural irrigation and return flows, wetland conversion and other landscape alterations, hydroelectric power operations, dams, and other water withdrawls, as examples.
2. The SSOs for DO in the Klamath River mainstem are based on day time grab samples and thereby do not include the daily minima DO conditions typically expected in the pre-dawn hours of the night.
3. Continuous monitoring data collected by DataSondes are predominantly being used in the Klamath River mainstem to collect DO data and include both day time and night time DO data; this data can not be reasonably compared to the existing SSOs for DO.

Staff concludes that the SSOs for DO in the Klamath River mainstem must be updated to: a) accurately depict daily minima conditions and b) deliberately define background conditions. As they are currently set, the SSOs for DO in the Klamath River mainstem are outdated with respect to the monitoring tools currently available. And, they erroneously establish as background, conditions which very likely reflect significant anthropogenic influence. More accurate and protective SSOs for DO would reflect the actual daily minima expected during the early morning hours and would be based on natural background conditions.

CHAPTER 6.
New Site Specific Information

The Klamath River watershed has been the subject of ecological study for many years, including water quality evaluations. Most recently, the Regional Water Board has been engaged in a project to define the total maximum daily load (TMDL) of pollutants that can be discharged into the Klamath River mainstem and still meet water quality objectives. The Regional Water Board has listed the portions of the Klamath River from the Oregon-California state line to the Pacific Ocean for impairments due to elevated water temperatures, elevated nutrients, and organic enrichment/low dissolved oxygen. Further, the portion of the Klamath River watershed downstream of the Trinity River is listed for sedimentation/siltation impairment. Finally, in March 2008, the U.S. Environmental Protection Agency (USEPA) added the reach of the Klamath River that incorporates Copco 1 and 2 and Iron Gate Reservoirs to the 303(d) List for the blue-green algae toxin microcystin. Table 1.1 summarizes the waterbody-pollutant combinations for the Klamath River in California as identified on the current (2006) section 303(d) List.

Work on the Klamath River TMDLs has resulted in the development of new information regarding water quality conditions in the Klamath River mainstem. Two assessments of interest to the evaluation of the existing SSOs for DO are:

1. Assessment of the range of DO concentrations possible under 100% and 85% saturation. As described in Chapter 4.0, this assessment looks at the physical characteristics of the basin with respect to the ability of the water to hold DO in solution.
2. Assessment of DO under natural water quality conditions as simulated by a series of computer models developed to calculate the TMDLs for the Klamath River mainstem.

The discussion in Chapter 5.0 seeks to demonstrate that the existing SSOs for DO do not achieve the intended goal of establishing as the water quality objective, background conditions in the mainstem. The discussion here in Chapter 6.0 seeks to demonstrate that the existing DO objectives as contained in Table 3-1 of the Basin Plan are unachievable even under natural water quality conditions and therefore require recalculation. The computer simulation of natural water quality conditions provides model output suitable for the recalculation. The model and its output are described below. Alternative methods of recalculating the SSOs for DO are presented in Chapter 7.0.

6.1 *Assessment of 85% and 100% Saturation in the Klamath River Mainstem*

The Klamath River mainstem flows approximately 209 miles from the Oregon-California state line to the Pacific Ocean at Requa, CA. It has a maximum river elevation of 2,885 feet and summer water temperatures that exceed 23 ºC under natural conditions.

Figure 6-1: Range of DO Concentrations at 100% Saturation in the Klamath River Mainstem

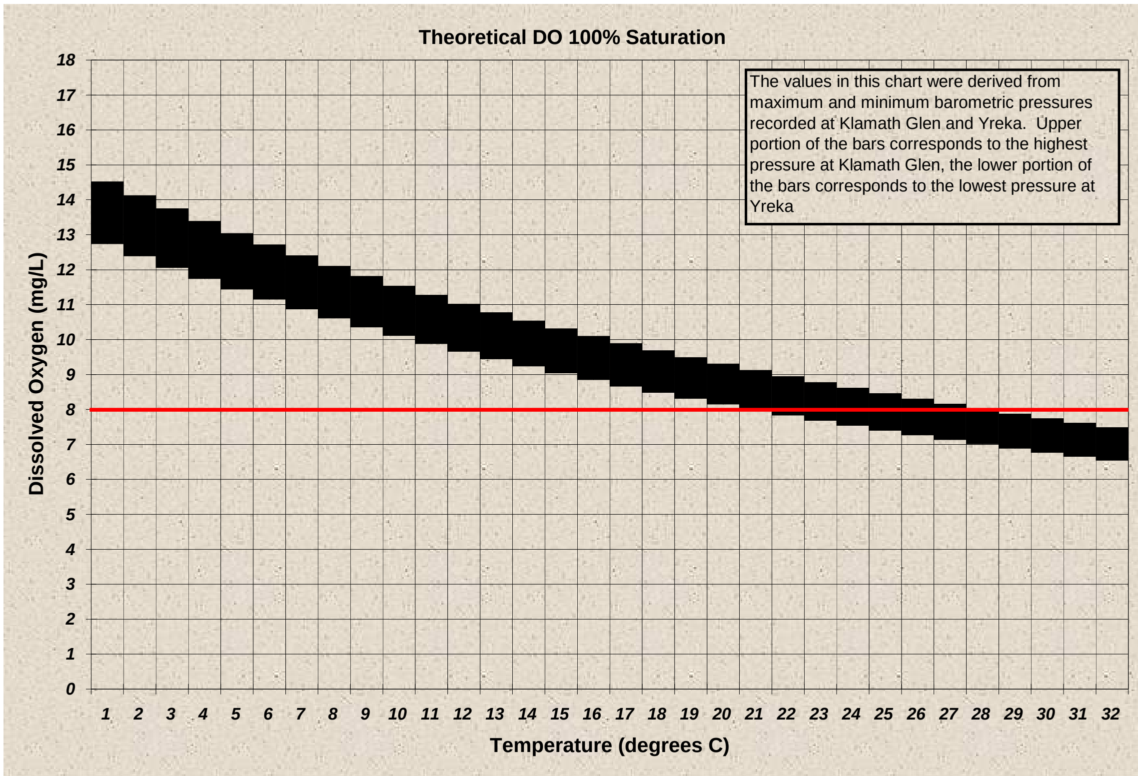


Figure 6-1 depicts the range of DO concentrations at 100% saturation estimated in the Klamath River mainstem at various temperatures. The range is defined by the elevations at two weather stations in the watershed: Yreka, CA (2,648 feet) and Klamath Glen, CA (56 feet). Both stations are within that portion of the Klamath River watershed downstream of Iron Gate Dam in which the existing SSO for DO is 8 mg/L. Figure 6.1 shows the DO concentrations that are theoretically possible when conditions of temperature, barometric pressure and salinity are in equilibrium. The figure demonstrates that during the hottest summer days, when temperatures exceed 21°C, DO concentrations can not physically meet the existing SSO for DO of 8 mg/L at all locations. This is in the absence of other moderating influences such as photosynthesis, turbulence, respiration, decomposition, and chemical oxygen demand.

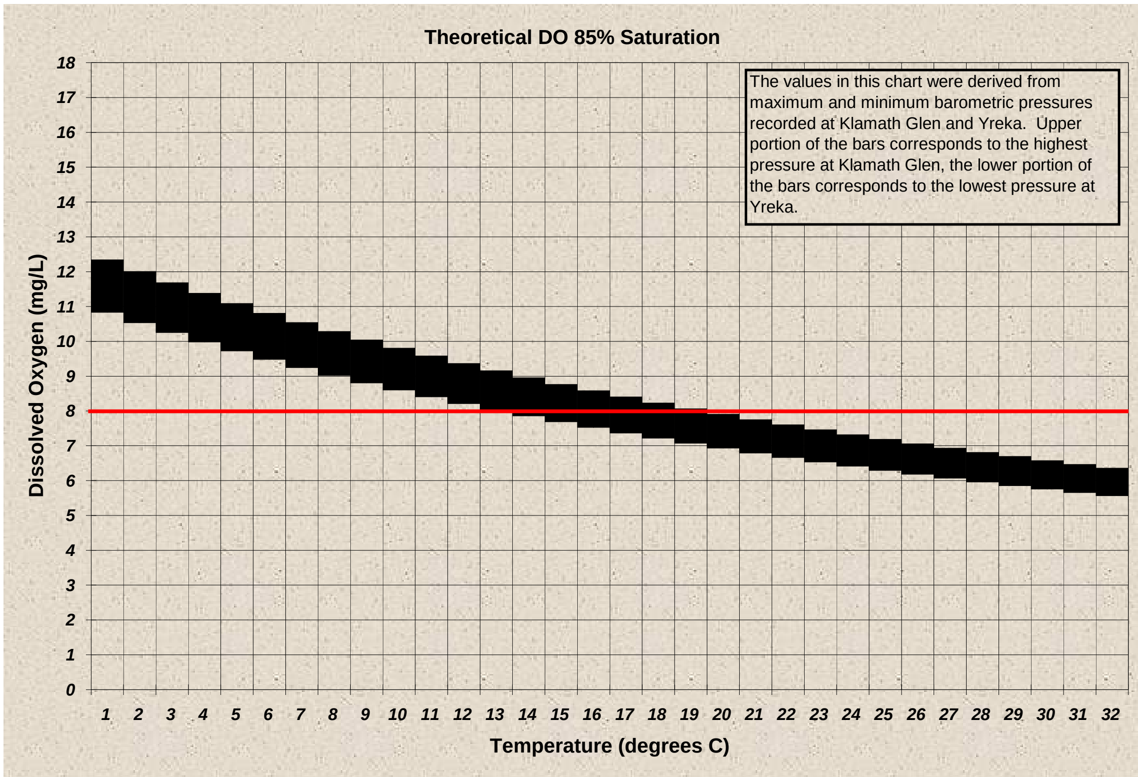
Figure 6-2 presents the range of DO concentrations at various temperatures when DO saturation is at 85%. The 85% saturation figure is chosen because it represents a reasonable range of variation from equilibrium that occurs in healthy, free-flowing streams, considering the effects of photosynthesis, turbulence, respiration, decomposition, and chemical oxygen demand. In addition, the computer models used to simulate natural water quality conditions (described in detail in Section 6.2.1 and the TMDL Staff Report) also indicate that in the Klamath River mainstem, natural DO conditions maintain a minimum of 85% saturation. At 85% saturation, then, Figure 6.2 illustrates that during even modestly warm days, when temperatures exceed 14 °C, the water column can not physically hold oxygen in solution at concentrations sufficient to meet the existing SSOs for DO of 8 mg/L at all locations.

Figure 6-2: Range of DO Concentrations at 85% Saturation in the Klamath River Mainstem



This assessment provides a basic framework for understanding the range of DO conditions that can physically occur in the Klamath River mainstem. Figures 6-1 and 6-2 do not provide a basis for recalculating SSOs for DO in the Klamath River mainstem. But, they provide further evidence that the existing SSOs for DO are unattainable at all locations at all times, even under the best possible natural conditions (i.e., 100% DO saturation) and certainly when considering the natural variation that occurs due to photosynthesis, turbulence, respiration, decomposition, and chemical oxygen demand (i.e., 85% DO saturation).

6.2 Assessment of Simulated Natural DO Conditions in the Klamath River Mainstem

Tetra Tech, Inc., under contract to USEPA and with assistance from Regional Water Board staff, and staffs at the Oregon Department of Environmental Quality (ODEQ), and USEPA Regions 9 and 10, has developed a tool for estimating the natural water quality conditions in the Klamath River mainstem. It is with this tool that Regional Water Board staff has unequivocally determined that the existing SSOs for DO are unattainable even under natural conditions and thereby must be recalculated. It is also with this tool that Regional Board staff has recalculated the SSOs for DO. The alternatives by which the

SSOs for DO can be recalculated are presented in Chapter 7.0. In this chapter, staff describes the tool and its results.

6.2.1 Description of the Model

To support TMDL development for the Klamath River system, the need for an integrated receiving water hydrodynamic and water quality modeling system was identified. A model for the Klamath River had already been developed by PacifiCorp to support studies for the Federal Energy Regulatory Commission hydropower relicensing process (PacifiCorp 2005) when this project commenced. The version of the model available in 2004 is hereafter referred to as the *PacifiCorp Model*. The Regional Water Board, ODEQ, and USEPA determined that this existing *PacifiCorp Model* would provide the optimal basis, after making some enhancements, for TMDL model development. The *PacifiCorp Model* used hydrodynamic and water quality models with a proven track record in the environmental arena and had already been reviewed by stakeholders in the Klamath River watershed. Additionally, it allowed direct comparison to ODEQ, Regional Water Board and tribal water quality criteria.

The original *PacifiCorp Model* consisted of Resource Management Associates (RMA) RMA-2 and RMA-11 models and the U.S. Army Corps of Engineers' CE-QUAL-W2 model. The RMA-2 and RMA-11 models were applied to riverine segments including Link River, Keno Dam to J.C. Boyle Reservoir, Bypass/Full Flow Reach, and Iron Gate Dam to Turwar (See Figures 6-3 and 6-4). RMA-2 simulates hydrodynamics while RMA-11 represents water quality processes. The CE-QUAL-W2 model was applied to reservoir segments including Lake Ewauna-Keno Dam, J.C. Boyle Reservoir, Copco Reservoir, and Iron Gate Reservoir (see Figure 6-3). CE-QUAL-W2 is a two-dimensional, longitudinal/vertical (laterally averaged), hydrodynamic and water quality model (Cole et al. 2003). For the purposes of TMDL development, enhancements to the RMA/CE-QUAL-W2 portions of the *PacifiCorp model* were made in the following areas: BOD/organic matter (OM) unification, algae representation in Lake Ewauna, Monod-type continuous Sediment Oxygen Demand (SOD) and OM decay, pH simulation in RMA, OM-dependent light extinction simulation in RMA, re-aeration formulations, and dynamic OM partitioning. The Klamath TMDL staff report and appendices provide more detail on this subject.

Since the estuarine portion of the Klamath River (Turwar to the Pacific Ocean) was not included in the original *PacifiCorp Model*, it was updated to include an estuarine model. USEPA's Environmental Fluid Dynamics Code (EFDC), which is a 3-D hydrodynamic and water quality model, was selected to model the complex estuarine environment. The hydrodynamics and water quality within the estuary are spatially and temporally variable and are greatly influenced by time of year, river flow, tidal cycle, and location of the estuary mouth (which changes due to sand bar movement). Additionally, transect temperature and salinity data in the lower estuary show significant lateral variability, as does DO to a lesser extent.

THIS SPACE INTENTIONALLY LEFT BLANK

EFDC is capable of predicting hydrodynamics, nutrient cycles, DO, temperature, and other parameters and processes pertinent to the TMDL development effort for the estuarine section. It is capable of representing the highly variable flow and water quality conditions within years and between years for the estuary. As with RMA-2, RMA-11, and CE-QUAL-W2, EFDC has a proven record in the environmental arena and model results can be directly compared to ODEQ, Regional Water Board and tribal water quality criteria. It is an USEPA-endorsed and supported model and available freely in the public domain.

Table 6-1: Models applied to each Klamath River and estuary segment

Modeling Segment #	Modeling Segment	Segment Type	Model(s)	Dimensions
1	Link River	River	RMA-2/RMA-11	1-D
2	Lake Ewauna-Keno Dam	Reservoir	CE-QUAL-W2	2-D
3	Keno Dam to J.C. Boyle Reservoir	River	RMA-2/RMA-11	1-D
4	J.C. Boyle Reservoir	Reservoir	CE-QUAL-W2	2-D
5	Bypass/Full Flow Reach	River	RMA-2/RMA-11	1-D
6	Copco Reservoir	Reservoir	CE-QUAL-W2	2-D
7	Iron Gate Reservoir	Reservoir	CE-QUAL-W2	2-D
8	Iron Gate Dam to Turwar	River	RMA-2/RMA-11	1-D
9	Turwar to Pacific Ocean	Estuary	EFDC	3-D

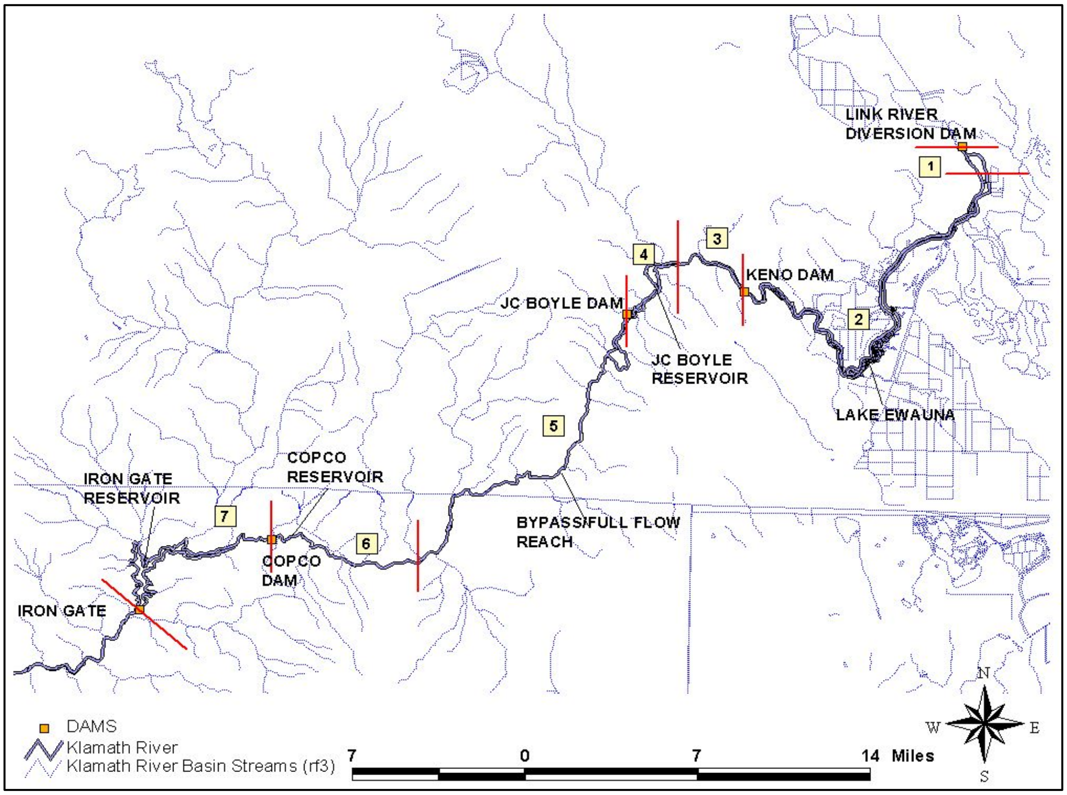
The combination of the *PacifiCorp Model* (RMA and CE-QUAL-W2), with enhancements, and the EFDC model for the estuary resulted in the *Klamath TMDL Model* used for TMDL development. Table 6-1 identifies the modeling elements applied to each river segment. Within each reservoir segment, the model further divides the segment into layers 0.61 to 1.0 meter in depth and 37 to 714 meters in length. Within each river segment, the model further divides the segment into nodes of 75 to 300 meters in length (assumed to be homogeneous in the vertical direction). These nine segments are depicted graphically in Figures 6-3 and 6-4. Linkages between the different modeling segments are made by transferring time-variable flow and water quality from one model to the next (e.g., output from the Link River model became input for the Lake Ewauna-Keno Dam model).

To run the *Klamath TMDL model*, external forcing factors known as boundary conditions must be specified for the system. These forcing factors are a critical component in the modeling process and have direct implications on the quality of the model's predictions; and include: upstream inflow boundary conditions, tributary inflow boundary conditions, withdrawal boundary conditions, downstream boundary conditions, and surface boundary conditions.

As summarized above, the upstream boundary condition is replicated from the downstream boundary condition produced by the model in the segment above. The surface boundary conditions are determine by meteorological or atmospheric conditions and include air temperature, dew point temperature, wind speed, wind direction, and cloud cover. Data obtained from the U.S. Bureau of Reclamation's (USBR) AgriMet

Station (KFLO) near Klamath Falls were used to represent the boundary conditions from J.C. Boyle Dam to Seiad Valley. Data from Brazie Ranch meteorological station represent the surface boundary conditions from Seiad Valley to Turwar. The weather data from Hoopa and Somes Bay were used to represent the meteorological boundary conditions for those areas. Data from the Arcata Eureka Airport were applied to the estuarine portion of the Klamath River (Turwar to the Pacific Ocean). In addition, tributary and withdrawal boundary conditions are also modeled, including: major springs, tributary streams, stormwater outfall, point source discharges, irrigation withdrawals, agricultural return flows, etc.

Figure 6-3: Model segments in Oregon and Northern California

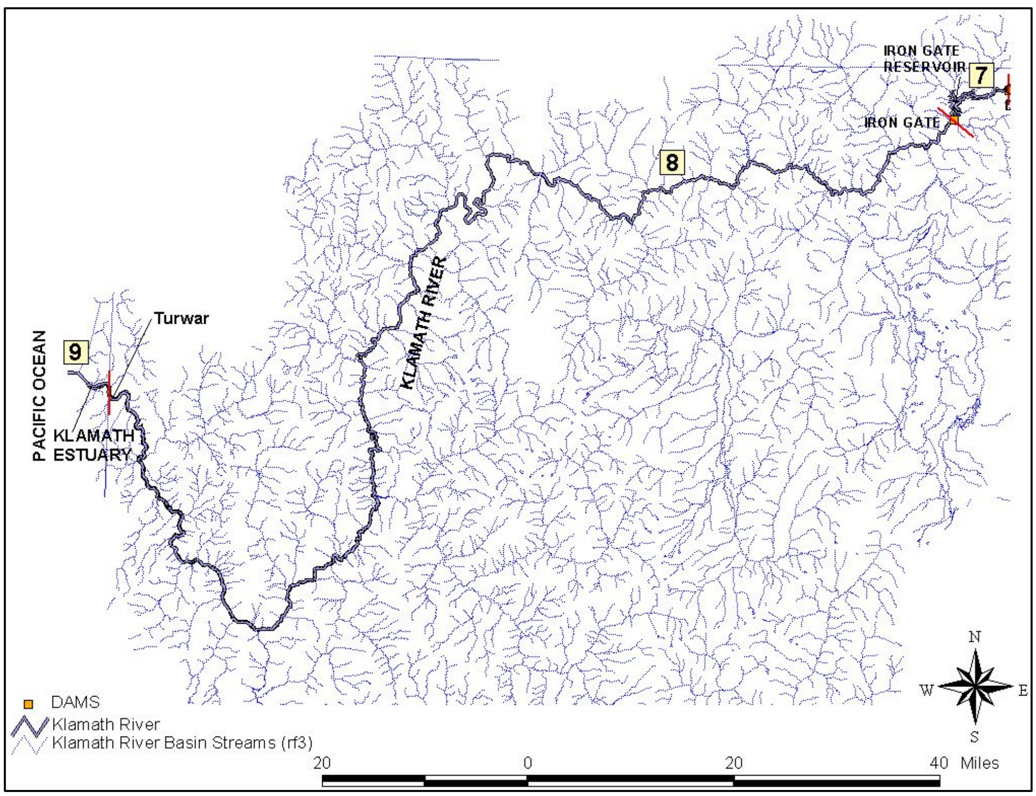


The model was calibrated and validated to known water quality conditions in the Klamath River mainstem. It was then run to simulate natural water quality conditions (referred to as the Natural Conditions *Klamath TMDL model run* and identified in model documentation as T1BSR) and calculate appropriate TMDLs for the listed parameters. These became the basis for the draft TMDL Staff Report and draft DO Staff Report submitted for public review with the comment period ending in September 2009.

Prior to the Regional Water Board's release of the Public Review Draft TMDL Staff Report, the development team initiated various peer reviews related to the *Klamath TMDL model*. In 2005, peer reviews of the *Klamath TMDL model* were completed by Dr. Scott Wells (developer of CE-QUAL-W2 model), Portland State University; Brown

& Caldwell (under contract to the City of Klamath Falls, Oregon); and the U.S. Bureau of Reclamation (Technical Services Center – Environmental Applications and Research Group, Denver). Peer review materials were also sent to Dr. Michael Deas of Watercourse Engineering, Inc. as developer of the *PacifiCorp Model* and technical consultant to PacifiCorp; but, neither Dr. Deas nor PacifiCorp submitted comments at that time. Between 2005 and 2007 the TMDL development team and Tetra Tech, Inc. had informal consultation with Dr. Deas, on behalf of PacifiCorp, regarding the *Klamath TMDL model*. Then, in accordance with Section 57004 of the California Heath and Safety Code, in 2009 the Regional Water Board's draft Staff Report was reviewed by four external scientific peer reviewers. The model has been developed and refined through a process of expert consultation, calibration, validation, and peer review. Finally, the TMDL Staff Report, including details regarding model development were released for public review during two comment periods beginning in June 2009 and

Figure 6-4: Model segments in California



December 2009. These rounds of peer and public review have resulted in additional refinements to the model. The results discussed below reflect the most recent model refinements (November 5, 2009), including refinements to barometric pressure made as a result of consultation with representatives of the Hoopa Valley Tribe (and others). Those refinements are represented for the reach of the Klamath River from Iron Gate Dam to

Turwar and are based on a run of the model (T1BSR) for that reach conducted February 2, 2010.

6.2.2 Description of Mainstem Reaches in California
The Klamath River mainstem is divided into three reaches for the purposes of evaluation and modeling. Reach 1 includes that portion of the mainstem from the Stateline to Iron Gate Dam. Iron Gate Dam represents the upper limit of anadromy in the mainstem. Reach 2 includes that portion of the mainstem from Iron Gate Dam to Turwar, downstream of the Klamath's confluence with the Trinity River. And, the third reach encompasses the whole estuary from Turwar to the Pacific Ocean.

6.2.2.1 Stateline to Iron Gate Dam (Reach 1)
The region from the Oregon-California border to Iron Gate Dam currently includes both Copco and Iron Gate dams; though prior to 1917 it was free flowing. The *Klamath TMDL model* evaluates this reach of the river in three model segments: 1) Segment 5 (Bypass/Full Flow Reach), Segment 6 (Copco Reservoir), and Segment 7 (Iron Gate Reservoir); though, Segment 5 originates in Oregon before crossing into California.

The T1BSR run of the *Klamath TMDL model* configures the Klamath River mainstem as a free flowing river from it's headwaters at Upper Klamath Lake (UKL) to the Pacific Ocean. As such, in the Stateline to Iron Gate Dam reach, both Segments 6 and 7 are modified to eliminate the dams. The water quality boundary conditions are defined by the UKL TMDLs at the headwaters and at the Lost River and Klamath Straits Drain, elimination of all point sources, and natural or TMDL conditions for all other tributaries. There are 3 springs in Segment 5 which are estimated to flow at 75 cubic feet per second (cfs).

6.2.2.2 Iron Gate Dam to Turwar (Reach 2)
The mainstem Klamath River from Iron Gate Dam to Turwar is a free flowing river. It is represented in the *Klamath TMDL model* by a single segment (Segment 8) and includes twenty-three tributaries. Five of the tributaries are actively gauged: Shasta River, Scott River, Salmon River, Indian Creek and Trinity River. The remaining minor tributaries are represented in the *Klamath TMDL model* as daily accretion/depletions. Water quality constituent concentrations in the tributaries for all parameters except DO are based on U.S. Fish and Wildlife Service, U.S. Bureau of Reclamation, and USEPA data. Temperature data is based on USGS-estimated temperatures for 2002. According to Tetra Tech (2009), the USGS study showed that there is no significant inter-year variation in the predicted in-stream temperature.

DO in the tributaries is estimated based on percent saturation and natural temperatures as follows: 1) 100% saturation in minor tributaries and the Trinity River and 2) 95% saturation in the Shasta, Scott and Salmon rivers.

6.2.2.3 Klamath River Estuary
The Klamath River Estuary is the lower most reach of the river and flows from Turwar to the Pacific Ocean. This reach is established as Segment 9 in the *Klamath TMDL model*.

For Segment 9, the EFDC model was used (Tetra Tech 2009), allowing for three dimensional water quality predictions. The model was calibrated using data collected in 2004 and including chlorophyll *a,* DO, PO_4, NH_4, and NO_2/NO_3. The model reproduces the observed diel fluctuation of DO in both the surface and bottom water. Since the model and observed data both show very low algae concentrations in the estuary, significant diel fluctuations of DO do not occur as a result of phytoplankton. Periphyton biomass, however, is predicted at high levels in the shallow regions of the estuary. This is likely a key contributor to diel DO fluctuation. The T1BSR run of the *Klamath TMDL model* generates simulated data for the Upper, Middle and Lower Estuary. With respect to DO, the Upper and Middle Estuary act like freshwater reaches. The Lower Estuary, however, does not.

6.2.3 Natural Watershed Characteristics

The Klamath River TMDL models were applied to characterize natural baseline water quality conditions of the Klamath River. To estimate natural conditions, several characteristics of the Klamath River watershed had to be considered, including the natural nutrient loading, limited buffering capacity, and elevated summer temperatures.

6.2.3.1 Nutrient Loading

The underlying geology in much of the Upper Klamath basin is of volcanic origin. Soils derived from this rock type are naturally high in phosphorus (Walker 2001). Through natural erosion and leaching processes these soils contribute a high background phosphorous load to Upper Klamath basin waters. In a nutrient loading study conducted by Rykbost and Charlton (2001), monitoring of several natural artesian springs in the upper Klamath basin were characterized by high levels of nitrogen and phosphorus, demonstrating the high natural background loading of nutrients. Upper Klamath Lake has long been noted for its eutrophic condition and demonstrated presence of high levels of organic matter (algae), including nitrogen fixing blue-green algae (Kann and Walker 2001). This nutrient and organic-matter rich Upper Klamath Lake water is the headwaters source of the Klamath River.

Within the Klamath Mountains Province of the mid- and lower-Klamath River, the underlying geology is not volcanic, and therefore does not tend to have the high levels of nitrogen and phosphorus characteristic of the Upper Klamath basin. Consequently, the tributaries that drain to the Klamath River within this province have considerably lower nutrient concentrations. As a result, the quality of the Klamath River generally improves as it flows from the Upper Klamath basin to the Pacific Ocean.

6.2.3.2 Buffering Capacity

Alkalinity is a measure of the ability of water to neutralize acids. In the natural environment, alkalinity comes primarily from the dissolution of carbonate rocks. Carbonate rock sources are rare in much of the Klamath basin due to its volcanic origin. As a result, the Klamath River has a relatively low alkalinity (<100 mg/L). The low alkalinity provides for a weak buffering capacity of Klamath River water. Photosynthetic activity removes carbon dioxide in the water (in the form of carbonic acid) which increases the water pH. Natural alkalinity serves as a buffer to minimize the photosynthetically induced increase in pH. In low alkalinity waters such as the Klamath River, this buffering capacity is frequently exceeded and high pH values are observed during daytime hours when photosynthesis is occurring. The large daily variation of pH observed in the Klamath River is caused by photosynthetic activity in the low alkalinity water.

6.2.3.3 Summer Temperatures
Further exacerbating the effect of the naturally productive and weakly buffered system is the presence of regionally high ambient summer air temperatures, and the resulting high heat load to the shallow and predominantly un-shaded Upper Klamath Lake. These naturally warm waters are the source of the Klamath River. In addition, the east-west aspect of much of the Klamath River also makes it prone to heating, even within the steep gorges of some reaches of the river.

6.2.3.4 Summary
In summary, the high ambient air temperatures, coupled with the high levels of biological productivity and respiration that is enhanced by the high levels of biostimulatory nutrients, yield large volumes of organic matter, seasonally high water temperatures, daily low dissolved oxygen, and high pH levels. All of these water quality conditions can be extremely stressful to many forms of aquatic life. These natural background nutrient, heat, and organic matter loads to the Klamath River underscore the very limited capacity of the river to assimilate anthropogenic pollutant sources.

6.2.4 Natural Baseline Conditions (T1BSR) Model Configuration
The natural baseline conditions scenario (T1BSR) of the *Klamath TMDL model* run simulates the Klamath River from Upper Klamath Lake to the Pacific Ocean in the absence of all dams and uses a different configuration than for the current conditions scenario. For example, the entire length of the river from Upper Klamath Lake to just upstream of the estuary is simulated using the riverine RMA model. No CE-QUAL-W2 modeling segments are included since the natural configuration includes no impoundments.

The Upper Klamath Lake (UKL) boundary is the starting point for the *Klamath TMDL model*. The UKL boundary condition for the model is derived from the Upper Klamath Lake TMDL (ODEQ 2002) which has been adopted by the State of Oregon and approved by USEPA. The median concentrations for water quality constituents and existing temperature are applied at the outlet and based on 1995 Upper Klamath Lake model output. Flow from Upper Klamath Lake is set at existing conditions, in order to maintain consistency with the existing conditions modeling scenario. Without this consistency, the TMDL team would not have been able to compare the existing conditions scenario to the natural background conditions scenario, impeding their ability to establish appropriate TMDLs for the pollutants of concern.

The flow balance for the current conditions model (when dams are present) and the reservoir operations limit the ability of the model to represent natural flows. It should be noted however, that results for two model runs: one that uses current conditions flows from Upper Klamath Lake and one that uses estimated flows from a natural regime (USBR 2005), were compared and not found to be substantially different.

Permitted point sources are removed from the model (i.e., both flow and water quality contributions were removed). The Lost River Diversion Channel (LRDC) and Klamath Straits Drain (KSD) are represented using current conditions flow however, their water quality and temperature are set to be the same as the Upper Klamath Lake (TMDL compliant water quality conditions). Current flow is again used to maintain consistency with the current conditions scenario in order to calculate pollutant load reductions, and associated TMDL load allocations, necessary to meet water quality standards. For major springs and tributaries to the Klamath River in California, natural and TMDL conditions are represented, depending on the tributary.

In summary, the key components of the natural conditions baseline scenario are:

- Representation of the river with no dams;
- The Upper Klamath Lake (UKL) boundary condition based on existing UKL TMDL compliant conditions;
- Absence of all point sources;
- LRDC and KSD represented using current conditions flow, but water quality set equal to UKL TMDL compliant conditions; and
- California major springs and tributaries flow and water quality conditions set at estimated natural and existing TMDL compliant conditions.

The model simulation was run for the year 2000.

6.2.4.1 Barometric Pressure

As described in Chapter 4.0, barometric pressure plays an important role in determining the concentration of DO that a body of water is capable of holding in solution. The model was originally configured using barometric pressure data at three locations. Data from KFLO near Klamath Falls was used to define the barometric pressure from J.C. Boyle Dam to Seiad Valley. Data from Brazie Ranch was used to define the barometric pressure from Seiad Valley to Turwar and, data from the Arcata Eureka Airport was used to define the barometric pressure in the estuary. These data provide an accurate depiction of barometric pressure for those locations on the river closest to the stations from which the data were collected. However, the accuracy is reduced at locations as one moves farther from the station of origin. In addition, there is a large jump in estimated barometric pressure between locations where a switch is made from one dataset to the next. This results in inaccuracies in the associated estimates of DO at the downstream location.

To resolve this problem, Tetra Tech, Inc. with guidance from Regional Water Board staff and as a result of consultation with representatives of the Hoopa Valley Tribe (and others), corrected the barometric pressure data as collected at the given meteorological stations. The barometric pressure data was refined to reflect elevations at the locations downstream of Iron Gate Dam to Turwar, correcting for elevation at each modeling node. A single barometric pressure was applied to all locations above Iron Gate Dam. A single barometric pressure was also applied to all locations in the estuary, downstream of Turwar..

There still is to be expected a minor artifact relating to the barometric pressure jumps, particularly at the first location represented by an elevation correction. But, the node dependent barometric pressure assignment in Reach 2 serves to smooth out any jumps considerably. As a result of the correction to barometric pressure, new data simulating DO under natural conditions was made available February 2, 2010 and is reflected in this updated Staff Report.

6.2.4.2 Percent Saturation

Percent DO saturation is one of the surface boundary conditions requiring assignment for individual tributaries throughout the watershed. Regional Water Board staff evaluated historic data and applied best professional judgment to make the following percent saturation assignments:

1. For minor tributaries, 100% saturation
2. For the Shasta, Scott and Salmon Rivers, 95% saturation
3. For the Trinity River, 100% saturation

These are the percent saturation assignments made in the most recent (December 2009) run of the *Klamath TMDL model*. They vary only slightly from previous runs of the model.

6.2.5 Discussion of Modeled DO Results

The results of T1BSR, the natural conditions baseline model run of the *Klamath TMDL model*, simulate DO concentrations and saturation values at selected nodes for every hour of the modeled year. Staff presents the modeling results in a number of different ways. First, staff presents the daily minimum and monthly average DO concentrations resulting from the T1BSR natural conditions model run. Second, staff compares these model outputs to the existing SSOs for DO. Third, staff compares the T1BSR model output to the life stage requirements of salmonids as presented in Chapter 3.0. Finally, staff evaluates percent saturation model output.

6.2.5.1 DO Output for the T1BSR Natural Conditions Model Run

Monthly data output for several stations down the length of the Klamath River mainstem from Stateline to the lower estuary have been developed.

These data indicate that in the Klamath River mainstem, when considering *24-hour* data, the *natural background* baseline DO concentrations are as follows:

Upstream of Iron Gate Dam	6.9 mg/L as a daily minimum
	9.4 mg/L as an annual median of the monthly means
Downstream of Iron Gate Dam	6.9 mg/L as a daily minimum
	9.4 mg/L as an annual median of the monthly means
Bottom of the Lower Estuary	7.0 as a daily minimum
	8.8 mg/L as an annual median of the monthly means

6.2.5.2 Comparison of Natural Conditions to Existing SSOs for DO

As described in Chapter 5.0, the existing SSOs for DO were developed with the intention of establishing background conditions as the water quality objective, keeping in mind the prohibition against point source discharge in the basin. By comparing the simulated natural conditions with the existing SSOs for DO, staff is able to determine how well the existing SSOs for DO represent background conditions, as intended. With respect to this comparison, Table 6-2 illustrates a number of important points.

As shown in Tables 6-2 and 6.3, neither the existing daily minimum nor the monthly mean requirements as contained in Table 3-1 of the Basin Plan reasonably represent that which is achievable under natural conditions as simulated by the T1BSR run of the *Klamath TMDL model*. There are a number of locations where the simulated DO concentrations meet neither the daily minimum requirement (7.0 mg/L above Iron Gate Dam and 8.0 mg/L below Iron Gate Dam) nor the monthly mean requirement (10.0 mg/L) and the months of violation range from May to September for the daily minima and March to October for the monthly mean. Violations of the daily minima occur from Iron Gate Dam to the Pacific Ocean. Violations of the monthly mean requirement occurs from the Stateline to Seiad and in the lower estuary.

The lower estuary does not meet the daily minimum requirement for 4 months of the year at the surface and 6 months of the year at depth. The monthly mean criteria is met at the surface 50% of the year as required. But , it is only met 25% of the year at depth. As shown even more dramatically in Section 6.2.5.4, the lower estuary, with its tidal influence, presents a special case with respect to DO and deserves separate consideration and treatment. Chapter 7.0 (Alternatives) offers some suggestions to address the unique DO conditions present in the lower estuary.

6.2.5.3 Comparison of Natural Conditions to Salmonid Life Stage Requirements

A fundamental element of recalculating appropriate SSOs for DO in the mainstem Klamath is determining the degree to which beneficial uses are protected given the natural biochemical processes of the Klamath River (under natural conditions). As described in Chapter 3.0, salmonid cold water habitat, including spawning habitat, is identified as the most sensitive beneficial uses of the Klamath River with respect to DO and stands as a surrogate for the other beneficial uses for which DO is important. Chapter 3.0 identifies the DO concentrations demonstrated by laboratory studies as necessary to ensure little to no population impairment. Staff have compared the DO output from the T1BSR (natural conditions) run of the *Klamath TMDL model* to these life cycle requirements as well as National DO Criteria.

Of the range of DO conditions identified in Chapter 3.0 appropriate for the protection of salmonids, staff has chosen for comparison purposes daily minima and monthly averages that reflect USEPA (1986) guidance on DO criteria development to ensure "no production impairment" or "slight production impairment". Specifically, staff has taken heed of USEPA's (1986) recommendation that

> "if slight production impairment or a small but indefinable risk of moderate production impairment is unacceptable, then continuous exposure conditions should use the no production impairment values as means and the slight production impairment values as minima."

This approach results in DO criteria for the protection of salmonid life stages as follows:

- 6.0 mg/L as a daily minimum to protect other life stages,
- 8.0 mg/L as a 30-day average to protect other life stages,
- 9.0 mg/L as a daily minimum to protect early life stages, assuming a 3 mg/L difference between the intergravel DO and water column DO, and
- 11.0 mg/L as a 30-day average to protect early life stages, assuming a 3 mg/L difference between the intergravel DO and water column DO.

In addition, staff began its assessment by presuming that the period in which salmonids spawn in the Klamath River, including early development and fry emergence, is the same as the period identified for the Trinity River: September 15 through June 4.

A comparison of these criteria to Tables 6.2 and 6.3 illustrate several important phenomena. With respect to the daily variation in DO, the T1BSR natural conditions modeled results show that DO at all locations in the mainstem, including the estuary, are consistently above 6.0 mg/L. This suggests that under natural conditions, the mainstem provides adequate daily DO conditions to protect other (non-embryo, non-larval) life stages against growth effects, avoidance behavior, acute lethality, and synergistic effects. This is critical because the mainstem Klamath provides the corridor through which adult fish migrate upstream to high quality spawning habitat and juveniles migrate downstream to the estuary and ocean. In addition, the mainstem Klamath provides rearing habitat for numerous species of salmonids and other fishes.

The T1BSR natural condition modeled results also show that daily DO conditions in the mainstem do not consistently meet a 9.0 mg/L daily minimum requirement designed to protect early (embryo and larval) life stages during the spawning season (presumed to be September 15 through June 4). A 9.0 mg/L DO requirement is only met from November 1 through March 31. National criteria, as described in USEPA (1986), however, require a daily minimum of 8.0 mg/L as protection of early life stages. The *Klamath TMDL model* (Table 6.2) indicates consistent compliance with 8.0 mg/L as a daily minimum from October 1 through April 30 and compliance at most locations from September 1 through May 31.

With respect to the 30-day average requirements, The T1BSR natural conditions run of the *Klamath TMDL model* (Table 6.3) indicates consistent compliance with an 8.0 mg/L as a 30-day average throughout the mainstem Klamath and throughout the year. As above, this suggests that under natural conditions, the mainstem provides adequate monthly average DO conditions to protect other (non-embryo, non-larval) life stages against growth effects, avoidance behavior, acute lethality, and synergistic effects. This is critical because the mainstem Klamath provides the corridor through which adult fish migrate upstream to high quality spawning habitat and juveniles migrate downstream to the estuary and ocean. In addition, the mainstem Klamath provides rearing habitat for numerous species of salmonids and other fishes.

DO under natural conditions as estimated by the *Klamath TMDL model* and depicted in Table 6.3 does not meet an 11 mg/L monthly average during the spawning and incubation period, except from about November through January. The National criterion for the protection of early life stages is a 7-day mean of 9.5 mg/L. If raised to 10.0 mg/L and applied as a 30-day mean, then the *Klamath TMDL model* (Table 6.3) indicates consistent compliance with early life stage criteria from November through February and from October through April with a some exceptions above the Scott River.

It is possible that the weekly average SPWN-related metric as derived by using USEPA (1986) for no production impairment may overstate the DO requirements of salmonids in the Klamath River. For example, it may be that less than 3 mg/L DO is lost between the water column and intergravel environment in the mainstem Klamath, such that no production impairment in the intergravel environment is assured by water column DO concentrations less than 11.0 mg/L as a monthly average. Future monitoring efforts should investigate the relationship between water column DO concentrations and intergravel DO concentrations in the mainstem Klamath and important spawning tributaries.

Further, Chapter 3.0 highlights the spawning and incubation periodicity of salmonids in the Klamath River, to the degree they are known. Shaw et al. (1997) reports that coho spawning occurs from November through January with emergence occurring from late February through April. They also report that spring-run Chinook migrate up the Klamath River beginning in June and hold over until the fall to spawn, primarily in the tributaries (Shaw et al. 1997). For fall-run Chinook "spawning in the mainstem Klamath begins during the second week of October, peaks during the last week of October and declines by the end of November (Shaw et al. 1997)." Juveniles emerge from early February through the end of April (Shaw et al. 1997). Chum salmon are said to be at the southern end of their historic range and are rare in the Klamath River, historically present primarily in the estuary (Hamilton et al. 2005). No Klamath-specific spawning and incubation periodicity information was identified for cutthroat trout. However, their preference for smaller tributaries was noted.

Though not definitive, these observations coupled with the results of T1BSR natural conditions model run suggest that the spawning and incubation period for salmonids in the mainstem Klamath is primarily from October through April.

Staff believe that under natural conditions, when the upper watershed was open to migration and tributaries were free of excess sediment and other migration barriers, the mainstem may have provided only secondary spawning habitat, the primary spawning and incubation occurring in conjunction with cold springs and in high quality tributary streams. In support of this, NRC (2004) reports that coho salmon, spring-run Chinook salmon and summer steelhead in particular depended heavily on tributaries to complete their life cycles and sustain their populations. The *Klamath TMDL model* indicates that under natural conditions, daily minimum and monthly mean DO concentrations ensure no production impairment and no more than slight production impairment, respectively, of other (non-embryo and non-larval) life stages of salmonid. It also indicates that under natural conditions, daily minimum and monthly mean DO concentrations essentially meet National criteria for the protection of all early (embryo and larval) life stages if the primary spawning and incubation season in the mainstem Klamath River is understood to occur from about October 1 through April 30.

6.2.5.4 <u>Percent Saturation under Natural Conditions</u>
The *Klamath TMDL model* was used to produce an estimate of percent saturation at each location in the Klamath River mainstem as a corollary to the concentration estimates. Tetra Tech, Inc. has compiled the monthly percent saturation values for each of the stations and they are included in Table 6-5.

As described in Section 6.2.4.1, the *Klamath TMDL model* has been adjusted to account for differences in elevation at specific locations as compared to the meteorological stations from which barometric pressure data was collected. The elevations used to calculate percent saturation at each of the locations are given in Figure 6.5. For those locations from the Stateline to Iron Gate Dam and from Turwar to the Pacific Ocean, barometric pressure is not corrected for elevation (e.g. 909.83 millibars from Stateline to Iron Gate Dam and 1012.60 millibars from Turwar through the estuary). As a result, there may be a small artifact of the modeling process represented in the DO data associated with the locations within each of these reaches where the elevation is different from that of the associated weather station. But, from Iron Gate Dam to Turwar, the barometric pressure has been adjusted for elevation at every modeling node. This has resulted in a far smoother depiction of DO conditions throughout this reach. By adjusting barometric pressure at more locations throughout the mainstem than was the case in previous model runs, jumps in barometric pressure have been significantly minimized.

Figure 6.5:Barometric Pressure as assigned at individual nodes within the Klamath River mainstem from Iron Gate Dam to Turwar in the January 2010 T1BSR run (new pressure assignment) of the *Klamath TMDL Model*

THIS SPACE INTENTIONALLY LEFT BLANK

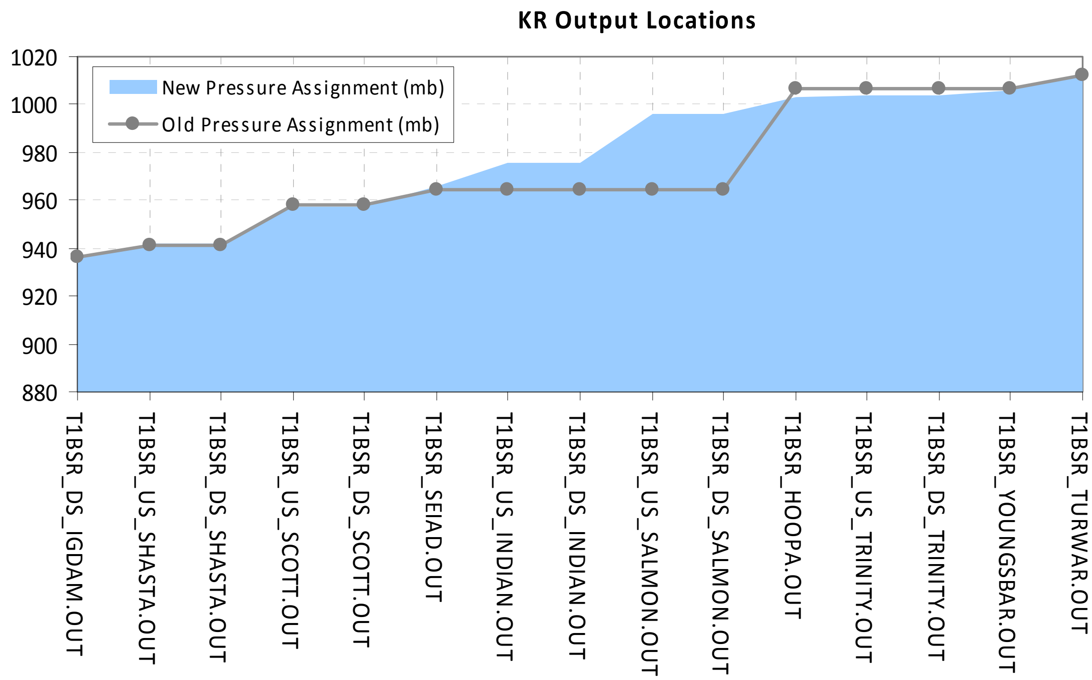

Table 6.5 presents the monthly minimum percent saturation values estimated by the T1BSR run of the *Klamath TMDL model* to occur at specific locations. It also presents the annual minimum percent DO saturation, as well as the minimum to occur in the Klamath River mainstem, overall. (The mainstem minima exclude the data associated with the Klamath River estuary.) The T1BSR model run estimates that under natural conditions, the minimum percent DO saturation in the mainstem Klamath River is 86%. It estimates that the minima range from 86% to 98% depending on the location; and, that the lowest percent DO saturation occurs during the months of July and August.

Figure 6.6 depicts the monthly minimum percent DO saturation within the mainstem over the course of the year. With the exception of the lower estuary, the graph shows a relatively smooth pattern of change in saturation in which saturation is at its lowest during the summer months, rises in the fall and winter and then decreases again in the spring. The T1BSR data output for percent DO saturation demonstrates even more clearly than the DO concentration data output, the need to consider the lower estuary separately from the freshwater-dominated portion of the river.

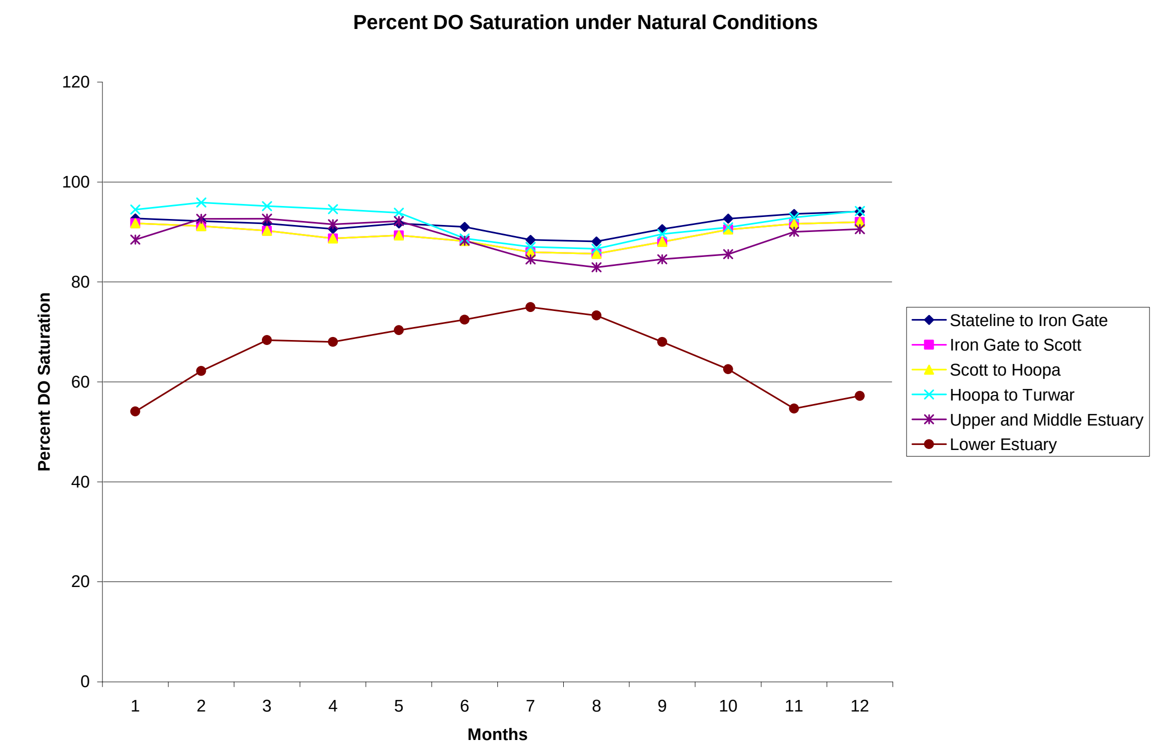
Figure 6.6: Fluctuation in percent DO saturation under natural conditions (T1BSR simulation) in individual reaches from the Stateline to the estuary.



6.3 Summary of Findings

Water has a limited ability to hold oxygen in solution that is defined by barometric pressure, temperature, and salinity. An assessment of the theoretical DO concentrations at 100% and 85% saturation indicate that water in the Klamath River is unable as a result of these simple physical properties to consistently meet the existing SSOs for DO. The *Klamath TMDL model* simulates, among other things, water quality conditions in the Klamath River mainstem under natural conditions, including DO concentration and percent DO saturation. It indicates that the daily minimum DO values above Iron Gate Dam and below Iron Gate Dam are less than the existing SSO for DO. Similarly, the annual median of monthly means is less than the existing SSO for DO, as well. . In short, the *Klamath TMDL model* demonstrates that even under natural conditions, water quality in the mainstem Klamath River is of insufficient quality to consistently attain the existing SSOs for DO.

A closer assessment of the DO output from the natural conditions run of the *Klamath TMDL model* indicates the following:

- The lower estuary experiences DO fluctuations that are dissimilar from the fluctuation that occurs elsewhere in the mainstem.
- The period in which DO concentrations meet the "no production impairment" or "slight production impairment" requirements of salmonid embryos and alevin (as defined by USEPA 1986) is from October through April.

- Under natural conditions, the transfer of DO from the water column to the intergravel environment is likely to be more efficient than estimated by USEPA (1986). If this is the case than water column DO concentrations less than 11.0 mg/L as a monthly average may sufficiently ensure intergravel DO concentrations of 8.0 mg/L DO as a monthly average to ensure “no production impairment” of salmonid embryos and alevin.
- The protection of salmonid refugia may be an important companion to the recalculation of the SSOs for DO in the Klamath River mainstem.
- Under natural conditions, the daily minimum DO upstream of the Lower Estuary is 6.9 mg/L. The annual median of monthly means is 9.4 mg/L. In the lower estuary, the daily minimum is 7.0 mg/L and the annual median of the monthly means in 8.8 mg/L.
- Under natural conditions, the Klamath River (excluding the estuary) maintains a minimum DO saturation greater than or equal to 86% at all times.

CHAPTER 7.
ALTERNATIVES ANALYSIS AND PROPOSED RECALCULATION OF THE SSOs FOR DO IN THE KLAMATH RIVER MAINSTEM

In this chapter, staff analyzes the new information presented in Chapter 6.0 and discusses the alternatives for recalculating the SSOs for DO in the Klamath River mainstem. As a result of the assessment of the existing SSOs for DO, staff has determined that the four main goals of the recalculation are to:

1. Represent an improved understanding of *natural background* conditions,
2. Accommodate updated monitoring techniques that allow for 24-hour DO sampling,
3. Be protective of identified beneficial uses, and
4. Represent physically achievable DO conditions.

The alternatives presented are 1) no change, 2) recalculated SSOs based on simulated DO concentrations under natural conditions, or 3) recalculated SSOs based on simulated percent DO saturation under natural conditions. Staff has not developed an alternative based on salmonid life cycle DO requirements. This is because, as shown in Chapter 6.0, the *Klamath TMDL model* indicates that DO under natural conditions does not consistently meet criteria designed to ensure no production impairment. Recovery of threatened and endangered species requires protection against further production impairment.

Staff uses the simulations resulting from the T1BSR run of the *Klamath TMDL model* because it offers the best estimate, to date, of DO under natural conditions. A description of the model and the natural conditions run are given in Chapter 6.0. T1BSR simulates DO in the mainstem considering conditions of barometric pressure, salinity, natural temperatures, and diel fluctuation. Staff believes that the T1BSR run of the *Klamath TMDL model* represents a more accurate and protective basis for establishing background DO objectives than the day time data collected in the 1950s and 1960s which was used to establish the existing SSOs for DO. This is because the T1BSR model run simulates conditions in the absence of anthropogenic influence (e.g., without dams), incorporates 24-hour data, and is directly comparable to data collected by datasondes, as well as grab samples.

Of importance is the observation in Chapter 6.0 that DO conditions in the lower Klamath estuary are different enough from conditions in the mainstem to warrant separate treatment. The existing SSOs for DO are given as two separate criteria: those that apply above Iron Gate Dam and those that apply below Iron Gate Dam. As a consequence, the criteria established for locations below Iron Gate Dam are applied to the estuary without consideration of the unique hydrological, ecological, and water quality (e.g., salinity concentrations) conditions present in the estuary.

THIS SPACE INTENTIONALLY LEFT BLANK

USEPA (1986) guidance says:

> "Where natural conditions alone create dissolved oxygen concentrations less than 110 percent of the applicable criteria means or m inima or both, the m inimum acceptable concentration is 90 percent of the natural concentration."

Based on this guidance, staff has assessed various means by which DO objectives based on natural concentrations could be developed. The proposed recalculation of the SSOs for DO in the mainstem Klamath River are designed to protect salmonids and other aquatic resources by ensuring that DO in the mainstem Klamath River is consistent with natural background conditions.

7.1 Alternative 1- No Change of the Criteria

Alternative 1 proposes to make no changes to the existing SSOs for DO in the Klamath River mainstem, except to add a footnote making clear that the objectives represent background conditions during daylight hours and can not reasonably be compared to data collected during the night. In this way, the potential for inaccuracies resulting from comparison of 24-hour data collected by DataSondes to the SSOs for DO is reduced. It leaves unaddressed however, the fact that the SSOs for DO represent background conditions as measured during the 1950s and 1960s after over 100 years of widespread anthropogenic influence on water quality. It also leaves unaddressed the fact that during the summer months, the SSOs for DO downstream of Iron Gate Dam are frequently unachievable due to conditions of barometric pressure and natural temperatures. Further, it does not address the unique conditions found in the lower estuary.

7.2 Alternative 2- DO Concentration Limits

Alternative 2 is to replace the SSOs for DO now existing in Table 3-1 of the Basin Plan with new concentration limits that are more precisely based on natural background DO conditions and can be compared to 24-hour data as have been more commonly collected in the last few years. The Alternative 2 DO concentration limits are intended to be the 24-hour equivalent replacement of the existing SSOs which were designed to be compared to day time samples, only. This means that the data set used to recalculate the SSOs includes the nighttime DO low, thereby resulting in true daily minima. This alternative is divided into Alternative 2a and 2b to allow for two differing ways of configuring the reaches within the mainstem.

Tables 6.2 and 6.3 presents the simulated minimum and monthly mean DO data resulting from the T1BSR run of the *Klamath TMDL model*. These simulated data are the basis for the Alternative 2 proposal.

USEPA's (1986) recommendation to derive water quality objectives as 90% of natural background accommodates naturally occurring inter-annual variation. For example, the T1BSR run of the *Klamath TMDL model* provides hourly estimates of natural DO concentration for every day of a given year. It provides a data record which is orders of magnitude greater than the one used to establish the original SSOs for DO in the Klamath mainstem. Yet, it is based on the climatic conditions of a single test year. Inter-annual variability in DO concentration due to variation in climatic conditions is predicted. As such, establishing water quality objectives as 90% of natural conditions is appropriate. With this correction, the potential for confusing natural variation for anthropogenic influence is reduced. Thus, in accordance with USEPA (1986), staff proposes for Alternative 2 criteria that are 90% of the natural concentrations estimated in the Klamath River mainstem.

7.2.1 Alternative 2a - DO Concentration with Existing Reach Configuration

Alternative 2a is to replicate the format of the existing SSOs for DO (adding new criteria for the estuary), but replace the numeric criteria with the simulated data resulting from the T1BSR run of the *Klamath TMDL model,* corrected with a 90% factor as recommended by USEPA (1986). Table 6.3 depicts the minimum monthly DO concentrations from the Stateline through the Lower Estuary.

7.2.1.1 Stateline to Iron Gate Dam

The minimum DO concentration from Stateline to Iron Gate Dam is 6.9 mg/L with an annual median of the monthly means of 9.4 mg/L. Staff recommends adding a monthly mean to better monitor for chronic DO impairment. The minimum monthly mean for this reach is 8.0 mg/L.

The DO concentrations under natural conditions are multiplied by 90% (0.90) to derive the following proposed concentration-based SSOs for DO in the Klamath River mainstem from the Stateline to Iron Gate Dam.

- 6.2 mg/L minimum
- 7.2 mg/L monthly mean
- 8.5 mg/L annual median of monthly means

7.2.1.2 Iron Gate Dam to Turwar

The minimum DO concentration from Iron Gate Dam to Turwar is 6.9 mg/L with an annual median of the monthly means of 9.5 mg/L. Staff recommends adding a monthly mean to better monitor for chronic DO impairment. The minimum monthly mean for this reach is 8.0 mg/L.

The DO concentrations under natural conditions are multiplied by 90% (0.90) to derive the following proposed concentration-based SSOs for DO in the Klamath River mainstem from Iron Gate Dam to Turwar, excluding the reach under the jurisdiction of the Hoopa Valley Indian Tribe.

- 6.2 mg/L minimum
- 7.2 mg/L monthly mean
- 8.6 mg/L annual median of monthly means

7.2.1.3 Upper and Middle Estuary

For the Upper and Middle Estuary, the DO is fairly uniform from the top of the water column to the bottom. The minimum DO concentration in this reach is 7.5 mg/L while the annual median of monthly means is 10.4 mg/L. As above, staff recommends adding a monthly mean to better monitor for chronic DO impairment. The minimum monthly mean for this reach is 8.8 mg/L.

The concentrations under natural conditions are multiplied by 90% (0.90) to derive the following proposed concentration based SSOs for DO in the upper and middle Klamath River estuary.

- 6.8 mg/L minimum
- 7.9 mg/L monthly mean
- 9.4 mg/L annual median of monthly means

7.2.1.4 Lower Estuary

The Basin Plan lists over 30 rivers and creeks as providing estuarine habitat (EST) in the North Coast Region, including the Klamath River. At present however, the Basin Plan does not include water quality objectives specifically designed to protect the EST beneficial use. In part this is because estuarine water quality data is fairly sparse and extensive estuarine studies rare.

The estuarine portion of the Klamath River is relatively short in relation to the watershed, though the length of the estuary varies seasonally with salt water intrusion achieving its greatest length during low flow when brackish water extends a couple of miles upriver (NRC 2004). NRC (2004) reports that the tidal amplitudes in the estuary vary up to 2 m.

The T1BSR run of the *Klamath TMDL model* provides some insight into the DO conditions in the Lower Klamath Estuary. Tables 6.2 and 6.3 provide simulated minimum and mean DO concentrations at the top and bottom of the water column. Of note is the fact that DO remains fairly constant at the bottom of the water column, fluctuating under natural conditions by only 1 mg/L from 7.0 to 8.0 mg/L. This is likely a function of the relatively constant water quality characteristics of salt water which, heavier than fresh water, forms a wedge at the bottom of the estuary. At the surface, on the other hand, DO fluctuates more widely (7.6 to 11.1 mg/L). This is likely a function of freshwater which forms a wedge at the surface of the estuary and varies in temperature, nutrients, and other water quality characteristics.

Estuarine DO conditions vary daily, seasonally, and annually. The degree and pattern of variation in the Lower Klamath Estuary is not yet very well understood. Without further study, staff does not believe the simulated estuarine data is sufficient to establish SSOs for this reach.

As an alternative, staff proposes the development of a narrative objective that identifies the water quality protection goals for this reach. Staff further proposes that as part of its Triennial Review of the Basin Plan, the Regional Water Board consider the development of numeric water quality standards for North Coast estuaries, including the Lower Klamath Estuary.

Under this alternative, staff proposes the following narrative objective:

"For the protection of estuarine habitat (EST), the dissolved oxygen content of the lower Klamath estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors."

7.2.1.5 Summary of Alternative 2a

Table 7.1- Alternative 2a

	Minimum (mg/L)	**Monthly Mean (mg/L)**	**Annual Median of Monthly Means (mg/L)**
Stateline to Iron Gate Dam	6.2	7.2	8.5
Iron Gate Dam to Turwar	6.2	7.2	8.6
Upper and Middle Estuary	6.8	7.9	9.4
Lower Estuary (Reach 4)	For the protection of estuarine habitat (EST), the dissolved oxygen content of lower Klamath estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors.		

7.2.2 Alternative 2b - DO Concentration with Reconfiguration of Reaches

The simulated DO concentration data resulting from the T1BSR run of the *Klamath TMDL model* suggests a configuration of reaches that differs from that used with the existing SSOs for DO. For example, Table 6.2 shows minimum DO concentrations under natural conditions from the Stateline to the Shasta River ranging from 6.9 to 7.2. From the Shasta to the Trinity River, the natural DO concentrations range from 7.2 to 7.4 mg/L. From the Trinity River to the Lower Estuary, the natural DO concentrations range from 7.5 to 7.7 mg/L. If the river is divided in this way, the ranges of minimum values are reduced in each reach ensuring that the daily minimum objective more closely mimics the natural conditions throughout the reach.

7.2.2.1 Stateline to Shasta River

The daily minimum for this reach is given in Table 6.2 as 6.9 mg/L. The monthly mean is given in Table 6.3 as 8.0 mg/L and the annual median of monthly means is given as 9.4 mg/L. Applying a 90% correction factor, the resulting criteria are as follows:

- 6.2 mg/L minimum
- 7.2 mg/L monthly mean
- 8.5 mg/L annual median of monthly means

7.2.2.2 Shasta River to Trinity River

The daily minimum for this reach is given in Table 6.2 as 7.3mg/L. The monthly mean is given in Table 6.3 as 8.0 mg/L and the annual median of monthly means is given as 9.9 mg/L. Applying a 90% correction factor, the resulting criteria are as follows:

- 6.6 mg/L minimum
- 7.2 mg/L monthly mean
- 8.9 mg/L annual median of monthly means

7.2.2.3 Trinity River to Lower Estuary

The daily minimum for this reach is given in Table 6.2 as 7.5 mg/L. The monthly mean is given in Table 6.3 as 8.5 mg/L and the annual median of monthly means is given as 10.4 mg/L. Applying a 90% correction factor, the resulting criteria are as follows:

- 6.8 mg/L minimum
- 7.7 mg/L monthly mean
- 9.4 mg/L annual median of monthly means

7.2.2.4 Lower Estuary

As with Alternative 2a, staff recommends a narrative objective describing the water quality protection goals for the lower estuary.

7.2.2.5 Summary of Alternative 2b

Table 7.2: Alternative 2b

	Minimum (mg/L)	**Monthly Mean (mg/L)**	**Annual Median of Monthly Means (mg/L)**
Stateline to Shasta	6.2	7.2	8.5
Shasta to Trinity	6.6	7.2	8.9
Trinity to Lower Estuary	6.8	7.7	9.4
Lower Estuary (Reach 4)	For the protection of estuarine habitat (EST), the dissolved oxygen content of the lower Klamath estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors.		

7.3 Alternative 3 - Percent DO Saturation

An alternative to recalculating the SSOs as concentration based objectives is to establish the objectives based on percent saturation. DO in healthy streams and rivers approaches saturation, fluctuating slightly due to the natural processes associated with photosynthesis and decomposition (Deas and Orlob 1999). The range of fluctuation in saturation in such a system is generally defined as 80-100% (Hauer and Hill 2007; SFBRWQCB 2007; Moyle 2008).

There are numerous regions, states and countries that utilize percent saturation as a water quality criterion for DO. For example, the San Francisco Bay Regional Water Quality Control Board (Region 2) requires that the median DO concentration for any three consecutive months not be less than 80% of the DO content at saturation (SFBRWQCB 2007). It further states that in areas unaffected by waste discharges, a level of about 85% of oxygen saturation exists (SFBRWQCB 2007). The Central Coast Regional Quality Control Board (Region 3) requires that median values not fall below 85% saturation as a result of controllable water quality conditions (CCRWQCB 1994). The Central Valley Regional Water Quality Control Board (Region 5) requires that for those surface water bodies outside the legal boundaries of the Delta, the monthly median of the mean daily DO concentration shall not fall below 85% of saturation in the main water mass (CVRWQCB 2007). It further requires that for water bodies unable to meet concentration-based DO objectives due to natural conditions, DO must be maintained at or above 95% of saturation (CVWQCB 2007). Finally, the Santa Ana Regional Water Quality Control Board (Region 8) requires that waste discharges shall not cause the median DO concentration to fall below 85% of saturation (SARRWQCB 2008).

The State of Oregon applies a 90% saturation criterion in those COLD waterbodies unable to meet concentration-based limits due to conditions of barometric pressure, altitude and temperature, and 95% saturation in SPWN waterbodies under the same conditions. The Hoopa Valley Tribe has proposed a 90% saturation criterion under natural receiving water temperatures in those COLD and SPWN waterbodies unable to meet concentration-based limits due to natural conditions. The National Rivers Authority of England requires DO in their RE1 waterbodies (very high quality, suitable for all fisheries) to be at or above 80% of saturation (NRA 1994).

One of the appealing aspects of percent saturation as a DO criterion is that it establishes a relationship between DO and temperature so that as temperatures decline in the winter, DO concentrations naturally increase even if percent saturation remains the same. This natural pattern of DO fluctuation—rising through the fall, reaching a peak in the winter, and declining in the spring—follows the same pattern as required of salmonids and other aquatic organisms (see Chapter 3.0). This natural pattern of DO concentration and DO life cycle requirements is better represented by a percent saturation criterion than a static minimum concentration limit.

The T1BSR run of the *Klamath TMDL model* produces simulated percent saturation data as presented in Table 6.5. The model calculates percent saturation based on estimates of natural temperatures, salinity, and barometric pressure as adjusted by elevation at locations throughout the mainstem. With the exception of the Hoopa proposal, the percent saturation criteria as described above are applied based on *actual* temperature. As a result, the DO concentrations associated with the criteria adjust based on changes in temperature, including anthropogenically influenced changes such as loss of riparian canopy or decrease in flow to water diversions.

A Technical Advisory Committee (TAC), chaired by Dr. Gary Chapman the author of USEPA's guidance on water quality criteria development for DO (USEPA 1986), was established to review the State of Oregon's water quality criteria for DO. In its' review (Oregon 1995), the TAC made the following observation.

> "Saturation criteria may result in inadequate protection at high temperatures and greater than necessary criteria at low temperatures, often inversely related to the needs of the resource. Because of the high level of protection warranted for salmonid spawning, concentration and saturation criteria would be similar for this use."

To overcome the problem of under protection at high temperatures, staff recommend that a percent DO saturation criterion be calculated based on estimates of *natural* water temperatures rather than existing water temperatures as is more widely done. By this method, the DO concentrations resulting from a calculation of percent saturation will reflect *natural* background conditions rather than allow for anthropogenic influences on temperature, particularly injurious during otherwise warm summer months. Further, by calculating the DO concentration associated with a given percent DO saturation criteria as based on natural temperatures, the criteria easily can be adjusted to accommodate improvements in the estimate of natural temperatures, including consideration of the effects of climate change, as necessary.

Lightly shaded cells are months and locations at which a 90% saturation criterion is always met under natural conditions. Dark shaded cells are months and locations at which a 90% saturation criterion is violated no more than 1% of the time. Unshaded cells are months and locations at which a 90% saturation criterion is violated under natural conditions.

THIS SPACE INTENTIONALLY LEFT BLANK

As described above, USEPA (1986) recommends with respect to concentration based objectives, applying a 10% correction factor when deriving objectives from estimates of natural DO concentrations. Staff has considered whether or not a similar correction factor should be applied when deriving objectives from estimates of natural DO percent saturation. As an example, 90% of an 85% DO saturation criterion is 77% (85*0.9).

DO objectives must protect beneficial uses and, if derived from estimates of natural conditions should be established in such a way as to accommodate natural, inter-annual variation. Staff does not believe a criterion less than 80% would adequately protect the beneficial uses. Indeed, establishing a percent saturation criteria for an entire reach or for the entire year, necessarily allows for some flexibility at some locations during some times of the year. To better identify a protective yet implementable and appropriate program, staff has reviewed compliance statistics for assumed percent DO saturation criteria of 95, 90, and 85%.

None of the locations in the Klamath River mainstem achieve a 95% DO saturation criteria for the whole year while all of the locations achieve an 85% DO saturation criteria, except the Upper and Middle Estuary during the month of August. In question, then, is whether or not there are reaches or seasons in which a 90% DO saturation criteria might be appropriate.

Table 7.3 presents the compliance statistics for an assumed percent DO saturation criterion of 90%. Dark shaded cells indicate noncompliance with a 90% DO saturation criterion less than 1% of the time, under natural conditions. Light shaded cells indicate full compliance with a 90% DO saturation criterion. From Table 7.3 staff makes the following observations.

- From the Stateline to Shasta, a 90% criterion is met under natural conditions from October to March.
- From upstream of the Scott River to Hoopa, a 90% criterion is met under natural conditions for the entire year.
- From Hoopa through the Turwar, a 90% criterion is met under natural conditions from October through May. A 90% criterion is estimated to be violated 1% of the time during the month of September based on a daily minimum of 89.53% DO saturation which occurs during 6 one-hour increments during this period.

Upper and Middle Estuary- 90% November 1 through May 31, 85% September 1 through October 31 and June 1 through July 31, 80% August 1 through August 31												
Upper Estuary	10.9	10.6	10.1	9.5	8.6	7.3	7.1	6.7	7.6	8.0	10.0	10.7
Middle Estuary	10.9	10.6	10.1	9.6	8.6	7.3	7.2	6.8	7.8	8.2	10.1	10.8
Lower Estuary—Narrative Objective												

The goal in choosing the appropriate set of percent DO saturation criteria for the mainstem Klamath River is to provide maximum protection of the beneficial uses, particularly the rare, threatened, and endangered aquatic species. Simultaneously, criteria must be implementable and reasonably accommodate natural inter-annual variation and other uncontrollable influences.

To accomplish these goals, then, Alternative 3 is presented in Table 7.5. The proposal is based on the simulation of *natural* background DO data (T1BSR) and accommodates 24-hour DO datasets. It also reflects the improvement in DO conditions that naturally occurs during the spawning season from late fall through early spring. Finally, it is intended as a means of balancing the need to establish maximum resource protection and simultaneously ensure that the objectives reasonably accommodate inter-annual variation.

Table 7.5 Alternative 3 Summary

Location	**Percent DO Saturation based on natural receiving water temperatures**	**Time period**
Stateline to Scott River	90%	October 1 through March 31
	85%	April 1 through September 30
Scott River to Hoopa	90%	Year round
Hoopa to Turwar	90%	September 1 through May 31
	85%	June 1 through August 31
Upper and Middle Estuary	80%	August 1 through August 31
	85%	September 1 through October 31 and June 1 through July 31
	90%	November 1 through May 31
Lower Estuary	For the protection of estuarine habitat (EST), the dissolved oxygen content of the Lower Klamath Estuary shall not be depressed to levels adversely affecting beneficial uses as a result of controllable water quality factors.	

Alternative 3 is implemented by calculating the corresponding DO concentration resulting from a given percent DO saturation using site-specific barometric pressure, site-specific salinity, and an estimate of site-specific natural temperatures as derived from the T1BSR run of the *Klamath TMDL model.* Staff envision the future possibility that new data may be developed or the modeling tool improved in such a way as to improve the estimate of natural receiving water temperatures. In this case, an opportunity for public review should be offered and use of improved or updated estimates of natural receiving water temperatures first reviewed and approved by the Executive Officer.

For the purpose of this assessment, site-specific natural temperatures are estimated by the *Klamath TMDL model*. Table 7.4 presents the minimum monthly DO concentrations resulting from Alternative 3 as calculated by the *Klamath TMDL model.*

7.4 Comparison of Alternatives

To identify the most protective and appropriate alternative, staff has had to develop a means of comparing Alternatives 1, 2a, 2b, and 3. This is made difficult by the fact that

Alternative 1 (No Change) is based on daytime DO samples while Alternatives 2a, 2b, and 3 are based on 24-hour simulated data. Because of the diel pattern of DO fluctuation, with daily minima generally occurring during the night, Alternative 1 is not reasonably compared to the other alternatives.

Further, as described in Chapter 4.0, Alternative 1 is not consistently achievable, particularly during the summer months at higher elevations when temperatures exceed 16 ºC and at lower elevations when temperatures exceed 22 ºC (see Figure 7.1). This is due simply to conditions of barometric pressure and temperature and the effect these parameters have on the ability of water to hold oxygen in solution (see Chapter 4). A review of Table 6.2 further indicates that under natural conditions from June to September, the daily minimum DO concentration is less than 8.0 mg/L at many locations. During the months of July and August the daily minimum DO *throughout* the mainstem ranges from 6.9 to 7.9 m/L, never reaching 8.0 mg/L.

Tetra Tech has calculated the DO concentrations resulting from Alternatives 2a, 2b, and 3 when using simulated data generated for the hours of 9am to 5pm, only—excluding the nighttime simulations. By this means, Alternatives 1, 2a, 2b, and 3 can be directly compared to one another. This comparison is necessary to determine which of the alternatives offers the greatest overall water quality protection, particularly with respect to the life cycle requirements of sensitive salmonid species. One must keep in mind that Table 7.6 is for comparison purposes, only. With respect to Alternatives 2a, 2b, and 3, it does not represent the actual proposed criteria. In addition, with respect to Alternative 1, the 8.0 mg/L DO required downstream of Iron Gate Dam is unachievable at higher elevations during the month of June and throughout the mainstem during the months of July and August.

For ease of presentation, Table 7.6 does not include all listed sampling locations. A subset of locations has been chosen as representative of the conditions found throughout the mainstem. These locations include: Stateline, downstream of Iron Gate Dam, downstream of the Scott River, downstream of the Trinity River, and the Middle Estuary.

In Table 7.6 the Alternative 1 objective of 8.0 mg/L DO downstream of Iron Gate Dam is crossed out for some of the summer months because they have been demonstrated to be unachievable solely due to the effects of barometric pressure and natural temperatures. The resulting comparison of the 4 alternatives strongly recommends Alternative 3 as the most protective alternative, overall. Table 7.6 demonstrates that during the summer, Alternative 1 requires higher DO concentrations than do Alternatives 2a, 2b, and 3 during some months at some locations with DO concentrations ranging from 0.1 to 0.7 mg/L higher and on one occasion, 0.9 mg/L higher. Table 7.6 also demonstrates, however, that the protection offered by Alternative 3 during the salmonid spawning and incubation period is far superior to that offered by any of the other alternatives. For this reason, staff recommends the adoption of Alternative 3 as the recalcualtion of the SSOs for DO in the Klamath River.

Alternative 3 offers one additional benefit over the other alternatives. DO saturation is based on the relationship of barometric pressure, temperature, and salinity. As such, a percent saturation criteria inherently incorporates temperature, a closely related water quality parameter. Alternative 3 uniquely calls for the implementation of the percent DO saturation criteria using estimates of *natural* temperature, rather than existing temperatures as is more common. Using natural temperatures as the basis for calculating the DO concentrations associated with the given percent DO saturation criteria ensures that the resulting concentrations more closely mimic natural DO conditions than would

occur using existing temperatures, in most cases. Further, using an estimate of natural temperatures as the basis for calculating DO concentration allows for consideration of the effects of climate change. If convincing data is developed which confirms a rise in natural temperatures due to the effects of climate change, then consideration can be given to adjusting the estimate of natural temperatures upon which the percent saturation criteria are based. Staff do not intend to pre-judge whether or not a rise in natural temperature due to climate change will be considered natural but, only mean to acknowledge the flexibility of this approach, as compared to others, for dealing with the effects of climate change. For example, if the percent saturation criteria were applied based on existing temperatures, no specific consideration would be given to climate change and all increase in natural temperature would automatically adjust the DO objective without executive or public review.

7.5 Proposed Alternative

Staff proposes the adoption of Site Specific Objectives (SSOs) for the Klamath River mainstem, to replace the existing SSOs for DO in Table 3-1 of the Basin Plan, as given in Table 7.5. Staff further proposes that the *Klamath TMDL model* as described in the Klamath TMDL Staff Report be used to determine natural receiving water temperatures with which to calculate the DO concentrations associated with the given percent saturation criteria. Finally, staff propose that a clause be included in the Basin Plan that allows for the re-evaluation of natural temperatures as new data or modeling improvements become available, but only after public review and if the Executive Officer finds that re-evaluation is warranted. It must be understood that the proposed alternative will be applied to the maximum extent allowed by law. To the extent that the State lacks jurisdiction, the proposed SSO is extended as a recommendation to the applicable regulatory authority. Proposed Basin Plan Amendment language is presented in Appendix A of this Staff Report.

CHAPTER 8.
REGULATORY REQUIREMENTS

The protection of water quality in the State of California is guided by the Porter-Cologne Water Quality Control Act as amended. Section 13000 states that

> "The Legislature finds and declares that the people of the state have a primary interest in the conservation, control and utilization of the water resources of the state, and that the quality of all the waters of the state shall be protected for use and enjoyment by the people of the state."

To this end, nine Regional Water Quality Control Boards were established and each created water quality control plans with which to regulate water quality within their respective regions. The first comprehensive water quality control plans were approved for the North Coast Region in 1975, including a the Klamath Basin Plan for all waters draining to the Pacific Ocean from the mouth of the Klamath River north to the Oregon border and a separate North Coast Basin Plan for those waters draining to the Pacific Ocean south to San Antonio Creek at the Sonoma-Marin County boundary. The Water Quality Control Plan for the North Coast Region (Basin Plan), combining the Klamath and North Coast Basin Plans into one document, was approved in 1988. A triennial review of the Basin Plan is required, resulting in periodic updates and alterations.

As part of the 2007 Triennial Review, the Regional Board directed staff to develop revised water quality objectives (objectives) for dissolved oxygen (DO). To this end, a draft Staff Report has been developed, resulting from CEQA scoping and scientific peer review. Staff intends to bring a final report and proposed Basin Plan Amendment to the Regional Board for their consideration in late 2010. This Staff Report has been developed to support a proposed amendment of the site-specific DO objectives to the Klamath River mainstem, only.

Chapter 5.0 describes the existing Klamath River Site Specific Objectives (SSO) for DO currently contained in Table 3-1 of the Basin Plan. In this chapter, staff concludes that the existing SSOs for DO in the Klamath are established at levels too high to represent actual daily minima. This is because they are based on data collected during day light hours only. In fact, they are higher than is physically possible at all locations and during all times of the year, based on conditions of barometric pressure, temperature, and salinity. Staff also concludes that the human activities in the basin prior to and including the 1950s and 1960s were such that the pattern and range of DO in the basin was very likely altered from natural conditions. In particular, the presence of dams in the upper basin likely perpetuates downstream the effects of natural organic and nutrient loading from Upper Klamath Lake which would otherwise have been assimilated in the reaches above Iron Gate Dam.

Chapter 6.0 describes the new information available as a result of the Klamath TMDLs being developed to assess and control impairments due to elevated nutrients, temperatures, and organic enrichment/low DO. As described in Chapter 6.0 of this Staff

Report, a general assessment of DO saturation, based on the range of barometric pressures and temperatures observed in the basin indicates that at summer temperatures, the existing 8.0 mg/L DO requirement downstream of Iron Gate Dam is physically impossible to achieve. This is the case for an assumed 100% DO saturation and even more pronounced at an assumed 85% DO saturation, as is expected in a healthy, free-flowing river with moderate levels of organic and nutrient loading.

The *Klamath TMDL models* simulate, among other things, hourly DO conditions throughout the length of the mainstem Klamath River. The T1BSR run of the *Klamath TMDL models* unequivocally demonstrate that during the summer months, in various reaches of the mainstem, DO conditions do not meet the existing DO objectives under natural conditions. This is an indication that the existing DO objectives are ill-suited for comparison to data collected using modern tools for sampling and data analysis. In the 1950s and 1960s, day time samples were collected as grab samples and analyzed in the field as were compliance samples. Compliance samples can now be collected with datasonde data probes, however, which allow for 24 hours of sampling. These compliance data can not usefully be compared to the existing day time DO objectives.

Chapter 7.0 describes several alternatives for recalculating the SSOs for DO in the Klamath River mainstem. The alternatives include: 1) No Action, 2) recalculation of existing SSOs using simulated concentration data produced by the T1BSR run of the *Klamath TMDL models*, and 3) recalculation of existing SSOs using simulated percent saturation data produced by the T1BSR run of the *Klamath TMDL models.* Staff recommends the adoption of Alternative 3, creating a new approach to DO compliance by applying a percent DO saturation criteria based on an estimate of natural temperatures. By applying a percent DO saturation requirement based on natural temperatures, the objective reflects natural DO conditions in the basin. Using percent DO saturation (based on natural temperatures) as the metric ensures that it is physically possible to achieve, unlike a static DO concentration requirement that may not be achievable at some elevations and/or at some temperatures. And, not only does a percent DO saturation requirement (based on natural temperatures) ensure a given minimum DO condition, it also ensures a normal pattern of DO fluctuation, including elevated DO in the winter when salmonid eggs are incubating.

Chapter 8.0 provides an assessment of the proposed alternative to confirm that it meets the following requirements:

1. Section 13241 of Porter-Cologne Water Quality Act
2. State and Federal antidegradation requirements
3. Protection of the Hoopa Valley Tribal Waters downstream of California waters.

In addition, Chapter 8.0 provides a discussion of how the proposed alternative is to be applied in the reservoir portions of the Klamath River mainstem. This later part is described in detail in the Klamath TMDL Staff Report.

8.1 Section 13241 of Porter Cologne Water Quality Act

Section 13241 of the Porter Cologne Water Quality Act requires that each regional board establish water quality objectives to ensure the reasonable protection of beneficial uses and the prevention of nuisance, recognizing that it may be possible for the quality of water to be changed to some degree without unreasonably affecting beneficial uses. Section 13241 lists the following factors for consideration:

a. Past, present and probable future beneficial uses of water;
b. Environmental characteristics of the hydrographic unit under consideration, including the quality of water available thereto;
c. Water quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area;
d. Economic considerations;
e. The need for developing housing within the region; and,
f. The need to develop and use recycled water.

8.1.1 Past, Present, and Probable Future Beneficial Uses of Water

The past, present and probable future beneficial uses of Klamath River water are listed in Section 2 of the Basin Plan and summarized in Chapter 5.0 of this Staff Report. The mainstem Klamath River is listed as providing benefit for both human uses (e.g. MUN, AGR, IND, PRO, NAV, POW, REC1, REC2, COMM, SHELL, AQUA, and CUL) and environmental uses (e.g., GWR, FRSH, WARM, COLD, WILD, RARE, MAR, MIGR, SPWN, and EST). With respect to DO, the most sensitive beneficial uses are those associated with salmonids threatened with extinction.

Staff considered the needs of past, present and probable future beneficial uses of water in the following ways. First, staff determined the beneficial use most sensitive to DO conditions so as to ensure a conservative approach to the protection of beneficial uses. As above, staff determined that the spawning and incubation of salmonids forms the most sensitive of the mainstem Klamath uses.

Second, staff identified the DO requirements of all fish species at risk in the Klamath River mainstem; focusing on those of salmonids. Chapter 3.0 describes the DO requirements of the fish species evaluated.

Third, staff compared simulated natural DO conditions to the requirements of salmonids and determined that under natural conditions the Klamath River has never consistently provided ideal DO conditions, particularly during hot summer months. The *Klamath TMDL model* is a tool developed over the course of many years by an interdisciplinary and intergovernmental team of representatives of two States and two USEPA regions, including their consultant. The tool has been calibrated, validated, peer reviewed (multiple times), and reviewed by the public. It is this tool that staff has relied on to determine natural DO conditions under a scenario absent anthropogenic influences. Staff is confident that the *Klamath TMDL model* provides simulated data of sufficient quality to reasonably represent natural conditions in the Klamath River. (See Tetra Tech 2009, Appendix 6 of the Klamath TMDL Staff Report for a more detailed discussion of this topic).

Fourth, to ensure the best possible DO regime, for the benefit of threatened and endangered salmonids, staff proposed the adoption of DO objectives based on *natural conditions*. Specifically, staff proposed the adoption of percent DO saturation objectives based on natural temperatures as the method by which to establish natural DO conditions. This approach ensures that not only reasonable minimum DO conditions are maintained, but the natural seasonal pattern of DO fluctuation is also maintained. This is important to the protection of salmonids because spawning and incubation requires DO concentrations higher than other life cycle stages. And, these uses occur during the late fall, winter, and early spring when DO naturally increases with decreasing temperatures. The proposed SSO for DO incorporates the spawning and incubation DO needs of salmonids by applying a metric that more accurately depicts the natural seasonal pattern and ensures its preservation.

Fifth, in Chapter 6.0 staff determined that ideal salmonid DO conditions (i.e., "no production impairment" as defined by USEPA 1986) have never been consistently met, even under natural conditions. To determine how salmonids once thrived in the Klamath River basin, despite periodically moderate DO, staff further evaluated the spawning habits of salmonids. Staff determined that salmonids do indeed spawn in the mainstem; but, by far the largest majority of salmonids make more use of tributaries for spawning, particularly the large tributaries such as the Trinity, Salmon, Scott and Shasta rivers. Further, salmonids historically made considerable use of the tributaries of the upper basin which are now blocked from use by a series of dams, Iron Gate Dam being the first encountered.

These facts have led staff to develop two hypotheses. One hypothesis is built upon the fact that incubating salmonid embryos and alevin require a greater concentration of DO in the water column than do other life stages. This is because they reside in the gravels which, depending on the degree of sedimentation, sediment oxygen demand, and other factors, may receive only a percentage of the DO contained in the water column. Thus, to meet their DO needs for growth and development in the intergravel environment, DO in the water column must be higher. USEPA (1986) argues that DO in the water column must be 3 mg/L higher than that required in the intergravel environment to protect incubating salmonids. Others argue that the factor more accurately ranges from 1-6 mg/L. Still others argue that the factor difference between the water column and intergravel environment is best determined on a site-by-site basis.

Using USEPA (1986) guidance, staff compared the DO needs of incubating salmonids to simulated DO conditions during the spawning and incubating season and determined that a daily minimum of 9.0 mg/L was reasonably met under natural conditions; but, a weekly average of 11.0 mg/L was not. Staff hypothesizes that under natural conditions, sedimentation, especially during the late fall through early spring, may not historically have posed a significant problem in the mainstem Klamath. As such, the transfer of oxygen from the water column to the intergravel environment may have been relatively efficient. Unfortunately, neither historic nor current intergravel DO data exists for the Klamath River mainstem with which to assess the validity of this hypothesis. For the protection of the beneficial uses of intergravel waters, however, the Basin Plan includes several narrative objectives associated with the settling of suspended material, including sediment. For example, the Basin Plan requires that "Waters shall not contain suspended material in concentrations that cause nuisance or adversely affect beneficial uses." The Basin Plan also requires that "Water shall not contain substances in concentrations that result in deposition of material that causes nuisance or adversely affect beneficial uses." In addition, it reads "The suspended sediment load and suspended sediment discharge rate of surface waters shall not be altered in such a manner as to cause nuisance or adversely affect beneficial uses." Thus, whatever the validity of staff's hypothesis regarding historic mainstem sedimentation, the Basin Plan provides adequate current protection.

With respect to staff's second hypothesis, there appears to be general agreement that the tributaries to the Klamath River have played a critical role in the historic success of salmonids in the Klamath River basin (NRC 2004). Staff hypothesize that the loss of access to tributaries upstream of Iron Gate Dam, as well as the degradation of water quality and habitat in tributaries downstream of Iron Gate Dam have severely impacted the ability of salmonid populations to rebound from other assaults such as overfishing, disease, drought, water withdrawals, water impoundment, and loss of mainstem habitat, to name a few. The tributaries have offered refuge.

In addition to the TMDLs for the Klamath River, of which this Staff Report is a part, the Regional Board and/or USEPA has also adopted TMDLs for several of the main tributaries to the Klamath River, including: the Lower Lost River, Shasta River, Scott River, Salmon River, Trinity River, and South Fork Trinity River. The implementation of these TMDLs will result in the improvement of tributary water quality conditions so as to better support the salmonid populations that make use of them. In the mean time, however, staff believes that known, existing salmonid refugia should be afforded special protection as a way of more immediately providing for the needs of these threatened and endangered species. To that end, Chapter 6.0 of the Klamath TMDL Staff Report describes the plan to implement the Klamath TMDL and SSOs for DO in the Klamath River. The implementation plan includes the proposed protection measures in and around known thermal refugia. The known refugia are named and mapped.

Finally, staff have conducted an environmental analysis of the likely impacts associated with the potential means by which landowners/dischargers in the Klamath River watershed will achieve compliance with the plan for implementing the Klamath River TMDLs and the recalculated SSOs for DO. This analysis was conducted in compliance with the requirements of CEQA and are included as Chapter 9 of the Klamath TMDL Staff Report of which this staff report is a part. The CEQA analysis is incorporated as a part of the DO Staff Report by reference. The CEQA analysis considers the beneficial uses of the Klamath River in the context of determining whether or not any significant environmental impacts are likely.

In summary, staff has considered the past, present and probable future beneficial uses of the Klamath River mainstem by proposing SSOs for DO designed to protect the most sensitive of the listed beneficial uses-- salmonids. The proposed SSOs for DO protect salmonids by protecting not the anthropogenically altered DO conditions in the basin, but the natural DO conditions. The proposed SSOs for DO do this by approximating natural DO conditions through the application of percent DO saturation criteria based on natural temperatures. This is a unique approach to the use of percent DO saturation criteria that serves to better associate the protection of DO conditions with the protection of temperature conditions. Further, to ensure immediate protection of salmonids, staff also proposes—as described in the Klamath TMDL Staff Report of which this is a part—the adoption of protective measures in known thermal refugia. This further cements the relationship between DO and temperature.

8.1.2 Environmental characteristics of the hydrographic unit

Section 13241 of the Porter Cologne Act requires when developing water quality objectives that the Regional Board consider the environmental characteristics of the hydrographic unit under consideration, including the quality of water available thereto. This Staff Report describes the site specific assessment that is the basis for the proposed alternative for the recalculation of the SSOs for DO in the mainstem Klamath. Chapter 2.0 describes the physical setting of the Klamath River basin. Chapter 3.0 describes the fishes of the Klamath region. Chapter 4.0 provides a general discussion of DO. Chapter 5.0 describes the existing water quality objectives for DO in the Klamath River. Chapter 6.0 describes new site specific environmental data and information associated with the Klamath River basin. This includes the development and implementation of the *Klamath TMDL model* which assesses on an hourly basis the effects of various input parameters at thousands of points throughout the river from Upper Klamath Lake in Oregon to the Pacific Ocean. Further, this Staff Report is a companion to the Klamath TMDL Staff Report, an even more thorough and detailed analysis of the environmental characteristics of the Klamath River basin and its water quality.

Staff believes the environmental characteristics of the Klamath River hydrographic unit have been thoroughly and completely considered and form the foundation for the proposed action. In addition, staff believes that the analysis of the environmental characteristics of the Klamath River basin as represented by this Staff Report and the Klamath TMDL Staff Report is significantly broader and deeper than that represented by the existing SSOs for DO in the mainstem Klamath River. This is due to an improvement in monitoring and analytical tools which allows to staff to better represent the diel and seasonal cycling of DO and to better simulate alternate conditions, such as natural conditions.

8.1.3 Water quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area;

Section 13241 of the Porter Cologne Act requires when developing water quality objectives that the Regional Board consider the water quality conditions that could reasonably be achieved through the coordinated control of all factors which affect water quality in the area. This Staff Report and the associated Klamath TMDL Staff Report describe the relationships among several related parameters and propose a coordinated approach to their control.

This Staff Report considers the relationship between DO and water temperature as well as DO and sedimentation. It also considers the relationship between DO impairment and protection of refugia. The proposed SSO for DO in the mainstem Klamath River relates DO and temperature by establishing a percent DO saturation criteria that is calculated based on an estimate of natural temperatures. This is a unique approach to the application of percent DO saturation as a water quality objective which is otherwise more often calculated based on existing temperatures. But, staff proposes the use of percent saturation based on natural temperatures as a technique for estimating natural DO conditions because the simulation of natural temperatures is viewed as a much easier task than the simulation of DO conditions (Tetra Tech 2009). Further, DO concentration varies inversely to fluctuations in temperature and thus must be viewed together to ensure an accurate understanding of the water quality dynamics and appropriate implementation measures.

In addition, this Staff Report describes the importance of thermal refugia to the success of salmonids in the Klamath River basin. Thermal refugia, particularly in the tributary streams, provides a place for salmonids, otherwise stressed by mainstem water quality conditions, to find respite from environmental stress, including stress due to low DO conditions. As a companion to the proposed recalculation of the SSOs for DO in the mainstem Klamath River, staff has also proposed the adoption of protective measures in thermal refugia, including known mapped refugia. More discussion of this is included in the Klamath TMDL Staff Report, Chapter 6.0.

The Klamath TMDL Staff Report addresses several other related parameters, assesses the degree of water quality impairment, proposes point and nonpoint source load reductions, and a plan for implementing the reductions. The pollutants of concern include: temperature, dissolved oxygen, nutrient and microcystin.

Chapter 6.0 of the Klamath River TMDL Staff Report describes a plan for the implementation of measures necessary to control the discharge of pollutants responsible for temperature, DO, nutrient and microcystin impairment. The implementation plan contained in the Klamath River TMDL Staff Report is incorporated by reference into this Staff Report and includes the actions staff believes are necessary to control DO impairment.

Finally, the Basin Plan already contains several other numeric and narrative objectives which are applied to the protection of water quality in coordination with one another. Most notable with respect to salmonids and the issues associated with water quality in the Klamath River are the objectives designed to protect against harmful suspended material, settleable material, biostimulatory substances, sediment, turbidity, bacteria, temperature, toxicity, and pesticides.

Staff believes a thorough and complete assessment of the related parameters of concern to DO conditions in the mainstem Klamath River has been conducted and described in this Staff Report. More detail is provided in the Klamath River TMDL Staff Report, of which this Staff Report is a part. Staff further believes that the implementation plan contained in Chapter 6.0 of the Klamath River TMDL Staff Report describes all the actions necessary to ensure achievement of the proposed DO objective and control of the other related parameters.

8.1.4 Economic considerations

Section 13421 of the Porter Cologne Act requires when developing water quality objectives that the Regional Board consider economic factors. Chapters 6, 9 and 10 of the Klamath TMDL Staff Report consider two proposed actions: adoption of a Basin Plan Amendment to incorporate the Klamath TMDLs and adoption of a Basin Plan Amendment to update the SSOs for DO for the mainstem Klamath River. As such, Chapters 6, 9 and 10 of the Klamath TMDL Staff Report are incorporated here by reference.

Chapter 6 of the Klamath TMDL Staff Report describes the policies; including a waste discharge prohibition staff believes are necessary to implement the proposed TMDL load allocations and recalculated SSOs for DO. Chapter 9 of the Klamath TMDL Staff Report presents the California Environmental Quality Act (CEQA) analysis, including an analysis of the potential means by which landowners and land managers may comply with the load allocations, recalculated SSOs for DO, and proposed policies and prohibitions. Chapter 10 of the Klamath TMDL Staff Report presents an analysis of the costs associated with the potential means of compliance.

Chapter 10 of the Klamath TMDL Staff Report, incorporated here by reference, highlights the potential costs associated with each of the potential means of compliance but does not present a total cost. A total cost was deemed impossible to calculate because of the unknown condition of much of the landscape within the Klamath River watershed. Many of the potential compliance measures are measures that may be required by other regulatory programs, as well. And, many of the potential compliance measures are measures typically identified in TMDLs for the control of sediment, temperature, nutrients and DO. Many of these measures are earmarked by state and federal grant programs for full or partial government funding.

The identification of the potential compliance measures necessary for PacifiCorp to achieve compliance with the SSOs for DO and TMDLs were identified in work conducted by PacifiCorp, including their own pricing of these measures. In some instances, PacifiCorp has through other negotiations made obligations with respect to the funding of these measures and/or their testing.

As such, staff concludes that the costs associated with the implementation of the SSOs for DO are reasonable when compared with the water quality benefits that will ensue and generally represent the costs associated with good land stewardship.

8.1.4.1 <u>Point Source Discharges</u>

The Basin Plan prohibits the point source discharge of waste to the Klamath River except as stipulated by the Thermal Plan, the Ocean Plan, and the action plans and policies contained in the Point Source Measures section of the Basin Plan. Under the "Policy on the Regulation of Fish Hatcheries, Fish Rearing Facilities, and Aquaculture Operations" (Hatchery Policy), an exception to this prohibition has been granted to the California Department of Fish and Game and PacifiCorp for the operation of the Iron Gate Hatchery. The Hatchery Policy recognizes the potential for beneficial uses to be enhanced by the operation of fish hatcheries.

The Hatchery Policy allows for discharge from a fish hatchery as long as the discharge does not adversely impact beneficial uses, does not include wastes generated from cleaning activities, and does not include detectable levels of disease treatment and control chemicals. A permit can be issued depending on the characteristics of the discharge, and in the case of the Iron Gate Hatchery is issued as NPDES Permit No. CA0006688. The Iron Gate Hatchery is the only permitted point source discharge to the Klamath River within the boundaries of State of California.

NPDES Permit No. CA0006688 was last issued in 2000 and is overdue for renewal. Issuance of a renewed permit has been delayed to ensure that a new permit is compliant with the Hatcheries Policy and includes the discharge limitations necessary to comply with the Klamath River TMDLs and recalculated SSOs for DO. The Iron Gate Hatchery currently treats water released from the fish production ponds in a set of two settling ponds which discharge directly to the Klamath River below Iron Gate Dam and immediately below Bogus Creek. The current permit is designed to achieve an ambient DO of 7.0 mg/L as a daily minimum. The proposed recalculated SSOs for DO at that location range from 6.3 mg/L during the summer to 10.6 mg/L during the winter. Monitoring data for 2008 indicates upstream and downstream ambient DO conditions as shown in Table 8.1

These data indicate that the Iron Gate Hatchery discharge may be responsible for a reduction in ambient DO during the months of February, May, August, and September as shown by a lower DO downstream of the discharge as compared to that measured upstream of the discharge. On the other hand, the Iron Gate Hatchery discharge may be responsible for an increase in ambient DO during the months of January, March, April, and June as shown by a higher DO downstream of the discharge as compared to that measured upstream of the discharge. Ambient Klamath River water upstream and downstream of Iron Gate Dam, as shown by 2008 monitoring data, does not meet proposed SSOs for DO during the months of October through January. Downstream DO conditions do not meet proposed SSOs for DO during the month of September, as well.

THIS SPACE INTENTIONALLY LEFT BLANK

Table 8.1: DO Monitoring Results Upstream and Downstream of the Iron Gate Hatchery Discharge for the Year of 2008.

2008	Proposed SSO for DO Downstream of Iron Gate Dam (mg/L)	Klamath River Upstream of Iron Gate Hatchery (mg/L)	Klamath River Downstream of Iron Gate Hatchery (mg/L)
January	10.8	9.2	9.5
February	9.9	11.4	10.8
March	8.8	12.8	13.0
April	7.8	13.2	15.3
May	7.1	10.55	8.72
June	6.5	10.96	11.14
July	6.5	9.47	9.44
August	6.5	7.36	6.65
September	7.1	7.6	6.34
October	8.1	6.15	6.3
November	9.7	6.0	6.11
December	10.9	6.01	6.23

Light grey shaded cells indicate upstream ambient waters that do not meet proposed SSOs for DO. Dark grey shaded cells indicate downstream ambient waters that do not meet proposed SSOs for DO.

Staff has evaluated the monitoring data of only one year (e.g., 2008). Renewal of the NPDES permit will require a thorough analysis of the monitoring data from additional years. From this one dataset, however, it appears that some additional treatment may be necessary to achieve compliance during the month of September. It also appears that an evaluation of the role of Iron Gate Dam on the ambient DO conditions downstream during the months of October through January is warranted, including consideration of the effects of water withdrawals by the Hatchery from the nutrient-rich waters of the reservoir's hypolimnion.

As described in Chapter 10 of the Klamath TMDL Staff Report, the California Department of Fish and Game and PacifiCorps will have to conduct an engineering study to determine what additional treatment will be necessary to meet new permit limits designed to attain TMDL allocations and recalculated SSOs for DO. Until that time, any estimate of the cost of compliance would be unreasonably speculative. PacifiCorps, however, has signed an agreement by which it will provide funding to the Hatchery, perhaps including some portion of the cost of treatment upgrade.

8.1.4.2 <u>Nonpoint Source Discharges</u>

The nonpoint source discharges of concern to the Klamath TMDLs and proposed SSOs for DO include:

- Modifications to water quality resulting from the Klamath Hydroelectric Project
- Road construction and maintenance activities
- Grazing
- Irrigated agriculture
- Timber harvest activities

The economic analysis (Chapter 10 of the Klamath TMDL staff repot) considers the costs associated with each of these activities. It also considers the costs associated with the proposed prohibition against discharge in the vicinity of thermal refugia. Finally, it highlights several public funding sources, as well as funding associated with other similar programs such as the Recovery Strategy for Coho Salmon. Staff believes Chapter 10 of the Klamath TMDL Staff Report presents information sufficient to satisfy the requirements of Section 13421 of the Porter Cologne Act.

8.1.5 Housing

Section 13421 of the Porter Cologne Act requires when developing water quality objectives that the need for developing housing within the region be considered. The population in the Klamath River basin was estimated in the 2000 US Census to be about 114,000 (United States Census Bureau [USCB] 2000). The largest population concentrations lie in the upper Klamath agricultural area, the Shasta River Valley, and Scott Valley. The largest population center is Klamath Falls in Oregon (19,462 people in 2000) followed by Yreka, California (7,290 people). The Klamath River basin can generally be characterized as a rural watershed with limited population-related water quality issues.

More than two thirds of the Klamath River watershed is in federal ownership. The largest blocks of private ownership are agricultural areas in the upper Klamath watershed and agricultural and timber properties in the Shasta and Scott Valleys and adjacent areas of the mainstem. Also, much of the Klamath River Valley near the mouth of the river is privately owned.

The Hoopa Valley Tribe owns land, 12 miles by 12 miles, primarily in the Trinity River watershed but intersecting the Klamath River at Saints Rest Bar upstream of the confluence with the Trinity. The Yurok Reservation's lands extend from 1 mile on each side from the mouth of the Klamath River and upriver for a distance of 44 miles. The Karuk Tribe owns 800 acres of tribal trust land along the Klamath River between Orleans and Happy Camp, and in Yreka, California. The Quartz Valley Indian Reservation is located near Fort Jones and encompasses 174 acres along the Scott River. The Resighini Rancheria spans 228 acres along the south shore of the mouth of the Klamath River. The Klamath River basin is primarily a rural river basin.

Population growth and the need for housing are of limited concern in the Klamath River basin. As described in Chapter 9 of the Klamath TMDL Staff Report (CEQA Analysis) none of the actions required by the adoption of the Klamath TMDL or the recalculated SSOs for DO on the mainstem Klamath River will result in displacement of existing housing or the need for additional development.

In any event, the recalculation of the SSOs for DO in the mainstem Klamath does not impact the ability of entities to develop land in the basin for housing, if necessary. With the existing prohibition against the discharge of waste in the Klamath River, any discharge of organic or nutrient waste, such as point source domestic wastewater, must be discharged to land. Staff believes it has thoroughly considered the issue of housing in the development of the recalculated SSOs for DO in the mainstem Klamath River.

8.1.6 Recycled water

Section 13421 of the Porter Cologne Act requires when developing water quality objectives consideration of the need to develop and use recycled water. The existing prohibition against the discharge of waste to the Klamath River ensures as the baseline that any development be predicated on the development first of recycled water as a means of reducing the amount of land necessary for the treatment of discharged waste. With respect to the recalculation of the SSOs for DO specifically, one of the primary producers of organic and nutrient rich discharge to the Klamath River comes from agricultural activities. Chapters 6 and 9 of the Klamath TMDL Staff Report (Implementation Plan and CEQA Analysis, respectively) describe the required and likely actions necessary for the agricultural community to comply with the TMDL and recalculated SSOs for DO. These actions include development and use of recycled water, particularly the reuse of irrigation return flows to reduce water quality impacts.

Staff believes it has thoroughly considered the issue of recycled water in the development of the recalculated SSOs for DO in the mainstem Klamath River.

8.2 State and Federal Antidegradation Requirements

There are two applicable antidegradation policies pertinent to water quality in the North Coast Region – a state policy and a federal policy. The state antidegradation policy is titled the *Statement of Policy with Respect to Maintaining High Quality Waters in California* and is commonly known as "Resolution 68-16." The federal antidegradation policy is found at 40 CFR section 131.12. Both policies are incorporated in the Basin Plan for the North Coast Region.

8.2.1 State Antidegradation Resolution 68-16

While requiring the continued maintenance of existing high quality waters, Resolution 68-16 provides conditions under which a change in water quality is allowable. A change must:

- Be consistent with maximum benefit to the people of the state;
- Not unreasonably affect present and anticipated beneficial uses of water; and
- Not result in water quality less than that prescribed in water quality control plans or policies.

Table 7.6 provides a comparison of the daytime values associated with the three alternatives evaluated in the recalculation of the SSOs for DO. Alternative 1 is to leave the existing SSOs for DO as they are, including a footnote indicating their applicability during the daytime, only. Alternative 3—the proposed alternative—is to calculate natural DO concentrations based on given percent DO saturation criteria and estimates of natural temperature. In the comparison of criteria, one sees that the existing SSOs for DO provide a more protective DO concentration value during the summer months. But, for many of these months, the given concentration is unattainable simply due to conditions of barometric pressure, temperature and salinity and are therefore inappropriate. During the fall, winter, and spring, however, Alternative 3 provides significantly greater protection and this during the spawning and incubation period of the basin's most sensitive beneficial use. It is on this basis that Alternative 3 is proposed.

Staff argues the proposed recalculation of the SSOs for DO in the mainstem Klamath River provide greater protection to the beneficial uses than the existing SSOs for DO. Because of the ambiguous nature of the analysis during the summer months, however, staff believes it important to consider the three issues presented by Resolution 68-16 with respect to any change in water quality.

1). Staff believes that protecting the rare and threatened salmonids of the Klamath River is of maximum benefit to the people of the state. This is because of the inherent value of protection species from extinction. It is also because of the value of restoring a fishery which once supported an important cultural and commercial fishing use. As one of the State's largest salmon fisheries, impacts to the Klamath fisheries have State wide impacts.

2) Staff believes this action does not unreasonably affect the present and anticipated beneficial uses of water; in fact, it serves to better protect the beneficial uses of water.

3) Staff believes the water quality resulting from this action is greater than that prescribed in the existing water quality control plan, particularly in the fall, winter and spring when the most sensitive beneficial use requires greater DO conditions.

8.2.2 Federal Antidegradation Policy

The federal antidegradation policy is found at 40 CFR Section 131.12. The federal policy must be addressed whenever it is proposed to relax a standard (beneficial use or water quality objective) for surface water. As described above, staff believes that the recalculation of the existing SSOs for DO does not result in a relaxed standard but, in fact, results in an improved standard providing greater protection of beneficial uses, particularly the spawning and incubation of salmonids—the most sensitive beneficial use. During the summer months when the existing SSOs for DO are represented as higher than those associated with the proposed recalculated SSOs, many of these values are unattainable due simply to conditions of barometric pressure, natural temperature, and salinity. As such, they are inappropriate for use during that period. The proposed SSOs for DO, on the other hand, represent conditions that are achievable year round under natural conditions and represent the highest DO conditions physically possible for the mainstem.

8.3 Hoopa Valley Tribe's Water Quality Objectives for DO

The Hoopa Valley Tribe has a water quality control plan, approved by USEPA and implemented by the Tribe. With respect to DO, the <u>Water Quality Control Plan for the Hoopa Valley Indian Reservation</u> (Hoopa 2008) requires the following in the mainstem Klamath:

> *Water Column Dissolved Oxygen* –Klamath River D.O. criteria based on the designated use COLD (year-round), the 7-day moving average of the daily minimum D.O. in the water column shall not drop below **8.0 mg/L**, whereas SPWN (whenever spawning occurs, has occurred in the past or has potential to occur), the 7-day moving average of daily minimum D.O. in the water column shall not drop below **11.0 mg/L**. If dissolved oxygen standards are not achievable due to natural conditions, then the COLD and SPAWN standard shall instead be dissolved oxygen concentrations equivalent to 90% saturation under natural receiving water temperatures.

If water quality monitoring indicates that dissolved oxygen levels are below the criteria listed, then an investigation of impact will be conducted.

Inter-gravel Dissolved Oxygen-- Klamath River D.O. criteria that are based on the designated use SPWN (whenever spawning occurs, has occurred in the past or has potential to occur), where the 7- day moving average of the daily minimum D.O. in the inter□gravel water shall not drop below **8.0 mg/L**. If dissolved oxygen standards are not achievable due to natural conditions, then the COLD and SPAWN standard shall instead be dissolved oxygen concentrations equivalent to 90% saturation under natural receiving water temperatures.

USEPA approved Hoopa (2008) with one exception; it did not approve the use of the 90% saturation criteria until the Hoopa Valley Tribe could develop a method for determining if natural conditions prevent the attainment of the approved concentration based criteria. For the purposes of this report, staff compares the proposed recalculation of the SSOs for DO in the California portion of the Klamath mainstem to both the concentration limits and the percent DO saturation limits. This is because, while the concentration limits are the approved limits associated with the Hoopa (2008), Regional Water Board staff have participated in the development of the *Klamath TMDL models,* a tool with which to assess DO under natural conditions.

Based on conversations with representatives of the Hoopa Valley Tribe (and others), staff directed Tetra Tech to rerun the *Klamath TMDL model* for that portion of the river from Iron Gate Dam to Turwar to improve the way in which barometric pressure was represented. This was undertaken to improve the DO model output in the reach just above and including the Hoopa Valley Tribe Reservation and thereby improve the potential for the Hoopa Valley Tribe to adopt the *Klamath TMDL model* as it's own tool for establishing natural conditions. Further, it allowed staff to propose a SSO for DO in the reach up to the California-Hoopa boundary which is consistent with the Hoopa objective.

THIS SPACE INTENTIONALLY LEFT BLANK

8.3.1 Life cycle-based DO objectives

Figure 8-1: T1BSR modeled daily DO concentrations at Hoopa-California boundary

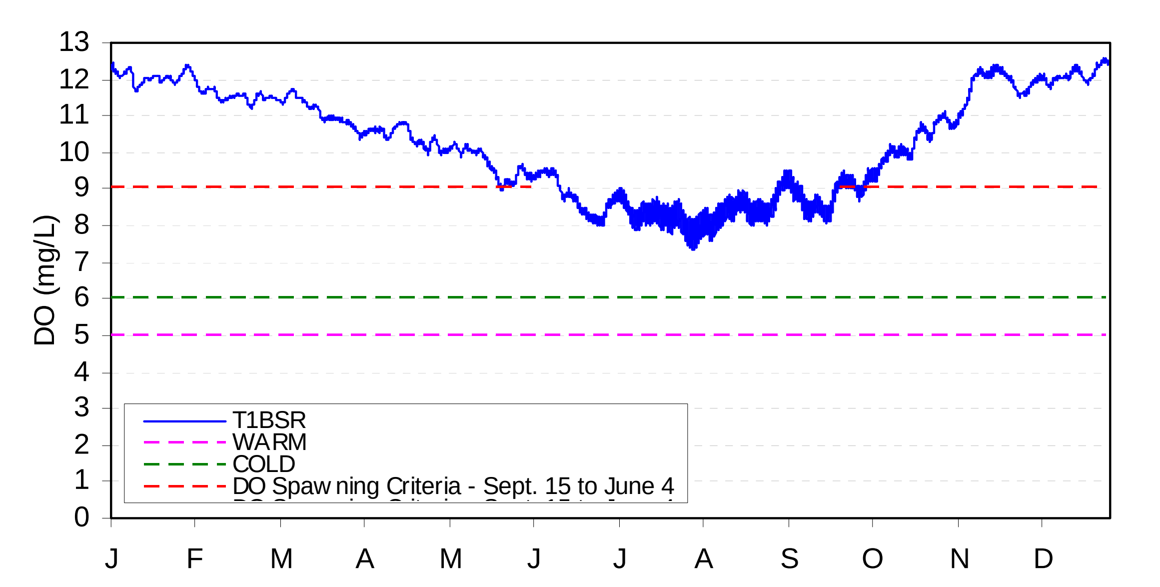

Figure 8-1 depicts simulated daily minimum DO concentrations at the Hoopa-California border. A line drawn at the 8.0 mg/L mark indicates that except from about July through mid-August, the daily minima are otherwise above 8.0 mg/L under natural conditions. As such a moving 7-day average of the daily minima is also above 8.0 mg/L. During the period from July through mid-August, the daily minima drop to a low of about 7.3 mg/L in late July making it possible that under natural conditions a 7-day moving average of the daily minima from late July through mid-August may not meet an 8.0 mg/L objective.

With respect to spawning and incubation requirements, a line drawn at 11.0 mg/L on Figure 8-1 indicates that from early November through mid-March, the daily minima under natural conditions are greater than 11.0 mg/L ensuring that the 7-day average of the daily minima is also above 11.0 mg/L. Under natural conditions from mid-March to June, however, the daily minima drop steadily from 11.0 mg/L to about 9.0 mg/L ensuring that the moving 7-day average of the daily minima fall short of 11.0 mg/L for at least some portion of this period. Similarly, under natural conditions from mid-September through October, the daily minima rise steadily from 9.0 mg/L to 11.0 mg/L ensuring that the moving 7-day average of the daily minima fall short of 11.0 mg/L for some portion of this period, as well.

Hoopa (2008) requires the application of objectives designed to protect SPWN during the period and in those locations in which spawning actually occurs, has occurred in the past, or has the potential to occur. Though not specifically mentioned in the definition of beneficial uses, SPWN is intended to apply not only to spawning but incubation, as well. The period of SPWN, as estimated in the Trinity River is from September 15 through June 4. The T1BSR (natural conditions) run of the *Klamath TMDL model* indicates that

DO conditions favor spawning and incubation [as based on Regional Water Board staff's reading of USEPA (1986)] from about October through April. In either case, ambient water quality under natural conditions does not achieve the life cycle objectives for SPWN for several weeks to months of the year.

This analysis demonstrates that ambient water quality conditions are unable to achieve the SPWN objectives as contained in Hoopa (2008) within the California-Hoopa boundary.

8.3.2 Percent saturation

The *Klamath TMDL model* provides an excellent, validated, calibrated, and peer-reviewed tool with which to demonstrate that under natural conditions DO life cycle objectives as defined by Hoopa (2008) are unachievable. It was the lack of such a tool in 2007 that prevented USEPA from approving the 90% saturation element of Hoopa (2008). With the current availability of the *Klamath TMDL model* the Hoopa Valley Tribe can consider applying the 90% DO saturation criteria (under natural receiving water temperatures) as is contained in its water quality control plan.

- For the reach of the Klamath from the Scott River to the California-Hoopa boundary, the recalculated SSOs for DO call for a 90% DO saturation criteria (based on natural temperatures) year round. This is supported by the T1BSR run of the *Klamath TMDL model* and is identical to the percent saturation criteria contained in the Hoopa Basin Plan. At a monitoring location on Hoopa land, the T1BSR (natural conditions) run of the *Klamath TMDL model* indicates a minimum percent DO saturation for every month of the year as listed below. In only two months does the minimum percent DO saturation fall below 90% under natural conditions; and then achieves a minimum 89% DO saturation. The rate of violation of the 90% DO saturation objective is 2% during the month of July (based on 14 one-hour excursions during the month) and 6% during the month of August (based on 44 one-hour excursions during the month).
    - January 96%
    - February 97%
    - March 96%
    - April 96%
    - May 95%
    - June 92%
    - July 89%
    - August 89%
    - September 91%
    - October 93%
    - November 95%
    - December 96%

Regional Water Board staff concludes that the proposed SSOs for DO in the reach from the Scott River to the Hoopa boundary are consistent with the Hoopa percent DO saturation objective. Staff also conclude that the *Klamath TMDL model,* as improved by consultation with representatives of the Hoopa Valley Tribe (and others), provides a reasonable tool by which to establish natural conditions in that portion of the Klamath River on the Hoopa Valley Tribe Reservation. When applying the *Klamath TMDL model* as the tool by which to establish natural DO conditions, the State's proposed 90% DO saturation objective (based on natural receiving water temperatures) for that reach from the Scott River to the Hoopa-California boundary achieves the Hoopa's 90% DO saturation objective and is consistent with these downstream requirements.

8.4 Application of Recalculated SSOs for DO in Impounded Reaches

The mainstem Klamath River is impounded behind dams in several places above the Shasta River confluence. Behind the dams, the biochemical interactions associated with nutrient and organic loading differ from those in the free-flowing portions of the river. The proposed recalculated SSOs for DO do not speak to these differences because the Klamath TMDL addresses the issue by requiring that the DO objectives be applied across a depth and width of the reservoirs that is equivalent to the depth and width of the river as it would exist without the impoundments. Further, the DO objective is to be applied in a zone that overlaps with a zone in which the temperature objectives apply, ensuring that a lens of water of sufficient quality to support beneficial uses exists within the reservoirs.

8.5 Summary

Staff conclude that the proposed Site Specific Dissolved Oxygen Objectives for the Klamath River in California meet all the regulatory requirements associated with the adoption of a basin plan amendment, including Section 13241 of Porter Cologne Water Quality Act, federal and state antidegradation requirements, and the downstream water quality requirements of the Hoopa Valley Tribe.

CHAPTER 9.
PUBLIC PARTICIPATION

Chapter 1 describes the history of the effort to revise Dissolved Oxygen objectives in the existing Basin Plan. In the fall of 2008, staff released a CEQA scoping document for public review and presented the concept for DO objective revision at two scoping meetings: one in the southern part of the Region (Santa Rosa) and the other in the northern portion (Weaverville). A peer review draft was produced and submitted for formal peer review in the spring of 2009. The project was modified to focus only on the mainstem Klamath River and a public review draft was released as an appendix to the Klamath TMDL Staff Report in June 2008. This Staff Report (Appendix 1 of the Klamath TMDL Staff Report,) was presented for public review beginning on December 23, 2009. Public comments were received by February 9, 2010 and are incorporated into this March 2010 draft, as appropriate. This March 2010 draft also reflects consultation with representatives of the Hoopa Valley Tribe (and others) regarding the means by which barometric pressure was represented in the *Klamath TMDL model* for that portion of the river from Iron Gate Dam to Turwar. The *Klamath TMDL model* was updated for this portion and rerun on February 2, 2010, the resulting revised DO data incorporated into this Staff Report. A proposed Basin Plan Amendment, based on the findings of this Staff Report, will go before the Regional Water Board in March 2010 in a public hearing regarding its adoption.

Chapter 11 of the Klamath TMDL Staff Report describes in detail the public participation process with respect to the Klamath TMDL. During 2009, public meetings addressing the Klamath TMDL have also addressed the development of the SSOs for DO.

CHAPTER 10.
IMPLEMENTATION PLAN

Chapter 6 of the Klamath TMDL Staff Report includes implementation measures necessary to achieve the proposed recalculated SSOs for DO in the mainstem Klamath River. Chapter 6 of the Klamath TMDL Staff Report is incorporated into this Staff Report by reference.

CHAPTER 11.
ECONOMICS

Chapter 10 of the Klamath TMDL Staff Report assesses the economics associated with implementation of the Klamath TMDL and SSOs for DO. Chapter 10 of the Klamath TMDL Staff Report is incorporated into this staff report by reference.

CHAPTER 12.
CALIFORNIA ENVIRONMENTAL QUALITY ACT (CEQA)

Chapter 9 of the Klamath TMDL Staff Report assesses the environmental impacts associated with implementation of the Klamath TMDL and SSOs for DO as required under the California Environmental Quality Act (CEQA). Chapter 9 of the Klamath TMDL Staff Report is incorporated into this staff report by reference.

CHAPTER 13.
MONITORING

Chapter 7 of the Klamath TMDL Staff Report describes a monitoring plan for the assessment of ambient water quality conditions and compliance with the Klamath TMDL and SSOs for DO. Chapter 7 of the Klamath TMDL Staff Report is incorporated into this staff report by reference.

1 Introduction: The California NNE Approach

The Klamath River in California is listed as impaired for temperature, nutrients, and low DO/organic enrichment. The North Coast Regional Board is developing TMDLs in collaboration with Oregon and USEPA to address these impairments. For TMDL development, Tetra Tech is applying a set of linked simulation models consisting of CE-QUAL-W2 (for reservoirs) and RMA (for free-flowing reaches). The TMDL runs have primarily addressed numeric criteria for DO and temperature.

Tetra Tech, under contract to EPA Region IX and the California State Water Resources Control Board also developed an approach for calculating nutrient numeric endpoints (NNE) for use in California Water Quality Programs (Tetra Tech, 2006). The "Technical Approach to Develop Nutrient Numeric Endpoints for California," referred to as the California NNE approach, is a risk-based approach in which targets are developed for response variables (or secondary indicators) such as algal density. These response targets can then be converted to site-specific nutrient targets through use of modeling tools.

The California NNE approach recognizes that there is no clear scientific consensus on precise levels of nutrient concentrations or response variables that result in impairment of a designated use. To address this problem, waterbodies are classified in three categories, termed Beneficial Use Risk Categories (BURCs). BURC I waterbodies are not expected to exhibit impairment due to nutrients, while BURC III waterbodies have a high probability of impairment due to nutrients. BURC II waterbodies are in an intermediate range, where additional information and analysis may be needed to determine if a use is supported, threatened, or impaired. Tetra Tech (2006) lists consensus targets for response indicators defining the boundaries between BURC I/II and BURC II/III.

Tetra Tech (2006) also documents a set of relatively simple but effective spreadsheet tools for application in lake/reservoir or riverine systems to assist in evaluating the translation between response indicators and nutrient concentrations or loads.

One important use of the NNE is for setting initial nutrient endpoints for waterbodies requiring nutrient TMDLs. Tetra Tech (2007), under contract with USEPA, conducted a case study of potential NNE endpoints on the Klamath River. That study, "Nutrient Numeric Endpoints for TMDL Development: Klamath River Case Study", addressed only periphyton in the riverine portion of the watershed and used water quality data for 2000-2003, coupled with periphyton observations from 2004. Since that time, significantly more data have become available, and corrections have been made to earlier data. At the request of the North Coast Regional Water Quality Control Board, USEPA has funded this follow-on study. The two major purposes are (1) to extend the NNE analysis to the two reservoirs (Iron Gate and Copco) on the California portion of the Klamath system, and (2) to update the stream periphyton analysis to reflect more recent and corrected data.

(This page left intentionally blank.)

2 Iron Gate and Copco Reservoirs

2.1 Uses and Impairments

Beneficial uses of Copco and Iron Gate reservoirs are defined in the Water Quality Control Plan (NCRWQCB, 2007) and are summarized in Table 1. Both existing and potential uses are protected. Uses related to the protection of endangered salmonid fish species (COLD, RARE, MIGR, SPWN) are of particular interest to many stakeholders in the Klamath River system.

Table 1. Beneficial Uses of Copco and Iron Gate Reservoirs

Code	Use	Copco	Iron Gate
MUN	Municipal and Domestic Supply	E	P
AGR	Agricultural Supply	E	P
IND	Industrial Service Supply	E	P
PRO	Industrial Process Supply	P	P
FRSH	Freshwater Replenishment	E	E
NAV	Navigation	E	E
POW	Hydropower Generation	E	E
REC1	Water Contact Recreation	E	E
REC2	Non-Contact Water Recreation	E	E
COMM	Commercial and Sport Fishing	E	E
WARM	Warm Freshwater Habitat	E	E
COLD	Cold Freshwater Habitat	E	E
WILD	Wildlife Habitat	E	E
RARE	Rare, Threatened, or Endangered Species	E	E
MIGR	Migration of Aquatic Organisms	E	E
SPWN	Spawning, Reproduction, and/or Early Development	E	E
SHELL	Shellfish Harvesting	NA	E
AQUA	Aquaculture	E	E

Notes: E – Existing Use; P – Potential Use; NA – Use not applicable.

California's 2006 Section 303(d) list identified the Klamath River hydrologic unit from the Oregon border to Iron Gate (including both Iron Gate and Copco reservoirs) as impaired due to nutrients, organic enrichment/low dissolved oxygen, and temperature.

By letter of 13 March 2008, Alexis Strauss, Director, Water Division, USEPA Region IX determined that, in addition to this listing, "one Klamath River segment is impaired due to the presence of elevated concentrations of microcystin toxins, specifically the Oregon to Iron Gate segment which includes the Copco and Iron Gate reservoirs." EPA's decision came in response to a suit filed by the Klamath

Riverkeeper on 30 July 2007 (*Klamath Riverkeeper v. USEPA,* Docket No. C 07-3908 (SBA) (N.D. Cal.)). Microcystins are a class of toxic chemicals produced by some strains of the cyanobacteria *Microcystis aeruginosa* that are released into waters when cyanobacterial cells die or cell membranes degrade. These chemicals are a human health risk, capable of inducing skin rashes, sore throat, oral blistering, nausea, gastroenteritis, fever, and liver toxicity (USEPA Region IX, 2008). Microcystin toxins have also been shown to produce effects on animals including acute livestock poisoning and tumor production in fish guts and liver. Microcystin can thus potentially impair a number of beneficial uses of a waterbody. While California has not established numeric water quality objectives for microcystin toxins, EPA based its decision on observations that exceed the World Health Organization guidelines for moderate probability of adverse health effects of microcystin concentrations above 20 µg/L in recreational waters (WHO, 2003), resulting in impairment of the REC-1 beneficial use and the narrative toxicity objective for Iron Gate and Copco reservoirs.

2.2 POTENTIAL NNE TARGETS

Nutrient concentrations in Iron Gate and Copco reservoirs, along with associated physical conditions, are associated with the formation of summer algal blooms, including the formation of extensive blooms of the cyanobacteria *Microcystis aeruginosa*. Algal blooms in the Klamath reservoirs potentially impact designated beneficial uses in a number of ways, including the following linkages between algal growth and beneficial use impairment:

1. The presence of visible algal blooms can directly impact contact and non-contact recreational uses (REC1, REC2) by creating unaesthetic conditions and unpleasant conditions for contact recreation. This is foremost a function of the total algal biomass present during blooms, but a given biomass of cyanobacteria that form visible scums or mats may present a greater problem than a comparable biomass of planktonic algae.
2. Microcystin toxins, produced by blooms of *Microcystis aeruginosa*, have been determined by EPA to cause impairment in the reservoirs. The beneficial uses threatened by elevated microcystin levels include MUN, AGR, REC1, REC2, COMM, WARM, COLD, WILD, RARE, MIGR, SPWN, AQUA and SHELL.
3. Excess algal growth disrupts the dissolved oxygen (DO) balance, leading to super-saturation during daylight periods of high productivity, and depletion of DO during nighttime respiration and as a result of the decay of dead biomass in the water column. Excess productivity typically results in an increase in organic matter loading to the bottom (hypolimnetic) waters of a reservoir, resulting in rapid DO depletion during stratified conditions. In addition, there can be a self-reinforcing feedback loop, as oxygen depletion at the sediment-water interface can promote the release of phosphorus and ammonium from the sediment, which in turn can support additional algal growth. High algal densities can also disrupt pH, as CO_2 is consumed during the day (at depths with sufficient light for photosynthesis) and released during nighttime respiration. Algal-induced changes to the DO balance can thus impair REC1, REC2, COMM, WARM, COLD, WILD, RARE, SPWN, and AQUA beneficial uses.
4. Excess algal growth results in an increase in the export of organic matter from the reservoirs, which in turn can exert an oxygen demand and potentially impair the DO balance and associated beneficial uses in the stretches of the Klamath River downstream from the reservoirs. On the other hand, algal uptake and settling may reduce the transport of inorganic nutrients downstream during the growing season, potentially mitigating impacts in the reaches below the reservoirs.
5. Conditions that lead to dominance by cyanobacteria in the plankton community can have adverse effects on the fishery (other than direct toxicity), as cyanobacteria generally support a much less rich population of planktonic invertebrates, which in turn support forage and juvenile game fish

populations. This potentially affects REC2, COMM, WARM, COLD, WILD, RARE, and SPWN uses.

Of these five impact linkages, the current TMDL effort, driven by the Consent Decree schedule, focuses on numbers 3 and 4, specifically addressing the need to meet DO (as well as temperature) numeric criteria. For these impacts, the target is already established in the numeric water quality criteria.

The required reductions in nutrient and organic matter loads to meet DO criteria will also reduce impacts associated with the other three impact linkages, but are not developed to specifically address these issues. These three risk hypotheses involve narrative, rather than numeric criteria. The Basin Plan contains the following statements of objectives relevant to nutrients in the Klamath:

> ***Biostimulatory Substances***
>
> *Waters shall not contain biostimulatory substances in concentrations that promote aquatic growths to the extent that such growths cause nuisance or adversely affect beneficial uses.*
>
> ***Toxicity***
>
> *All waters shall be maintained free of toxic substances in concentrations that are toxic to, or that produce detrimental physiological responses in human, plant, animal, or aquatic life. Compliance with this objective will be determined by use of indicator organisms, analyses of species diversity, population density, growth anomalies, bioassays of appropriate duration, or other appropriate methods as specified by the Regional Water Board.*

EPA, in establishing the 303(d) listing for microcystin toxins, cites WHO guidance on microcystin targets. However, the scientific understanding does not seem to be sufficiently advanced to translate microcystin levels into quantitative target levels of *Microcystis* biomass or biovolume. As stated in the 2008 EPA staff report

> "WHO used a number of studies to estimate an approximate microcystin concentration that would be expected from a given cell density of *Microcystis aeruginosa*. However, WHO acknowledges that the cyanobacterial cell density may not be a reliable proxy for microcystin toxin concentrations, because different cyanobacterial strains may be present and their genetic capacity may not produce toxins. In fact, some blooms of *Microcystis aeruginosa* may produce little to no microcystin toxins… For Section 303(d) purposes, EPA considered the cyanobacterial cell density results as part of our assessment but we did not rely on this ancillary information as definitive evidence of corresponding ambient concentrations of microcystin toxins."

Further, quantitative prediction of *Microcystis* cell density as a function of nutrient loading is exceedingly difficult, as it involves a combination of the total potential algal growth supported by nutrient loads, the factors that may promote cyanobacterial dominance within the planktonic algal community, and the factors that may enable *Microcystis* to out-compete other cyanobacteria. To achieve narrative standards and protect beneficial uses, linkage (1) requires an appropriate limit on total algal biomass, linkage (5) requires control of cyanobacterial dominance within blooms, and linkage (2) requires control of toxin-producing strains of *Microcystis* within cyanobacterial blooms. Notably, the risks associated with impact linkages (2) and (5) would also be controlled if the general risk of algal blooms was reduced.

Proposed nutrient numeric endpoints developed for the draft CA NNE framework are expressed as two numbers: the boundary between BURC I/II, indicating a concentration below which impacts are unlikely, and the boundary between BURC II/III, indicating a concentration above which impacts are likely. Table 3-2 in Tetra Tech (2006) recommended algal density targets for summer average chlorophyll *a*. These proposed targets were selected by Regional and State Board staff, based on input from Tetra Tech, at the State Water Board Nutrient Numeric Training Workshop held on May 18-19, 2005 in Sacramento, CA, as shown in Table 2.

Table 2. Proposed CA NNE Planktonic Algal Biomass Targets in Lakes and Reservoirs (as µg/L chlorophyll *a* expressed as a summer mean)

Risk Category Boundary	Beneficial Use				
	COLD	WARM	REC1	REC2	MUN
I/II	5	10	10	10	5
II/III	10	25	20	25	10

The most restrictive recommendations are for the COLD and MUN beneficial uses, both of which apply to Copco and Iron Gate reservoirs. Therefore, the BURC II/III boundary of 10 µg/L summer average chlorophyll *a* provides one potential target for managing these reservoirs. It should be noted, however, that the CA NNE targets are still in draft form, and have not been adopted by the State Board or incorporated into the North Coast Water Quality Control Plan at this time.

The CA NNE document (Tetra Tech, 2006) also considered cyanobacterial density as a potential target, but did not propose specific BURC boundary values. One potential target for cyanobacteria would be to reduce the frequency of cyanobacterial dominance. For example, British Columbia states that waters classified for primary recreation and aquatic life uses should have planktonic populations consisting of less than 50 percent of cyanobacterial cells by volume (MELP, 1992). Volumetric predictions are difficult with simple models, and Downing et al. (2001) instead recommend a target of less than 50 percent of total algal biomass for cyanobacteria. Their work demonstrated that there is typically a rapid phase change between low cyanobacteria densities (less than 20 percent of biomass) to cyanobacterial dominance (> 80 percent of biomass) as nutrient concentrations and total phytoplankton biomass increase. Cyanobacterial dominance is also conveniently expressed using the BG index (BGI), where BGI = ln(%BG/(100 - %BG)), in which %BG is the cyanobacterial biomass expressed as a percentage of the total algal biomass (Trimbee and Prepas, 1987). The 50 percent breakpoint is equivalent to BGI = 0, while values greater than zero indicate increasing cyanobacterial dominance. Downing et al. also found that the risk of greater than 50% cyanobacteria in individual lakes increased proportionately with the BGI.

Downing et al. also undertook regression analysis for prediction of BGI, using data from 99 lakes around the world. Contrary to expectation, they found that TN/TP ratio was not a good predictor of BGI (R^2=26%). The best predictors were phytoplankton biomass, total chlorophyll *a*, and total nitrogen, with R^2 value of 42-43 percent. Total phosphorus was also a better predictor of BGI than TN/TP (R^2 = 34%). The authors argue that "the most potentially useful of these relationships is that with total P, because total P predicts phytoplankton biomass…and discriminates incisively the lakes dominated by Cyanobacteria…," although the correlation coefficient is decreased by a few outliers and a nonlinear asymptote. The equations for predicting BGI from TN and TP are given as follows:

$$BGI = -10.0 + 3.03 \log_{10} TN$$

$$BGI = -4.16 + 1.88 \log_{10} TP$$

In sum, management of Iron Gate and Copco reservoirs to achieve designated beneficial uses appears to require some or all of the following: controls on total algal biomass, the percent of cyanobacteria within total algal biomass, and the dominance of *Microcystis* within the cyanobacterial population.

2.3 APPLICATION OF NNE SCOPING TOOLS

The NNE BATHTUB scoping tool was applied to Copco and Iron Gate reservoirs for the two years of 2002 and 2005, selected because these are the years for which extensive monitoring data are available.

After documenting a reasonable agreement with observations, the tool was then applied to the 2000 TMDL model year.

2.3.1 BATHTUB Tool

In support of the CA NNE approach, Tetra Tech developed a spreadsheet application of the U.S. Army Corps of Engineers BATHTUB model (Walker, 1996) to establish screening level nutrient loading targets for lakes and reservoirs by estimating algal response to nutrient loading. BATHTUB is a steady-state model that calculates nutrient concentrations, chlorophyll *a* concentrations (or algal densities), turbidity, and hypolimnetic oxygen depletion based on nutrient loadings, hydrology, lake morphometry, and internal nutrient cycling processes. It explicitly addresses conditions in run-of-river, and short residence time reservoirs. BATHTUB uses a steady-state mass balance model approach that estimates the distribution of external and internal nutrient loads between the water column, outflows, and sediments. External loads can be specified from various sources including stream inflows, nonpoint source runoff, atmospheric deposition, groundwater inflows, and point sources. Internal nutrient loads from cycling processes may include sediment release and macrophyte decomposition. Since BATHTUB is a steady-state model, it focuses on long-term average conditions rather than day-to-day or seasonal variations in water quality. Algal concentrations are predicted for the summer growing season when water quality problems are most severe. Annual differences in water quality, or differences resulting from different loading or hydrologic conditions (e.g., wet vs. dry years), can be evaluated by running the model separately for each scenario.

BATHTUB first calculates steady-state phosphorus and nitrogen balances based on nutrient loads, nutrient sedimentation, and transport processes (lake flushing, transport between segments). Several options are provided to allow first-order, second-order, and other loss rate formulations for nutrient sedimentation that have been proposed from various nutrient loading models in the literature. The resulting nutrient levels are then used in a series of empirical relationships to calculate chlorophyll *a*, oxygen depletion, and turbidity. Phytoplankton concentrations are estimated from mechanistically based steady-state relationships that include processes such as photosynthesis, settling, respiration, grazing mortality, and flushing. Both nitrogen and phosphorus can be considered as limiting nutrients, at the option of the user. Several options are also provided to account for variations in nutrient availability for phytoplankton growth based on the nutrient speciation in the inflows. The empirical relationships used in BATHTUB were derived from field data from many different lakes, including those in EPA's National Eutrophication Survey and lakes operated by the Army Corps of Engineers. Default values are provided for most of the model parameters based on extensive statistical analyses of these data.

It is important to emphasize that the model is a simple screening tool for prediction of average conditions, and that more informative results can be obtained from more detailed, calibrated models. However, BATHTUB's ease of use makes it ideal for rapid evaluation of potential nutrient-algal interactions.

2.3.2 Data Assembly

BATHTUB application to Copco and Iron Gate reservoirs addressed conditions observed near the dams, representing each reservoir as a single longitudinal segment with a stratified water column. Relatively intensive monitoring data for the two reservoirs exists for 2002 and 2005. These data, along with an analysis of mass balances, are presented in Kann and Asarian (2005), and Kann and Asarian (2007). Due to very short residence times in the winter high-flow season, summer algal concentrations in these reservoirs are most strongly affected by loading in and shortly prior to the growing season, consistent with the recommendations of Walker (1996). Flows and loads were therefore calculated for April to September in 2002 and May to September in 2005 (data are not available for April 2005), based on the results calculated by Kann and Asarian, as shown in Table 3.

Table 3. Flow and Nutrient Data for BATHTUB Application

	Copco		Iron Gate	
	2002 (Apr-Sep)	2005 (May-Sep)	2002 (Apr-Sep)	2005 (May-Sep)
Inflow (hm^3)	434	379	532	402
TP Load (kg)	119,380	59,000	122,300	53,700
TN Load (kg)	480,710	545,100	511,500	421,400
TIP Load (kg)	71,489	35,331	79,925	35,094
TIN Load (kg)	182,031	206,414	130,586	107,583
Summer TP (mg/L)	0.24	0.15	0.19	0.13
Summer TN (mg/L)	1.14	1.23	1.19	1.01
Summer Chlorophyll *a* (µg/L)	8.3	12.2	19.5	19.2

2.3.3 BATHTUB Application

Both Copco and Iron Gate reservoirs are known to have low net trap efficiency for nutrients, due to a combination of short residence times and apparent nutrient regeneration from the sediments under stratified conditions (Butcher, 2008). Kann and Asarian (2007) estimated that Copco Reservoir (for 2004-2005 conditions) retained about 9 percent of influent TN and TP, while Iron Gate retained about 3 percent of influent TP and 10 percent of influent TN. The TMDL model estimated (for 2000 conditions) that Copco retained about 1 percent of TP and 4 percent of TN, while Iron Gate retained about 6 percent of TP and 18 percent of TN. The low net retention rates suggest that net sedimentation rates should be lower than the defaults specified for the BATHTUB scoping tool. Accordingly, the TN and TP sedimentation calibration factors were set to 0.1.

With the revised sedimentation factors, the BATHTUB scoping tool provides a good representation of summer average TN and TP observed in the epilimnion near the dam in both reservoirs (Figure 1 and Figure 2). The model also captures the spatial gradient from Copco to Iron Gate and the relative temporal change between 2002 and 2005 conditions for TP.

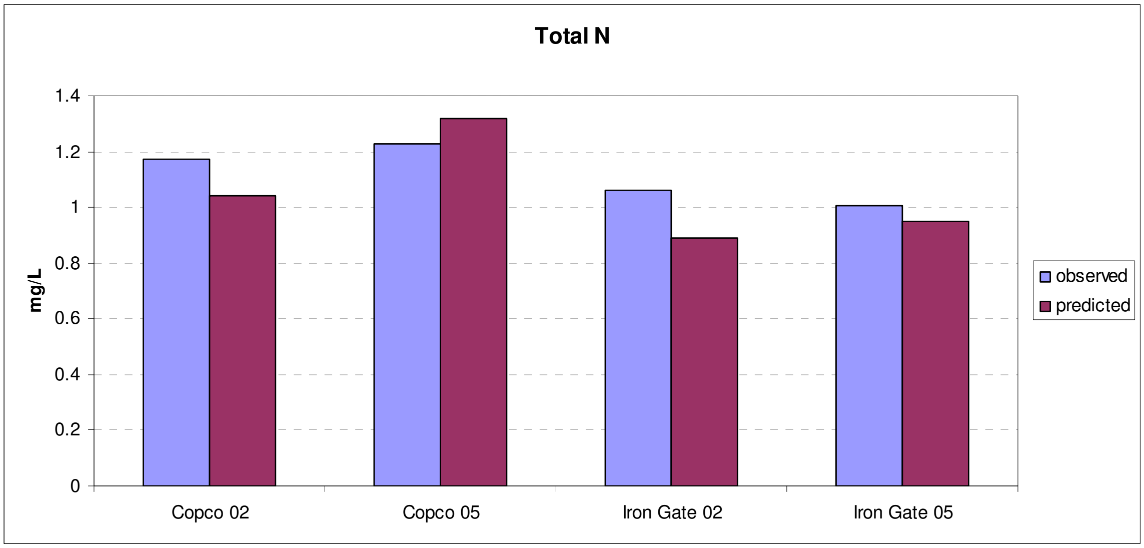

Figure 1. Observed and Predicted Total Nitrogen Concentrations in Copco and Iron Gate Reservoirs

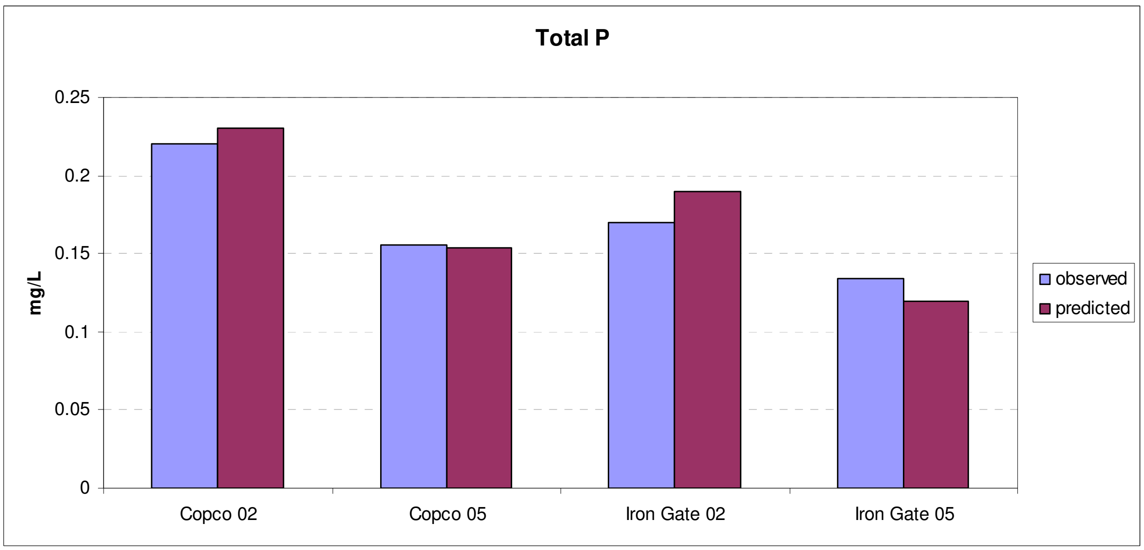

Figure 2. Observed and Predicted Total Phosphorus Concentrations in Copco and Iron Gate Reservoirs

Chlorophyll *a* results were generated without any changes to the default calibration factor of 1.0, and provide a reasonable match to observations (Figure 3). Given that chlorophyll *a* concentrations are highly variable in space and time, as well as the fact that chlorophyll *a* measurements may provide an imprecise measure of cyanobacterial density, these results are considered reasonable. In particular, small samples from right-skewed distributions, such as is typically observed for chlorophyll *a*, are prone to under-estimate the true mean concentration. Predictions for Copco could be brought closer in line with observations by decreasing the chlorophyll *a* calibration factor; however, the quantity and precision of available data do not appear to be sufficient to warrant such fine-scale adjustments.

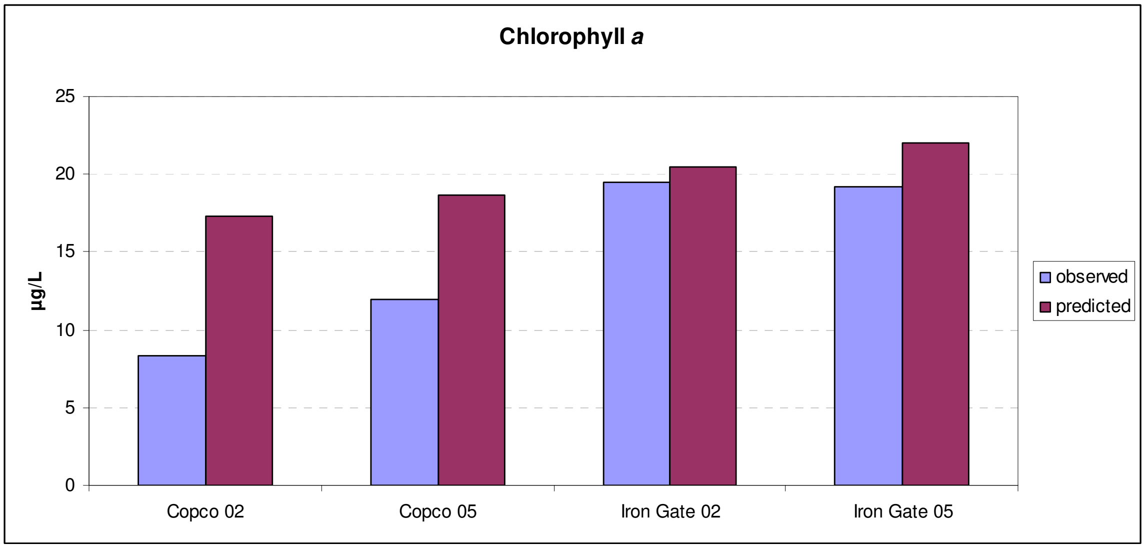

Figure 3. Observed and Predicted Chlorophyll *a* Concentrations in Copco and Iron Gate Reservoirs

The scoping model also predicts the exceedance probability for different concentration levels, based on the coefficient of variation (CV, standard deviation normalized to the mean) of concentrations. Results using the BATHTUB default CV (in natural log space) of 0.42 are shown in Figure 4, suggesting that occasional blooms in excess of 100 µg/L are consistent with the predicted summer average concentrations in Iron Gate, as well as in Copco Reservoir.

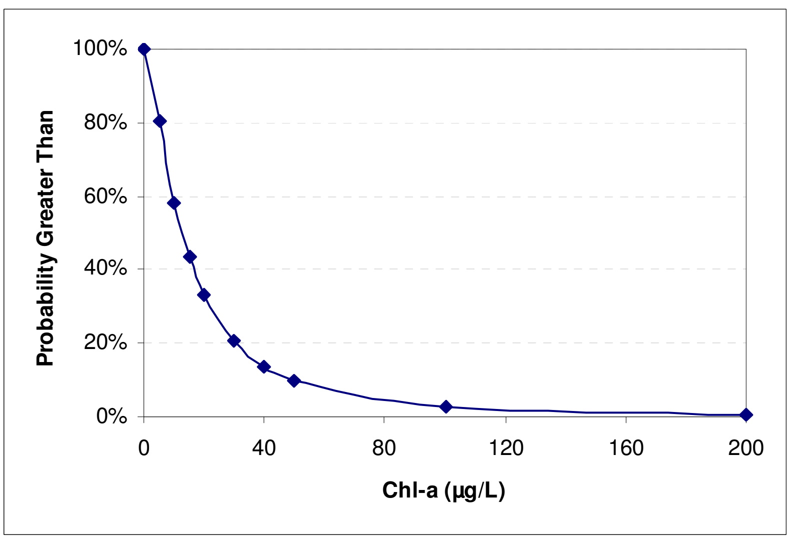

Figure 4. Predicted Distribution Curve for Chlorophyll *a* in Iron Gate Reservoir, 2005

Downing et al.'s (2001) regression equations for BGI as a function of TN and TP concentrations were applied to the predicted nutrient concentrations, and suggest that the algal community is likely to include a significant fraction of cyanobacteria on average (Table 4). The percentage of cyanobacteria predicted from TN concentrations is consistently lower than that predicted from TP concentrations, but both relationships indicate a potential for episodic cyanobacterial blooms, increasing the risk for microcystin toxin production.

Table 4. Cyanobacterial Dominance Predicted for Copco and Iron Gate Reservoirs

	Copco 2002	Copco 2005	Iron Gate 2002	Iron Gate 2005
BGI-P	0.27	-0.15	0.14	-0.27
Cyanobacteria % from BGI-P	56.7%	46.3%	53.5%	43.2%
BGI-N	-0.85	-0.54	-1.06	-0.98
Cyanobacteria % from BGI-N	29.8%	36.7%	25.7%	27.3%

Note: The "Blue Green Index" (BGI) is calculated using the regression relationships presented by Downing et al. (2001).

Application of the spreadsheet tool for year 2000 based on flows and nutrient loads predicted by the Klamath TMDL model yield similar results, with growing season average chlorophyll *a* estimated at 19.7 µg/L for Copco and 23.2 µg/L for Iron Gate. The cyanobacterial fractions of algal biomass are estimated at 64.0 and 59.9 percent using BGI-P, and 39.2 and 30.2 percent using BGI-N.

2.3.4 Potential Nutrient Numeric Endpoints

The BATHTUB scoping tool solves for combinations of TN and TP loading that are consistent with achieving a target growing season average concentration of chlorophyll *a*. Results consistent with achieving the CA NNE recommended BURC II/III boundary of 10 µg/L chlorophyll *a* as a growing season average concentration are shown in Figure 5 for the three years of model application.

The scoping tool predicts that the desired chlorophyll *a* target can be met by reducing phosphorus loading *or* nitrogen loading. The percentage reductions needed to achieve the 10 µg/L target are shown in Table 5. In terms of total algal biomass, it is not necessary to reduce loads of both nutrients to meet the target, as the growth will be controlled by the availability of the most limiting nutrient. These suggest that beneficial uses can be attained by reducing the TP load by approximately 90 percent or by reducing the TN load by approximately 65 percent. However, control by reducing only one nutrient would alter the N:P ratio, and changing the N:P ratio may well have other consequences for algal dynamics in the reservoir, as is discussed further in Section 2.4.

Year	Copco	Iron Gate
2000		2002		2005		
Figure 5. Allowable Load Curves to Achieve a 10 µg/L Summer Average Chlorophyll *a* Target

Table 5. Single Component Nutrient Reductions to Achieve a 10 µg/L Summer Average Chlorophyll *a* Target (April-September Loads)

Year	Total Phosphorus		Total Nitrogen	
	Copco	Iron Gate	Copco	Iron Gate
2000	89%	92%	67%	60%
2002	85%	89%	54%	53%
2005	81%	80%	65%	58%

The TMDL model is already calling for significant nutrient reductions to meet DO criteria. Under the dams-in water quality compliance scenario (T4BS1), the April-September 2000 phosphorus loads to Copco are reduced by 89 percent while the nitrogen loads are reduced 73 percent; the reductions in loads to Iron Gate are 88 percent and 74 percent, respectively. Notably, the proposed phosphorus reductions are very similar to those suggested in Table 5, while the proposed total nitrogen reductions in the compliance scenario are greater. Therefore, the T4BS1 scenario developed for dissolved oxygen management would also be expected to meet the algal density target, as developed in this document, to support the COLD and other beneficial uses in Iron Gate and Copco reservoirs.

In addition to reducing the total nitrogen and phosphorus loads, the T4BS1 scenario results in a change in the inorganic fraction of incoming nutrients, with a smaller inorganic fraction, which should also help damp algal response. Application of the BATHTUB tool for 2000 conditions with the T4BS1 nitrogen and phosphorus loads results in a predicted growing season average concentration of 6.6 µg/L in Copco and 4.1 µg/L in Iron Gate. Using Walker's default coefficient of variation for the natural log of chlorophyll *a* of 0.42 suggests that concentrations would be greater than 10 µg/L on 17.4 percent of growing season days in Copco and 2.8 percent of growing season days in Iron Gate.

The T4BS1 scenario also predicts reductions in cyanobacterial populations. With the reduced nutrient and algal settling rates used for BATHTUB application to existing conditions, calculations of the BGI from TN are low (10.8 and 7.2 percent of biomass as cyanobacteria in Copco and Iron Gate, respectively), while the BGI based on TP is reduced to near 25 percent (24.9 and 22.9 percent, respectively).

These results should be considered conservative (that is, including an implicit margin of safety) because the low net sedimentation rates of nutrients assumed for the application to existing conditions have not been altered. In fact, the T4BS1 scenario should result in greater dissolved oxygen concentrations at the sediment-water interface, resulting in lower rates of recycling of nutrients from the sediments, in turn causing higher net sedimentation rates for nutrients. If it is assumed that the effective net sedimentation rates increase to the default values given by Walker, the predicted summer average chlorophyll *a* concentrations in Copco and Iron Gate would decline to 5.0 and 3.0 µg/L, while the predicted cyanobacterial fractions of algal biomass would be 21 and 20 percent, respectively.

Predicted summer average nutrient concentrations in Iron Gate from the BATHTUB scoping tool – relevant to the analysis of downstream effects – are summarized in Table 6 for year 2000 conditions.

Table 6. Summer Average Nutrient Concentrations Predicted for Iron Gate Reservoir (Year 2000 Conditions)

	Existing Loads	T4BS1 Loads with Existing Sedimentation	T4BS1 Loads with Default Sedimentation	Change
TN (mg/L)	1.057	0.288	0.255	-76%
TP (mg/L)	0.267	0.037	0.030	-89%

These BATHTUB results are in good agreement with the CE-QUAL-W2 simulation of concentrations in Iron Gate outflow for the June-September 2000 period. The T4BS1 simulation (without benthic nutrient flux) shows a change relative to existing conditions of -73 percent for TN concentrations and -88.5 percent for TP concentrations.

2.4 MANAGEMENT TO REDUCE *MICROCYSTIS* BLOOMS IN RESERVOIRS

Conditions in Iron Gate and Copco reservoirs, including the risk of microcystin toxins, can clearly be mitigated by a general decrease in eutrophication potential, which would in turn reduce the frequency of cyanobacterial blooms, including *Microcystis* blooms. Other potential strategies to address microcystin levels include control of cyanobacterial dominance within blooms, and control of toxin-producing strains of *Microcystis* within cyanobacterial blooms. As demonstrated by Downing et al. (2001), the risk of cyanobacterial dominance increases with increasing levels of TN, TP, and algal biomass, and is also best addressed through a general reduction in eutrophication potential.

Many Cyanobacteria are able to control buoyancy, enabling them to alternate between light-rich (but nutrient poor) surface waters and nutrient rich (but light poor) waters lower in the water column, yielding a competitive advantage against passively floating algal species (Hyenstrand et al., 1998). Many bloom-forming Cyanobacteria are also able to tolerate higher temperatures than true algae. Lake management strategies that increase vertical mixing (counteracting the cyanobacterial buoyancy advantage) and decrease surface water temperatures may thus be useful pieces of an overall control strategy.

Earlier authors (e.g., Smith, 1983) had theorized that a key factor in promoting cyanobacterial dominance was a low N:P ratio, as many bloom-forming Cyanobacteria can fix atmospheric N_2 (although not *Microcystis aeruginosa*). Downing et al. demonstrate that this ratio is not a good predictor of cyanobacterial dominance.

While the N:P ratio is not a good predictor of general cyanobacterial dominance, it may play an important role in competition between different species of Cyanobacteria. Significantly, *Microcystis aeruginosa* does not fix atmospheric nitrogen, but the competing cyanobacterium *Aphanizomenon* does – suggesting that manipulation of nutrient ratios could cause a shift within cyanobacterial blooms from the toxin-producing *Microcystis* to non-toxin producing *Aphanizomenon*. Moisander et al. (2008) recently reported results of ongoing nitrogen and phosphorus fertilization experiments in Iron Gate and Copco using in-lake incubation chambers. Addition of inorganic nitrogen resulted in an increase in total phytoplankton biomass, *Microcystis* abundance, and microcystin concentrations under both high and low light conditions. Phosphorus additions increased *Microcystis* abundance only under low light conditions, whereas the addition of nitrogen or phosphorus decreased the relative abundance of *Aphanizomenon* by promoting growth of *Microcystis*. Based on this research, Moisander concluded that inputs of dissolved inorganic nitrogen to the reservoirs during the summer season are maintaining and increasing toxic blooms of *Microcystis*, and that reduction of nitrogen inputs to the reservoirs would reduce blooms of *Microcystis*. This suggests that management by reduction of nitrogen loads would yield dual benefits by both reducing the total algal biomass and shifting the cyanobacterial population away from *Microcystis* toward *Aphanizomenon*. The work is ongoing, and may yield valuable insights into optimal management of the reservoirs.

In sum, the proposed nutrient reductions appear to have good potential to address all five of the linkages between algal growth and beneficial use impairment discussed in Section 2.2.

1. Frequency of visible algal blooms will be reduced as average algal biomass decreases.
2. Production of microcystin toxins should decline as total algal biomass decreases and cyanobacterial dominance within the algal population is reduced.
3. Algal effects on the DO balance will be mitigated, as demonstrated in the existing TMDL model.

4. Export of organic matter downstream will be reduced as algal growth is reduced.
5. Reduction in cyanobacterial dominance will potentially result in a healthier aquatic ecosystem that supports an improved fishery.

3 Klamath River below Iron Gate

The Klamath River watershed encompasses 15,722 square miles in the states of Oregon and California, flowing from the Cascades in Oregon westerly and southerly to the Pacific Ocean in Del Norte Co., CA (see Figure 6). The analysis in this section addresses the major part of the flowing, freshwater portions of the mainstem Klamath River in California, running from the outlet of Iron Gate Reservoir near the Oregon border in Siskiyou County, CA to the confluence with the Trinity River in Humboldt County, CA and represents a major update to the analysis presented in Tetra Tech (2007).

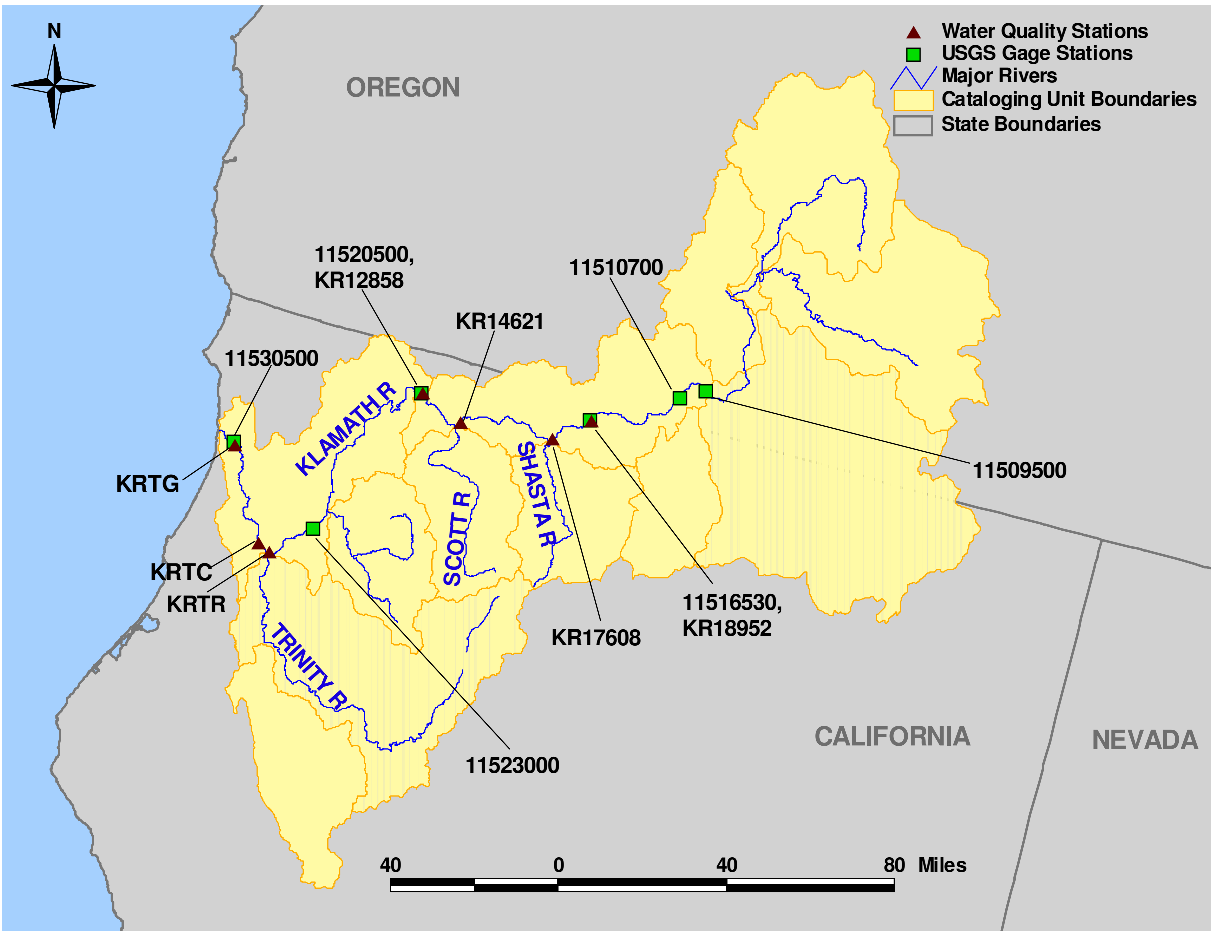

Figure 6. The Klamath River, Showing Selected Water Quality Sampling Stations and Flow Gages on the Lower Klamath River

3.1 Uses and Impairments

The Water Quality Control Plan (NCRWQCB, 2007) establishes multiple beneficial uses for the Klamath River below Iron Gate Reservoir (Table 7). A small portion of the river just upstream of the confluence with Trinity River is under the jurisdiction of the Hoopa Valley Tribe, while much of the Klamath River downstream of the Trinity River is under jurisdiction of the Yurok Tribe.

Table 7. Beneficial Uses of Klamath River below Iron Gate Reservoir

Code	Use	Status
MUN	Municipal and Domestic Supply	E

MIGR	Migration of Aquatic Organisms	E
SPWN	Spawning, Reproduction, and/or Early Development	E
AQUA	Aquaculture	P
CUL	Native American Culture	E

Notes: E – Existing Use; P – Potential Use; NA – Use not applicable.

California's North Coast Regional Water Quality Control Board has included the free-flowing portion of Klamath River down to the Trinity River on its Clean Water Act Section 303(d) list of impaired waters. Identified impairments include excursions of criteria for nutrients, temperature, and organic enrichment/low DO for segments of the river in California, which are classified for COLD and SPWN beneficial uses.

3.2 POTENTIAL NNE TARGETS

Nutrient loading in the Klamath River produces high levels of periphytic algae. The Hoopa Valley Tribal Environmental Protection Agency has adopted periphyton criteria for the reach of the Klamath River within the Hoopa Valley Indian Reservation. To date, the North Coast Regional Board has not established targets for this endpoint.

While periphyton is included in the Klamath River TMDL models, limited periphyton data were available for model calibration during the years of interest. Calibration focused largely on DO concentrations and diurnal variability in DO, which implicitly include the effects of periphyton and other aquatic vegetation, rather than calibrating directly to periphyton density.

It is important to evaluate periphyton as a response endpoint for several reasons. First, periphyton affects the balance of DO and pH in the river. Second, excess periphyton growth can directly impair COLD, SPWN, and REC designated uses. Finally, in the Klamath River excess periphyton growth (particularly development of *Cladophora* beds) may present an additional important source of risk for maintenance of a healthy salmonid population. This risk hypothesis is summarized in Kier Associates (2005) as follows:

> …*Ceratomyxa shasta* is a myxozoan parasite that causes major problems for the health of juvenile salmonids in the Klamath River. Infection rates are extremely high and in many years results in the death of significant portion of the juvenile salmonids in the Klamath River. Nichols and Foott (2005) estimated that in 2004, 45% of juvenile fall-run Chinook salmon were infected with *C. Shasta* and that the majority of those fish would not survive, and that impact of a loss of that many fish could rival the 2002 adult fish-kill where over 33,000 adult salmon died.
>
> High nutrient levels may be stimulating luxuriant growth of *Cladophora*, a filamentous green algal species. *Cladophora* beds are a favored habitat for polychaete worms that are a host for *C. Shasta* (Stocking and Bartholomew, 2004). The high incidence of *C. Shasta* in the Klamath River may be due to an increase in polychaete populations caused by an increase in polychaete habitat (Stocking and Bartholomew, 2004)… To reduce the incidence of *C. Shasta* infection in the Klamath River, it may be insufficient to improve pH and D.O. alone to reduce fish stress. It also may require reduction in parasite loads by reducing nutrients to reduce the prevalence of *Cladophora* and hence *C. Shasta*'s polychaete host.

Water quality objectives for DO and pH are defined in basin plans, and the relationship between these endpoints, planktonic algal growth, and nutrients is well addressed in the existing calibrated TMDL model. Where a site-specific calibrated nutrient response model exists, this provides the best means of developing appropriate site-specific nutrient numeric endpoints. The North Coast Regional Water Quality Control Board, however, has not yet proposed criteria for periphyton in this river (although the Hoopa have), and this aspect of nutrient response was not the primary focus of the existing TMDL modeling effort.

The Hoopa Valley Tribal Environmental Protection Agency (Kier Associates, 2005; Hoopa Valley TEPA, 2008) recently adopted periphyton standards for the short section of the lower Klamath River on the Hoopa Valley Reservation at Saints Bar just upstream of Trinity River. In addition to DO and pH, they selected periphyton density as an endpoint for criteria development, and initially recommended a maximum annual periphyton biomass of 100 mg/m^2 of periphyton chlorophyll *a*. The criterion was subsequently revised to read as follows (Hoopa Valley TEPA, 2008):

> *Periphyton -For the Klamath River only (Trinity River standards yet to be developed), the maximum annual periphyton biomass shall not exceed 150 mg chlorophyll a/m^2 of streambed area.*

The California NNE Approach (Tetra Tech, 2006) recommends setting response targets for benthic algal biomass in streams based on maximum density as mg/m^2 chlorophyll *a*. For the COLD and SPWN beneficial uses, the recommended BURC I/II boundary is 100 mg/m^2, while the BURC II/III boundary is 150 mg/m^2. Existing conditions in the Klamath are clearly often above the BURC II/III boundary, indicating impairment of these uses.

Of particular interest for the Klamath, the risk of *Cladophora* (a filamentous green algae) prevalence (and corresponding large polychaete populations) increases with increasing maximum benthic chlorophyll *a*. Welch et al. (1988) found that 20 percent or more cover by filamentous green algae was correlated with maximum benthic chlorophyll *a* greater than 100 mg/m^2, while Horner et al. (1983) concluded that biomass levels greater than 150 mg/m^2 often occurred with enrichment and when filamentous forms were more prevalent. These findings support the use of the BURC boundaries in establishing targets for the Klamath River. The Klamath River was historically mesotrophic (Kier Associates, 2005), and water quality conditions in the lower river are exacerbated by large blooms of nitrogen-fixing cyanobacteria (blue-green algae) in Upper Klamath Lake and in the Klamath reservoirs. This suggests that the BURC II/III boundary of 150 mg/m^2 maximum benthic chlorophyll *a* may be most appropriate for the Klamath. The CA NNE approach, however, also recognizes that nutrients occur naturally, and vary in relationship to soils, geology, and land cover, in some cases potentially resulting in benthic chlorophyll *a* concentrations in excess of 150 mg/m^2 under natural conditions. Where this is the case, the natural condition would supersede the proposed target.

3.3 Application of NNE Scoping Tools

The CA NNE approach proposes a numeric target for benthic chlorophyll *a*, which is a secondary or response indicator relative to nutrients. To achieve the target, an analysis is required to link nutrient concentrations or load to benthic algal response. Under a previous Work Assignment, Tetra Tech (2007) developed an analysis of potential nutrient numeric endpoints for the lower Klamath downstream of Iron Gate. That analysis relied on a compilation of nutrient monitoring data through 2004. Since that time, data have become available for 2005-2007, and a detailed review of the monitoring data has resulted in modifications of the data through 2004. The sections that follow thus represent an update, revision, and extension of the previous analysis for the free-flowing reaches of the Klamath River below Iron Gate Dam.

3.3.1 Benthic Biomass Tool

The CA NNE *Technical Approach to Develop Nutrient Numeric Endpoints for California* (Tetra Tech, 2006) includes (Appendix 3) the development of a simplified scoping tool of maximum periphyton density in streams. This NNE Benthic Biomass spreadsheet tool is distributed as an Excel spreadsheet. The tool calculates both algal density under average conditions and benthic chlorophyll *a*. Both are estimated using a variety of methods:

- Dodds (1997) method (both mean and maximum)
- Dodds (2002) method (both mean and maximum, using corrected parameters from 2006 erratum[1])
- Standard QUAL2K Model method (maximum)
- Revised QUAL2K Model method (maximum)
- Revised QUAL2K, with adjustment for days of biomass accrual (maximum)

The maximum algal contribution to dissolved oxygen deficit is also calculated, using the Revised QUAL2K Model method. Lastly, the tool allows the user to supply a target (either algal density or benthic chlorophyll *a*), select a calculation method, and the tool will display a graph of allowable TN and TP to meet the target.

The QUAL2K approach is based on the steady-state limit approximation of the benthic algae simulation contained in version 1 of the QUAL2K model (Chapra and Pelletier, 2003). This simulates benthic algal response to nutrient concentrations and light availability. An estimate of the maximum (spatially averaged) response to a given set of forcing functions is obtained as the steady-state asymptote of the model. Because detailed validation data were not available for California, parameters of the model were

[1] The original equations appeared in Dodds, W.K., V.H. Smith, and K. Lohman, 2002, Nitrogen and phosphorus relationships to benthic algal biomass in temperate streams (*Can. J. Fish. Aquat. Sci.*, 59:865-874). The equations were corrected in a 2006 erratum (*Can. J. Fish. Aquat. Sci.*, 63: 1190-1191). The Algal Biomass Spreadsheet beginning with v. 13 (2/28/07) incorporates the corrected coefficients provided in the erratum.

adjusted to obtain approximate agreement with the Dodds (2002) empirical model when applied to California EMAP and Regional Board 6 periphyton data (see Tetra Tech, 2006). It should be noted that this approach introduces considerable uncertainty into predictions for individual streams, and development of a calibrated, site-specific model would be preferable when sufficient data are available. Version 2 of QUAL2K (Chapra et al., 2006) contains significant modifications to the simulation of benthic algae, including an evaluation of nutrient limitation based on the Droop model of changes in intracellular nutrient quotas. Our analysis shows, however, that the changes to Version 2 result in only minor changes to the shape of the steady-state solution, and do not improve the ability of the model to match the Dodds predictions.

Tetra Tech (2006) also developed a "revised QUAL2K" method for predicting maximum periphyton biomass – also tuned to the Dodds (2002) results for the California data set. This approach uses the QUAL2K v.1 solution, but assumes that the "available" fraction of total nutrient used in the model varies as a function of concentration:

$$Availability\ Fraction\ (AF) = 1 - \frac{\gamma}{1 + \exp(\alpha - \beta \log_{10} C)}$$

in which α, β, and γ are parameters from a logistic regression model fit to data, as described in Tetra Tech (2006), and *C* is the total nutrient concentration. Availability here represents more than just the inorganic fraction of nutrients, as it may also reflect factors such as mat thickness, vertical gradients in the water column, and temporal variability in the inorganic fraction.

Interestingly, the total effect on the Monod growth limitation can be equivalently expressed as an effect on nutrient availability or as an inverse effect on the half-saturation constant:

$$\phi = \frac{AF \cdot C}{k_s + AF \cdot C} = \frac{C}{k_s / AF + C},$$

in which *AF*, the available fraction, is a function of total nutrient concentration, *C*, and k_s is the constant Monod half-saturation constant used in the standard QUAL2K model.

The NNE Benthic Biomass spreadsheet tool provides a simple, but robust method for relating nutrient concentrations to benthic algal density. Specifically, the maximum spatially averaged periphyton density is predicted as a function of summer nutrient concentrations and other hydrologic and physical characteristics. A variety of established prediction methods are included. These yield results that are generally similar but differ from one another, reflecting the uncertainty that is present in such predictions.

It is important to provide some clarification on the "maximum" density that is predicted by the tool. What the model predicts is the spatially averaged maximal supported response to a given set of forcing conditions, without reductions by grazing or intermittent die off. In other words, it is the average concentration expected under optimal growth conditions for a given set of nutrient concentrations. It is not the maximum point density that can be observed on a single rock, which can be considerably higher. In addition, it should not be considered as the maximum response to average nutrient conditions: if nutrient concentrations fluctuate above average conditions for a sufficient length of time, additional algal growth will likely occur. Finally, it should be noted that the maximum is difficult to observe. Even if accurate spatially averaged densities are measured, they will often be less than the model-predicted maximum. When performing correctly, the tool should provide an approximate upper-bound envelope on spatially averaged observations.

Because the NNE tools provide only a scoping-level analysis of nutrient targets, they may be superseded by a site-specific calibrated nutrient response model where available. The existing Klamath River TMDL models include, but are not calibrated to periphyton. Instead, calibration focused on DO because of concerns regarding the representativeness of the periphyton data that are available from the Klamath, due to small sample size and lack of replication. As noted above, accurate prediction of DO implicitly requires a reasonable representation of periphyton and other aquatic vegetation. Continued and improved periphyton sampling would further strengthen the TMDL model application and allow its extension to quantitative analysis of impacts other than DO.

3.3.2 Data

Data have been collected at many sites on the Klamath River, but few stations have consistent long runs of data. For the purpose of this analysis, seven sites on the mainstem Lower Klamath River in California were selected that had reasonable amounts of water quality and periphyton data. These sites are (see also Figure 6 above):

Table 8. Selected Water Quality Monitoring Stations on the Lower Klamath River

Station Number	Station Name	River Mile
KR18952	Klamath River below Iron Gate Dam	189.52
KR17608	Klamath River above Shasta River	176.08
KR14261	Klamath River above Scott River	142.61
KR12858	Klamath River at Seiad Valley	128.59
KRWE	Klamath River above Trinity River (Weitchpec)	43
KRTC	Klamath River below Trinity River above Tulley Creek	35.5-39.2
KRTG	Klamath River at Turwar	5.79

3.3.2.1 Algal Response Data

USEPA and cooperators undertook four rounds of periphyton sampling in the river in 2004 (Eilers, 2005). The published report describes the results of only one of these sampling rounds; results for the remainder were provided by the North Coast Regional Water Quality Control Board. All four sampling rounds followed the same sampling and analytical methodology.

Results of the periphyton sampling include benthic chlorophyll *a*, percent coverage, wet weight, and ash-free dry weight (AFDW). Unfortunately, the information on periphyton density (benthic chlorophyll *a* and AFDW) was obtained from relatively small and separate samples. Specifically, as described in Eilers (2005), determinations of benthic chlorophyll *a* and AFDW were each made by scraping an area of 25 mm x 75 mm from a single rock. The two measurements were made on separate samples, from separate rocks. Because there is not information from multiple points on multiple transects, the measurements may reflect a considerable amount of local variability, and may not be assumed to be representative of average densities in the reach sampled. Further, as the chlorophyll *a* and AFDW estimates come from separate rocks they are not necessarily paired samples, and inferences regarding the ratio of chlorophyll *a* and AFDW are suspect.

Results of the 2004 sampling are summarized for selected stations in Table 9.

Table 9. Summer 2004 Periphyton Sampling in the Klamath River

Station	Average Periphyton Chlorophyll *a* (mg/m²)	Maximum Periphyton Chlorophyll *a* (mg/m²)	Average Ash-Free Dry Weight (g/m²)	Maximum Ash-Free Dry Weight (g/m²)	Autotrophic Index (Average)
KR18952 – Klamath River below Iron Gate Dam	304.1	462.0	20.9	33.9	606.3
KR17608 – Klamath River above Shasta River	706.1	186.0	44.8	150.9	528.0
KR14261 – Klamath River above Scott River	120.4	353.0	68.7	141.3	684.6
KR12858 – Klamath River at Seiad Valley	65.5	122.0	25.6	54.4	1,982.2
KRWE – Klamath River above Trinity River	126.4	312.5	84.7	202.0	2,420.9
KRTC – Klamath River below Trinity	8.0	10.6	47.6	106.1	6,283.0
KRTG – Klamath River at Turwar	15.1	15.1	71.4	122.5	1,596.5

Notes: Samples at KR14261 combined with nearby samples from Walker Bridge Rd. Samples at KR17608 combined with nearby samples at Colliers Rest and Cottonwood Creek.

As noted above, the chlorophyll *a* and ash-free dry weight (AFDW) results are obtained from separate samples. Nonetheless, the autotrophic index (AI; ratio of AFDW to chlorophyll *a*) values are generally high, and appear to increase downstream. Collins and Weber (1978) suggest that an AI value greater than 400 is generally representative of "polluted" conditions in which the periphyton contains a high percentage of heterotrophs. In the lower Klamath, the AI values may reflect high levels of input of organic matter from eutrophic reservoirs upstream. The 2004 samples at KRTC and KRTG have very low chlorophyll *a* densities, but moderately high AFDW, suggesting largely heterotrophic communities.

Unfortunately, this sampling effort does not appear to provide a firm basis for calculating the ratio of chlorophyll *a* to AFDW (as mg/g), which is a key parameter for application of the QUAL2K-based prediction methods. The ratios from individual sample events reported by Eilers range from 0.1 to 96 mg/g, well outside of the range expected from algal stoichiometry, with a median of 1.1 and average of 7.1 (Figure 7) – probably due to the fact that the analyses are not from the same samples.

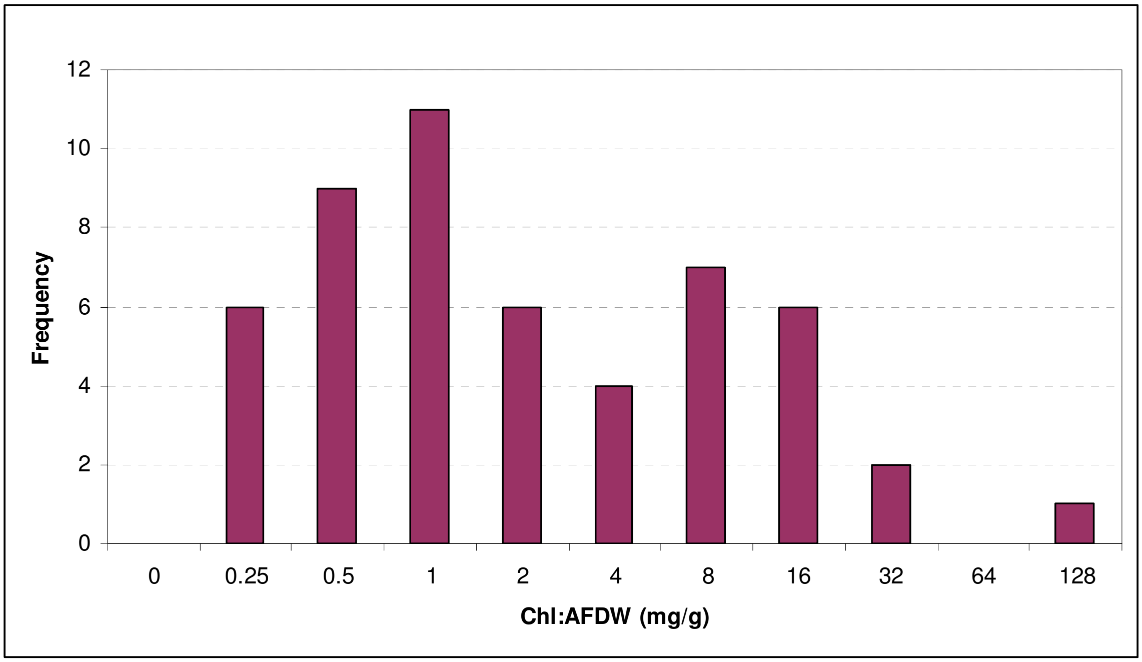

Figure 7. Histogram of Apparent Chlorophyll *a* to AFDW Ratios in 2004 Periphyton Data

Additional periphyton samples were collected by the Yurok Tribe in 2004 and 2006-2007 at KRWE (Weitchpec) and KRTG (Turwar). The 2004 results contain species composition data and AFDW, but not chlorophyll *a*. At KRWE, the average AFDW was 87.2, the maximum 122.5. At KRTG, the average AFDW was 108.2, the maximum 134.5. The 2006-2007 chlorophyll *a* results are shown in Table 10, reflecting revisions to the 2007 laboratory results reported to Tetra Tech by the Regional Board on April 7, 2008. AFDW was not reported for these data. The 2006 chlorophyll *a* results appear anomalously high, for unknown reasons. Communities at these stations were usually dominated by diatoms.

Table 10. Yurok Periphyton Sampling Results for 2006-2007

Station	Year	Average Periphyton Chlorophyll *a* (mg/m^2)	Maximum Periphyton Chlorophyll *a* (mg/m^2)
KRWE (Weitchpec)	2006	609.3	1086.2
	2007	123.6	326.0
KRTG (Turwar)	2006	325.8	651.7
	2007	73.4	163.0

It should be emphasized that it is very difficult to obtain reach average chlorophyll *a* densities in the Klamath, due to its size, depth, and velocity. It appears that all samples taken to date do not qualify as spatially averaged values, but are more representative of point concentrations. As a result, some of the observed maximum values are likely to be greater than the model predictions, which represent spatially averaged algal response under optimal growth conditions, not the maximum point density.

3.3.2.2 Chemical Water Quality

In contrast to periphyton, an extensive database of chemical water quality exists collected by multiple agencies. Earlier data were compiled into an Access database in 2004. Some of the earlier data have since been corrected and substantial amounts of additional data have been collected since 2004. Accordingly, Tetra Tech worked with the Regional Board to develop a comprehensive tabulation of nutrient monitoring data in the Klamath.

The river data were separated into three time periods, 1996-2001, 2002-2004, and 2005-2007, which correspond approximately to the periods for which the reservoir BATHTUB scoping tools have been developed (2000, 2002, and 2005), and the periods during which periphyton samples are available (2004 and 2006-2007).

Statistics were calculated for the summer season (June – September). As periphyton is expected to have a moderately long response time to ambient nutrient concentrations, extreme values may not be particularly relevant. Therefore, the central tendency and range of the ambient data were described by the mean, median, 25th percentile, and 75th percentile (Table 11). To account for the influence of fluctuations in nutrient concentration on maximum algal response, predictions are made at the 75th percentile value. The ratio of total N to total P at these stations is typically less than the Redfield ratio of 7.2 (representing the typical cellular composition of algae), suggesting that nitrogen may frequently be the nutrient that is most limiting on algal growth.

3.3.2.3 Physical Data

Flow gaging data, and associated measurements, are available from five USGS gages between Iron Gate Dam and the Klamath estuary. Additional information on stream geometry, velocity, and stage is available from the calibrated hydrodynamic model of the Lower Klamath (PacifiCorp, 2005).

Table 11. Summer Nutrient Water Quality at Klamath River Stations below Iron Gate

		1996-2001				2002-2004				2005-2007			
	Station	Count (days)	Mean	25%^{le}	75%^{le}	Count (days)	Mean	25%^{le}	75%^{le}	Count (days)	Mean	25%^{le}	75%^{le}

Notes: Total Nitrogen calculated as some of Total Kjeldahl Nitrogen (TKN) plus NO_3-N plus NO_2-N where available. Non-detects treated as one-half the detection limit. Organic N calculated as TKN minus NH_3-N. Organic P calculated as Total P minus PO_4-P.

3.3.3 NNE Tool Application

The California NNE benthic biomass scoping tool was applied to the Klamath River in California to provide a scoping-level estimate of nutrient targets. Details on the development and use of this tool are available in Tetra Tech (2006).

Physical parameters for the scoping tool are summarized in Table 12 and explained further below.

Table 12. Parameters Specified for the NNE Tool Application

Station	Typical Summer Velocity (m/s)	Summer Depth for Analysis (m)	Unshaded Summer Solar Radiation (cal/cm^2/d)	Light Extinction Coefficient (m^{-1})	Days of Accrual	Chlorophyll *a* to AFDW Ratio
KR18952	0.65	0.45	528	0.725	185.7	5
KR17608	0.65	0.45	584	0.725	185.7	4
KR14261	0.69	0.45	527	0.725	122.8	4
KR12858	0.61	0.45	527	0.725	122.8	4
KRWE	0.69	0.45	524	0.760	81.9	4
KRTC	0.69	0.45	524	0.760	81.9	4
KRTG	0.69	0.45	526	0.760	69.1	4

Velocity

Stream velocity at each site was input as the “typical” summer value shown in the output of the RMA model of the Klamath River.

Depth

The RMA model output provides information on stage (or maximum depth) at each station, and average depth can be inferred from flow and cross-sectional area. However, the Klamath is a relatively wide river, and much of the potential benthic algal problem is believed to be associated with shallower water. It is therefore appropriate to evaluate impact at shallower depths, where light extinction in the water column is less of a factor. The 2004 periphyton samples were all collected in shallow water at a depth of approximately 0.45 m. Therefore, this depth was used in the scoping model applications.

Solar Radiation

Unshaded solar radiation for the summer period (June-August) was estimated based on latitude using the routine incorporated in the Benthic Biomass spreadsheet. The spreadsheet incorporates an approximation for shading effects on light availability as well. No data on local canopy and topographic shading were available; however, the majority of the Lower Klamath channel appears to be relatively open, so no shading was assumed, except at Seiad Valley. In that reach, the river flows in a N-S direction, whereas other sampled reaches have an approximately E-W orientation. Therefore, there is likely to be more topographic and canopy shading at Seiad Valley, and a value of 40 percent shading was selected.

Light Extinction Coefficient

Light extinction was estimated from turbidity. In general, light extinction is a function of water itself, dissolved colored organic material, phytoplankton, and inanimate particulate matter (Effler et al., 2005), and occurs through a combination of adsorption and scattering. In flowing streams, scattering by inorganic particulates is usually the dominant factor in light extinction, while scattering in the water column is directly measured by a nephelometric turbidity meter as NTU (Gallegos, 1994). Therefore, an approximately linear relationship of light extinction to turbidity is expected in streams. Rather than implementing a complete optics model, we therefore rely on the simple empirical relationship of Walmsley et al. (1980), who established a regression relationship $K_e(PAR) = 0.1\ T + 0.44$, where $K_e(PAR)$ is the extinction rate of photosynthetically active radiation (PAR, per meter) and T is nephelometric turbidity (NTU). The relationship will vary according to the nature of suspensoids (Kirk, 1985), but is similar to results of other authors who suggest slopes of K_e relative to turbidity in the range of 0.06 to 0.12. Because turbidity has only a small effect on available light at the depths analyzed, the Walmsley relationship appears acceptable. The extinction coefficient was then estimated based on median summer turbidity, which ranged from 2.5 to 3.2 NTU.

Accrual

The scoping model provides an option to evaluate effects on expected maximum algal density based on days of accrual, using the relationship of Biggs (2000), where accrual time is defined as the number of days between events three-times the median flow. Accrual time was analyzed at each of the USGS gages. Because the Klamath is a large river with a multi-day response time, the number of events per year was estimated based on the count of times the hydrograph crossed the three-times-median threshold, rather than the number of individual days above the threshold. Resulting estimates (Table 13) were extrapolated to the nearest water quality monitoring station. The system shows a pattern of decreasing time between scouring events with distance downstream as additional major tributaries join.

Table 13. Estimated Days of Accrual (1985-2005 Data)

USGS Gage	Average Days of Accrual
11516530: Klamath River below Iron Gate	185.7
11520500: Klamath River near Seiad Valley	122.8
11523000: Klamath River at Orleans	81.9
11530500: Klamath River at Klamath	69.1

Half-Saturation Constants

Lacking site-specific data, half-saturation constants for nutrients are set at the levels described in Tetra Tech (2006). For the standard QUAL2K model, the optimized half-saturation constants were 0.206 mg/L for inorganic N and 0.00853 mg/L for inorganic P (Table 4 in Appendix 3 of Tetra Tech, 2006). For the revised QUAL2K model, the half-saturation constants are defined in relation to total nutrient concentrations, and vary from 0.0260 to 2.83 mg/L for total N, and from 0.0205 to 0.0470 mg/L for total P following the logistic regression model (Table 6 in Appendix 3 of Tetra Tech, 2006).

Chlorophyll *a* to AFDW Ratio

One of the most problematic parameters is the chlorophyll *a* to AFDW ratio (mg/g), where AFDW represents the fixed carbon biomass. The need for this parameter arises when the model formulation predicts biomass (as is done in the QUAL2K-based approach), while the target is specified as chlorophyll *a*. The ratio translates between the two, but can be highly variable. As noted above, only the 2004 sampling examined both AFDW and benthic chlorophyll *a*, but analyses were from small samples and the chlorophyll *a* and AFDW measures were obtained from scrapings from different rocks. These data do not provide a reliable basis for estimating the ratio in the Klamath.

Selection of an appropriate ratio is complicated by the fact that periphytic communities contain a mix of photosynthesizing autotrophs and heterotrophs, including bacteria and fungi, whose growth is based on allochthonous carbon sources. The models are supposed to predict only photosynthetic biomass, but heterotrophs can also take up nutrients from the water column, so the predicted response of biomass as a function of nutrient concentrations likely includes both heterotrophic and autotrophic biomass. Further complications arise because (1) some algae exhibit mixotrophy, in which they are able to assimilate energy from fixed carbon compounds as well as by photosynthesis, and (2) exudates of benthic phototrophic algae may support bacterial and fungal heterotrophic populations, thus tying the heterotroph density to photosynthetic production.

In the development of the QUAL2K method (Tetra Tech, 2006), parameters of QUAL2K were "tuned" to provide a match to the predictions of Dodds' (2002) empirical model of maximum algal density when a chlorophyll *a* to AFDW ratio of 2.5 was assumed. Selection of this value was an appropriate compromise for a cross-sectional dataset, as the ratio of 2.5 corresponds to an autotrophic index of 400, generally presented as the upper limit of clean water conditions.

The CA NNE document (Tetra Tech, 2006) also noted that "alternate, site-specific ratios may be appropriate in specific waterbodies where appropriate information is available." For the Klamath, the Dodds method appears to underpredict maximum observed chlorophyll *a*, which also introduces a tendency for the QUAL2K-based methods, which are tuned to the Dodds method, to underpredict the maxima. Therefore, the chlorophyll *a* to AFDW ratio was increased from 2.5 to 4.0 at all stations except the station below Iron Gate, where a value of 5.0 was used.

3.3.4 Exploratory Data Analysis

Before applying the spreadsheet tool, an exploratory analysis was undertaken to examine the correlation between benthic chlorophyll *a* and nutrient concentrations. Both the average and the maximum benthic chlorophyll *a* from the 2004 sampling are plotted against the 75th percentile of summer average TN and TP concentrations from 2002-2004 water quality monitoring data in Figure 8. This suggests that observed periphyton density is indeed correlated to nutrient concentrations, with the strongest correlation (shown by higher R^2 value) between the observed maximum chlorophyll *a* and TN concentrations.

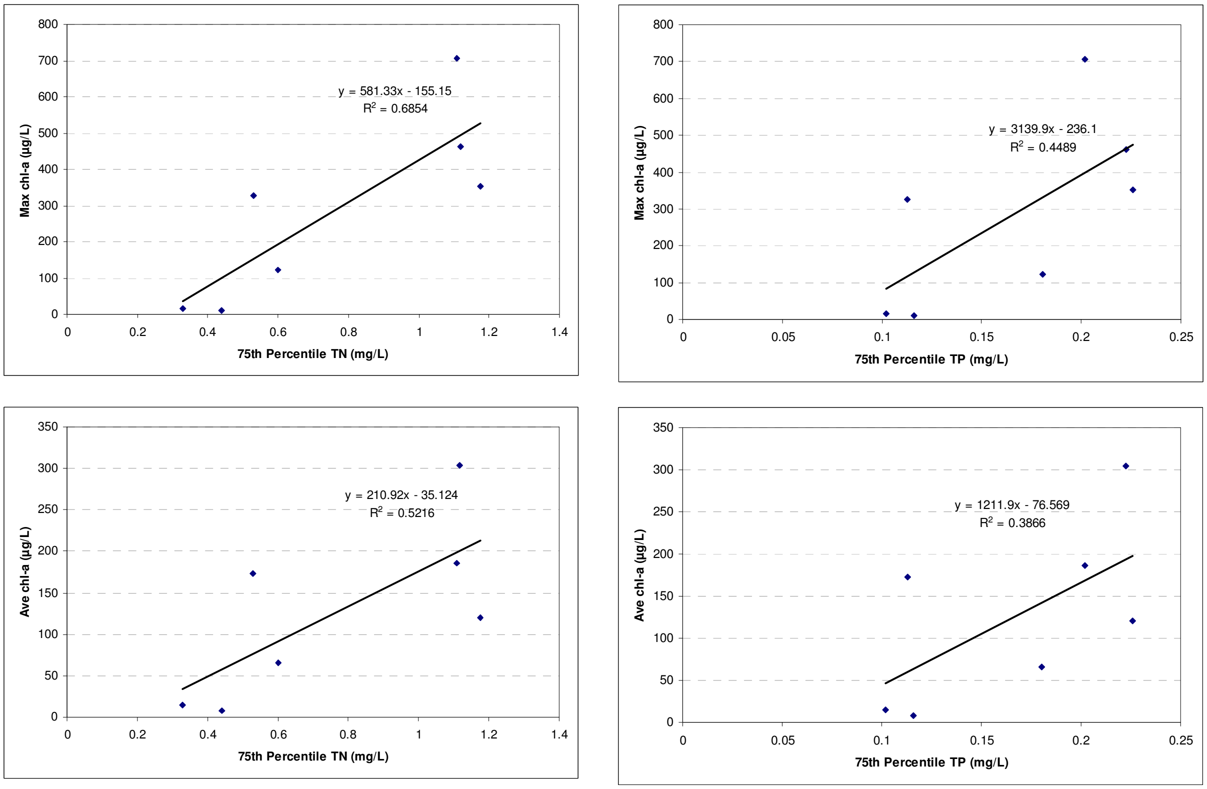

Figure 8. Relationship of Observed Periphyton Chlorophyll *a* to Nutrient Concentrations, 2004 Klamath Sampling

3.3.5 NNE Results

The NNE Benthic Biomass Predictor tool provides a variety of empirical and simplified parametric model approaches to predicting benthic algal response to ambient physical and chemical conditions. For this application, the tool was first used to predict maximum benthic chlorophyll *a* at each of the sites. As discussed in Tetra Tech (2006), benthic algal density is highly variable in time and space, and simplified models generally seem to do a better job of predicting the upper-bound estimate that describes maximum benthic algal density. The tool provides access to multiple predictions, but only three are presented here, all calculated at the 75^{th} percentile summer nutrient concentration, as described above in Section 3.3.2. Of the empirical approaches, results are shown for the latest version of the Dodds model (Dodds, 2002), while for parametric approaches the results for both the standard QUAL2K and revised QUAL2K models (which are tuned to correspond to the Dodds' results on small streams) are shown, the latter both with and without an accrual adjustment (Table 14). The accrual adjustment has little effect on the upstream stations (where the estimated days of accrual are large), but does have a noticeable effect from station KRWE downstream. Of the other available methods, the 1997 version of the Dodds model has been superseded by the more detailed analysis of Dodds (2002). The Dodds method is of particular interest for comparison because results do not depend on the chlorophyll *a* to AFDW ratio.

Table 14. Predicted and Observed Maximum Benthic Chlorophyll *a* (mg/m^2)

Model predictions of maximum benthic chlorophyll *a* concentrations for 2002-2004 are plotted against the 2004 observations of maximum and average concentrations in Figure 9.

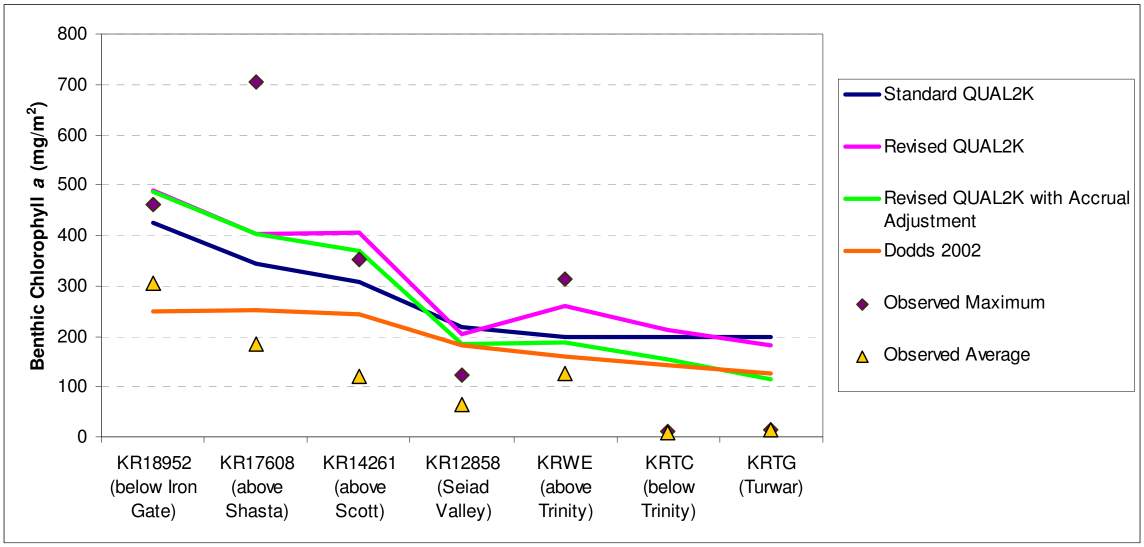

Figure 9. Model Predictions of Maximum Benthic Chlorophyll *a* for 2002-2004 and Observed Densities for 2004

None of the methods provide a perfect match to observations. Indeed, only general qualitative comparisons can be made, as the model predicts spatially averaged responses, whereas the observations reflect point data. In general, the revised QUAL2K approaches appear to do a reasonable job of replicating the spatial trend in observed maxima, while the Dodds results tend to be low. At three of seven stations, the predicted maximum using the QUAL2K approach is greater than the observed – which may only mean that the maximum was not sampled. At two other stations, the QUAL2K predictions are well less than the observed maximum. This may reflect the fact that the observed data are obtained from very small samples, without replication, that may not be representative of spatially averaged conditions in the reach.

Additional comments are warranted regarding several of the stations. For the station above Shasta, the plotted maximum of 706.1 mg/m^2 is for a sample taken at the mouth of Cottonwood Creek, a few miles upstream of station KR17608. Two samples taken at KR17608 had a maximum of only 81.5 mg/m^2. Reported maxima at the downstream stations of KRTC and KRTG were very low in 2004 (less than 20 mg/m^2); however, the Yurok samples from 2006 had a maximum of 652 mg/m^2 at KRTG. The 2004 results at these stations may be biased low relative to the seasonal maximum because they do not include samples from late summer, when periphyton densities are typically at their peak.

Both the data and the model representation of the data are subject to considerable uncertainty. Conditional on the suitability of the model, the tool can then be used to predict nutrient concentration targets needed to achieve a specified maximum algal density. As noted above, for the COLD and SPWN uses present in the Klamath, Tetra Tech (2006) recommends that the target should generally be between 100 mg/m^2 (BURC I/II boundary below which conditions may be deemed acceptable) and 150 mg/m^2 (BURC II/III boundary above which conditions are deemed unacceptable) for these designated uses.

For the Klamath, the models generally suggest that smaller reductions in total nitrogen than in total phosphorus are needed to reach the target range, and further that total phosphorus concentrations would need to be reduced to very low levels to achieve control of benthic algal growth by phosphorus alone. (Achieving the 100 mg/m^2 target by limiting phosphorus alone would require a total P goal of 2 µg/L.) This is consistent with the low observed total N to total P ratios, which suggest nitrogen limitation on algal growth. Therefore, nutrient limitations to achieve the maximum chlorophyll *a* targets are best expressed in terms of total nitrogen goals (from which corresponding total phosphorus goals may be inferred through use of the Redfield ratio of 7.2, as in Dodds et al., 1997). The resulting total nitrogen goals for a maximum benthic chlorophyll *a* concentration target of 150 mg/m^2 are shown in Table 15, while Table 16 shows the corresponding estimates for a target of 100 mg/m^2 maximum benthic chlorophyll *a*.

Results for the 150 mg/m^2 target are re-expressed as reductions in TN concentration relative to observed summer average concentrations for the 2005-2007 period based on the revised QUAL2K with accrual adjustment analysis in Table 17. Concentrations observed in the 1996-2001 period are somewhat different, but suggest a similar spatial pattern of needed reductions (Table 18).

Table 17. Reductions in TN Concentrations Relative to 2005-2007 Observations to Achieve the 150 mg/m^2 Target

Table 18. Reductions in TN Concentrations Relative to 1996-2001 Observations to Achieve the 150 mg/m^2 Target

Station	Percent Reduction in Summer TN Concentration	TN/TP 2005-2007 Summer Average Concentration (mg/L)	TN/TP Goal (mg/L)
KR18952	85%	1.21/0.20	0.18/0.025
KR17608	73%	0.85/0.22	0.23/0.032
KR14261	66%	0.83/0.23	0.28/0.039
KR12858	44%	0.78/0.23	0.44/0.061
KRWE	No data	No data	0.41/0.057
KRTC	5%	0.43/0.077	0.41/0.057
KRTG	0%	0.49/0.093	0.51/0.071

Table 17 and Table 18 suggest that to achieve the desired reductions in benthic algal density at all stations would require reductions in summer TN concentrations of up to 85 percent. (Achieving targets by controlling TP directly would require reductions of approximately 98 percent at stations through Seiad Valley.) The results for the T4BS1 allocation scenario in Iron Gate Reservoir (see Section 3.3) indicate that this scenario, which is predicted to achieve lake targets, would result in reductions of about 73 percent in summer TN concentrations and about 89 percent in summer TP concentrations for the 2000 simulation. Thus, load reductions in excess of those needed to meet DO criteria and achieve lake planktonic chlorophyll *a* targets may be needed to meet maximum periphyton chlorophyll *a* targets in the Klamath below Iron Gate.

Application of the benthic biomass tool using the 75th percentile summer concentrations in the outflow from Iron Gate predicted by the T4BS1 scenario with benthic flux off results in a prediction of maximum benthic algal chlorophyll *a* at Station KR18952 below Iron Gate of 164 mg/m^2 – slightly in excess of the target – using the revised QUAL2K-based methods. For the same conditions, the Dodds (2002) approach yields a prediction of 84 mg/m^2, well below the target.

3.3.6 Natural Conditions Analysis

The draft CA NNE document (Tetra Tech, 2006) recommended an upper limit of 150 mg/m^2 chlorophyll *a* to support uses in waters of the State of California, yet also recommends that the target should not be set lower than the value expected under natural conditions. This target of 150 mg/m^2 has not been adopted by the State Board and remains open for further evaluation. [The Hoopa Valley Tribe has a regulatory target of 150 mg/m^2 that has been adopted and approved, and applies to the small section of the Klamath River that passes through the Hoopa Valley Tribal lands.]

To examine potential natural conditions in the Klamath River, concentration results from the TMDL Model T1BS natural conditions run were summarized for summer (June-September) conditions. This model run has point sources eliminated and dams out. Current flow leaving Upper Klamath Lake and Klamath Straits Drain in Oregon is continued, but with concentrations reduced to be compliant with the Upper Klamath Lake TMDL. The T1BS run uses 2000 meteorological conditions.

In the dams out simulation, nutrient retention and processing by the Klamath reservoirs is eliminated. This results in changes in the magnitude, timing, and speciation of nutrient loads reaching the lower Klamath River.

Output from the T1BS natural conditions was used to provide input to the NNE benthic biomass tool. Evaluation was made at four locations: below Iron Gate (KR18952), Seiad Valley (KR12858), above Trinity (KRWE), and at Turwar (KRTG). The range of summer average water quality for the natural conditions run is summarized at the 75th percentile level (as was done with the NNE tool to predict maximum benthic chlorophyll *a* in previous sections) and compared to recent observed water quality in Table 19.

Table 19. 75th Percentile of Natural Condition Water Quality (Model Run T1BS) Compared to Observed Water Quality in the Klamath River

	Station	T1BS	1996-2001 Observed	2002-2004 Observed	2005-2007 Observed

Unlike monitoring results for existing (dams-in) conditions (see above, Table 11), the 75th percentile total nutrient concentrations during the summer tend to increase downstream under the TMDL Model T1BS run. This seems to occur because concentrations in most of the downstream tributaries were kept at existing levels for the T1BS scenario, while upstream concentrations leaving Iron Gate Dam decreased significantly. In addition, the model output reflects continuous subhourly simulation, while the observations are discrete day time grab samples, which may confound direct comparison.

Table 19 also shows that the 75th percentile summer total nitrogen concentrations under natural conditions appear to be greater than the concentrations estimated as needed to meet the 150 mg/m^2 maximum benthic chlorophyll *a* target in the analysis of existing conditions provided above in Table 15. This suggests that natural conditions may result in a tendency for elevated benthic algal densities in the Klamath River.

The dams-out condition will also result in more frequent scouring flows and less days of accrual (time between potential scouring events), which may tend to reduce maximum benthic algal growth. However, data were not available for a long-term analysis of the frequency of scouring flows for the T1BS model conditions. To approximate this effect, the days of accrual for the Revised QUAL2K application with accrual adjustment was set at 69.1 days – the value currently used for the Turwar gage, which is furthest downstream and least affected by the dams on the upper Klamath.

Results of applying the benthic biomass spreadsheet tool to the TMDL Model T1BS conditions are summarized in Table 20. Consistent with the predicted nutrient concentrations, there is no longer a strong spatial gradient in predicted maximum benthic chlorophyll *a* concentrations under the T1BS natural conditions scenario. The standard QUAL2K predictions are much higher than the other approaches due to the increased fraction of inorganic nutrients, which enter directly into the solution for this model, but not the other approaches. The Revised QUAL2K model with accrual adjustment suggests maxima right around the 150 mg/m^2 target, while the QUAL2K approaches without accrual adjustment predict higher densities. The Dodds (2002) approach also predicts maximum densities less than 150 mg/m^2, but results from this model were generally much lower than that obtained for other approaches in the analysis of existing conditions.

The predicted ability to meet the 150 mg/m^2 target using the Revised QUAL2K approach (with accrual adjustment) only occurs due to the assumption of reduced days of accrual. For example, if days of accrual at KRWE are assumed to be 81.9, as in the existing conditions (dams-in) application, the resulting predicted maximum benthic chlorophyll *a* density would be 166, rather than 145 mg/m^2. It is thus not clear from the benthic biomass spreadsheet analysis that the 150 mg/m^2 target could be met under natural conditions A more detailed analysis of the frequency of scouring flows expected under the dams-out natural conditions may be advisable to ascertain the extent to which this phenomenon is likely to limit excess benthic algal density.

Table 20. Predicted Maximum Benthic Chlorophyll *a* (mg/m2) Under TMDL Model Run T1BS Natural Conditions (Dams Out) for Year 2000

Station	Standard QUAL2K	Revised QUAL2K	Revised QUAL2K with Accrual Adjustment	Dodds 2002
KR 18952 (below Iron Gate)	338	250	157	113
KR12858 (Seiad Valley)	246	174	109	135
KRWE (above Trinity)	350	231	145	137
KRTG (Turwar)	377	246	154	147

3.4 DISCUSSION OF KLAMATH RIVER NNE RESULTS

Prediction of periphyton biomass is inherently difficult. This problem is compounded by several factors, including the weak relationship between periphyton biomass and benthic chlorophyll *a* and the sparse and uncertain data available for the Klamath River. The biomass to chlorophyll *a* relationship is expressed through the chlorophyll *a* to AFDW ratio, which is clearly a major source of uncertainty in the QUAL2K-based applications. The observed data are limited, and have been obtained from small samples that may not accurately reflect the reach-averaged conditions predicted by the tool.

Due to the uncertainties in predicting benthic chlorophyll *a*, it may be preferable to define periphyton targets for the Klamath River in terms of AFDW, although more data are needed to establish such a target.

As a result of these caveats, the main value of the benthic biomass tool is in predicting relative changes in benthic chlorophyll *a*, rather than precise estimates. It is clear that significant reductions in summer nutrient concentrations would be needed to meet a target of 150 mg/m^2 maximum benthic chlorophyll *a*; however, the predicted magnitude of the needed reductions is highly uncertain. The reductions that would occur as a result of the T4BS allocation scenario to achieve DO criteria will certainly result in improvements in periphyton density in the Klamath River, but may or may not be sufficient to achieve the BURC II/III target of 150 mg/m^2 maximum benthic chlorophyll *a*. Due to the considerable uncertainty in the NNE analysis. additional data should continue to be collected to build a better understanding of the relationship between nutrient concentrations and periphyton density and support the development of more sophisticated, site-specific models. The RMA model application for Klamath River TMDL development already provides a potential framework for evaluating the benthic algal target in the river; however, the model predictions need to be refined with more data to better assess impacts on beneficial uses in addition to effects on DO, including the formation of periphyton mats that may impair recreational uses, alter the benthic community, and potentially increase the detrimental effects of parasites on salmonid populations.

Finally, although the draft CA NNE document (Tetra Tech, 2006) recommends an upper limit of 150 mg/m^2 chlorophyll *a* to support uses, this target has not been adopted by the State or Regional Board and remains open for further evaluation. As mentioned previously, this target does apply to the small section of the Klamath River that passes through the Hoopa Valley Tribal lands, where a criterion of 150 mg/m^2 has been adopted and approved.

Targets should not be set lower than a value expected under natural conditions. As discussed in Section 3.3.6, the natural condition maximum benthic chlorophyll *a* concentration on Hoopa Valley lands is likely to be near 150 mg/m^2, but may be somewhat higher, depending on the assumptions regarding frequency of scour.

Perhaps more importantly, it would be consistent with the CA NNE approach to develop a site-specific target based on a risk analysis to support beneficial uses in the system. A key here may be establishing the periphyton conditions (and relevant indicator metrics) that are consistent with managing the parasite *Ceratomyxa shasta* at levels that are consistent with maintaining a healthy salmonid population; however, research has not yet advanced to the point where a quantitative target can be set on this basis.

MEMORANDUM

To:	Klamath TMDL Technical Team	**Date:**	February 12, 2008
From:	Jonathan Butcher	**Project:**	Klamath
Subject:	Nutrient Dynamics in the Klamath	**Tt Pjn:**	20729-02

Oregon DEQ (DEQ) and California's North Coast Regional Water Quality Control Board (Board) are developing Total Maximum Daily Loads (TMDLs) for the Klamath River to address impairments associated with dissolved oxygen, temperature, nutrients, pH, and chlorophyll *a* – all of which are ultimately affected by the dynamics of nutrients, algal growth, and organic matter transport in the system. The river begins at Upper Klamath Lake in Oregon and encompasses 15,722 square miles in the states of Oregon and California, flowing from the Cascades in Oregon westerly and southerly to the Pacific Ocean in Del Norte, CA. The system has several unusual characteristics. First, the gradient increases downstream. Second, the source of the river is an aging eutrophic lake, which leads to nutrient concentrations that are highest in the headwaters, while downstream tributaries generally have lower nutrient concentrations than the mainstem. Finally, there are a series of dams in the upper third of the watershed, forming a segmented system.

The Klamath is one of the major salmon rivers of the western United States, so interest in the protection, management, and restoration of the system is high. Nutrients in the system are dominated by the loading leaving Upper Klamath Lake, which cannot easily be controlled. The temporal and spatial pattern of water quality downstream is largely controlled by processes that retain, transform, or release nutrients within the impounded and free-flowing reaches, including growth of planktonic algae (primarily in impoundments), settling of nutrients to and regeneration of nutrients from the sediment (also primarily in impoundments), and uptake/release of nutrients by periphytic algae (primarily in free-flowing reaches).

PacifiCorp, which operates federally-licensed hydroelectric projects on the river, developed a simulation model of the river, linking CE-QUAL-W2 models of the impoundments with an RMA-11 model of the free-flowing reaches (PacifiCorp, 2005). This model was subsequently updated and recalibrated by Tetra Tech for USEPA, DEQ, and the Board, and forms a basis for developing the TMDL and potential management scenarios to meet the TMDL. While Tetra Tech has developed a draft model calibration report, a final public version of the report has not yet been released. Stakeholder review of the modeling effort has, however, provoked some questions regarding the processes controlling nutrient dynamics in the impounded and free-flowing reaches (particularly their relative importance), and whether the model accurately represents these processes (Asarian, 2007; PacifiCorp, 2007). In addition, several reports have been published on nutrient dynamics in the system.

To help resolve these issues, the Board and USEPA requested a review of the reports that analyze nutrient dynamics in the Klamath River system, with particular emphasis on evaluation of the effects of reservoirs in California on water quality relative to free-flowing reaches. The review was conducted by Dr. Jonathan Butcher, who is familiar with the Klamath River system, but was not directly involved in the model development effort.

1 Key Issues

The disputes over nutrient dynamics in the Klamath River system are intimately tied to the policy debate over the potential removal of hydropower dams in the Upper Klamath. PacifiCorp (2005) created the original linked water quality simulation models of the system (RMA-11 for the free-flowing reaches and CE-QUAL-W2 for the impoundments), and applied them to the 2000-2004 period, with calibration based on more intensive data collected in 2000. In a series of reports, Asarian and Kann (working variously on behalf of the Yurok and Karuk tribes) raised concerns that the model overestimated nutrient retention rates in the impoundments, while underestimating nutrient retention rates in the free-flowing reaches, resulting in an unrealistic estimate of benefits of the impoundments in controlling downstream nutrient concentrations (see Asarian and Kann, 2006a, 2006b).

Tetra Tech, for USEPA, subsequently recalibrated the PacifiCorp models for year 2000 (with validation application to the reaches above Iron Gate Dam for 2002). The recalibration effort did result in lower nutrient retention rates within the reservoirs and higher retention rates within the free-flowing segments – suggesting that some of the original criticisms of the model were correct. Asarian (2007) has continued to express concerns that the model under-represents nutrient retention in the free-flowing reaches of the river downstream of Iron Gate Dam – and thus does not provide a fair evaluation of the conditions that would result from conversion of impoundments back to free-flowing reaches. On the other side, PacifiCorp (2007) has contended that the analyses of Asarian and Kann are flawed in a variety of ways, while defending the model results.

The truth of the matter is that water quality data are fairly sparse in this system – which lends considerable uncertainty to both direct evaluations of observations and model setup and calibration. The station immediately below Iron Gate Dam (RM 189.73) has samples from 1996-2004, on a biweekly basis for 1998-2002 and monthly in other years. The key downstream station for evaluating nutrient retention at Seiad Valley (RM 130.85) has a similar density of samples only for 1998-2001. Further, samples have generally not been collected in January through April, meaning that a large portion of the total annual flow has not been sampled (see Figure 1). As a result, the mass balance and retention calculations of Asarian and Kann (2006a) are based on June through October, not complete years, preventing full closure of the mass balance.

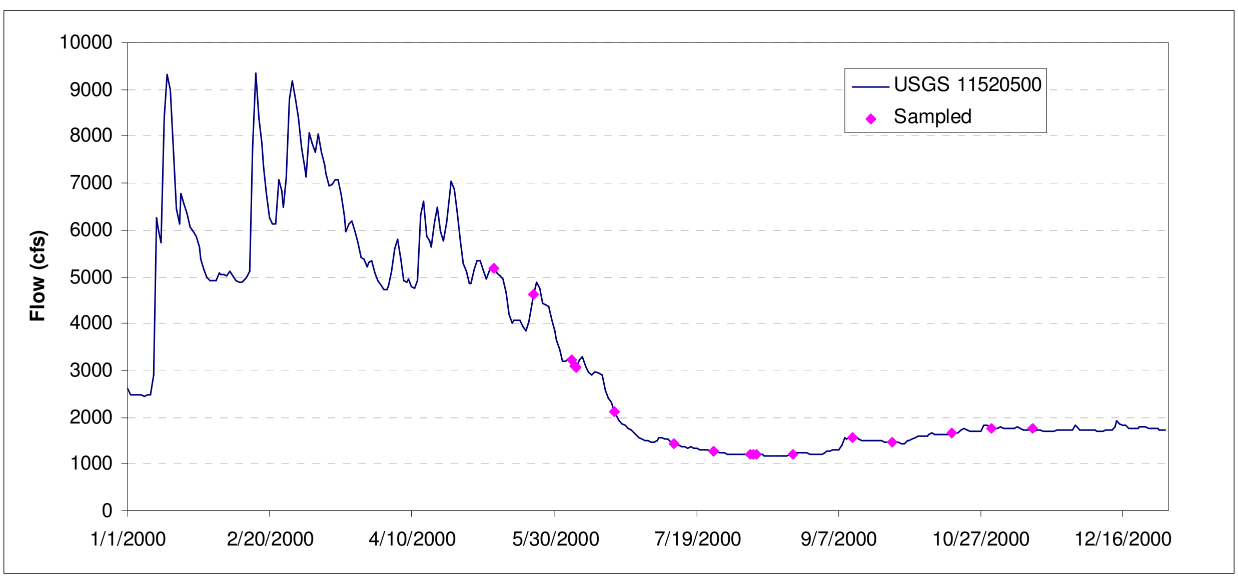

Figure 1. Daily Flows and Water Quality Samples, Klamath River at Seiad Valley, 2000

For the modeling, focus has been on 2000, as this is the year with the best information on tributary loads. Tetra Tech has run the complete, recalibrated model *only* for 2000. Indeed, due to the short residence time and elevated loads from the headwaters at Upper Klamath Lake, the model predictions are strongly determined by the boundary conditions (upstream load and relative dilution provided by the downstream tributaries), and results for years in which the boundary conditions are not well-defined are largely speculative.

It is also important to recognize that the patterns of nutrient retention are likely to vary significantly from year to year. The data analyzed by Asarian and Kann (2006a) show consistent seasonal retention of total Nitrogen between Iron Gate and Seiad Valley in some years (e.g., 2001 and 2002), but not in others. Notably, for 2000 the retention calculated for most sample dates appears to be close to the expected range of uncertainty for nitrogen concentration measurements[1] except for one date, which results in an estimation of net retention over the June-October period. The authors note (p. 42): "most of the positive retention in the Iron Gate (KR18973) to Seiad Valley (KR12858) reach for the 2000 season was due to a single high sample on 7/11/2000 at Iron Gate, when TKN was 4.5 mg/L… There are 313 TKN samples in the database below Iron Gate taken from 1971 to 2004 and this was the highest measurement, with no other samples above 2.0 mg/L…"

Both the empirical analyses of nutrient trend and the model predictions are uncertain as a direct result of the sparse data. Biweekly or monthly samples are likely to provide an inaccurate estimate of the nutrient mass entering or leaving a reach, introducing uncertainty into direct estimates of load, while similarly creating uncertainty in model forcing functions. Further, it is not appropriate to compare long term trends from the data to model results from a single year, as year-to-year variability is likely significant.

In sum, the empirical work of Asarian and Kann is most appropriate as a long-term, statistical estimate of typical removal rates. The model output, while also uncertain, provides an estimate for a specific set of flow and boundary conditions. The two should be qualitatively similar, but not identical.

2 River Retention of Nutrients

Physical and biological processes in river reaches can result in net removal or temporary retention of nutrients. One of the major processes for temporary retention is uptake of nutrients by periphyton. Periphytic algae, as well as heterotrophic organisms, require nutrients for growth and remove inorganic nutrients from the water column, converting them to organic biomass. Heterotrophs also remove organic matter as foodstock. This storage, however, is temporary. In addition to normal dieoff and predation, periphyton is subject to scour and transport downstream during high flow events.

Tanner and Anderson (1996) demonstrated that periphyton (dominantly *Cladophora*) were very effective in reducing dissolved inorganic nitrogen loads downstream of wastewater treatment plants in the South

[1] Total nitrogen is estimated as the sum of total Kjeldahl nitrogen (TKN) and nitrite-plus-nitrate nitrogen. For USGS analyses, relative standard deviations (RSDs) for these measurements in natural waters are typically in the range of 8 to 10 percent (e.g., Lambing and Cleasby, 2006), although Campbell (2001) reported RSD's less than 5 percent for Klamath River nutrient samples. Other laboratories may achieve differing levels of precision. More importantly, TKN is reported to the nearest 0.1 mg/L, while nitrite and nitrate nitrogen are reported to the nearest 0.01 mg/L, reflecting the underlying precision in the analytical methods. In the Klamath below Iron Gate, TKN often constitutes about 90 percent of total nitrogen. At a typical total nitrogen concentration of about 0.8 mg/L, there is thus a built in reporting uncertainty (reflecting the underlying analytical uncertainty) of around ±14 percent. Additional uncertainty is introduced by sampling procedures, as samples may not be fully representative of the complete flow-weighted average concentration passing a given point, and there may also be systematic changes in nutrient concentrations over the diurnal cycle due to algal influences. Finally, calculation of nutrient retention requires use of flows, which are also subject to measurement uncertainty, further decreasing the precision of mass transport estimates obtained by multiplying flow times concentration.

Umpqua River, OR. Similarly, locations in the Bow River in Alberta supported dense *Cladophora* and macrophyte growths that were sensitive to nitrogen load and effective in removing inorganic N from the water column (Sosiak, 2002). Such biological uptake is, however, largely temporary in nature, as biomass follows seasonal cycles with release of nutrients as biomass declines in the fall. Decaying periphyton mats may also promote anoxic conditions that lead to denitrification and loss of nitrogen from the system. Dodds (2003) summarized the role of periphyton in removing phosphorus from aquatic systems. Some of this storage is also temporary; however, Dodds also points out that localized increases in pH during photosynthesis can lead to increased precipitation of calcium phosphate, concurrent deposition of carbonate-phosphate complexes, and long term burial losses of phosphorus.

Temporary retention in river reaches also occurs as a result of settling and storage of particulate matter, including organic detritus. Inorganic orthophosphate and, to a lesser extent, ammonium can also sorb to sediment particles and settle out. These processes also largely constitute temporary retention, as the stored particulate matter can be remobilized by scouring flows.

Permanent removal of nutrient mass can also occur in several ways. For nitrogen, denitrification and conversion to nitrogen gas results in a loss of nitrogen from the water to the air. This may be balanced by fixation of atmospheric nitrogen by certain types of cyanophytes, but these are usually not dominant in flowing waters. Water lost to deep groundwater, agricultural diversions, or riparian wells can remove nutrients, and is more important for nitrogen, which is more soluble than phosphorus. Effective removal of phosphorus may also occur due to burial in deposits that are not readily remobilized (due, for instance, to stream meander and cutoffs), export to the floodplain, or conversion to tightly bound, insoluble mineral forms. These latter processes tend to be of less importance in higher gradient systems, so net rates of removal for TP are expected to be less than net rates of removal for TN in a system like the Klamath.

In general, temporary retention is most important during lower flow periods, which tend to coincide with the growing season. Temporary retention does not, in the end, change the nutrient load that is delivered downstream; however, it can significantly affect both the timing and bioavailability of load delivery. While extensive periphyton communities remain intact below a source area, they may substantially reduce the nutrients available to support algal growth downstream – as appears to be observed in the Klamath. High flows in the Klamath typically occur in the winter and spring. The net effect of temporary retention should thus be to shift much of the nutrient load from the summer and fall to the winter and early spring – a period for which there are very few water quality observations.

The likelihood of significant scour of periphyton can be evaluated in terms of days of accrual, using the relationship of Biggs (2000), where accrual time is defined as the number of days between events three-times the median flow. Accrual time was analyzed at each of the USGS gages. Because the Klamath is a large river with a multi-day response time, the number of events per year was estimated based on the count of times the hydrograph crossed the three-times-median threshold, rather than the number of individual days above the threshold. Resulting estimates (Table 1) show a pattern of decreasing time between scouring events with distance downstream as additional major tributaries join.

Table 1. Estimated Days of Accrual (1985-2005 Data)

USGS Gage	Average Days of Accrual
11516530: Klamath River below Iron Gate	185.7
11520500: Klamath River near Seiad Valley	122.8
11523000: Klamath River above Shasta River	81.9
11530500: Klamath River at Klamath	69.1

Nutrient concentrations measured in the Klamath tend to decrease with distance downstream from Iron Gate Dam, as has been noted by various authors. It is important to note, however, that nutrient retention needs to be evaluated as a mass balance, based on loads, not concentration trends. In the Klamath below Iron Gate, the concentrations of nutrients in many of the tributaries are generally lower than those in the mainstem; thus a reduction in mainstem concentration is expected solely as a result of dilution, regardless of whether there is any true retention.

2.1 REVIEW OF NUTRIENT MASS BALANCE ESTIMATES FOR THE LOWER KLAMATH

Asarian and Kann (2006b) evaluated the PacifiCorp modeling and contended that it overestimated retention in the reservoirs, while underestimating retention in flowing reaches. This analysis, however, is based primarily on comparison of longitudinal concentration distributions in the Klamath mainstem. This is potentially misleading for two reasons. First, the rate of change in concentration along the length of the river is in large part a function of nutrient concentrations in incremental tributary flow, which is not well characterized. Second, the sparseness of the monitoring data introduces considerable uncertainty into the analysis.

Asarian and Kann (2006a) do provide a mass balance evaluation in terms of loads, again concluding that retention in flowing reaches is underestimated by the model. The conclusions of this effort depend in part on how loads are estimated, which can be problematic for sparse data. Asarian and Kann did this as follows:

- Total N is calculated as the sum of Total Kjeldahl Nitrogen (TKN) and NO_3-N+NO_2-N.
- The biweekly (or monthly) concentration data were used to create a continuous daily estimate using linear interpolation between points.
- Resulting daily TN concentration was multiplied by flow to obtain load.
- Retention rates between stations were calculated for June-October, the period for which most monitoring is available.

As noted above, because only a seasonal estimate can be made, the approach measures net retention, not removal, and a significant portion of the retained load may be mobilized and moved downstream by winter flows. Methodologically, the other major concern is the use of linear interpolation.

Estimating constituent mass loads from point-in-time measurements of water-column concentrations presents many difficulties. Load is determined from concentration multiplied by flow, and while measurements of flow are continuous, only intermittent measurements of concentration are available. Calculating total load therefore requires “filling in” concentration estimates for days without samples. The process is further complicated by the fact that concentration and flow are often highly correlated with one another, and many different types of correlation may apply. For instance, if a load occurs primarily as a result of nonpoint soil erosion, flow and concentration will tend to be positively correlated; that is, concentrations will increase during high flows, which correspond to precipitation-washoff events. On the other hand, if load is attributable to a relatively constant point discharge, concentration will decrease as additional flow dilutes the constant load. In most cases, a combination of processes is found.

Preston et al. (1989) undertook a detailed study of advantages and disadvantages of various methods for calculating annual loads from tributary concentration and flow data. Their study demonstrates that simply calculating loads for days when both flow and concentration have been measured and using results as a basis for averaging is seldom a good choice. A method dependent on interpolation between measured concentrations is likely to have similar problems. Depending on the nature of the relationship between flow and concentration, more reliable results may be obtained by one of three approaches:

- Averaging Methods: An average (e.g., yearly, seasonal, or monthly) concentration value is combined with the complete time series of daily average flows
- Regression Methods: A linear, log-linear, or exponential relationship is assumed to hold between concentration and flow, thus yielding a rating-curve approach
- Ratio Methods: Adapted from sampling theory, load estimates by this method are based on the flow-weighted average concentration times the mean flow over the averaging period and performs best when flow and concentration are only weakly related.

No single method provided superior results in all cases examined by Preston et al.; the best method for extrapolating from limited sample data depends on the nature of the relationship between flow and concentration, which is typically not known in detail.

Thus, the accuracy of the interpolation approach will depend in large part on whether there is correlation between flow and concentration. If the two variables are truly independent, then no error will be introduced by this approach. If they are correlated, the approach is sub-optimal.

Reducing the potential impact of these issues is the fact that the Upper Klamath is a highly controlled system, with multiple reservoirs. These reservoirs should serve to damp out correlations between flow and concentration, particularly for the reach between Iron Gate and Seiad. As the river accumulates more uncontrolled tributary flow downstream, correlation may reemerge, rendering the load estimates suspect. (Indeed, this might be why Kann and Assarian detected no nitrogen retention below Orleans).

Campbell (2001) analyzed monitoring data from 1996 through 1998 from Keno Dam to Seiad Valley, and concluded that there was a negative correlation between flow and concentration for all nutrient species, and that this negative correlation became stronger downstream (as far as Seiad Valley). This type of situation can arise when nutrient loads are dominated by lake sources, and tributary stormflow contributions – even if elevated relative to baseflow – serve to dilute the mainstem concentration. Reexamination of the detailed 2000 USGS monitoring at Seiad Valley confirmed a negative correlation between TKN and flow, but showed essentially no correlation between TP and flow.

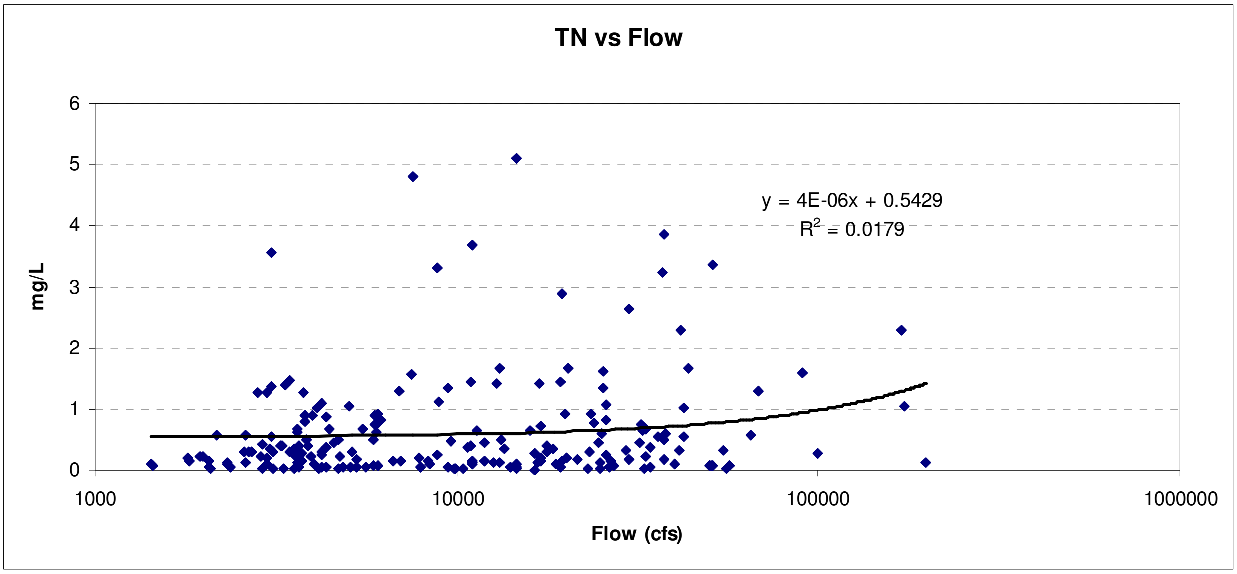
Further downstream, USGS nutrient water quality monitoring from 1973 to 2003 is available at Klamath, CA (USGS gage 11530500), and these data were examined as a check. As shown in Figure 2, concentration is only weakly related to flow at this station, and, while the slope is positive, it is not significant. The relationships remain weak if results are stratified into summer and winter seasons.

To the extent that flow and concentration are truly independent of one another, the simple interpolation method used by Asarian and Kann will not introduce error. However, where and when a negative correlation between flow and concentration exists, the interpolation approach will tend to overerestimate total load – because concentrations that are too high will tend to be applied to the high flow events that constitute the bulk of the total movement of mass. If, as expected, the negative correlation is strongest immediately downstream of Iron Gate and decreases downstream, this could introduce a bias that results in overestimation of the nutrient retention between Iron Gate and Seiad Valley.

Despite these caveats, the approach taken by Asarian and Kann seems likely to provide reasonable estimates of seasonal nutrient retention over the long term (although not removal, as full-year mass balances are not available). Asarian and Kann, however, attempt to take the analysis further, evaluating retention by reach first on a yearly, and then on a monthly basis. As each month is represented by only one or two sampling events (and these events likely did not sample the same parcel of water), this is asking too much of the sparse data. Due to the uncertainty present in the data and the method, the best that can be hoped for is a statistical convergence to a reasonable estimate. Interpretations of the magnitude of retention for individual months are at best suspect.

Due to changes in sample locations, more than two years of data are available only for the reach Iron Gate to Seiad Valley. For the whole analysis period evaluated by Asarian and Kann (1998-2002), the June-

October net retention of TN is 18.6 percent, or 0.31 percent per mile. It should be remembered that this seasonal estimate is likely an upper bound on the annual retention, as it includes temporary storage that will be flushed downstream during winter high flows.



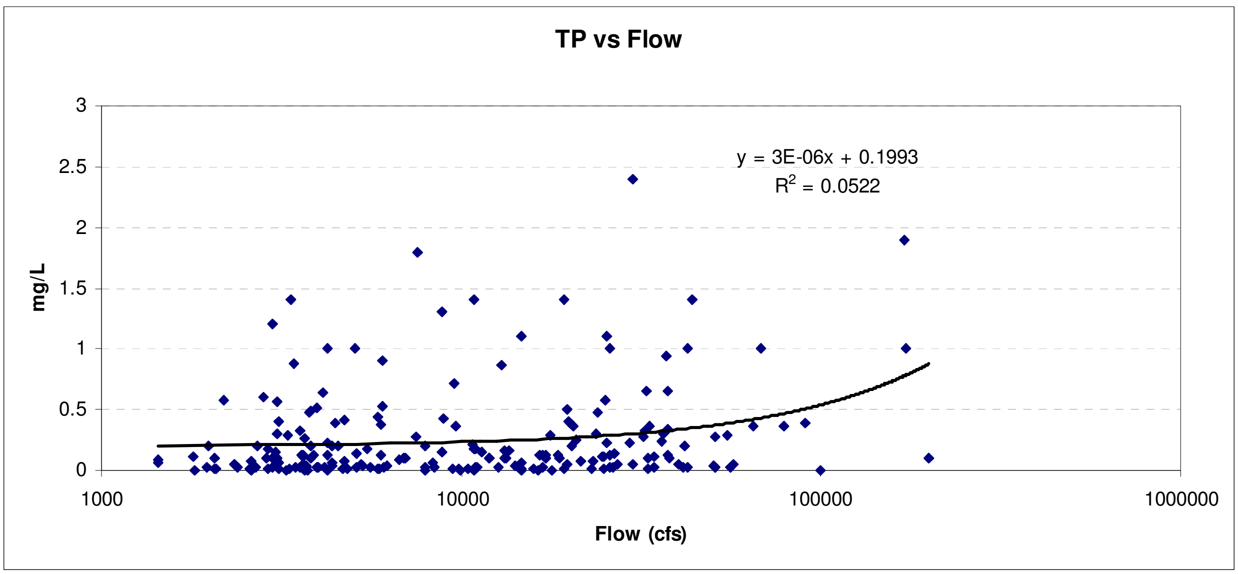


Figure 2. Relation of Nutrient Concentration to Flow, Klamath River at Klamath, CA

2.2 EXPECTED RANGE OF RIVER RETENTION ESTIMATES

USGS, as part of its Spatially Referenced Regressions on Watershed Attributes (SPARROW) project had developed generalized reach removal coefficients for TN and TP based on analysis of monitoring records of 381 USGS National Stream Quality Accounting Network (NASQAN) monitoring sites throughout the US (Smith et al., 1997). Removal is represented as an exponential decay process, such that the retention in a reach is given by

$$\text{Retention} = 1 - \exp(-\delta t),$$

where δ is a loss coefficient (day^{-1}) and t is travel time in days. The national coefficients originally developed by Smith et al. (1997) were revised by Smith et al. (2003a), as reported in Smith et al. (2003b). Median flows in the Klamath downstream of Iron Gate are greater than 1000 cfs, but less than 10,000 cfs, so the relevant national decay coefficients are 0.118 day^{-1} for TN and 0.098 day^{-1} for TP. The mean travel time from Iron Gate to Seiad is on the order of 2 days, so we would expect, as a long-term average, loss rates of about 21 percent for TN and 17 percent for TP. The growing season TN retention estimates for this reach given by Asarian and Kann range from 20 to 61 percent – but retention over the growing season is likely to be higher than annual net retention due to temporary storage in periphyton.

The SPARROW estimates of loss depend entirely on the decay coefficients, which are subject to considerable uncertainty and vary as a result of site-specific conditions. Other evidence is available in recently completed work of Armstrong and Ward (2008), who developed a simplified model of Klamath summer monitoring data for 2001-2005. Their application is a spreadsheet plug-flow model in which the decay rates for TN and TP are taken as calibration parameters. The methodology has some potential problems: First, it is sensitive to assumptions about tributary loads, which are poorly characterized for many of these years. Second, the approach fits individual decay rate estimates for each month in the dataset, which likely leads to over-fitting of the data. Finally, a single decay rate is applied for each month to the entire distance between Iron Gate and Turwar. However, the results are useful in providing another independent estimate of potential retention / loss rates in the Klamath River. Finally, the analyses cover only the June through October period, so one can examine only seasonal retention, not ultimate loss.

The decay rates fit by Armstrong and Ward range between 0.005 and 0.15 day^{-1} for both TN and TP, and are generally higher in the summer, suggesting that periphyton uptake may be a significant component of the retention. The authors do not provide an integrated summary of their decay rate estimates; however, examination of their Figure 33 suggests that the median decay rates were 0.005 day^{-1} for TN and 0.075 day^{-1} for TP. For two day travel between Iron Gate and Seiad, this would imply nitrogen retention of only 1 percent and phosphorus retention of 14 percent. (For individual months in which the estimated decay rate reached 0.15 day^{-1} the retention would be 26 percent.) These results suggest that the seasonal retention rate for TN in the Klamath could well be much less than predicted by SPARROW; however, they do not preclude the possibility that retention rates are much higher between Iron Gate and Seiad Valley than between Seiad Valley and Turwar, as suggested by Asarian and Kann (2006a). The results of Armstrong and Ward are also subject to considerable uncertainty. They report relative percent error on model-predicted concentration by month, ranging from 2 to 102 percent for total nitrogen (with median of 19 percent) and 3 to 22 percent for total phosphorus (with median of 11 percent).

2.3 RMA-11 IMPLEMENTATION

RMA-11 (King, 1998) simulates four state variables for nitrogen (nitrate, nitrite, ammonia, and organic N) and two state variables for phosphorus (dissolved P and organic P). Algal biomass also acts as a store of nutrients. Sorption of inorganic P to suspended sediment is represented as a sink, not a state variable, and thus forms a loss pathway from the system. Settling rates can be specified for organic N and organic P, again representing losses. While both deposition and scour of sediment are simulated by the model, the sediment mass balance is not directly linked to the nutrient mass balance (except through sorption of inorganic P). Algae take up inorganic nutrients during photosynthesis and convert them to organic nutrients, which are released during respiration (as inorganic nutrients) or decay (as organic nutrients). Algae can settle to the sediment, creating a sink for nutrients. (While the model documentation also discusses algal losses to grazing, this is apparently not implemented in the version of the model used for the Klamath.)

Thus, RMA-11 can potentially simulate internal nutrient losses (other than advection out of the system) in four ways: settling or grazing of algae, settling of organic N, settling of organic P, and sorption of inorganic P. RMA-11 can also simulate releases from the sediment of inorganic P and ammonium. Within the model, the phytoplankton settling rate was initially set to zero (PacifiCorp, 2005), but subsequently revised by Tetra Tech to match organic matter settling rates (0.05 m/day). PacifiCorp does not document the values for the other relevant rate constants; however, inspection of the model input shows that sorption losses of inorganic P are not simulated because TSS is not simulated. Net settling of organic N and organic P occurs in accordance with an organic matter settling velocity of 0.05 m/day (a very low value based on assumptions that net settling will be minimal in a fast-flowing river). No sediment releases of inorganic P or ammonium are specified.

Within the Klamath, periphytic algae can play an important role in nutrient cycling although quantitative data are limited and have been cited as a significant data gap (Flint et al., 2005). RMA-11 (King, 1998) has a rather simplistic representation of periphytic algae and algal-related nutrient cycling. This was somewhat remedied by project-motivated modifications to the RMA-11 (v41) code that separated algal respiration and death and added organic matter as a state component. Benthic algae are simulated as if they were planktonic algae, except not subject to advection or settling.

Despite the modifications to the algal code for the Klamath project, RMA-11 omits various processes that could potentially reduce its ability to accurately represent nutrient cycling in the free-flowing reaches of the Klamath. The importance of these processes is generally not known for the Klamath, so they can only be discussed in a speculative context. The majority of these processes are omitted from most other river water quality models as well. Among these are the following:

- RMA-11 does not simulate **denitrification**, the rationale being that this is not a significant pathway in free-flowing, relatively shallow rivers since denitrification bacteria require hypoxic conditions, as well as ample fixed carbon and nitrate supplies. In some rivers, however, there is evidence of significant denitrification occurring within the bed. The general thinking is that denitrification is of little significance in the well-oxygenated sediments of gravel-bed streams (Allan, 1995), and gravel-bed streams are more likely to convert ammonium to nitrate (e.g., research in the Williamette reported by Fernald et al., 2006). Denitrification in the Klamath mainstem is likely limited by the availability of organic matter in the bed. Anoxia under decaying periphyton mats could, however, form a locus for denitrification (Triska and Oremland, 1981). Omission of this pathway may cause the RMA-11 model to underestimate nitrogen loss rates in the river; however, the magnitude of this error is not known. Similarly, RMA-11 (like most other river water quality models) does not simulate chemical reactions that may precipitate inorganic phosphorus in inorganic forms.
- RMA-11 does not simulate **luxury uptake** of nutrients by periphytic algae. In many cases, algae may be able to uptake and store excess nutrients against future growth requirements (Droop, 1983). This phenomenon is more likely to be a significant factor when there is strong temporal variability in nutrient availability. The presence of upstream impoundments tends to smooth out temporal variability in the lower Klamath, and may thus reduce the impact of luxury uptake on retention.
- The Klamath version of RMA-11 simulates respiration as the inverse of photosynthesis. That is, while photosynthesis involves the uptake of inorganic nutrients and inorganic carbon to form biomass, respiration is assumed to release equal amounts of inorganic nutrients and carbon (PacifiCorp, 2005, Appendix A). In reality, the releases of nutrients (if they occur) are likely to be at least in part in organic form. Related to the previous bullet, there is no provision for intracellular storage of nutrients as fixed-carbon energy sources are oxidized. The result is that the model simulation of diurnal ammonium concentrations shows greater variability than

observed data during the growing season, with concentrations depressed during periods of photosynthesis, then enhanced during night-time respiration.

- The RMA-11 model, like most other river models, does not consider the interaction of stream nutrients with riparian perennial vegetation, which may provide for long term sequestration of nutrients. Riparian vegetation is most often thought to intercept nutrients derived from upland sources. However, in a gravel bed river nitrogen in the hyporheic zone derived from the river can be taken up directly by the roots of woody vegetation (Peterjohn and Correll, 1994; Naiman et al., 2000). Species such as alder may act as net nitrogen sources, however, due to their ability to fix atmospheric nitrogen. The net balance of these processes is unknown for the Klamath.

Together, these simplifying assumptions in RMA-11 would tend to result in an underestimate of retention and an over-estimation of the downstream transport of inorganic nutrients during the algal growing season. Denitrification seems likely to be the most significant omitted factor in the Klamath, but its impact is not known for this system.

As implemented for the Klamath, there are very few ultimate sinks for nutrients in RMA-11. Settling of organic nutrients and algae will constitute a loss, but this loss will be small, given the low settling velocity and short travel times. Nutrients taken up by periphyton will be temporarily retained, but will be re-released as periphyton dies off or is scoured. The simulation of periphyton in the model indeed begins with low periphyton biomass, increases to higher biomass in summer, then declines back toward zero (Figure 3).

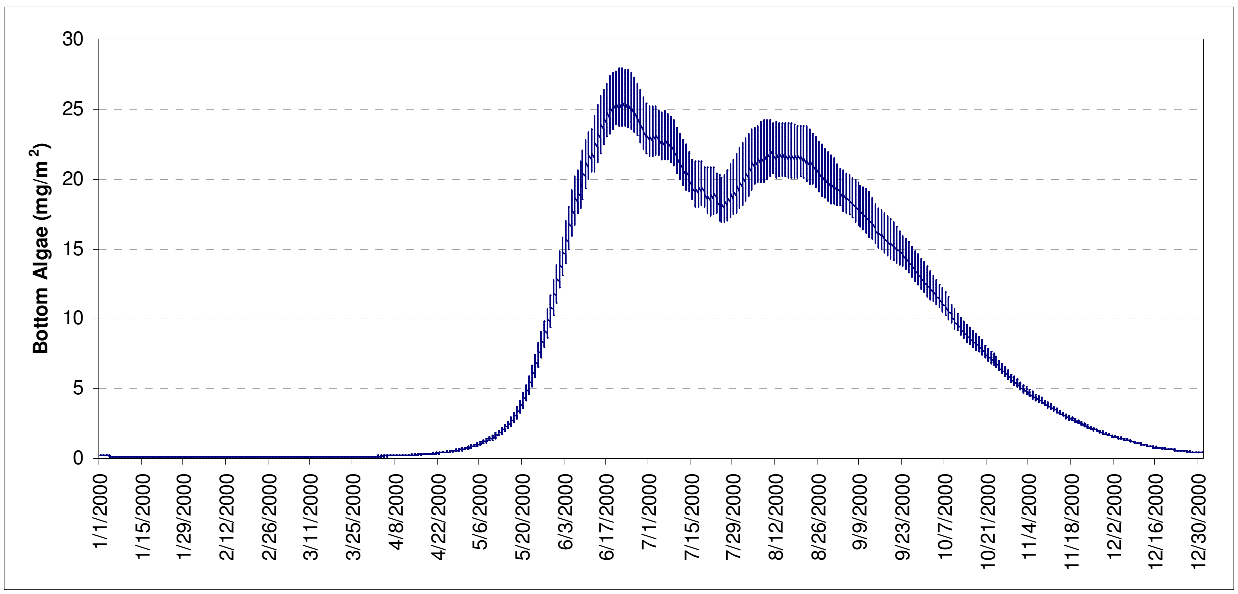

Figure 3. Periphyton Biomass Concentration Simulated for Klamath Upstream of Scott River

From Figure 3 we can conclude that periphyton, as simulated in the model, do not represent a significant net sink of nutrients, because the biomass declines back toward zero by the end of the year. It is also of interest to note that there is only one brief period (late May to early June) in which rapid accrual of periphyton biomass is simulated. Only during this period would we expect to see significant nutrient retention predicted for periphyton. During other periods, the periphyton are simulated as remaining at approximately steady biomass (in which case inorganic nutrient uptake should be balanced by output of inorganic and organic nutrients), or declining (in which case they will be creating a net increase in nutrient loads.)

Given the limitations of the RMA-11 code and the way it is parameterized for the Klamath, it appears clear that the model would not be expected to predict net removal of more than a few percent of total nutrient loads in free-flowing reaches of the river over the course of a year.

To test model behavior, a mass balance was constructed from the river and boundary flow and concentration data in the model. Loads were estimated on a monthly basis for TN, TP, NO_2+NO_3, PO_4, organic N, and organic P. The organic N and P components of non-living organic matter were calculated from organic matter concentrations according to the stoichiometry described in the model calibration report (organic N = 0.07 x organic matter; organic P = 0.0055 x organic matter). Within the Klamath, a noticeable fraction of the nutrient load may be transported in the form of living planktonic algae. Therefore, the planktonic algal biomass was also converted to organic N and organic P, using the same stoichiometry.

Model mass balance results were calculated for each river reach from Iron Gate to Seiad, but the net results over this whole distance are most informative (Table 2 and Table 3). For 2000, the model predicts TN loss/retention of 0.37 percent and TP loss/retention of 0.52 percent. For the period of June – September analyzed by Asarian and Kann (2006a), the TN retention predicted by the model is 1.05 percent. These results are less than estimated from the SPARROW methods or by the analyses of Asarian and Kann. They are, however, generally consistent with the analyses of the 2001-2005 data by Armstrong and Ward (2008), which suggest a TN retention rate of approximately 1 percent between Iron Gate and Seiad. As noted above, all these estimates of retention are subject to considerable uncertainty. This is an unavoidable result of the sparse data available. It is possible that RMA-11 would tend to underestimate seasonal nutrient retention rates due to the omission of various processes that can enhance nutrient retention and loss. However, the data are not sufficient to determine whether such an underestimation exists or is statistically significant. A comparison of nutrient losses on a full-year basis cannot be made, because both Asarian and Kann (2006a) and Ward and Armstrong (2008) worked with only seasonal nutrient data.

Table 2. Total P Mass Balance (kg) for RMA-11 Application for Year 2000, Klamath River from Iron Gate Dam to Seiad, CA

Month	IN	OUT	Change	Retention
1	37,751	36,027	-1,724	4.57%
2	68,409	68,106	-303	0.44%
3	72,501	72,325	-176	0.24%
4	55,820	55,551	-270	0.48%
5	56,498	56,220	-277	0.49%
6	38,889	39,155	266	-0.68%
7	23,875	23,416	-460	1.93%
8	27,364	26,949	-416	1.52%
9	25,776	26,123	348	-1.35%
10	23,951	24,095	143	-0.60%
11	19,410	19,746	337	-1.73%
12	15,159	15,288	129	-0.85%
Whole Year	465,403	462,999	-2,404	0.52%

Table 3. Total N Mass Balance (kg) for RMA-11 Application for Year 2000, Klamath River from Iron Gate Dam to Seiad, CA

Month	IN	OUT	Change	Retention
1	260,614	260,409	-205	0.08%
2	264,131	261,344	-2,787	1.06%
3	281,346	278,604	-2,742	0.97%
4	244,653	243,079	-1,573	0.64%
5	154,400	156,288	1,888	-1.22%
6	105,152	105,184	32	-0.03%
7	62,008	59,356	-2,652	4.28%
8	73,882	71,031	-2,852	3.86%
9	78,354	80,464	2,110	-2.69%
10	86,365	87,557	1,192	-1.38%
11	83,931	84,289	357	-0.43%
12	88,934	89,489	555	-0.62%
Whole Year	1,783,771	1,777,092	-6,679	0.37%

The model does predict a seasonal pattern of temporary retention in the spring and summer, followed by releases in the fall as periphyton densities decline. Plots of the cumulative changes in nitrogen and phosphorus component loads over the simulation year 2000 (Figure 4 and Figure 5) suggest that the spring to early summer period is dominated by the decay of organic matter to inorganic nutrients, followed by uptake of ammonium and inorganic P as periphyton growth accelerates in May and release of organic nutrients as the periphyton reaches senescence.

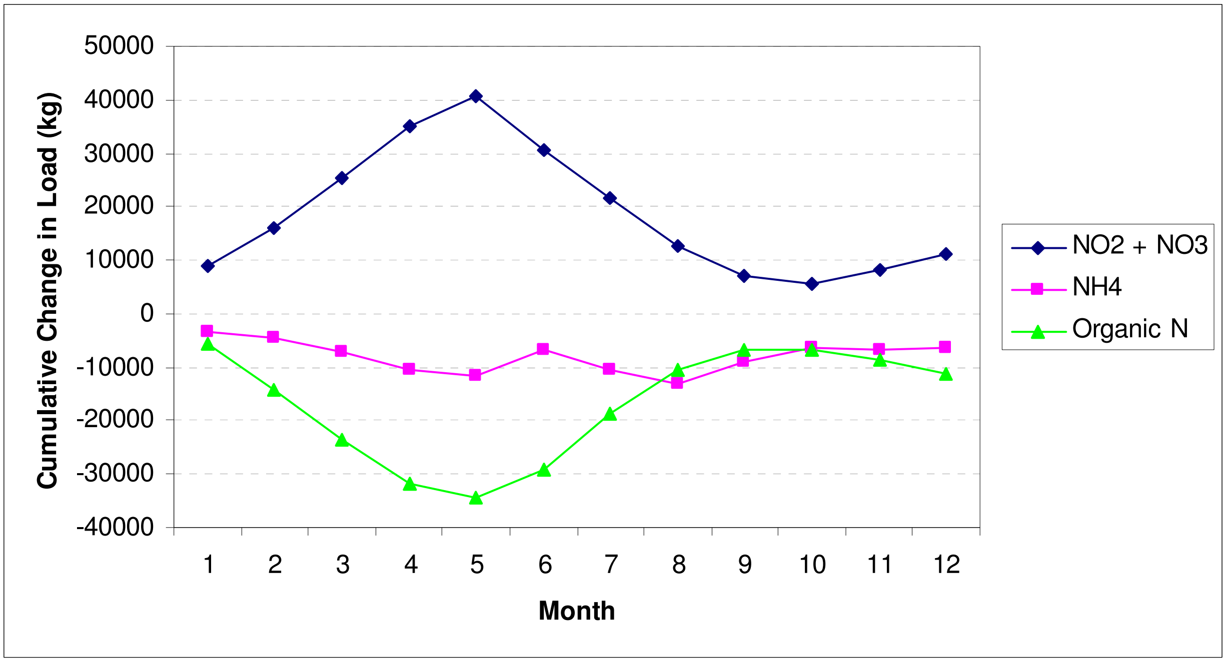

Figure 4. Cumulative Change in Nitrogen Load Predicted by Klamath River Model, Iron Gate to Seiad, for Year 2000

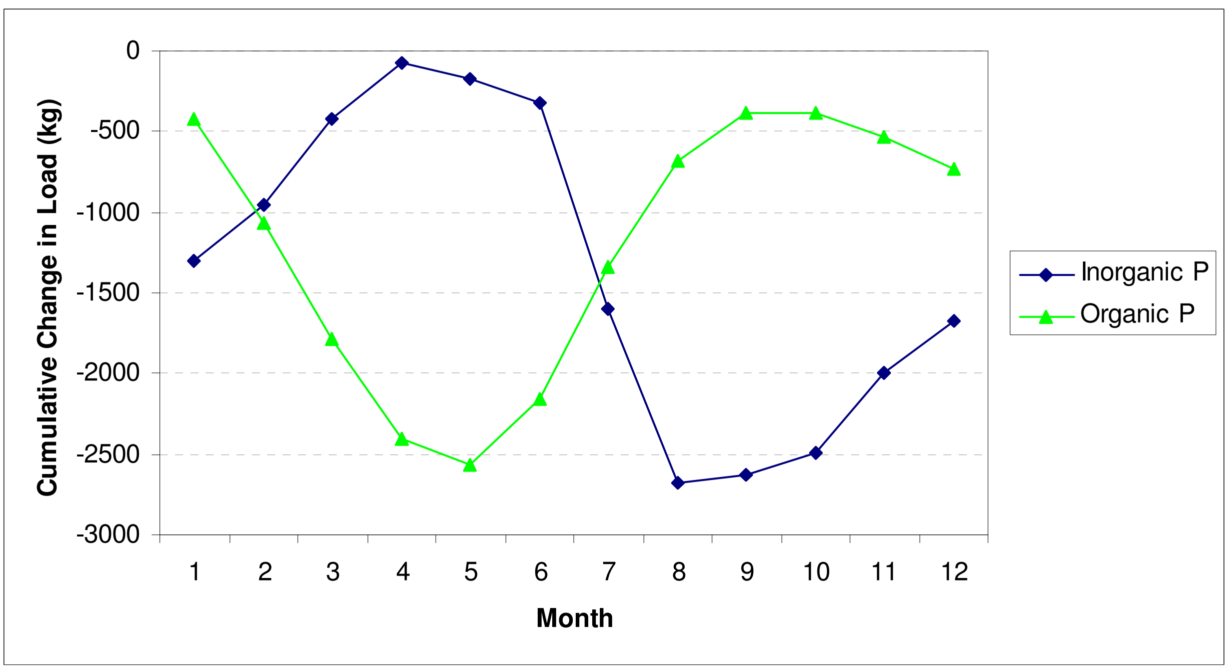

Figure 5. Cumulative Change in Phosphorus Load Predicted by Klamath River Model, Iron Gate to Seiad, for Year 2000

While the model predicts little change in total loads over the course of a year during transit from Iron Gate to Seiad Valley, the annual flow-weighted concentration does decline, by about 17 percent for TN and 19.5 percent for TP (Figure 6). This decline is almost entirely due to accumulation of flow from cleaner tributaries, which dilutes the load originating above Iron Gate dam – and points out the pitfalls inherent in trying to assess retention based only on concentration.

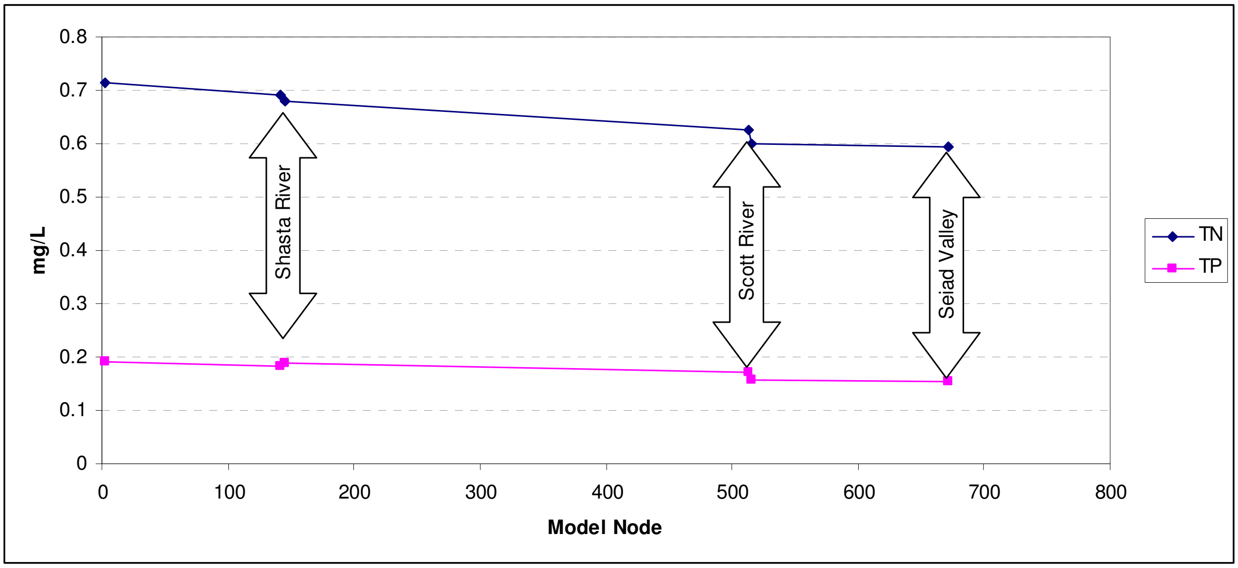

Figure 6. Annual Flow-Weighted Concentrations for 2000 Model Run

In sum, the RMA-11 model application predicts little nutrient loss in the free-flowing reaches of the Klamath, although there is seasonal retention. Even adjusted for partial year estimates, this is at odds with the estimates of Asarian and Kann (2006a), as well as estimates from the USGS SPARROW model. The result is not unexpected, given that RMA-11 provides few permanent sinks for nutrients. The importance of potential sinks (such as denitrification) is unclear, and the estimates from Asarian and Kann (based on limited data) and SPARROW (an approximate, national-scale method) are subject to considerable uncertainty. However, it does appear that the RMA-11 model may have some tendency to underestimate nutrient losses in the free-flowing reaches of the Klamath. The data are not sufficient to resolve whether these factors are significant relative to the overall mass balance, and the magnitude of any such effect cannot be fully resolved without more intensive sampling, coupled with model application to intensively sampled years.

3 Reservoir Retention of Nutrients

Reservoirs can be effective traps of influent nutrients. By design, reservoirs represent areas of a river system in which velocity is decreased and residence time increased. This encourages the settling of particulate material, including both nutrient-bearing organic detritus and nutrients sorbed to inorganic sediment. Reservoirs also encourage the growth of planktonic algae, and settling of dead algal detritus can increase loss rates.

In general, these factors would lead to increased nutrient loss in reservoirs as opposed to free-flowing reaches. The difference, however, depends on reservoir residence time (which is short in the Klamath reservoirs). In addition, there are several compensating factors. First, algal growth in deeper reservoirs is primarily planktonic, and plankton are readily advected downstream, unlike periphytic algae, so reservoirs with short retention times may provide less retention of nutrients than free-flowing reaches.

Second, under anoxic conditions there is typically significant evolution of phosphorus and ammonium from lake sediments (internal loading).

3.1 MASS BALANCE ANALYSES FOR RESERVOIR RETENTION IN THE KLAMATH

The first attempt at nutrient budgets for Iron Gate Reservoir was made by USEPA (1978), based on 1975 monthly sampling. They concluded that the mass of nitrogen leaving Iron Gate was 21 percent higher than inflow, while the reservoir retained 7 percent of the phosphorus mass. As noted by Kann and Asarian (2005), these estimates are based on limited data and are not corrected for changes in reservoir storage.

Kann and Asarian (2005, 2007) have produced two reports on the nutrient budgets of Iron Gate and Copco reservoirs. The first evaluated monthly sampling collected for relicensing purposes in 2002. Unfortunately, data were collected only for March through November, and do not include the full turnover period, so a full year mass balance cannot be created. As with their work on mass balances in the river, Kann and Asarian interpolated concentrations between sampling dates and attempted to evaluate the mass balance on a monthly basis. As with the river, the limited sampling basis and the associated uncertainty in mass calculations renders monthly calculations suspect. Over the period from April 1 to November 13, they estimated net retention in Copco of 36.29 metric tons of TP (26.3 percent of influent loads), and 48.20 metric tons of TN (8.1 percent of influent loads). Over the same period, Iron Gate was estimated to retain 32.4 metric tons of TP (27.3 percent of influent loads) and 65.8 metric tons of TN (12.4 percent of influent loads). Because the calculations do not include the full fall turnover or winter flushing flows, these can be taken as upper bounds on the annual retention. Both reservoirs showed a noticeable shift from inorganic N in the influent to organic N in the effluent, apparently due to algal uptake.

Kann and Asarian (2007) analyzed a complete year of biweekly data collected from May 2005 to May 2006 at several locations in Iron Gate and Copco and their tributaries. Over the entire year, Copco was estimated to retain 9.4 percent of influent phosphorus and 9.1 percent of influent nitrogen, while Iron Gate was estimated to retain 3.1 percent of influent phosphorus and 10.0 percent of influent nitrogen. The annual balances are, however, subject to considerable uncertainty due to large uncertainties in flow measurements (as well as the uncertainties in water quality sampling) over the winter high flow period. For the growing season, defined as May 18 2005 to October 5 2005, Copco was estimated to retain 3.3 percent of influent phosphorus and 18.2 percent of influent nitrogen, while Iron Gate was estimated to retain 0.5 percent of influent phosphorus and 15.3 percent of influent nitrogen. The phosphorus retention rates estimated for the 2005 growing season are dramatically lower than those obtained for 2002 data. Kann and Asarian attribute this difference to higher levels of dissolved P in inflows, coupled with internal P loading. Nitrogen retention estimates for the growing season are twice those obtained earlier for Copco and similar to the 2002 results for Iron Gate.

The differences in the retention rates estimated in the two studies may reflect actual differences in reservoir behavior from year to year. However, it is likely that much of the difference in estimates reflects uncertainties in estimation from limited data. For example, in the 2005-2006 data for Copco inflows, the coefficient of variation (standard deviation divided by the mean) is 0.29 for TP and 0.25 for TN, while the standard error on the mean is 6.2 percent of the influent mean value for TP and 5.3 percent of the influent mean value for TN. Over the summer growing period, the standard errors on the mean for both TP and TN are approximately 9 percent of the influent mean value. The retention estimates are thus generally within the range of two standard errors on the influent mean. This uncertainty or variation in the data supports the need for a modeling approach to interpolate through the limited observations.

As in the earlier report, Kann and Asarian (2007) attempted analyses of mass balances on a monthly basis, and detected periods of negative retention. As each month has only two samples, these estimates are highly uncertain, and results for any given month may be only an artifact of the data. As noted by PacifiCorp (2006), there is a lag time between nutrients entering Copco and being discharged from Iron Gate. As a result of this lag, "it is expected that at times the nutrient concentration in release waters from Iron Gate Reservoir…may be greater than in the inflowing waters to Copco reservoir on the same day, even though the reservoirs act to retain and reduce the loads from these nutrient 'events' as they move through the reservoirs."

3.2 EXPECTED RANGE OF RETENTION

As with the SPARROW estimates for stream reaches, there are simplified empirical methods for estimating nutrient retention in reservoirs that can be used to evaluate whether estimates based on limited observations are reasonable.

Under steady-state conditions,

$$\text{Retention} = 1 - \frac{C}{C_i},$$

where C is the mixed concentration at the dam, and C_i is the influent concentration. In a simple, first-order representation of sedimentation loss, this yields

$$\text{Retention} = 1 - \frac{1}{1 + BT},$$

where B is a first-order sedimentation loss coefficient and T is residence time. For TN, Bachman (1980) gives an estimate of B in terms of flushing rate, as

$$B_{TN} = 0.693\, T^{-0.55}.$$

Similarly, for TP, Vollenweider (1976) estimated

$$B_{TP} = T^{-0.5}.$$

An alternate analysis of TP retention based on an analysis of oxic lakes, exclusive of internal sources, is given by Nürnberg (1984) as

$$\text{Retention} = \frac{15}{18 + z/T},$$

where z is the average depth.

For the two downstream reservoirs in the Klamath system, Copco and Iron Gate, the relevant parameters are given in Table 4. Determination of a residence time is problematic for run-of-river reservoirs that are dominated by winter flow-through. Not only does residence time vary throughout the year, but in addition the reservoirs are not well-mixed in summer, and retention time in the hypolimnion may be much longer than in the epilimnion. For the period of May 2005 through May 2006 reported by Kann and Asarian (2007), the overall residence time in both reservoirs was on the order of 6 days, but the summer residence time of surface waters was around 20-25 days for Copco and 25-35 days for Iron Gate (but can reach as high as 50 days in Iron Gate). For this simple comparison, compromise values of 14 and 16 days were used, combined with summer mean depth.

Table 4. Hydraulic Parameters for Klamath Reservoirs (May 2004 – May 2005)

Impoundment	Residence Time (*T*, yrs)	Mean Depth (*z*, m)
Copco	0.0384	11.7
Iron Gate	0.0484	16.6

Note: Approximate values for summer growing period based on analysis of 2002 and 2004-2005 data in Kann and Asarian (2005, 2007)

Reservoir nutrient retention estimates obtained from the several empirical methods are shown in Table 5, along with the full-year estimates provided by Kann and Asarian (2007). The latter also provide a range of literature-based estimates (Kann and Asarian, 2007, Section 3.4.5.2). For short residence time lakes, the Vollenweider method gives significantly higher retention than that of Nürnberg, with the latter likely being more appropriate. The estimates of Kann and Asarian (2007) on an annual basis are in general agreement with the empirical estimates. Estimated retention is perhaps a little higher than predicted in Copco and lower in Iron Gate – which may reflect the fact that these two reservoirs are in series, with more easily removable material being retained upstream in Copco.

Table 5. Estimated Nutrient Retention for Copco and Iron Gate Reservoirs, 2004-2005

Parameter	Method	Copco	Iron Gate
TP	Vollenweider (1976)	16.4%	17.3%
TP	Nürnberg (1984)	4.6%	3.8%
TP	Range of 5 methods cited by Kann and Asarian (2007)	1.4% - 29%	-1.9% - 29%
TP – 2004-2005 data	Kann and Asarian (2007)	9.4%	3.1%
TN	Bachman (1980)	13.8%	14.5%
TN	Range of 2 methods cited by Kann and Asarian (2007)	8.7% - 10.3%	9.4% - 10.0%
TN – 2004-2005 data	Kann and Asarian (2007)	9.1%	10.0%

3.3 CE-QUAL-W2 IMPLEMENTATION

The CE-QUAL-W2 model (Cole and Wells, 2005) is a two-dimensional, longitudinal/vertical (laterally averaged) hydrodynamic and water quality model that is frequently applied to reservoirs. The model simulates inorganic nutrients (orthophosphate, ammonium, nitrite/nitrate) along with organic matter (labile and refractory, dissolved and particulate) and algae. Decay of organic matter and respiration/death of algae releases inorganic nutrients, while algal growth converts inorganic nutrients to organic matter. In addition to inflow and outflow, the model represents the following internal sources and sinks of nutrients:

Sources	Sinks
Release of PO_4 from sediment under anaerobic conditions Release of NH_4 from sediment under anaerobic conditions	Settling of PO_4 Settling of organic matter Settling of algae Denitrification (loss to atmosphere)

Unlike RMA-11 applications to rivers, the nutrient sinks in CE-QUAL-W2 can be significant. The current version of the model also has the ability to simulate macrophytes with direct uptake of nutrients from the sediment; however, this pathway is not considered important and is not implemented in the Klamath models.

Several other potential source/sink pathways are not included in the model, including:

- Release of inorganic nutrients from the sediment under aerobic conditions (usually not a significant process except in shallow lakes where wind-induced scour can redistribute sediment-sorbed nutrients into the water column).
- Release of organic matter from the sediment.
- Settling of NH_4 (like phosphorus, ammonium can sorb to particulate matter and settle out of the water column).
- Nitrogen fixation (some cyanophytes can fix gaseous nitrogen, resulting in a net input of nitrogen to the system).

It is expected that none of these pathways will be significant in the nutrient mass balance for the Klamath reservoirs. Nitrogen fixation is important in some systems where nitrogen supply is limited. The Klamath reservoirs, however, usually have adequate inorganic nitrogen supplies to support algal growth. Under these circumstances, N-fixing algae tend to uptake dissolved nitrogen directly from the water column as opposed to the air, as nitrogen fixation is a highly energy-demanding process (Welch and Jacoby, 2004).

As with the river simulation, the Klamath River model run output for year 2000 was used to examine the mass balance of nutrients in Iron Gate and Copco Reservoirs. The modelers provided the initial and ending storage volumes, which were combined with concentrations to estimate the change in nutrient storage over the course of the simulation. TN and TP mass balances for the two reservoirs for 2000 are summarized in Table 6 through Table 9.

For TP, the annual retention rate estimated for the model is 6.11 percent for Iron Gate and 1.22 percent for Copco. These are in the range predicted by the Nürnberg (1984) model, although the retention rate for Copco appears a bit low, and also in the range of literature estimates reported by Kann and Asarian. For TN, the annual retention rate estimated by the model is 17.63 percent for Iron Gate and 3.61 percent for Copco. The estimate for Iron Gate is similar to that from the Bachman (1980) estimator and higher than that estimated by Kann and Asarian (2007) for 2004-2005. The TN retention rate for Copco appears low relative to both the Bachman estimate and the analysis of Kann and Asarian based on 2004-2005 data. This could simply reflect differences between years. For instance, dam operations vary significantly over time and can have a major impact on nutrient retention. Another potential explanation for lower retention rates in Copco is the low concentrations of particulate organic matter in inflow to this reservoir, while the buildup of algal biomass in both Copco and Iron Gate may contribute to higher retention rates in the downstream impoundment.

Table 6. Total P Mass Balance (kg) for CE-QUAL-W2 Application for Year 2000, Iron Gate Reservoir

Month	IN	OUT	Change	Retention

Model-predicted reservoir cumulative retentions for nitrogen and phosphorus species are summarized for the two reservoirs in Figure 7 through Figure 10 (uncorrected for changes in storage). For Iron Gate, there is a steady loss of organic nutrients, accompanied by seasonal patterns in inorganic nutrient uptake and release that result in little net change over the course of the year. For Copco, the predicted cumulative loss of organic nutrients is smaller, with increases in inorganic nutrient mass in the fall.

4 Conclusions

The available monitoring data in the Klamath River system is not sufficient to provide a tight closure for nutrient mass balances, and estimates of nutrient retention and loss rates are thus uncertain. It is important to keep in mind the distinction between retention – which delays the transport of nutrients, but does not ultimately remove them – and loss – which results in the long-term removal of nutrients through transfer to stable sediments or the atmosphere.

Both flowing and impounded reaches of the Klamath provide opportunities for retention and loss of nutrients. The dominant process for retention in the system appears to be uptake by algae, which both delays transport downstream and converts inorganic to organic nutrient forms. Given the short residence time in the Klamath reservoirs, retention is likely more significant in flowing reaches, dominated by attached algae, than in the reservoirs, where planktonic algae may be washed downstream. Temporary retention benefits downstream reaches by reducing nutrient loads during the growing season; however, nutrient mass retained in algae is ultimately transported downstream to the estuary, largely after the end of the growing season.

Important loss pathways include denitrification with loss to the atmosphere of nitrogen and deposition of relatively insoluble forms of phosphorus to the sediment. These processes occur in both flowing and impounded reaches. Denitrification permanently removes nitrogen from the aquatic system, and is likely to be significant in the impoundments when the hypolimnion is anoxic. The argument is less clear for the flowing reaches, where oxic conditions are maintained, although some losses likely do occur in conjunction with decaying periphyton mats. For phosphorus, complexes that are insoluble under oxic conditions can often be remobilized under anoxic reducing conditions. This likely limits the annual removal of phosphorus in reservoirs where rapid deep burial is not occurring. (For the Klamath, the presence of reservoirs in series likely limits deep burial rates in the more downstream reservoirs.) For flowing reaches that maintain oxygenation, precipitated phosphorus may remain insoluble – but is prone to transport downstream sorbed to sediment.

Both the CE-QUAL-W2 model and the data analyses of Kann and Asarian (2005, 2007) predict limited amounts of TN and TP removal in Copco and Iron Gate reservoirs. Given the limitations of the available data and associated uncertainty, the model and data-based analyses appear to be in reasonable agreement with one another and with retention estimates based on empirical methods in the literature. The uncertainty in the data supports the need for a modeling approach to interpolate through the limited observations.

For the free-flowing reaches of the Klamath below Iron Gate dam, the RMA-11 model predicts some seasonal retention, but little ultimate loss of nutrients (less than 1% of annual TN and TP loads). In contrast, Asarian and Kann (2006a) contend that there is significant retention of TN between Iron Gate and Seiad. Their estimates are based on seasonal data only, so the annual rate of loss is unknown; however, the estimated seasonal retention rates are much greater than predicted by RMA-11, while appearing to be in approximate agreement with the USGS SPARROW model (Smith et al., 1997). The independent analyses of Armstrong and Ward (2008) do suggest that nutrient loss rates in the Klamath may indeed be quite low, which is consistent with the representation in the calibrated RMA-11 model. Overall, the available data are insufficient to precisely determine the true rates of annual nutrient loss in the free-flowing reaches of the Klamath. Although the RMA-11 model omits several processes such as denitrification that potentially affect nutrient loss rates, most of these processes are also omitted from most other river quality models and it is unclear if they are significant in the Klamath River.

In sum, the linked CE-QUAL-W2 and RMA-11 models of the Klamath appear to provide reasonable estimates of nutrient dynamics in the impoundments, while it is inconclusive whether or not nutrient retention and loss rates in the free-flowing reaches of the Klamath are significantly underestimated.

Despite this unresolved issue, the RMA-11 model appears to be a reasonable tool for assembling the TMDL, as long as the influence of model uncertainty on management decisions is acknowledged.

For the purposes of TMDL-based load allocations, the potential for underestimation of nutrient retention could be treated as a margin of safety (MOS). That is, the actual deleterious impacts of nutrient loads are likely to extend a lesser distance, and create less total algal biomass, than is predicted by the model. Therefore, a TMDL based on the model would include an implicit MOS insofar as the efficacy of nutrient reductions in controlling periphytic algal biomass in the river and its effect on the diurnal DO cycle is likely to be underestimated to some degree. Scenario analyses that depend on the relative retention rates of nutrients in flowing and impounded reaches (such as dam removal scenarios) must be approached with particular care, given the current level of uncertainty in the simulation of retention and loss rates. Interpretation of such scenarios will need to include an evaluation of the decision implications of model and data uncertainty. Additional, focused studies on potential nutrient loss mechanisms are recommended to further reduce uncertainty.

CHAPTER 1. TEMPERATURE

1.1 Introduction

Temperature is one of the most important environmental influences on salmonid biology. Most aquatic organisms, including salmon and steelhead, are poikilotherms, meaning their temperature and metabolism is determined by the ambient temperature of water. Temperature therefore influences growth and feeding rates, metabolism, development of embryos and alevins, timing of life history events such as upstream migration, spawning, freshwater rearing, and seaward migration, and the availability of food. Temperature changes can also cause stress and lethality (Ligon et al. 1999). Temperatures at sub-lethal levels can effectively block migration, lead to reduced growth, stress fish, affect reproduction, inhibit smoltification, create disease problems, and alter competitive dominance (Elliott 1981, USEPA 1999a). Further, the stressful impacts of water temperatures on salmonids are cumulative and positively correlated to the duration and severity of exposure. The longer the salmonid is exposed to thermal stress, the less chance it has for long-term survival (Ligon et al. 1999).

A literature review was performed to evaluate temperature needs for the various life stages of steelhead trout (*Oncorhynchus mykiss*), coho salmon (*Oncorhynchus kisutch*), and Chinook salmon (*Oncorhynchus tschawytscha).* The purpose of this review was to identify temperature thresholds that are protective of salmonids by life stage, as a basis for evaluating stream temperatures in California temperature TMDLs within the North Coast region.

This review included USEPA temperature guidance, Oregons' and Washingtons' temperature standards reviews, reports that compiled and summarized existing scientific information, and laboratory and field studies. When possible, species-specific needs were summarized by the following life stages: migrating adults, spawning and incubation/emergence, and freshwater rearing and growth. Additionally, the effects of temperature on disease and lethality are also discussed. Some of the references reviewed covered salmonids as a general class of fish, while others were species specific. Information for fall run coho salmon, spring/summer, fall, and winter steelhead, and spring and fall run Chinook salmon are compiled by life stage in Table 1 through Table 12.

1.2 Temperature Metrics

In considering the effect of temperature on salmonids, it is useful to have a measure of chronic and acute (i.e. sub-lethal and lethal) temperature exposures. A common measure of chronic exposure is the maximum weekly average temperature (MWAT). The MWAT is the maximum seasonal or yearly value of the mathematical mean of multiple, equally spaced, daily temperatures over a running seven-day consecutive period (Brungs and Jones 1977, p.10). In other words, it is the highest single value of the seven-day moving average temperature. A common measure of acute effects is the instantaneous maximum. A third metric, the maximum weekly maximum temperature (MWMT), can be used as a measure of both chronic and acute effects. The MWMT is also known as the seven-day average of the daily maximum temperatures (7-DADM), and is the maximum seasonal or yearly-value of the daily maximum temperatures over a running seven-day consecutive period. The MWMT is useful because it describes the maximum temperatures in a stream, but is not overly influenced by the maximum temperature of a single day.

Much of the information reported in the literature characterizes temperature needs with terms such as "preferred" or "optimum". Preferred stream temperatures are those that fish most frequently inhabit when allowed to freely select temperatures in a thermal gradient (USEPA 1999a). An optimum range provides suitable temperatures for feeding activity, normal physiological response, and normal behavior (without symptoms of thermal stress) (USEPA 1999a). Optimal temperatures have also been described as those temperatures at which growth rates, expressed as weight gain per unit of time, are maximal for the life stage (Armour 1991).

Salmonid stocks do not tend to vary much in their life history thermal needs, regardless of their geographic location. In the 2001 USEPA document, *Summary of Technical Literature Examining the Physiological Effects of Temperature on Salmonids*, the case is made that there is not enough significant genetic variation among stocks or among species of salmonids to warrant geographically specific water temperature standards.

> Climate conditions vary substantially among regions of the State and the entire Pacific Northwest. …Such [varying climatic] conditions could potentially have led to evolutionary adaptations, resulting in development of subspecies differences in thermal tolerance. …[However,] the literature on genetic variation in thermal effects indicates occasionally significant but very small differences among stocks and increasing differences among subspecies, species, and families of fishes. Many differences that had been attributed in the literature to stock differences are now considered to be statistical problems in analysis, fish behavioral responses under test conditions, or allowing insufficient time for fish to shift from field conditions to test conditions (Mathur & Silver 1980, Konecki et al. 1993, both as cited in USEPA 2001).

Additionally:

> There are many possible explanations why salmonids have not made a significant adaptation to high temperature in streams of the Pacific Northwest. Temperature tolerance is probably controlled by multiple genes, and consequently would be a core characteristic of the species not easily modified through evolutionary change without a radical shift in associated physiological systems. Also, the majority of the life cycle of salmon and steelhead is spent in the ocean rearing phase, where the smolt, subadults, and adults seek waters with temperatures less than 59°F (15°C) (Welch et al, 1995, as cited in USEPA 2001).

As a result, literature on the temperature needs of coho and Chinook salmon and steelhead trout stemming from data collected in streams outside Northern California are cited in this document and are considered relevant to characterizing the thermal needs of salmonids, which use Northern California rivers and streams.

1.3 Adult Migration and Holding

All of the adult migration and holding temperature needs referenced in this section can be found in Table 1 through Table 3. Salmon and trout respond to temperatures during their upstream migration (Bjornn and Reiser 1991). Delays in migration have been observed in response to temperatures that were either too cold or too warm. Most salmonids have evolved with the temperature regime they historically used for migration and spawning, and deviations from the normal pattern can affect survival (Spence et al. 1996).

In a 2003 USEPA document entitled *EPA Region 10 Guidance for Pacific Northwest State and Tribal Water Quality Standards*, it is recommended that the 7-DADM should not exceed 18°C in waters where both adult salmonid migration and "non-core" juvenile rearing occur during the period of summer maximum temperatures. The document does not define what constitutes the "summer" period. Non-core juvenile rearing is defined as moderate to low density salmon and trout rearing usually occurring in the mid or lower part of the basin, as opposed to areas of high density rearing which are termed "core" rearing areas. This criterion is derived from analysis and synthesis of past laboratory and field research. The USEPA believes that this temperature recommendation will protect against lethal conditions, prevent migration blockage, provide optimal or near optimal juvenile growth conditions, and prevent high disease risk by minimizing the exposure time to temperatures which can lead to elevated disease rates.

A 7-DADM temperature of 20°C is recommended by the USEPA (2003) for waterbodies that are used almost exclusively for migration during the period of summer maximum temperatures.

> EPA believes that a 20°C criterion would protect migrating juveniles and adults from lethal temperatures and would prevent migration blockage conditions. However, EPA is concerned that rivers with significant hydrologic alterations (e.g., rivers with dams and reservoirs, water withdrawals, and /or significant river channelization) may experience a loss of temperature diversity in the river, such that maximum temperatures occur for an extended period of time and there is little cold water refugia available for fish to escape maximum temperatures. In this case, even if the river meets a 20°C criterion for maximum temperatures, the duration of exposure to 20°C temperatures may cause adverse effects in the form of increased disease and decreased swimming performance in adults, and increased disease, impaired smoltification, reduced growth, and increased predation for late emigrating juveniles…(USEPA 2003).

Therefore, the USEPA recommends a narrative provision to protect and, if possible, restore the natural thermal regime accompany the 7-DADM 20°C criterion for rivers with significant hydrologic alterations.

In an exhaustive study of both laboratory and field studies of temperature effects on salmonids and related species, USEPA (1999a, 2001) concluded that temperatures of approximately 22-24°C limit salmonid distribution, i.e., they totally eliminate salmonids from a location. USEPA (1999a) also notes that changes in competitive interactions between fish species can lead to a transition in dominance from salmonids to other species at temperatures 2-4°C lower than the range of total elimination.

1.3.1 Steelhead Trout Migration

In a 2002 review of numerous studies, Washington State Department of Ecology (WDOE) concluded that daily average temperatures of 21-24°C are associated with avoidance behavior and migration blockage in steelhead trout. WDOE suggests that the MWMT should not exceed 17-18°C, and daily maximum temperatures should not exceed 21-22°C to be fully protective of adult steelhead migration.

1.3.2 Chinook Salmon Migration and Holding

USEPA (2001) cited various literature sources that identified thermal blockages to Chinook salmon migration at temperatures ranging from 19-23.9°C, with the majority of references citing migration barriers at temperatures around 21°C.

A radio tracking study on spring Chinook revealed that when maximum temperatures of 21.1°C were reached, a thermal barrier to migration was established (Bumgarner et al. 1997, as cited by USEPA 1999a). Bell (1986) reviewed various studies and notes spring Chinook migrate at water temperatures ranging from 3.3-13.3°C, while fall Chinook migrate at temperatures of 10.6-19.6°C. Preferred temperatures for Chinook range from 7.2-14.5°C (Bell 1986). Based on a technical literature review, WDOE (2002) concluded that daily maximum temperatures should not exceed 21-22°C during Chinook migration.

Sources: (1) USEPA 2003, (2) WDOE 2002, (3) USEPA 2001, (4) Bell 1986, (5) USEPA 1999a, (6) Strange 2006

Utilizing radio telemetry to track the movements and monitor the internal body temperatures of adult fall Chinook salmon during their upriver spawning migration in the Klamath basin, Strange (2006) found that fall Chinook will not migrate upstream when mean daily temperatures are ≥22°C. Strange also noted that adult fall Chinook in the

Klamath basin will not migrate upstream if temperatures are 21°C or above and rising, but will migrate at temperatures as high as 23°C if temperatures are rapidly falling.

Spring Chinook begin entering freshwater streams during a relatively cool-water season but must hold throughout the warm summer period, awaiting cooler spawning temperatures (ODEQ 1995a). The cumulative effects of management practices such as elevated water temperatures, reduced cover from large woody debris, and reduced resting pool area due to pool filling increase the susceptibility of holding adult fish to mortality from thermal effects (The Oregon Department of Environmental Quality [ODEQ] 1995a). WDOE states that where spring Chinook are holding over for the summer prior to spawning the average daily water temperature should be below 13-14°C and the MWMT should be below 16-17°C (WDOE 2002).

1.3.3 Coho Salmon Migration

Migration for coho is delayed when water temperatures reach 21.1°C, and the preferred water temperatures for coho range from 11.7-14.5°C (Bell 1986). In California coho salmon typically migrate upstream when water temperatures range from 4-14°C (Briggs, 1953 and Shapovalov and Taft, 1954, as cited by Hassler, 1987). WDOE reviewed various studies and concluded that to be protective of adult coho migration, MWMTs should not exceed 16.5°C (WDOE 2002).

1.4 Spawning, Incubation, and Emergence

All of the spawning, incubation, and emergence temperature needs referenced in this section can be found in Table 4 through Table 7. Many sources have stated that temperature affects the time of migration i adults and thus the time of spawning, which influences the incubation temperature regime, which in turn influences survival rates, development rates, and growth of embryos and alevins (Murray and McPhail 1988). USEPA Region 10 recommends that the 7-DADM temperatures should not exceed 13°C for salmonid spawning, egg incubation, and fry emergence (USEPA 2003). Optimum temperatures for salmonid egg survival ranges from 6-10°C (USEPA 2001).

1.4.1 Steelhead Spawning, Incubation, and Emergence

In a discussion paper and literature summary evaluating temperature criteria for fish species including salmonids and trout, WDOE (2002) cites studies showing that steelhead were observed spawning in temperatures ranging from 3.9-21.1°C, and that the preferred temperatures for steelhead spawning range from 4.4-12.8°C. In a review of various studies, Bell (1986) concludes that steelhead spawning occurs at water temperatures ranging from 3.9-9.4°C.

Steelhead and rainbow trout eggs had the highest survival rates between 5-10°C according to Myrick and Cech (2001), and while they can tolerate temperatures as low as 2°C or as high as 15°C, mortality is increased at these temperatures. WDOE (2002) reviewed literature on the survival of steelhead and rainbow trout embryos and alevins at various temperatures and concluded that the average water temperature should not exceed 7-10°C throughout development, and the maximum daily average temperature should be below 11-12°C at the time of hatching (WDOE 2002).

1.4.2 Chinook Spawning, Incubation, and Emergence

ODEQ (1995a) reviewed numerous studies and recommended a temperature range of 5.6-12.8°C for spawning Chinook. A discussion paper and literature summary by WDOE in 2002 found that the literature reviewed noted a wide range of temperatures associated with Chinook spawning (5.6-17.7°C), although the majority of these temperature observations cite daily maximum temperatures below 14.5°C. A spawning temperature range of 5.6-13.9°C is recommended for spring, summer, and fall Chinook salmon populations in the Pacific Northwest (Reiser and Bjornn 1979, as cited by Armour et al. 1991). When ripe adult spring Chinook females experience temperatures above 13-15.5°C, pre-spawning adult mortality becomes pronounced (ODEQ 1995a). Additionally, there is decreased survival of eggs to the eyed stage and alevin development is inhibited due to the exposure of the ripe female to warm temperatures, even if the stream temperatures during the egg and alevin development are appropriate (ODEQ 1995a).

Sources: (1) USEPA 2003, (2) WDOE 2002, (3) Myrick and Cech 2001, (4) Reiser and Bjornn 1979, as cited by Armour et al. 1991, (5) USEPA 2001, (6) Murray and McPhail 1988

WDOE (2002) reviewed numerous references on the effects of various temperatures on Chinook incubation and development and used these studies to derive the temperatures that are protective of Chinook salmon from fertilization through fry development. These reviewed references include laboratory studies assessing Chinook embryo survival at various constant temperatures, studies attempting to mimic naturally fluctuating temperatures experienced by incubating eggs, studies which have made stepwise reductions in the incubation temperatures as incubation progressed to evaluate survival of eggs, and studies on the effects of transferring eggs to optimal constant incubation temperatures after they had been exposed to higher temperatures for various periods. As a result of this review, WDOE (2002) recommends that average daily temperatures remain below 11-12.8°C at the initiation of incubation, and that the seasonal average should not exceed 8-9°C in order to provide full protection from fertilization through initial fry development. The highest single day maximum temperature should not exceed 17.5-20°C to protect eggs and embryos from acute lethal conditions (WDOE 2002).

USEPA (2001) reviewed multiple literature sources and concluded that optimal protection from fertilization through initial fry development requires that temperatures be maintained below 9-10°C, and that daily maximum temperatures should not exceed 13.5-14.5°C. Reiser and Bjornn (1979, as cited by Armour et al. 1991) recommended temperatures of 5.0-14.4°C for spring, summer and fall Chinook salmon incubation in the Pacific Northwest. Myrick and Cech (2001) reviewed studies on the Sacramento-San Joaquin River and concluded that the lowest levels of Chinook egg mortality occurred at temperatures between 4-12°C, and while eggs can survive at temperatures from 1.7-16.7°C, mortality is greatly increased at the temperature extremes.

Embryo survival was studied in a laboratory experiment conducted by Murray and McPhail (1988). They incubated five species of Pacific salmon, including Chinook, at five incubation temperatures (2, 5, 8, 11, 14°C). Chinook embryo survival was high at 5, 8, and 11°C, but survival was moderate at 14°C and poor at 2°C. As a result of their study, Murray and McPhail concluded that the range of temperatures for normal embryo development is > 2°C and <14°C (Murray and McPhail 1988).

1.4.3 Coho Spawning, Incubation, and Emergence

In 2002, WDOE found that several studies and literature reviews state that spawning activity in coho may typically occur in the range of 4.4-13.3ºC. According to a review by Bell (1986), preferred spawning temperatures range from 4.5-9.4ºC. Brungs and Jones (1977) used existing data on the optimum and range of temperatures for coho spawning and embryo survival to create criteria using protocols from the National Academy of Sciences and National Academy of Engineering. The resultant criteria were that the MWAT should not exceed 10ºC and the daily maximum temperature should not exceed 13ºC to be protective of coho (Brungs and Jones 1977, p.16).

In a discussion paper and literature summary WDOE (2002) reviewed studies that assessed the survival of embryos and alevin at various temperatures. Based on the findings of these studies WDOE (2002) has determined that the average daily temperature during the incubation period should be at or below 8-10ºC to fully support this coho salmon life stage. According to a review of various literature sources by Bell

(1986), the preferred emergence temperatures for coho range from 4.5-13.3ºC. USEPA (2001) concluded that to fully support pre-emergent stages of coho development MWMTs should not exceed 9-12°C.

Murray and McPhail (1988) incubated five species of Pacific salmon, including coho, at five temperatures (2, 5, 8, 11, 14°C) to determine embryo survival at various temperatures. Coho embryos suffered increased mortality above 11°C although survival was still high. They concluded that the upper limit for normal coho embryo development is 14°C (Murray and McPhail 1988).

1.5 Freshwater Rearing and Growth

All of the freshwater rearing and growth temperature needs referenced in this section can be found in Table 8 through Table 10. Temperature affects metabolism, behavior, and survival of both juvenile fish as well as other aquatic organisms that may be food sources. In streams of the Northern California Coast, including the Klamath River, young Chinook, coho and steelhead may rear in freshwater from one to four years before migrating to the ocean.

In an exhaustive study of both laboratory and field studies of temperature effects on salmonids and related species, USEPA (1999a) concluded that temperatures of approximately 22-24°C limit salmonid distribution, i.e., they totally eliminate salmonids from a location. USEPA (1999a) also notes that changes in competitive interactions between fish species can lead to a transition in dominance from salmonids to other species at temperatures 2-4°C lower than the range of total elimination.

To protect salmon and trout during summer juvenile rearing the USEPA (2003) for Region 10 provided a single guidance metric designating 16°C as the 7-DADM temperature that should not be exceeded in areas designated as "core" rearing locations. Core rearing areas are defined as areas with moderate to high densities of summertime salmonid juvenile rearing generally found in the mid- to upper portions of river basins. This criterion will protect juvenile salmonids from lethal temperatures, provide optimal to upper optimal conditions for juvenile growth depending on the time of year, avoid temperatures where salmonids are at a competitive disadvantage with other fish species, protect against increased disease rates caused by elevated temperatures, and provide temperatures which salmonids prefer according to scientific studies.

1.5.1 Steelhead Freshwater Rearing and Growth

Nielsen et al. (1994) studied thermally stratified pools and their use by juvenile steelhead in three California North Coast rivers including the Middle Fork Eel River, Redwood Creek at Redwood National Park, and Rancheria Creek, located in the Navarro River watershed. In detailed observations of juvenile steelhead behavior in and near thermally stratified pools in Rancheria Creek, Nielsen et al. (1994) noted behavioral changes including decreased foraging and increased aggressive behavior as pool temperature reached approximately 22°C. As pool temperature increased above 22°C, juveniles left the observation pools and moved into stratified pools where temperatures were lower.

Wurtsbaugh and Davis (1977, as cited by USEPA 2001) found that steelhead trout growth could be enhanced by temperature increases up to 16.5°C. Using a risk assessment approach which took into account "realistic food estimates", Sullivan et al. (2000) report temperatures of 13-17.0°C (MWAT), 14.5-21°C (MWMT), and 15.5-21°C (annual maximum) will ensure no more than a 10% reduction from maximum growth for steelhead. Reduction from maximum growth will be ≤20% for temperatures ranging from 10-19.0°C (MWAT), 10-24°C (MWMT), and 10.5-26°C (annual maximum).

A literature review was conducted by WDOE (2002) in which studies to determine the water temperature that would allow for maximum growth of steelhead trout were analyzed. These included laboratory studies conducted at constant and fluctuating temperatures. One of the studies was conducted using feeding rates comparable to those observed in natural creeks, although most of the laboratory studies were conducted under satiated feeding conditions. As a result of this review of laboratory studies conducted at constant temperatures, WDOE (2002) concludes that under satiated rations growth may be maximized at temperatures as high as 17.2-19°C. Results from laboratory studies using variable temperatures show maximum growth occurs at average daily temperatures between 15.5-18°C, and that under feeding rates similar to natural conditions at various times of the year maximum growth rates occurred at mean temperatures of 13.3°C (spring season), 15.2°C (fall season) and 16.2°C (summer season).

1.5.2 Chinook Freshwater Rearing and Growth

In a laboratory study, Brett (1952) demonstrated that juvenile Chinook salmon, acclimated to a temperature of 20°C, selectively aggregated in areas where the temperature was in the region of 12-13°C.

ODEQ (1995a), reviewed numerous studies and concluded for juvenile spring Chinook salmon rearing, positive growth takes place at temperatures between 4.5-19°C, and that optimum rearing production is between 10.0-15.6°C. However, as the extremes of this temperature range are reached growth reaches zero. Above and below these thresholds growth becomes negative as feeding ceases and respiration rates increase and/or decrease rapidly.

After synthesizing data from several sources USEPA (2001), came up with the same recommended optimum temperature zone for all Chinook salmon as ODEQ (1995a) of 10.0-15.6°C. While there is research suggesting that some Chinook stocks exhibit adequate rearing capabilities above 15.6°C, USEPA (2001) conclude that anything over this threshold significantly increases the risk of mortality from warm-water diseases.

In a laboratory study Marine and Cech (2004) studied the incremental effects of chronic exposure to three temperature regimes (13-16 °C, 17-20 °C, and 21-24 °C) on Chinook juveniles during rearing and smoltification. Their findings reflected that Chinook juveniles reared at the 17-20 ºC and 21-24 ºC temperature ranges experienced significantly decreased growth rates, impaired smoltification indices, and increased predation vulnerability compared with juveniles reared at 13-16 ºC.

In a field study Chinook grew faster in a stream where temperatures peaked at 16°C compared to a stream where temperatures peaked at 20°C (ODFW 1992, as cited by WDOE 2002). WDOE (2002) reviewed literature on Chinook growth including laboratory studies conducted at a constant temperature, laboratory studies conducted at fluctuating temperatures, and field studies to evaluate the water temperature that would be protective of Chinook and allow for maximum growth. Most of the laboratory studies were conducted under satiated feeding conditions, although one of the studies was conducted using feeding rates more comparable to those observed in natural creeks. As a result of this review of laboratory studies conducted at constant temperatures, WDOE (2002) concludes that maximum growth is expected to occur with exposure to constant temperatures from 15.6-19°C. However, increased growth at temperatures above 15.6°C was inconsistently greater, and under natural rations the temperatures at which maximum growth occurs may decline by as much as 4.2°C. Recommendations based on the review of two laboratory studies conducted at fluctuating temperatures are that "…average temperatures below 19°C are necessary to support maximum growth rates in Chinook salmon, and that the average temperature that produces maximum growth rates likely lies between 15-18°C (median 16.5°C)".

1.5.3 Coho Freshwater Rearing and Growth

In a study of juvenile coho presence and absence in the Mattole watershed, Welsh et al. (2001) used logistic regression to determine that an MWAT greater than 16.8°C or a MWMT greater than 18.1°C may preclude the presence of juvenile coho salmon in the stream. The criterion correctly determined the presence or absence of juvenile coho in 18 of 21 streams. Welsh et al. (2001) also reported that juvenile coho were found in all streams with an MWAT less than 14.5°C, or a MWMT less than 16.3°C.

Sullivan et al. (2000) reviewed sub-lethal and acute temperature thresholds from a wide range of studies, incorporating information from laboratory-based research, field observations, and risk assessment approaches. Using a risk assessment approach based on "realistic food estimates" Sullivan et al (2000) suggest that MWATs ranging from 12.5-14.5°C for coho will result in no more than a 10% reduction from maximum growth, and that a range for the MWAT of 9-18.5°C will reduce growth no more than 20% from maximum. Sullivan et al. (2000) also calculated temperature ranges for MWMT (13-16.5°C) and the annual maximum temperature (13-17.5°C) that will result in no more than a 10% reduction in maximum growth. They further calculated ranges for MWMT (9-22.5°C) and the annual maximum temperature (9.5-23°C) that will result in no more than a 20% growth loss.

In an attempt to determine the water temperature that will allow for maximum growth of coho salmon, WDOE (2002) reviewed literature on laboratory studies conducted at a constant temperature and fluctuating temperatures, and field studies. The two laboratory studies reviewed were conducted under satiated feeding conditions. Shelbourn (1980, as cited by WDOE 2002) found that maximum growth occurred at a constant temperature of 17°C, while Everson (1973, as cited by WDOE 2002) tested fish at different temperatures and determined that coho had the greatest growth at the temperature test regime from 12.1-20.8°C (median 16.5°C). While the various field studies reviewed did not provide an estimate of the temperature best for maximum growth they did allow for WDOE (2002) to conclude that weekly average temperatures of 14-15°C were more beneficial to growth than lower temperature regimes, and daily maximum temperatures of 21-26°C were detrimental to growth.

Brett (1952) acclimated five different species of salmon to various temperatures ranging from 5-24°C and found that coho salmon showed the greatest preference for temperatures between 12-14°C. It was also determined that coho showed a general avoidance of temperatures above 15°C even in fish who were acclimated to temperatures as high as 24°C.

Konecki et al. (1995a) raised two groups of juvenile coho salmon under identical regimes to test the hypothesis that the group from a stream with lower and less variable temperature would have a lower and less variable preferred temperature than the group from a stream with warmer and more variable temperatures. Results reflected that the two groups tended to differ in their preferred temperature range as predicted above, but the differences were slight. Konecki et al. (1995a) concluded that the temperature preference of juvenile coho salmon in their study was 10-12°C.

1.6 Lethality

All of the lethal temperatures referenced in this section can be found in Table 11. WDOE (2002) reviewed literature on three types of studies (constant exposure temperature studies, fluctuating temperature lethality studies, and field studies) and used this information to calculate the MWMT that, if exceeded, may result in adult and juvenile salmonid mortality. The resultant MWMTs for these various types of studies are as follows: constant exposure studies 22.64°C, fluctuating lethality studies 23.05°C , and field studies 22.18°C.

1.6.1 Steelhead Lethality

Coutant (1970, as cited by USEPA 1999a) found that Columbia River steelhead, which were acclimated to a river temperature of 19°C, had a lethal threshold of 21°C. Bell (1986) reviewed various studies and states that the lethal threshold for steelhead is 23.9°C. According to the California Department of Fish and Game (2001, p.419), temperatures of 21.1°C have been reported as being lethal to adults.

1.6.2 Chinook Lethality

In a laboratory study, Brett (1952) acclimated five different species of juvenile salmon to various temperatures ranging from 5-24°C. At temperatures of 24°C and below there was 100% survival of fish during the one-week duration of the experiment. Brett (1952) concluded that the lethal temperature (temperature where survival becomes less than 100%) was between 24.0 and 24.5°C, and the ultimate upper lethal temperature was 25.1°C (temperature at which 50% of the population is dead after infinite exposure). A review of numerous studies led Bell (1986) to conclude that the upper lethal temperature for Chinook is 25°C. Myrick and Cech (2001) reviewed literature on studies from the Central Valley and found data to suggest that the chronic (exposure >7 days) upper lethal limit for juvenile Chinook is approximately 25°C.

1.6.3 Coho Lethality

In a review of various literature sources, Bell (1986) found that the upper lethal temperature for coho is 25.6°C. Brett (1952) concluded that the ultimate upper lethal temperature of juvenile coho salmon was 25.0°C (temperature at which 50% of the population is dead after infinite exposure). Thomas et al. (1986) conducted a study to determine the mortality of coho subjected to fluctuating temperatures. It was determined that the LT50 (the temperature at which 50% of the population will die) for fish acclimated to a 10-13°C cycle was 26°C for presmolts (age-2 fish), and 28°C for age-0 fish.

Table 11: Effects of Temperature in Considering Lethality and Salmonids

°C	Steelhead	Chinook	Coho	All Salmonids
28			28 LT50[1] for age 0-fish acclimated to a 10-13C cycle (6)	
27				
26			26 LT50[1] for presmolts (age 2-fish) acclimated to a 10-13C cycle (6)	
25		25.1 Upper lethal temp. at which 50% of the population would die after infinite exposure, juvenile Chinook acclimated to temperatures from 5-24C (4)	25.6 Upper lethal threshold (3)	
		25 Upper lethal threshold (3)	25 Upper lethal temp. at which 50% of the population would die after infinite exposure, juvenile coho acclimated to temps. from 5-24C (4)	
		25 Chronic (exposure >7 days) upper lethal limit for juvenile Chinook (5).		
24		24-24.5 Survival becomes less than 100% for juvenile Chinook acclimated to temperatures from 5-24C (4)		
23	23.9 Upper lethal threshold for steelhead (3)			23.05 do not exceed this value to prevent adult and juvenile mortality, data from fluctuating temp. studies (1)
22				22.64 do not exceed this value to prevent adult and juvenile mortality, data from constant exposure studies (1)
				22.18 do not exceed this value to prevent adult and juvenile mortality, data from field studies (1)
21	21.1 Temperature lethal to adults (7)			
	21 Lethal threshold for steelhead acclimated to 19C (2)

1.7 Disease

All of the effects of temperatures on disease risk in salmonids referenced in this section can be found in Table 12. WDOE (2002) reviewed studies of disease outbreak in salmonids and estimates that an MWMT of less than or equal to 14.38°C (midpoint of 12.58-16.18 range) will virtually prevent warm water disease effects. To avoid serious

In a summary of temperature considerations, USEPA (2003) states that disease risks for juvenile rearing and adult migration are minimized at temperatures from 12-13°C, elevated from 14-17°C, and high at temperatures from 18-20°C.

Acknowledging that there are many diseases that affect salmonids, the following discussion will focus on three which are common in the Klamath Basin: Ichthyophthiriasis (Ich), Ceratomyxosis, and Columnaris. *Ichthyophthirius multifiliis* is a protozoan parasite that causes the disease known as Ichthyophthiriasis (Ich). The disease ceratomyxosis is caused by a parasite, *Ceratomyxa shasta* (*C. shasta*). Columnaris disease is a bacterial infection caused by *Flavobacterium columnare* (synomyms*: Bacillus columnaris, Chondrococcus columnaris, Cytophaga columnaris, Flexibacter columnaris*).

1.7.1 Ichthyophthiriasis (Ich)
Nigrelli et al. (1976, as cited by Dickerson et al. 1995) proposed that there are physiological races of Ich, which are related to the temperature tolerance of the host fishes. Thus, there are races of Ich that infect cold-water (7.2-10.6°C) fishes such as salmon, and others that infect warm-water (12.8-16.1°C) tropical fishes. Bell (1986) discusses Ich and states that at water temperatures above 15.6°C, this disease often breaks out in salmon fingerlings, especially Chinook. CDWR (1988) states that serious outbreaks of Ich occur at temperatures from 18.3-21.2°C.

Numerous studies and reviews have been conducted on the optimal temperature for Ich. Piper et al. (1982, p.316.) wrote that optimal temperatures range from 21-23.9°C. CDWR (1988) stated the optimum temperature for Ich is in the range of 25 to 26.7°C, while Bell (1986) states optimum temperatures are noted from 21.2-26.7°C.

Temperature is an important factor in the persistence of Ich infections in salmonids. The growth period varies from 1 week at 20 °C to 20 days at 7 °C (Nigrelli et al. 1976, as cited by Dickerson et al. 1995). Piper et al. (1982, p.316) state that at optimal temperatures of 21-23.9°C, the life cycle may take as few as 3-4 days. The cycle requires 2 weeks at 15.5°C, and more than 5 weeks at 10°C (Piper et al. 1982, p.316). Durborow et al. (1998) note that to complete its lifecycle, Ich requires from less than 4 days at temperatures higher than 24°C, to more than 5 weeks at temperatures lower than 7°C. Although studies report varying lengths of time for Ich to complete its lifecycle at similar temperatures, it is clear that the speed at which Ich develops increases as temperatures increase.

1.7.2 Ceratomyxosis
In reviewing the literature on Ceratomyxosis (a disease caused by the parasite, C. shasta), it is clear that as water temperatures increase, the intensity of the disease increases, and the incubation period decreases (CDWR 1988, Letritz and Lewis, Udey et al. 1975). At

water temperatures greater than 10°C, steelhead will show evidence of Ceratomyxosis in approximately 38 days (Leitritz and Lewis 1976, p.154). In a study of juvenile coho salmon by Udey et al. (1975), time from exposure to death was more than 90% temperature dependent, and increased from 12.5 days at 23.3°C, to 146 days at 9.4°C. These results show the accelerating effect of higher temperatures on the progress of the disease. The time from exposure to death of juvenile rainbow trout was nearly 97% temperature dependent, increasing from 14 days at 23.3°C to 155 days at 6.7°C (Udey et al. 1975).

C. shasta appears to become infective at temperatures around 10-11°C (CDWR 1988). According to Leitritz and Lewis (1976, p.154), steelhead from the Klamath River are quite susceptible to *C. shasta* infections and suffer severe losses when exposed.

Udey et al. (1975) conducted a study to determine the relation of water temperature to Ceratomyxosis in juvenile rainbow trout and coho salmon. Rainbow trout from the Roaring River Hatchery, and coho from Fall Creek Salmon Hatchery (both in Oregon) were used in this experiment. Groups of 25 fish exposed to *C. shasta* were transferred to 12.2°C water, and then were tempered to one of eight experimental temperatures from 3.9 to 23.3°C (2.8°C increments).

In the juvenile coho salmon experiment, Udey et al. (1975) found that percent mortality increased progressively from 2% at 9.4°C to 22% at 15.0°C and 84% at 20.5°C. No deaths occurred in coho salmon maintained at 3.9 and 6.7°C, indicating that ceratomyxosis in coho can be suppressed by water temperatures of 6.7°C or below (Udey et al. 1975).

Tests conducted by Udey et al. (1975) on rainbow trout juveniles indicate that once infection is initiated, juvenile rainbow trout have little or no ability to overcome *C. shasta* infections at water temperatures between 6.7 and 23.3°C. Fatal infections varied from 75-86% at temperatures ranging from 6.7 to 15.0°C (Udey et al. 1975). Mortality in trout held at 20.5 and 23.3°C were lower (72% and 52% respectively) due to losses from *Flexibacter columnaris*, which occurred well before the onset of deaths caused by *C. shasta*, in spite of efforts to control it with terramycin (Udey et al. 1975). The results from Udey et al. (1975) also reflected no deaths occurred in juvenile trout held at 3.9°C.

1.7.3 Columnaris

The importance of temperature on infections of Columnaris has been demonstrated in numerous laboratory studies. Ordal and Rucker (1944, as cited by Pacha et al. 1970) exposed juvenile sockeye salmon to *C. columnaris* and studied the effect of temperature on the disease. In these studies, the overall mortality ranged from 30% in fish held at 16.1°C to 100% in those held at 22.2°C (Ordal and Rucker 1944, as cited by Pacha et al. 1970). USEPA (1999a) cites studies that conducted surveys of Columnaris infection frequency on Chinook in the Snake River in July and early August of 1955-1957, which revealed 28-75% of fish infected when water temperature was >21.1°C.

Low virulence strains of Columnaris show signs of outbreak when average water temperatures are over 20°C (Bell 1986, Pacha et al. 1970). Bell (1986) states that outbreaks of high virulence strains occur when average water temperatures reach 15.6°C, and Pacha et al. (1970) found mortalities of 60-100% (majority of tests 100%) occur at temperatures of 12.8°C after 7 days of infection. With regard to strains of higher virulence, while these strains are capable of beginning infection and producing disease at water temperatures as low as 12.8°C, the disease process becomes progressively slower as the water temperature is lowered (Pacha et al. 1970).

Holt et al. (1975) performed a study on the relation of water temperature to Columnaris in juvenile steelhead trout and juvenile coho and spring Chinook salmon. Tests were performed on groups of 25-35 fish at eight temperatures ranging from 3.9°C to 23.3°C (2.8°C increments). At 20.5°C mortality was 100% in juvenile steelhead trout and coho salmon, 70% in juvenile spring Chinook salmon, and at temperatures 23.3°C juvenile spring Chinook mortality was 92% (Holt et al. 1975). Mortality rates were 52, 92, and 99% at 17.8°C for juvenile spring Chinook, steelhead trout, and coho salmon respectively, and mortality dropped to 31, 56, and 51% at 15.0°C (Holt et al. 1975). At 12.2°C mortality varied from 4 to 20% among juveniles of the three species, and at temperatures of 9.4°C and below, no deaths due to the experimental infection with *F. columnaris* occurred (Holt et al. 1975). Holt et al. (1975) state that these results indicate that under the conditions of these experiments Columnaris disease was completely suppressed by water temperatures of 9.4°C or below.

In general, data from laboratory studies indicates that as water temperatures increase, the time to death decreases (Pacha et al. 1970). With juvenile steelhead trout and juvenile coho and spring Chinook salmon as the temperature increased above 12.2°C, the disease process was progressively accelerated, resulting in a minimum time to death at 20.5 or 23.3°C and a maximum at 12.2°C (Holt et al. 1975). In these juvenile salmonids Holt et al. (1975) found the mean time to death decreased from 7.6-12.2 days at 12.2°C to 1.6-1.7 days at 20.5°C for juvenile coho and steelhead, and 2.3 days at 23.3°C for juvenile spring Chinook (Holt et al. 1975).

1.8 TMDL Temperature Thresholds

Currently there are no numeric temperature standards in the *Water Quality Control Plan for the North Coast Region* (Basin Plan). Thus, information from this literature review will be utilized by Regional Water Board staff to selected chronic and acute temperature thresholds for evaluation of stream temperatures in TMDLs. Chronic temperature thresholds (MWMTs) were selected from the USEPA document *EPA Region 10 Guidance For Pacific Northwest State and Tribal Temperature Water Quality Standards* (2003), and are presented in Table 13. The Region 10 guidance is the product of a three-year interagency effort, and has been reviewed by both independent science review panels and the public. Acute lethal temperature thresholds were selected based upon best professional judgment of the literature, and are presented in Table 14.

Table 13: Life Stage Temperature Thresholds

Life Stage	MWMT (°C)
Adult Migration	20
Adult Migration plus Non-Core[1] Juvenile Rearing	18
Core[2] Juvenile Rearing	16
Spawning, Egg Incubation, and Fry Emergence	13

[1] Non-Core is defined as moderate to low density salmon and trout rearing usually occurring in the mid or lower part of the basin (moderate and low not defined).
[2] Core is defines as areas of high density rearing (high is not specifically defined).
Source: USEPA 2003

Table 14: Lethal Temperature Thresholds

Lethal Threshold[1] (°C)			
Life Stage	**Steelhead**	**Chinook**	**Coho**
Adult Migration and Holding	24	25	25
Juvenile Growth and Rearing	24	25	25
Spawning, Egg Incubation, and Fry Emergence	20	20	20

[1] The lethal thresholds selected in this table are generally for chronic exposure (greater than seven days). Although salmonids may survive brief periods at these temperatures, they are good benchmarks from the literature for lethal conditions.

In some cases it may be necessary to calculate MWATs for a given waterbody, and compare these to MWAT thresholds. USEPA (2003) states that for many rivers in the Pacific Northwest the MWMT is about 3°C higher than the MWAT (USEPA 2003, as cited by Dunham et al. 2001and Chapman 2002). Rather than list MWAT thresholds in this document using the 3°C difference suggested above, the Regional Water Board will consider stream temperatures within each individual TMDL waterbody. Thus the Regional Water Board will calculate both MWMTs and MWATs for the waterbody, and characterize the actual difference between these temperature metrics for the watershed using an approach similar to that used in Sullivan et al. (2000). Once this relationship is understood, MWAT thresholds for each life stage can be identified and compared to the watershed MWATs.

The freshwater temperature thresholds presented in this section are applicable during the season or time of year when the life stage of each species is present. Periodicity information is not discussed in this document and will be presented in each individual TMDL staff report. Where life history, timing, and/or species needs overlap, the lowest of each temperature metric applies.

CHAPTER 2. DISSOLVED OXYGEN and TOTAL DISSOLVED GAS

2.1 Introduction

Adequate concentrations of dissolved oxygen in fresh water streams are critical for the survival of salmonids. Fish have evolved very efficient physiological mechanisms for obtaining and using oxygen in the water to oxygenate the blood and meet their metabolic demands (WDOE 2002). Reduced levels of dissolved oxygen can impact growth and development of different life stages of salmon, including eggs, alevins, and fry, as well as the swimming, feeding and reproductive ability of juveniles and adults. Such impacts can affect fitness and survival by altering embryo incubation periods, decreasing the size of fry, increasing the likelihood of predation, and decreasing feeding activity. Under extreme conditions, low dissolved oxygen concentrations can be lethal to salmonids. High levels of total dissolved gas concentrations (TDG), including dissolved oxygen, can result in gas bubble disease and death for salmonids.

Literature reviewed for this analysis included EPA guidance, other states' standards, reports that compiled and summarized existing scientific information, and numerous laboratory studies. When possible, species-specific requirements were summarized for the following life stages: migrating adults, incubation and emergence, and freshwater rearing and growth. The following information applies to salmonids in general, with specific references to coho, Chinook, steelhead, and other species of salmonids as appropriate.

2.2 Effects of Low Dissolved Oxygen Concentrations on Salmonids

2.2.1 Adult Migration

Reduced concentrations of dissolved oxygen can negatively affect the swimming performance of migrating salmonids (Bjornn and Reiser 1991). The upstream migration by adult salmonids is typically a stressful endeavor. Sustained swimming over long distances requires high expenditures of energy and therefore requires adequate levels of dissolved oxygen. Migrating adult Chinook salmon in the San Joaquin River exhibited an avoidance response when dissolved oxygen was below 4.2 mg/L, and most Chinook waited to migrate until dissolved oxygen levels were at 5 mg/L or higher (Hallock et al. 1970).

2.2.2 Incubation/Emergence

Low levels of dissolved oxygen can be directly lethal to salmonids, and can also have sublethal effects such as changing the rate of embryological development, the time to hatching, and size of emerging fry (Spence et al. 1996). The embryonic and larval stages of salmonid development are especially susceptible to low dissolved oxygen levels as their ability to extract oxygen is not fully developed and their relative immobility inhibits their ability to migrate to more favorable conditions. The dissolved oxygen requirements for successful incubation of embryos and emergence of fry is tied to intragravel dissolved oxygen levels. Intragravel dissolved oxygen is typically a function of many chemical, physical, and hydrological variables, including: the dissolved oxygen concentration of the overlying stream water, water temperature, substrate size and porosity, biochemical oxygen demand of the intragravel water, sediment oxygen demand, the gradient and velocity of the stream, channel configuration, and depth of water. As a result the dissolved oxygen concentration within the gravels can be depleted causing problems for salmonid embryos and larvae, even when overlying surface water oxygen levels are suitable (USEPA 1986a).

Studies note that water column dissolved oxygen concentrations are typically estimated to be reduced by 1-3 mg/L as water is transmitted to redds containing developing eggs and larvae (WDOE 2002). USEPA (1986a) concluded that dissolved oxygen levels within the gravels should be considered to be at least 3 mg/L lower than concentrations in the overlying water. ODEQ (1995b) expect the loss of an average of 3 mg/L dissolved oxygen from surface water to the gravels.

2.2.3 Incubation Mortality

Phillips and Campbell (1961, as cited by Bjornn and Reiser 1991) concluded that intragravel dissolved oxygen must average 8 mg/L for embryos and alevins to survive well. After reviewing numerous studies Davis (1975) states that a dissolved oxygen concentration of 9.75 mg/L is fully protective of larvae and mature eggs, while at 8 mg/L the average member of the incubating population will exhibit symptoms of oxygen distress, and at 6.5 mg/L a large portion of the incubating eggs may be affected. Bjornn and Reiser (1991) reviewed numerous references and recommend that dissolved oxygen should drop no lower than 5 mg/L, and should be at or near saturation for successful incubation.

In a review of several laboratory studies, ODEQ (1995b) concluded that at near optimum (10°C) constant temperatures acute mortality to salmonid embryos occurs at relatively low concentrations of dissolved oxygen, near or below 3 mg/L. Field studies reviewed by ODEQ (1995b) demonstrate that embryo survival is low when the dissolved oxygen content in the gravels drops near or below 5 mg/L, and survival is greater at 8 mg/L.

Silver et al. (1963) performed a study with Chinook salmon and steelhead trout, rearing eggs at various constant dissolved oxygen concentrations and water velocities. They found that steelhead embryos held at 9.5°C and Chinook salmon embryos held at 11°C experienced complete mortality at dissolved oxygen concentrations of 1.6 mg/L. Survival of a large percentage of embryos reared at oxygen levels as low as 2.5 mg/L appeared to be possible by reduction of respiration rates and consequent reduction of growth and development rates.

In a field study Cobel (1961) found that the survival of steelhead embryos was correlated to intragravel dissolved oxygen in the redds, with higher survival at higher levels of dissolved oxygen. At 9.25 mg/L survival was 62%, but survival was only 16% at 2.6 mg/L. A laboratory study by Eddy (1971) found that Chinook salmon survival at 10.4 mg/L (13.5 °C) was approximately 67%, however at dissolved oxygen levels of 7.3 mg/L (13.5 °C) survival dropped to 49-57.6%. At temperatures more suitable for Chinook incubation (10.5 °C) Eddy (1971) found the percent survival remained high (over 90%) at dissolved oxygen levels from 11 mg/L to 3.5 mg/L; however, as dissolved oxygen levels decreased, the number of days to hatching increased and the mean dry weight of the fry decreased substantially. WDOE (2002) also points out that the studies above did not consider the act of emerging through the redds, and the metabolic requirements to emerge would be expected to be substantial. Therefore, it is likely that higher oxygen levels may be needed to fully protect hatching and emergence, than to just support hatching alone.

2.2.4 Incubation Growth

Embryos can survive when dissolved oxygen is below saturation (and above a critical level), but development typically deviates from normal (Bjornn and Reiser 1991). Embryos were found to be smaller than normal, and hatching either delayed or premature, when dissolved oxygen was below saturation throughout development (Doudoroff and Warren 1965, as cited by Bjornn and Reiser 1991).

Garside (1966) found the number of days it took for rainbow trout to go from fertilization to hatching increased as dissolved oxygen concentrations and water temperature decreased. In this study, rainbow trout were incubated at temperatures between 2.5 - 17.5°C and dissolved oxygen levels from 2.5 - 11.3 mg/L. At 10°C and 7.5°C the total time for incubation was delayed 6 and 9 days respectively at dissolved oxygen levels of 2.5 mg/L versus embryos incubated at approximately 10.5 mg/L.

Silver et al. (1963) found that hatching of steelhead trout held at 9.5°C was delayed 5 to 8 days at dissolved oxygen concentrations averaging 2.6 mg/L versus embryos reared at 11.2 mg/L. A smaller delay of hatching was observed at oxygen levels of 4.2 and 5.7 mg/L, although none was apparent at 7.9 mg/L. For Chinook salmon held at 11°C, Silver et al. observed that embryos reared at oxygen levels lower than 11 mg/L experienced a delay in hatching, with the most significant delay in those reared at dissolved oxygen levels of 2.5 mg/L (6 to 9 days). The size of both Chinook and steelhead embryos increased with increases in dissolved oxygen up to 11.2 mg/L. External examination of embryos revealed abnormal structural development in Chinook salmon tested at dissolved oxygen concentrations of 1.6 mg/L, and abnormalities in steelhead trout at concentrations of 1.6 and 2.6 mg/L. The survival of Chinook salmon after hatching was only depressed at the 2.5 mg/L level, the lowest level at which hatching occurred, with lower mortalities occurring at higher velocities. Post hatching survival of steelhead trout could not be determined due to numerous confounding factors.

Shumway et al. (1964) conducted a laboratory study to determine the influence of oxygen concentration and water movement on the growth of steelhead trout and coho salmon embryos. The experiments were conducted at a temperature of 10°C and oxygen levels generally ranging from 2.5 - 11.5 mg/L and flows from 3 to 750 cm/hour. It was concluded that the median time to hatching decreased and size of fry increased as dissolved oxygen levels increased. For example, steelhead trout embryos reared at 2.9 mg/L hatched in approximately 41 days and had a wet weight of 17 mg, while embryos reared at 11.9 mg/L hatched in 36 days and weighed 32.3 mg. The authors found that a reduction of either the oxygen concentration or the water velocity will reduce the size of fry and increase the incubation period, although the affect of various water velocities tested was less than the effect of the different dissolved oxygen concentrations tested.

WDOE (2002) reviewed various references and found that at favorable incubation temperatures a mean oxygen concentration of 10.5 mg/L will result in a 2% reduction in growth. At other oxygen concentrations, growth is reduced as follows: 8% reduction at oxygen levels of 9 mg/L, 10% reduction at 7 mg/L, and a 25% reduction at 6 mg/L.

2.2.5 Incubation Avoidance/Preference

Alevin showed a strong preference for oxygen concentrations of 8 - 10 mg/L and moved through the gravel medium to these concentrations, avoiding concentrations from 4 - 6 mg/L (WDOE 2002).

2.2.6 Emergence Mortality

"The hatching time, size, and growth rate of developing embryos is proportional to the dissolved oxygen concentrations up to 8 mg/L or greater. The ability of fry to survive their natural environment may be related to the size of fry at hatch (ODEQ 1995b)." McMahon (1983) recommends dissolved oxygen levels be ≥ 8 mg/L for high survival and emergence of fry. In a review of controlled field and lab studies on emergence, WDOE (2002) states that average intragravel oxygen concentrations of 6 - 6.5 mg/L and lower can cause stress and mortality in developing embryos and alevin. It is also noted that field studies on emergence consistently cite intragravel oxygen concentrations of 8 mg/L or greater as being associated with or necessary for superior health and survival, oxygen concentrations below 6 - 7 mg/L result in a 50% reduction in survival through emergence, and oxygen concentrations below 5 mg/L result in negligible survival. According to various laboratory studies, the threshold for complete mortality of emerging salmonids is noted to occur between 2 - 2.5 mg/L (WDOE 2002).

After reviewing numerous literature sources, the USEPA (1986a) concluded that the embryonic and larval stages of salmonid development will experience no impairment when water column dissolved oxygen concentrations are 11 mg/L. This translates into an intragravel dissolved oxygen concentration of 8 mg/L (USEPA assumes a 3 mg/L loss between the surface water and gravels). Table 15 from the USEPA (1986a) lists the water column and intragravel dissolved oxygen concentrations associated with various health effects. These health affects range from no production impairment to acute mortality.

Table 15: Dissolved oxygen concentrations and their effects salmonid embryo and larval stages

Level of Effect	Water Column DO (mg/L)	Intragravel DO (mg/L)
No Production Impairment	11	8*
Slight Production Impairment	9	6*
Moderate Production Impairment	8	5*
Severe Production Impairment	7	4*
Limit to Avoid Acute Mortality	6	3*

* A 3 mg/L loss is assumed between the water column dissolved oxygen levels and those intragravel.
Source: USEPA 1986a

2.2.7 Freshwater Rearing and Growth

2.2.7.1 Swimming and Activity

Salmonids are strong active swimmers requiring highly oxygenated waters (Spence 1996), and this is true during the rearing period when the fish are feeding, growing, and avoiding predation. Salmonids may be able to survive when dissolved oxygen concentrations are low (<5 mg/L), but growth, food conversion efficiency, and swimming performance will be adversely affected (Bjornn and Reiser 1991). Davis (1975) reviewed numerous studies and reported no impairment to rearing salmonids if dissolved oxygen concentrations averaged 9 mg/L, while at oxygen levels of 6.5 mg/L "the average member of the community will exhibit symptoms of oxygen distress", and at 4 mg/L a large portion of salmonids may be affected. Dahlberg et al. (1968) state that at temperatures near 20°C any considerable decrease in the oxygen concentration below 9 mg/L (the air saturation level) resulted in some reduction of the final swimming speed. They found that between dissolved oxygen concentrations of 7 to 2 mg/L the swimming speed of coho declined markedly with the decrease in dissolved oxygen concentration.

In a laboratory study, Davis et al. (1963) reported that the maximum sustainable swimming speeds of wild juvenile coho salmon were reduced when dissolved oxygen dropped below saturation at water temperatures of 10, 15, and 20°C. Air-saturation values for these dissolved oxygen concentrations were cited as 11.3, 10.2, and 9.2 mg/L respectively. They found that the maximum sustained swimming speeds (based on first and second swimming failures at all temperatures) were reduced by 3.2 - 6.4%, 5.9 - 10.1%, 9.9 - 13.9%, 16.7 - 21.2%, and 26.6 - 33.8% at dissolved oxygen concentrations of 7, 6, 5, 4, and 3 mg/L respectively. The authors also conducted tests on juvenile Chinook salmon and found that the percent reductions from maximum swimming speed at temperatures ranging from 11 to 15°C were greater than those for juvenile coho. At the dissolved oxygen concentrations listed above swimming speeds were decreased by 10%, 14%, 20%, 27%, and 38% respectively.

WDOE (2002) reviewed various data and concluded that swimming fitness of salmonids is maximized when the daily minimum dissolved oxygen levels are above 8 - 9 mg/L. Jones et al. (1971, as cited by USEPA 1986a) found the swimming speed of rainbow trout was decreased 30% from maximum at dissolved oxygen concentrations of 5.1 mg/L and 14°C. At oxygen levels of 3.8 mg/L and a temperature of 22°C, they found a 43% reduction in the maximum swimming speed.

2.2.7.2 Growth

In a review of constant oxygen exposure studies WDOE (2002) concluded salmonid growth rates decreased less than 10% at dissolved oxygen concentrations of 8 mg/L or more, less than 20% at 7 mg/L, and generally less than 22% at 5 - 6 mg/L. Herrmann (1958) found that the mean percentage of weight gain in juvenile coho held at constant dissolved oxygen concentrations was 7.2% around 2 mg/L, 33.6% at 3 mg/L, 55.8% near 4 mg/L, and 67.9% at or near 5 mg/L. In a laboratory study Fischer (1963) found that the growth rates of juvenile coho exposed to constant oxygen concentrations ranging from 2.5 to 35.5 mg/L (fed to satiation, temperature at approximately 18 °C) dramatically decreased with decreases in the oxygen concentration below 9.5 mg/L (air saturation level). WDOE (2002) concludes that a monthly or weekly average concentration of 9 mg/L, and a monthly average of the daily minimum concentrations should be at or above 8 - 8.5 mg/L to have a negligible effect (5% or less) on growth and support healthy growth rates.

Food conversion efficiency is related to dissolved oxygen levels and the process becomes less efficient when oxygen concentrations are below 4 - 4.5 mg/L (ODEQ 1995b). Bjornn and Reiser (1991) state that growth, food conversion efficiency, and swimming performance are adversely affected when dissolved oxygen concentrations are <5 mg/L. The USEPA (1986a) reviewed growth data from a study conducted by Warren et al. (1973) where tests were conducted at various temperatures to determine the growth of coho and Chinook. USEPA cites that, with the exception of tests conducted at 22 °C, the results supported the idea that the effects of low dissolved oxygen become more severe at higher temperatures.

Brett and Blackburn (1981) performed a laboratory study to determine the growth rate and food conversion efficiency of young coho and sockeye salmon fed full rations. Tests were performed at dissolved oxygen concentrations ranging from 2 to 15 mg/L at a constant temperature of 15°C, the approximate optimum temperature for growth of Pacific Salmon. Both species showed a strong dependence of growth on the environmental oxygen concentrations when levels were below 5 mg/L. For coho, zero growth was observed at dissolved oxygen concentrations of 2.3 mg/L. The mean value for maximum coho growth occurred at 4 mg/L, and at dissolved oxygen concentrations above this level growth did not appear to be dependant on the dissolved oxygen. Sockeye displayed zero growth at oxygen levels of 2.6 mg/L, and reached the zone of independence (growth not dependant on dissolved oxygen levels) at 4.2 mg/L. Brett and Blackburn (1981) conclude that the critical inflection from oxygen dependence to independence occurs at 4 - 4.2 mg/L for coho and sockeye.

Herrmann et al. (1962) studied the influence of various oxygen concentrations on the growth of age 0 coho salmon held at 20 °C. Coho were held in containers at a constant mean dissolved oxygen level ranging from 2.1 - 9.9 mg/L and were fed full rations. The authors concluded that oxygen concentrations below 5 mg/L resulted in a sharp decrease in growth and food consumption. A reduction in the mean oxygen levels from 8.3 mg/L to 6 and 5 mg/L resulted in slight decreases in food consumption and growth. Weight gain in grams per gram of food consumed was slightly depressed at dissolved oxygen concentrations near 4 mg/L, and were markedly reduced at lower concentrations. At oxygen levels of 2.1 and 2.3 mg/L, many fish died and the surviving fish lost weight and consumed very little food.

USEPA (1986a) calculated the median percent reduction in growth rate of Chinook and coho salmon fed full rations at various dissolved oxygen concentrations. They calculated no reduction in growth at dissolved oxygen concentrations of 8 and 9 mg/L, and a 1% reduction in growth at 7 mg/L for both species. At 6 mg/L Chinook and coho growth were reduced by 7% and 4% respectively. Dissolved oxygen levels of 4 mg/L result in a

29% reduction in growth for Chinook salmon and 21% reduction in growth for coho. At 3 mg/L there was a 47% decrease in Chinook growth and a 37% reduction in coho growth. USEPA (1986a) states that due to the variability inherent in growth studies the reductions in growth rates seen above 6 mg/L are not usually statistically significant, while reductions in growth at dissolved oxygen levels below 4 mg/L are considered severe.

2.2.7.3 Avoidance and Preference

Salmonids have been reported to actively avoid areas with low dissolved oxygen concentrations, which is likely a useful protective mechanism that enhances survival (Davis 1975). Field and laboratory studies have found that avoidance reactions in juvenile salmonids consistently occur at concentrations of 5 mg/L and lower, and there is some indication that avoidance is triggered at concentrations as high as 6 mg/L. Therefore these dissolved oxygen levels should be considered a potential barrier to the movement and habitat selection of salmonids (WDOE 2002).

Spoor (1990) performed a laboratory study on the distribution of fingerling brook trout in dissolved oxygen concentration gradients. Sixteen gradients between 1 and 8.9 mg/L were used for the study to determine what level of dissolved oxygen is preferred by the brook trout. It was found that in the absence of a gradient with dissolved oxygen concentrations at 6 mg/L or more throughout the system, the fish moved freely without showing preference or avoidance. Movement from low to higher oxygen concentrations were noted throughout the study. Fish moved away from water with dissolved oxygen concentrations from 1 - 1.9 mg/L within one hour, moved away from water with dissolved oxygen concentrations of 2 - 2.9 mg/L within 1 - 2 hours, and moved away more slowly from concentrations of 3 - 3.9 mg/L. From his study, Spoor (1990) concluded that brook trout will avoid oxygen concentrations below 4 mg/L, and preferred oxygen levels of 5 mg/L or higher.

Whitmore et al. (1960) performed studies with juvenile coho and Chinook salmon to determine their avoidance reaction to dissolved oxygen concentration of 1.5, 3 , 4.5, and 6 mg/L at variable river water temperatures. Juvenile Chinook salmon showed marked avoidance of oxygen concentrations near 1.5, 3, and 4.5 mg/L in the summer at mean temperatures ranging from 20.7 - 22.8°C, but no avoidance to levels near 6 mg/L at a mean temperature of 18.4°C. Chinook did not show as strong an avoidance to these oxygen levels in the fall when water temperatures were lower, ranging from 11.8 - 13.2°C. Chinook showed little avoidance of dissolved oxygen concentrations near 4.5 mg/L during the fall, and no avoidance to concentrations near 6 mg/L. In all cases avoidance became progressively larger with reductions in the oxygen concentration below 6 mg/L. Seasonal differences of avoidance are most likely due to differences in water temperature. At temperatures ranging from 18.4 - 19°C juvenile coho salmon showed some avoidance to all of the above oxygen concentrations, including 6 mg/L. Their behavior was more erratic than that of Chinook, and their avoidance of concentrations near 4.5 mg/L and lower was not as pronounced at corresponding temperatures. The juvenile coho often started upon entering water with low dissolved oxygen and then darted around until they found their way out of the experimental channel.

USEPA (1986a) performed a literature review and cites the effects of various dissolved oxygen concentrations on salmonid life stages other than embryonic and larval (Table 16). These effects range from no impairment at 8 mg/L to acute mortality at dissolved oxygen levels below 3 mg/L.

Table 16: Dissolved oxygen concentrations and their effects on salmonid life stages other than embryonic and larval

Level of Effect	Water Column DO (mg/L)
No Production Impairment	8
Slight Production Impairment	6
Moderate Production Impairment	5
Severe Production Impairment	4
Limit to Avoid Acute Mortality	3

Source: USEPA 1986a

2.2.8 Lethality

Salmonid mortality begins to occur when dissolved oxygen concentrations are below 3 mg/L for periods longer than 3.5 days (USEPA 1986a). A summary of various field study results by WDOE (2002) reports that significant mortality occurs in natural waters when dissolved oxygen concentrations fluctuate the range of 2.5 - 3 mg/L. Long-term (20 - 30 days) constant exposure to mean dissolved oxygen concentrations below 3 - 3.3 mg/L is likely to result in 50% mortality of juvenile salmonids (WDOE 2002). According to a short-term (1 - 4 hours) exposure study by Burdick et al. (1954, as cited by WDOE, 2002), in warm water (20 - 21°C) salmonids may require daily minimum oxygen levels to remain above 2.6 mg/L to avoid significant (50%) mortality. From these and other types of studies, WDOE (2002) concluded that juvenile salmonid mortality can be avoided if daily minimum dissolved oxygen concentration remain above 3.9 mg/L, and the monthly or weekly average of minimum concentrations remains above 4.6 mg/L.

2.3 Effects of High Total Dissolved Gas Concentrations on Salmonids

High levels of total dissolved gas (TDG), including dissolved oxygen, can be harmful to salmonids and other fish and result in “gas bubble disease”. This occurs when dissolved gases in their circulatory system come out of solution and form bubbles which block the flow of blood through the capillary vessels (USEPA 1986b). There are several ways TDG supersaturation can occur, including excessive algal photosynthesis which can create supersaturated dissolved oxygen conditions (USEPA 1986b). Thus, to protect salmonids and other freshwater fish the USEPA has set criteria for TDG stating that levels should not exceed 110% of the saturation value.

Numerous studies have been conducted to determine the mortality rate of salmonids exposed to various levels of TDG. Mesa et al. (2000) conducted laboratory experiments on juvenile Chinook and steelhead, exposing them to different levels of TDG and found no fish died when held at 110% TDG for up to 22 days. When fish were exposed to 120% TDG, 20% of juvenile Chinook died within 40 to 120 hours while 20% of juvenile steelhead died within 20 to 35 hours. At TDG levels of 130% Chinook mortality reached 20% after 3 to 6 hours and steelhead mortality was 20% after 5 to 7 hours. Gale et al. (2001) held adult female spring Chinook at mean TDG levels ranging from 114.1% to 125.5% and found the time to first mortality ranged from 10 to 68 hours.

USEPA (1986b) discusses various studies on the effects of TDG on salmonids. The following studies are all cited from the USEPA 1986 water quality criteria document. Bouck et al. (1975) found TDG levels of 115% and above to be acutely lethal to most species of salmonids, and levels of 120% TDG are rapidly lethal to all salmonids. Conclusions drawn from Ebel et al. (1975) and Rulfison and Abel (1971) include the following:

- Adult and juvenile salmonids confined to shallow water (1 m) with TDG levels above 115% experience substantial levels of mortality.
- Juvenile salmonids exposed sublethal levels TDG supersaturation are able to recover when returned to normally saturated water, while adults do not recover and generally die.

CHAPTER 3. AMMONIA

3.1 Introduction

According to the USEPA (1986b, p.17), acute concentrations of ammonia can cause loss of equilibrium, hyperexcitability, increased breathing, cardiac output and oxygen uptake, and, in extreme cases, convulsions, coma, and death of fish. Lower concentrations of ammonia can result in reduced hatching success, reduced growth and morphological development, and pathologic changes in tissues of gills, livers, and kidneys.

The information in the following sections was extracted from the USEPA document titled: *1999 Update of Ambient Water Quality Criteria for Ammonia*. The information presented applies to salmonids in general.

3.2 Ammonia Speciation

Ammonia in water exists primarily in two forms, un-ionized ammonia (NH_3) and ammonium ion (NH_4^+) (USEPA 1999b, p.2). The fraction of each of these two forms, or ammonia speciation, varies markedly with temperature and pH (USEPA 1999b, p.2). The pH-dependence of the relative amounts of un-ionized ammonia and ammonium ion at 25°C are presented in Figure 1 below (USEPA 1999b, p.2). Ammonia speciation also depends on ionic strength, although in freshwater this effect is much smaller than the effects of temperature and pH (USEPA 1999b, p.3)

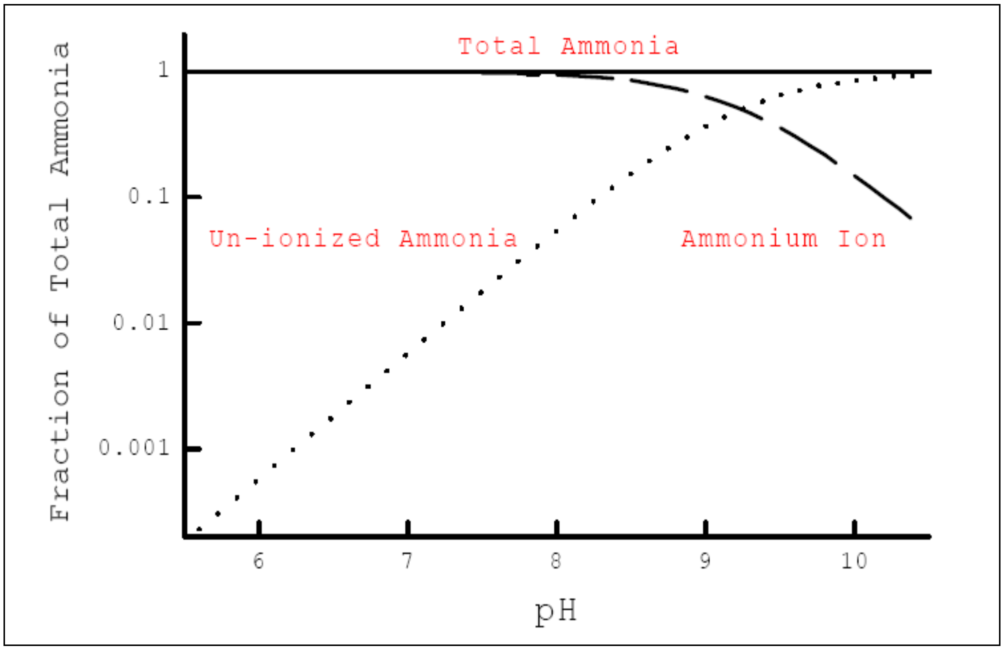

Figure 1: Chemical Speciation of Ammonia
Source: USEPA 1999b, p.3

3.3 Ammonia Toxicity

These speciation relationships are important to ammonia toxicity because un-ionized ammonia is much more toxic than ammonium ion. The importance of un-ionized ammonia was first recognized when it was observed that increased pH caused total ammonia to appear to be much more toxic (Chipman 1934; Wuhrmann and Woker 1948). It is not surprising that un-ionized ammonia is the more toxic form, because it is a neutral molecule and thus is able to diffuse across the epithelial membranes of aquatic organisms much more readily than the charged ammonium ion. Ammonia is unique among regulated pollutants because it is an endogenously produced toxicant that organisms have developed various strategies to excrete, which is in large part by passive diffusion of un-ionized ammonia from the gills. High external un-ionized ammonia concentrations reduce or reverse diffusive gradients and cause the buildup of ammonia in gill tissue and blood (USEPA 1999b, p.3).

Because of the importance of un-ionized ammonia, it became a convention in the scientific literature to express ammonia toxicity in terms of un-ionized ammonia, and water quality criteria and standards followed this convention. However, there are reasons to believe that ammonium ion can contribute significantly to ammonia toxicity under some conditions. Observations that ammonia toxicity is relatively constant when expressed in terms of un-ionized ammonia come mainly from toxicity tests conducted at pH>7.5. At lower pH, toxicity varies considerably when expressed in terms of unionized ammonia and under some conditions is relatively constant in terms of ammonium ion (Erickson 1985). Also, studies have established that mechanisms exist for the transport of ammonium ion across gill epithelia (Wood 1993), so this ion might contribute significantly to ammonia exchange at gills and affect the buildup of ammonia in tissues if its external concentration is sufficiently high. Thus, the very same arguments employed for the importance of un-ionized ammonia can also be applied in some degree to ammonium ion. This is not to say that ammonium ion is as toxic as unionized ammonia, but rather that, regardless of its lower toxicity, it can still be important because it is generally present in much greater concentrations than un-ionized ammonia (USEPA 1999b, p.3,4).

3.4 Ammonia Criteria

The USEPA has utilized the above information to create pH-dependant acute and pH- and temperature-dependent chronic criterion for total ammonia (NH_3 and NH_4^+) as nitrogen in freshwater (Tables 17, 18, 19).

Table 17: pH-Dependent Values of the Criterion Maximum Concentration (CMC) of Total Ammonia as Nitrogen (mg N/L) in Freshwater when Salmonids are Present

Acute Criterion[1]			
pH	**CMC Total NH3 mgN/L**	**pH**	**CMC Total NH3 mgN/L**
6.5	32.6	7.8	8.11
6.6	31.3	7.9	6.77
6.7	29.8	8.0	5.62
6.8	28.1	8.1	4.64

CHAPTER 4. pH

4.1 Introduction

The pH of freshwater streams is important for adult and juvenile salmonid development. Chronic effects from low pH can occur at levels that are not toxic to adult fish but that impair reproduction including altered spawning behavior, reduced egg viability, decreased hatchability, and reduced survival of the early life stages (Jordahl and Benson 1987). The early life stages of salmonid development are most vulnerable to low pH (Jordahl and Benson 1987). Chronic high pH levels in freshwater streams can decrease activity levels of salmonids, create stress responses, decrease or cease feeding, and lead to a loss of equilibrium (Murray and Ziebell 1984; Wagner et al. 1997). Additionally, high temperatures can exacerbate the effects of high pH levels on salmonids (Wagner et al. 1997). If pH reaches extremely low or high levels, death can occur (Wagner et al. 1997).

Literature reviewed for this analysis included numerous laboratory and field studies. The following information applies to salmonids in general.

4.2 Effects of High pH

Wagner et al. (1997) conducted laboratory and field studies and found that pH values of greater than 9.4 will result in the death of rainbow trout, especially at temperatures ranging from 19-22 C. Fresh water pH values of 9.0 or greater resulted in significant stress responses in rainbow trout.

Wilkie and Wood (1996) found that Lahontan cutthroat trout exposed to high pH waters (9.4) permanently lowered their rate of nitrogenous waste production to avoid the potentially toxic build-up of internal ammonia. However, rainbow trout, kokanee, and brown trout were unable to adapt to the high pH and died.

Murray and Ziebell (1984) found that rainbow trout are not able to acclimate to pH levels of 10.0 or higher and that their ability to tolerate pH above 9.0 depends on the rate of acclimation. Gradual acclimation (0.2 to 0.4 of a pH unit/day) allowed rainbow trout to acclimate to a pH of 9.8 and continue feeding, although they showed signs of distress and their activity was greatly reduced by the end of 4 days when the pH reached 9.9 (Table 20). The maximum pH tolerated before fish began dying was 10.2.

Rapid acclimations tests conducted by Murray and Ziebell (1984) yeilded the following results:

> Rainbow trout mortalities were 40% or greater in preliminary acclimation tests in which pH was increased to 9.6 and 9.7 in 3 and 5 hours. These results were comparable to previous shock tests (unpublished data). Consequently, in later experiments, acclimation time was increased to 6 hours and pH values were lowered to 9.3 and 9.5.

Trout in the pH 9.5 experiments exhibited adverse reactions and mortalities were similar to those seen in preliminary tests at pH 9.6 and 9.7. All fish began to show marked signs of stress within 12 hours, and within 24 hours the mortalities in replicated experiments were 30, 40, and 50% respectively. At 49 hours the last deaths occurred that brought mortalities to 50% in each replicate. All remaining living fish were distressed and did not feed. After 72 hours had elapsed, the survivors resumed feeding and their condition improved until the experiments were terminated at 120 hours.

In the pH 9.3, 6-hour acclimation experiments trout exhibited only minor adverse reactions. The primary behavioral changes were a decrease in swimming activity and a temporary loss of appetite. After 48 hours all fish resumed normal feeding and became progressively more active. No mortalities occurred in any of the replicated experiments, and all fish behaved normally when the experiments were terminated at 120 hours Murray and Ziebell (1984).

Table 20: Reactions of 10 rainbow trout to various pH levels during gradual acclimation experiments (0.2 to 0.4 of a pH unit/day)

Day	pH Range	Reactions and Condition of Trout
1	8.6-8.9	Normal
2	8.9-9.2	Activity decreased but feeding normal
3	9.2-9.7	Activity further decreased but feeding continued
4	9.7-9.9	Minor distress shown but feeding continued
5	9.9-10.3	Some fish lost equilibrium at 10.0, and feeding ceased. Loss of equilibrium increased at 10.1 and eyes of some fish developed corneal opacities; 50% of fish lost equilibrium at pH 10.2 and mortality was 60% at pH 10.3

Source: Murray and Ziebell (1984)

4.3 Effects of Low pH

"Chronic effects of low pH on fish populations may occur at pH levels that are not toxic to adult fish but that impair reproduction, and ultimately lead to population extinction (Jordahl and Benson 1987)." A study was conducted by Weiner et al. (1986) to determine the effects of low pH on the reproductive success of rainbow trout. It was determined that exposure of adult salmonids to pH values below 5.5 negatively effected reproduction. Adult rainbow trout were exposed to pH 4.5, 5.0, 5.5, and 6.5-7.1 during the final 6 weeks of reproductive maturation. Weiner et al. found that pH values of 5.5 and below impaired the creation of eggs in females and sperm in males.

Jordahl and Benson (1987) report that reproductive failure occurred in adult brook trout due to low pH in a freshwater stream with pH levels ranging from 5.0-5.8, while trout in a reference stream with pH ranging from 6.1-7.2 did not experience reproductive failure. Additionally, brook trout were absent from a highly acidic freshwater stream with pH ranging from 4.7-5.4 leading Jordahl and Benson to conclude that breeding females may avoid acidic tributaries.

In addition to effecting adult salmonids, highly acidic freshwater (low pH) can have a detrimental effect on eggs and juvenile salmonids. Weiner et al. (1986) determined that juvenile rainbow trout mortality was greatly increased at pH levels of 5.5 and below, and that no eggs survived when exposed to pH levels below 4.5. Hulsman and Powels (1983) found the mortality of rainbow trout yolk-sac larvae approached 100% within 5 days of exposure to pH 4.6 and 5.4, whereas exposure to pH 6.0 resulted in less than 3% mortality.

Jordahl and Benson (1987) conducted a study to determine the effect of low pH on juvenile brook trout survival and found that survival rates were highest in a freshwater stream with pH values ranging from 6.1-7.2 and lower in acidified streams with pH levels of 4.7-5.8. At pH values of 5.0 and lower, growth was retarded and the development of yolk-sac larvae was considerably prolonged. Additionally, larval activity was depressed, pigmentation was reduced, and incomplete hatching was observed in streams with low pH values of 4.7-5.8, but not in the stream with pH ranging from 6.1-7.2. Jordahl and Benson concluded that mean pH values of 5.0-5.4 can cause acid stress on developing juveniles, while pH levels from 6.1-7.2 are above ranges that negatively effect juvenile brook trout development and survival.

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

1.1 Introduction

The Klamath River basin contains 83 species of fish, 45 of which are native to the Klamath drainage and 38 that have been introduced and are non-native. Fourteen of the native fish species in the basin have been granted special federal and/or state status (Table 1).

Table 1: Native Fish Species in the Klamath River Basin with Special Federal and/or State Status

SPECIES	STATUS
Shortnose sucker, *Chasmistes brevirostris*	Endangered-OR, CA, and Federal
Lost River sucker, *Deltistes luxatus*	Endangered-OR, CA, and Federal
Coho salmon, *Oncorhynchus kisutch*	Critical -OR; Threatened-CA and Federal;
Bull trout, *Salvelinus confluentus*	Critical-OR; Endangered-CA; Threatened-Federal
Delta Smelt, *Hypomesus transpacificus*	Threatened-CA and Federal
Coastal cutthroat trout, *Oncorhynchus clarki clarki*	Special Concern-CA
Eulachon, *Thaleichthys pacificus*	Special Concern-CA
Longfin smelt, *Spirinchus thaleichthys*	Special Concern-CA
Redband/Rainbow trout, *Oncorhynchus mykiss gairdneri*	Vulnerable-OR
Chum Salmon, *Oncorhynchus keta*	Special Concern-CA
Klamath largescale sucker, *Catostomus snyderi*	Special Concern-Federal
Slender sculpin, *Cottus tenuis*	Special Concern-Federal
Pacific Lamprey, *Lampetra tridentata*	Vulnerable-OR; Special Concern-Federal
Green sturgeon, *Acipenser medirostris*	Special Concern- CA and Federal

Sources: California Department of Fish and Game (CDFG) 2006b, p.4-6; National Research Council (NRC) 2004, p.181, 251, & 252; Oregon Natural Heritage Information Center (ONHIC) 2004, p.8-11.

The following discussion of fish species and resources in the basin is divided into three parts: fish species found above Iron Gate Dam in California and Oregon, fish species found from Iron Gate Dam to the Ocean in California, and Chinook, steelhead, and coho salmonids from Iron Gate Dam to the Ocean in California.

1.2 Fish above Iron Gate Dam in the Klamath River Basin, California and Oregon

The Klamath River basin above Iron Gate Dam hosts 18 native and 19 non-native fish species (Table 2). Native fish persisting in this area of the basin include lamprey, trout, and sucker species including the endangered shortnose and Lost River suckers. Introduced fish include various sunfish, catfish, and perch species.

Table 2: Fish Found Above Iron Gate Dam in the Klamath River Basin

NATIVE	
Klamath River lamprey, *Lampetra similis*	Klamath largescale sucker, *Catostomus snyderi*
Miller Lake Lamprey, *Lampetra milleri*	Klamath smallscale sucker, *Catostomus rimiculus*
Pit-Klamath brook lamprey, *Lampetra lethophaga*	Redband/Rainbow trout, *Oncorhynchus mykiss gairdneri*
Klamath tui chub, *Siphatales bicolor bicolor*	Bull trout, *Salvelinus confluentus*
Blue chub, *Gila coerulea*	Klamath Lake sculpin, *Cottus princeps*
Klamath speckled dace, *Rhinichthys osculus klamathensis*	Slender sculpin, *Cottus tenuis*
Shortnose sucker, *Chasmistes brevirostris*	Upper Klamath marbled sculpin, *Cottus klamathensis klamathensis*
Lost River sucker, *Deltistes luxatus*	

Table 2 (continued): Fish Found Above Iron Gate Dam in the Klamath River Basin

NON-NATIVE	
Goldfish, *Carassius auratus*	Brown trout, *Salmo trutta*
Golden shiner, *Notemigonus chrysoleucas*	Sacramento perch, *Archoplites interruptus*
Fathead minnow, *Pimephales promelas*	White crappie, *Pomoxis annularis*
Yellow bullhead, *Ameiurus natalis*	Black crappie, *Pomoxis nigromaculatus*
Brown bullhead, *Ameiurus nebulosus*	Green sunfish, *Lepomis cyanellus*
Black bullhead, *Ameiurus melas*	Bluegill, *Lepomis macrochirus*
Channel catfish, *Ictalurus punctatus*	Pumpkinseed, *Lepomis gibbosus*
Kokanee salmon, *Oncorhynchus nerka*	Largemouth bass, *Micropterus salmoides*
Brook trout, *Salvelinus fontinalis*	Yellow perch, *Perca flavescens*

Source: NRC 2004, p.181, 189; PacifiCorp 2004, p.4-5 to 4-7.

1.2.1 Distribution and Status of Native Fish

The following information on fish distribution and status is mainly derived from NRC 2004, p.181-193, with additional information taken from Behnke 1992, p.19, 20 and PacifiCorp 2004, p. 4-12, 4-13, and 4-33.

Four species of suckers inhabit the Klamath River basin above Iron Gate Dam. The shortnose and Lost River suckers are large, long-lived, late-maturing and live in lakes but spawn primarily in streams. Shortnose and Lost River suckers have been found in the reservoirs between Keno and Iron Gate Dam. The Klamath Tribes refer to the shortnose and Lost River suckers as qapdo and c'waam, respectively. These fish were a primary food source for the Klamath and Modoc Indians from historic times until the 1980s when severe declines in the fish populations caused the Klamath Tribes to close their fishery. Historically, Lost River and shortnose suckers were present in the Lost River and Klamath River above Iron Gate Dam and their tributaries (Moyle 2002, USFWS 2002 Appendix D as cited by NRC 2004, p.190, 191). Their current distribution and numbers have decreased from a combination of extirpations and redistribution through water management (NRC p.191). The Klamath Tribes historically harvested tens of thousands of pounds of c'waam and qapdo. Now they are restricted to a single fish each year for ceremonial purposes. Both species are currently on the federal, Oregon, and California endangered species list. Klamath smallscale suckers are considered to be rare in the Klamath River basin. The status of Klamath largescale suckers is poorly understood although it is surmised that lake populations are probably declining in abundance while river populations are probably abundant. Periodicity information for all four sucker species within the Klamath River basin in Oregon is presented in Figure 1.

Ancestors of the redband trout (resident rainbow trout) entered the Klamath River basin when it was connected to the Columbia basin via the Snake River, and coastal rainbow trout (steelhead) later entered the basin from the ocean. Redband/rainbow trout have persisted in the basin above Iron Gate Dam because of their ability to thrive in lake and stream conditions that would be lethal to most salmonids. Currently, redband/rainbow trout numbers are high in both lakes and rivers of the basin above Iron Gate Dam, and these trout support a strong summer fishery. Redband/rainbow trout are currently present in both Copco and Iron Gate Reservoir (Pacificorp 2004, p.4-53 – 4-55, 4-58).

The redband/rainbow trout population in the J.C. Boyle peaking reach (J.C. Boyle Dam to Copco 1 reservoir) supports a high quality recreational fishery and has been described by the National Park Service as highly productive and self-sustaining. In 1984 the adult population in the upper 6 miles of the reach was estimated as 890 fish per mile, and in the 5 miles below this area (near the Oregon-California border) the population was estimated to be 1,911 fish per mile. Populations in Shovel Creek are healthy according to CDFG surveys in the early 1990's. Periodicity information for redband/rainbow trout within the Klamath River basin in Oregon is presented in Figure 1.

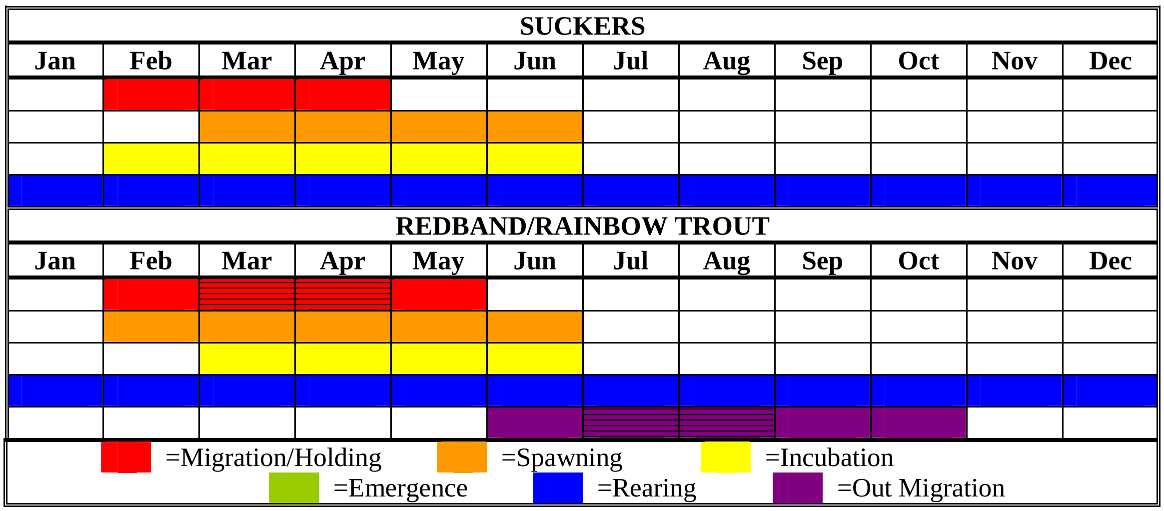

Figure 1: Sucker and Redband/Rainbow Trout Periodicity for the Klamath River in Oregon

= Lesser Use =Lesser Use

Source: FISHPRO 2000

Bull trout have been extirpated, or are at risk of extirpation, from most of the areas they once existed in the Klamath River basin. Bull trout are known to be or have been present in 10 creeks in the basin above Iron Gate Dam: four tributaries to the Sprague River, four tributaries to the Sycan River, and two tributaries to Upper Klamath Lake. The current distribution of bull trout is limited to the headwaters upstream of Upper Klamath Lake. Populations are listed as threatened by the federal government, critical by Oregon, and endangered by California.

The abundance of Klamath Lake sculpin in the basin above Iron Gate Dam is estimated to be in the millions. The presence of these sculpin has not changed from historical distributions and they are found in springs and creeks flowing into the west side of Upper Klamath Lake, Upper Klamath Lake, and Agency Lake. Upper Klamath marbled sculpin are the most widely distributed sculpin present in the basin. They are found in most streams and rivers in the Klamath River basin above Iron Gate Dam, and common in Upper Klamath Lake although they are largely absent from the reservoirs in California. Although slender sculpin were historically common in Upper Klamath Lake and the Williamson, Sprague, Sycan, and Lost Rivers, a survey conducted during the mid 1990's found them to be present only in Upper Klamath Lake and the Lower Williamson River. Overall, the slender sculpin have disappeared from much of their native range, are uncommon in areas where they are present today, and are listed as a species of concern by the federal government.

Klamath River and Pit-Klamath brook lamprey are abundant and widespread in small streams of the basin above Iron Gate Dam. Klamath tui chub have decreased in abundance in the Lost River over the last 30 years, but are typically among the most abundant species found during fish kills in Upper Klamath Lake. Blue chub populations throughout the basin are in decline, however they are probably the most abundant native fish in Upper Klamath Lake. The status of Klamath speckled dace is currently unknown although it appears to be common in the basin with the exception of the Lost River.

1.2.2 Distribution and Status of Non-Native Fish

The following information on fish distribution and status is mainly derived from NRC 2004, p.188-189, with additional information taken from PacifiCorp 2004, p.4-30, 4-31.

Fifteen of the non-native species in the Klamath River basin above Iron Gate Dam were introduced for sport fishing or for bait. Most of these species are not common in the basin, although some are abundant and widespread. The effect of these fish on native fishes is poorly understood.

Yellow perch, brown bullhead, and pumpkinseed are abundant in the reservoirs, sloughs and ponds of the basin above Iron Gate Dam. Brook trout, brown trout, and non-native strains of rainbow trout are common in streams above Iron Gate Dam and have replaced native redband/rainbow trout and bull trout in many areas. Bullhead and perch are the most abundant non-native species found in Copco Reservoir, while Iron Gate Reservoir hosts large populations of perch, bass, and crappie. Non-native trout are also found in Iron Gate and Copco reservoirs. Fathead minnows are often the most abundant species encountered during fish sampling, and are common in Upper Klamath Lake and the Lost River system. Declines in tui and blue chub numbers have been associated with the increased presence of fathead minnows. Sacramento perch is also present in the Klamath River in the area from below Upper Klamath Lake to Iron Gate Reservoir and throughout the Lost River, although its numbers are not particularly high where present.

1.3 Fish below Iron Gate Dam in the Klamath River Basin, California

A total of 46 fish species (27 native and 19 non-native) are found in the Klamath River basin below Iron Gate Dam (Table 3). Native fish currently present in this region of the Klamath River include lamprey, sturgeon, sculpin, and salmonids including the state and federally listed coho salmon. Introduced fish include bass, bullheads, and several species of sunfish.

Table 3: Fish Found Below Iron Gate Dam in the Klamath River Basin

NATIVE	
Pacific Lamprey, *Lampetra tridentata**	Eulachon, *Thaleichthys pacificus**
River lamprey, *Lampetra ayersi**	Surf smelt, *Hypomesus pretiosus*
Klamath River lamprey, *Lampetra similes*	Longfin smelt, *Spirinchus thaleichthys**
Green sturgeon, *Acipenser medirostris**	Prickly sculpin, *Cottus asper*
White sturgeon, *Acipenser transmontanus**	Sharpnose sculpin, *Clinocottus acuticeps*
Klamath speckled dace, *Rhinichthys klamathensis osculus*	Coastrange sculpin, *Cottus aleuticus*
Klamath smallscale sucker, *Catostomus rimiculus*	Pacific staghorn sculpin, *Leptocottus armatus*
Shiner perch, *Cymatogaster aggregata*	Lower Klamath marbled sculpin, *Cottus klamathensis polyporus*
Starry flounder, *Platichthys stellatus*	Threespine stickleback, *Gasterosteus aculeatus***
Pacific herring, *Clupea pallasi*	Arrow goby, *Clevelandia ios*
Topsmelt, *Atherinops affinis*	Pink salmon, *Oncorhynchus gorbuscha**
Coho salmon, *Oncorhynchus kisutch**	Steelhead (rainbow trout), *Oncorhynchus mykiss**
Chinook salmon, *Oncorhynchus tshawytscha**	Coastal cutthroat trout, *Oncorhynchus clarki clarki**
Chum salmon, *Oncorhynchus keta**	
NON-NATIVE	
American shad, *Alosa sapidissima**	Sockeye salmon, *Oncorhynchus nerka*

1.3.1 Distribution and Status of Native Fish

Unless otherwise noted, the following information on fish distribution and status is derived from NRC 2004, p.252-277. Chinook and coho salmon, and steelhead trout habitat and distribution, populations, and periodicity are discussed in great detail in section 1.4.

Anadromous species present in the Klamath River basin below Iron Gate Dam include Chinook, coho, pink, and chum salmon, steelhead and coastal cutthroat trout, eulachon, white and green sturgeon, and Pacific lamprey.

Chum salmon are periodically observed in the basin, and maintain a small population in the Klamath River. Historically chum were more abundant, although their numbers were never very large. Coastal cutthroat trout mainly occur in smaller tributaries in the lower 22 miles of the Klamath River, and have been observed in tributaries to the Trinity River. Pink salmon probably once existed in the Klamath River, although they appear to be extirpated from all areas in California and only occasionally stray into streams along the California coast. In 2003, 2 pink salmon fry were found in the Klamath River between Iron Gate Dam and the Interstate 5 bridge (Corum 2006).

Spring/summer steelhead were once widely distributed in the Klamath River and Trinity River basins and were present in the headwaters of most larger tributaries. Their numbers have declined from historic levels, and NMFS considers stocks depressed and in danger of extinction. Fall and winter steelhead are currently widely distributed in the basin below Iron Gate Dam. Their numbers are believed to be declining from historic levels although past and present estimates of abundance are not readily available. NMFS considers winter steelhead to be in low abundance and at some risk of extinction (Busby et al. 1994 as cited by NRC 2004, p.233), but has not listed them under the ESA (NRC 2004, p.274).

Spring and fall run Chinook populations and distribution have decreased dramatically since the early 1900's. Historically, spring Chinook were found in tributaries throughout the basin, although they are now only present in the Salmon and Trinity Rivers. Large numbers of fall Chinook used to spawn in the basin above Iron Gate Dam, but no longer have access to these areas. In the early 1900's as many as 100,000 spring Chinook were found in the basin, but current populations range from 100 to 1000 fish. Fall Chinook populations have also declined as is evidenced by the Shasta River run which were around 80,000 fish in the 1930's and in the last 10 years have generally been well below 10,000 fish.

Coho were once abundant and widely distributed in the Klamath River and its tributaries at least as far up as Spencer Creek in Oregon (Hamilton et. al. 2005, p.16). Trinity River wild coho stocks have experienced a 96% decline in numbers from historic levels. Coho in the Klamath River basin are currently on the state and federal endangered species lists due to the long-term decline in numbers and distribution.

Eulachon were historically present in large numbers in the lower 8 miles of the river, however since the 1970's their numbers have been too low to support the once flourishing tribal fishery. It is estimated that 70-80% of all green sturgeon are produced in the lower Klamath and Trinity Rivers where several hundred are taken every year by the tribal fishery. There is some evidence that green sturgeon numbers in the basin below Iron Gate Dam have decreased in recent years, although a proposal to list them as threatened was declined by the NMFS in 2003. At the present time they are listed as a species of special concern by the federal government. The historic distribution of Pacific lamprey is unknown, however it is certain that they entered the area above Klamath Falls, Oregon in the basin above Iron Gate Dam at least occasionally. Today Pacific lamprey populations are declining in all coastal rivers, and they are listed as a species of concern by the federal government.

Non-anadromous species common in the Klamath River below Iron Gate Dam and its low gradient tributaries include speckled dace, Klamath smallscale suckers, lower Klamath marbled sculpin, threespine stickleback, and Klamath River lamprey. Dace, stickleback, sculpin, and suckers probably utilize nutrients brought into the streams by anadromous species, and may suffer heavy predation by juvenile salmonids.

1.3.2 Distribution and Status of Non-Native Fish

The following information on non-native fish distribution and status is derived from NRC 2004, p.236-237.

The Klamath River basin below Iron Gate Dam is dominated by native fish, although non-native species have a stronger presence in highly altered areas such as reservoirs and ponds. Large populations of brown bullhead and other non-natives are present in the Shasta River due to introductions and the warmth of these waters. Non-native fish continually enter the Klamath River below Iron Gate Dam from the basin above the Dam where they are extremely abundant (NRC 2004, p.277).

1.4 Chinook salmon, steelhead trout, and coho salmon below Iron Gate Dam in the Klamath River Basin, California

Anadromous salmonids in the Klamath River basin are limited to the area of the basin within California below Iron Gate Dam, which is a barrier to anadromy. Anadromous salmonid runs currently utilizing this portion Klamath River basin include spring and fall Chinook, coho salmon, and spring/summer, fall, and winter steelhead trout. Some authors recognize three runs of steelhead in the basin based on the timing of their entrance to the estuary and tributaries (Hopelain 1998; Shaw et al. 1998; Trihey and Associates, Inc. 1996; USFWS 1979), while others recognize two runs based on sexual maturity at the time of entrance to the river (Hardy 1999; Hardy and Addley 2006; KRBFTF 1991; Moyle 2002). This appendix discusses steelhead based on three runs: spring/summer, fall, and winter. All six salmonid runs in the Klamath River basin have experienced declines in populations and distribution since the early 1900's. The decline of anadromous species in the basin can be attributed to a variety of factors including over harvest, land-use practices, mining, stream habitat alterations, agriculture, and changes in water quality and temperature (Hardy and Addley 2006, p.7). Significant effects are also attributed to water allocation practices and dam construction, which has altered flow regimes (Hardy and Addley 2006, p.7). The following discussion reviews the habitat and distribution, status, and periodicity of these six salmonid runs.

1.4.1 Habitat and Distribution

The information in this section was synthesized from the following sources: CDFG 1965, p.369; Hamilton et al. 2005; Hardy 1999, p.19, 20; Hardy and Addley 2006, p.3, 5, 10-20; and NRC 2004, p.289, 290, 295, & 296.

The continued survival and persistence of sustainable populations of salmonids in the Klamath River basin depends on the amount and suitability of the habitat. Historically, anadromous species within the basin extended above Upper Klamath Lake in Oregon, and into the Sprague and Williamson River systems and other tributaries. Chinook salmon historically migrated into tributaries of Upper Klamath Lake, and steelhead trout were found in the Klamath River basin above Iron Gate Dam as well. Coho salmon distribution extended at least to the vicinity of Spencer Creek.

In 1918, the completion of Copco No.1 Dam on the Klamath River became the first migration barrier for anadromous species and eliminated over 100 miles of potential anadromous fish habitat in the basin. However, reduced access to tributaries in the upper areas of the Klamath River basin likely occurred as early as 1912-1914 when the Lost River diversion canal and Chiloquin Dam were constructed (Hardy and Addley 2006, p.5). The final barrier to upstream migration in the mainstem Klamath River occurred in 1962 with the completion of Iron Gate Dam. The construction of Lewiston and Trinity dams on the Trinity River in 1963 blocked access to over 109 miles of salmonid spawning habitat. Dwinnell dam was constructed on the Shasta River in 1926 and created a barrier to migration, blocking access to 22% of the historical salmonid spawning habitat.

A habitat survey published by the CDFG in 1965 found that there were 805 miles of habitat in the Klamath River basin below Iron Gate Dam suitable for Chinook, 813 miles of habitat suitable for coho, and 1,616 miles of habitat suitable for steelhead. More current information from Hardy and Addley estimate that there are about 701 miles of Chinook, 786 miles of coho, and 1121 miles of steelhead habitat in the basin below Iron Gate Dam.

The following figures show the current distribution of Chinook (Figure 2), steelhead (Figure 3), and coho (Figure 4) runs in the Klamath River basin as well as the areas where these species have been extirpated in the basin. These figures are based on readily available data and thus do not necessarily reflect all locations of presence or areas of extirpation. Rather, the figures show the general decrease in the distribution of salmonids in the basin from historic levels. Locations at which fish presence is not indicated on the map do not necessarily indicate the absence of fish in these areas, as surveys to determine presence/absence may not have been conducted at all locations within the basin.

“Spring Chinook have been known to occupy the lower reaches of many mid-Klamath tributaries during their adult migration (Cyr 2006).” In addition to those areas shown in Figure 2, spring Chinook are occasionally found in very small numbers in the following locations: Beaver Creek, Lower Scott River, and Bogus Creek (Brucker 2006; USFS 2006). The occasional presence of spring Chinook in tributaries of the Klamath River above the Salmon River in very low, dwindling numbers, reflects the fact that they are at high risk of extirpation from these areas.

It is believed that fall and spring Chinook and coho, in addition to steelhead, were once present above Dwinnell Dam on the Shasta River. Hardy and Addley (2006, p.12) report that Dwinnell Dam blocked access to habitat that was historically utilized by steelhead in the headwaters of the Shasta River, and thus Figure 3 reflects steelhead extirpation above Dwinnell Dam. The NRC (2004, p.289) state that the construction of Dwinnell Dam blocked access to 22% of the historical salmonid habitat above the dam. However, to date no reference was found which specifically stated the historic presence of Chinook or coho above Dwinnell Dam, though the habitat was suitable for their presence in many tributaries above the dam.

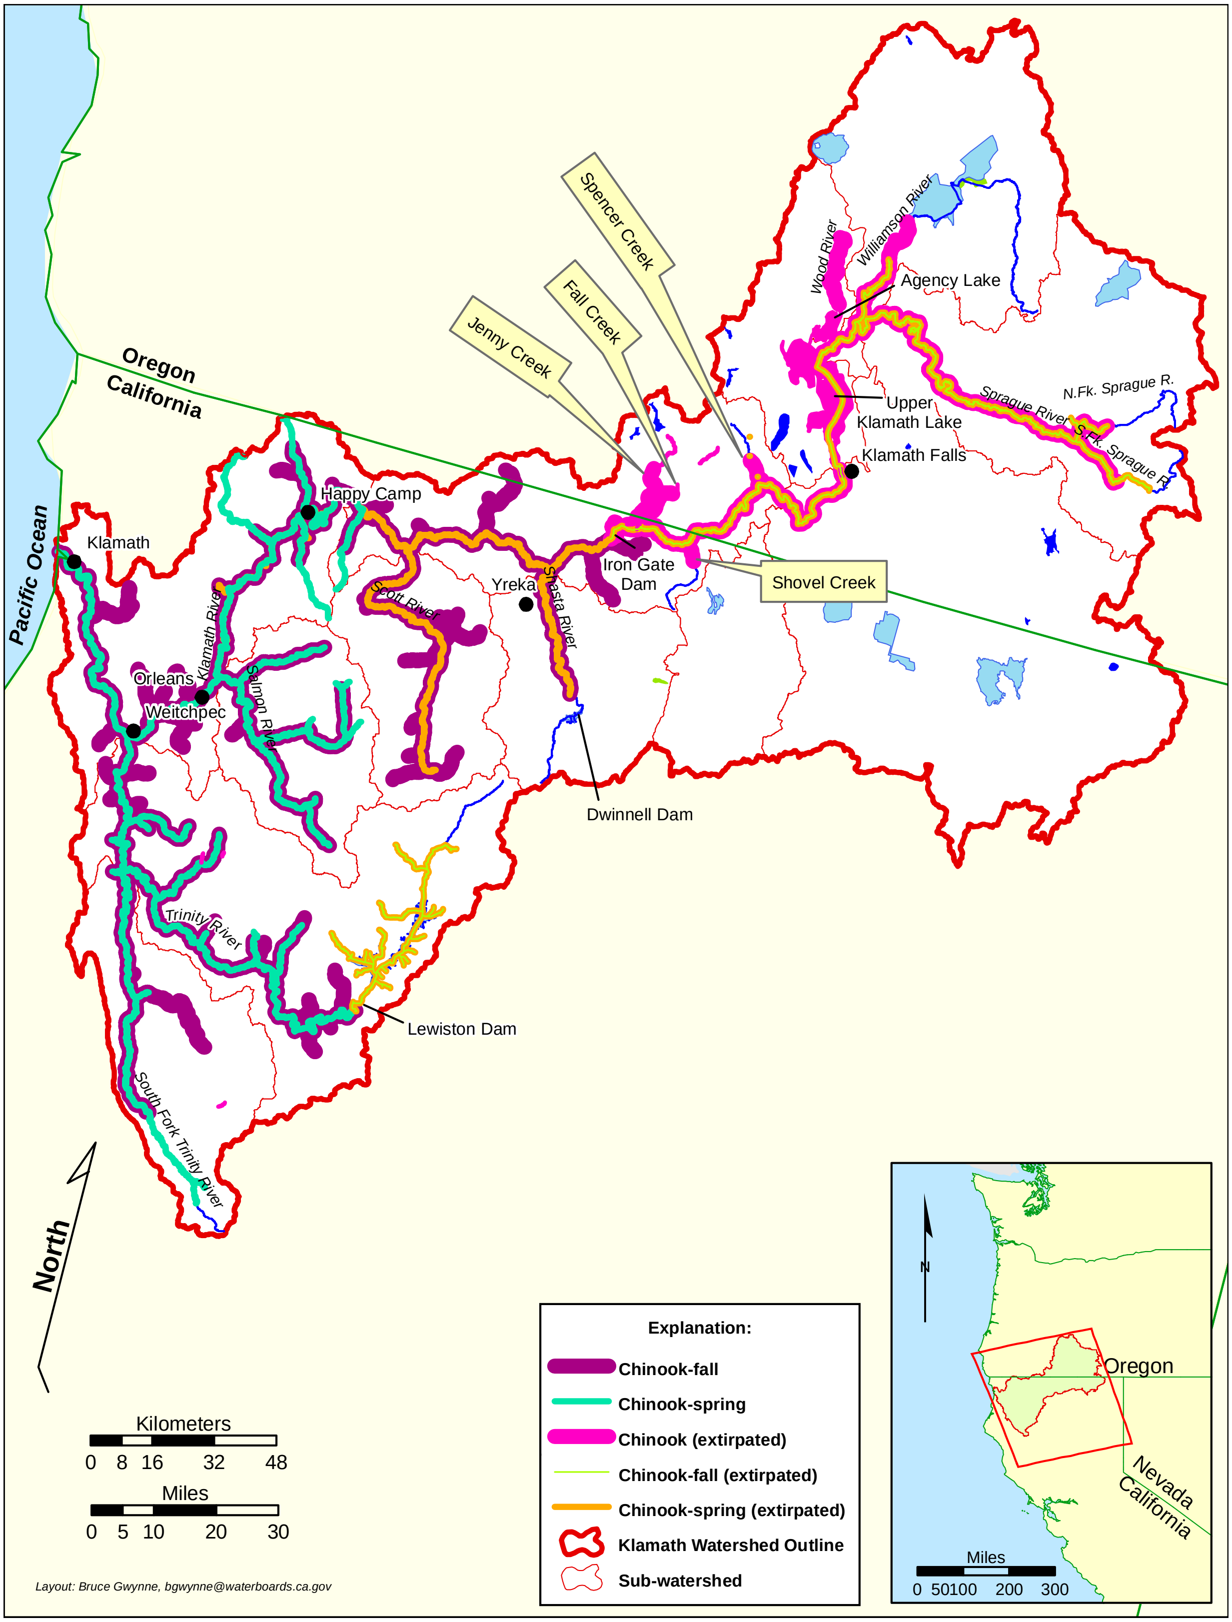

Figure 2: Current Distribution and Areas of Extirpation of Chinook Salmon Runs in the Klamath River Basin
Note: The data for “Chinook (extirpated)” did not differentiate between fall and spring Chinook runs.
Sources: Hamilton et al. 2005, p.12; Moffett and Smith 1950, p.23 & 27; Moyle 2002, p.259; USFS 1996; USFS 2006.

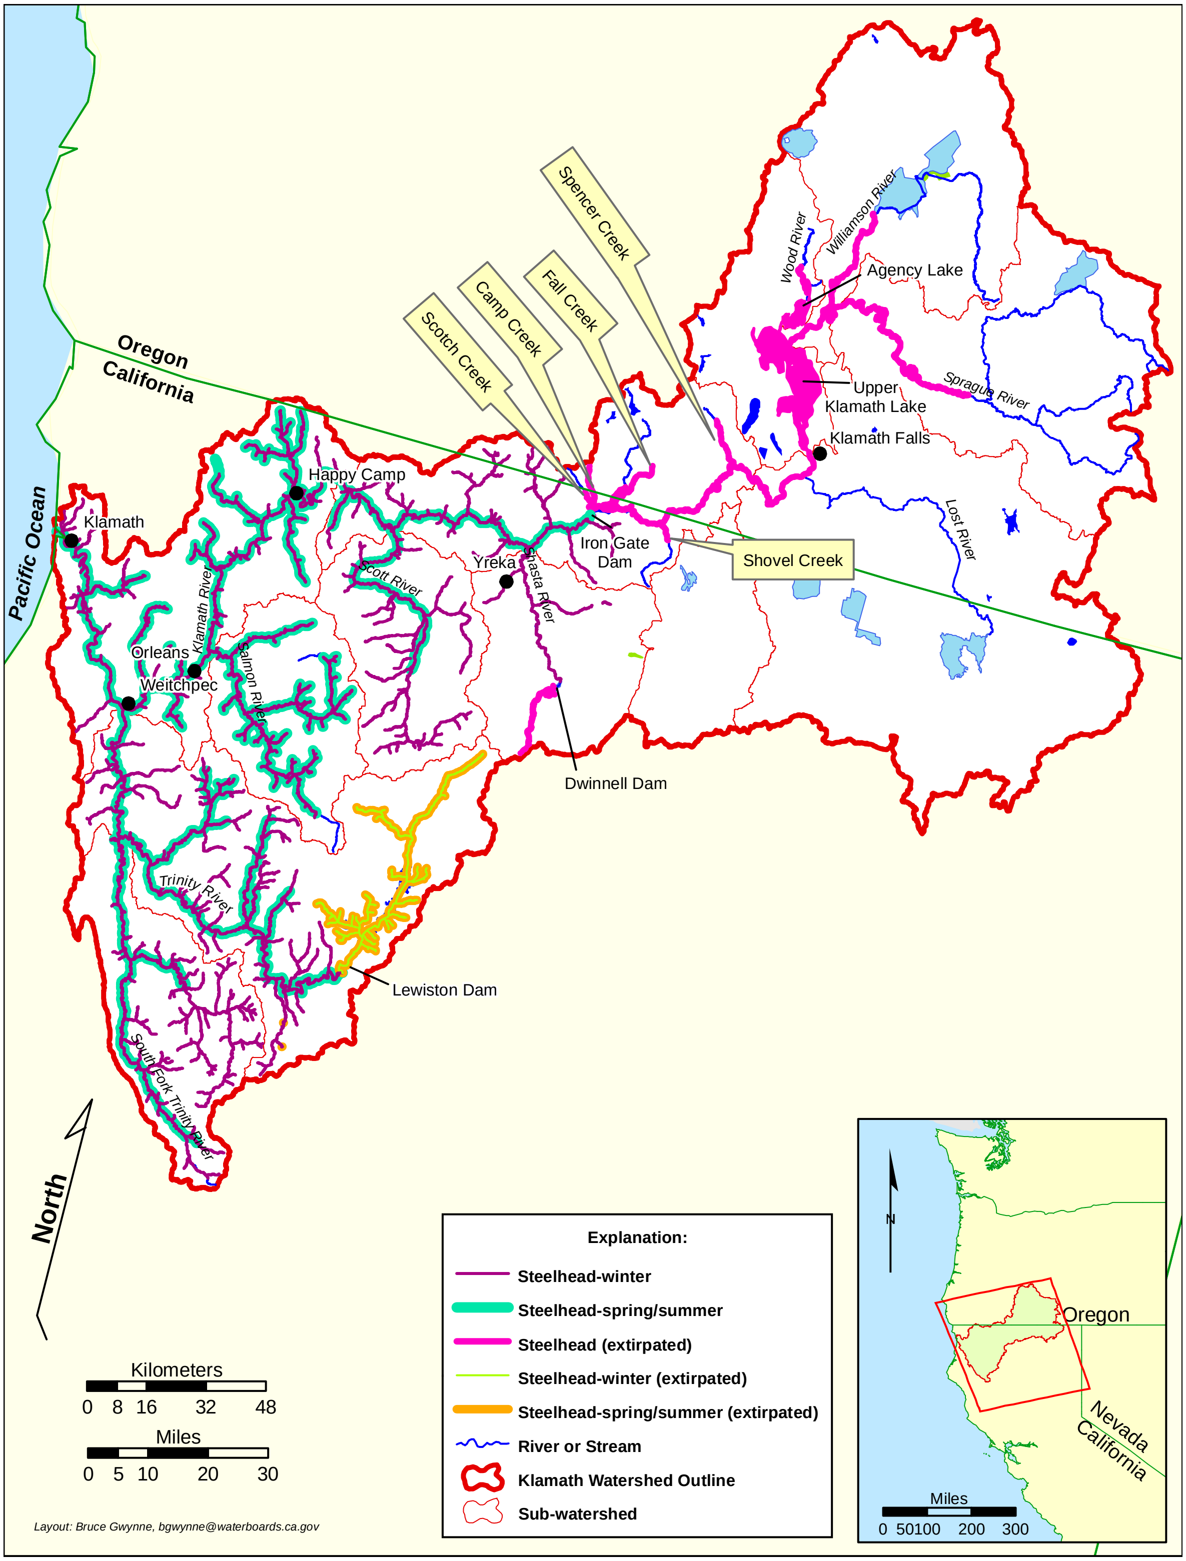

Figure 3: Current Distribution and Areas of Extirpation of Steelhead Trout Runs in the Klamath River Basin
Note: The data for "Steelhead (extirpated)" did not differentiate between spring/summer, fall, and winter runs. The USFS recognizes only winter steelhead (as opposed to fall and winter) and thus information for "Steelhead-winter" and "Steelhead-winter (extirpated)" included data on both fall and winter steelhead runs.
Sources: Hamilton et al. 2005, p.12; Hardy and Addley 2006, p.12; Rushton 2005, p.16 & 17; USFS 1996.

1.4.2 Populations

Salmonid populations in the Klamath River basin have declined since the early 1900s. During the period from 1876 to 1933 the salmon runs entering the Klamath River supported a large commercial fishery and several canneries near the mouth of the river (Moyle 2002, p.258). In 1931, Snyder wrote that the fishery of the Klamath River basin is very important because with proper management it can be maintained, although he also states that depletion of the Klamath salmon is apparent and occurring at an "alarming rate" which artificial propagation alone may not remedy (Snyder 1931, p.9, 121). Utilizing information from Snyder (1931), the NRC (2004, p.267, 268) estimated that the annual total catch in the Klamath River basin during the period from 1916-1927 was probably 120,000 to 250,000 fish, and thus the number of potential spawners was considerably higher. Although historically there were large runs of salmonids in the basin, data indicate that current populations are much lower than historic levels.

1.4.2.1 Chinook Salmon

Historic and current records reflect that Chinook salmon were, and continue to be, the most abundant anadromous species in the Klamath River basin. An approximation of total annual catch plus escapement for the period from 1915-1928 estimated there were 300,000 to 400,000 Chinook in the basin (Rankle 1982 as cited by Hardy and Addley 2006, p.7). An estimate of spawner abundance from CDFG in 1965 estimated that on average there were 168,000 Chinook per year in the Klamath River basin (CDFG 1965, p.369). In 1972, Coots estimated that 148,000 Chinook entered the basin (Coots 1973 as cited by Hardy and Addley 2006, p.7).

1.4.2.2 Fall Chinook Salmon

Overall, fall Chinook numbers in the Klamath River basin have dramatically declined during the past century (Hardy and Addley 2006, p.7). The fall Chinook run once totaled as many as 500,000 fish annually (Moyle 2002, p.258). Fall Chinook numbers in the Shasta River watershed alone, historically numbered 20,000-80,000 fish per year (Regional Water Board 2006, p.1-25). Fall Chinook population estimates in the Klamath River basin for the period from 1978-2007 have ranged from a high of 239,559 fish in 1987 to fewer than 35,000 fish in 1991 (Figure 5). In 2002 it was estimated that the fall Chinook population in the basin was 170,014 fish, of which approximately 32,533 were killed (97.1% of the total fish killed) in mid to late September due to a combination of factors including disease, high water temperatures, and low river flow (CDFG 2004, p.III; USFWS 2003a, p.ii; USFWS 2003b, p.ii). This conservative estimate of the number of fall Chinook killed in 2002 is figured from the number of dead fish observed in the area of the fish kill and does not included dead fish that were washed out of the estuary or settled too deep in the water to be visible during surveys (USFWS 2003b, p.1-7). Thus, the estimate of 32,533 dead fall Chinook (19% of the estimated population in 2002) is very conservative and it is likely the actual number of fall Chinook killed was much higher (CDFG 2004, p.III, 158; USFWS 2003b, p.13). Information for 2007 reflect a total estimated run size of 132,167 fall Chinook in the Klamath River basin (CDFG 2008). NRC (2004, p.268) states that in some respects, "…it is remarkable that fall-run Chinook salmon in the Klamath River are doing as well as they seem to be. Both adults migrating upstream and juveniles moving downstream face water temperatures that are bioenergetically unsuitable or even lethal."

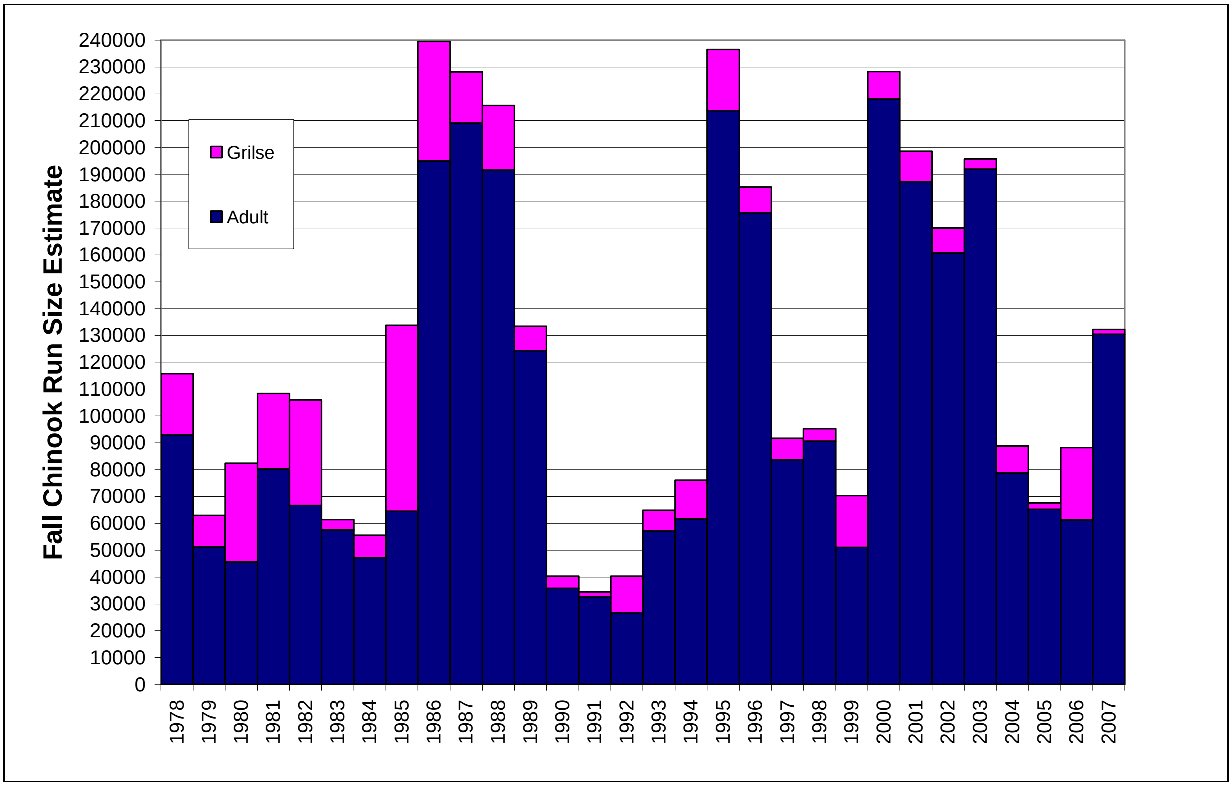

Figure 5: Klamath River Basin Fall Chinook Run Size Estimate, 1978-2007
Note: Run size estimate includes hatchery spawners, natural spawners, and in-river harvest totals. Data from 2007 is preliminary. Grilse are Chinook that return to freshwater to spawn after spending only one year in the ocean.
Source: CDFG 2008

Hatchery returns to Iron Gate and Trinity River hatcheries comprised 6-44% of the fall Chinook populations during the period from 1978-2007 (CDFG 2008). Natural spawners in the Klamath River and its tributaries comprised and estimated 13-39% (Figure 6) of the population during 1991-2007 (CDFG 2008). During 2004 and 2005 the estimated number of fall Chinook natural spawners in the basin has fallen below the Pacific Fishery Management Council goal of a minimum of 35,000. Natural spawning numbers in the basin during these years was estimated to be 28,516 and 27,857 respectively.

In 2006, the National Marine Fishery Service expected the number of natural spawners to be below 35,000 and established an emergency management measure, which closed a majority of the commercial fisheries and greatly reduced the recreational fishery from Cape Falcon, OR, to Point Sur, CA during the period from May 1 through August 31, 2006 (Federal Register 2006, p.26254, 26257). The actual number of natural spawners returning to the Klamath River basin in 2006 (as estimated by CDFG) was 44,546.

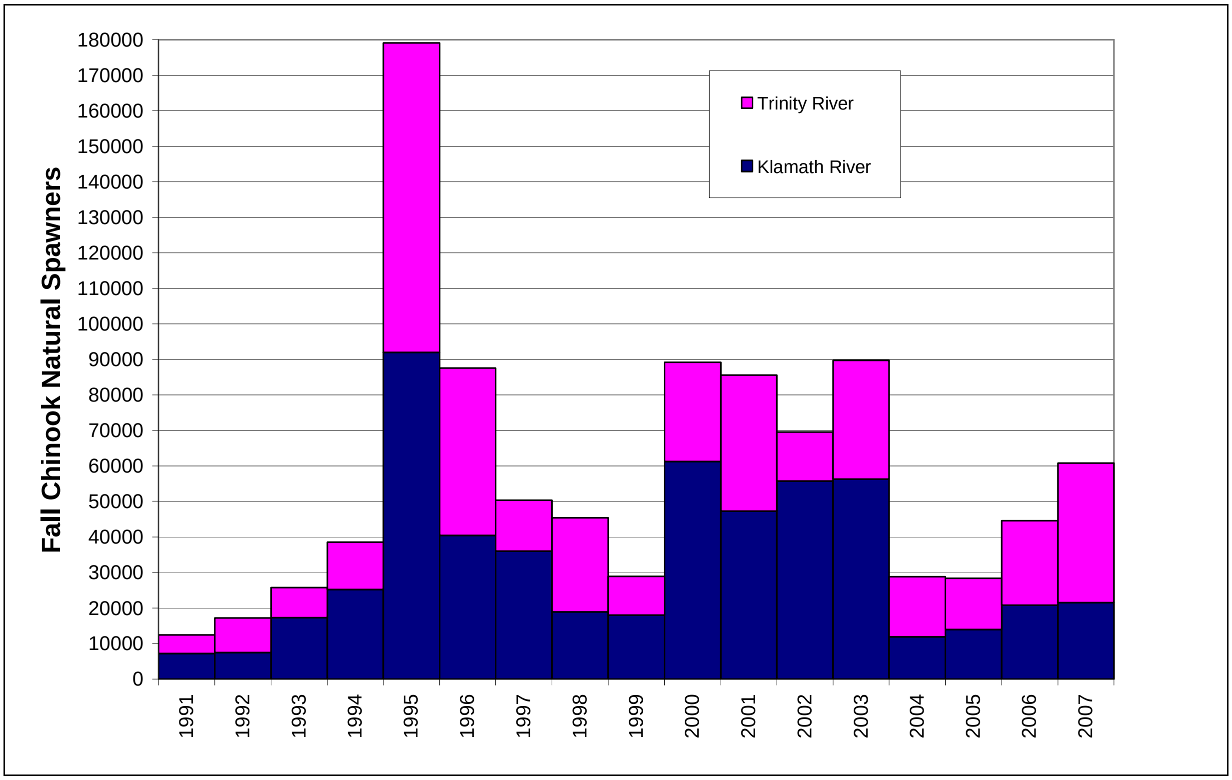

Figure 6: Klamath River Basin Fall Chinook Natural Spawner Estimate, 1991-2007
Note: Data from 2007 is preliminary.
Source: CDFG 2008

The following text on hatchery fall Chinook is from NRC (2004, p.267):

> Hatcheries for Chinook salmon have been operating continuously since 1917. Both the Iron Gate Hatchery and the Trinity River Hatchery produce large numbers of spring-run (13%) and fall-run (87%) juvenile Chinook of native stock (Myers et al. 1998). The hatcheries release 7-12 million juveniles into the river each year (about 70% from the Iron Gate Hatchery, all fall run). The fish generally have been released over a 2-3 days in late May or early June and take 1-2 mo (mean, 31 days) to reach the estuary (M. Wallace, CDFG, unpublished data, 2002), although some fish probably remain in pools for most of summer. Smaller fish take longer than larger fish to reach the estuary, but because they are feeding and growing on the way downstream, all juveniles are about the same size when they reach it. About 40% of the juvenile fish in the estuary in 2000 were of hatchery origin (CDFG, unpublished data, 2000); this is presumably a fairly typical figure. Adult Chinook returning to the hatcheries are roughly one third of the total run—30% in 1999, 44% in 2000, and 28% 2001 (CDFG, unpublished data, 2001). There has been an increase in the percentage of hatchery fish in the run in recent years—up from 18% in 1978-1982, and 26% in 1991-1995 (Meyers et al. 1998). Their contribution to natural spawning is not known, but estimates for the

> Trinity River suggest that it is roughly the same as the percentage of hatchery returns (Myers et al. 1998).

1.4.2.3 Spring Chinook Salmon

The Klamath River basin was known historically for its large run of spring Chinook salmon, which is currently a vestige of its former self (West 1991, p.3). In 1931, Snyder wrote that the spring Chinook migration in the basin, while once very pronounced, “has now come to be limited as to the number of individuals, and is of relatively little economic importance” (Snyder 1931, p.19). A population of more than 100,000 spring-run Chinook was once present in the basin, although this estimate is probably low because spring-run fish were the main run of Chinook in the Klamath River in the 1800’s (Moyle 2002, p.259). Access to prime coldwater habitat in the headwaters of the Shasta, Klamath, and Trinity Rivers has been blocked by the construction of dams thus contributing to the decline of spring Chinook. Spring Chinook runs above Trinity Dam historically included an estimated 5,000 fish in the mainstem Trinity and 1,000-5,000 fish in each of four tributaries above Lewiston Dam (Moyle et al. 1995, p.40). Historic run size estimates in each of the Sprague River, Williamson River, Shasta River, and Scott River alone were at least 5,000 fish (CDFG 1990 as cited by Moyle 2002, p.259).

> Runs in the Sprague and Williamson Rivers were probably extirpated before 1900 as the result of dams constructed in Oregon; if any fish remained, they were eliminated with the construction of Copco Dam across the main river in California in 1917. The run in the Shasta River, probably the largest tributary run in the Klamath drainage, disappeared in the early 1930s as a result of habitat degradation and increased summer water temperatures caused by Dwinnell Dam. The smaller Scott River run was extirpated in the early 1970s by a variety of causes (Moyle 2002, p.259).

By the 1980’s, habitat alterations had reduced or eliminated much of the cold water habitat and deep pools that spring-run Chinook require resulting in their elimination from much of their former habitat (NRC 2004, p.269). It is estimated that only 3% of the historic habitat available to spring Chinook is currently used by this run (Spring Salmon Summit 2005, p.10). Extant spring run Chinook populations in the Klamath River basin only remain in the Trinity and the Salmon Rivers. Population estimates for spring Chinook during the period from 1980-2006 have ranged from a high of 69,004 fish to fewer than 1,945 (Figure 7). Trinity River Hatchery returns have made up 14-68% of these populations during 1980-2006, and on average comprise 28% of the population.

An average of 10,320 natural spring Chinook spawners have returned to the Klamath River basin annually during the period from 1990-2006, and estimates have ranged from 1,618-35,719 fish (Figure 8). The only substantial wild populations still persisting in the basin are found in the Salmon River (Campbell and Moyle 1991 as cited by Moyle et al. 1995, p.40). Monitoring records of spring Chinook adults in the Salmon River during this period reflect an average of 601 fish returning to the stream annually, with a range from 90 (2005) to 1,485 (1995).

1.4.2.4 Steelhead Trout

Steelhead are common in the Klamath River basin below Iron Gate Dam where three runs are known to occur: spring/summer, fall, and winter. All three of these runs have a life-history stage called the half-pounder, which is an immature fish that migrates to the sea in the spring but returns to freshwater in the late summer. Fall and winter run steelhead are fairly common in the basin, although they are less abundant than historical levels, while spring/summer steelhead are in danger of extinction (Moyle 2002, p.280). It is likely that steelhead runs exceeded several million fish prior to the 1900s (Hardy and Addley 2006, p.6). An estimate of steelhead spawner abundance by CDFG (1965, p.369) estimated an average of 221,000 steelhead in the Klamath River basin annually.

Hardy and Addley (2006, p.6) state:

> The best quantitative historical run sizes in the Klamath and Trinity river systems were estimated at 400,000 fish in 1960 (USFWS 1960, cited in Leidy and Leidy 1984), 250,000 in 1967 (Coots 1967), 241,000 in 1972 (Coots 1972) and 135,000 in 1977 (Boydston 1977). Busby et al., (1994) reported that the hatchery influenced summer/fall-run in the Klamath Basin (including the Trinity River stocks) during the 1980's numbered approximately 10,000 while the winter-run component of the run was estimated to be approximately 20,000. Monitoring of adult steelhead returns to the Iron Gate Hatchery have shown wide variations since monitoring began in 1963. However, estimates during the 1991 through 1995 period have been extremely low and averaged only 166 fish per year compared to an average of 1935 fish per year for 1963 through 1990 period (Hiser 1994). In 1996, only 11 steelhead returned to Iron Gate Hatchery. The National Marine Fisheries Service (NMFS) considers that based on available information, Klamath Mountain Province steelhead populations are not self-sustaining and if present trends continue, there is a significant probability of endangerment (NMFS 1998); however, steelhead were not listed under the Endangered Species Act of 1973 (ESA).

Annual counts of spring/summer steelhead in holding areas throughout the Klamath River basin have ranged from 500 to 3,000 fish (Roeloffs 1983, as cited by Hopelain 1998, p.1). In the 1990’s it was estimated that there were 1000-1500 spring/summer steelhead adults divided among eight populations in the basin (Barnhart 1994, Moyle et al. 1995, Moyle 2002 as cited by NRC 2004, p.274). NMFS considers spring/summer steelhead stocks depressed and in danger of extinction (Busby et al. 1994 as cited by NRC 2004, p.274).

Fall steelhead represent the largest of the three steelhead runs and were estimated to include 55,000-75,000 spawning adults and 150,000-225,000 half-pounders during the period from 1980-1982 (D.P. Lee, CDFG, pers. comm. as cited by Hopelain 1998, p.1).

Run size estimates for winter steelhead were 170,000 in the 1960s, 129,000 in the 1970s, and 100,000 in the 1980s (Busby et al. 1994 as cited by NRC 2004, p.273). Current population estimates for winter steelhead have not been conducted, although Hopelain (1998, p.1) estimated a run-size of about 5,000 to 25,000 during 1980-1982. It is presumed that winter steelhead abundance is still declining although estimates, both past and present, are not very reliable (NRC 2004, p.273).

The following text on hatchery winter steelhead is from NRC (2004, p.272, 273):

> The Iron Gate Hatchery produces about 200,000 and the Trinity River Hatchery about 800,000 winter steelhead smolts per year (Busby et al. 1994). The fish are released into the rivers in the last 2 wk of March, and most reach the estuary about a month later (M. Wallace, CDFG, personal communication), coincident with the emigration of wild smolts. Diets of outmigrating smolts are similar to those of wild smolts, although the consumption of a greater variety of taxa and fewer organisms by the hatchery fish than by wild fish suggests that they have lower feeding efficiency than wild fish (Boles 1990). Otherwise, the interactions between hatchery and wild fish in the Klamath are not known, although hatchery steelhead released into a stream will dominate the wild steelhead (McMichael et al. 1999), potentially increasing the mortality in wild fish from predation, injury, or reduced feeding. Hatchery steelhead also can have adverse effects on juveniles of other salmonids, especially Chinook and coho salmon, through aggressive behavior and predation (Kelsey et al. 2002).
>
> In the 1970s and early 1980s, adults of hatchery origin made up about 8% of the run of Klamath River steelhead and 20-34% of the run in the Trinity River (Busby et al. 1994). As numbers of wild steelhead decline, the percentage of hatchery fish in the population presumably will increase. There is some indication that the runs most heavily influenced by hatchery steelhead in the Trinity River have a lower frequency of half-pounders in the population than do wild populations (Hopelain 1998).

Although steelhead population estimates for the Klamath River basin have not been conducted on a regular basis, adult steelhead return numbers to the Iron Gate Hatchery, Trinity River Hatchery, and Shasta River Fish Counting Facility are available and are presented for the period from 1970-2005 in Figure 9. Adult steelhead returns to these three locations in the basin have ranged from a high of 10,837 fish in 2004 to a low of 529 fish in 1999, with an average return of 3,328 fish over the last 36 years.

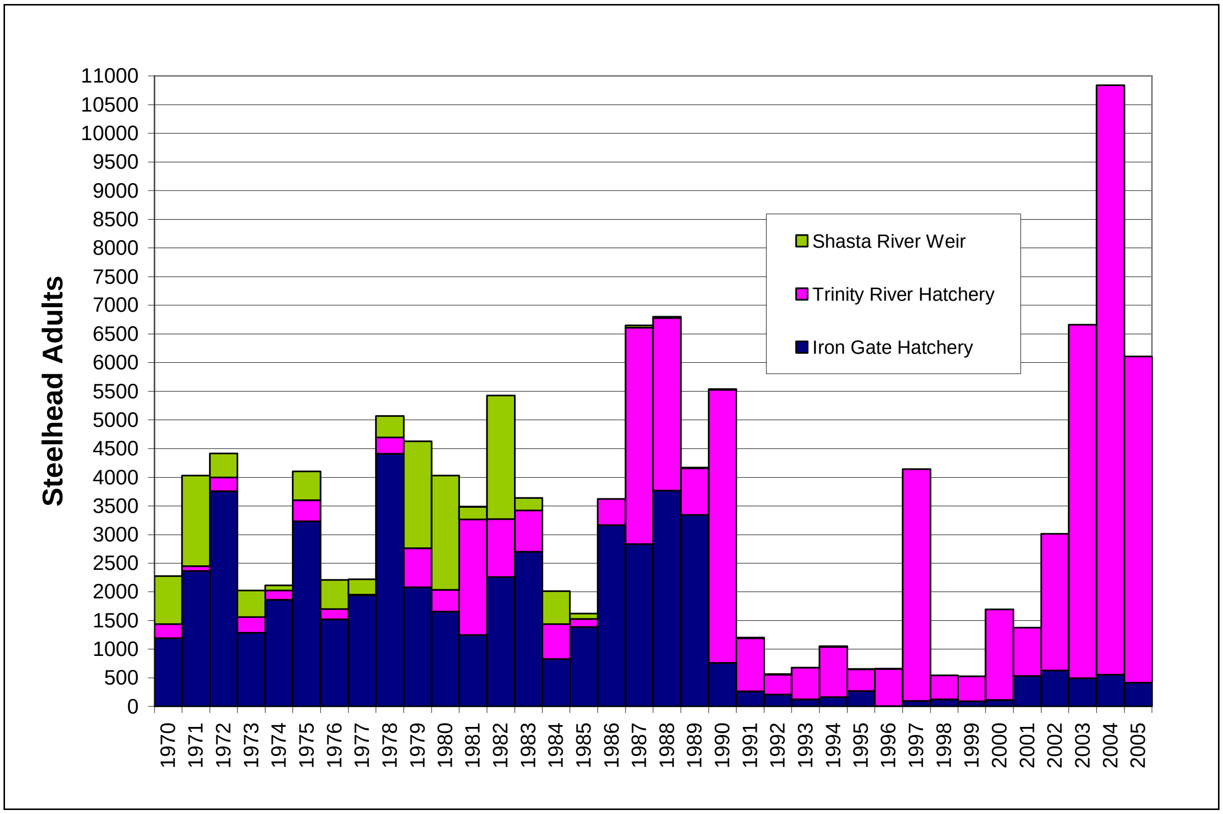

Figure 9: Klamath River Adult Steelhead Returns to Iron Gate Hatchery, Trinity River Hatchery, and the Shasta River Fish Counting Facility, 1970-2005
Note: Steelhead data were not available from the Shasta River Fish Counting Facility for the period of 1997-2005 and thus information is only presented for Iron Gate and Trinity River Hatchery Returns.
Sources: Klamath River Information System (KRIS) 2006; Marshall 2005; and Rushton 2005.

1.4.2.5 Coho Salmon

It is clear from the information available that coho salmon populations statewide have undergone a dramatic decline from historic levels (Brown and Moyle 1991, p.8; Brown et al. 1994; CDFG 2002, p.1). The Southern Oregon/Northern California Coast Evolutionary Significant Unit (SONCC ESU), which encompasses Klamath River basin stocks, has been listed as threatened by the State of California and the federal government. Coho salmon occupy only 61% of the SONCC ESU streams that were previously identified as historical coho salmon streams (CDFG 2002, p.2).

Maximum estimates for coho spawners in California during the 1940's range from 200,000-500,000 fish (Sagar and Glova 1988 as cited by Moyle 2002, p.250). Brown et al. (1994) state that California coho populations are probably less than 6% of what they were in the 1940s, and there has been at least a 70% decline since the 1960s. In 1994, Brown et al. estimated the coho salmon population in California to be 30,000 fish, with natural spawners comprising 43% of the total population or 13,240 fish. This figure is said to be "optimistic because we assumed coho salmon still occur in streams for which there are no current data; it is likely, therefore, that we have underestimated the magnitude of decline (Brown et al. 1994)."

Historical spawning escapement estimates for the Klamath River basin approximate 15,400-20,000 coho, with 8,000 of these fish originating in the Trinity River (USFWS 1979, App. as cited by Brown et al. 1994). In 1965, CDFG estimated 15,400 coho spawners per year in the basin (CDFG 1965, p.369). In 1994, Brown et al. estimated a total abundance of 18,125 coho in the basin, including 1,860 native and naturalized fish. Brown et al. (1994) published the results of presence and absence counts for coho salmon in the basin. Of the 41 tributaries monitored (113 tributaries where they were known to have existed historically), coho were detected in only 21 and absent in the other 20 (Brown et al. 1994). Current population estimates for coho in the Klamath River basin have not been conducted, although adult coho return numbers to the Iron Gate Hatchery, Trinity River Hatchery, and Shasta River Fish Counting Facility are available and are presented for the period from 1964-2005 in Figure 10. Adult coho returns from these combined locations during the last 42 years averaged 5949 fish.

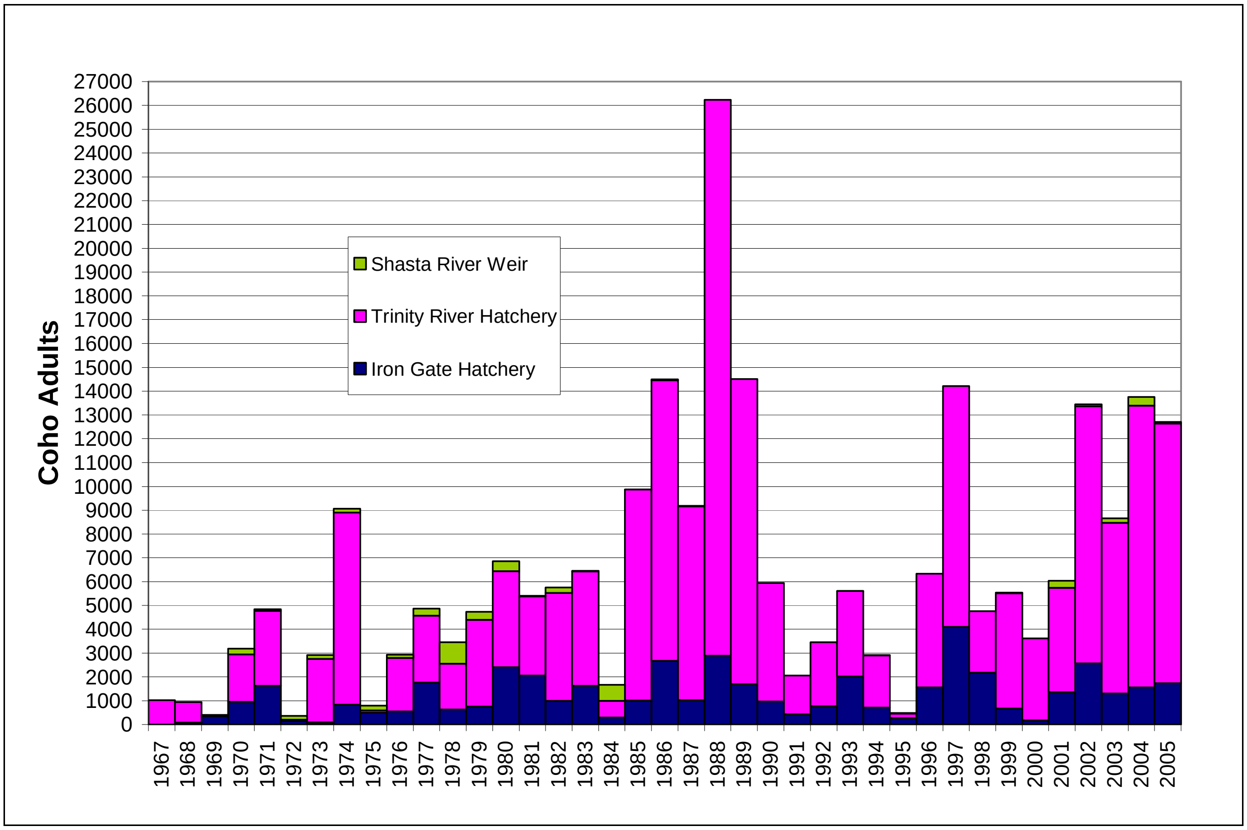

Figure 10: Klamath River Adult Coho Returns to Iron Gate Hatchery, Trinity River Hatchery, and the Shasta River Fish Counting Facility, 1964-2005

Sources: Hampton 2004, p.1; Hampton 2005a, p.1; Hampton 2005b; KRIS 2006; Marshall 2005; and Rushton 2005.

Natural production of coho salmon in the Klamath River basin is considered minimal, with Iron Gate and Trinity River Hatcheries the major sources of most coho salmon in the basin (KRFMC 1991, App. as cited by Brown et al. 1994). The following text from NRC (2004, p.262, 263) discusses hatchery coho in the Klamath River basin:

Coho salmon have been an important part of the Klamath basin fish fauna since prehistoric times (CDFG 2002), and many attempts have been made to augment their populations in the Klamath basin. The first attempt occurred in 1895, when 460,000 fish from Redwood Creek—part of the same evolutionarily significant unit (ESU) as Klamath River coho—were stocked in the Trinity River. It is not known whether these fish, which were taken from a small stream, survived and contributed to later populations. Hatchery production of coho salmon in the Klamath basin began in the 1910-1911 season and continued for another 5 yr. From 1919 to 1942, six additional plants of hatchery-reared fish, all apparently of local origin, were conducted (CDFG 2002). The principal hatcheries today are the Iron Gate Hatchery (operating since 1966) on the Klamath and the Trinity River Hatchery (operating since 1963) on the Trinity River. Faced with a declining egg supply, operators of the two hatcheries at various times brought in fertilized eggs from the Eel and Noyo rivers in California and the Cascade and Alsea rivers in Oregon (CDFG 2002). Thus, present hatchery stocks probably are of mixed origin. Although a few hatchery fish have been planted in tributaries, hatchery fish are for the most part released as smolts into the main stem on the assumption that they will head directly to the sea.

Genetic studies of the contribution of hatchery coho to wild populations in the Klamath basin are not available. Brown et al. (1994) inferred that most wild coho stocks in the basin were partially mixed with hatchery stocks because the two hatcheries are at the far upstream end of coho distribution and produce large numbers of fish. In recent years, the Trinity River Hatchery has released an average of 525,000 coho per year and the Iron Gate Hatchery about 71,000 per year (CDFG 2002), although historically the Iron Gate Hatchery has released about 500,000 coho per year (CDFG, unpublished data, 2002). The coho typically are reared to the smolt stage and marked with a maxillary clip before release, which occurs between March 15 and May 1. They reach the estuary in concert with wild smolts, which peak in late May and early June, but typically are longer than the wild fish—about 170-185 mm vs 135-145 mm (M. Wallace, CDFG, unpublished data, 2002). Although the effect of large numbers of hatchery coho on wild coho is not known for the Klamath, hatchery fish may dominate wild fish when the two are together (Rhodes and Quinn 1998). In any event, hatchery fish are apparently more numerous than their wild counterparts. In 2000 and 2001, 61% and 73%, respectively, of the smolts captured in the estuary were of hatchery origin (M. Wallace, CDFG, unpublished data, 2002).

The percentage of hatchery fish in the spawning population has not been estimated directly, but Brown et al. (1994) estimated that 90% of the adult coho in the system returned directly to the hatcheries or spawned in the rivers in their immediate vicinity. Other hatchery coho no doubt stray into other streams, but the percentage is not known (CDFG 2002). In a survey of spawning coho in the Shasta River in 2001, individuals from the Iron Gate and Trinity River hatcheries were identified; seven of 23 carcasses examined were hatchery fish (CDFG, unpublished data, 2001). Regardless of origin, natural-spawning coho in the basin's tributaries have managed to maintain timing of runs and other life-history features that fit the basin's hydrologic cycle well.

1.4.3 Periodicity

Adult and juvenile Chinook and steelhead are present year round in the Klamath River basin below Iron Gate Dam (Figures 11 and 13), and mainstem Klamath River below the Dam (Figures 12 and 14). Adult coho are present in the basin from August to February (Figure 15) and in the mainstem Klamath River from September through January (Figure 16), while juvenile coho are present year round. The following sections discuss the presence of salmonids in the Klamath River basin at various life stages throughout the year, known as "periodicity." Data on individual Chinook and steelhead runs in Figures 11, 12, 13, 14 below, are based on readily available information and do not necessarily reflect the entire use period for that run/species. The "All" information rows for Chinook and steelhead represent periods where one or more of the runs are utilizing the basin, and thus is a summary of all information on the individual runs and run timing information for the species in general.

Unless otherwise noted, the text in the following section is primarily from Hardy 1999 (p.5-7), Hardy and Addley 2006 (p.14), NRC 2004 (p.254-258, 264-266, 270-274), and USFWS 1979 (p.16, 27, 29, 30), with additional information from Moyle (2002, p.254), and Salmon River Restoration Council (SRRC) and Klamath Tribe Department of Natural Resources (KTDNR) 2006.

1.4.3.1 <u>Chinook Salmon</u>

Chinook periodicity information for the Klamath River basin below Iron Gate Dam is presented in Figure 11, and information for Chinook periodicity in the mainstem Klamath River is presented in Figure 12.

Fall Chinook are generally slower in their upstream migration than spring Chinook. It takes approximately 2-4 weeks for fall Chinook to reach upstream spawning grounds (USGS 1998 as cited by NRC 2004, p.265). Fall Chinook spawn in the lower reaches of tributaries and in the mainstem Klamath River, although less than 33% spawn in the mainstem. Half of the spawning that occurs in the mainstem takes place in the 13 miles of the river below Iron Gate Dam, although significant spawning occurs as far down as Happy Camp and limited spawning occurs as far downstream as Orleans. Eggs generally incubate for 50-60 days when water temperatures range from 5-14.4 C. Fry move downstream after emergence and often take up residence in shallow water on the edges of the stream in flooded vegetation, where they remain for various lengths of time, although some outmigrate directly to the estuary. The NRC (2004, p.265) reports that juveniles rearing in the Klamath River or larger tributaries reside there for 3-9 months but move downstream continuously. Shaw et. al. (1998, p.29) state that juvenile rearing in the mainstem between Iron Gate Dam and Seiad Creek is likely to occur year round. Belchik (1997) reports that rearing juvenile salmonids reside in pockets of cool water, thermal refugia, in the Klamath River when mainstem water temperatures become unsuitable during the summer. Type I, II, and III Chinook exist in the Klamath River basin and thus outmigration occurs year round. Juvenile fall Chinook move into the estuary at a smaller size and reside there longer when conditions in the river are unfavorable, such as times of warm water temperatures. It appears that many juveniles leave the estuary after only a few weeks, and outmigrate to the ocean (Wallace 2000 as cited by NRC 2004, p.265).

Spring Chinook are thought to migrate more deliberately and further upstream than fall Chinook. Spring Chinook migrate as far upstream as they can go in larger tributaries, which allows them to access habitat often inaccessible to fall Chinook due to low flows and high temperatures during the summer and fall. Spring Chinook are persistent in their upstream migration and don't rest until they have reached holding areas where they remain until they spawn. Migrating spring Chinook hold in deep pools for 2-

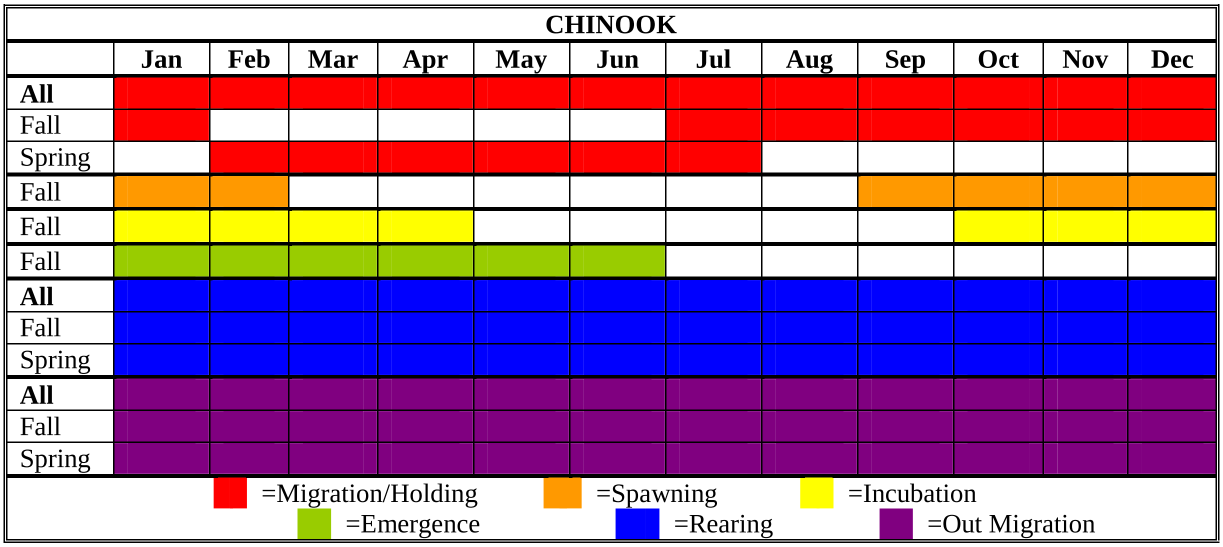

Figure 12: Chinook Periodicity in the Mainstem Klamath River

Sources: Hardy 1999, p.34; Hardy and Addley 2006, p.96; NRC 2004, p.264-267; Rushton 2005; Shaw et al. 1998; USFWS 1979, p.16; USFWS 1999, p.16; USFWS 2001, p. 59, 62, 65, & 68

4 months (throughout the summer) as their gonads fully develop, and then spawn the following fall and winter. Spring Chinook are susceptible to high water temperatures that can result in decreased fecundity of females (decreases egg viability) as they hold throughout the summer (McCullough 1999 as cited by NRC 2004, p.269). Incubation takes approximately 40-60 days, and alevin and fry remain in the gravel for 2-4 weeks before emergence. Spring Chinook will typically rear in freshwater for a year after emergence before heading to the ocean (Healey 1991 as cited by NRC 2004, p.268).

1.4.3.2 Steelhead Trout

Information on steelhead periodicity in the Klamath River basin below Iron Gate Dam is presented in Figure 13, and steelhead periodicity in the mainstem Klamath River is presented in Figure 14.

With the exception of half-pounders, steelhead remain in the ocean for 1-3 years before initiating their spawning run and may spawn 3-4 times during their life. Incidence of repeat spawning reported by Hopelain (1998, p.21) were 17.6-47.9% for fall steelhead, 40-63.3% for spring/summer steelhead, and 33.1% for winter steelhead. Although steelhead generally use the mainstem Klamath River as a migration corridor, some spawning does occur in the mainstem. The mainstem is also very important to the juvenile rearing life stage of steelhead. Fall run steelhead typically enter the Klamath River basin during the summer and hold for several months before moving to spawning areas in smaller tributaries. The early part of the fall steelhead run consists primarily of half-pounders. Franklin (2006) notes that half-pounders have entered the Klamath River as early as July, although most references cite migration beginning in August. Spring/summer steelhead enter the Klamath River in early spring and hold in deep pools until they spawn the following winter. High water temperatures can decrease the viability of eggs in female spring/summer steelhead holding throughout the summer and fall. Steelhead eggs typically incubate for 4 –7 weeks, although the length of time for incubation is a function of water temperature, taking longer in cooler temperatures.

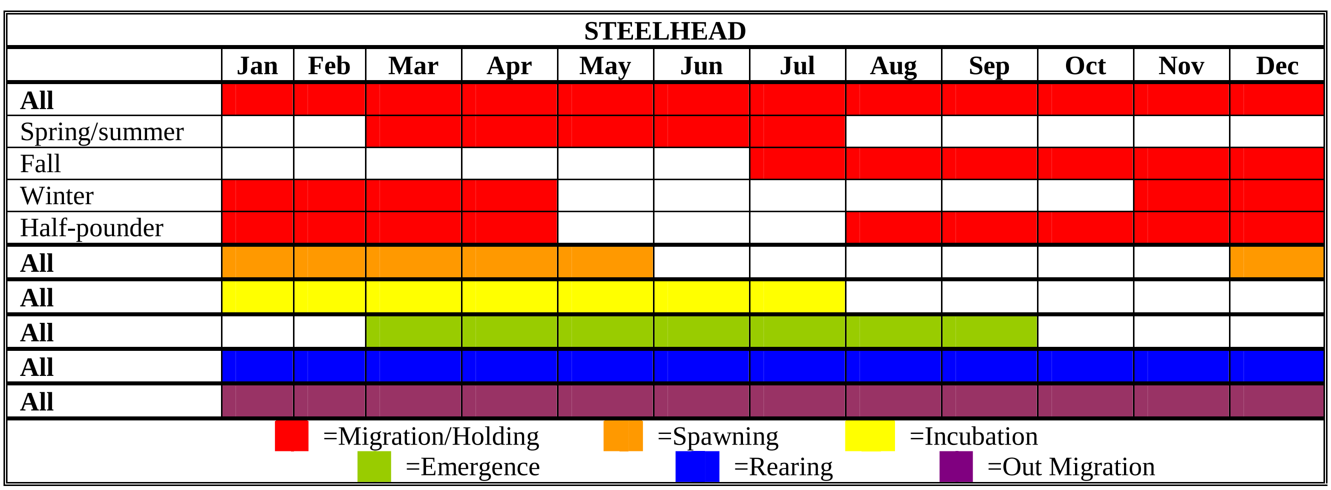

Figure 14: Steelhead Periodicity in the Mainstem Klamath River

Sources: Hardy 1999, p.34; Hardy and Addley 2006, p.96; Hopelain 1998, p.12; NRC 2004, p.271-273; Rushton 2005; Shaw et al. 1998; USFWS 1979, p.29 & 30; USFWS 1999, p.27; USFWS 2001, p. 61, 64, 67, & 70.

After emergence, fall and winter steelhead juveniles distribute themselves widely throughout the basin, and many move out of the tributaries and into the mainstem to rear (NRC 2004, p.271). Juvenile spring/summer steelhead typically occupy the same upper stream reaches where they were spawned. Shaw et al. (1998, p.31) report that young of the year steelhead emigrate to the mainstem and most likely rear there for a year before emigrating as two year olds. Cool water areas, thermal refugia, of the mainstem Klamath River are utilize by rearing juvenile salmonids during the summer once mainstem temperatures become unsuitably warm (Belchik 1997). Juvenile steelhead normally spend 2 years in freshwater before they enter the ocean, although some emigrate after 1 or 3 years.

1.4.3.3 Coho Salmon

Coho periodicity information for the Klamath River basin below Iron Gate Dam is presented in Figure 15, and information on coho periodicity in the mainstem Klamath River is presented in Figure 16.

In the Klamath River basin, coho salmon have a 3-year lifecycle during which they spend 1-1½ years in freshwater before moving to the ocean, and then return to the river to spawn at age 3. Occasionally males, called "jacks", will return to the river to spawn as 2-year-olds. Coho upstream migrations are typically linked to pulse flows associated with rain events in the basin. They generally spawn in tributaries, however they have been observed spawning at tributary confluences, in side channels, and along the shoreline of the mainstem Klamath River. Eggs incubate for approximately 7 weeks and alevins remain in the gravel for 2-3 weeks before emerging.

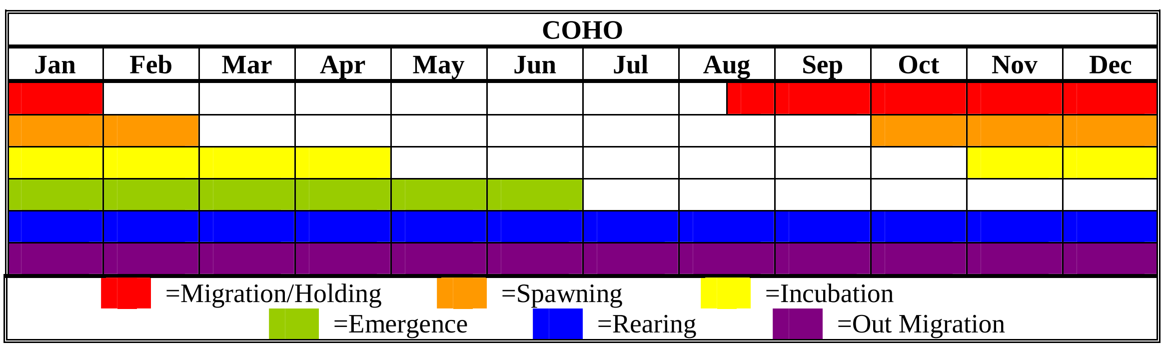

Figure 15: Coho Periodicity in the Klamath River Basin

Sources: Hardy 1999, p.6 & 34; Hardy and Addley 2006, p.96; Leidy and Leidy 1984; NRC 2004, p.7, 8; Shaw et al. 1998; Snyder 1931, p.16, 23; SRRC and KTDNR 2006; SRWC 2004, p.6-17; Trihey and Associates, Inc. 1996, p.13, 17; USFWS 1979, p.27; USFWS 1999, p.26, 43; USFWS 2001p.32, 40.

Upon emergence from the gravels coho juveniles seek areas of low velocity with an abundance of food, such as the stream margins. The NRC reports that coho juveniles live in the mainstem Klamath River despite temperatures that regularly exceed 24C (M. Rhode, CDFG, personal communication, USFWS, unpublished data, 2002 as cited by NRC 2004, p.257). These juveniles are mainly found in pools at the mouths of tributaries where temperatures are 2-6C lower than in the mainstem. Belchik (1997) reports that cool water areas, thermal refugia, of the mainstem Klamath River are utilize by rearing juvenile salmonids, including coho, during the summer once mainstem temperatures become unsuitably warm. The Karuk tribe have collected data which shows that coho use the mainstem Klamath River even during the hottest periods of the year if suitable thermal refugia is available (Corum 2006). Shaw et. al. (1998, p.30) states that coho likely rear in the mainstem Klamath River between Iron Gate Dam and Seiad Creek year round, although they do not necessarily inhabit the mainstem on a continuous basis due to the high bioenergetic demands. Coho juveniles typically rear in freshwater for 1 year before outmigration occurs.

Tetra Tech, Inc.

Contents

Acknowledgments

Completion of the Klamath River Hydrodynamic and Water Quality Model for TMDL development was made possible by the generous support and responsiveness of many people. The authors would like to acknowledge the following professionals, in particular, for their contributions:

Ben Cope	U.S. Environmental Protection Agency, Region 10
Clayton Creager	North Coast Regional Water Quality Control Board
Michael Deas	Watercourse Engineering, Inc.
Mark Filippini	U.S. Environmental Protection Agency, Region 10
Susan Keydel	U.S. Environmental Protection Agency, Region 9
Steve Kirk	Oregon Department of Environmental Quality
David Leland	North Coast Regional Water Quality Control Board
Gail Louis	U.S. Environmental Protection Agency, Region 9
Bryan McFadin	North Coast Regional Water Quality Control Board
Matt St. John	North Coast Regional Water Quality Control Board
Daniel Turner	Oregon Department of Environmental Quality

Andrew Parker, Rui Zou, and Mustafa Faizullabhoy led Tetra Tech’s model development and application effort.

1.0 INTRODUCTION

The Klamath River watershed traverses the states of Oregon and California, encompassing an area of approximately 15,722 square miles. The headwaters of the Klamath River originate in the Cascade Mountains and the river flows to the southwest from Oregon into northern California toward its confluence with the Pacific Ocean (Figure 1-1). Major tributaries to the Klamath River include the Lost River Diversion Channel and the Shasta, Scott, Salmon, and Trinity Rivers.

The watershed includes portions of Jackson, Josephine, Klamath, and Lake Counties in Oregon, and Del Norte, Humboldt, Modoc, Siskiyou, and Trinity Counties in California. Nearly 63 percent of the watershed (approximately 9,933 square miles) lies in California, while 37 percent (5,727 square miles) is in Oregon. The Klamath River watershed includes twelve U.S. Geological Survey (USGS) 8-digit hydrologic cataloging units, numbers 18010201 through 18010212.

The Oregon Department of Environmental Quality (ODEQ) and California's North Coast Regional Water Quality Control Board (NCRWQCB) have both included the Klamath River on their corresponding Clean Water Act section 303(d) lists as a result of observed water quality criteria exceedances. Impairments include dissolved oxygen (DO), chlorophyll *a*, temperature, pH, and ammonia for various portions of the Klamath River and its tributaries in Oregon and nutrients, temperature, and organic enrichment/low DO for segments of the river and its tributaries in California.

The states are required to develop total maximum daily loads (TMDLs) for applicable water quality parameters. The TMDL process identifies the maximum load of a pollutant a waterbody is able to assimilate and still fully support its designated uses. The TMDL process also allocates portions of the allowable load to all sources, identifies the necessary controls that may be implemented voluntarily or through regulatory means, and describes a monitoring plan and associated corrective feedback loop to ensure that uses are fully supported. Watershed and water quality modeling is often used during the development of TMDLs to help with one or more of these tasks. Modeling is a quantitative approach to better understand complex environmental processes and relationships. Models can be used to help fill in gaps in observed water quality data, estimate existing pollutant sources throughout a watershed, calculate allowable loads, and assess the potential effectiveness of various control options.

The first steps in the TMDL development process were previously conducted, including compiling available data; evaluating monitoring data to identify the extent, location, and timing of water quality impairments; and developing a technical approach to analyze the relationship between source pollutant loading contributions and in-stream response. These steps were detailed in *Data Review and Modeling Approach—Klamath and Lost Rivers TMDL Development* (Tetra Tech, Inc. 2004). Subsequent steps include model configuration, model testing (calibration), and scenario analysis. This document discusses the configuration of the Klamath River model and presents modeling results for the Klamath River from Upper Klamath Lake (UKL) to the river's outlet at the Pacific Ocean for the river and reservoir segments (2000 and 2002) and estuarine segment (2004).

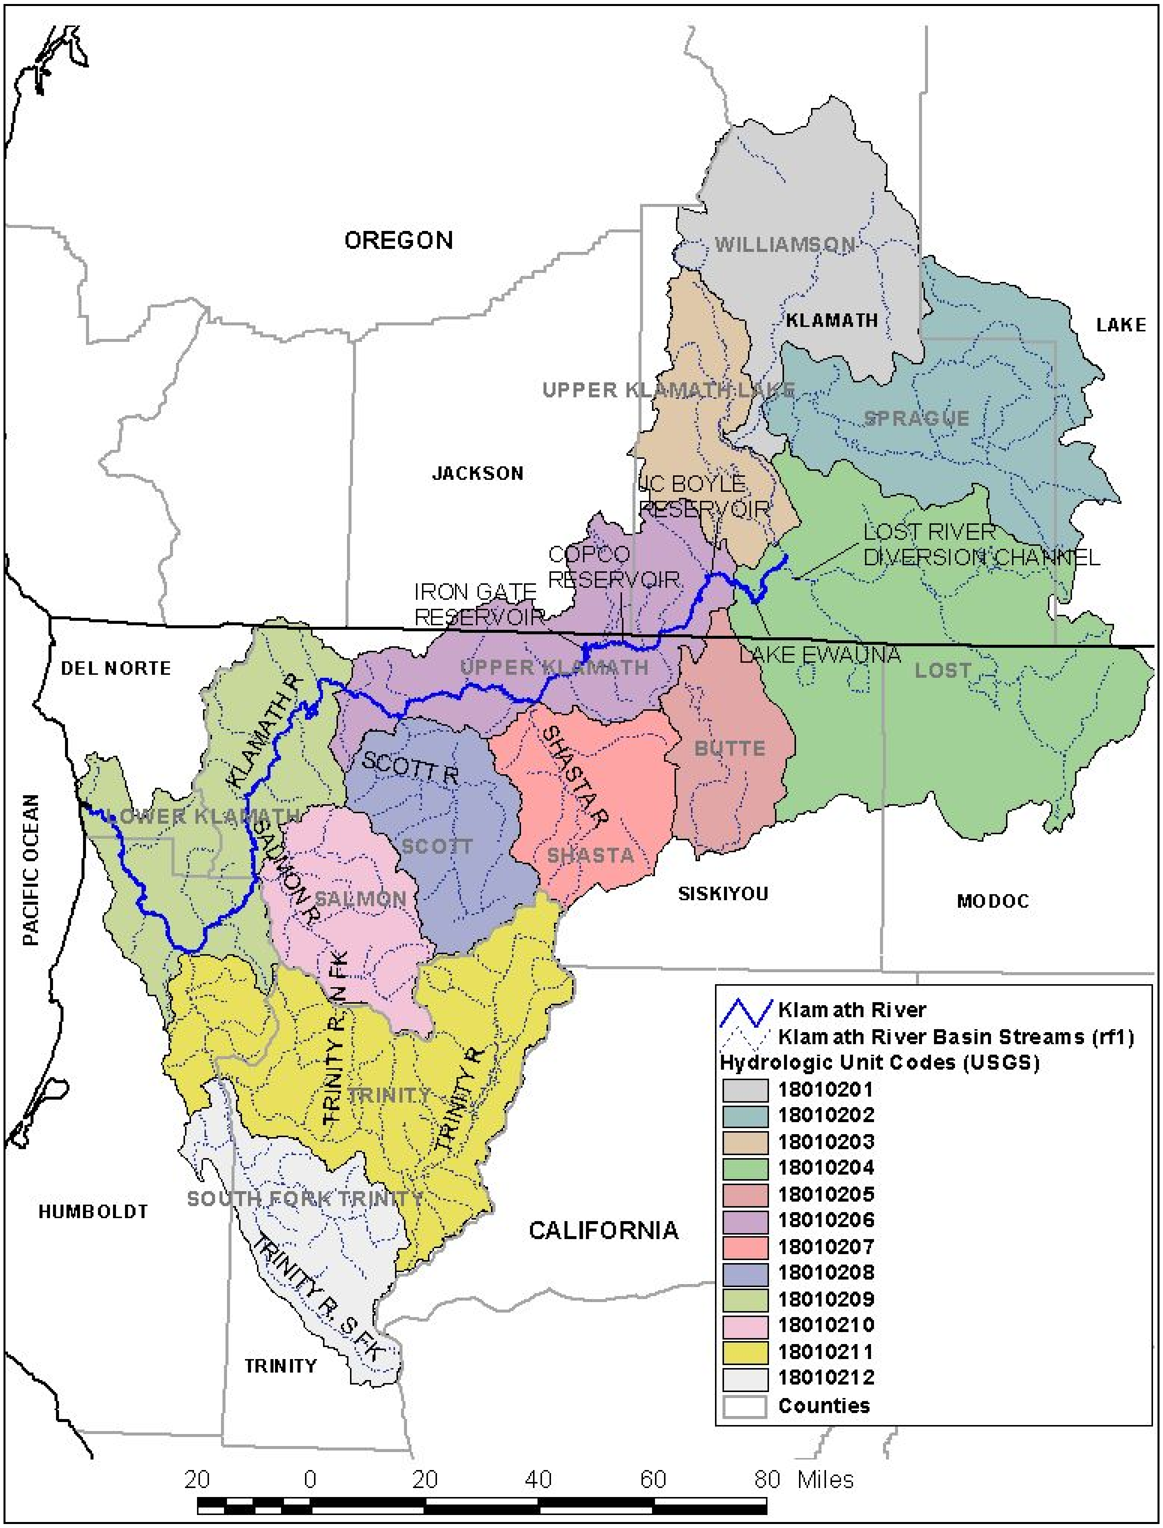

Figure 1-1. Extent of the Klamath River watershed

2.0 MODELING APPROACH

2.1 Model Selection

To support TMDL development for the Klamath River system, the need for an integrated receiving water hydrodynamic and water quality modeling system was identified. The following model capabilities were identified as being necessary to support TMDL development. The model must be

- Capable of predicting hydrodynamics, nutrient cycles, DO, temperature, pH, and other parameters and processes pertinent to the TMDL development effort;
- Capable of simulating the multiple flow control structures along the length of the Klamath River;
- Dynamic (time-variable) and thus capable of representing the highly variable flow and water quality conditions within years and between years;
- Capable of considering the steep channel slope of the Klamath River; and
- Capable of representing conditions in the Klamath Estuary.

A model for the Klamath River had already been developed by PacifiCorp to support studies for the Federal Energy Regulatory Commission Hydropower relicensing process (Watercourse Engineering, Inc. 2004) when this project began. The version of the model available in 2004 is hereafter referred to as the *PacifiCorp Model*. The PacifiCorp Model and other models, including the operational models MODSIM and CALSIM, were evaluated for applicability to Klamath River TMDL development (Tetra Tech, Inc. 2004). NCRWQCB, ODEQ, and the U.S. Environmental Protection Agency (EPA) determined that the existing PacifiCorp Model would provide the optimal basis, after making some enhancements, for TMDL model development. Section 2.2 provides a description of the enhancements made to the PacifiCorp Model. It should be noted that PacifiCorp has since updated the model after receiving comments from reviewers (PacifiCorp 2005).

The original PacifiCorp Model consisted of Resource Management Associates (RMA) RMA-2 and RMA-11 models and the CE-QUAL-W2 model. Specifically, the RMA-2 and RMA-11 models were applied for Link River (which is the stretch of the Klamath River from UKL to Keno Dam), Keno Dam to J.C. Boyle Reservoir, Bypass/Peaking Reach (hereafter referred to as the Bypass/Full Flow Reach), and Iron Gate Dam to Turwar. RMA-2 simulates hydrodynamics, while RMA-11 represents water quality processes. The CE-QUAL-W2 model was applied for Lake Ewauna-Keno Dam, J.C. Boyle Reservoir, Copco Reservoir, and Iron Gate Reservoir. In addition to addressing the model needs identified above, the PacifiCorp Model

- Uses hydrodynamic and water quality models with a proven track record in the environmental arena, including historical application to the Klamath River;
- Has already been reviewed by most stakeholders in the watershed;
- Can be directly compared to ODEQ, NCRWQCB and tribal water quality criteria;
- Has been preliminarily calibrated for the Klamath River and its applicability demonstrated; and
- Uses the public domain model CE-QUAL-W2 and a version of RMA that can be distributed to the public for purposes of TMDL application.

Because the estuarine portion of the Klamath River (Turwar to the Pacific Ocean) was not included in the original PacifiCorp Model, it was necessary to identify a model appropriate for modeling that portion of the river. After reviewing a 2004 bathymetric survey and grab, multiprobe, and cross-sectional profile data, it was determined that a laterally averaged 2-D model, such as CE-QUAL-W2, was not the ideal choice for modeling the estuarine portion of the Klamath River.

Hydrodynamics and water quality within the estuary are highly variable spatially and throughout the year and are greatly influenced by time of year, river flow, tidal cycle, and location of the estuary mouth (which changes because of sand bar movement). Additionally, transect temperature and salinity data in the lower estuary showed significant lateral variability, as did DO to a lesser extent. The Environmental Fluid Dynamics Code (EFDC), which is a full 3-D hydrodynamic and water quality model, was selected to model the complex estuarine environment instead.

EFDC is an EPA-endorsed and widely applied 3-D model (particularly for TMDL development). EFDC allows for representing the complex geometry of the Klamath Estuary with a boundary-fitted, curvilinear grid. The model is capable of simulating important physical processes and features, such as the circulation pattern near the funnel-shaped mouth and islands. The mouth of the estuary is very wide; however, it does not open to the Pacific Ocean completely because of the presence of a sand bar. As a result, the estuary can communicate with the ocean only through a very narrow opening in the sand bar. Configuring a CE-QUAL-W2 grid for this portion of the system would likely result in a very wide segment at the downstream end of the river. The wide segment would be linked to a very narrow segment representing the opening in the sand bar. This configuration runs the risk of resulting in computational error because of the sudden change in segment width at the most dynamic portion of the system (Cole and Wells, 2003). Although it is impossible to simulate the evolution of the existing sand bar at the estuary mouth with available technology, EFDC can potentially be used to efficiently evaluate the implications of mouth locations on hydrodynamics and water quality.

Hydrodynamics and water quality in the estuary are also highly variable throughout the year and are greatly influenced by time of year, river flow, tidal cycle, and location of the mouth. Hydrodynamic data also show significant lateral variability, as does DO to a lesser extent. It is desirable to apply a model that has the potential to represent this variability and EFDC is capable.

Additional factors leading to the choice of EFDC for modeling the estuary include the following:

- EFDC is capable of predicting hydrodynamics, nutrient cycles, DO, temperature, and other parameters and processes pertinent to the TMDL development effort for the estuarine section.
- The EFDC model is dynamic (time-variable) and thus capable of representing the highly variable flow and water quality conditions within years and between years.
- EFDC has a proven track record in the environmental arena—particularly with regard to TMDLs.
- Model results can be directly compared to ODEQ, NCRWQCB and tribal water quality criteria.
- EFDC is EPA-endorsed and supported and is included in the EPA TMDL Modeling Toolbox. It is a public domain model, fully transparent (i.e., model code), and is available free of charge. EPA also provides training and support on the application free of charge.

- EFDC has a function for blocking flows between computational cells, and this allows for efficiently evaluating the effect of the location and size of the sand bar opening, with a single grid configuration.
- The EFDC water quality module possesses a fully numerical sediment diagenesis module to predict sediment oxygen demand (SOD) and benthic nutrient flux based on organic loading to the waterbody. This improves the reliability of the model for DO and nutrient TMDLs. Although this component was not used in this study because of time and data limitations, it can be implemented in the future using the existing framework when sufficient data become available.

The combination of the enhanced PacifiCorp Model (RMA and CE-QUAL-W2) and EFDC resulted in the Klamath River model used for TMDL development. Table 2-1 identifies the modeling elements applied to each river segment.

Table 2-1. Model components applied to each Klamath River segment

Modeling segment	Segment type	Model(s)	Dimensions
Link River	River	RMA-2/RMA-11	1-D
Lake Ewauna-Keno Dam	Reservoir	CE-QUAL-W2	2-D
Keno Dam to J.C. Boyle Reservoir	River	RMA-2/RMA-11	1-D
J.C. Boyle Reservoir	Reservoir	CE-QUAL-W2	2-D
Bypass/Full Flow Reach	River	RMA-2/RMA-11	1-D
Copco Reservoir	Reservoir	CE-QUAL-W2	2-D
Iron Gate Reservoir	Reservoir	CE-QUAL-W2	2-D
Iron Gate Dam to Turwar	River	RMA-2/RMA-11	1-D
Turwar to Pacific Ocean	Estuary	EFDC	3-D

The linkages between the riverine and reservoir/estuary models identified in Table 2-1 were made by transferring time-variable flow and water quality from one model to the next (e.g., output from the Link River model became input for the Lake Ewauna-Keno Dam model). This modeling framework is consistent with available models appropriate for application to riverine/reservoir systems and is based on the PacifiCorp Model's existing modeling approach for the river system.

Each model type included (RMA, CE-QUAL-W2, and EFDC) is discussed in more detail below.

RMA

The hydrodynamic component of the RMA modeling suite, RMA-2, is a model specifically designed to assess flow response in complex river systems (Deas 2000). RMA-2 solves the full-flow equations, known as the St. Venant Equations. These equations use all terms of the conservation of momentum formulation and provide a complete description of dynamic flow conditions. The model has been widely applied (it is one of the most used full hydrodynamic models in the United States) to a variety of river and estuary systems in the United States as well as internationally.

The water quality component, RMA-11, is a general-purpose water quality model, compatible in geometry with the configuration of the RMA-2 hydrodynamic model. The model simulates advective heat transport and air-water heat exchange processes, as well as fate and transport of water quality parameters (e.g., nutrients), to produce dynamic descriptions of temperature and constituent concentration along the river reach. Input requirements include temperatures and quality of boundary flows, and meteorological data defining atmospheric conditions governing heat exchange at the air-water interface. Model output is in the form of longitudinal profiles of temperature and water quality parameters along river reaches, or time series at fixed locations.

CE-QUAL-W2

The U.S. Army Corps of Engineers' CE-QUAL-W2 is a 2-D, longitudinal/vertical (laterally averaged), hydrodynamic and water quality model (Cole and Wells, 2003). The model allows for application to streams, reservoirs, and estuaries with variable grid spacing, time-variable boundary conditions, and multiple inflows and outflows from point/nonpoint sources and precipitation.

The two major components of the model include hydrodynamics and water quality kinetics, which simulate changes in constituent concentrations. Both of these components are coupled (i.e., the hydrodynamic output is used to drive the water quality at every timestep). The hydrodynamic portion of the model predicts water surface elevations, velocities, and temperature. The ULTIMATE-QUICKEST numerical scheme used in the CE-QUAL-W2 model is designed to reduce the numerical diffusion in the vertical direction to a minimum and in areas of high gradients, reduce the undershoots and overshoots that could produce small negative concentrations. The water quality kinetics portion can simulate 21 water quality parameters including DO, nutrients, phytoplankton interactions, and pH.

EFDC

EFDC is a general purpose modeling package for simulating 1-D, 2-D, and 3-D flow, transport, and biogeochemical processes in surface water systems including rivers, lakes, estuaries, reservoirs, wetlands, and coastal regions. The EFDC model was originally developed at the Virginia Institute of Marine Science for estuarine and coastal applications. This model is now being supported by EPA and has been used extensively to support TMDL development throughout the country. In addition to hydrodynamic, salinity, and temperature transport simulation capabilities, EFDC is capable of simulating cohesive and non-cohesive sediment transport, near-field and far-field discharge dilution from multiple sources, eutrophication processes, the transport and fate of toxic contaminants in the water and sediment phases, and the transport and fate of various life stages of finfish and shellfish. Cohesive sediment refers to silt and clay particles while non-cohesive refers to anything larger than silt (e.g., sand, gravel). The EFDC model has been extensively tested, documented, and applied to environmental studies worldwide by universities, governmental agencies, and environmental consulting firms.

The structure of the EFDC model includes four major modules: (1) a hydrodynamic model, (2) a water quality model, (3) a sediment transport model, and (4) a toxics model. The water quality portion of the model simulates the spatial and temporal distributions of 22 water quality parameters including DO, suspended algae (3 groups), attached algae, various components of carbon, nitrogen, phosphorus and silica cycles, and fecal coliform bacteria. Salinity, water temperature, and total suspended solids are needed for computation of the 22 water quality parameters, and they are simulated by the hydrodynamic model.

EFDC's water quality model also includes a sediment process model, which uses a slightly modified version of the Chesapeake Bay 3-D model (Park et al. 1995). Upon receiving the particulate organic matter (OM) deposited from the overlying water column, it simulates its diagenesis and the resulting fluxes of inorganic substances (ammonium, nitrate, phosphate and silica) and SOD back to the water column. The coupling of the sediment process model with the water quality model not only enhances the model's predictive capability of water quality parameters, but also enables it to simulate the long-term changes in water quality conditions in response to changes in nutrient loads.

2.2 Model Enhancements

Although the original PacifiCorp Model (Watercourse Engineering, Inc. 2004) is capable of addressing the identified water quality issues, a number of enhancements to the model were necessary to expedite and strengthen the model for the rigors of TMDL development for the Klamath River.

Selected algorithms in the PacifiCorp Model were considered for augmentation of the modeling framework to address specific processes and support TMDL development. Enhancements were made in the following areas:

- BOD/OM unification
- Two-state algae transformation algorithm in Lake Ewauna
- Monod-type continuous SOD and OM decay
- pH simulation in RMA
- OM-dependent light extinction simulation in RMA
- Reaeration formulations
- Dynamic OM partitioning
- Periphyton carrying capacity
- Additional shading in RMA
- Second order polynomial spillway representation

2.2.1 BOD/OM Unification

It was determined that biochemical oxygen demand (BOD) should not be modeled in addition to OM because BOD itself is a surrogate for OM. The BOD compartment in the modeling system was eliminated for both the riverine (RMA model component) and reservoir (CE-QUAL-W2 model component) sections. To maintain consistency between the new version of the model and the original version in terms of organic loading, the BOD concentration in the original version was converted to an OM component by using a stoichiometric ratio of BOD:OM = 1.4. This stoichiometric coefficient was derived on the basis of the original RMA-11 model and is also consistent with representation in the CE-QUAL-W2 model. This converted OM was combined with the OM in the original version to form the total OM in the new version. This conversion allowed the model to represent consistent amounts of OM in the original and new versions.

Additionally, in the original CE-QUAL-W2 models for the reservoirs, particulate OM was not included in the tributary boundary condition files. This is expected to result in an underestimation of particulate OM into the system. Therefore, for the major tributaries that are highly productive, such as the Lost River Diversion Channel, particulate OM loading was represented on the basis of data and appropriate assumptions. Concentration boundary condition files were modified using a labile particulate OM (LPOM) to labile dissolved OM (LDOM) ratio of 4.0 (LPOM:LDOM = 0.8:0.2), which is same as for the Link River boundary condition. Labile OM refers to the portion that is decomposed relatively quickly. The state variable slots in the CE-QUAL-W2 models for labile OM (i.e., LDOM and LPOM) were used to represent all dissolved OM and particulate OM, respectively. Therefore, even though the terms “LDOM” and “LPOM” are used when referring to model results, the values essentially represent all OM, without differentiating between labile and refractory components.

2.2.2 Two-state Algae Transformation Algorithm in Lake Ewauna

Very low levels of phytoplankton were observed in lower Lake Ewauna, as shown in the year 2000 monitoring data for the Highway (Hwy) 66 station. Phytoplankton biomass in Lake Ewauna also shows significant variability from upstream (Miller Island water quality station) to downstream (Hwy 66 water quality station). In addition, observed data show that there was a sharp drop in algae concentration at the Miller Island station during the summer. These phenomena were not predicted by the existing PacifiCorp Model, although it is configured to simulate all algae-DO-nutrient interactions represented in the W2 model code.

Simulated algae biomass in the existing PacifiCorp Model is similar at both locations, and algae concentrations remained high throughout the summer period. This is due to the dominant upstream inflow (from UKL) that causes water to flow quickly from upstream to downstream. The inability to accurately predict the temporal and spatial distribution of phytoplankton has significant implications on the water quality dynamics. Therefore, model refinement was needed to better represent the algae dynamics in this lake.

It appears that with the existing kinetic structure in the model, it is not possible to reproduce this type of spatial distribution of algae biomass. During the model testing process, which is described later in this report, the algae growth and mortality parameters were varied significantly in an attempt to reproduce the observed spatial algae pattern in Lake Ewauna. Regardless of the parameter combinations used, the model predicted similar algae magnitudes and patterns at the Miller Island and Hwy 66 stations (due in large part to the rapid transport of algae in Lake Ewauna). It is believed that the summer hypoxia/anoxia in the lake influences the spatial variability of algae biomass in Lake Ewauna. Data show that sometimes during the summer, the entire Lake Ewauna water column becomes hypoxic (exhibiting very low DO concentrations), and even anoxic (exhibiting DO concentrations near zero). Figure 2-1 shows the observed DO data, along with chlorophyll *a*, at the Miller Island and Hwy 66 locations for 2000 (at approximately 1 meter from the surface). Algal mortality has been causally linked with low DO in UKL (National Research Council 2004) and found to be related to anoxic conditions in other systems (Baric et al. 2003). Available data show no other explanation for the observed phenomenon.

This space intentionally left blank

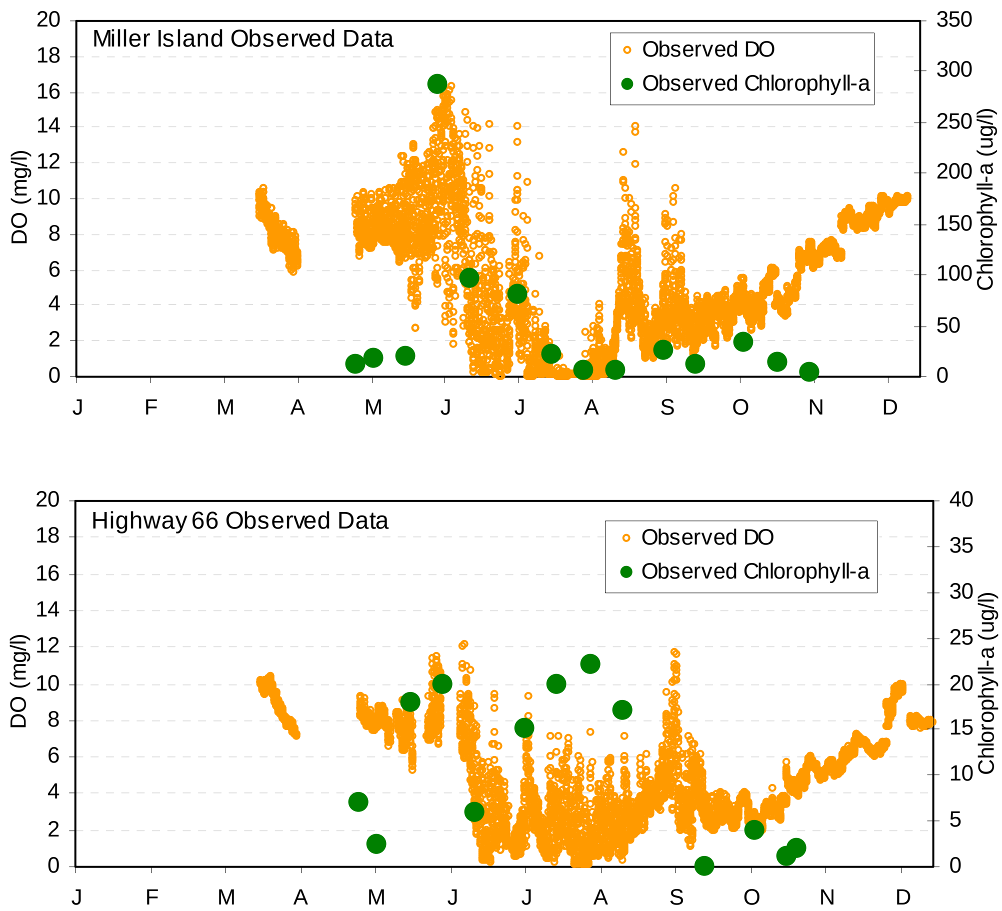

Figure 2-1. Observed DO and Algae at sites in Lake Ewauna (2000)

Algae need oxygen to respire. Thus, when oxygen levels become low or depleted, algae metabolism might be affected. Growth is likely to be slowed down, and death/excretion is likely to increase. In addition to directly affecting algae metabolism, the hypoxia/anoxic condition from top to bottom in the lake can result in excessive concentration of undesirable chemicals such as H2S in the water column, which is highly toxic to phytoplankton. Previous scientific investigations do not indicate whether DO or other undesirable chemicals directly cause the observed pattern, however the impacts of all these factors (since they are manifested under low DO conditions) can be mathematically represented through DO concentration alone. Therefore, DO-dependent algae kinetics representation was deemed the most appropriate approach for representing the phenomenon.

The major assumptions associated with the DO-dependent algae kinetics are the following:

- Low DO concentrations can restrict algae growth and enhance algae death due to either the directly effect on metabolism or indirect effect through chemical toxicity.
- The longer algae are exposed to hypoxia/anoxia or toxic water environment associated with these conditions, the more the algae mortality is enhanced.

Using these assumptions, a model capable of simulating the impact of hypoxic/anoxic conditions on algae dynamics not only needs to represent the dependence of algae on DO concentrations, but it needs to track the duration of exposure of algae to these conditions. For example, a cluster of algae in Link River (before entering hypoxic Lake Ewauna) is free of the effects of low DO concentrations. However, after this cluster enters Lake Ewauna, it is subjected to local hypoxic conditions (while being transported downstream). The effect of the hypoxic/anoxic conditions on the algae becomes more severe with distance downstream because the exposure time to these conditions increases. This exposure time is hereby referred to as *ET*, and it is not the same as the time that the DO is hypoxic/anoxic at a specific location, which is referred to as *THA*.

CE-QUAL-W2, like most numerical hydrodynamic and water quality models, is based on the Eulerian system that does not track the history of travel of particles. Therefore, it is very difficult to directly track the ET of a specific cluster of algae. The PacifiCorp Model was unable to reproduce the sharp algae decline from upstream to downstream in Lake Ewauna, in part because it was unable to consider exposure time. In this study, a two-state algae transformation approach was applied to the model as a surrogate for representing the effect of the ET. The approach involves defining two states of algae, where one state represents the *healthy* group which is free of the hypoxic/anoxic impact and the other state represents the *unhealthy* group (for which the physiological condition is severely disturbed because of hypoxia/anoxia). The healthy group is represented using typical algae growth and respiration rates; however, the unhealthy algae growth and respiration rates are very low or 0.0 (because of the hypoxic/anoxic condition's effect on the algae's physiology).

The ET is indirectly represented through conversion of healthy algae to unhealthy algae using a first-order transformation mechanism when the algae are in the presence of low-DO conditions. The longer the algae are exposed to hypoxia/anoxia, the higher the fraction of algae transformed into the unhealthy state becomes. Thus, the overall growth and respiration rate of the entire algae cluster is reduced because of the larger amount of unhealthy algae. In the following equations, *A* denotes the healthy group and *B* denotes the unhealthy group:

$$\frac{dC_A}{dt} = L_A - K_1 C_A + K_2 C_B \qquad (1)$$

$$\frac{dC_B}{dt} = L_B + K_1 C_A - K_2 C_B \qquad (2)$$

where

C_A = concentration of algae group A
C_B = concentration of algae group B
L_A = total sources and sinks including kinetics for algae group A as represented in the original model
L_B = total sources and sinks including kinetics for algae group B as represented in the original model
K_1 = transformation rate from algae group A to B
K_2 = recovering rate from algae group B to A

This space intentionally left blank

The effect of low DO on the kinetic parameters K_1 and K_2 is represented as:

$$K_1 = K_{1(0)} \frac{HDO_1}{HDO_1 + DO} \quad (3)$$

$$K_2 = K_{2(0)} \frac{DO}{HDO_2 + DO} \quad (4)$$

where

$K_{1(0)}$ = the base transformation rate from algae group A to B
$K_{2(0)}$ = the base recovering rate from algae group B to A
DO = the DO concentration in the water column
HDO_1 = the half saturation coefficient in mg oxygen /L for K_1
HDO_2 = the half saturation coefficient in mg oxygen/L for K_2

The mechanisms described in Equations (1) through (4) were incorporated into the CE-QUAL-CE-QUAL-W2 source code. The model was then run for Lake Ewauna, and the results indicated that the model was capable of explaining the observed algae patterns reasonably well. It should be noted that the assumptions, mathematical formulations, and code development for algae kinetics are based on general scientific knowledge of algae metabolism. It is recommended that further research be conducted to investigate the impact and response relationships among DO, water chemistry changes, and algae metabolism to better understand this complex phenomenon.

2.2.3 Monod-Type SOD and OM Decay

The PacifiCorp Model used the CE-QUAL-W2 code, which represents SOD and OM decay as a delta function. With the delta function, the SOD and OM decay are activated when DO is greater than a pre-specified value (generally close to zero), and deactivated when DO is lower than the value. This leads to abruptly turning SOD and OM decay on and off when DO is low or fluctuates around the pre-specified value. A Monod-type continuous SOD and OM decay formulation was thus incorporated into the CE-QUAL-W2 code to represent a smoother transition of SOD and OM decay effects when DO is low.

$$SOD = \frac{DO}{DO + HDO} SOD_s$$

$$Kd = \frac{DO}{DO + HDM} Kd_s$$

where

SOD = effective SOD (g O_2/m^2/day)
DO = DO concentration in the water column for Kd, or in the bottom water for SOD (milligrams per liter [mg/L])
HDO = half saturation DO concentration (mg/L)
SOD_s = SOD before being adjusted by the water column DO (g O_2/m^2/day)

Kd = effective OM decay rate (1/day)
HDM = half saturation DO concentration for OM decay rate adjustment (mg/L)
Kd_s = OM decay rate before DO adjustment (1/day)

2.2.4 pH Simulation Module in RMA

The standard RMA modeling framework does not have the capability of simulating interactions among nutrients, phytoplankton/benthic algae, and pH. Because pH is a key water quality target for Klamath TMDL development, the modeling framework was enhanced to dynamically simulate pH dynamics.

A pH simulation module was developed and incorporated into the RMA framework to simulate the pH in the river, considering the impact of boundary conditions, phytoplankton, periphyton, benthic sources, and atmospheric-water exchange. The state variables for the pH module include Total Inorganic Carbon (TIC) and Alkalinity (Alk). Their transport is simulated using the same algorithms used for transporting other dissolved constituents in RMA. While Alk is assumed to be conservative in the water column, TIC changes due to several physical (water-air interface exchange), chemical (OM decay and benthic sources), and biological (phytoplankton and benthic algae metabolism) factors. The mathematical equations for the pH module are based on those described in Chapter 39 of Chapra (1997), and are detailed in Appendix A.

2.2.5 OM-dependent Light Extinction Formulation in RMA

The existing RMA model does not have the capability of representing the effect of OM on light conditions. Thus, it can inaccurately predict periphyton or phytoplankton growth in the presence of OM. OM can reduce sunlight and limit aquatic vegetation growth. An OM-dependent light extinction formulation was developed using the same formulation in the CE-QUAL-W2 model and incorporated into the RMA code to provide a more realistic representation of the system:

$$Ke = Ke' + OM \times KEOM$$

where

Ke = effective light extinction coefficient
Ke' = light extinction coefficient before OM adjustment
OM = OM concentration
KEOM = light extinction coefficient adjustment factor related to OM concentration

2.2.6 Reaeration Formulation Modification

In the existing RMA-11 model, the flow velocity used for reaeration calculation was forced to be greater than or equal to 0.5 meters per second (m/s). This resulted in excessive reaeration when the flow velocity was actually slower (e.g., during low-flow conditions). A modification was made to this formulation to set the lower bound of the velocity to 0.03 m/s based on Chapra (1997). This modification results in more reasonable DO predictions under low flow, critical conditions.

A scaling factor was also introduced into the RMA-11 model to enhance reaeration just downstream of Iron Gate Dam. At this location, the observed summer DO concentration is much higher than what can be predicted by RMA-11 using the available empirical formulas. In the model, the DO concentration of water exiting Iron Gate Reservoir during the summer is low due to vertical stratification in the reservoir (and thus low DO concentrations at depths from which water is drawn). Significant reaeration is necessary over a very short distance to increase the low DO concentrations to the significantly higher observed concentrations. The RMA-11 formulas, however, are unable to replicate this phenomenon, which is caused by the presence of significant turbulence downstream of Iron Gate Dam. To account for this observed phenomenon, a scaling factor (or multiplier) was introduced into the RMA-11 model. After multiple iterations during model testing, a value of 100.0 was selected. Application of this scaling factor results in a significantly higher coefficient than what is typically used with the RMA-11 formulas, however, it is necessary (and justifiable) to simulate the observed DO concentrations.

2.2.7 Dynamic OM Partitioning

Key updates were made to the original PacifiCorp Model to transfer model results between segments represented using CE-QUAL-W2 and those represented using RMA. Originally, the upstream boundary conditions for a CE-QUAL-W2 reservoir model were based on model results from the upstream riverine RMA model. In RMA all the OM is represented as a lumped parameter, while in W2 they are partitioned into four different components: LPOM, RPOM, LDOM, and RDOM. Therefore, when transferring the RMA OM results to W2, the OM output must be partitioned into the four components for W2. In the existing PacifiCorp Model, a static partitioning ratio of 0.8:0.2 was used to partition the OM into LPOM and LDOM, respectively. This static conversion factor does not account for the change in OM composition that occurs throughout the system. Therefore, a dynamic OM partitioning scheme was implemented that calculates and tracks the time-variable partitioning ratio in the reservoir models and applies the ratios to downstream segments. Using this approach, different ratios are implemented for J.C. Boyle and Copco reservoirs. For J.C. Boyle Reservoir, the OM in the upstream river flow is partitioned in such a way that, on average, LDOM accounts for 62 percent, LPOM 36 percent, RDOM 1 percent, and RPOM 1 percent. For Copco Reservoir, the corresponding values are: 67 percent, 30 percent, 2 percent, and 1 percent. These values demonstrate that the fraction of dissolved OM increases with downstream distance, while the fraction of particulate OM decreases (because of the effect of settling). The percentages noted above are not fixed for all simulations.

2.2.8 Periphyton Carrying Capacity

In the RMA-11 model code used in the PacifiCorp Model, the carrying capacity of periphyton biomass was implemented such that when the simulated periphyton biomass exceeds a prescribed maximum value, the simulated biomass is set to that value. This method of handling the periphyton carrying capacity results in unbalanced nutrient representation in the system. When the simulated biomass exceeds the prescribed maximum value, additional nutrients are not utilized by the periphyton biomass (as they would be should no maximum be set). The PacifiCorp Model predicts that the periphyton biomass remains constant for an extended period of time during the summer. Not only is this unrealistic, but it is equivalent to artificially removing nutrients from the system.

A more reasonable way of reflecting the growth limitation when the simulated periphyton approaches the carrying capacity is to relate the growth rate to the biomass itself. Thus growth is depressed when biomass is high, but it has no impact when biomass is low. The formula is:

$G_e = Gx(1 - C/Cmax)$

where

G_e = effective growth rate of periphyton (day^{-1})
G = growth rate before adjusting for carrying capacity (self-limiting) effects
C = periphyton biomass (g/m^2)
C_{max} = periphyton carrying capacity (g/m^2)

When the periphyton biomass increases, the corresponding effective growth rate decreases. When the biomass reaches the carrying capacity, the effective growth rate becomes 0.0. Since nutrient uptake is coupled with periphyton growth in water quality models, formulating the effect of carrying capacity in this manner guarantees a balanced nutrient budget in the system.

2.2.9 Additional Shading in RMA

Temperature simulated by the PacifiCorp Model for the Bypass/Full Flow Reach downstream of J.C. Boyle Reservoir was significantly higher than the observed data. Therefore, during the model testing process one of the most influential factors, the representation of solar radiation, was explored. RMA-11 uses empirical equations to internally calculate solar radiation for the thermal and bio-chemical simulations. These equations are based on longitude, altitude, sunrise and sunset time, and cloud condition. To evaluate whether or not RMA-11 was appropriately estimating solar radiation in this area, the RMA-11-estimated solar radiation was compared to the solar radiation data used in the Copco Reservoir CE-QUAL-W2 model. It was found that the solar radiation estimated using RMA-11 is approximately 20% higher than that used in the Copco Reservoir CE-QUAL-W2 model. This apparent over-estimation of solar radiation likely caused the overprediction of temperature noted above. To account for this discrepancy and to reduce the solar radiation calculated by RMA-11, additional shading was configured in the model. A value of 20% was selected based on the comparison made. To maintain consistency among all the RMA-11 models used for the Klamath River, this 20% additional shading was applied to all RMA-11 models. No changes were necessary for the CE-QUAL-W2 or EFDC models since solar radiation is handled differently for those models and because temperature predictions were not uniformly over- or under-estimated.

2.2.10 Second Order Polynomial Spillway Representation

To support TMDL development, The Klamath River model will not only be used to represent the current condition, but it will be used to represent conditions prior to the creation of Keno Dam. Based on information provided by the U.S. Bureau of Reclamation (USBR), a version of the CE-QUAL-W2 model for Lake Ewauna-Keno Dam was developed to represent the historical presence of Keno Reef (McGlashan and Dean 1913). The approach taken to represent the reef required modification of the CE-QUAL-W2 model code. Specifically, Keno Reef was represented in the model using a second-order spillway equation derived by USBR from historical data. The formulation of the spillway equation is:

This space intentionally left blank

$$Q=101.265(H-1244.5)^2-15.030(H-1244.5)+12.35$$

where

Q = flow rate over Keno Reef (cms)
H = water surface elevation (m)
1244.5 = the Keno Reef datum (m).

2.3 Model Configuration

Model configuration involved setting up the model computational grid (bathymetry) using available geometric data, designating the model's state variables, setting boundary conditions, and setting initial conditions. This section describes briefly the configuration process and key components of the model in greater detail.

2.3.1 Segmentation/Computational Grid Setup

The computational grid setup defines the process of segmenting the entire Klamath River into smaller computational segments for application of the model. In general, bathymetry is the most critical component in developing the grid for the system.

The Klamath River model includes the entire Klamath River from Link Dam (at the outlet of the UKL) to the Pacific Ocean. The river is impounded by five dams along its length: Keno, J.C. Boyle, Copco, Copco 2, and Iron Gate Dam. For this modeling study, the Klamath River was divided into nine waterbodies (or Model Segments). Figures 2-2 and 2-3 show each of the waterbodies from upstream to downstream. Note that distances for each waterbody are approximate. Appendix B presents an excerpt (verbatim) from *Klamath River Water Quality Model Implementation, Calibration, and Validation* (PacifiCorp 2005) that summarizes geometric information for all waterbodies. Each of these waterbodies was represented using unique geometric and hydrological characteristics in the model and is detailed in subsequent sections.

This space intentionally left blank

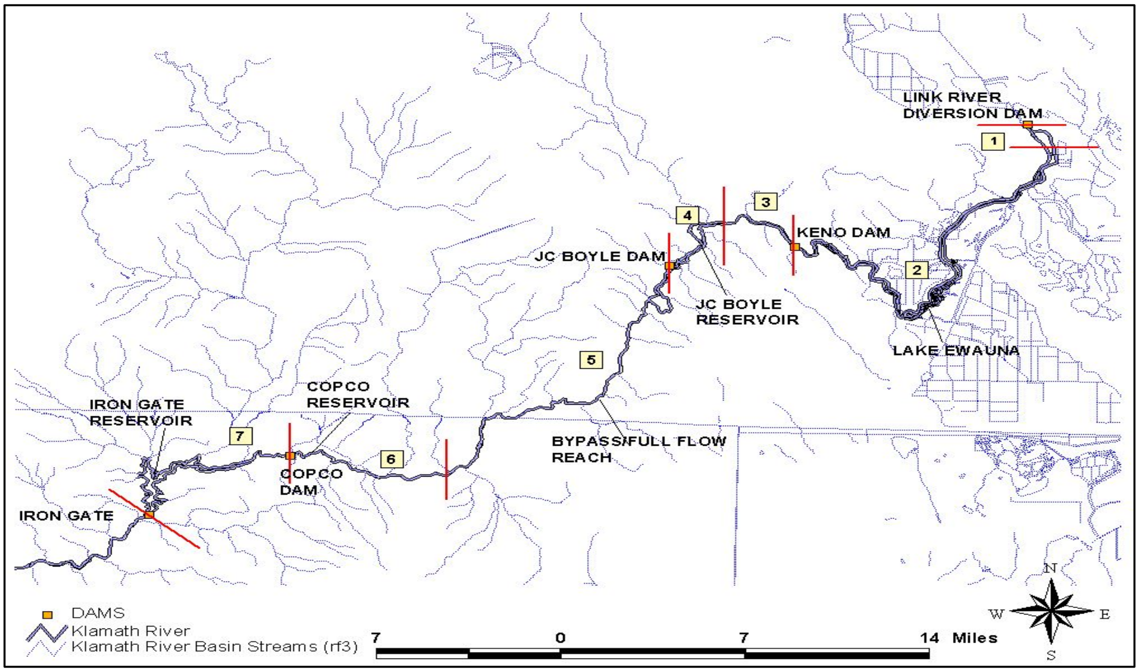

Figure 2-2. Location of waterbodies 1 through 7 along the Klamath River

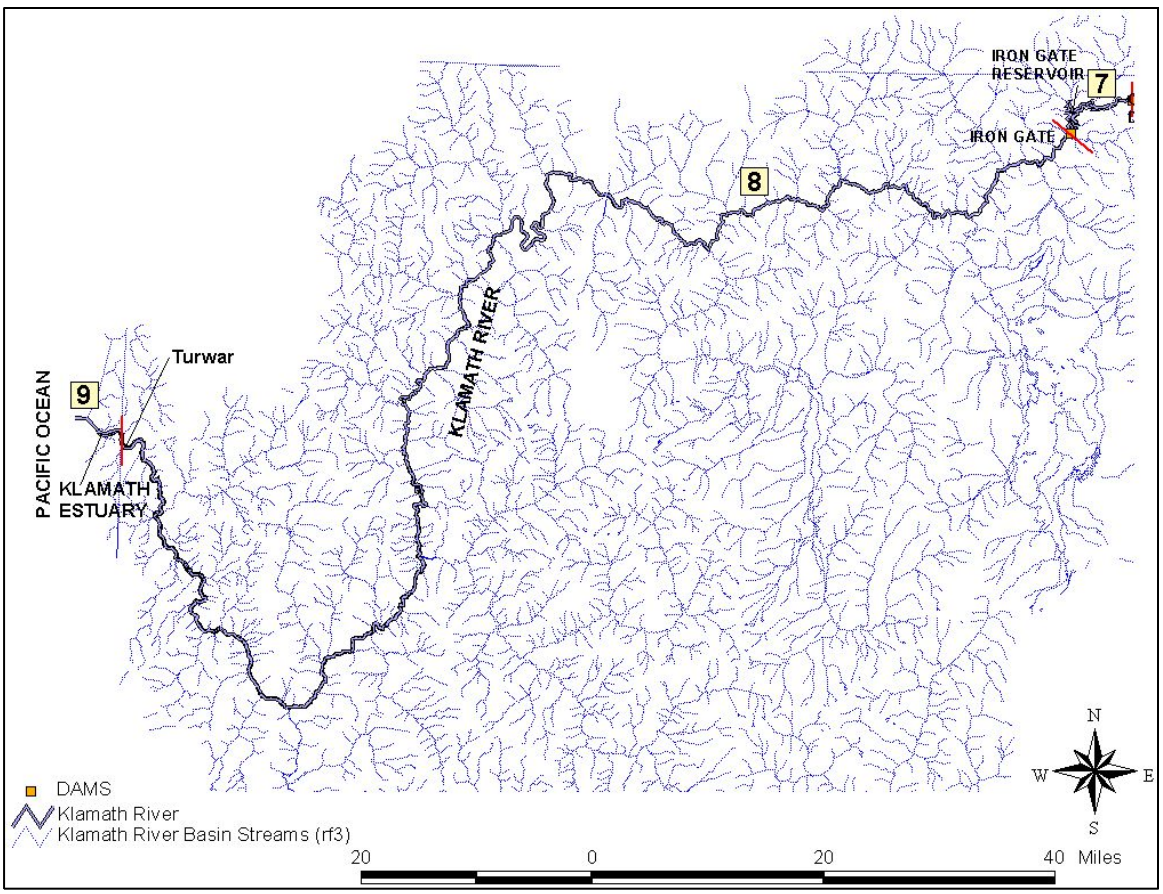

Figure 2-3. Location of waterbodies 7 through 9 along the Klamath River

2.3.1.1 Segmentation of River and Reservoir Segments

Within each of these separate Model Segments (excluding the Klamath Estuary) the primary waterbody (either a Klamath River section or a reservoir) was subdivided into higher resolution elements for greater detail in modeling. The TMDL modeling framework components were segmented similarly to the existing PacifiCorp Model. For the reservoir/lake models in the existing PacifiCorp Model (Lake Ewauna, J.C. Boyle Reservoir, Copco Reservoir, and Iron Gate Reservoir), the corresponding CE-QUAL-W2 models have layer thicknesses (depths) ranging from 0.61 to 1.0 meters and segment lengths ranging from 37 to 714 meters. For the riverine reaches (Link River, Keno reach, Bypass/Full Flow Reach downstream of J.C. Boyle Reservoir, and Klamath River from Iron Gate Dam to Turwar), the corresponding finite element model RMA has node distances ranging from 75 to approximately 300 meters (and are assumed to be homogeneous in the vertical direction). For greater detail on model segmentation in the river and reservoir segments of the Klamath River model, see Section 2.3 of the *PacifiCorp Report.*

Only the mainstem Klamath River and its reservoirs were simulated with the Klamath River model. All tributaries to the river were represented as boundary conditions (i.e., they were not explicitly modeled). More detailed information regarding the specific tributaries to be included or inflows to the model are included in Section 2.3.3 of this report.

2.3.1.2 Segmentation of the Klamath Estuary Segment

The tidal portion of the Klamath River from Turwar to the Pacific Ocean, which was not included in the existing PacifiCorp Model, was modeled using EFDC. The first step to configure EFDC was to discretize the waterbody into a computational grid. A boundary-fit curvilinear grid was developed to accurately represent the shape of the river. Significant hydraulic features (channels, shorelines, and major bathymetric variability) and their locations were considered in preparation of the grid. The grid consists of 138 curvilinear grid cells, with widths ranging from 99 to 209 meters and lengths from 192 to 1590 meters. Within the modeling domain, each cell is represented by four vertical layer(s), therefore a 3-D spatial representation represents the estuary portion.

The open boundary at the downstream end of the estuary was extended into the Pacific Ocean to reduce the effect of boundary reflection. This would likely occur if the open boundary was set directly at the opening of the sand bar. Appendix C presents the computational grid for the Klamath Estuary EFDC model. The bold red line in Appendix C represents the impermeable barriers added to the EFDC grid. The barriers allow for the water to flow through the outlet, as seen in the 2004 bathymetry data. These barriers may be reconfigured in the future, if needed, to simulate the sandbar opening at a different location. It should be noted that this grid was developed and refined through an iterative process wherein model resolution, accuracy, and simulation time were optimized. The number of layers was determined by configuring a model with eight vertical layers in addition to the version with four vertical layers and comparing predictions. The comparison indicated that refining the vertical resolution beyond four vertical layers would not lead to significantly improved model predictions with regard to vertical variability in salinity and water quality. The four layer representation reduced computational time without compromising model accuracy.

Bathymetry data for the Klamath Estuary were obtained from the NCRWQCB and represent bathymetric conditions in the year 2004. These data contain xyz format coordinate elevation data relative to North American Datum of 1988 (NAVD88) and were directly incorporated into the grid generation process. Bathymetry data were available from the outlet of the Klamath at the

Pacific Ocean upstream to the Rt. 101 Bridge (Hwy 101 @ Klamath). No bathymetry data were available from the Rt. 101 Bridge upstream to the USGS Klamath River near Klamath station (USGS 11530500) (a distance of approximately 3,300 meters). To address this data gap, a constant bed slope similar to the upstream portion of the bathymetry data (where the bathymetry was measured) was assumed. This slope was refined until tidal impacts were properly represented (i.e., no tidal effect was observed at Turwar).

River bank boundaries for the grid were defined using digital orthophotography obtained from the California Spatial Information Library (CaSIL) (http://gis.ca.gov/). Orthophotography was used instead of USGS quadrangle images due to the age of the USGS quadrangles. For example, the Requa, CA USGS quadrangle was last revised in 1966, while Requa orthophotography represents conditions in 1998. The images were georeferenced to a Universal Transverse Mercator (UTM) Zone 10 projection, using a NAD 1927 horizontal datum. This coordinate system was then used to develop the horizontal dimensions of the grid and calculate the dimensions of the computational cells.

2.3.2 State Variables

Selection of appropriate model state variables to represent water quality processes of concern is a critical factor in model configuration. For this study, state variables were selected to most accurately predict TMDL impairments and related physical, chemical, and biological processes. State variables varied for each model type in the Klamath River model (RMA, CE-QUAL-W2, and EFDC). Note that pH is not a state variable. It is computed from alkalinity and TIC. Alkalinity and TIC are transported by the model and are thus state variables. In addition, TDS was inherited from the PacifiCorp model. No effort was made to remove it since it has no impact on the water quality simulation. The following state variables were configured for the riverine segments of the Klamath River model (for the RMA portions of the model):

1. Arbitrary Constituent (configured as a tracer to evaluate the mass balance)
2. DO
3. Organic matter (OM)
4. Orthophosphorus (PO_4)
5. Ammonium (NH_4)
6. Nitrite (NO_2)
7. Nitrate (NO_3)
8. Phytoplankton
9. Temperature
10. Periphyton
11. Total inorganic carbon (TIC)
12. Alkalinity (Alk)

The reservoir segments of the Klamath River, where the CE-QUAL-W2 model was applied, were configured using the following active state variables:

1. Labile dissolved organic matter (LDOM)
2. Refractory dissolved organic matter (RDOM)
3. Labile particulate organic matter (LPOM)
4. Refractory particulate organic matter (RPOM)
5. Inorganic Suspended Solids (ISS)
6. PO_4
7. NH_4

8. NO_2/NO_3
9. DO
10. Phytoplankton
11. Alk
12. TIC
13. Temperature
14. Tracer
15. TDS
16. Age (to track detention time at different locations)
17. Coliform bacteria

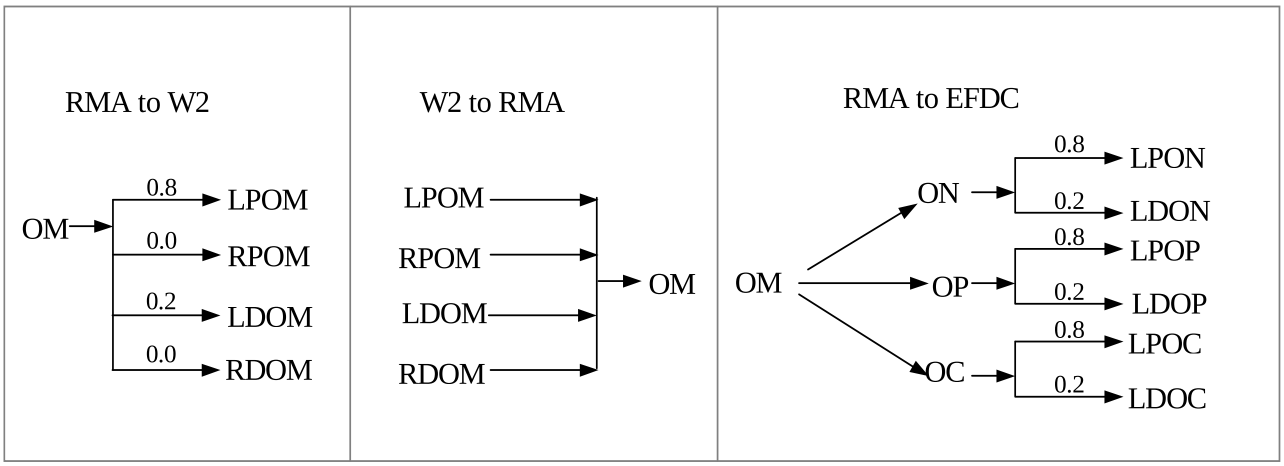
The estuarine portion of the Klamath River, which was modeled using EFDC, was configured with the following constituents as state variables:

1. Phytoplankton
2. Labile particulate organic carbon (LPOC)
3. Labile dissolved organic carbon (LDOC)
4. Labile particulate organic phosphorous (LPOP)
5. Labile dissolved organic phosphorous (LDOP)
6. PO_4
7. Labile particulate organic nitrogen (LPON)
8. Labile dissolved organic nitrogen (LDON)
9. NH_4
10. NO_2/NO_3
11. DO
12. Temperature
13. Salinity
14. Periphyton

The RMA model considers a single, lumped OM constituent while the CE-QUAL-W2 model contains four compartments (LDOM, RDOM, LPOM, and RPOM). Because available data are insufficient to accurately partition between labile and refractory components and because RMA only considers lumped OM, all the OM boundary conditions configured for the reservoir models were partitioned between only dissolved and particulate components. Further partitioning between labile and refractory components was not implemented. It's important to note that the state variable slots in the CE-QUAL-W2 models for labile OM (i.e., LDOM and LPOM) were used to represent the all dissolved OM and particulate OM, respectively. Therefore, even though the terms "LDOM" and "LPOM" are used when referring to model results, the values essentially represent all OM, without differentiating between labile and refractory components. Because average values are used in the model to represent characteristics such as decay rate, the model can be considered to inherently include some amount of both fast- and slow-decaying OM material (i.e., some amount of labile and refractory material). The model was configured such that a small amount of true refractory OM can be generated through algal metabolism, however, this amount is typically negligible. For the EFDC model of the estuary, the organic nutrients were not partitioned between labile and refractory components either. Rather ,they were lumped together and represented using the labile state variable slots.

The schematic below (Figure 2-4) shows the flow of OM to and from each of the models. The 0.8:0.2 ratio for partitioning OM was used in the existing PacifiCorp Model and was based on the CE-QUAL-W2 algae partition coefficient (APOM = 0.8). The RMA to W2 conversion shown in Figure 2-4 does not apply to the upstream boundary conditions for J.C. Boyle and Copco reservoirs, because dynamic OM partitioning was implemented (as previously discussed). For Link River, where no upstream dynamic reservoir model was available, the static partitioning shown in Figure 2-4 was implemented.

For model calibration, the EFDC upstream boundary condition was derived using 2004 monitoring data. Therefore, no OM conversion from the upstream RMA model was necessary. When modeling scenarios were run (which are not addressed in this report), the upstream RMA model representing Irongate to Turwar was linked to the estuary EFDC model. For this case, OM from the RMA model was converted into organic nitrogen (ON), organic phosphorous (OP), and organic carbon (OC) components for the EFDC model. This conversion is based on the stoichiometric ratio used in the upstream W2 and RMA models, where OM multipliers are the following: ON = 0.07, OP = 0.0055, and OC = 0.45 (Cole and Wells 2003). To further partition the ON, OP, and OC into particulate/dissolved components, the ratios presented in Figure 2-4 were used.



Note: The RMA to W2 conversion shown above does not apply to the upstream boundary conditions for J.C. Boyle and Copco reservoirs, where dynamic OM partitioning was applied. The RMA to EFDC representation does not reflect calibration conditions, rather it summarizes transfer used during scenario analysis.

Figure 2-4. Schematic showing the transfer of OM between models

2.3.3 Boundary Conditions

To run the Klamath River model, external forcing factors known as boundary conditions must be specified for the system. These forcing factors are a critical component in the modeling process and have direct implications on the quality of the model's predictions. External forcing factors include a wide range of dynamic information:

- Upstream Inflow Boundary Conditions: Upstream external inflows, temperature, and constituent boundary conditions
- Tributary (or Lateral) Inflow Boundary Conditions: Tributary inflows, temperature, and constituent boundary conditions
- Withdrawal Boundary Conditions
- Surface Boundary Conditions: Atmospheric conditions (including wind, air temperature, solar radiation)

Upstream external inflows essentially represent the inflow at the model's *starting* point. Tributary inflows represent the major tributaries that feed into the Klamath River. All water removed from the system is combined within the withdrawals category.

The surface boundary conditions are determined by the meteorological or atmospheric conditions and include air temperature, dew point temperature, wind speed, wind direction, and cloud cover. The meteorological file from the original PacifiCorp Model was maintained since it was based on real data and was intensively reviewed. Data obtained from station KFLO near Klamath Falls were used to represent the conditions from Link Dam to J.C. Boyle Dam. Data from Brazie Ranch represent the boundary conditions from J.C. Boyle Dam to Seiad Valley. For the reach from Seiad Valley to Turwar, the weather data from Hoopa and Somes Bar were used to represent the meteorological boundary conditions. Data from the Arcata Eureka Airport were applied to the estuarine portion of the Klamath River (Turwar to the Pacific Ocean), as described later in Section 2.3.3.9.

The following subsections provide a detailed description of the boundary conditions used to represent each modeled segment. The descriptions begin upstream at the Link River segment and continue downstream to the Klamath Estuary segment. In the existing PacifiCorp Model, boundary conditions were set as time series at each location on the basis of observed data or other assumptions where data were not available. For periods when no data were available, the model internally estimates the boundary on the basis of linearly interpolating the time series provided in the boundary condition files. In some situations, boundary conditions were updated using more recently acquired monitoring data. Both types of modification are further described in this section.

The upper and middle segments of the model (Model Segments 1 through 8) were tested (calibrated) using data from the year 2000. In addition, the calibration of the upper segments (Model Segments 1 through 5) was further corroborated (validated) with observed data for 2002. The estuarine portion (Model Segment 9), which was modeled with EFDC, was calibrated using data from the year 2004. As described in Section 3.0, these periods were selected because of data availability. In subsequent discussions, boundary condition descriptions are first described for the year 2000. Any deviations from the year 2000 representation for the year 2002 are then noted.

2.3.3.1 Model Segment 1: Link River

The Link River segment begins at the outlet of UKL (Link Dam) and ends at Lake Ewauna. Four types of boundary conditions were included in this model segment: upstream inflow boundary conditions, tributary boundary conditions, downstream stage-discharge boundary conditions, and surface boundary conditions (discussed above).

<u>Upstream Inflow Boundary Conditions:</u> The inflow to Link River is from UKL through releases from Link Dam. Since there were no observed data available at the head of Link River for 2000, observed water quality data at Pelican Marina (in UKL) were used as the basis for upstream boundary conditions. This representation is different than that in the existing PacifiCorp Model which used multiple year composite data for Link River at Fremont Bridge as the basis of boundary condition. Considering the significant inter-year variability in water quality in UKL, it is preferable to use data collected during the modeling year rather than other years to represent the external forces at boundaries. Monitoring data for NH_4, NO_2/NO_3, phytoplankton, DO, and temperature were directly applied to the boundary conditions using a linear interpolation method

to obtain daily values for dates without data. OM boundary conditions were derived using observed total phosphorus (TP), dissolved PO_4, and chlorophyll *a* data and following these steps:

Step 1: derive algal P as: $OP_{alg} = Chla \times CCHA / AGP$
Step 2: derive non-algal P as: $OP_{non\text{-}alg} = TP$ – dissolved $PO_4 - OP_{alg}$
Step 3: derive OM as: $OM = OP_{non\text{-}alg} \times OMP$

where

Chla = observed chlorophyll *a* concentration (µg/L)
CCHA = 0.067 (mg-algae per µg-chlorophyll *a*); derivation: Algae = Chla × 67 × (1 mg/1000 ug), where 67 represents the Algae:Chla ratio defined as 30/0.45 (on the basis of the WASP model default ratio of 30 for Algae-C:Chla and the CE-QUAL-W2 model default ratio of 0.45 for Algae-C:Algae)
AGP = algal P content coefficient (mg-algae / mg-P)
OMP = organic matter P content coefficient (mg-OM / mg-P)

OMP was determined to be 180.0 based on 2002 data for Link River at Fremont Bridge (where the average organic carbon:organic phosphorus ratio is 81, and thus the OM:OP ratio is 81 / 0.45 = 180.0). AGP was assumed to be the same as OMP because phytoplankton is the major source of OM in UKL. BOD was not configured for the model because all OM are represented using a single state variable (as previously noted).

Initially, the total PO_4 boundary condition was represented using the dissolved PO_4 monitoring data at Pelican Marina. It was found, however, that setting the PO_4 boundary concentration at Link River to the observed dissolved PO_4 value resulted in a significant underprediction of PO_4 concentration at Miller Island, in Lake Ewauna. Because Link River flow is dominant in upper Lake Ewauna, the PO_4 concentration at Miller Island should be similar in magnitude and pattern to that at the head of Link River. Several model sensitivity analyses confirmed this. The difference between the dissolved PO_4 data at Pelican Marina and the PO_4 data at Miller Island suggests that the dissolved PO_4 at Pelican Marina is likely not a good representation of conditions at the head of Link River. Therefore, the observed PO_4 data at Miller Island were used as the basis for configuring the PO_4 boundary condition at Link Dam.

The alkalinity boundary condition was configured on the basis of alkalinity monitoring data at Link River and Miller Island. In 2000 there was a limited amount of alkalinity data at Link River (on seven discrete dates). These data were insufficient to accurately predict alkalinity concentrations at Miller Island. Therefore, Miller Island data were used to supplement the Link River data in constructing the boundary condition. The first step in doing this was to compare the flow from Link River and the Lost River Diversion Channel to determine the period during which Link River flow was dominant. For this period the alkalinity at Miller Island would be similar in magnitude to that at Link River. Therefore, data at Miller Island were incorporated into the Link River data to form an expanded data set. The upstream boundary condition for alkalinity was then configured using this expanded data set. There were no data available for TIC; therefore, the TIC boundary condition was obtained through the pH calibration process for Miller Island. Initially, TIC at the Link River boundary was derived on the basis of pH at Miller Island and alkalinity at Link River. These estimates were refined to achieve a better calibration of pH at Miller Island in Lake Ewauna.

The upstream boundary condition for the 2002 model was derived using a method similar to that used for 2000. Available data at both the head of Link River (Fremont Bridge) and at Pelican

Marina were combined to form a composite data set for 2002 boundary condition derivation. Monitoring data for PO_4, NH_4, NO_2/NO_3, phytoplankton, DO, and temperature were directly applied to the boundary conditions using a linear interpolation method to obtain daily values for dates without data. The OM boundary condition was derived using the same approach used for the 2000 model. The alkalinity boundary condition was derived on the basis of monitoring data at Fremont Bridge. And the TIC boundary condition was derived on the basis of alkalinity data and pH data at the same location.

Tributary Boundary Conditions: There are two diversions from UKL at Link Dam. These diversions are two powerhouses that discharge water from UKL into the Link River segment (East Side and West Side). USGS gage 11507500 (Link River at Klamath Falls, Oregon) is between the powerhouse discharges.

The constituent concentrations for the tributary boundary conditions were set to be the same as the upstream boundary conditions because the powerhouses have the same water source as the upstream boundary (UKL).

Downstream Boundary Conditions: Downstream boundary conditions were configured using a stage-discharge relationship. Although this type of boundary condition does not allow for representation of the backflow condition that occasionally occur at the mouth of Link River, it is a better predictive tool than using the Lake Ewauna elevation as the downstream boundary condition. The backflow condition does not have a significant impact on the loading rate from Link River to Lake Ewauna, thus, it does not significantly impact the water quality in the lake.

2.3.3.2 Model Segment 2: Lake Ewauna to Keno Dam

This segment extends from the point where Link River enters Lake Ewauna to the outlet at Keno Dam. Five types of boundary conditions were included in the Klamath River model for the Lake Ewauna segment. They are upstream inflow boundary conditions, tributary boundary conditions, withdrawal boundary conditions, downstream outflow boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: The upstream boundary condition was defined as the water flowing into Lake Ewauna from Link River (Model Segment 1). Link River’s flow was determined by using the observed flows at USGS flow gage 11507500 plus the flow from the PacifiCorp West Turbine (powerhouse) gage, which is downstream of the USGS gage.

The upstream boundary conditions for water quality constituent concentrations were based on the model results in the downstream region of the Link River Model Segment. PO_4, NH_4, NO_2/NO_3, DO, phytoplankton, Alk, TIC, and temperature were directly transferred from the RMA-11 model (from Link River) to the CE-QUAL-W2 input data file for Lake Ewauna. Output for OM from Link River was applied to the Lake Ewauna segment and partitioned into four components: LDOM, RDOM, LPOM, and RPOM with partition ratios as 0.2, 0.0, 0.8, and 0.0, respectively. These ratios were based on the CE-QUAL-W2 ALPOM value and the decision not to further partition OM between labile and refractory components. These assumptions were justified because the majority of the organic matter from UKL are likely generated by phytoplankton blooms and metabolism. Therefore, the CE-QUAL-W2 ALPOM value can be used to represent partitioning. In reality significant spatial and temporal variability associated with organic matter composition may exist, however insufficient data are available to more accurately represent the organic matter boundary conditions. In addition, CE-QUAL-W2 isn't capable of representing seasonal variability of OM composition for the boundary conditions.

Tributary Boundary Conditions: There are 18 definable tributary discharges in the Lake Ewauna to Keno Dam river segment. These discharges include 11 stormwater locations, Columbia Plywood discharge, Klamath Falls Wastewater Treatment Plant, South Suburban Sanitation District, two discharges at Collins Forest Products, Lost River Diversion Channel, and Klamath Straits Drain (KSD).

The inflow from the stormwater locations was calculated as an average percentage of total stormwater runoff. The flow from Columbia Plywood was calculated from the discharger's monthly monitoring reports as an average of 0.01 cubic feet per second (cfs). Variable daily flows were used for the Klamath Falls Wastewater Treatment Plant and ranged from approximately 4 to 12 cfs. Variable daily flows were also used for South Suburban Sanitation District and generally ranged from 1 to 4 cfs. The two discharges at Collins Forest Products had average daily flows of approximately 1.4 cfs and 0.1 cfs. Daily flows from Lost River Diversion Channel and KSD into Lake Ewauna were obtained from USBR's flow gages at these locations.

The water quality constituent concentrations of the tributary boundary conditions were set to be the same as in the previous PacifiCorp Model except for the major tributaries and point sources, including KSD, Klamath Falls Wastewater Treatment Plant, and South Suburban Sanitation District. For these major tributaries and point sources, available data for 2000 and 2002 were used to update the boundary conditions. The details of updating these boundary conditions are summarized as follows:

a) KSD

The concentration boundary condition at KSD was represented using data at station Pump F in the KSD. The formulas used to convert observed data to model boundary conditions are listed below. For each constituent notation, the one on the left-hand side corresponds to the model boundary condition, while the one on the right-hand side corresponds to observed data. For parameters not listed, observed values were used directly.

- Algae [mg/L] = Chlorophyll *a* [µg/L] × 0.067, where 0.067 was derived similarly to CCHA for the UKL boundary condition (previously described)
- LDOM [mg/L] = (TP [mg/L] – PO_4 [mg/L]) × 180.0 × 0.7, where 180.0 was derived similarly to OMP for the UKL boundary condition (previously described), and 0.7 was derived on the basis of 2002 data at KSD (Dissolved TP / TP)
- RDOM [mg/L] = 0.0
- LPOM [mg/L] = (TP – PO_4) × 180.0 × 0.3, where the ratio 0.3 was derived from (1.0–0.7, where 0.7 represents LDOM).
- RPOM [mg/L] = 0.0
- ISS [mg/L] = TSS [mg/L]
- TIC [mg/L] = *f*(Alk, temperature, pH), where *f* represents the functional form relating TIC to Alkalinity [mg/L], temperature [^oC], and pH. Detailed equations can be found in Chapra 1997.

This space intentionally left blank

b) Klamath Falls Wastewater Treatment Plant and South Suburban Sanitation District

The water quality constituent concentrations for both the Klamath Falls Wastewater Treatment Plant and South Suburban Sanitation District were set to be the same as in the previous PacifiCorp Model, except for where more recent facility discharge monitoring report data were available. The formulas used to derive the boundary conditions based on data are as follows:

- BODu [mg/L] = BOD5 [mg/L] × 3.386, where the ratio 3.386 is based on the assumption that the treatment plants provide secondary treatment, thus the BOD has a decay rate around 0.07/day (Chapra, 1997)
- LDOM [mg/L] = BODu / 1.4 × 0.2, where the ratio 1.4 is based on the W2 stoichiometric ratio, and 0.2 is the same as that used for the UKL boundary condition
- LPOM [mg/L] = BODu / 1.4 × 0.8, where the ratio 1.4 is based on the W2 stoichiometric ratio, and 0.8 is the same as that used for the UKL boundary condition
- OM [mg/L] = LPOM + LDOM, which is based on the conservative assumption that all OM are labile for boundary inputs
- ISS [mg/L] = TSS [mg/L]
- PO_4 [mg/L] = TP [mg/L] – BODu / 1.4 / 180.0
- Org-P [mg/L] = OM × 0.0055, where the coefficient 0.0055 is the stoichiometric ratio used in the model
- TP [mg/L] = Org-P + PO_4
- Org-N [mg/L] = OM × 0.07 where the coefficient 0.07 is the stoichiometric ratio used in the model
- TN [mg/L] = Org-N + NH4 [mg/L] + NO2/NO3 [mg/L]

The 2000 boundary conditions for LDOM, LPOM, and DO at the Klamath Falls Wastewater Treatment Plant were updated using data from 2000. No data were available for ISS, PO_4, or NH4 for 2000, therefore data from 2002 were used for the 2000 model. For the 2002 model, LDOM, LPOM, DO, ISS, PO_4 and NH4 were all based on the 2002 data.

The 2000 and 2002 boundary conditions for LDOM, LPOM, DO, ISS, PO_4, and NH4 at South Suburban Sanitation District were configured based on data available for the corresponding year. For dates when PO_4 data were not available and thus could not be directly applied, PO_4 was derived based on the TP and BOD data using the formulas listed above.

<u>Withdrawal Boundary Conditions:</u> Three withdrawals in this segment are explicitly represented, including the Lost River, North Canal, and ADY Canal. Daily flows at all three of these withdrawals are gaged by USBR.

There is a lack of available daily withdrawal rates for a few non-USBR irrigation diversions, therefore they are not explicitly represented. Water diversion is grossly represented in the distributed flow, which was derived through a flow balance analysis.

The hourly flow rate at Keno Dam was available from USGS gage 11509500 (Klamath River near Keno, Oregon). The flows ranged from less than 500 cfs to more than 4,000 cfs. All these boundary conditions were kept the same as in the previous PacifiCorp Model.

<u>Downstream Outflow Boundary Conditions:</u> For Lake Ewauna, the downstream boundary condition was set as the outflow at the point before entering Keno Reach (Keno Dam to J.C.

Boyle Reservoir). The downstream boundary condition was set to be outflow; therefore, no water quality concentration boundary condition was needed.

2.3.3.3 Model Segment 3: Keno Dam to J.C. Boyle Reservoir (Keno Reach)

There were three types of boundary conditions included in this section of the model: upstream inflow boundary conditions, downstream outflow boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: The upstream inflow to this reach for the 2000 and 2002 models is based on the outflow from Lake Ewauna for the corresponding year. This segment was dominated by upstream water quality, therefore the simulated loading time series for phytoplankton, temperature, PO_4, NH_4, NO_2/NO_3, DO, TIC, and Alk from the Lake Ewauna to Keno Dam segment were applied. The four OM constituents predicted by the CE-QUAL-W2 model were combined into one OM constituent and applied to the boundary conditions (as previously discussed).

Downstream Outflow Boundary Conditions: Hydrodynamic downstream boundary condition was set as a stage-discharge relationship, which represents the downstream flow as only outflow; therefore, no concentration boundary condition was needed.

2.3.3.4 Model Segment 4: J.C. Boyle Reservoir

The J.C. Boyle Reservoir extends from the J.C. Boyle headwaters (Keno Reach to J.C Boyle Reservoir) to the J.C. Boyle Dam. There were four types of boundary conditions included in this portion of the model. They are upstream inflow boundary conditions, tributary boundary conditions, downstream outflow boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: Klamath River inflow for the 2000 and 2002 models to J.C. Boyle dam is represented by discharge from the Keno Reach during the corresponding year. The upstream boundary conditions for water quality constituents were based on the model results at the downstream node of the Keno Reach portion of the model for the corresponding year. PO_4, NH_4, NO_2/NO_3, DO, phytoplankton, temperature, TIC, and Alk were directly transferred from the RMA-11 model results for Keno Reach to the CE-QUAL-W2 input data file for J.C. Boyle Reservoir. Output for OM from the Keno Reach model was applied to the J.C. Boyle Reservoir (see Section 2.2.1) and was partitioned into four components: LDOM, RDOM, LPOM, and RPOM. The aforementioned dynamic partitioning scheme was applied. This scheme uses the LDOM, RDOM, LPOM, and RPOM fractions derived from model results from the last segment of Keno Reservoir to partition the OM into the four components.

Tributary Boundary Conditions: There is one tributary to J.C. Boyle Reservoir, Spencer Creek. Spencer Creek has very limited inflow information. Therefore, it is not configured as a separate tributary in this model. The minor contribution of flow from Spencer Creek is lumped into the upstream headwater in the original PacifiCorp Model, and directly adopted in the TMDL model. The net reservoir accretion/depletion was calculated through a flow balance process aiming to reproduce the observed surface water elevation in the reservoir. This accretion/depletion was configured as a distributed tributary boundary condition in the model. The concentration of the tributary inflow was set to be the same as in the upstream boundary condition.

Downstream Outflow Boundary Conditions: The outflow from the reservoir was calculated as the sum of all recorded releases to the four outlets in the reservoir (powerhouse canal, dam spillway, bypass releases, and fish ladder releases).

The downstream boundary condition was set to be outflow; therefore, no concentration boundary condition was needed.

2.3.3.5 Model Segment 5: Bypass/Full Flow Reach

The Bypass/Full Flow Reach extends from the J.C. Boyle Dam to the headwaters of Copco Reservoir. There were four types of boundary conditions included in this portion of the model: upstream inflow boundary conditions, tributary boundary conditions, downstream outflow boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: There are two inflows to the Bypass/Full Flow Reach. They are releases from J.C. Boyle Dam directly to the Klamath River and the J.C. Boyle Powerhouse tailrace. Measured releases from the dam for 2000 and 2002 were obtained from PacifiCorp and used to represent both inflows for the model for the corresponding years.

For the upstream water quality constituent concentration boundary conditions, the simulated loading time series for phytoplankton, temperature, PO_4, NH_4, NO_2/NO_3, and DO from the J.C. Boyle Reservoir were applied. The four OM constituents predicted by the CE-QUAL-W2 model were combined into one OM constituent as applied in the Keno Reach boundary condition.

Tributary Boundary Conditions: There are no major tributaries, but there are three springs represented by a constant flow of 75 cfs each. The flow rate, temperature, DO, and phytoplankton boundary conditions for the springs were the same as in the original PacifiCorp Model, while the concentrations for the major nutrients (i.e., PO_4, NH_4, and NO_2/NO_3) were derived through model calibration. After several iterations, the concentrations for NH_4, NO_2/NO_3, and PO_4 were determined to be 0.029 mg/L, 0.25 mg/L, and 0.066 mg/L, respectively. OM concentrations were assumed to be a small value of 0.5 mg/L considering the springs are mainly groundwater. These concentrations were applied to both the 2000 and 2002 models for this reach.

Downstream Outflow Boundary Conditions: The downstream boundary condition for the Bypass/Full Flow Reach was configured as a stage-discharge relationship. No concentration boundary condition was needed for the downstream boundary conditions because only outflow exists there.

2.3.3.6 Model Segment 6: Copco Reservoir

The Copco Reservoir model segment extends from Copco Reservoir's headwaters to Copco Dam. Four types of boundary conditions were included in the portion of the model for Copco Reservoir. They are upstream inflow boundary conditions, tributary boundary conditions, downstream outflow boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: The inflow for Copco Reservoir was represented as the sum of the inflow into the reservoir and the estimated accretion/depletion for the reservoir. The flows from Bypass/Full Flow Reach were used as inflow to the Copco Reservoir because there are no flow data available at the headwaters of Copco Reservoir. The daily accretion/depletion was the sum of the daily change in storage in the Copco reservoir and the daily average outflow from the reservoir (minus the daily average inflows from Bypass/Full Flow Reach) as derived in the original PacifiCorp Model.

The upstream water quality constituent concentration boundary conditions were based on the model results at the downstream node of the Bypass/Full Flow Reach portion of the model. PO_4, NH_4, NO_2/NO_3, DO, phytoplankton, and temperature were directly transferred from the RMA-11 model results for Bypass/Full Flow Reach to the CE-QUAL-W2 input data file for Copco Reservoir. Output for OM from the Bypass/Full Flow Reach portion of the model was applied to Copco Reservoir (see Section 2.2.1) and is partitioned into four components: LDOM, RDOM, LPOM, and RPOM using the dynamic-partitioning approach as described above.

Tributary Boundary Conditions: The concentrations of the distributed tributary boundary conditions were set to be the same as the upstream concentration boundary condition in the same manner as in the original model.

Downstream Outflow Boundary Conditions: The two main outlets for the Copco Dam are a spillway and two waterway intakes at the Copco powerhouse (treated as a single outlet). Hourly outflow data for the powerhouse and the spillway were available from PacifiCorp and used as reservoir outflow flows.

The downstream boundary condition was set to be outflow; therefore, no concentration boundary condition was needed.

2.3.3.7 Model Segment 7: Iron Gate Reservoir

The Iron Gate Reservoir model segment extends from the headwaters of the Iron Gate Reservoir to Iron Gate Dam. Five types of boundary conditions were included in the portion of the model for Iron Gate Reservoir. They are upstream inflow boundary conditions, tributary boundary conditions, withdrawal boundary conditions, downstream outflow boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: There is no gage to measure inflow to Iron Gate Reservoir; therefore, the flows from the Copco Reservoir were used to represent inflow.

Simulated water quality outflow values from Copco Reservoir were applied as the Iron Gate Reservoir inflow water quality constituent concentration boundary conditions, and they were the same configuration as for Lake Ewauna.

Tributary Boundary Conditions: There are three tributaries to the Iron Gate Reservoir. They are Camp Creek, Jenny Creek, and Fall Creek. Limited flow information was available for these creeks. The hourly accretion/depletion for the reservoir was calculated as the sum of the daily inflow, outflow, and change in storage in Iron Gate Reservoir. Jenny Creek was represented by this accretion/depletion, as in the original PacifiCorp Model. Neither Camp Creek nor Fall Creek were explicitly configured with contributions in the model. Tributary boundary conditions were not changed from the original PacifiCorp Model. Since Jenny Creek is represented as an accretion/depletion flow, its water quality is represented using the upstream inflow concentrations. This follows the same assumptions as for the upstream reservoirs.

Withdrawal Boundary Conditions: The dam's spillway was modeled as a withdrawal because it draws water to the side of the dam, not over or through the dam. Representing the spillway as a withdrawal more accurately represents the system. If the spillway were represented as a spillway in W2, water would flow to the end of the reservoir instead of the side, and this can affect the hydrodynamic simulation.

Downstream Outflow Boundary Conditions: The Iron Gate dam has four primary outlets: a spillway, penstock, and two fish hatchery intakes. Outflow from the reservoir was based on the outflow in the original PacifiCorp Model. Outflow was determined from PacifiCorp daily flow records for the Powerhouse release and spill and estimates of fish hatchery releases (50 cfs for lower hatchery release and 0 cfs for upper hatchery release).

The downstream boundary condition was set to be outflow; therefore, no concentration boundary condition was needed.

2.3.3.8 Model Segment 8: Iron Gate Dam to Turwar

Four types of boundary conditions were included in the portion of the model for Iron Gate Dam to Turwar. They are upstream inflow boundary conditions, tributary boundary conditions, downstream outflow boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: The upstream inflow boundary conditions for Iron Gate Dam to Turwar were based on PacifiCorp's original model, which used PacifiCorp's measured releases from Iron Gate Dam during 2000.

Upstream water quality constituent boundary conditions were the simulated outflow values from the Iron Gate reservoir.

Tributary Boundary Conditions: There are 23 tributaries to this segment of the Klamath River, including four major tributaries (Shasta, Scott, Salmon, and Trinity rivers). Five tributaries to this reach are actively gauged, including the Shasta, Scott, Salmon, and Trinity rivers, and Indian Creek. Inflows for minor tributaries were defined and quantified as daily accretion/depletions, as in the original PacifiCorp Model.

The Scott and Trinity rivers were assigned by summing USGS-gaged flows and daily accretion/depletions. The daily accretion/depletions were determined on the basis of a USGS methodology. Monthly average values were used to determine accretions and depletions for each river segment on the basis of differences in gage readings, and these accretions and depletions were then assigned to individual tributaries according to the estimated basin area. Appendix D presents the USGS methodology for estimating these flows for tributaries (PacifiCorp 2004). Model node and element numbers and type of flow record employed for each tributary are summarized in Table 2-2.

This space intentionally left blank

Table 2-2. Element flow information for the Iron Gate to Turwar simulation

Location	Node	Element	Flow Type
Bogus Creek	7	4	7 day average
Willow Creek	55	28	7 day average
Cottonwood Creek	86	43	7 day average
Shasta River	144	72	Daily measured
Humbug Creek	204	102	7 day average
Beaver Creek	319	160	7 day average
Horse Creek	468	234	7 day average
Scott River	513	257	Daily measured + A/D Ft. Jones to Klamath
Grider Creek	656	328	7 day average (A/D Scott to Seiad)
Thompson Creek	735	368	7 day average
Indian Creek	906	453	Daily measured
Elk Creek	925	463	7 day average
Clear Creek	1000	500	7 day average
Ukonom Creek	1098	549	7 day average
Dillon Creek	1162	581	7 day average
Salmon River	1357	679	Daily measured
Camp Creek	1466	733	7 day average
Red Cap Creek	1511	756	7 day average
Bluff Creek	1547	774	7 day average
Trinity River	1609	805	Daily measured + A/D Hoopa to Klamath
Pine Creek	1644	822	7 day average
Tectah Creek	1850	925	7 day average
Blue Creek	1908	954	7 day average

Shasta River daily flows were taken from USGS Gage 11517500 (Shasta River near Yreka). Scott River daily flows were calculated from USGS Gage 11519500 (Scott River near Ft Jones) and accretion/depletions. Daily Indian Creek flows were taken from USGS Gage 11521500 (Indian Creek near Happy Camp). Salmon River daily flows were from USGS Gage 11522500 (Salmon River at Somes Bar). Trinity River daily flows were calculated from USGS Gage 11530000 (Trinity River at Hoopa) and accretion/depletions.

Water quality constituent concentrations in the tributaries for all parameters except DO were based on U.S. Fish and Wildlife Service (USFWS), USBR, EPA, USGS, California Department of Water Resources (CDWR), NCRWQCB Surface Water Ambient Monitoring Program, and Yurok Tribe Environmental Program (YTEP) data.

Temperature data for the tributaries were very limited, therefore the temperature boundary conditions for all the tributaries were configured on the basis of USGS-estimated temperature for 2002 (Flint, L.E. and Flint, A. L. 2008). It was found that by directly using the USGS-estimated temperatures in these tributaries, the model reproduced observe temperatures in the Klamath River quite well. This is not surprising since the USGS study did show that there is no significant inter-year variation in the predicted in-stream temperature.

There were very little to no water quality data available for most tributaries. The only tributaries with sufficient data to represent seasonal variations for 2000 were the Shasta and Scott Rivers (USBR 2003 data). For the other two major rivers, Salmon and Trinity, NCRWQCB derived representative data to approximate the boundary conditions for 2000, based on statistical analysis of historical tributary data. Several historical datasets (1960s to 1980s) with water quality data from CDWR, STORET, USBR, and USGS were supplemented with more recent data (2000 to 2006) from USFWS, USBR, EPA, USGS, CDWR, NCRWQCB, and YTEP. The data were split into two seasonal periods – Wet (November – April) and Dry (May – October), and years which had similar hydrologic conditions to the year 2000 were selected based on statistical measures. The median water quality values for the two seasonal periods were used for boundary conditions.

In addition to the USBR data, the NCRWQCB compiled nutrient data for several minor tributaries including Beaver Creek, Bluff Creek, Clear Creek, Dillon Creek, Elk Creek, Red Cap Creek, Indian Creek, and Bogus Creek for the period from 2001 to 2006. These data were divided into two categories. The first was data for Bogus Creek that were used to derive the boundary condition for Bogus Creek. Bogus Creek exhibits significantly higher nutrient concentrations than the other tributaries. The second was data for all other minor tributaries, which were combined to derive values representing all the minor tributaries. Because of a lack of sufficient data to characterize temporal variability, it was deemed appropriate to use an annual average value to represent the boundary conditions from the minor tributaries.

DO in all minor tributaries was estimated using 90 percent saturated conditions, except for the Shasta and Scott rivers, where DO data were available. DO saturation concentrations were based on the temperature data and atmospheric pressure corrected for elevation. A detailed description of the boundary conditions for each of the tributaries is provided in Table 2-3.

Table 2-3. Description of Boundary Conditions for Tributaries within the Irongate to Turwar Segment

Tributary name	Temperature	Nutrients	DO	TIC/ALK
Bogus Creek	Based on USGS estimated data	Based on NCRWQCB data	90 % saturation value	Based on the data in the Scott River
Willow Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the data in the Scott River
Cottonwood Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the data in the Scott River
Shasta River	Based on 2000 data	Nutrients were set based on USFWS data at the mouth of the Shasta River	DO was based on observed data, except for the period without monitoring data, which was set to be 90% of the saturation value.	Based on the data at the Shasta River mouth
Humbug Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the data in the Scott River
Beaver Creek	Based on USGS estimated data	Based on NCRWQCB data	90% saturation value	Based on the data in the Scott River, except for August and September, when limited data were available for 2006. For August and September, the data were used directly.
Horse Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Set to be the same as in the Beaver Creek boundary condition
Scott River	Based on 2000 data	Based on USFWS data at the mouth of the Scott River	Based on USFWS data at the mouth of the Scott River. Periods without data were set at 90% saturation value	Based on USFWS data at the mouth of the Scott River
Grider Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Set based on the observed data at the mouth of Salmon River
Thompson Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Set based on the observed data at the mouth of Salmon River
Indian Creek	Based on USGS estimated data	Based on NCRWQCB data	90% saturation value	Based on the observed data at the mouth of the Salmon River, except for August and September, when 2006 data were available at Indian Creek. For this

Tributary name	Temperature	Nutrients	DO	TIC/ALK
				period, the data were used directly.
Elk Creek	Based on USGS estimated data	Based on NCRWQCB data	90% saturation value	Based on the observed data at the mouth of the Salmon River except for August and September, when 2006 data were available at Elk Creek. For this period, the data were used directly.
Clear Creek	Based on USGS estimated data	Based on NCRWQCB data	90% saturation value	Based on the observed data at the mouth of the Salmon River, except for August and September, when 2006 data were available at Clear Creek. For this period, the data were used directly.
Ukonom Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the observed data at the mouth of the Salmon River
Dillon Creek	Based on USGS estimated data	Based on NCRWQCB data	90% saturation value	Based on the observed data at the mouth of the Salmon River, except for August and September, when 2006 data were available at Dillon Creek. For this period, the data were used directly.
Salmon River	Based on 2000 data	Based on USFWS data	90% saturation value	Based on the observed data at the mouth of the Salmon River
Camp Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the observed data at the mouth of the Trinity River
Red Cap Creek	Based on USGS estimated data	Based on NCRWQCB data	90% saturation value	Based on the observed data at the mouth of the Trinity River, except for August and September, when 2006 data were available. For this period, the data were used directly.
Bluff Creek	Based on USGS estimated data	Based on NCRWQCB data	90% saturation value	Based on the observed data at the mouth of the Trinity River, except for August and September, when 2006 data were available. For this period, the data were used directly.

Tributary name	Temperature	Nutrients	DO	TIC/ALK
Trinity River	Based on 2000 data	Based on USFWS data	90% saturation value	Based on the observed data in the Trinity River
Pine Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the observed data at the mouth of the Trinity River
Tectah Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the observed data at the mouth of the Trinity River
Blue Creek	Based on USGS estimated data	Based on NCRWQCB estimated data	90% saturation value	Based on the observed data at the mouth of the Trinity River

Downstream Outflow Boundary Conditions: The downstream boundary condition for this section is a stage-discharge condition. No water quality boundary condition is needed because only outflow is represented at the downstream.

2.3.3.9 Model Segment 9: Klamath Estuary (Turwar to the Pacific Ocean)

The estuarine portion of the Klamath River (Turwar to the Pacific Ocean) was modeled using EFDC and was not included in the original PacifiCorp Model. This model segment was ultimately calibrated using data from the year 2004 because it had the most available data for all parameters. Insufficient data were available to calibrate for the year 2000 in the estuarine portion of the Klamath River. Boundary conditions were thus prepared using monitoring data at Turwar. Three types of boundary conditions were included in the Klamath Estuary portion of the model. They are upstream inflow boundary conditions, downstream open boundary conditions, and surface boundary conditions.

Upstream Inflow Boundary Conditions: The portion of the Klamath River represented by EFDC was delineated from the USGS 11530500 streamflow gage at Klamath to the Klamath River's intersection with the Pacific Ocean (Appendix C). Streamflow data from the Klamath River at Klamath USGS gage (11530500) were used as the upstream inflow boundary for model calibration (described in Section 3.0). Model results from the Iron Gate Dam to Turwar portion of the model are used as input for the modeling scenarios.

The upstream boundary condition for water quality was configured using the USFWS/Yurok's 2004 water quality monitoring data at Turwar (for model calibration). The USFWS station was sampled five times from June to September 2004. A time series was generated for water quality using linear interpolation of the five available data points. The following constituents were configured as state variables in the upstream boundary water quality input file using the Turwar data:

1. Phytoplankton
2. LPOC
3. LDOC
4. LPOP
5. LDOP
6. PO_4
7. LPON

8. LDON
9. NH_4
10. NO_3/NO_2
11. DO

Not all data were available to be directly used in the EFDC water quality input file. The following assumptions were made to derive parameters to create the water quality input file:

- The particulate to dissolved OM ratio was assumed to be 0.8:0.2. This ratio was also used to derive the particulate and dissolved components of phosphorus, nitrogen and carbon. It maintains consistency with upstream segments.
- Due to a lack of data to further partition OM between labile and refractory components, labile and refractory components were not considered separately.
- Organic phosphorous was derived by subtracting PO_4 from total phosphorous.
- The ON:OM and OP:OM ratios were assumed to be the same as in upstream reaches, which are ON:OM=0.07, and OP:OM=0.0055. These ratios were used to derive ON from OP data.
- The algae biomass to chlorophyll ratio was assumed to be 0.067 mg algae/ug Chla, which is the same as those in the upstream reaches.

Diel DO and temperature data were not readily available at the Turwar gage for 2004 when this model was developed. Thus, daily average values were computed on the basis of the diel data for the Upper Estuary monitoring site (at Hwy 101) and specified as the upstream boundary condition at Turwar. The model can be updated to reflect additional monitoring data as these data become available.

For modeling scenarios, model output from the Iron Gate Dam to Turwar segment are used. OM conversion from the RMA model to EFDC is presented in Figure 2-4 of Section 2.3.2.

Two tributaries to the Klamath Estuary, Hunter Creek and Salt Creek, were also initially considered as part of the boundary conditions but were later eliminated. Flow estimates were available for Hunter Creek, based on drainage area for the period May 1 through September 30, and were found to be relatively insignificant (median value of 5.9 cfs in 2004) in comparison to the Klamath River flows. Salt Creek flows were smaller than those for Hunter Creek.

Downstream Open Boundary Conditions: The outlet of the Klamath River at the Pacific Ocean is characterized by a widening of approximately 1,400 meters. Depending on the conditions, the outlet may be largely closed off by a transient sand bar. The opening through this sand bar was set to approximately 200 meters in width for the model, based on measured 2004 bathymetry data. To reduce the influence of boundary reflection, the downstream open boundary of the model was set well into the Pacific Ocean, beyond the physical opening in the sand bar (Appendix C). To allow for flexibility in evaluating the effect of different locations of the sand bar opening, the sand bar is included in the grid system as a column of active cells. It has an internal barrier that blocks the water from penetrating all cells except those representing the opening.

Tidal data from the National Oceanic and Atmospheric Administration (NOAA) gage at Crescent City (9419750) were used to represent the tidal boundary of the model. Tidal elevation data from the Crescent City gage are referenced to a mean lower low water (MLLW) vertical datum, while bathymetry data obtained from the NCRWQCB use the NAVD88. The difference between the two data at this location is approximately 0.38 feet, or 0.116 meters. Tidal elevation data from the Crescent City gage station were adjusted to correspond to the bathymetry datum obtained for the lower portion of the Klamath River.

Surface Boundary Conditions: The surface boundary conditions are based on meteorological conditions. The meteorological data required by the EFDC model are specified in two separate files (*aser.inp* and *wser.inp*). The *aser.inp* file is used to specify the atmospheric pressure, air temperature, relative humidity, precipitation, evaporation, solar radiation and cloud cover. The *wser.inp* file is used to specify the wind speed and direction. Meteorological data from the Arcata Eureka Airport (WBAN 24283), approximately 35 miles downstream of the estuary along the Pacific coastline, were used. Hourly, unedited local meteorological data (atmospheric pressure, air temperature, relative humidity, precipitation, cloud cover, wind speed and direction) were available from this NOAA-NCDC station and were used in creation of the *aser.inp* and *wser.inp* files for the estuary model. These data provided the most complete data set of required surface airways parameters for the EFDC model meteorological file. Solar radiation data were not available. Clear sky solar radiation was computed on the basis of the latitude and longitude and corrected using cloud cover to generate the solar radiation data.

2.3.4 Initial Conditions

The Klamath River model requires specifying initial conditions in the input files. The initial conditions from the original PacifiCorp Model (Model Segments 1 through 8) were maintained for all segments, except BOD was eliminated from the initial condition setting for Link River, Keno Reach, and Bypass/Full Flow Reach (see Section 2.2.1). Where field data were unavailable, the conditions of the first day of available field data were applied. In general, the impact of the initial conditions was insignificant and lasted for less than 10 days in the winter period. The initial condition for Model Segment 9 was set to values similar in magnitude as observed data. Because of the relatively large flow from the Klamath River, however, the impact of initial conditions is noticeable only for a very short (insignificant) time period.

2.4 Modeling Assumptions, Limitations, and Sources of Uncertainty

2.4.1 Assumptions

The major underlying assumptions associated with Klamath River model development are as follows:

- The initial condition and the boundary conditions set for the winter and early spring period do not have a significant effect on the simulated water quality during the critical summer and early fall periods. This assumption permits assigning the initial conditions and winter/early spring boundary conditions using best professional judgment, without impairing the model performance for the critical period.
- Time series flow data were not available for all tributaries and withdrawals. Reliable time series flow data were also not available for many monitoring locations along the length of the Klamath River. In light of the limitations, it was assumed that tributary flows could be reasonably represented through interpolation on the basis of limited flow measurements.

- One phytoplankton species and one periphyton species were assumed to be sufficient for representing the overall primary production and nutrient interactions in the system given no data is available to support multiple species modeling.
- Alkalinity is conservative (as stated in CE-QUAL-W2 manual). Therefore, no internal sources or sinks were considered.
- All the OM in the water column (and that from other sources) has the same stoichiometric ratio unless data are available to derive site-specific ratio.
- The effect of zooplankton and benthic creatures do not have a significant impact on the algal/periphyton dynamics and nutrient recycling.
- A stage-discharge relationship was applied at the Link River boundary to enable predictive simulation downstream. This adjustment was made on the basis of previous peer review comments for the Klamath River Model. Although this configuration does not explicitly simulate backwater effects, it was deemed suitable for TMDL development scenarios. The magnitude of the Link River flow is significant. And because Link River is fairly steep, flow velocities into Lake Ewauna are relatively high. If backwater flow exists, it would not have a significant effect on the nutrient budget downstream.
- The OM in the boundary conditions is lumped (and thus not partitioned between labile and refractory components) due to lack of sufficient data for accurate OM partitioning.
- Denitrification in the riverine sections is not simulated due to the fact that the majority of the river bed is rocky and DO in the water column is high. Neither of these conditions are favorable for denitrification bacteria and corresponding denitrification processes. This assumption may potentially cause overprediction of NO_2/NO_3 in the riverine sections, however the impact is expected to be minimal.
- The sand bar opening at the mouth of the Klamath Estuary has relatively constant dimensions and physical characteristics for a period of time; thus, a fixed grid configuration can be used for a simulation.
- The impact of sediment transport and siltation on channel geometry is not significant; therefore, the same bathymetric configuration can be used for different scenario simulations. Additionally, insufficient data are available to dynamically simulate the time-dependent effect of sediment transport on bathymetry.

2.4.2 Limitations

Potential limitations that have been identified include the following:

- The model's capabilities are constrained by the limited availability and quality of monitoring data. This is particularly the case for boundary conditions to the model, but it is also the case for in-stream model calibration data. The Klamath River model is not expected to be able to mimic the exact timing and location of all water quality conditions. The model can be used to represent the overall water quality trends in response to external loading and internal system dynamics.
